Update: My naive questions here have attracted comments pointing to very interesting work I wasn't aware of that is along the lines of what I've been looking for (a quantum model of what actually happens in a measurement that leads to the sort of classical outcomes expected, such that one could trace the role of probability to the characterization of the initial state and its decomposition into a system + apparatus). What I learned about was

- Work of Klaas Landsman, I liked a lot his survey article on the measurement problem
  https://link.springer.com/chapter/10.1007/978-3-319-51777-3_11
  where he describes the "flea on Schrodinger's cat" speculative idea as an example of the "instability" approach to the measurement problem. Also interesting is his paper on "Bohrification"
  https://arxiv.org/abs/1601.02794
- Work on a detailed analysis of a "Curie-Weiss" model of a measurement. The authors have a long, detailed expository paper
  https://arxiv.org/abs/1107.2138
  and more explanation of the relations to measurement theory here
  https://arxiv.org/abs/1303.7257
  and here
  https://link.springer.com/chapter/10.1007%2F978-3-319-55420-4_9
  There are also comments about this from Arnold Neumaier here
  https://physicsoverflow.org/39105/curie-weiss-model-of-the-quantum-measurement-process

In these last references the implications for the measurement problem are discussed in great detail, but I'm still trying to absorb the subtleties of this story.

I'd be curious to hear what experts think of Landsman's claim that there's a possible distinct "instability" approach to the measurement problem that may be promising.

Update: From the comments, an explanation of the current state of my confusion about this.

The state of the world is described at a fixed time by a state vector, which evolves unitarily by the Schrodinger equation. No probability here.

If I pick a suitable operator, e.g. the momentum operator, then if the state is an eigenstate, the world has a well-defined momentum, the eigenvalue. If I couple the state to an experimental apparatus designed to measure momenta, it produces a macroscopic, classically describable, readout of this number. No probability here.

If I decide I want to know the position of my state, one thing the basic formalism of QM says is "a momentum eigenstate just doesn't have a well-defined position, that's a meaningless question. If you look carefully at how position and momentum work, if you know the momentum, you can't know the position". No probability here.

If I decide that, even though my state has no position, I want to couple it to an experimental apparatus designed to measure the position (i.e. one that gives the right answer for position eigenstates), then the Born rule tells me what will happen. In this case the "position" pointer is equally likely to give any value. Probability has appeared.

So, probability appeared when I introduced a macroscopic apparatus of a special sort: one with emergent classical behavior (the pointer) specially designed to behave in a certain way when presented with position eigenstates. This makes me tempted to say that probability has no fundamental role in quantum theory, it's a subtle feature of the emergence of classical behavior from the more fundamental quantum behavior, that will appear in certain circumstances, governed by the Born rule. Everyone tells me the Born rule itself is easily explicable (it's the only possibility) once you assume you will only get a probabilistic answer to your question (e.g. what is the position?)

A macroscopic experimental apparatus never has a known pure state. If I want to carefully analyze such a setup, I need to describe it by quantum statistical mechanics, using a mixed state. Balian and collaborators claim that if they do this for a specific realistic model of an experimental apparatus, they get as output not the problematic superposition of states of the measurement problem, but definite outcomes, with probabilities given by the Born rule. When I try and follow their argument, I get confused, realize I am confused by the whole concept: tracking a mixed quantum state as it evolves through the apparatus, until at some point one wants to talk about what is going on in classical terms. How do you match your classical language to the mixed quantum state? The whole thing makes me appreciate Bohr and the Copenhagen interpretation (in the form "better not to try and think about this") a lot more…

Comments

1. **Another Anon**
   September 7, 2018

   If you want to avoid the tricky question "What is a measurement?", just consider an electron orbiting a nucleus, jumping to a lower energy state. Einstein asked what caused the jump. Bohr said it was probabilistic. So there's an example of fundamental probability entering QM which avoids the "What is a measurement?" problem

2. **Charles Xu**
   September 7, 2018

   It doesn't quite get at the interpretational issues you raised earlier (in that it assumes an underlying Hilbert-space description), but Gleason's theorem https://en.wikipedia.org/wiki/Gleason%27s_theorem comes close to the kind of functional derivation of Born's rule you're asking about.

3. **Peter Woit**
   September 7, 2018

   Another Anon,
   The situation you describe involves not just a single particle in a potential (where an energy eigenstate will stay an energy eigenstate), but a particle coupled to a quantized electromagnetic field. In this case, you don't know exactly what the initial quantum state of the electromagnetic field is, no? You also don't know the state of the environment, and are going to have to perform a measurement to detect the photons that show that the electron has changed energy levels.

4. **Mateus Araújo**
   September 7, 2018

   There is a simple answer to your simple question: probability can come from lack of knowledge of the initial state.

   The problem is that it is not at all easy to recover the probabilistic predictions of quantum mechanics from this idea. The only way people found to do it is with Bohmian Mechanics. Which is not a satisfactory theory, in my opinion.

5. **Oren**
   September 7, 2018

   This, in particular the discussion around Gleason's theorem, seems relevant. https://www.scottaaronson.com/democritus/lec9.html

6. **Peter Woit**
   September 7, 2018

   Mateus Araújo,

   I'm not interested in what I suspect 't Hooft or the Bohmians would like to do, deriving the Born rule from some underlying more classical picture. I'd like to know if you can do it starting with standard QM initial states, can you point to literature where people try to do this? I seem to be hearing from some quarters that Gleason's theorem or other very general arguments can constrain probabilities and perhaps give Born's rule, is that not the case?

   Also, where can I find a precise definition of a "measurement"? Or, not generally, but specifically, a detailed analysis of exactly what is happening in some simple case of a measurement?

7. **Another Anon**
   September 7, 2018

   Mateus: "There is a simple answer to your simple question: probability can come from lack of knowledge of the initial state."

   Yes it can, but that's not the fundamental uncertainty of quantum mechanics – that is not about lack of knowledge.
   The uncertainty principle explains why quantum mechanics must be probabilitic. If you have two peroperties which don't commute, then you have fundamental limitations on your knowledge. In which case, you can only ever talk about the probability of the position of a particle, say, rather than knowing with certainty.

8. **Perry Rice**
   September 7, 2018

   Not all measurements are projective, so that needs to be taken into account.

9. **Peter Woit**
   September 7, 2018

   Another Anon,
   The fact that quantum states are different than classical states is a different issue, and has nothing to do with the question about the Born rule.

   For example, I can start with a state of a single particle. Quantum mechanics tells me what such states look like, there aren't any that are both position and momentum eigenstates. If I start with a single particle in a momentum eigenstate, I can ask what happens when I "measure its position". To do this I'm going to have to couple it to some very complicated (as a quantum system) measuring device + environment. Born's rule says that the probability of any position will be the same. Can I derive this from some very general characterization of a what a measuring device is and how an environment behaves?

10. **Peter Woit**
    September 7, 2018

    Perry Rice,
    Can you point to a precise definition of what a "measurement" is?

11. **Mateus Araújo**
    September 7, 2018

Peter Woit,

"I'd like to know if you can do it starting with standard QM initial states, can you point to literature where people try to do this?"

So what you want to know is if one can get probability from a lack of knowledge of the initial quantum state? The only work I know in this direction is A Flea on Schroedinger's Cat. The authors are more concerned about causing a collapse of the wavefunction by introducing a perturbation in the effective Hamiltonian of a system (which can always be interpreted as a change in the quantum state of the measurement apparatus), but since the perturbation determines the result of the measurement, lack of knowledge about the perturbation is the source of probabilities in their model. The paper is just a numerical analysis of a double-well model, so it is more of a hope instead of worked-out solution.

As for Gleason's theorem, it shows that if the probability of an outcome is a (non-contextual) linear function of the projector associated with that outcome, then it must be given by the Born rule. So if you want non-Born probabilities you either need to give up on describing measurements with projectors or do some really funky stuff. But it says nothing about whether the probabilities come from lack of knowledge of a initial state.

There are dozes of derivations of Born's rule from general arguments, it is really hard to get a sensible theory without it.

12. **Kevin S. Van Horn**
September 7, 2018

I can't claim to be an expert here, but have you looked at Sebens and Carroll's paper "Self-Locating Uncertainty and the Origin of Probability in Everettian Quantum Mechanics"?
https://arxiv.org/abs/1405.7577

13. **RalphB**
September 7, 2018

Thank you so much for the link to Weinberg's talk. It's interesting that he lumps Everett in with the consistent quantum theory folks (Gell-Mann, Hartle, Griffiths). Consistent quantum theory defines measurements but I assume that's not what you are looking for.
Finally, I link to a short clip of Gell-Mann which basically summarizes why I like his approach to quantum theory.
https://www.youtube.com/watch?time_continue=127&v=gNAw-xXCcM8

14. **Peter Woit**
September 7, 2018

Kevin S. Van Horn,
I have looked at that, but it seems to me to be a more elaborate and less clear version of Zurek's 2004 argument for a derivation of the Born rule, see here
https://arxiv.org/abs/quant-ph/0405161

I should have pointed to Zurek's argument in my posting. My question might be rephrased as "does something like Zurek's argument give what I want?"

15. **Joking**
September 7, 2018

The standard version of Gleason's theorem tells you that if you assume that your physical theory is a probabilistic interpretation of a Hilbert space structure, then those probabilities have to be calculated according to Born's rule. So when people worry about "deriving the Born rule", they usually don't mean its particular form, but rather the very probabilistic interpretation itself. Asking for a "derivation" of this interpretation as you do is asking for a hidden variables description, which is impossible — For an "alternative" to Bohmian mechanics that seems less well known (and fails for different reasons), you might want to look at Wetterich's work on "quantum mechanics from classical statistics" — Derivations of the Hilbert space structure from axioms of physical measurements were given by Jauch and his followers, at a time when Boolean lattices were a popular subject. At their best, the "information theoretic derivations" are a modern reincarnation of these older insights.

16. **Peter Woit**
September 7, 2018

Joking,
I'm not asking for a hidden variables description. I think the quantum state is a complete description of the state of the world, there is nothing else. But when you discuss going from an initial state to a final state via a process that is supposed to qualify as a "measurement", you are assuming a measurement apparatus of some kind (and an environment), and it seems to me that you aren't going to know the initial state of this apparatus + environment.

Can this lack of knowledge about the initial state explain why your predictions about measurements have to be probabilistic? Can Gleason or Zurek be invoked to explain why Born's rule must govern these probabilities?
I suspect what is confusing here are issues of circularity: you have to have some theory that tells you how to deal with your lack of knowledge of the initial state, and one may argue there is no way to do this without invoking Born's rule itself.

Still, what's wrong with the argument that here is the place that probability enters, and Born's rule is the only consistent way it can enter?

17. **alex**
September 7, 2018

I think there are two aspects. One is, in the mathematics of Hilbert spaces, non-Boolean lattices, or whatever mathematical structure one prefers to write the mathematical formalism of qm, what liberty one has for the mathematical form of the Born rule?. This is a purely mathematical question, which has been, in my opinion and taste, pretty much sorted out since the 50s by Gleason's theorem. Now, assume for a moment that we physically interepret this probability measure as some sort of real property of the particle, say its 'propensity'. Now, when this particle interacts with a device, we randomly get a value for, say, spin, and the probability distribution of those values fits with the previous Born probability measure that the particle had before the interaction. Now, one asks, how is it that in such a complex dynamical interaction, the probability is somehow 'transferred' from the particle, before the interaction, to the distribution of the measured values? Is the sole role of the interaction just to produce a single outcome without affecting anything else? This would be the second aspect, and, if I understand correctly, the one that troubles Peter. And, indeed this seems to be more a complex physical question rather than a purely mathematical one, on that needs some physical modeling of the situation and some adequate physical insight and interpretation of what's going on there. Of course, since this problem has not been solved yet, one can either make an operationalist physical interpretation of the mathematical formalism of qm (in which one physically interprets the Born measure as the experimental frequency of values in measurements, thing which simply builds on the behaviour observed on the second issued, and just takes it for granted to build a pragmatic interpretation), or, in the case in which the probability is, say, propensity, use the law of large numbers to get the frequency and, again, accept that this probability is transferred to the results of experiments or try to investigate why this is the case. Only this second case has some right to do that, since the operationalist take simply incorporated it into the very way in which one physically interprets the math. Back to the other approach, one can take three positions, either the known quantum dynamics will explain how this happens (thing which leads to the measurement problem, since usual dynamics+no hidden variables+defined outcomes is a trilemma), and then one has to deny defined outcomes in the usual sense (this leads to many worlds or to Landsman flea on S's cat), or (non-local, contextual-)hidden variables (in which the mechanism that makes the values to define is outside standard qm, is an outside variable; in this case, the probabily is, of course, not a real property, but, still one has to explain why the measurement context doesn't change it, like in the other approach), or one denies the standard dynamics (like GWR).

18. **Blake Stacey**
September 7, 2018

I think Adrian Kent's critique of the Sebens–Carroll business is exactly on target.

Everything I have seen in the Zurekian vein ends up being circular, though some arguments have a larger radius of curvature than others.

19. **Blake Stacey**
September 7, 2018

> What I wonder about is whether it is possible to argue that, given that your result is going to be probabilistic, and given some list of properties a "measurement" should satisfy, can you show that the Born rule is the only possibility?

As others have said, Gleason's theorem is exactly this, but the "list of properties a 'measurement' should satisfy" is apt to be unsatisfying if one wants a story about energy flow or mechanical transformations. Instead, the assumptions are a list of conditions for expressing "measurements" in terms of Hilbert spaces. To each physical system we associate a complex Hilbert space, and each measurement corresponds to a resolution of the identity operator — in Gleason's original version, to an orthonormal basis. The crucial assumption is that the probability assigned to a measurement outcome (i.e., to a vector in a basis) does not depend upon which basis that vector is taken to be part of. The probability assignments are "noncontextual", as they say. The conclusion of Gleason's argument is that any mapping from measurements to probabilities that satisfies his assumptions must take the form of the Born rule applied to some density operator. In other words, the theorem gives the set of valid states and the rule for calculating probabilities given a state.

I have a sneaky suspicion that a good many other attempted "derivations of the Born rule" really amount to little more than burying Gleason's assumptions under a heap of dubious justifications.

20. **Scott Aaronson**
September 7, 2018

I agree with almost everything Mateus said. If you want the randomness of quantum measurement outcomes to be due solely to lack of knowledge about the initial state, and you also want to reproduce all the predictions of QM correctly, and you also don't want an insane cosmic conspiracy ('t Hooft's "superdeterminism"), then you're pretty much going to be forced to something like Bohmian mechanics—which, in some sense, does exactly what you're asking for, but only at the cost of importing the entire ontology of ordinary QM and then adding something additional and underdetermined on top of it. A few people had placed hopes in so-called "psi-epistemic" theories, wherein each pure state would correspond to a probability distribution over underlying "ontic states," with the distributions for non-orthogonal states overlapping each other—but I would say that no-go theorems have basically ruled that idea out, for explaining anything more complicated than a single qubit. Reproducing the probabilistic predictions of QM from ordinary statistical ignorance is not actually that easy! Think for example about the Bell experiment, or Shor's factoring algorithm, or better yet a quantum algorithm that simply outputs a sample from some crazy distribution over n-bit strings (what's now called a "quantum supremacy experiment"). If the probabilities in such cases merely reflected ignorance of the initial state, then it must be in a radically different way from what anyone is used to, a way that involves nonlocality and exponential computational complexity and so forth. Which … to my mind, if you're going to have to swallow all those things anyway, then why not just accept the probabilities as fundamental and be done with it? 🙂

The question "why the Born rule?" is a different one, at most indirectly related to the problem of finding an ignorance/statistical interpretation of QM. To my mind, Gleason's theorem, and many other results, have made a pretty compelling case that once you've
(1) assumed the "non-probabilistic" part of QM (the state space, orthogonality relations, etc.), and also
(2) decided that you want SOME rule for converting amplitudes to probabilities,
nothing other than the Born rule really makes internal mathematical sense. And intuitively, this is not surprising. After all, the non-probabilistic part of QM already singles out the 2-norm of the amplitude vectors as their most basic conserved property. So then if your probability law isn't also based on the 2-norm, but on some other norm or whatever, then no duh you're going to have trouble with conservation of probability!

21. **akhmeteli**
September 7, 2018

Peter Woit wrote: "Also, where can I find a precise definition of a "measurement"? Or, not generally, but specifically, a detailed analysis of exactly what is happening in some simple case of a measurement?"

I would think https://arxiv.org/abs/1107.2138 (Phys. Rep. 525 (2013) 1-166) fits the bill. The authors model measurement of a component of a spin using a Curie-Weiss magnet. They derive definite outcome of measurement (as a practical result), although, strictly speaking, this is incompatible with unitary evolution, but the change of the outcome can happen after a long time (of the order of Poincare reversal time). They derive the Born rule as an approximate result.

22. **Peter Woit**
September 7, 2018

akhmeteli,

Thanks! That's exactly the sort of thing I've been looking for and not seeing. It's a long paper and I'll have to find some time to understand what they are doing.

Scott,

Your claims seem incompatible with Weinberg's. He seemed to me to be saying that the problem with getting probability from uncertainty about the initial state is getting the Born rule, you seem to be saying getting the Born rule is straightforward, but there's some other problem with the idea.

I really need to look at and think about the paper akhmeteli points to. But, until I do that, here's the kind of specific question about "measurement" I'm wondering about. As in my earlier comment, consider a free particle in a momentum eigenstate. I think that's a complete description of the particle, has no info about position. If you want to measure position, I don't want to hear some formal abstract characterization of a position measurement. I'd like to see some physical system, describable by quantum mechanics, that you can couple to the free particle in such a way that the final state will give you a "position measurement". My problem is that I haven't seen any analysis of such a system. How do I know that the indeterminacy in the initial state of this "measurement system" doesn't correspond to the indeterminacy in the "position" result?

Blake Stacey,
The Kent paper you link to seems to just be about the many-worlds part of Carrol-Sebens (which I'm willing to believe Kent makes no sense). There's nothing there about the Zurek argument. What's the best paper critically dealing with the Zurek argument (note that Zurek claims he has no need for "many-worlds")?

23. **akhmeteli**
September 8, 2018

to Peter Woit: You are very welcome. Yes, the paper is extremely long, so you may wish to look at their earlier work https://arxiv.org/abs/quant-ph/0702135 first (just 13 pages).

24. **Joking**
September 8, 2018

Peter:

Can this lack of knowledge about the initial state explain why your predictions about measurements have to be probabilistic?

No. Probabilities and Born's rule apply even when you have complete knowledge of the entire pure state. So unitary evolution forbids this kind of mechanism. The environment is necessary to make the quantum mechanical probabilities behave like classical probabilities (with high probability, and for the pointer states).

Can Gleason or Zurek be invoked to explain why Born's rule must govern these probabilities?

Exactly!

I suspect what is confusing here are issues of circularity: you have to have some theory that tells you how to deal with your lack of knowledge of the initial state, and one may argue there is no way to do this without invoking Born's rule itself.

Indeed, there is no non-circular derivation of the probabilistic interpretation of quantum mechanics. The standard fallacy is to say that a probabilistic description follows if we neglect terms that are small in the norm. But neglecting small norms because they correspond to low probability is exactly assuming what one is trying to derive!

Still, what's wrong with the argument that here is the place that probability enters, and Born's rule is the only consistent way it can enter?

There's nothing wrong here. Assuming the relationship between physical measurement and mathematical theory to be probabilistic, Born's rule is the only possibility.

25. **Jochen**
September 8, 2018

Are you looking for something like Mott's 1929 analysis of alpha scattering in cloud chambers? It treats the atoms of the surrounding gas essentially as a quantum mechanical measuring device, and derives the classical straight trajectories from there. It's often considered an important forerunner to decoherence theory. Here is a modern discussion of the paper: https://arxiv.org/pdf/1209.2665

I'm not sure how much it really relates to the probabilistic aspect, though.

On that front, I think a fundamental difference to the classical case is that there, you can at least in principle imagine getting rid of the ignorance about the state of the measurement apparatus, which isn't the case for quantum mechanics. Although I suppose that basically ends up being kinda circular…

Maybe things get clearer if we think about QM in the same arena as classical mechanics, i. e. phase space. Then, the Liouville distribution becomes deformed into the Winger distribution, which describes the quantum state. This now can't ever be perfectly sharp, so if the interpretation of the Liouville distribution carries over, this would mean a residual fundamental uncertainty you can't get rid of.

Trouble with this is, of course, that the Winger distribution isn't a probability distribution, but rather, a pseudoprobability, which can take negative values. So maybe your question becomes one of whether you can attach an ignorance interpretation to such a pseudoprobability?

I know I've seen arguments to that effect, but I don't recall where right now…

26. **Urs Schreiber**
September 8, 2018

> If this is a well-known possibility for "interpreting" QM, what is the name of this interpretation?

I'd say this is the perspective of "algebraic quantum physics" in view of *quantum probability theory* (also "non-commutative probability"), as nicely surveyed for instance in Gleason's "The C*-algebraic formalism of quantum mechanics" (pdf) .

Here the Born rule becomes but the theorem that expectation values in probability theory may equivalently be characterized as star-linear functionals on algebras of observables, commutative or not (algebraic quantum states).

The allegend conundrum of "wave function collapse" disappears in this perspective, becoming but a part of the general formula for conditional expectation values (see here)

27. **Mateus Araújo**
September 8, 2018

Żurek's derivation of the Born rule is, technically speaking, the same thing as Deutsch's, but stripped down of the decision theory stuff and the talk about Many-Worlds (deriving uniform probabilities for uniform superpositions from a symmetry argument, and using ancillas to reduce non-uniform superpositions to uniform superpositions).

He might refuse to talk about Many-Worlds, but is essential for his proof that a measurement is a unitary process, which for me is rather Many-Worldy.

But the main problem with his proof is that he avoids the hard question of what probability \emph{is}, he just assumes that there is a probability that somehow makes sense. This is actually the only point about which I disagree with Scott: one cannot "just accept the probabilities as fundamental and be done with it". One must explain what "fundamental probabilities" even are in order to accept them.

The value of the Deutsch-Wallace argument is that they try to answer this, by proposing that probabilities are only subjective, and should be understood as tools to make decisions in a branching universe. On one hand I find it nice, as it explains why should we regard deterministic branching as a probabilistic process, but on the other hand rather unsatisfactory, as the whole thing about quantum probabilities is that they are somehow objective, and they don't address this.

I recently wrote a paper simplifying the Deutsch-Wallace argument and exploring its objectivity problem, it might interest you.

28. **Mateus Araújo**

September 8, 2018

Joking,

Indeed, there is no non-circular derivation of the probabilistic interpretation of quantum mechanics. The standard fallacy is to say that a probabilistic description follows if we neglect terms that are small in the norm. But neglecting small norms because they correspond to low probability is exactly assuming what one is trying to derive!

This circularity plagues the frequentist derivations of the Born rule, that were not even mentioned here. None of the proofs discussed here suffer from this problem.

Woit,

Your claims seem incompatible with Weinberg's. He seemed to me to be saying that the problem with getting probability from uncertainty about the initial state is getting the Born rule, you seem to be saying getting the Born rule is straightforward, but there's some other problem with the idea.

The solution to the puzzle is that it is easy to get the Born rule from general arguments that are *not* about lack of knowledge of the initial state. If you insist on probabilities coming from lack of knowledge of the initial state, it is rather hard to get the Born rule, and the only success I know is Bohmian Mechanics.

29. **CM**
September 8, 2018

Dear Woit,

the answers to your and Weinberg questions were given in 1932 by Johann Von Neumann in its masterpiece book "Mathematical foundations of quantum mechanics". There is a new 2018 English edition that makes the book more easily readable compared with the 1955 edition. Chapter IV, "The deductive development of the theory", explains why probabilities and derives the "Born rule".

30. **Scott Aaronson**
September 8, 2018

Peter: Weinberg points out, and I agree with him, that there seems to be no way to derive from the unitary part of QM that probabilities should ever enter the theory in the first place, without making some additional assumption. On the other hand, I don't think he disagrees with the statement that, once you've decided you want some probability rule, there are strong mathematical arguments that choices other than the Born rule are going to lead to serious problems (superluminal communication and so forth). If you like, though, I can ask him next time I see him.

31. **Aris Papadopoulos**
September 8, 2018

The paper "Quantum Mechanics of individual systems"

by James Hartle,
American Journal of Physics 36(8)

attempts a "derivation" of the Born rule. I mention it only as an entry point into the literature, by a well-respected, physicist, written in a readable fashion, meant to be understood even by undergraduate physics majors. Of course its conclusions are by no means universally accepted.

32. **GoletaBeach**
September 8, 2018

Gordon Baym's QM text has a useful description of the Stern Gerlach measurement process. I seem to remember that he bridges the gap between the idea that a spin component measurement always gets an eigenvalue and the Born interpretation of the wave function. So perhaps all there is is the Born wave function.

The mathematical arguments are far less interesting to me than experiments that could distinguish between QM interpretations. I guess the Bell's tests where choices are made in a causally disconnected fashion seem to be the most interesting, but I haven't kept up.

33. **Lee Smolin**
September 8, 2018

Dear Peter,

I've just picked up my head from doing the final corrections to my new book on realism in quantum foundations to find you asking, "where exactly does probability enter the theory?"

My understanding, after a lot of study, is that you have the following options:

1) Put the probabilities in at the beginning, as did Bohr, Heisenberg and von Neumann. This requires an operational approach which introduces measurement and probabilities as primitive concepts, ie through a "collapse" or "projection" postulate, which postulates Born's rule and "eigenvalue realism", or through a Hardy-style operational reconstruction. These are elegant but they do not answer your question as measurement and probability are primitive concepts.

2) You can attempt to derive probabilities from a formalism that has only unitary, Schrodinger evolution, which has no notion of probabilities to begin with. This is Everett's MWI route.

This is by now a very long story. It took me a lot of time to sort out for the book, and I had help from Saunders and Wallace and others. At best, there is no consensus amongst experts that this can be done. (This agrees with Scott's remark, above.) The rough outline is

i) the original version due to Everett fails, because you can show that with certainty there are branches of the wavefunction whose observers record measurements that disagree with Born's rule. Because there is no primitive notion of probability you cannot say that these observers are improbable, in fact there are an infinite number of them, and also an infinite number whose observations agree with Born's rule.

ii) There are recently several very sophisticated attempts to derive subjective probabilities and the Born rule. These are centred at Oxford, were initiated by David Deutsch and developed in different versions by Hillary Greaves, Wayne
Myrvold, Simon Saunders and David Wallace. These all use decoherence and also give up on recovering objective probabilities. Instead, they try, (in one version) from the axioms of decision theory, to show that it is rational for an observer to bet (ie choose subjective probabilities) as if Born's rule were true. (Even though objectively Born's Rule is false.)

If you read the literature you can only conclude, after some challenging technical arguments, that the experts disagree about whether this kind of approach succeeds or fails, and what the implications should be.

3) Invent a new physical theory which gives a complete description of individual processes from which the quantum probabilities are derived from ignorance about the initial state. This would then be a completion of QM rather than an interpretation. de Broglie-Bohm and collapse models are existence proofs that this is a possible route. There are also other approaches of this kind, such as Adler's trace dynamics and my real ensemble formulation.

I have the impression you don't find any of these 3 options satisfactory. The kind of answer to your question of where the probabilities come from would be one in which we start with QM without measurement, probabilities etc and derive them. But this was option 2 and a whole lot of very bright people have tried and failed to make it work (in a way that convinces all the experts).

My personal view is that option 3) is the only way forward for physics. But I wouldn't try to do more here than argue that unless some notion of subjective probability can be made to work, as in option 2), you simply cannot get an answer to your question. You then either need to conclude with Bohr that the only kind of theory of atomic phenomena is operational, and has probabilities and measurement as primitive terms
or agree with Einstein, de Broglie, Schrodinger, Bohm, Bell ets that QM requires a completion that gives a complete description of individual experiments.

Thanks,

Lee

September 8, 2018

All,
I noticed that Tom Banks in 2011 wrote up a long explanation of his views, posted at Sean Carroll's blog, which attracted an interesting discussion involving Scott and others. I've added a link and some comments as an update to the posting here.

Another good reference for work pointed to by akhmeteli is
https://arxiv.org/abs/1406.5178
This gives the kind of analysis of a measurement I've been asking for, but its implications for the question I'm wondering about are still unclear to me, since the authors are starting from a different "statistical interpretation" point of view. I need to find time to read this and think about it.

Lee,
Thanks for the comment. I look forward to seeing your book. In your categorization, I'm following option 2, and my question is being asked in that context.

Scott,
My initial thought was to ask Banks about his views, since those were what Weinberg was referring to, but as mentioned above, I see there is a good source already for his answer. If you do talk to Weinberg, I would be curious to know more about his discussions with Banks, whether he really would characterize Banks as seeing probability as having the same origin as in classical mechanics, and if so why he sees getting out Born's rule as the problem with this.

35. **Blake Stacey**
September 8, 2018

I hesitate to say what the "best" critiques of the Zurekian program have been, but arXiv:1406.4126 and arXiv:1603.04845 may provide a reasonable jumping-off point.

36. **Peter Woit**
September 8, 2018

Blake Stacey,
Those aren't very convincing. Especially the second: four pages in large type?

The question of how classical emerges from quantum is clearly a complex and subtle subject and I don't see the value of crude arguments like Kastner's four pager.

37. **Blake Stacey**
September 8, 2018

The problem is that in quantum foundations, the state of the literature is appalling. Clear statements of what is presumed in approach X, what is novel about Y, whether Z is seen as successful, etc., are harder to find than they should be. Issues that are, as you say, complex and subtle, get addressed in ways that appear at first to be sophisticated, but then turn out to be passing off intricate notation as subtlety. (Maybe this is not so different from the state of affairs in the study of non-Riemannian hypersquares, now that I think about it.) Sometimes the best one can do is a statement like Mateus Araújo's above: "But the main problem with his proof is that he avoids the hard question of what probability *is*, he just assumes that there is a probability that somehow makes sense." Yet statements that plain don't make for papers in *Stud. Hist. Phil. Mod. Phys.*

(Looking at what I posted before, I think I got snowed under by open arXiv tabs; the second link I meant to give was arXiv:1404.2635, which has a little evaluation of what decoherence can and can't do at the very end.)

38. **Peter Woit**
September 8, 2018

Blake Stacey,
Thanks, that Schlosshauer reference is much more promising. I was impressed by his book on the topic, should go back and look at that again.

The literature on quantum foundations I definitely find frustrating. Part of this is its sheer size, part of it is that it's difficult to figure out what people are actually saying, with, beside lots of notation and formalism, thickets of natural language words applied to contexts outside of where those words have clear meanings.

39. **Blake Stacey**
September 8, 2018

An older paper by Schlosshauer and Fine, arXiv:quant-ph/0312058, goes into more detail about where probabilities are introduced so that probabilities can come back out.

40. **Bruno Galvan**
September 9, 2018

A possibility (maybe the only) for the answer to the question "is the source of probability in quantum mechanics the same as in classical mechanics: uncertainty in the initial state of the measurement apparatus + environment?" is yes (without introducing hidden variables) is that there is no collapse, quantum states evolve always deterministically, and the different outcomes of a measurement depend on different initial microstates of system + apparatus + environment. A line of research in this sense has been developed by Schulman in his book [Time's arrows and quantum measurement](#) (from chapter 6). In order that the final state of the laboratory is not a superposition of macroscopically different states, the initial microstate must by hyperfine-tuned. To avoid this drawback Schulman proposes two-times boundary conditions, with a teleological flavor similar to that of the least action principle.

41. **Lee Smolin**
September 9, 2018

Dear Peter,

I appreciate you are trying to follow path 2: "attempt to derive probabilities from a formalism that has only unitary, Schrodinger evolution, which has no notion of probabilities to begin with". The point of my remark is that this is much harder than seems at first. A lot of really smart people have devoted years to trying to make this work and have not convincingly succeeded. Several arguments such as Everett's original attempt, and related arguments of Hartle, Finkelstein, Banks, etc. turn out to be circular because they sneak in a measure related to probability and/or a special role for measurement. Then there are issues with the use of decoherence first pointed out by Abner Shimony, because the dynamics is unitary and reversible so there is a quantum Poincare time after which the state recoheres. So if you attempt to argue that decoherence defines the branches you can't get an irreversible outcome to associate objective probabilities to.

It thus seems you also have to give up objective notions of probability so what you end up trying to show is that observers should chose their subjective probabilities as if Born's rule is correct, when it is actually false. Would this much weaker notion of probability satisfy you?

So my query to you? What are you willing to give up in your beliefs about probability to make route 2 succeed?

Thanks,

Lee

42. **Anonymous**
September 9, 2018

> the dynamics is unitary and reversible so there is a quantum Poincare time after which the state recoheres. So if you attempt to argue that decoherence defines the branches you can't get an irreversible outcome to associate objective probabilities to.

So what? The same problem exists in the derivations of thermodynamics from the equations of classical mechanics, because they are time-reversible and even if the dynamics is chaotic the Liouville theorem still stands and you get Poincare returns. Boltzmann knew that his "mechanical" entropy wasn't really time-irreversible. Supposedly he riposted to Zermelo arguing that the entropy will go back to the original value after Poincare time with "you'll have to wait long" and to Loschmidt arguing that the entropy will go back to the original value if the velocities of all particles were to be reversed with "try to reverse them". Has this ever been satisfactorily solved? I've read that Prigogine had tried to, but his mathematics didn't quite work.

43. **Another Peter**
September 9, 2018

It seems you might be interested in looking at

http://www.compphys.org/pdf/Ann.Phys347.45.2014.pdf

and some of the several follow-up papers that they have.

44. **RBG**
September 9, 2018

I'm not smart enough to know how useful it is, but this topic of probability in the foundation of quantum mechanics is discussed in detail in several chapters of Karl Popper's autobiography Unended Quest.

45. **Mateus Araújo**
September 9, 2018

Dear Lee Smolin,

Are you by any chance confusing Everett's derivation with the old frequentist derivations by Graham, DeWitt, and others? Because those derivations do suffer from the problem you point out (and more), but Everett's does not. He did derive the Born rule to start with, and having it he can legitimately claim that observing non-Born relative frequencies is improbable. The problem with his derivation is that he starts from extremely strong assumptions (essentially that the probability of a branch i depends only on its amplitude \alpha_i, and that states must be normalised with the 2-norm), so nobody regards his derivation as better than just postulating the Born rule.

Also, I don't understand what you mean by "objectively Born's Rule is false" in the Deutsch-Wallace approach. They regard Born's rule as a guide to rational action, and prove that you should follow it. What's false about it?

46. **Peter Woit**
September 9, 2018

Mateus Araújo,

I finally got a chance to start looking at
https://arxiv.org/abs/quant-ph/0405161
which is the kind of thing I was looking for. I've gotten a lot out of other things Klaas Landsman has written, looking through his papers I'm interested to see that he's quite concerned with the subtleties of the classical limit, likely with one motivation of seeing if these give insight into the measurement problem.

47. **Peter Woit**
September 9, 2018

Lee,
The problem here is that I lack much in the way of beliefs about probability to either stick to or give up. And I know that you're correct that trying to get probability from the quantum formalism minus probability leads to great difficulties (and circularities).

I guess my fundamental point of view though is that I find the QM axioms (minus probability) to be part of an extremely compelling mathematical picture, and the probability-based results to be extremely well tested, all of this so much so that I'm not optimistic you're going to find room for something different. I'd be a lot more convinced there was a problem here that needed some new ingredient to explain if I had in hand a detailed quantum model of a realistic measurement, and could be sure that the apparent "measurement problem" was real, and not getting resolved in a subtle way.

48. **akhmeteli**
September 9, 2018

Peter Woit wrote: "I guess my fundamental point of view though is that I find the QM axioms (minus probability) to be part of an extremely compelling mathematical picture, and the probability-based results to be extremely well tested, all of this so much so that I'm not optimistic you're going to find room for something different."

Irreversibility is also extremely well tested, yet, strictly speaking, it is incorrect. The results by Allahverdyan, Balian, Nieuwenhuisen that I quoted show that the projection postulate and the Born rule are good approximations, but still approximations, so they cannot be derived from quantum axioms minus probability as exact laws (let me also note that the projection postulate and the Born rule do not reflect the fact that any measurement requires some time to perform). On the other hand, if one believes that probability-based results are exact laws, one gets some strong results, such as violations of the Bell inequalities in quantum theory, that cannot be proven based on QM axioms minus measurement theory.

As for "room for something different"… It is with some hesitation that I would like to mention mathematical results of my paper http://link.springer.com/content/pdf/10.1140%2Fepjc%2Fs10052-013-2371-4.pdf (Eur. Phys. J. C (2013) 73:2371). One of the models I consider there is scalar electrodynamics (Klein-Gordon field minimally interacting with electromagnetic field). It turns out the Klein-Gordon field can be algebraically eliminated (in the unitary gauge), and the resulting equations for the electromagnetic field describe its independent evolution. This local theory can be embedded into a quantum field theory using generalized Carleman linearization. Thus, even if a quantum field theory's predictions are in agreement with experiments, the results of the experiments can also be explained by a local theory.

49. **GoletaBeach**
September 10, 2018

https://arxiv.org/abs/1406.5178 is a bit peculiar from an experimentalists' perspective… maybe OK but hardly communicative… G. Baym, Lectures on QM, 1969 & 1973, end of chapter 14, much better, at least for those who build experiments. But not sure neutral atoms can be born in EPR-type states… photons present other experimental challenges… would need the equivalent of Baym for the gamma measuring process.

Without practical designs of apparatus, it may be fruitless to speculate.

50. **Peter Woit**
September 10, 2018

Goleta Beach,
Stays away from the measurement problem, but for the experimentally inclined, a wonderful book is Haroche and Raimond, Exploring the Quantum

All,
Thanks for pointers that have been very helpful. I've added an update to the posting listing some of these. All of this has very much deepened my understanding (as well as my confusion…) about these issues.

51. **Eric Dennis**
September 11, 2018

Peter,

You seem to be hoping that the basic problem might be resolved by some deep analysis of a complicated many-body model capturing interactions between a system and a measuring device. But the critical facts are already on the table, and such an analysis doesn't have any room to get around them–namely the facts:

1. An initial system state comprising a superposition of mutually orthogonal terms, unentangled with the measuring device state
2. An entangling (unitary) operation between system and device
3. A resulting superposition of FAPP orthogonal terms, each one with a different system state and corresponding device state

I am curious how you think there is any chance of this final superposition going away in favor of a single term? How could a more detailed analysis of a specific model possibly achieve that?

Have I misunderstood your goal here? If not, Lee Smolin's remark should be clear: there is no way to magically inject the empirical concept of (measurement result) *probability* into this abstract Hilbert space set-up without adding something else. And there is also no way to get a unique measurement result out of that superposition without adding something else. So your solution is going to fall into one of three buckets:

1. Renounce the assumption that there is a unique result
2. Add something else
3. Flip the table over, scream incoherently, and run away

Or using their technical names:

1. Many Worlds
2. "Hidden Variables"
3. Copenhagen, postulated state reduction, QBism, or something similar

52. **Jan Reimers**
September 11, 2018

1. An initial system state comprising a superposition of mutually orthogonal terms, unentangled with the measuring device state
2. An entangling (unitary) operation between system and device
3. A resulting superposition of FAPP orthogonal terms, each one with a different system state and corresponding device state

*****

How can we be sure #3 follows from #2? If I understand Peter's position correctly, the unitary evolution of "device"+"system" is horrendously complicated. The device is almost certainly not in an energy eigen-state at finite temperature, rendering its state is unknown. So the question becomes: can we contrive a simple enough "device" and show what happens after unitary evolution of the interacting system. For example system=1 Qubit and device = N Qubits where N is small enough that we can see what's going on during unitary evolution? **Perhaps** one would find that all coefficients in the superposition except one, approach zero and N grows larger, AND that the one selected to grow with N depends on the initial state of the device (N Qubits).

Is this just wishful thinking?

I would think this is at least worth a shot before giving up and diving into MWI and pilot wave fantasies. Maybe one of the references demonstrates something along these lines.

53. **Peter Woit**
September 11, 2018

Eric Dennis,
I'm not assuming the initial apparatus is in a pure state. Not that I know how to do this, but my question was based on treating the apparatus probabilistically (as opposed to the system state). What do you see wrong with
https://arxiv.org/abs/1107.2138
They treat the apparatus using quantum statistical mechanics, and claim:
"Any subset of runs thus reaches over a brief delay a stable state which satisfies the same hierarchic property as in classical probability theory. Standard quantum statistical mechanics alone appears sufficient to explain the occurrence of a unique answer in each run. "

54. **Andrew**
September 11, 2018

There is a nice interview with Roger Balian (of the Curie-Weiss model of quantum measurement) in which he and Francois David discuss their responses to Schlosshauer's questions in Elegance and Enigma here: https://www.youtube.com/watch?v=-K_8W9lnSp8

55. **Perry Rice**
September 12, 2018

Peter Woit

Here are my thoughts on measurement, informed by my work in quantum optics. (apologies for length, 35 years ago I was gonn make a unfied field theory! I got stuck in interference and how detectors work. And our atom-field interaction, the Jaynes Cummmings model is a non-relativistic SUSY SHO so….)

Measurement is an interaction between two subsystems, one subsystem in principle knowable at least in part, and one not. It need not be a classical and quantum cut but it often is. The moon is there because it scatters light from the sun, it is there when you don't look at it.
But if I am observing part of a system, interacting with it, there has to be a cut. Defined by what the user can and cannot know in principle. And a cut means a partial trace of the density matrix and hence a mixed states.

Lets start with photodetection. When a single photon hits a PMT, it excites an electron to the continnum, and from there we get amplification and an avalanche to make a classical current. There is noise in this process called shot noise. Does it come from the source or is it a property of the detector. The "interpretation" depends on which operator ordering (normal, antinormal, symmetric, or any other you want) is used in the calculation. It can be either or some of both. All I know is a photon has been emitted and caused a click. I cannot ascribe a "path" or "cause". And at what point did that current become classical??

With just emission from an excited state, spontaneous emission, that is "due" to two effects. Vacuum fluctuations and radiation reaction. Again, what percentage of those "causes" SpE depends on the operator ordering. And with commutators, this is different from putting things in normal ordering with no commutators as that is what you do for absorptive photodetection. If I use symmetric ordering, I get 1/2 RR and ½ VF. Symmetric ordering (i.e. adag*a=1/2(adag*a+a*adag+1) by definition leaves us with Hermitian operators. So in principle the two things could be separately measured, and there might be some physical reason to say ½ RR and ½ VF.

And not all measurements result into projection onto an eigenstate of a Hermitian operator, as in continuous weak measurement. Vaidman has talked about this somewhat correctly. You have a weak interaction and the "measurement" takes some non-zero time.

As an example, consider how we detect squeezed light. You have two photodetectors behind a beam splitter, and subtract the two photocurrents. With classical local oscillator(coherent state) at one input port of the beam splitter, the currents cancel. Even classical noise is cancelled. EE's have used this for years, called coherent detection, or in QO terms "balanced homodyne detection". Now just have one classical beam input, zero photocurrent (except for the shot noise level described above), and a quantum field on the other port of the BS. The two photodetectors click like crazy due to the strong classical field, and the presence of the quantum signal will unbalance the thing and give rise to a difference current. For strong local oscillator the output is proportional to E_{LO}*a_{theta}, you can measure the fluctuations in a_{theta}, any quadrature you want.

a_0 =1/2(a+adag), a_pi/2=i/2(a-adag)

You cannot measure THE field as that would mean you can have an amplitude operator (adag a) and a phase. The latter does not exist; if it did we would have a time operator.
So you change that phase and watch the noise go BELOW the shot noise limit, and then above. I think they are bolting squeezed light into LIGO as we speak.

You can have Quantum Non-Demolition experiments where you can measure x over and over again, and all the "detection" noise goes into p, or vice versa.

Stimulated emission is kind of classical, spontaneous quantum (for the field anyway), but you cannot tell the difference between the two in detection .A photon is a photon is an excitation of a field leading to a click in a detector). Glauber taught us (knowing QFT) that one had to look to correlations involving two detections. A two point Greens function if you will. Then you can tell a SP em source from a Stem source.

As an example of a "cut", think about a black hole. Hawking radiation is a sum of two-mode squeezed states. There is a horizon, so you trace over the bits you can't see. Then you get a thermal state. It's like a Rindler observer seeing a thermal field in Unruh, and Minkowski can see both (or their effects)

There is no unique classical limit in QM. For the SHO, oh lets say large n is classical. Well it is except for the n zeros in the wave function. OK so then eigenstates of a are classical, coherent states. Then you have a wavepacket bouncing back and forth in the well. The first is appropriate if you look at the same time every look. If you look randomly you will see a coherent state. What is the classical limit?

And for an electron dropping down to a lower level, that is indeed an interaction. The ATOM and the vacuum field know that it happened, and in principle you could detect it. No looking at the meter, or rather not HAVING a meter is not natures fault

It seems funny that QM pretty much tells us you can just know transition amplitudes and probabilities between some initial and final states. Yet we persist in looking for the watchmaker in there somewhere. I guess I am a Bayesianist, but not those that have elevated it to consciousness.

So what is a measurement? An irreversible interaction (at least on the lifetime of the universe. And to give "causes" you have to make a split of the users choice. And its not unique (as density matrices are not)

Any this is in my somewhat informed opinion, I am an experimentalist trapped inside a theorists body, so this suits me. Density matrix is fundamental and represents what we are able to know about a system at any time. You want “cause?” Invent one and see if it matches the voltmeter.

56. **Daniel Tung**
September 12, 2018

Hi Peter,
Regarding your preferred approach: to model quantum measurement as a dynamical process and its outcome probabilities as explainable by quantum statistical mechanics (without assuming any underlying ontic states beyond quantum theory), you would still have to assume the initial states of measured system or the apparatus (or both) to be describable by quantum states.
Then one can always ask why is it being described by quantum to begin with? A quantum state is essentially a list of outcome probabilities. So this approach seems to assume a list of probabilities from the start, and therefore begs the question of where the quantum probabilities come from.

57. **Peter Woit**
September 13, 2018

Daniel Tung,
I don’t see why I have to think of a quantum state as “a list of outcome probabilities”. It’s a fundamental, complete, mathematically very deep description of the the state of the world at a given time. If I want to do a “measurement”, I couple it to a macroscopic quantum object which I have to define by a density matrix due to its macroscopic nature. This evolves in time during measurement as a density matrix. If I believe Balian and collaborators, they give an example of a solution of the “outcome” problem, showing why the final result can be thought of as a single outcome (the cat is dead or alive, not a superposition). I’m not a positivist, so don’t see why I have to think of the quantum state just in terms of the frequencies of these outcomes of very special setups coupled to the state I care about.

I’m surprised that this work hasn’t gotten a lot more attention. I’ll add to the posting a bit more information about it, would love to hear from experts why or why not this isn’t “a solution to the measurement problem.”.

58. **Eric Dennis**
September 13, 2018

Peter,

I have not read that mammoth paper (1107.2138) but it looks like a goose chase. The opaque terminology is inauspicious. Based on some selective skimming, this “hierarchic property” is related to how, e.g., the probability of a number chosen from {1, 2, 3, …, 100} being prime is independent of how you order the subset of primes from that set. Great, so some density matrices have a property isomorphic to a property of probability distributions. Of course we already knew that density matrices have many such isomorphic properties. I don’t see anything earth-shattering about adding this particular property to that list.

More fundamentally, the structure of their argument doesn’t show any evidence of getting to where you want to go. The apparatus starting in a mixed state, rather than a pure state, means simply this: for an experiment run many times, within each run we don’t know *which* pure state the apparatus starts in. But, rest assured, in each run, the apparatus starts in *some* particular pure state.

And now we are back to the basic problem I named above. In *each run*, unitary evolution demands that the final system+apparatus state still contains all the possible system eigenstates (entangled with corresponding apparatus/pointer states), all superposed. Even if in some model they find that density matrices describing *multiple runs* share some extra mathematical properties with classical probability distributions, they are still totally failing to show (i) how a particular eigenstate can possibly be singled out in each run, or (ii) how one could possibly *derive* a probability statement about that undescribed singling-out process. Hilbert spaces in, Hilbert spaces out. No real-event probabilities are in sight.

A smart person tells you he can turn a snail into a giraffe. How? He says he follows it around for 12 miles and administers a very special sequence of taps to its shell along the way. Which is more likely? That he actually can do it. Or that, at some point close to mile 12, he will declare success, and when you look down and say “Still seems like a snail to me,” he will reveal that by “giraffe” he meant a snail underneath a tree.

59. **Peter Woit**
September 13, 2018

Eric Dennis,

Thanks, although I still would like to see a better explanation of exactly what these authors are claiming, along with what exactly goes wrong. A short version of their claims that others may find gives insight is
http://iop.uva.nl/binaries/content/assets/subsites/institute-of-physics/quantum-measurement.pdf?1489502855021
Longer version
https://arxiv.org/abs/1303.7257
At the level of sloganeering, Balian in an interview claims that the situation is analogous to that of classical stat mech and thermodynamics, where one consistently has reversible microphysics, irreversible macrophysics.

For a short critique, see
http://people.bss.phy.cam.ac.uk/~mjd1014/readings.html
One problem for me is that subtleties about what probability is seem to be coming up here, ones beyond my ability to see my way through.

60. **Eric Dennis**
September 13, 2018

Peter,

Those other links are helpful. Note how in the new paper you cite, they are shifting their claim from that of the previous paper, which says: “Standard quantum statistical mechanics alone appears sufficient to explain the occurrence of a unique answer in each run and the emergence of classicality in a measurement process.”

In the newer paper (1303.7257) it’s not “standard quantum statistical mechanics alone” anymore. Now it’s that augmented by some mild-mannered “interpretative principles.” The last one of these “principles” (i.e., separate postulates that must be made besides the Schrodinger equation) is as follows (p. 17, excuse my re-formatting):

“Interpretative principle 5. Consider a set of macroscopic orthogonal projectors Π_i, a state D~ associated at a given time with an ensemble E and the states Dˆ(k)_sub associated with its sub-ensembles E^(k)_sub. If the projectors have in these states the commutative behaviour expressed by Eqs. (12a-b), their q-expectation values q^(k)_i can be interpreted as physical probabilities for exclusive events, i. e., as relative frequencies.”

In the abstract of the paper, this move is described as follows:

"The latter property supports the introduction of a last interpretative principle, needed to switch from the statistical ensembles and sub-ensembles described by quantum theory to individual experimental events. It amounts to identify some formal "q-probabilities" with ordinary frequencies, but only those which refer to the final indications of the pointer."

The "q-probabilities" are apparently just the squared-norms of terms in some decomposition of a Hilbert space vector. So we finally get actual probabilities only by "identifying" them with Hilbert space norms–by hand.

I conclude that this whole enterprise has moved itself squarely into my original bucket #3 containing Copenhagen, postulated state reduction, and other similar gambits. This was the bucket I had identified with the interpretative principle of "flip the table over, scream incoherently, and run away."

61. **Anonyrat**
September 14, 2018

This from Balian, et. al. on resolving Bell, GHZ type experiments:

"As a quantum measurement is a joint property of S{ystem} and A{pparatus}, we are not allowed to interpret simultaneously as real properties of the initial state of S the results of experiments obtained with different apparatuses (here with different directions of the detectors). This deep property of quantum measurements is in line with the absence, for quantum states, of a sample space as in ordinary probability theory [46, 47, 48, 49, 50]."

IMO, this might be the thing to look at to see if it all makes sense.

62. **Peter Woit**
September 14, 2018

Anonyrat,
That just sounds to me like a standard fact going back to Copenhagen. What looks new and confusing here are claims about what "probability" means in the context of getting a supposed single outcome.

63. **Doug McDonald**
September 14, 2018

I've not commented on this, as all my previous posts on similar subjects have been rejected. But I must. I and my former boss have though about this a lot, especially because of experiments we did long ago.

The crux is that you cannot start with a single pure eigenstate. You must include all of the "apparatus" … including the measurement apparatus and the "test particle generation apparatus". And the original state must be a very complicated state vector. This is because both apparatus must be above T = 0. In any real experiment this is true because both are macroscopic. "Near" zero won't do because macroscopic things have low energy phonon states. You can't deexcite them. You can of course choose an energy for the apparatus … but since you are limited in how long you can take to establish that, the uncertainty principle makes a spread in the energy of "true eigenstates" necessary. Because of this the "quantum recurrence time" of the apparatus is incredibly long.

And these complicated composite states are described by a state vector, which changes with time (Schrodinger picture). There are "observables" on that state vector that are macroscopic. Because of the huge number of eigenstates that are excited, these observables follow classical paths. You tell what the outcome is by looking at them (i.e. did a bunch of electrons flow to just one pixel on an LCD?). This can be seen on a computer solving the Scrodinger equation. And, just like in classical mechanics, a tiny change in a wave function a certain point is space and time can, and does, grow with time into a macroscopic change. This can and has been computer simulated. This is probabilistic, based on the state when, say, an electron wave packet hits the surface of a CCD from space. But remember that that wave packet was generated by an apparatus with a finite temperature. Its not a uniform plane wave.

The size of the "apparatus" necessary is surprisingly small, but macroscopic … at least a few hundred atoms. Its not yet exactly simulatable on a computer but is getting closer.

Many people have problems understanding because they try to use a descriptivive "system" and "apparatus" that are impossibly small. They say "well, we'll use a "classical bath" "weakly coupled" to that small system/apparatus … you can't do that, in time weak couplings add up. You can't use perturbation theory, just like you can't use perturbation theory in bound state QCD problems. The apparatus is bound states.

This is an attempt at a wordy explanation of what I believe
https://arxiv.org/abs/1107.2138 says.

September 16, 2018

Mateus Araújo, and Peter,
I appreciate the contribution by Landsman and Reuvers to the understanding of the Born rule. Yet, they do not mention that the instability in their asymmetric double well scenario was described, in a more idealized "Einstein's boxes" version, by J. Gea-Banacloche, "Splitting the wave function of a particle in a box", Am. J. Phys. 70 (3), March 2002, p. 307-312. On the other hand, neither does J. Gea-Banacloche seem to know the work of Jona-Lasinio et al. (1981) cited by Landsman and Reuvers. A survey on "Einstein's Boxes" can be found in T. Norsen, "Einstein's Boxes", arXiv:quant-ph/0404016v2, 8 Feb 2005 (Dated: February 1, 2008), published Am. J. Phys. 73, 164-176 (2005); and S. J. van Enk extends the subject to "Splitting the wavefunction of two particles in two boxes", arXiv:0806.4932v2 [physics.ed-ph] 5 Aug 2008. I guess that Einstein would have been pleased about the instabilities described in these articles. –
One more thing: akhmeteli wrote on September 9, 2018 at 10:32 pm: "[The] projection postulate and the Born rule do not reflect the fact that any measurement requires some time to perform." I agree: This requires that the Born rule must have a sibling on the time axis, where the actual "occurance" of the measurement is undetermined in standard QM, as it is in space. This of course plays an important role e. g. in radioactive decay, but is not covered by text book derivations of the (statistical) decay process.

It looks like I've missed the party – which for "interpretation of quantum mechanics" parties is usually fine – but since it's interesting to see Peter getting interested in this, here are my quick thoughts.

> What I wonder about is whether it is possible to argue that, given that your result is going to be probabilistic, and given some list of properties a "measurement" should satisfy, can you show that the Born rule is the only possibility?

For Hilbert space quantum mechanics I would just take probability as a primitive concept. For any two unit vectors u and v we have "the probability that the system is in state u given that it is in state v". It's odd that this can be nonzero when u is not equal to v, but that's life. Then various choice of mathematically natural axioms will force this probability to be the square of the absolute value of the inner product of u and v.

(You can give this setup a more epistemological spin by saying "the probability that the system is found to be in state u if we check this when we know that it's in state v". However, most days I consider "is found" and "we know" to be distracting fluff. We could add such verbiage to the laws of classical mechanics as well. It doesn't hurt much, but it doesn't help much either.)

In the way I'm putting it, all the interpretive difficulty is packed into the word "probability". By leaving probability as an undefined primitive, I'm leaving it as a separate task to say what "probability" actually means in experimental contexts. This is a very interesting quagmire, with various kinds of "Bayesians" and "frequentists" fighting it out. A lot of the fight over quantum mechanics, I claim, is secretly a fight over what "probability" actually means.

> To clarify the question I'm asking, a better version might be: "is the source of probability in quantum mechanics the same as in classical mechanics: uncertainty in the initial state of the measurement apparatus + environment?

This seems like a completely different question. But it's better in that I can give my preferred answer more rapidly: no.

67. **Peter Woit**
September 17, 2018

John,

Thanks for writing. Now that the party has died down, I'm still confused, but can at least express a bit more clearly what is bothering me. I'll also add this to the bottom of the posting itself.

The state of the world is described at a fixed time by a state vector, which evolves unitarily by the Schrodinger equation. No probability here.

If I pick a suitable operator, e.g. the momentum operator, then if the state is an eigenstate, the world has a well-defined momentum, the eigenvalue. If I couple the state to an experimental apparatus designed to measure momenta, it produces a macroscopic, classically describable, readout of this number. No probability here.

If I decide I want to know the position of my state, one thing the basic formalism of QM says is "a momentum eigenstate just doesn't have a well-defined position, that's a meaningless question. If you look carefully at how position and momentum work, if you know the momentum, you can't know the position". No probability here.

If I decide that, even though my state has no position, I want to couple it to an experimental apparatus designed to measure the position (i.e. one that gives the right answer for position eigenstates), then the Born rule tells me what will happen. In this case the "position" pointer is equally likely to give any value. Probability has appeared.

So, probability appeared when I introduced a macroscopic apparatus of a special sort: one with emergent classical behavior (the pointer) specially designed to behave in a certain way when presented with position eigenstates. This makes me tempted to say that probability has no fundamental role in quantum theory, it's a subtle feature of the emergence of classical behavior from the more fundamental quantum behavior, that will appear in certain circumstances, governed by the Born rule. Everyone tells me the Born rule itself is easily explicable (it's the only possibility) once you assume you will only get a probabilistic answer to your question (e.g. what is the position?)

A macroscopic experimental apparatus never has a known pure state. If I want to carefully analyze such a setup, I need to describe it by quantum statistical mechanics, using a mixed state. Balian and collaborators claim that if they do this for a specific realistic model of an experimental apparatus, they get as output not the problematic superposition of states of the measurement problem, but definite outcomes, with probabilities given by the Born rule. When I try and follow their argument, I get confused, realize I am confused by the whole concept: tracking a mixed quantum state as it evolves through the apparatus, until at some point one wants to talk about what is going on in classical terms. How do you match your classical language to the mixed quantum state? The whole thing makes me appreciate Bohr and the Copenhagen interpretation (in the form "better not to try and think about this") a lot more…

68. **AB**
September 17, 2018

Dear Peter,

Long-time reader, first time commenter (I think).

I agree with everything you write in your latest, third update. My problem with the Balian et al. paper is the same: once you start using density matrices which are not pure, so mixed, you have lost the possibility to describe ordinary unitary time evolution, and you have introduced a probabilistic feature in your theory. In decoherence language, if you neglect the off-diagonal parts of the density matrix in the pointer basis, you have gone from an exact to a probabilistic model.

I think Landsman is on the right track, but I also think most people in foundational QM are looking at this from a too microscopic and/or mathematical point of view, trying to analytically derive neat and exact results for messy many-body systems. Condensed-matter physicists know this is a foolish undertaking.

If you believe like Landsman and myself and perhaps you that everything obeys unitary time evolution, you should put your money where your mouth is and start a project to conduct large-scale computer quantum simulations in which you describe measurement apparatuses as quantum many-body systems like Balian et al., but *in pure states*, couple it to your test particle and see how the combined system evolves for a large number of initial states, for both test particle and apparatus (the last one with a slight perturbation from pure symmetric in the pointer basis). If Born's rule is robust, it should emerge while each run is definite and unitarily evolving.

The problem will be to find the correct Hamiltonian to describe the apparatus: it needs to be in an almost-symmetric, metastable state, unstable to the tiny interaction with the test particle, while the stable states are those in the pointer basis. But any experimentalist can tell you this is a very real problem in nature.

Personally I think this will solve the measurement problem to a large extent, but it will not, immediately, solve non-locality. It everything happens by unitary time evolution, like measurement of one half of a Bell-photon pair, then information including the change of the wavefunction due to interaction with the detector can only travel at the speed of light. I also think the usual interpretation of particles as wavepackets (two photons as two wavepackets within one wavefunction?) may be insufficient to this end.

Finally let me mention this completely ignored and/or unknown paper with does something like Landsman in a QFT model:

https://arxiv.org/abs/quant-ph/0505077

And one unpublished paper which does something like the simulation I mentioned:

https://arxiv.org/abs/0809.1575

69. **Peter Woit**
September 18, 2018

AB,

Thanks very much for the comments and references. The project you suggest sounds worth doing, but needs to be done by people with much different expertise than mine.

One thing I've always been curious about is whether some part of the quantum computing story intersects with this problem, which might make it much more interesting to people.

About non-locality, I confess I've never thought much about that, beyond the vague thought that "the apparatus is non-local, so what's surprising about non-locality"? But I really don't want to start a discussion of this here and educate myself right now, best to leave for another time.

70. **John Baez**
September 18, 2018

Peter Woit wrote:

> The state of the world is described at a fixed time by a state vector, which evolves unitarily by the Schrodinger equation. No probability here.

And perhaps no physics here, either, unless we say *how* the state of the world is described by that vector: that is, how we can use the vector to make predictions of experimental results.

Every theory of physics has this issue: it consists of precise mathematics surrounded by a vaguer and much more complicated cloud of "interpretation": instructions on how to connect this mathematics to things we can do and see in a laboratory.

Those of us who like precision prefer to focus on the mathematics. We'd be happy if this mathematics were, ultimately, "all there really is". Maybe it can somehow provide its own interpretation. But it's hard to see how. To address this rigorously, we'd need to say very precisely what we *mean* by an interpretation, and prove theorems saying that such-and-such a theory can admit only the following interpretations. But I haven't seen anyone do a good job of this yet.

It's particularly hard to see how to get probabilities out of some mathematics unless we put them in by hand – that is, *decree* that certain quantities in the mathematics stand for probabilities. The reason is that it's very hard to say what probabilities actually are, in a non-circular way.

It sounds like you're trying to put the probabilities in by hand as follows. When an experimental apparatus meets a microscopic system, the apparatus is in a mixed state, and we *decree* that mixture has a probabilistic interpretation. We then evolve the joint system unitarily, see what happens, and try to derive probabilities of results.

In other words, we try to bring in the probabilities through a probabilistic description of the measuring apparatus.

I don't see how this will work. When I take an electron with spin pointing up along the z axis, and measure its spin along the x axis, I should get "up" with probability 50%. I don't see how this probability is going to emerge from the probabilities in the mixed state representing the measuring apparatus. Indeed, a good measuring apparatus is usually considered to be one where our lack of knowledge about its state doesn't affect its functioning!

So I'm willing to entertain this line of thought, but I'm not optimistic.

I prefer to bite the bullet and say, right from the start, that a unit vector in a Hilbert space describes probabilities. The *meaning* of a unit vector v in Hilbert space is that given another unit vector u, the probability that "if the system is in state v, then it's in state u" is the square of the absolute value of the inner product of u and v.

Of course this leads to a host of further puzzles, but at least it's clear where I'm putting in the concept of probability.

(By the way, since a pure state of a joint system restricts to mixed states on each of its parts, if you're willing to decree that mixed states describe probabilities, you can reason backwards and get the probability interpretation of pure states as a corollary, given suitable side-assumptions. Wojciech Zurek gave a nice explanation of this in the workshop "Statistical Mechanics, Information Processing and Biology" at the Santa Fe Institute, and he probably has a paper on it.)

71. **Peter Woit**
September 18, 2018

John,

I guess it just doesn't seem to me obviously either necessary or a good idea to try and directly interpret the fundamental quantum state in terms of something very complicated and very different, the experimentally accessible probabilistic classical emergent behavior of a pointer. When you say

"When I take an electron with spin pointing up along the z axis, and measure its spin along the x axis, I should get "up" with probability 50%."

you're assuming a very simple and direct relationship between the microscopic state and the macroscopic emergent classical behavior. But that seems to me exactly where the mystery of measurement problem is, and any attempt to think through how to correctly model this makes clear it's a very hard problem. I'm having trouble finding convincing simple-minded (i.e., "it's just some pure state, evolving according to the Schrodinger equation") arguments about how a measurement apparatus is supposed to behave.

On a related note, I'm also not convinced by
"a good measuring apparatus is usually considered to be one where our lack of knowledge about its state doesn't affect its functioning! "
As I was trying to make clear, the problem occurs exactly when we're talking about observable quantities that have no meaning until we couple our system to the apparatus. It is the apparatus itself which, coupled to the system, is giving (in a complicated way involving emergent classical behavior) meaning to the observable quantity. I don't see at all why our uncertain knowledge of the state of the apparatus is not going to be relevant.

72. **Luuk van Dijk**
September 19, 2018

https://arxiv.org/abs/1805.08583

My summary: If your experiment is described in terms of a separate preparation and measurement step, and all you can do in the end is count events, i.e. you _start_ from statistics, you have to end up with the formalism of quantum mechanics without needing any weird postulates.

73. **David Metzler**
September 20, 2018

I appreciate John's comment that the notion of probability is a source of controversy even outside of any quantum concerns.

My question to the experts is, does Consistent Histories (Griffiths, Gell-Mann, Hartle) provide a useful perspective on Peter's dilemma? As an amateur in the subject of interpreting QM, it has always appealed to me.

74. **Peter Woit**
September 20, 2018

David Metzler,
I'm no expert, but from what I've seen, Consistent Histories just ignores the problem that is bothering me of understanding exactly how classical behavior emerges from quantum. As far as I can tell, it's just one of many ways of papering over that problem.

This Week’s Hype

September 10, 2018
Categories: Multiverse Mania, This Week's Hype

The Stanford string theory group is not taking the attack by Harvard’s Cumrun Vafa lying down. After an arXiv barrage of papers defending KKLT (see here), they’ve now enlisted the Stanford press office, which has produced a five part promotional series about the scientific glories of the string theory landscape. The first part of the series is online today, the rest to come soon.

The great thing about having your university press office write stories like this for you is that they will just print whatever you want, unlike journalists, who might ask your critics what they think and even quote them. Even better than not having to hear from your critics, you can try and discredit them as close-minded reactionaries unethically thwarting the search for truth, by misrepresenting their arguments:

> “One dominant view in the community is that believing in the Landscape might have the negative effect of leading people away from fundamental physics, so we shouldn’t even discuss it,” said Shamit Kachru, who holds the Wells Family Directorship of the Stanford Institute for Theoretical Physics (SITP).

I’ve never heard anyone argue that “we shouldn’t even discuss it”. There is a dominant view in the field that what the theorists at Stanford are doing is not science, but the arguments for this are scientific, not arguments about what is or what isn’t good PR. Will we see any of these arguments in the rest of the series?

Update: All five parts of this are now on-line. No critics of the string landscape are named and their serious arguments are ignored (they are described as “hating” the idea, creatures of their out-of-control emotions). In the context of the old arguments of the string wars, two things to note are

- This could be accurately described as a campaign by people who are losing in the scientific marketplace of ideas to, instead of doing science, start a PR effort aimed at the public.
- It’s once of the best examples of the kind of extreme tribalism and “group-think” Lee Smolin was pointing to that I’ve ever seen. Stanford is portrayed as uniformly of one opinion about this, other opinions are wrong and only held elsewhere. If you are (or want to be) at Stanford and have a different opinion, especially if you’re a postdoc or grad student, it’s being made very clear that you best keep this to yourself.

Update: For those who want to follow the latest on the “Swampland” challenge to the Stanford/KKLT landscape program being promoted by the Stanford press office, there’s a conference later this week in Madrid, talks here. Among the roughly 100 participants at the conference, no one from Stanford. Not invited? Invited, but refuse to participate in any scientific discussion critical of their program? Inquiring minds want to know…

Update: Nima Arkani-Hamed gave the colloquium talk ending the Madrid conference. At the end (1:30), he had these mystifying comments about the landscape, somehow relating this posting to the previous one:

> The raises the possibility that we are misinterpreting the string landscape – the different regions aren’t “out there” but are different APPROXIMATE “System/Observer” splits of A SINGLE OBJECT.

I have absolutely no idea what this is supposed to mean.

Comments

1. **clayton**
   September 11, 2018

   Yikes — I get the feeling that quote is going to haunt Shamit…

2. **Peter Woit**
   September 11, 2018

   clayton,

   I think Kachru was conflating two true things (and adding the silliness about “we shouldn’t even discuss it).

   1. Taking “community” as physicists in general, a “dominant” view would be that this is pseudo-science and discrediting science in general, so people shouldn’t do it.
   2. Taking “community” as string theorists, I don’t think this is “dominant”, but if you look at the video in the linked posting, you see that Vafa is arguing that acceptance of KKLT vacua and the Stanford landscape claims is discrediting string theory in particular (as unpredictive). Vafa’s conclusion though is the opposite of “shouldn’t even discuss it”, instead he’s trying to encourage discussion of the technicalities, hoping that these will show inconsistency of the KKLT vacua and remove the problem for string theory posed by the Stanford landscape philosophy.

   I think the reason we’re seeing a PR campaign from Stanford right now, given that there has been no recent progress on the landscape stuff, is just the perceived need of a response to the bad PR coming from press coverage of what Vafa is doing.

3. **Atreat**
   September 11, 2018

   Part 2 is out: https://news.stanford.edu/2018/09/11/cosmic-symphony-vibrating-strings/

   We depressing learn that we are a part of the Multiverse, but not how our particular universe came into being. What is tee’d up to describe this? Inflation and Andrei Linde are next. Here comes conflation of the string theory landscape with Linde’s inflationary multiverse…

4. **Roger**
   September 12, 2018

   Off topic but maybe relevant for a future post:
   http://www.hyper-k.org/en/news/news-20180912.html .
   It looks like Hyper-K is taking a big step forward towards approval.
   I don’t know what this means for hosting the ILC in Japan.

5. **Low Math, Meekly Interacting**

September 12, 2018

It's very disappointing to see such misinformation repeated so persistently. It's simply not true that most who disagree are perplexed by a modern analog of the Copernican Revolution. I think it's gone on long enough that we can dispense with niceties like "misperception" and call it what it is: a lie.

We're perplexed because a "framework" (if "theory" is a misnomer) one can get virtually anything out of is as good as one you get nothing out of, and redefining "science" to somehow make this glaring inadequacy permissible is beyond the pale.

So please, cut the bullshit.

6. **Peter Woit**
September 12, 2018

Roger,
To connect to the current topic, anyone unaware of what is going on here can get some clue by looking into the question: "what's the string landscape prediction for the proton lifetime?" This question won't appear in the Stanford press office PR campaign.

7. **Atreat**
September 12, 2018

Part 3 is out and the conflation with String Theory is very sad: https://news.stanford.edu/2018/09/12/the-fractal-universe/

Remember Part 2 told us that Linde would answer how the stringy multiverse was connected to ours. Instead all we get is this warm sauce:

"Linde took the multiverse idea even further by proposing that each pocket universe could have differing properties, a conclusion that some string theorists were also reaching independently."

Next up, Part 4 will tell us how this wholly novel idea – that is not at all like what your average stoner dreams up after a good bong hit – helps to explain dark energy. You see, "dark energy" was predicted by Linde and our String Heroes as those "differing properties" the multiverse explains.

8. **Narad**
September 14, 2018

Kevin Wells must have made a lot of bread in software engineering before starting to make unrestricted grants to Stanford, one of which seems to have produced SITP.

9. **Peter Woit**
September 14, 2018

Narad,
That is kind of an odd situation with the SITP Executive Director. Normally people in a position to make significant financial contributions to an institution don't also work in a staff position for the institution (generally, because if they have that much money, why go to work every day doing administrative tasks for a relatively modest pay?).

https://sitp.stanford.edu/people/kevin-wells
https://pgnet.stanford.edu/get/file/g2sdoc/highlights/W10_Wells_p13.pdf

10. **quasihumanist**
September 15, 2018

As a mathematician, this all seems very weird.

I'm used to not understanding anything my colleague next door does. I'm used to having only a dozen people in the world understand or care about the research I do. Having other mathematicians do mathematics that doesn't look anything like what I do is the normal state of affairs, and we generally regard the wide diversity of mathematics as a strength of the discipline. Some people even go to some pains to make sure their graduate students work on different topics so that they don't compete with each other in the future.

Theoretical physicists, on the other hand, seem to think that every other theoretical physicist in the world ought to be studying what they are studying, and regard studying something else as an attack on their work.

Someone explain?

11. **Joseph Conlon**
September 16, 2018

The landscape is topical again – I give my own take on it on my blog http://www.fickleandfreckled.com

12. **Peter Woit**
September 16, 2018

quasihumanist,

The culture of theoretical physics is quite different than that of mathematics, and there's a lot to be said about how that works and the reasons for it.

The story of the Stanford theorists and the anthropic landscape though is a very unusual and very peculiar one. It's nothing like anything that I've heard of in mathematics, or actually in other areas of theoretical physics What's going on here isn't related to what theorists actually work on: at this point, virtually no one (including anyone at Stanford) is trying to pursue the research direction that would connect the landscape to experiment (try to map the landscape and make statistical predictions). Although this looked impossible from the beginning, a few people did work on it, then gave up as it became clear this is a road to nowhere.

If you look at Joseph Conlon's blog entry that he links to above, what you'll see is a pretty typical opinion of string theorists about the landscape business: "far too soggy for physics", i.e. not really science. The Stanford group has from the beginning been faced by the fact that this is what the great majority of their colleagues believe. They've reacted to this by running a rather successful publicity campaign. This campaign has been running out of steam recently, and I suspect it's hard to get journalists to go along with it. Thus the odd situation of the Stanford press office being used as a promotional tool, even though there's no advance in the subject to base a story on.

13. **Reg Taylor**

September 18, 2018

Reading the five sections as a whole it seems to me that, firstly, this is a popular exposition of a singular viewpoint – with all that that entails – and, secondly, the writers(s) aren't fully on the side of the argument. Although 'pro' quotes by the main protagonists are used liberally the staff hacks appear to have tried to temper the claims with a degree of scepticism which is at odds with their paymasters; "the String Theory Landscape remains divisive among physicists", "theoretical physicists at Stanford … sparked a fierce and still ongoing debate about what science is and what it should be", "critics say the theory is ultimately untestable".
Whether the Stanford PR department has produced a useful contribution to the debate is questionable. It won't offend believers, non believers may well be left wondering about the "odd situation of the Stanford press office being used as a promotional tool" and the rest of us will just write the whole thing off as a PR exercise and, ultimately, pointless.

14. **Lars**
September 19, 2018

If you look at Joseph Conlon's blog entry that he links to above, what you'll see is a pretty typical opinion of string theorists about the landscape business: "far too soggy for physics", i.e. not really science. The Stanford group has from the beginning been faced by the fact that this is what the great majority of their colleagues believe. They've reacted to this by running a rather successful publicity campaign

If that is indeed what Stanford has been doing (and I'll have to take that claim at face value), I'd have to say that they have not been all THAT successful if it is also true that *a pretty typical opinion of string theorists about the landscape business: "far too soggy for physics", i.e. not really science.*

If that is indeed the case, why even bother writing about it on a blog?

Hasn't it already been decided among scientists? Isn't that how science is supposed to work?

Or, if the Stanford press release was intended for someone other than scientists, who might that be? Surely, John Q. Public neither knows nor cares about the string landscape.

15. **Peter Woit**
September 19, 2018

Lars,
While I think the majority of physicists have a negative view of the landscape business, there are others who don't, as well as many who just don't understand what the controversy is about. This is one reason I continue writing about it.

I think you underestimate the interest of John Q. Public in this kind of issue. Multi-million dollar book contracts are not unheard of for books about this aimed at the public.

As for the question of who the Stanford PR effort is aimed at, the physicists involved in this are well aware that a crucial audience is not the public, and not practicing physicists, but those who control the money: university and funding agency administrators and wealthy donors. Few people read the output of the Stanford press office, but one of the main targets of that sort of press operation is exactly these people.

16. **Jeff**
September 19, 2018

Lars,

I wouldn't be as dismissive of the public's interest. I think there is a decent percentage of folks who care; unfortunately, some of the interest is being generated by the unsubstantiated, "mind-blowing" claims coming out of places such as Stanford. And scientists don't arise via spontaneous generation; one goal of the PR blitz is surely recruiting. Another goal is surely shoring up support for funding, most of which is set by non-string-theorists, or even non-scientists in general.

17. **GoletaBeach**
September 19, 2018

Yawn. Old news. The interesting stuff is out among the young experimentalists and phenomenologists grappling with new ways to detect the "darks" and weird new experiments at CERN, FNAL, and elsewhere. Any one of those experiments is quite a bit more interesting than KKLT etc.

18. **tulpoeid**
September 20, 2018

GoletaBeach and Lars, unfortunately it's not yawn and old news. The part of the public that believes scientists have discovered the multiverse is real (with the aid of the landscape, the many-worlds interpretation and inflation [as if a multitude of unrelated possible causes lends credibility to a made-up outcome]) is growing.

Personally I think the war is lost for this and the next generation – theoretical physics as a means of enlightenment of the humankind at large is regressing. But we have to keep fighting for the coming ones and also for the unaffected individuals; and after all, when I want to relax I remind myself that science does not equal academia.

PS: Since you mention them, in general-physics experiments priority of allocation of resources has been determined to a large extent by which theories are deemed popular. Just to say that it's not a purely philosophical issue, and it's not only about theories without predictions (which of course affect funding on their own yada yada).

19. **Low Math, Meekly Interacting**
September 20, 2018

Agreed. Other disciplines have their own diseases, but evidence-based remedies have at least a fighting chance of working to counteract them. Not so the multiverse.

Fundamental physics, despite its daunting conceptual and technical challenges, is actually intensely interesting to many lay citizens. For many, it's the only branch of the natural sciences they would bother to buy a popular book about and read. Whatever the reason for that, stories about what HEP theorists like Einstein and Hawking think about and do professionally might be the layperson's most influential exposure to "science". That this is obviously far too limited a sample to make a fair assessment and people generally ought to know better is both true and moot. For better or worse, the more "mind-blowing" the subject, the more eyeballs will be drawn. I'm as guilty as anyone of having the craving.

I'm of the opinion the gains of scientific enlightenment can't be taken for granted, and nearly everything I see in the news these days fills me with alarm. So when the most beguiling of scientific disciplines is infected with mutiverse mania to any degree, it's a cause for some dismay. Though it should have an insignificant impact on the public perception of science, I tend to think it doesn't at all. And that could be a serious problem.

Scholze and Stix on the Mochizuki Proof

September 20, 2018
Categories: abc Conjecture

As discussed here a couple months ago, Peter Scholze and Jakob Stix believe they have found a serious problem with Mochizuki's claimed proof of the abc conjecture, and traveled to Kyoto in March to discuss it with him. Their write-up is now available here. Mochizuki has made public his response to this, creating a web-page available here. There's also an updated version of Ivan Fesenko's take on the story, as well as a possibly relevant FAQ on IUTeich from Go Yamashita.

Erica Klarreich has an excellent long and detailed article about this story at Quanta.

Update: Looking through these Scholze/Stix/Mochizuki documents, my non-expert opinion is that Mochizuki does not seem to effectively address the Scholze-Stix objections, which are aimed at a very specific piece of his argument. Unfortunately, he also does his own credibility a huge amount of damage by including over-the-top attacks on the competence of Scholze and Stix, in typefaces that make him look unserious. For instance, there's

> *I can only say that it is a* very challenging task to document the depth of my astonishment *when I first read this Remark! This Remark may be described as a* **breath-takingly (melo?)dramatic self-declaration**, *on the part of SS, of their* profound ignorance *of the* elementary theory of heights, *at the advanced undergraduate/beginning graduate level*.

or the last couple pages of his report.

Update: More of the same about IUT from Fesenko available here. His argument is that the overwhelming majority of leading experts in arithmetic geometry who are skeptical of the purported abc proof should be ignored, since they haven't put in the two years of continuous study of IUT necessary. I don't think this collection of ad hominem arguments will do anything to change anyone's mind. I also don't see why he doesn't instead produce what could change minds: a clear and convincing technical refutation of the Scholze-Stix argument.

Comments

   September 20, 2018

   This is very interesting, thank you. It is discouraging, on one hand, that agreement cannot be reached even when things are boiled down like this to (seemingly) one small issue. On the other hand, I feel more optimism than before that this will get finally resolved fairly soon. At the least, Scholze and Stix are doing a great service by highlighting and publicly discussing the problem area. Hopefully more mathematicians will now get involved.

2. **Mateus Araújo**
   September 20, 2018

   Thanks for posting the update, it is the same as my impression of Mochizuki's comments, which I didn't want to write out of politeness.

3. **Peter Woit**
   September 20, 2018

   S,
   Thanks. My impression is that for most people these documents will conclusively resolve the issue, in favor of the Scholze/Stix side that this proof has a serious flaw. Mochizuki does not do an effective job of answering their objections. His only hope is that some others interested in this will now be able to focus on the very specific problem that Scholze/Stix point out, and if they find that Scholze/Stix are mistaken, do a better job than Mochizuki of explaining why.

   This has been a very strange and unusual story since the beginning, fascinating because it illuminates well how mathematics normally works, because of the failures that occurred here. Here again, the situation is remarkable and illuminating. I've never heard of something like this happening before (experts writing long competing documents arguing about whether a specific part of a technical proof is correct). In other subjects you have experts publishing competing papers claiming the other person is wrong, with no resolution coming out of this. This doesn't happen in mathematics: experts discussing a technical question about a proof are supposed to converge on an understanding of what is correct and what isn't. In particular, I don't think any journal would even consider publishing both of these, the editor would just say "one or both of them is wrong, if we publish both, we'd be publishing an incorrect paper".

4. **S**
   September 20, 2018

   That's probably right, Peter; I lack competence to judge, and clearly there is a very subtle issue (either real or imagined) about whether and when to identify non-canonically-identified things, so it's hard for me to say for sure.

   One thing for certain is that your update is right. I hadn't read Mochizuki's reply carefully last time I posted. When I did, I was simply aghast at the remark you quote. How can anybody dare say such things about… well, honestly, ANY competent fellow-mathematician? But much less a Fields medalist widely regarded as the star of his generation? It really does feel like Mochizuki is working through some issues in public, but that of course is a sidelight to the mathematical questions here. (Except that, as you say, that impression does not underwrite confidence in his mathematical judgments here.)

5. **David Roberts**
   September 20, 2018

   What I find most telling is that Scholze–Stix provide explanations of some of Mochizuki's objects in terms that humans can understand, explain where their own simplifications may have been too strong, and where the simplifications are perfectly safe, whereas Mochizuki supplies yet more analogies based on manipulations of inequalities based on unspecified quantities, and then pages and pages of explanations about the importance of distinct labels. While Mochizuki is welcoming actual technical and precise discussion (while dismissing it at misunderstanding his work), I find his report *not technically precise enough*. As a category theorist I feel I'm capable of recognising the distinctions one makes between objects considered in different categories linked by various forgetful functors, and his treatment is less than clear. It's entirely possible there was a simplification made that accidentally identifies two isomorphic objects by an incorrect isomorphism, and Scholze–Stix are aware of this, but aren't convinced by M's protestations on their specific choices. At this point, M could make a very short and concrete rebuttal of their rebuttal, but pointing to just **one** such incorrect choice, but no, it needs a 41-page report…

   Also this quote:

> IUTch has been checked , verified, read and reread, and orally exposed in detail in seminars in its entirety countless times since the release of preprints on IUTch in August 2012 by a collection of mathematicians (not including myself) involved in this line of research. (For instance, Fesenko estimates, in the most recent updated version of §3.1 of his survey [Fsk], that IUTch has been verified at least 30 times.) This collection of mathematicians has (together with me) also been actively involved in detailed discussions and dialogues with mathematicians who have any questions concerning IUTch.

!

Voevodsky's proof of the Milnor conjecture was likewise discussed around the world in seminars for a six years (and was much better received and understood) before Deligne discovered an incorrect lemma that had to be replaced. The number of people who claim to understand IUTT is surely that much smaller… (Not to mention the Kapranov–Voevodsky paper on the homotopy hypothesis that V admitted he took over a decade to accept had a mistake.)

6. **tksfz**
September 21, 2018

As a casual non-at-all-expert observer, I find myself oddly reassured to see that mathematics is performed by flesh-and-blood human beings, faults and all. 🙂

7. **anon**
September 21, 2018

Wow. I thought that Fesenko's criticisms of people who don't understand Mochizuki were harsh, but now I see that also when it comes to hurling insults, he is just an apprentice of the great IUT master.

8. **MK**
September 21, 2018

Your quote does not seem to appear in the current version of the document on Mochizuki's website.

Also, the document seems full of highly technical content, I think you are doing a disservice to the discussion by highlighting the small bit of "sensationalistic" remarks (assuming they appeared in a previous version of the same document). One wonders whether you formed what you call your "non-expert opinion" by focusing on the mathematical content, or, as seems to be the norm in this saga (and the source of rightful protests from Mochizuki), the non-mathematical aspects of the discussion.

9. **Peter Woit**
September 21, 2018

MK,
The quote is not from the "Report", but from his second response to Scholze-Stix, see
http://www.kurims.kyoto-u.ac.jp/~motizuki/Cmt2018-08.pdf
and it is still there.

10. **zbornikp**
September 21, 2018

I wonder if Scholze and Stix expect their paper to be published when it contains comments like: *"When it comes to the more drastic simplifications indicated below […], these are inessential to the point we are making, and Mochizuki was not able to convince us during the week why such a simplification was not allowed."* (SS2018-08 2.1 (3))

However *"drastic simplifications"* should be proven, otherwise they are just conjectures. Claiming that *"Mochizuki was not able to convince us"* doesn't prove these conjectures. On the other hand, if the *"drastic simplifications"* are not needed to refute the proof, then they prevent the claimed refutation from being published, which also doesn't make sense, if the aim of the authors really is to have the paper published.

Indeed, rather than aiming at publishing their paper, might it be the case, that Scholze and Stix aim "lower", i.e. at preventing Mochizuki's proof from being published? Mochizuki states on his web page (http://www.kurims.kyoto-u.ac.jp/~motizuki/IUTch-discussions-2018-03.html), that *"it does not necessarily appear realistic to expect that further substantial efforts of the sort just described will be made by the authors of these files [SS2018-05], [SS2018-08]"*

Why otherwise would they write their paper and then walk away from the discussion?

What Mochizuki claims and what Scholze and Stix themselves admit being possible, is that Scholze and Stix with their simplifications have constructed the mathematical equivalent of a Straw man argument.

Here's what wikipedia has to say about the Straw man:
"The typical straw man argument creates the illusion of having completely refuted or defeated an opponent's proposition through the covert replacement of it with a different proposition (i.e., "stand up a straw man") and the subsequent refutation of that false argument ("knock down a straw man") instead of the opponent's proposition.[2][3]

This technique has been used throughout history in polemical debate, particularly in arguments about highly charged emotional issues where a fiery "battle" and the defeat of an "enemy" may be more valued than critical thinking or an understanding of both sides of the issue."
https://en.wikipedia.org/wiki/Straw_man

I wrote a short Science fiction script, somewhat inspired by this remarkable discussion. You can read it here: https://twitter.com/zbornikp/status/1033370752756719619

11. **Peter Woit**
September 21, 2018

zbornikp,
I don't think Scholze and Stix wrote that for publication. See the comments from David Roberts about the "simplification" issue. Yes, Scholze and Stix might be wrong about this, but if so Mochizuki should be able to point to a specific error and convincingly show it is an error. He doesn't appear to be able to do so.

It is true that one motivating reason for Scholze and Stix to get involved was the possibility that PRIMS might accept and publish the Mochizuki proof, even though Scholze (and many others) believed the proof was flawed. I think these documents are best thought of as standard sorts of referee reports and an author's response, which for unusual reasons are being made public. Up to the editor of PRIMS or another journal, but I don't see how an editor, faced with these reports, could possibly accept the proof and publish it. As in such cases, it's not the responsibility of the referees to keep working on this, once they feel they have found an error, explained what it is, and the author has no convincing response.

12. **Ryszard Kostecki**
September 21, 2018

I think it makes an interesting case that the Scholze-Stix paper is made public on the website of Mochizuki, together with a parallel emission of technically inconclusive yet strongly opinionated pieces by himself. This feels very paradoxal. It seems to me that all previous chapters of the story, including Mochizuki's refusal to travel abroad as well as his fabulous text "On the verification of inter-universal Teichmüller theory: a progress report (as of December 2014)" [http://www.kurims.kyoto-u.ac.jp/~motizuki/IUTeich%20Verification%20Report%202014-12.pdf%5D, which – if stripped out of the context – could be as well an artwork of a mathematically informed yet satirical western author, indicate some sort of difference of cultural values and mindset, rather than a personal oddity. I wonder, from the perspective of cultural anthropology (albeit I'm not an expert), to what extent such activity should be read in terms of the acting within the bounds of taboo of 'losing the face' (which is essential in Chineese and Japaneese cultures) or, more specifically and more speculatively, within the bounds of some sort of modernisation of samurai ethics. This would make it very different situation from e.g. the case of error(s) in Voevodsky's work(s). So, while the question how much of it can become useful in the long term run for the 'canonical' international mathematical community remains open, this story seems to carry also a meta-theoretical level that maybe could feed some PhD theses in (mathematically informed) social sciences.

As for science-fication of the inter-universal breath-taking (melo?)drama in the Hodge theatre [sic], here is a little fictional piece about the possible response to Scholze-Stix critique arriving from Mochizuki's camp, which follows the above anthropological speculation: http://www.fuw.edu.pl/~kostecki/inter-universal_samurai.html

13. **UF**
September 21, 2018

While I am by no means an expert on the subject (and agree that the over the top statements are not helpful), I have otherwise a somewhat different impression from reading the reports.

Scholze and Stix say at the beginning explicitly, that they use certain radical simplifications of IUT to get to the core of the proof and then show that this simplified procedure leads to nothing meaningful.

It seems to me that Mochizuki thinks, that if one makes these simplifying assumptions then one indeed arrives at a meaningless conclusion (specifically §12 (AD),(IUAD) in his report), but he disagrees that this would still be the case, if one does not make these simplifying assumptions (SSADFs).

I think this addresses the assertion that the procedure leads to a "meaningless result" by saying: Yes, the result of this procedure *under these simplifying assumptions* leads to meaningless result.

Mochizuki also attempts to explain why his procedure (without these simplifying assumptions) is supposed to be substantially different from a simplified procedure. Mochizuki seems to argue about a (more or less) specific simplified version of the theta link (§10 (SSid) in his report). He claims that while this specific simplified version (SSid) of the theta link is able (and well adapted) to satisfy a certain "switching condition" (SW), it is not sufficiently compatible with "large parts" of the ring structures on both sides of the theta link (i.e. he claims (SSidFs) it cannot satisfy condition 'Theta'CR from his §9).

I cannot judge the merits of this, but he seems to make specific claims, which properties fail in a certain simplified model (SSid). (I don't know how close/far (SSid) is from the simplified model Scholze and Stix consider in their reports).

Maybe relatedly, a rather stark contrast between the positions seems to be whether and to what degree anabelian geometry enters Mochizuki's argument: For Scholze and Stix it does not really seem to enter at all (their Remark 9), while Mochizuki seems to insist ((C5) in his July comments), that it is used in an essential way to guarantee certain symmetries of etale-like structures in the log-theta lattice.

These statements (and Q1,Q2 thereafter) seem to be purely about (non)existence of various versions of "theta links" with various properties (and about which compatibility properties of "theta links" are necessary to deduce Corollary 3.12). Thus they come logically before the disputed Corollary 3.12 (whose proof is based on the existence of a theta link with various properties). Corollary 3.12 seems to be the place, where the main (potential) problems seem to occur, since the reasoning in Corollary 3.12 leads (in the report of Scholze and Stix) to the meaningless inequality (1.6).

This could move the discussion a bit away from Corollary 3.12, whose proof may look quite initimidating, as it looks like it consists just of a summary/combination of nearly everything, which was achieved before.

14. **DrDave**
September 21, 2018

These are clearly ad hominem attacks leveled at people who are politely and rightly asking for clarification; the part about the group laughing out loud is particularly troubling as it has a sort of staged feel to it "a remarkably unanimous response of utter astonishment and even disbelief (at times accompanied by bouts of laughter!)." In addition, there is a the material that implies a lower academic level and "profound ignorance." These ad hominen attacks are now being extended to a wider circle. In this case, I think it is actually a good thing to point out what is obvious: the personal stuff weakens the argument. People should just focus on the math.

15. **Peter Woit**
September 21, 2018

UF (and others whose comments I've deleted…),

I don't think it's helpful for non-experts to try and argue here about the competing technical claims in these documents. Scholze and Stix are experts, have worked hard at this, interacted extensively and directly with Mochizuki, and are well aware of his response to their claims. They explicitly say that Mochizuki does not have a proof. Whatever Mochizuki says, the problem is not that they're ignorant people who aren't able to appreciate his arguments. It is of course possible that they are wrong and he is right. To show this, someone will have to identify a serious flaw in their argument, in a convincing way. Doing this will require a high level of expertise and some serious work. We're not going to see it in comments from non-experts on blogs a day after the documents came out.

16. **asdfasdf**
September 21, 2018

I am surprised that one of Mochizuki's friends or the university pr department has not gently suggested he revise his home page http://www.kurims.kyoto-u.ac.jp/~motizuki/top-english.html . The presence on the site of nonsensical legal proscriptions ("The author of this web site prohibits the use of the contents, such as images, of this site, as well as all linked sites, by the mass media") does not give a professional impression. The "Safety Confirmation Information for Shinichi Mochizuki" graphic on the "What's New" section is also rather strange (when clicked on, the graphic confirms that Mochizuki was safe on September 4, 2018, at 11:00 PM).

Some people, no matter how brilliant, are poor judges of how graphic and personal communications are received by others. Not sure why his supporters are not assisting him a bit here in an area – web page design – that is not his strength.

17. **mahmoud**
September 21, 2018

Is the optimism voiced by e.g. S above really warranted? True, actual mathematics has entered the discussion, but at the end we're left with Scholze&Stix saying that *The inequality derived in our simplified setup is trivial* and Mochizuki: *Indeed it is! And this shows that your simplification is wrong!* and he then dumps another 41 pages of analogies that doesn't seem to convince anyone (besides the people already sold on IUTeich). It's worth noting that S&S say that *they* are convinced the same problem they identify remains even without their simplifications.

So, is this situation any different from what has been going on all along? With the reaction of most experts being *We don't understand what Mochizuki is talking about* and his response: *You need to stop everything else you're doing and reflect on IUTeich in solemn contemplation for a few months and then you will see the Truth!*

18. **Simple**
September 21, 2018

Peter. Will you post something on Atiyah "proof" of the RH?

19. **sdf**
September 22, 2018

I'm still quite surprised that Scholze and Stix traveled to Japan at all… the only conclusion to draw from that is that they must have thought the gap could be fixed but the severely negative tone they take when explaining the gap in their write-up suggests otherwise, so I'm still rather mystified by all this…

20. **Peter Woit**
September 22, 2018

Simple,
No, and I don't think others should be publicizing this story, for reasons that I won't discuss here, but shouldn't be hard to figure out.

21. **Peter Woit**
September 22, 2018

sdf,
I think the reason Scholze and Stix went to Japan is pretty clear. They had decided it was important to resolve the issue of whether this was a proof, and the only way they were going to get to the bottom of things and find out if Mochizuki had an answer to the problem they saw was by talking to him in depth about it. He wasn't going to leave Kyoto, so they had to go there.

22. **FedupPleb**
September 23, 2018

Is not the whole point of a proof that it is an argument that convinces someone else?!
If you can't prove a thing to at least one other person, have you not by definition failed to prove anything?
Failure to be understood is the fault of the speaker!

23. **Aubrey de Grey**
September 23, 2018

Dear Peter (and others),

At this point (just a few days in), what is the state of expert opinion concerning the likelihood that detailed study of the two new papers will lead reasonably smoothly to a consensus on who is right? Focusing only on the substantive content, is there a sense that SM's response has a level of explanatory clarity comparable with the remark attributed to Scholze in Quanta that other number theorists "would have totally been able to follow the discussions that we had had this week with Mochizuki"? Or does SM's document seem, ro experts, to be just as impenetrable as the original papers? Or are things somewhere in between those two extremes?

24. **DH**
September 23, 2018

As a number theorist whose has previously put some effort into attempting to read the IUT papers, here are some miscellaneous thoughts after spending ~6 hours with the Scholze-Stix document and Mochizuki's report(s).

-First and foremost, Mochizuki does not explicitly address the main issue raised by Scholze-Stix, namely the necessity of differentiating between what they call "concrete" and "abstract" pilot objects. Nowhere in his report does one find any use of the words "concrete" or "abstract" in this context: he only refers to "*the* Theta-pilot object" and "*the* q-pilot object".

-The Remark which filled Mochizuki with undocumentable astonishment IS in fact a bit silly. However, it is completely immaterial w/r/t the substance of Scholze-Stix's objection, and could have been dropped from their document without affecting anything else.

-I find the discussion of "histories of operations performed on mathematical objects" in Mochizuki's report to be largely meaningless. A mathematical object is an object in some category, and/or a set with some extra structures; it does not have a "history". (Of course there are mathematical objects where one speaks of their histories, e.g. solutions of PDEs or trajectories of dynamical systems, but this is a precise technical use of the word.)

25. **Peter Woit**
September 23, 2018

Aubrey de Grey,

As far as I can tell, there already is a consensus. In a case like this, the burden is on the mathematician who believes they have a proof to convince other experts, and Mochizuki has conclusively failed to meet this burden. One can argue about the wide variety of claims he makes in response to the Scholze/Stix document (which is short, focused and precise), but the bottom line is that they found them unconvincing. They clearly put quite a bit of time into this, traveling to Kyoto and giving him a week to try and convince them. Mochizuki tries to explain away the problem of not convincing them by arguing that they are incompetent and need to spend more months studying his work. The first of these arguments is both ludicrous and offensive. The second is both not very plausible and likely to discourage anyone else from paying attention. If Mochizuki is saying you need to devote multiple Scholze-months of intellectual effort to understand why he is right, most mathematicians will figure that Scholze-months are equivalent to their years, so no point in even trying.

At this point the only way I see things changing is if some of those who supposedly understand the proof do a better job than Mochizuki of answering Scholze/Stix. The

"IUTeich FAQ" of Yamashita and Fesenko's recent article seem to be attempts along this line, but they're even less convincing than Mochizuki himself.

26. **UF**
September 23, 2018

DH,

SM addresses the issue of concrete/abstract pilot objects (to some degree) in (C16) in his comments to [SS2018-05].

27. **Mizan R Khan**
September 23, 2018

The mathematical community should ignore what is coming out of Kyoto. A number of very fine mathematicians have put in an inordinate amount of time and hard work in trying to understand Mochizuki's work and it looks like they have wasted their time. It is time for the community to move on!

28. **Marcus**
September 24, 2018

Wouldn't it be the right way for Scholze/Stix (or others) to respond to the mathematical content on the latest documents by Mochizuki (which is a response to the SS document) to move forward? Of course Mochizuki shouldn't try to make them look incompetent and this makes things suspicous in my view. But why is the mathematical content of the latest Mochizuki document 'not convincing'? This should be motivated mathematically.

29. **Peter Woit**
September 24, 2018

Marcus,
No, Scholze and Stix have no obligation to keep arguing with Mochizuki if they feel he doesn't have an answer to the problem with his proof they have pointed out. They have other, more important things to spend their time on. Scholze has been revolutionizing his subfield of mathematics and that's what he should be spending his time on, not arguing with an author who insults him and won't admit there's a problem with his manuscript.

One aspect of this whole story that hasn't been mentioned is that Mochizuki has made no substantive changes to his manuscript since his March meetings with Scholze and Stix. This is extremely odd. Normally if an expert tells you he thinks there's a gap or mistake in your manuscript giving a proof, even if you think this expert is wrong, you take this as an indication that you did not explain things well enough. Mochizuki is not just taking the attitude that there's nothing wrong with the logic of his proof, he's also taking the attitude that he does not need to even try to improve its exposition.

30. **HK**
September 25, 2018

I just find the comment of Mizan R Khan is bit offensive and political. It sounds like Univeristy of Kyoto is not a good at mathematics which is not true. I wonder why this comment is not sensored while other comments were taken out.
"The mathematical community should ignore what is coming out of Kyoto. …." You can take this comment out if you wish.

31. **Peter Woit**
September 25, 2018

HK,
I've deleted lots of comments, pro and anti-Mochizuki, on the grounds that they add nothing, just seem intent on carrying on a pointless argument. I interpreted Mizan R. Khan's "coming out of Kyoto" to just be a shorthand reference to Mochizuki and those around him who claim this is a proof, but have never been able to explain it satisfactorily to others. His "time to move on" take on this is a widely held one.

There is one other sense in which a complaint about "Kyoto" is justified. One of the main sources of the problem here seems to me to be the PRIMS refereeing of the paper. In the end, it appears they have decided not to accept the paper for publication, despite early reports they were going to do so, but that seems to have required the intervention of Scholze and other outsiders. The current state of affairs should have been reached much earlier, by expert referees in contact with Scholze and others who were pointing to the questions about Corollary 3.12.

32. **Mizan R Khan**
September 25, 2018

HK: I am very sorry. I should have put more thought into the phrasing of my statement about Kyoto. I did not mean any disrespect to the mathematical school in Kyoto. Clearly it is very strong mathematically.

When I said Kyoto I was solely referencing Mochizuki's work on abc. Mochizuki is
undoubtedly an extraordinarily talented mathematician. However, the enormous demands and expectations he has made of mathematicians of the stature of Scholze, Stix, et al is utterly ridiculous and self-centered! No matter how brilliant one is, one needs to show some consideration for other people's time and effort.

33. **Timothy Chow**
September 25, 2018

Peter, you wrote, "I've never heard of something like this happening before (experts writing long competing documents arguing about whether a specific part of a technical proof is correct)." Perhaps the closest analogue was the controversy over Hsiang's claim to have proved the Kepler conjecture. (Googling "hsiang hales rejoinder" will give you an entry point to the literature.) As far as I am aware, Hsiang still maintains that his proof is correct, but I am not aware of any other professional mathematician who publicly defends Hsiang's proof. One notable difference in this case is that quite a few mathematicians say that they understand Mochizuki's proof and believe that it is correct. If the current situation persists, with no argument materializing that persuades Stix and Scholze but with a sizable group of researchers continuing to study IUT in its current form, then I think that really would be unprecedented (at such a high level of mathematics, at least).

34. **Peter Woit**
September 25, 2018

Timothy Chow,
Thanks, that is an interesting historical analog, one that I was unaware of.

As for the claim "quite a few mathematicians say that they understand Mochizuki's proof and believe that it is correct", I've mainly heard that coming from Fesenko and Mochizuki, not from mathematicians themselves, especially not from well-known experts in the field. The Scholze-Stix paper may also change the minds of some who in the past thought the Mochizuki proof was probably right. At this point, saying you understand the proof and believe it is correct implies you know why Scholze-Stix are wrong, and can explain that to others.

35. **Andrew**
September 27, 2018

This is off-topic but the ICM plenary videos are now up (https://tinyurl.com/y96a9cn6). I've only watched Geordie Williamson's so far but IMO it is brilliant and of course there's also Scholze's!

36. **David Roberts**
September 28, 2018

I wrote some notes while trying understand the situation. They may be of interest to some people.

37. **David Roberts**
October 4, 2018

From Fesenko's new article:

> This oversimplification strikes as incorrect even people far from number theory, e.g. math physicists and categorists

Well if this isn't an anonymous pointer at myself and Urs Schreiber, then I don't know what is. Let it be put on the record that I do not claim Scholze and Stix's notes are incorrect, just that it is not clear how far they have moved from Mochizuki's work by their simplifications, because I cannot say for sure what Mochizuki's work is really doing, shorn of its verbiage, whereas I generally understand what Scholze and Stix have done.

Various and Sundry

September 28, 2018
Categories: Book Reviews, Uncategorized

First, news related in some way to Australia:

- This summer the Sydney Morning Herald published a nice profile of Geordie Williamson.
- By the way, the ICM plenary lectures are finally available on video, with Williamson's among those worth watching.
- The Sydney Morning Herald also recently had an article on quantum computing, motivated by a public talk by Patrick Hayden. The opening lines of the piece contain a classical superposition of quantum hype:

> Quantum computing will be so advanced that it will make your desktop computer look like an abacus, says Stanford University professor Patrick Hayden.
>
> However Professor Hayden, who will present a public lecture in Sydney on Wednesday, is keenly aware that "the hype is just out of control at the moment".

Among talks I wish I'd gotten to see or am sorry I won't be able to attend, there's

- The talks at the CMI at 20 conference this week in Oxford.
- Sabine Hossenfelder next week across the river.
- John Baez in Cambridge, talking about Unsolved Mysteries of Fundamental Physics.

If you just can't get enough of the debate over string theory:

- Over the last fourteen years I've written skeptically about Richard Dawid's defense of string theory as "post-empirical science", see here, here and here. For a new academic paper along similar lines, see Doubts for Dawid's non-empirical theory assessment.

On politics and quantum theory:

- I learned today from the Economist that the President of Armenia, Armen Sarkissian, is a theoretical physicist. Early in his career he worked in general relativity, see here. The Economist has Sarkissian promoting the idea of "quantum politics":

  > In his view, our interpretation of how politics traditionally works should be updated to reflect the way that physics has been reimagined. The classical world of post-Newtonian physics was linear, predictable, even deterministic. By contrast, the quantum world is highly uncertain and interconnected and can change depending on the position of the observer.
  >
  > "A lot of things in our lives have quantum behaviour. We are living through a dynamic process of change," he says. "I think we have to look at our world in a completely different way."

  I have no idea what's going on in Armenian politics and whether quantum theory is the way to understand it. As for the current horror-show that is US politics, one thing that doesn't deserve the blame for it is quantum theory.

A very quick mini-book review:

- I just got a copy of Alvaro de Rújula's Enjoy Our Universe, which is a short and entertaining, colorfully illustrated, overview of the current state of of high energy physics and the universe. The book brings back fond memories of a late-seventies course on particle physics that I took from de Rújula, whose humorous and lively character comes through in the book. For instance, about credit for discoveries:

  > There is increasingly convincing evidence that the Vikings set foot in America as early as the tenth century. There is no question that the Amerindians were there much before that. And yet, the glory of "discovering" America goes to Columbus. Thus, the point is not being the first to discover something, but the last.

  About the relation of theory and experiment (this comes with a hand drawn illustration):

  > In particle physics, discoveries – serendipitous or not – are generally made by *experimentalists*, in astrophysics and cosmology by *observers*. In both cases there are also the *theorists*. High time to explain the distinctions. This is done in Figure 53. The question is what the similarities between the two sets are. One set consists of a farmer, his pig, and the truffles, the other of the theorist, the experimentalist (or the observer), and the discoveries. The farmer takes his pig to the woods. The pig sniffs around and discovers a truffle. The farmer hits the pig with his bat and takes the truffle away. These are the similarities. The difference is that the theorist scarcely ever directs the experimentalist to woods where there are truffles.

  Beside the humor, the book is mostly succinct, clear and profusely illustrated explanations of important physics and astrophysics. The author early on explains that he plans to avoid discussing the sort of speculation popular in many other books, with a footnote justifying this:

  > There is nothing wrong in discussing these subjects, except, in my opinion, doing it without a very clearcut distinction between facts, reasonable conjectures, and outright fantasies.

Update: Some news and views on an open access development, courtesy of Mark Hillery:

- "Plan S has been put forward by a consortium of European funding agencies, including those of the UK, France, and the Netherlands, though not, as of now Germany, and it would require recipients of their funding to publish in gold open-access journals or vaguely defined compliant open access platforms by 2020. Hybrid journals, such as the Physical Review, will not be allowed. Gold open access requires that authors pay to have their papers published. The claim is that a cap on article processing charges (APC's) will be mandated, but the details have not been spelled out yet. More information can be found here.

  http://www.sciencemag.org/news/2018/09/european-science-funders-ban-grantees-publishing-paywalled-journals

  A good discussion of open access can be found here.

  https://otwartanauka.pl/in-english/experts-on-open-access/open-access-will-remain-a-half-revolution-interview-with-richard-poynder

  This is an attempt to force the gold open access model on all of scientific publishing. In a rebuttal to Plan S,

  > Response to Plan S from Academic Researchers: Unethical, Too Risky!

a group of young European researchers has pointed out that it would prohibit them from publishing in 85% of existing journals. They also point out a number of additional problems with Plan S.
1. While anyone can read an article in a gold open access journal without charge, publishing in one is a different story. APC's, or what used to be known as page charges, are typically several thousand dollars per article. This seriously restricts the pool of people who can publish is such journals.
2. What happens if the rest of the world does not go along with Plan S? Collaborations between EU and non-EU researchers would not be able to publish their results in many high-impact journals (Physical Review Letters, for example), and this could discourage such collaborations. It should be noted that Robert-Jan Smits, the Open Access Envoy of the European Commission, is tying to persuade funding agencies in North America to join in Plan S.
3. Telling people where they can publish violates academic freedom.
4. In a gold open access journal, the financial incentives favor publishing lots of papers; the more papers published, the greater the income of the journal. This could lead to quality problems.
The rebuttal also points to possible alternatives to Plan S, such as green open access, which would allow a researcher to deposit a version of their paper in an online depository, such as the arXiv, at the time of submission and then submit the paper to a journal of their choice.

While I am not a fan of commercial scientific publishers, whose profit margins are ridiculous, I am a fan of society journals (I work part time for one, Physical Review A). These journals are reasonably priced, and income from them helps support societies, such as the American Physical Society, and their activities. Plan S is a bureaucratic attempt to impose, from the top, a publishing model on the world with which many people disagree or have grave reservations."

Comments

1. **Sebastian Thaler**
   September 28, 2018

   Speaking of Richard Dawid and books, the lectures from his "Why Trust a Theory?" workshop are being published in the spring:
   https://www.cambridge.org/us/academic/subjects/physics/history-philosophy-and-foundations-physics/why-trust-theory-epistemology-fundamental-physics?format=HB

2. **Shantanu**
   September 30, 2018

   Peter: What does De Rujula say in his book about super-symmetry and BSM theories in general and also about string theory etc?
   shantanu

3. **CWJ**
   September 30, 2018

   As a researcher with an incredibly tight research budget, I find "no page charges" a greater benefit than "open access." If we had to pay for every article published, that would throw grant budgets into considerable chaos–and probably cut back on funding for grad students.

   Green open access works perfectly well.

4. **Matt Grayson**
   September 30, 2018

   But the Nobel Prize goes to the pig.

5. **Peter Woit**
   September 30, 2018

   Shantanu,
   de Rujula deals with string theory and most BSM stuff by ignoring it completely. Supersymmetry is mentioned in one footnote.

   Matt Grayson,
   Not necessarily, and especially not recently in HEP, where the experimental groups are large, without a recognizable leader. For example, in the case of the Higgs discovery, the Nobel went to the theorists, not to the experimentalists who made the discovery.

6. **Narad**
   September 30, 2018

   > I am a fan of society journals (I work part time for one, Physical Review A). These journals are reasonably priced, and income from them helps support societies, such as the American Physical Society, and their activities.

   I couldn't agree more, having worked as a manuscript editor on the portfolio of the American Astronomical Society. I cannot for the life of me figure out how, e.g., PLoS One (which doesn't bother with such niceties as editing in the first place and doesn't produce formatted PDFs) can justify so much as $1595, for "publication expenses – including those of peer review management, journal production and online hosting and archiving."

   I've worked as a freelance editor since, and the money is a pittance. Even if some of the Gold OA journals actually engage skilled editors (who are few and far between, especially when it comes to nonnative speakers), I doubt that it's a significant part of the overhead. Formatting? Give me a break. Sizing art is not a big deal, and nobody's going to fix your horribly prepared LaTeX.

   At least the AAS journals, after IoP took them over, paid a nominal 30 dollars an hour (more like 14 in real life) and kept the page charges low. One-year embargo, and your paper is open-access, and IIRC, you could host a copy yourself.

7. **Matt Grayson**
   September 30, 2018

   Peter,

   True, and Einstein was a theorist, too. I was thinking of the CMB prize, and just pointing out that it isn't quite as dire as the quote indicated. In the case of the Higgs, didn't the theorists, in fact, lead the experimentalists into the woods?

8. **SITPWatcher**
   September 30, 2018

Tom Rudelius from Princeton will be speaking October 1st at the SITP.

https://events.stanford.edu/events/798/79814/

9. **Peter Woit**
October 1, 2018

SITPWatcher,
Thanks, interesting to see that Team Stanford is inviting Team Vafa to play. I haven't checked to see if any of Team Stanford has been invited to Harvard. As noted in a previous posting, one of Vafa's motivations for this seems to be that he feels that Team Stanford's multiverse mania is discrediting string theory. Rudelius appears to have some other motivations for challenging the multiverse, see
https://www.youtube.com/watch?v=G4Pdz1S-6kc
and
http://augustinecollective.org/string-theory-multiverse-god/

10. **Francesco Ginelli**
October 1, 2018

Forcing golden open access is a disgrace, evidently pushed by people without any reasonable understanding of how collaborative science works. And no interest in practically solving the problem of granting a wider access to research papers.

The argument that funding agencies have the right decide what should be done with their money is a slippery slope. Public funding agencies should use public money to support academic freedom, not promote political agendas which suppress it.

Moving the cost from the reader to the writer is going to create obvious problems. Starting from incentives for journals to publish abysmally low quality papers to the problem of publication access for researcher that do not directly control the funds. Wait for the day a lab director with a tight budget has to chose which paper publication fees to cover.
This agenda should be resisted by the academic community.

I typically publish all my paper in green open access on the arXiv the very day I submit them (as much as I can to no-profit publishers such as APS, I do not see why private institution should profit from my work and public funds) and the system works perfectly. To push open access, it would be enough to forbid embargos and let everyone go green.

Frankly, seen from UK it looks like an effort to further compress regular research costs (standard journals fees in this case) and distribute even more money via the winners take all grant system. Which is of course is a well documented trend, which places more powers in the hand of funding agencies undermining academic freedom (UK being bottom in EU).

11. **Narad**
October 1, 2018

The AAS pricing structure is nothing if not baroque, but the Gold OA premium can be discerned.

12. **John Duffield**
October 2, 2018

John Baez's slides from his Unsolved Mysteries talk can be found on his web site/ He says *"In this century, progress in fundamental physics has been slow. The Large Hadron Collider hasn't yet found any surprises, attempts to directly detect dark matter have been unsuccessful, string theory hasn't made any successful predictions, and nobody really knows what to do about any of this"*. I do. You go over the old ground playing the detective looking for clues. And you find them everywhere, scattered around like low-hanging fruit. It's like Bert Schroer said: *"Perhaps the past, if looked upon with care and hindsight, may teach us where we possibly took a wrong turn"*.

13. **Yemon Choi**
October 2, 2018

Given that you mention Plan S and then also link to that interview with Poynder, might be worth adding a few words to clarify that the interview/discussion seems to date from 2016.

(FWIW I'm generally sympathetic to Poynder's views/analyses)

14. **Fred P**
October 2, 2018

As a consumer of research, I'll note that Green open access is more useful than Gold or a journal publication. Simply put, I have to look through fewer places to find research.

15. **Francesco Ginelli**
October 3, 2018

Fred P: exactly.
These days, even as a professional physicist, it is enough to skim through titles and abtracts of your arXiv daily list of papers from your chosen field(s) and that's it.

This not to say that the peer review validation is not extremely important, or that we could do away with journals (no we can't). It just points out how useful green repositories are.

16. **Marko**
October 3, 2018

After reading through all the relevant stuff, it seems to me that the essence of plan S has nothing whatsoever to do with either moral or practical benefits of open access publishing. Rather, this looks like a straight boxing match between the publishers, whose profit margins are outstandingly big, and science funding agencies, who are done watching that outstanding amount of money going to publishers over and over.

So funders decide to exercise their power over scientific researchers by imposing a requirement to publish exclusively in journals which are gold open access, and — crucially — put a (yet undefined) cap on how big a publisher's profit-per-paper can be. Simple, crude, accross-the-board calculated strategy, with the aim to blackmail publishers into (a) becoming gold OA, and (b) setting their gold OA fees to this overall cap. Otherwise, they risk being strangled with no papers to publish. If plan S receives global support from other funders worldwide, and this kind of blackmail gets enforced onto the publishers by the entire global scientific community, the funders will gain the power to dictate the gold OA price of the article to the publishers, rather than the other way around. Then, over time, the funders can gradually lower the cap to reasonable APC's, and the publishers would have to either obey or perish. One might call this kind of game bullying, but I guess this is a perfectly normal thing in the business world (as opposed to the world of academia).

Crucially, this kind of game relies on global support for plan S by all funders worldwide. But given the current outrageous profit margins of the publishers, it's actually quite likely that plan S will be met with positive sentiment by funding agencies across the board. Basically everyone, funders, librarians, scientific community at large, etc…, seem to be sick of being siphoned for outrageous amounts of money by the publishers, for very little added value.

It is important to note that this is a power struggle between two parties *with power* — namely those who give money for scientific research (funders), and those who take the money to transform that research into a quantifiable product (publishers). The scientists are a third party, the one with no power, since they depend on both funders and publishers. So nobody is asking their opinion, and nobody cares what this opinion might be, because both the funders and publishers have a clear-cut calculation in this whole turf-war. Whatever happens to scientific research, publication quality, international collaboration, young scientists, etc…, is just collateral damage, neither of the two big players could really care about. They only care about the flow and the amount of money.

I'm actually quite interested to see who is going to win this one, and at what cost…

🙂
Marko

17. **Peter Erwin**
October 3, 2018

At least the AAS journals, after IoP took them over, paid a nominal 30 dollars an hour (more like 14 in real life) and kept the page charges low. One-year embargo, and your paper is open-access, and IIRC, you could host a copy yourself.

All the main astronomical journals (the AAS journals, *Monthly Notices of the Royal Astronomical Society*, *Astronomy & Astrophysics*) allow posting preprints on the arXiv (and I believe always have), and everyone does this, so the entire field is "green open access." None of these journals meet the "Plan S" requirements, however, so astronomers funded by the agencies taking part in Plan S would be unable to publish in any of the field's main journals.

18. **anon**
October 3, 2018

Actually, why do libraries subscribe to astronomical journals? I work in astrophysics, but I don't even remember the last time when I read an article in a journal instead of arXiv (except maybe some old pre-arXiv articles, which are open access anyway).

19. **a1**
October 3, 2018

For the moment some of the major publishers are in position to collude with funding agencies to siphon money for a few more years and plainly that is what they are trying to do. The key claim is that only they are able to organize (and maintain) a good peer review system. The reviewing however is done by the scientific community. There are actually some journals that are just an index to papers from the arxiv which have obtained peer review approval. Thinking along these lines will make it obvious that publishers are easily eliminable: one has to realize that during the 20th they became involved in academic publishing mostly as distributors but currently they are obstructing the circulation of papers.
Let's hope that Gold OA wont get off the ground because if that happens soon the publishers will start lowering quality with the argument that the APCs are insufficient and need to be raised. The scientific community a sure loser for one more time.

20. **Narad**
October 3, 2018

> Actually, why do libraries subscribe to astronomical journals? I work in astrophysics, but I don't even remember the last time when I read an article in a journal instead of arXiv (except maybe some old pre-arXiv articles, which are open access anyway).

I dunno; the language improvements can sometimes be significant, and I've prevented more than one erratum. I've also found a surprising number of errors in supplementary tables. I realize that it's a field where one can pretty much rely on the authors, but there's always room for polishing. (Even the cleanest manuscript I ever saw admitted two reference corrections. Taylor was enthused, as I recall.)

@Peter Erwin: I was referring to the published version, not a preprint.

21. **Peter Erwin**
October 3, 2018

@ anon:

Actually, I frequently read articles in journal form (and prefer to get the official journal PDF rather than the arxiv PDF, if possible), for several reasons. One is what Narad said: it's nice to have an extra round of language and proofreading improvements. Plus its nice to have a properly formatted articles, given that some authors still post their manuscripts to the arXiv in outdated "referee format" (single-column, figures-at-the-end, or even double-spaced). Sometimes it's quicker to skim through an HTML page rather than wait for a PDF to download, and sometimes it's nice to be able to retrieve data tables in simple-text form from the journal. And there are still way too many authors posting to the arXiv who aren't aware that the gradually increasing arXiv file-size limits means they usually don't have to provide their figures in heavily compressed, semi-illegible JPEG format any more.

(I am, of course, talking about online versions of the journals; I'll admit I can't remember the last time I read an article in a physical paper journal.)

22. **Dr Beaker**
October 4, 2018

The SMH story on Geordie Williamson was actually published in winter.

23. **Marko**
October 4, 2018

a1,

"Let's hope that Gold OA wont get off the ground because if that happens soon the publishers will start lowering quality with the argument that the APCs are insufficient and need to be raised.”

Lowering quality (i.e. accepting more submitted papers than usual) will eventually reflect in the lower impact factor (since the latter is just the ratio of cited and published papers). Note that the funders will retain the IF as a metric of publication quality, but now with OA enforced and a cap on the APCs. Various publishers will have to compete for IF/APC ratio, as opposed to the current situation where they are trying to maximize both IF and APC independently.

So I don’t think that publishers will dare lowering the quality, since then the IF of their journal will drop wrt. to competition, and this will reflect badly in their relevance in the publication market — since scientists will keep getting grants based on their accumulated IF.

I don’t like IF as a measure of quality, but I bet that both funders and publishers will continue to use it as a primary metric — they have nothing else available. Btw, as a side-effect of OA, it will be substantially easier for any third party to calculate the IF of any journal — publishers will not be able to hide the citations behind a paywall anymore.

🙂
Marko

24. **Narad**
October 4, 2018

Marko,

> Lowering quality (i.e. accepting more submitted papers than usual) will eventually reflect in the lower impact factor (since the latter is just the ratio of cited and published papers).

I don’t generally like to cite The Scholarly Kitchen, as I view the general tone as being one of being apologists for industry, but they do have an item from 2017 showing that the IF of *PLoS One* has been dropping despite reduced submissions. The traffic instead seems to be going to Springer’s competing megajournal *Scientific Reports*.

The only criterion for acceptance in *PLoS One* was some sort of methodological soundness; *Scientific Reports* advertises its own similarly, for “all scientifically valid research.” I really have no idea what’s driving the shift.

25. **Francesco Ginelli**
October 4, 2018

Marko,
leaving society journals (like the superb gamma of Phys Rev by APS) out of your consideration is a dire omission.
They are essentially no-profit operations and do not squeeze money out of public funded research into private hands. They typically do not impose embargos and are the ones risking to be penalized from plan S and should be protected from it (explicitly stating that green open access without embargo is fully OK).
If you want to go after big private publishers, there are other ways, like refusing to referee for them (admittedly difficult if Nature is asking — as one would like to have a say in selecting the high profile papers in her/his community — but easier on other mid-range publications).
Or if you sit in hiring committees, stopping taking Nature & Science publications as automatic conditions for tenure.

For the remaining of your arguments, the too vague formulations about price caps leaves me with little hope that they will be effective. And the observation that a pay to publish model will not decrease quality will only work for top journals, mid range ones which already have a “normal IF” (lets say in the 2-5 range) will predictably just go for volume and more fees.

26. **chorasimilarity**
October 5, 2018

Plan S is the worst among the better solutions, so there are easy to find pros and cons. It is good news for publishers and funding agencies, bad news for researchers, because better solutions already exist, like green OA and Open Science.

27. **Brian Dolan**
October 10, 2018

I agree with Francesco Ginelli. Personally I do not believe that journals serve any function whatsoever in the dissemination of scientific knowledge in physics. The archive does that perfectly well (at least for physics). Journals are only relevant for job, promotion and grant applications. I am totally against gold OA as it essentially bars anyone without a grant from publishing (and as a theoretical physicist working in the Republic of Ireland, where the principle government funding agency does not fund basic science with no immediately foreseeable applications, I do not have a grant). In my opinion gold OA is nothing more than a way of funneling tax payers money into the pockets of commercial publishing houses, via government grants. No wonder that publishers are in favor of it.

28. **David Roberts**
October 10, 2018

For those that aren’t aware, the potted history of Gold OA (named because Gold=money, rather than Gold=’gold standard’) is this: Public Library of Sciences started up with a journal in biology (now *PLOS Biology*), and needed to fund it somehow, and since biologists paid page charges anyway, it wasn’t an issue to change from paying page charges for toll-access journals to Article Processing Charges. Especially as the APC was set at about the level that the cash-rich biologists were *paying anyway*: ~$1500 was the original price. See this archived FAQ page where it is said

> We ask that–as a small part of the cost of doing the research–the author, institution, or funding agency pays a modest fee, $1500, to help cover the actual cost of the essential final step, the publication. (As it stands, authors now often pay for publication in the form of page or color charges.)

and

> The ability of authors or their institutions to pay publication charges will never be a consideration in the decision whether to publish.

The journals that followed were all in similarly expensive areas of research: *Medicine*, *Computational Biology*, *Genetics* and *Pathogens*. So if you were already doing research in these areas, a few thousand dollars on top of the massive cost of doing the actual research was just change.

It’s when people for whom a single APC costs the same as their annual conference budget (if any), and they have no other large costs, are forced into paying similar fees that the model breaks down.

29. **anon**
October 11, 2018

I find it very strange that not-for-profit PLoS journals have page charges that are at the same level as those of commercial open-access publications. Especially as they make such a big deal of being there to serve scientists and the public good. Yet their CEO is paid $500k a year…

30. **Narad**
October 12, 2018

> Yet their CEO is paid $500k a year…

Even society journals are not immune to the flowing of money upward to administrative positions, rather than having it plowed back into development or, heaven help us, staff salaries. The difference, at least at the university press I worked for, was that the total amount was capped by the fee-for-service model. The spillover went to prop up the money-losing books division of the outfit. “Make it up in volume,” as they say.

High Life

October 3, 2018
Categories: Film Reviews

I spent yesterday night at the New York Film Festival, watching Claire Denis's new film High Life. For a detailed and accurate review of the film, see the one at Variety.

This film is about a voyage to a black hole, in some sense an anti-*Interstellar*. Where the scientific plot of *Interstellar* was inspirational and made no sense at all, in *High Life* you get a plot that is all too plausible, and completely depressing. There's a spaceship headed on a mission to a black hole, but this one doesn't have brilliant scientists, traveling in a clean and shiny environment, and out to save the world. Instead, the crew is a bunch of ex-Death Row inmates, stuck on a dead-end trip in a filthy spacecraft swarming with recycled excrement, being subjected to grotesque sexual experiments, with periodic violent assaults, murders, and screaming babies to liven things up.

The supposed mission of the spacecraft is to travel to a nearby black hole and test whether energy can be extracted by the Penrose process. Because of all the murdering and such, that doesn't work out too well. The ending involves another trip into a black hole, with discussion of whether they're going to hit a "firewall". One character thinks not, but that sure looks like one to me at the end. Theorist Aurélien Barrau is listed as "Cosmic Companion" or some such, and must have been responsible for providing the higher level of scientific verisimilitude than that of *Interstellar* (one of the images of a black hole does look like the famous one Kip Thorne provided for the earlier film).

I can't really recommend this film to the average viewer seeking enlightenment or entertainment. On the other hand, if you're looking for something unrelievedly grim, grotesque and disturbing, and really like black holes, maybe you should check it out.

Comments

1. **David Appell**
   October 3, 2018

   Peter, is this the picture of a black hole, from Interstellar, that you have in mind?

   https://goo.gl/images/LlWOau

2. **Peter Woit**
   October 3, 2018

   David Appell,

   Yes that's it. The one in High Life is somewhat different, but similar.

3. **Jon Orloff**
   October 3, 2018

   Sounds charming. Can't wait until it opens somewhere nearby.

4. **tulpoeid**
   October 4, 2018

   Excuse me Sir, Interstellar didn't have any spaceship with brilliant scientists.

   (You can tell I was annoyed by the naivety; however, it was admittedly "inspirational" to a wide audience, even though or, I'm worried, maybe because it "made no sense at all".)

5. **Low Math, Meekly Interacting**
   October 4, 2018

   Because I liked "Alphaville", some joker at work deduced I would enjoy this too. Even encouraged me to skip an off-site with him to go see it. Yeah, no.

   I thank you doubly for the review.

6. **CWJ**
   October 4, 2018

   I hated Interstellar. Almost nothing about it made sense. The planet-destroying plague made no sense. The shuttle craft that can fly in and out of a massive time-dilation gravity well, but doesn't work when moist. And worse of all, the effectively gobbledy-gook about the magical future aliens who rescue Matthew McConawhogivesafig. Yes, I recognized the words they were using–but they would be nonsense syllables to anyone not a physicist. It claimed to be physics, but plotwise, it functioned as magic.

   I did like the robots–non-humanoid, very interesting. And, actually, if they had ended the film when MM flies into the black hole, it would have been a much better film.

   Too bad High Life sounds bad, just in a different way.

7. **Petite Kabylie**
   October 5, 2018

   Dear Peter,
   How come there is no official trailer on YouTube for this movie?
   I can't find any elsewhere either. Could you provide a link where I can get an idea about the movie before going to see it?
   Thanks

8. **Amitabh Lath**
   October 5, 2018

   Wow, black holes are now a movie genre! I remember my parents bought us fitted bedsheets from Disney's "The Black Hole" (probably because they were cheaper than Star Wars ones and they didn't know the difference). Then there was Lawrence Fishburne in "The Event Horizon". Add in Interstellar and now High Life and pretty soon singularities will need their own agent.

9. **Peter Woit**
October 5, 2018

Petite Kabylie,

As far as I know, there's no trailer for the film. This may be related to it only recently finding a distributor. For more details of the film, see the Variety story I linked to, or here's another one that just appeared
https://www.filmcomment.com/blog/film-week-high-life

10. **Narad**
October 5, 2018

> Wow, black holes are now a movie genre!

I still recall 1975's "Into Infinity" from the afternoon show NBC's Special Treat.

11. **Jack Morava**
October 14, 2018

Claire Denis is an astonishing director, comparable to Tarkovsky,
cf eg Solaris, https://www.imdb.com/title/tt0069293/

Trouble every day, https://www.imdb.com/title/tt0204700/
for example is a kind of vampire movie;
The intruder, https://www.imdb.com/title/tt0110171/
is about loneliness, as is
I can't sleep, https://www.imdb.com/title/tt0110171/

They are all haunting, perhaps not for the faint of heart…

12. **Jack Morava**
October 15, 2018

Sorry, my bad:

The intruder, https://www.imdb.com/title/tt0422491/

13. **Peter Woit**
October 15, 2018

Jack Morava,

Thanks! I thought highly of some of the other Claire Denis films I've seen (so was looking forward to this one), recall in particular Beau Travail and Trouble Every Day. This film is definitely strongly influenced by Tarkovsky's Solaris, the spaceship environment and use of flashbacks are similar.

14. **Christopher Sahnwaldt**

Peter, Jack – thanks for the recommendations!

This Week's Hype

October 15, 2018
Categories: Swampland, This Week's Hype

The story of string theory as a theory of everything has settled into a rather bizarre steady-state, with these three recent links providing a look at where we are now:

- At his podcast site, Sean Carroll has an [interview with string theorist Clifford Johnson](). It's accurately entitled *What's So Great About Superstring Theory*, since it's an hour of unrelenting propaganda about the glories of string theory, save for a short mention that there had been some criticism from (unnamed) sources a decade or so ago.

  The truly odd thing about the discussion though was the way it seemed frozen in time back in 1998 just after the advent of AdS/CFT duality, with almost no discussion of developments of the last twenty years. Nothing about the string theory landscape and the controversy over it, nothing about the negative SUSY results from the LHC. The attitude of Carroll and Johnson towards the failure of string theory unification seems to be to simply refuse to talk about it, and try to keep alive the glory days just after the publication of *The Elegant Universe*. They've taken to heart the post-fact environment we now live in, one where if you keep insisting something is true (string theory unification is a great idea) despite all evidence, then for all practical purposes it is true. Johnson has famously admitted that he refuses to read my book or Lee Smolin's. As far as he's concerned our arguments do not exist, and Carroll goes along with this by not even mentioning them.

- For the latest on the Swampland (for background, see [here]()), there's [String Theorists' Heads Bobble Over Potential Dark Energy Wobble](), where we're told that string theorists are claiming "huge excitement" over the possibility that string theory might make a "prediction" about dark energy. Over the years there have been endless claims about "predictions" of string theory, none of which have ever turned out to actually exist, and this is just one more in that long line. The rather odd aspect of this latest prediction is indicated by how it is described in the last paragraph of the article:

  > The real excitement comes from how soon we might know whether Vafa's work has produced a testable prediction of string theory—which would be a first. Experiments like the Dark Energy Survey or the upcoming WFIRST telescope could possibly detect whether dark energy is constant or changing over time, and could perhaps do so within the next few years.

  Reading this, one gets the impression that we'll know what string theory "predicts" about dark energy just when there's a measurement. This actually does describe what's going on here: for some, string theory is a theory of everything as a matter of faith, so to them any new measurement tells us more about string theory, in particular that string theory "predicts" that measurement.

- Finally, there's [an article out by Thomas Hertog](), which contains more about his work with Hawking that was widely advertised after Hawking's death (see [here]()). Hertog claims another sort of "prediction" of string theory:

  > String theory predicts that our universe is fundamentally a hologram that reveals itself only in the most extreme conditions, such as those at the Big Bang.

  For the implications of this prediction, see [String Theory Summarized]().

Comments

1. **Paul in Tacoma**
   October 16, 2018

   Hi Peter,

   I heard about Vafa's "prediction" from another article(https://www.sciencedaily.com/releases/2018/10/181009102431.htm) the other day, where the impression I received was that if Vafa was correct then String Theory was essentially being ruled out based on current observations of dark energy: "String theory is said to be fundamentally incompatible with our current understanding of "dark energy" — but only with "dark energy" can we explain the accelerated expansion of our current universe". So the "excitement" seemed to arise just from the fact that a testable prediction was finally at hand!

   My questions are does this prediction really count against String theory based on our current understanding of dark energy? And if not, or if more observations are needed to test the prediction, what are those observations, and when might they be made?

2. **Geoffrey Dixon**
   October 16, 2018

   "Science advances one funeral at a time." This century-old meme is no longer relevant, methinks. I believe it was Sabine who pointed out that the easiest way for a financially strapped department to give itself some cachet is to hire a string theorist. It's self-perpetuating. It's alive. It is not enough that it fail; something else must succeed.

3. **Peter Woit**
   October 16, 2018

   Paul in Tacoma,
   I've added an answer to this as an FAQ, see
   http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=ive-just-read-that-string-theory-has-finally-made-a-prediction-isnt-that-exciting

   If you really want to know what's behind the misleading hype, see the more recent postings in this category
   http://www.math.columbia.edu/~woit/wordpress/?cat=27

4. **Peter Woit**
   October 16, 2018

   Geoffrey Dixon,
   Hiring a string theorist is no longer an obvious move for a physics department trying to get some cachet and show it is on the leading edge. Most physicists, grant officers and university officers have by now noticed that string theory has been promising breakthroughs for over thirty years, but nothing much has come of it, and skepticism is now widespread. It's exactly because of this worsening environment for string theory hires that those invested in it are involved in publicity efforts to try and prop it up.

   Unfortunately I think you're right though that the fad won't just die off naturally, absent something else that comes along to replace it. It has become oddly institutionalized, with a large and powerful group of "string theorists" of a wide variety of ages, most of whom have stopped working on string theory, but still retain "string theory" as a tribal affiliation.

5. **Atreat**
October 16, 2018

Paul in Tacoma,

My best attempt to understand that sciencedaily article…

Vafa group says assumptions that lead to Landscape are incompatible with constant dark energy because of other assumptions. Prediction: other assumptions are correct and thus Landscape/Multiverse assumptions are incorrect. Vindicates: A future "String Theory" that no one knows how to write down minus the Landscape/Multiverse ie., the hope that someone will find a pearl in the Swampland.

Stanford group says assumptions that lead to Landscape are correct and Swampland are incorrect, but hedging bets by saying dark energy might not be constant. Prediction: that dark energy will be constant and Swampland assumptions incorrect OR dark energy is inconstant and while Swampland assumptions are incorrect, they are based on other faulty assumptions ie, constancy of dark energy. Vindication: Anthropic Landscape with no need for finding a future "String Theory" cuz why bother since the multiverse did it.

Own prediction: no matter what happens experimentally neither side will rule out "String Theory" and claim vindication in some way meanwhile the rest of physics will move on ignoring them.

6. **NotNot**
October 16, 2018

Thanks for the references.

I think it's different to say 'we can't predict anything because we don't have a paradigm' than to say 'we can't predict anything because we have a paradigm and that's what it predicts'.

7. **Tsetrot**
October 17, 2018

You seem to be often scandalized that person X calls oneself a "string theorists" while not working on "string theory". First, who defines what string theory is? Second, who cares? The kind of research discussed at Strings conferences is not discussed at any other major series of conferences. So that series of conferences serves its intellectual purpose. And much of it is valid and great research by any measure (e.g. work on strongly coupled QFT).

8. **Peter Woit**
October 17, 2018

NotNot,

Feynman said it clearly 30 years ago: "String theorists don't make predictions, they make excuses ." Sometimes the excuse is "we don't understand the theory well enough", sometimes it's "we understand the theory and it is of a nature that makes no testable predictions". These are really all the same thing though, excuses for a failed idea about fundamental physics.

9. **Peter Woit**
October 17, 2018

Tsetrot,

I don't think "string theorists" calling themselves whatever they want is scandalous, what's scandalous is misleading the public about "string theory", the way Carroll and Johnson are doing.

I do think though that people interested in solving problems of strongly coupled QFTs are making a big mistake by deciding to adopt an inappropriate name for themselves and what they're doing. Why organize yourself in a tribal manner, branded with the name of a failed idea, and end up getting associated with very prominent ridiculous pseudoscience like the Landscape? Why not disown the failed ideas? In particular, why not change the name of your yearly conference?

10. **Tsetrot**
October 17, 2018

It's because what you brand as "failed idea" has not failed. It's an existence proof that the problem of quantum gravity has a weakly coupled solution. Even if we don't know yet which solution was chosen by Nature, an existence proof is better than nothing. Some discussed ideas may have some questionable parts here and there, and you choose to emphasize them as a sign that the whole field is rotten. That's wrong – the bulk of string theory is here to stay. It's based on actual correct and highly nontrivial calculations, related to properties of 2d CFTs and to moduli spaces of (super)Riemann surfaces. When I do strongly coupled QFT I use the results about CFTs obtained by string theorists. If they invite me to their conference, which they decide, for sentimental historical reasons or whatever, to call "Strings", I go. I love to speak to the audience of people whom I respect intellectually, and this is the case for that crowd. There are other conferences out there with sentimental historical names, who cares. You call this tribal as a pejorative, but there is also a good sense of tribalness. There is simply no other community devoted to think hard and steady about tough nonperturbative QFT questions, and having necessary mathematical background for that.

11. **Peter Woit**
October 17, 2018

Tsetrot,
Sorry, string theory as an idea about unification has failed, conclusively. Those who promote it to the public without acknowledging that "the stuff we told you about all particles and forces being vibrations of strings doesn't work, now we just mean an untestable idea about gravitational degrees of freedom at unobservable scales which doesn't really quite work either, but sucks less than the competition".

Sure, there are now often quite interesting talks about QFT (perturbative and non-perturbative) being given at "string theory" conferences. I disagree with you though that the tribe of "string theorists" have a monopoly on being willing to think hard about non-perturbative QFT.

12. **Peter Orland**
October 17, 2018

As Peter W. says, a minority who work on nonperturbative aspects of field theory make a point of not calling themselves string theorists (I avoid the label and I know others who do, from private discussions). Their reason for shunning the label is not just that it is a misnomer, but that it gives the impression to non-field-theorists that their work is connected to the better-publicized aspects of string theory (the landscape, etc.).

13. **Tsetrot**
October 17, 2018

Axions nor magnetic monopoles nor proton decay have not been found yet, but this does not mean all those ideas have failed conclusively. They may still be revealed experimentally one day. Supersymmetry is no different. Perturbative string theory is no different. It's just an idea about how high-scale physics can be made. It's mathematically consistent, but as yet experimentally untested.

14. **Peter Woit**
October 17, 2018

Tsetrot,
Perturbative string theory (1od, remember) is not just "experimentally untested" (and, by the way, it's not completely mathematically consistent either…). Describing string theory's problem as "not yet experimentally tested" is extremely misleading, since it implies you're talking about some well-defined predictive theory that just happens to be hard to test. One needs to figure out how to get 4d known physics out of the theory, and all attempts to do that have failed. One can argue about how many decades of failed work by thousands of people need to go by before you can describe the failure as "conclusive", but I think we passed that point a while ago.

Breaking News

October 17, 2018
Categories: Uncategorized

Two midday breaking news items:

- The ACME II experiment is reporting today a new, nearly order of magnitude better, limit on the electric dipole moment of the electron:
  $$|d_e|\leq 1.1 \times 10^{-29} e\ cm$$
  The previous best bound was from ACME I in 2014:
  $$|d_e|\leq 9.4 \times 10^{-29} e\ cm$$

  One significance of this is that while the SM prediction for the electron EDM is unobservably small, generically extensions of the SM predict much larger values. Already the 2014 bound was in conflict with typical SUSY models with LHC-scale supersymmetry, and was starting to rule out parts of the ranges expected for split-SUSY models (Arkani-Hamed's current "best bet") as well as the expected range for SO(10) GUTs (see for instance slide 25 here).

  Today's result pretty much completely rules out generic versions for both the most popular SUSY models still standing (Split SUSY), as well as the most popular class of GUTs. This provides another nail in the coffin of the SUSY-GUT paradigm which has dominated expectations for physics beyond the SM over the past forty years.

- The Breakthrough Prize people are having their usual sort of ceremony for the 2019 prizes on November 4, with an Oscars-like production, this year hosted by Pierce Brosnan. In a break with the past, this year they're announcing the winners in advance, see here. The $3 million physics prize goes to Kane and Mele for their work on topological insulators.

  The $3 million mathematics prize goes to Vincent Lafforgue, for his work on the Langlands correspondence. The prize description has some information about him I was unaware of:

  > Deeply concerned about the ecological crisis, Lafforgue is now focused on operator algebras in quantum mechanics and devising new materials for clean energy technologies.

Update: The promotional videos for the Breakthrough Prize winners that will be shown at the November ceremony are already available on Youtube.

Update: Those phenomenologists work fast! A detailed study of the implications of the ACME result for SUSY models is on the arXiv tonight. For a precise version of the crude claim that "generic split SUSY is now ruled out", look at the top two plots in figure 4.

Comments

1. **Rob**
   October 17, 2018

   Is it really the case that this new limit kills off "pretty much completely rules out generic versions for both the most popular SUSY models still standing (Split SUSY), as well as the most popular class of GUTs" ? This limit is only largely sensitive to CP-violating SUSY. Sure – there are a lot of CP-violating phases in the MSSM but, in true model-building fashion, they can be turned off.

2. **Peter Woit**
   October 17, 2018

   Rob,
   Absent some compelling motivation other than avoiding being ruled out by experiment, I think it's appropriate to describe models with CP-violating phases turned off as "non-generic".

3. **David Roberts**
   October 17, 2018

   \times, not x, please.

4. **Peter Woit**
   October 17, 2018

   David Roberts,

   OK, OK… Fixed.

5. **Rob**
   October 18, 2018

   Peter – following your definition of generic, the ACME II result may actually be fairly insensitive to generic SUSY. There is no compelling theoretical reason to keep R-parity conserved, an assumption on which popular SUSY models are based. As you know, R-parity conservation is imposed to stop the observed stability of the proton killing SUSY.

   This is of course all getting a bit absurd….

6. **Shantanu**
   October 18, 2018

   Does anyone know what version of SUSY, Pierre Ramond supports/supported when he said that Super- K results on neutrino mass point to evidence for low-energy SUSY?
   (See https://physics.aps.org/focus/supplement/neutrinoquotes.html)
   and this version of SUSY still alive?

Last Night’s Hype

October 18, 2018
Categories: Swampland, This Week's Hype

If you’re a Friend of the IAS ($1750/year and up), you were invited to a talk last night, at which IAS member Thomas Rudelius promised to explain to you How to Test String Theory. The video of the talk is now available here.

After a long introduction involving large amounts of misleading hype, Rudelius in the last couple minutes finally gets to the promised explanation of “How to Test String Theory”. What is it? It’s his discovery that some versions of axion cosmology are incompatible with the Weak Gravity Conjecture, and thus conjecturally incompatible with string theory.

I assume that the IAS Friends in attendance, besides being financially well off, are also not so dim-witted that they wouldn’t notice that they’d been had (there’s no evidence for axion cosmology, so conjectures about whether or not various axion cosmology models are consistent or not with string theory are completely irrelevant to “testing string theory”). Any questions asked after the talk didn’t make it to the video, so it’s unclear if anyone bothered to complain about what had just been done to them.

Update: For a sensible, informative video about string theory (as opposed to the IAS one), see this from Sabine Hossenfelder.

2. **FWIW**
   October 20, 2018

   the abstract seemed quite honest, as these thing go…

3. **Peter Woit**
   October 21, 2018

   FWIW,

   It’s “quite honest”, if you read
   “does not make unique predictions” as “does not make any predictions”
   and
   “will discuss some recent attempts to address this issue and extract testable predictions from string theory”
   as
   “will discuss some recent speculation that has nothing to do with extracting testable predictions from string theory, and hope you don’t notice”

The End of LHC Run 2 and the Road Ahead

October 24, 2018
Categories: Experimental HEP News

Some experimental HEP news items:

- Since 2015 the LHC experiments have been taking data from proton-proton collisions at 13 TeV. This is "Run 2" of the LHC, "Run 1" was at the lower energy of 8 TeV. The proton-proton Run 2 ended this morning, with the LHC shifting to other tasks, first machine development, later heavy ions. It will shut down completely in December for the start of "Long Shutdown 2 (LS2)", which will last for over two years, into early 2021. During LS2 there will be maintenance performed and improvements made, including bringing the collision energy of the machine up to the design energy of 14 TeV.

  ATLAS is reporting 158 inverse fb of collisions delivered by the machine during Run 2, of which 149 inverse fb were recorded, the CMS numbers should be similar. Most data analysis reported to date by ATLAS and CMS has only used the 2015 and 2016 data (about 36 inverse fb) although a few results have included data through 2017 (about 80 inverse fb). My impression is that for many searches they have been waiting for the full run 2 dataset to be available. Perhaps results of searches with the full dataset might start becoming available by the time of summer 2019 conferences.

  The LHC run 3 is planned for 2021-2023, producing perhaps 300 inverse fb of data, results perhaps available in 2024. It will thus be quite a long time after run 2 results start appearing before better ones due simply to more data become available.

- The Europeans are now starting a process that will lead to an update of the European Strategy for Particle Physics. Tommaso Dorigo has a blog post here, and there's a website here. A first stage of this process will ask for community input, with deadline December 18, via a portal that will open November 1. The next stage will be an Open Symposium to be held May 13-16 in Granada.
- This week there's a Workshop on Future Linear Colliders being held in ~~Austin~~ Texas. The big question being discussed there is whether the Japanese will decide to go ahead with a plan to build the ILC, a 250 GeV linear electron-positron machine. The current situation is described in detail here, with the crucial next step a decision from the Science Council of Japan expected by the end of November. If the ILC project does go forward, a tentative schedule has construction beginning in 2026 and commissioning in 2034.
- For a theorist's recent take on future colliders, see this from LianTao Wang. One thing Wang reports is an "excuse to have fun" (since it's based on an unrealistic assumption), a community study in particle theory being organized by Michael Peskin, which would address the question "What would we learn from an electron accelerator of energy 10-50 TeV?"

2. **Peter Woit**
   October 24, 2018

   dsm,

   Thanks! Corrected.

3. **Sabine Hossenfelder**
   October 25, 2018

   I just looked at the Wang slides. Well, it seems that now you need 100 TeV to probe naturalness, after the LHC ruled it out at 10 TeV. And are they seriously still talking about the WIMP miracle?

   You know, the most frequent question that journalists ask me about my book is: What's the reaction of physicists in the fields that you have criticized? The answer is: none. They keep on doing exactly the same thing that hasn't worked for 30 years. The Wang slides are a good demonstration of this utter lack of self-reflection.

   It really shouldn't surprise me. I mean, the reason I wrote the book is that I have given up hope this community is able to correct its ways. Still I continue to be stunned by just how unscientific their procedures are. They have the data IN THEIR FACE. The data scream: "It's not working. Naturalness doesn't work. The WIMP miracle doesn't work. There's nothing to see here, move on!" But no one is listening.

   All this obsession with numerical coincidences is bad math. It's wrong, and not even for particularly deep or interesting reasons. That a scientific community so large continues to use arguments that are not only wrong but clearly don't work worries me considerably. Not so much because of the mass of gluinos or swhatever (to borrow Lee's joke), because who really cares. It worries me because if this can happen in one scientific community, it can happen in others as well. Just that in the other cases I wouldn't be able to tell what's going on.

4. **Amitabh Lath**
   October 25, 2018

   Sabine, I am a little uncomfortable with statements like "LHC ruled it out at 10 TeV".

   Maybe we've ruled out the really obvious signatures like dilepton resonances and large missing momentum signatures. But R-parity conservation is not necessary (as you and others have pointed out elsewhere) and R parity violation would make new physics really hard to find at LHC (full disclosure, that's my area of interest).

   Also BSM could be long lived. Our tracking code is designed to find prompt tracks reasonably well but if displaced tracks? Not as good. It's an area of concern.

5. **jls**
   October 25, 2018

   Sabine, saying people aren't listening to the data is frankly ridiculous. Of course there are still people pushing SUSY + WIMP DM. But the main energy in the field right now is moving to other ideas, especially axion DM, other possibilities for DM, and qualitatively new ideas to address the hierarchy problem.

6. **Peter Woit**
   October 25, 2018

   Re Sabine's comment and responses,

   I think she's just properly reacting to Wang's claim on slide 23 that "Naturalness is the most pressing question of EWSB". The LHC results so far have disconfirmed the heavily promoted argument that "The naturalness problem means that BSM physics will show up at EWSB scale, so definitely by the TeV scale". Reacting to this by changing your old argument to the new argument "The naturalness problem means that BSM physics will show up at EWSB scale, so definitely by the 10 TeV scale" is not a good idea.

   I do think though that the LHC results have had real impact, even if there are some theorists who don't want to give up arguments they have been so comfortable with. Pre-LHC we saw a lot of claims about extra dimensions and black holes showing up at the TeV scale. Those quickly disappeared once data came in, and I haven't seen any significant attempt to justify a new machine by invoking such things. The negative SUSY results have had a big impact, I see a lot less about SUSY these days, and it's not a dominant topic used for justifying a next generation collider. The LHC searches now seem to be looking at a much wider range of possibilities than just SUSY signatures.

   Mostly Wang and others at these workshops discussing the future seem to me to be sensibly concentrating on the topic of investigating in detail the physics of the Higgs, which is something we know is there, and know that new machines could in principle study better than the LHC. Unless something new comes out of the LHC data that provides a compelling target for a new machine, questions about how good such a machine would be at studying the Higgs will be the dominant ones.

7. **tulpoeid**
   October 25, 2018

   Just an addition / correction:

   "The LHC searches now seem to be looking at a much wider range of possibilities than just SUSY signatures."

   This has been the case since the start (talking the two large experiments). Dozens of different signatures and theories have been consistently investigated since day one of simulated work and are regularly updated. Actually these form the majority of LHC searches in sheer number of different analyses, although of course susy makes sure that its own number of sub-analyses proliferates.

   At the same time, sure susyists had been too vocal and had an occasional real impact on the resources available to LHC analyses. (Which search gets priority in computing time is a very very real decision and the experiments' heads define clear priorities every few months.) But I don't think that there is a shift in the actual choice of work with respect to the previous years (which is both a good … and a bad thing).

8. **Amitabh Lath**
   October 25, 2018

   Thanks tulpoeid I was about to say that non-SUSY has been there from Run zero but probably major conferences are paying a little more attention now.

   Also just because an experimental result is cast as SUSY does not mean it's totally model dependent. For instance if one wants to search for a strong resonance decaying to 3 partons, you need some model to calculate acceptances and such. In the past you could have simulated a techni-rho going to 3 quarks via a intermediate techni-pion. But nowadays the best available simulation is an RPV gluino decaying via an intermediate squark. The detector acceptance is probably not all that different, but a "model independent" search just became a "gluino search".

9. **David Appell**
   October 25, 2018

   I really dislike the unit "inverse fb," but it's more palatable, I think, if written as 158/fb.

10. **Matt Grayson**
    October 25, 2018

    Indeed. Miles per Gallon has the same units as inverse fb. We should use MPG instead. The conversion factor, if I didn't make a silly mistake, is 1 inverse fb = 2.35215 10^37 MPG. Better? Inverse acres works as well. I'll leave the conversion factor as an exercise.

11. **Amitabh Lath**
    October 25, 2018

    I would not be so hard on LianTao. What he is doing is ok^{*}. He is plugging the next big collider by saying we haven't found what we know has to be there so let's go to the next step. I never understood naturalness so can't comment to appropriateness, but the LHC cannot be our last word in exploring fundamental interactions. We can talk about hadron vs. electron vs. muon but a civilization that has enough excess wealth to put a sports car in solar orbit for grins and PR shouldn't be arguing about affordability of machines like these.

    And before you say "but wouldn't those funds be better used doing research X", if the demise of the SSC taught us anything it's that funding is not a zero sum game. There was no $8Billion bump in {{insert your favorite research here}} because SSC got canned.

    *except the use of comic sans, that is inexcusable.

12. **Peter Woit**
    October 25, 2018

    Amitabh Lath,
    Personally I do hope we'll see a next generation collider, and besides the argument for better understanding the Higgs, I think it is worth doing simply to see what's there at a higher energy range, even if it turns out there's nothing new.

    I share though Sabine's reaction to some of the arguments being made that were not good arguments about what to expect at the LHC, failed conclusively there, and should now be allowed to rest peacefully underground. The case for SUSY-scale LHC was always a bad one (105 new parameters to explain nothing?), it's an even worse argument for the next generation.

13. **Steven Patenaude**
    October 25, 2018

    One slide had this as a bullet point:

"We are at a special historical juncture. About to make the next step beyond the Standard Model."

I know part of the reason for the presentation is to build excitement for the next project. Given that, for a layman, is there something particularly special about the next order-of-magnitude power increase? The lead up to the LHC was exciting because of the possibility of finding the Higgs and being able to test some important beyond-Standard Model theories.

(I was slow to post. You have already answered for the most part.)

14. **Sabine Hossenfelder**
October 26, 2018

Amitabh,

If you are uncomfortable with it, you don't know what I am talking about. The story has been that some new physics (particles or extra-dimensions or likewise) has to show up close by the Higgs-mass because otherwise the standard model is not natural and that shouldn't be the case. This criterion has been proved useless: The Higgs-mass is unnatural, period, according to the very quantifiers of naturalness that folks have used in these areas. It doesn't matter if there is something else lurking in the data still to be analyzed, we already know that all the "predictions" based on this idea of naturalness were wrong.

If you don't know what I am talking about, please read my book. I've made a lot of effort collecting references and quotes from people who now mostly pretend they never said what they said or in any case would rather not be reminded of it. For a brief summary, you may want to look at this. Or, in case you have a problem because the statement comes from me in particular, read this.

That they now try to move "tests of naturalness" to 100 TeV is patently ridiculous. The honest thing to say would be that naturalness turned out to be a useless criterion, in which case, let's please stop talking about it. And don't get me started on people who are now trying to come up with other measures of naturalness according to which the standard model would still somehow be natural.

Now, look, I don't care all that much about naturalness. I just pick on this because it's such a clear illustration for how badly knowledge discovery in this community works. If anyone had cared to look at the literature carefully they should have known it's a bad criterion 20 years ago. This would have prevented ten-thousands of useless papers and one might hope that maybe theorists would have come up with something better. Not only did this not happen, they now refuse to learn from their failure. This demonstrates that the self-correction that science relies so heavily on is just broken. It's not working. Someone, somewhere, should really do something about it.

15. **Sabine Hossenfelder**
October 26, 2018

jls,

You write: *"Sabine, saying people aren't listening to the data is frankly ridiculous. Of course there are still people pushing SUSY + WIMP DM. But the main energy in the field right now is moving to other ideas, especially axion DM, other possibilities for DM, and qualitatively new ideas to address the hierarchy problem."*

They are "listening" to the data to the extent that they have to. Since experiments haven't found anything, they can't go around any more and pretend those experiments will soon find it.

But your comment just illustrates the very problem I am talking about: They keep doing the same thing! It's still SUSY, it's still WIMPs and axions and trying to solve other problems that don't exist. SUSY was supposed to be at a TeV because of naturalness (ie, a numerological argument). WIMPs were supposed to be there because of the WIMP-miracle (also a numerological argument). The original axion was supposed to solve another finetuning problem (the strong CP problem – also a numerological argument). Since the original axion was ruled out in the 70s, the present ones are already a fix accounting for an earlier failure. The hierarchy problem itself is yet another numerological problem.

The data demonstrate those arguments are not working. Yet you think it's totally okay to keep using them. You and some thousand of other people who have learned nothing.

16. **Anon**
October 26, 2018

I think it is good for physics community if everyone does not have the same views. It is good for one set of people to still try and look for naturalness in exotic parts of parameter space (probe R-parity violating SUSY etc) while another set accepts that already the evidence is compelling that the Higgs mass has failed the naturalness test — and do their thinking and research assuming there is 1% or worse fine tuning.

Also I think the LHC has only implications for naturalness of quadratic divergences (Higgs mass). The naturalness of the dimensionless strong CP phase that Sabine Hossenfelder refers to is totally a different issue (and axion is just one approach to it — parity or left right symmetry is another approach).

In general there is enough evidence that naturalness based arguments actually work in physics, science, detective work etc. LHC results cannot lead us to abandon naturalness arguments based on electron and neutron EDM experiments for example…. those arguments are important to test models/BSM ideas at even higher scales than the LHC and future colliders can probe.

17. **Peter Woit**
October 26, 2018

Steven Patenaude,
Unfortunately, whatever indirect evidence we might have for something beyond the SM doesn't point to any particular energy scale, and in particular not the energy scale just above what the LHC can probe.

It's understandable that both those trying to get funding for a new machine and those who will work on such a project should take an optimistic view. At the same time the LHC story has shown the danger of people getting too involved with dubious models that don't really work or explain anything, just because these give hope for something observable at the required energy scale. Propaganda to the outside has an unfortunate way of blowing back.

18. **Amitabh Lath**
October 26, 2018

Sabine, I do know what you are talking about. I am familiar with theorists hanging on to pet theories well after the sell-by date. My dissertation was a precise measurement of the Weak mixing angle that basically killed Technicolor but they kept putting makeup on that corpse for several years after.

Same thing happened with my advisor Henry Kendall and colleagues in the late 60's. They found evidence of substructure inside the proton which severely contradicted Vector Meson Dominance but VMD kept happily chugging along for a long time.

Look, I don't have a dog in this intra-theorist fight. What I am afraid of is the collateral damage to experimental physics. You may not be saying this exactly, but someone reading could conjecture that the LHC has ruled out any new physics up to the Plank scale so let's pack up and go home. You have a following among young people. They like your give-no-effs style. We need them to work on the clever new hardware and analysis to pull BSM signal out of the muck. This won't happen if they come to believe that fundamental physics is dead.

PS: I've asked the university library to get copies of Lost in Math.

19. **Anon**
October 26, 2018

Amitabh,

You wrote "….ruled out any new physics up to the Plank scale…"

I would basically just say that null results from LHC/electron EDM experiments leave us with no strong reason for believing that there is new physics at multi TeV scale. There is no good theoretical reason either for new physics to be at multi-TeV scale.

The neutrino mass data provide strong hints for new physics below 10^15 GeV. Further, if we assume unknown dimesionless parameters ~1, this physics will kick in closer to 10^14 GeV than few TeV.

Don't know if this would demotivate experimentalists, but this seems to be the situation.

20. **Peter Woit**
October 26, 2018

Anon,
Pre-LHC, null LEP + edm experiments indicated there were no good reasons to expect new physics other than the Higgs (or something like a Higgs that played the same role). Theorists made various bad arguments promoting unpromising SUSY, extra-dimensional models, etc, claiming they were likely to turn up at the LHC (many of them even bet money on this). I don't see any reason to go from the mistake of announcing that our understanding of what lies beyond the SM implied new physics at the LHC to the opposite mistake of saying that our understanding of what lies beyond the SM implies no new physics at a higher-energy collider. We simply don't know what lies beyond the SM, whether it has to do with neutrino masses, dark matter, or perhaps unexpected physics of the Higgs field. Acting as if we do know about this and discouraging anyone from looking is not a good idea.

21. **Anon**
October 26, 2018

Hi Peter,

I think at LHC there was a strong theoretical reason to expect new physics — naturalness of Higgs mass/hierarchy problem meant that SUSY or some new physics which addresses the hierarchy problem is at the TeV scale that LHC would explore.

Post-LHC many people believe that this naturalness argument is ruled out or doesn't work for the Higgs mass…. and we are talking about colliders at 30 or 100 TeV scale (multi-TeV scale). For many people LHC may have been the last hope for a natural SUSY. Some believed that natural SUSY should have been found at LEP itself. Post LHC the Higgs mass fine tuning is at a 1% level. Pre-LHC it was pbly at a 10% level.

There may still be some pushing for a higher collider on naturalness grounds (I think Nima would like to verify fine tuning of Higgs mass to 0.01% level via a 100 TeV collider), but for me 1% is enough to give up the idea of naturalness of Higgs mass.

Agreed many things could be there at multi-TeV scale or higher scales — SUSY or heavier fermions etc. All I said was that there is no strong theoretical or experimental reason for anything to be there either at multi-TeV. I personally think this need not discourage experimentalists. There is no theoretical assurance or strong bias towards any discovery at multi TeV scale, but things can be there — they are not theoretically ruled out either.

Had the neutrino masses pointed to TeV or multi TeV scale physics, that would have been something.

Anyway maybe we differ in our beliefs.

22. **Amitabh Lath**
October 26, 2018

Anon, the era of precise roadmaps to new physics is fairly recent, starting with the W/Z discovery at the SppS, the top quark at the Tevatron, and most recently the Higgs at the LHC. Before that, our ancestors were sailing without charts not knowing what they would find. We are back to that previous era of wide open searches as opposed to a known signal where theory gives you production, decay, and everything else but the mass.

Demotivating? Maybe for some. I find it exhilarating, frankly.

PS: the electron EDM limits only rule out CP violating new physics.

23. **Niclas Granqvist**
October 27, 2018

There's a considerable chance that hl-lhc will point us in new directions. No reason to give up on particle physics right now. I am optimistic that in some 30 years we have a more fundamental understanding of the world. It will take more experiments to work things out.

24. **Urs Schreiber**
October 27, 2018

If the analysis of the Run 2 data confirms the flavour anomaly in B mesons that Run 1 has consistently been seeing at around 3 sigma, this seems apparently likely to push the statistics of B meson flavour anomalies beyond 5 sigma and thus reveal new physics not by direct scattering processes, but by precision measurement of loop corrections. (here)

25. **Peter Woit**
October 27, 2018

Anon,

I’ve often written about what’s wrong with the “hierarchy problem” (in short, it’s based upon making assumptions about what happens at higher energies that there is no evidence for, motivated by trying to get unsuccessful speculative ideas like SUSY to work). As for Arkani-Hamed and his vigorous promotion of the importance of naturalness, you should keep in mind this quote from him:
“It’s important for me while I’m working on something to be very ideological about it. And then, of course, it’s also important after you are done to forget the ideology and move on to another one.”
See
https://www.math.columbia.edu/~woit/wordpress/?p=8002
That “naturalness” has anything to do with the Higgs was a dubious ideology to begin with, now it’s a failed dubious ideology. Presumably Arkani-Hamed is now moving to a different ideology (the multiverse did it?), but whatever it is, one should keep in mind his quite self-aware quote.

Actually, if you believe in “the multiverse did it”, I suppose you could argue that now that we’re moving past the electroweak scale, we’re entering energy ranges of no anthropic relevance at all. So, we expect things to just be completely random: all sorts of new particles and forces galore!

26. **Anon**
October 28, 2018

Peter, If there are two mass scales in the theory then naively there is a hierarchy problem…. sometimes one can see this at the tree level itself, sometimes at the loop level.

Maybe it is a non-problem, but it is not clear to me why it would be a non-problem…. ie what is wrong with the naive analysis.

27. **Urs Schreiber**
October 28, 2018

It seems striking and unlikely to be a coincidence that the Higgs mass and potential comes out sitting right there on the metastability curve (here). (As opposed to the naturalness-argument, this is a numerical coincidence that does not depend on arbitrary choice of renormalization scheme.)
If anything, it’s that fact which would suggest some deeper principle worthy of investigation.

The Higgs metastability has been advertised as a hint of “asymptotic safety”, but I am not sure if closer inspection of the data justifies this (here).

Investigation of the implications/meaning of the near-criticality of the Higgs exists, but is rare (e.g. He-who-must-not-be-named et. al. arXiv:1307.3536).

Brave G. Kane dares to suggest that it’s actually this metastability which is a clue (“clue 4” in arXiv:1802.05199) for low energy susy. May be wrong, but is better than “naturalness”.

28. **Peter Woit**
October 28, 2018

Anon,
But, besides the electroweak scale, what is the other mass scale causing this supposed problem? The GUT scale? But there is zero evidence for a GUT. The Planck scale? But we know nothing at all about this. What people have been doing is postulating unsuccessful purely speculative models with these scales, then announcing that there is a “problem” due to the smallness of the electroweak scale.

29. **Anon**
October 28, 2018

Hi Peter,

In one of your replies on this thread I think you supported the idea of exploring the multi-TeV scale through a higher energy collider as new physics could be at that scale — say something that would need a 30 TeV or 100 TeV machine. So that scale — say 30 TeV — is then the second scale right? If we are to plan experiments to probe that scale, or start working out consequences of things that could be at that scale so that the experimentalists could look for those signals, we will see that there is a hierarchy problem in our calculations.

If you have the point of view that there is no second scale, and so there is no hiearchy problem, essentially you are saying it is just the standard model with Dirac neutrinos all the way up to the Planck scale — then why continue with experiments that probe higher energy scales beyond LHC? (see ** below)

If the neutrinos are Majorana particles (as most BSM theories assume), then there is a second scale, the seesaw scale < 10^15 GeV that the neutrino masses point to.

** You had written: " I don’t see any reason to go from the mistake of announcing that our understanding of what lies beyond the SM implied new physics at the LHC to the opposite mistake of saying that our understanding of what lies beyond the SM implies no new physics at a higher-energy collider. We simply don’t know what lies beyond the SM, whether it has to do with neutrino masses, dark matter, or perhaps unexpected physics of the Higgs field. Acting as if we do know about this and discouraging anyone from looking is not a good idea."

30. **Peter Woit**
October 28, 2018

Anon,
The Higgs expectation value is 250 GeV, the LHC is giving us limits on new particles that are roughly 2 Tev if they’re strongly interacting, less than 1 TeV if no strong interactions. So, it’s not even getting to an order of magnitude above the Higgs expectation value. A next generation proton-proton machine at 2-7 times the energy I still don’t think you could describe as probing a new energy scale, one with a hierarchy problem with respect to 250 GeV. Same goes for a next generation lepton collider.

I have absolutely no idea if there’s another relevant energy scale above the electroweak one, and I don’t think there’s a good argument either for or against one. Theorists just don’t have anything solid to say about this (seesaw models are not a solid argument), which is why experimentalists should try and go look.

31. **Anon**
October 28, 2018

Hi Peter,

An important thing you may have missed is that it is the square of the Higgs mass that enters the Lagrangian — so the ratio of (2.5 TeV)^2 and (250 GeV)^2 is already a factor of 100. Increase this by factors of 4 to 49 (ie (2)^2 to (7)^2 rather than 2 to 7) and you begin to see that the ratio of new (collider scale)^2 to (weak scale)^2 is a factor of 400 to 4900.

There is an undeniable hierarchy of scales.

In fact this is the exact reason why SUSY (as a solution to hierarchy problem) is in trouble. Because post LHC, we are far above the weak scale, that it cannot be saved.

If you are saying the next scale to be probed by the higher collider is pretty much same as the weak scale then you are essentially providing a hierarchy problem argument for the next collider, and succumbing to the physics is around the corner kind of ideology. Of course the argument is incorrect as you need to look at the square of the scales.

32. **Peter Woit**
October 28, 2018

Anon,
Yes, I'm just saying that the LHC + LEP will not have fully explored the weak scale, which is one argument for building something higher energy that will more fully do so.

The "hierarchy problem" is basically just the quadratic sensitivity of the Higgs field to the cut-off scale. Maybe this is a non-problem, maybe it's telling us something, but we don't know what (that it was telling us "you need a horrifically complicated extension of your theory with a hundred or more extra parameters" was always implausible). Either way, it's irrelevant to the question of whether to explore higher energies or not. I don't think it can be used as an argument for why or why not to build a new machine.

33. **Chris Oakley**
October 30, 2018

Just to note that expressing events recorded in ATLAS in miles per gallon would be a good way of showing the great value the public is getting.

158 inverse femtobarn = 158×(10^43)×(4.546×10^-3)/1609 MPG =4.464×10^39 MPG. Even my super-eco hybrid does not come close.

34. **Anonyrat**
October 31, 2018

CERN writing guidelines:
https://writing-guidelines.web.cern.ch/entries/inverse-femtobarn

> ….One inverse femtobarn corresponds to approximately 100 trillion (10^12) proton-proton collisions.
> ….
> *Note: Do not use inverse femtobarn in the public section of the website where it can be avoided – it is unnecessarily technical. Convert to approximate numbers of collisions instead.*

Langlands News

October 30, 2018
Categories: Langlands

Various Langlands program related news, starting with the man himself:

- For the latest from Langlands about the geometric theory, best if you read both Russian and Turkish. In that case you can read this and this. For the rest of us, all we get are this commentary on the Russian and Turkish documents and these last or very well last thoughts on them.
- In a couple of weeks there will be a conference celebrating the work of Langlands, organized in conjunction with his Abel Prize. Perhaps there will be live stream here.
- I hear that at his lecture at the CMI at 20 conference Scholze made some new conjectures about possible ways of getting the Langlands correspondence in certain cases of the number field case. I haven't however seen anywhere that one can read or hear more about these. It would be great if the Clay Mathematics Institute could make available videos of the talks at that conference.
- Scholze will be giving the Chow lectures in Leipzig next week. The program there includes some preparatory talks by others, including my ex-Columbia colleague Daniel Litt (now at the IAS). I see that Daniel has at least posted a problem set you can get started on.
- Also coming up next week is the Breakthrough Prize Symposium at Berkeley, where Vincent Lafforgue will talk about his (valued at $3 million) work on the Langlands program Monday morning (live stream here). On the physics side, in the evening a group of prize-winning theorists will talk about "Is Time Travel Possible", live stream here.
- A central idea conjecturally relating the geometric version of local Langlands to the number field version is the Fargues-Fontaine curve, which Jacob Lurie has been giving a course about at ~~Harvard~~ UCSD this fall.

  This fall in Bangalore there will be a meeting devoted to the Fargues-Fontaine curve, about which the organizers tell us: "This field will unravel in the coming years…"

- On the local geometric Langlands front, there's something new from Dennis Gaitsgory. I've always been fascinated by the way BRST appears in this story.
- I'm told by experts that one of the best recent results in the Langlands program is this work, which doesn't seem to have yet made it to the arXiv, but was explained in some detail in a blog post last year by Frank Calegari.

Update: Slides from the Chow Lectures are becoming available, see here. Remarkable in particular is Peter Scholze's wonderful introductory lecture on Numbers and geometry, which includes something one sees all too rarely, a set of drawings showing the sort of pictures arithmetic geometers have in their minds for how to think about number theory geometrically.

Update: I just watched Vincent Lafforgue's talk at the Breakthrough symposium. It included basically thanks to the CNRS for providing him a permanent position with freedom, a survey of Langlands, mainly talking about the topology of algebraic varieties, and comments on the ecological crisis. He says he'll put up the slides on his website http://vlafforg.perso.math.cnrs.fr/

He made one (to me) very striking claim, that the functoriality conjecture could be thought of as a quantization problem, how to pass from a classical system to a quantum system. Can an expert enlighten me on what exactly he was referring to here?

Update: Lafforgue's slides are here. James Milne has provided a Google-translated version of the Langlands Russian article here, with the comment:

> This may help readers gain some idea of what the manuscript is about until there is an official translation. Given that even native Russian speakers (not just google) have trouble understanding Langlands's Russian, this would best be done by the author.

Update: Edward Frenkel gave a talk at the Langlands Abel Prize conference discussing the geometric theory and a bit about recent ideas of Langlands on this topic. He has written up some detailed notes on his take on this, available here.

Update: Videos of the CMI-20 talks are available, with Scholze's here.

   October 31, 2018

   Lurie's course is actually happening at UCSD, even though the website is Harvard.

2. **Itai Bar-Natan**
   October 31, 2018

   Strangely, the live stream for "Is Time Travel Possible" indicates a starting time at 26 October. The website affirms that it's Monday 5 November.

3. **Yaakov Baruch**
   October 31, 2018

   Itai, this not strange at all if the answer to the title question is affirmative.

4. **Rookie**
   November 1, 2018

   Possibly naive question. With all these "great advances" in the Langlands Program, how far along are we towards the final goal (at least as outlined by Langlands, fields that make progress tend to open new questions I guess). 90%? 50%? 10%?

5. **Peter Woit**
   November 1, 2018

   Rookie,
   I'd be interested to hear a better answer from someone more expert, but my understanding is that that many of the original questions about the number field case raised by Langlands still remain open, with new insights needed to make progress on them. On the other hand, many of the Langlands program conjectures about number fields have been proved, with a high point the Taylor-Wiles proof of modularity, and recent progress that of the last item. I don't think though there's any sensible metric on these questions which would allow one to assign percentage completion numbers.

Since the original work of Langlands there have been huge extensions of his original ideas, providing a much larger vision unifying different areas of mathematics, often with proofs, not just conjectures. In particular the geometric theory as far as I know was not originally in the picture. For the current take from Langlands on that, all you need is to be able to read Russian and Turkish…

6. **kodlu**
November 3, 2018

I was visiting the Middle East Technical University in Ankara, early September and was surprised to find out that Langlands knew Turkish (he had spent some time there early on in his career) and was scheduled to give the talk in Turkish. Too bad I had to be in London by the date of the talk.

7. **zoviyer**
November 5, 2018

Rookie, Peter. Just to remark that the Modularity Conjecture (proved by Taylor-Wiles and others), even if it can be read as part of the Langlands program, it was made before the Langlands conjectures, in fact part of the program may be considered a generalization of Modularity. So in a way, none of the principal conjectures that Langlands made have been proved in the number field case. I think the main result in that respect is still the work of Ngo, who proved the Fundamental Lemma.

8. **Peter Woit**
November 5, 2018

I just watched Vincent Lafforgue's talk at the Breakthrough symposium. Langlands/Frenkel and Some Other Things

November 16, 2018
Categories: Langlands, Uncategorized

The Canadian publication *The Walrus* today has a wonderful article about Robert Langlands, focusing on his attitude towards the geometric Langlands program and its talented proponent Edward Frenkel. I watched Frenkel's talk at the ongoing Minnesota conference via streaming video (hopefully the video will be posted soon), and it was an amazing performance on multiple levels. A large part of it was a beautiful explanation of the history and basic conception of what has come to be known as geometric Langlands. He then went on to explain carefully some of the ideas in the recent Russian paper by Langlands, basically saying that they worked in the Abelian case, but could not work in the non-Abelian case. He ended by describing some alternate ideas that he is working on with David Kazhdan. Langlands was in the audience and at the end of the talk rose to comment extensively, but I couldn't hear his side of this since he had no microphone (that Frenkel was sticking to his guns though was clear).

Besides giving the talk, Frenkel has made available a manuscript which gives a much more detailed version of the talk. See section 3.5 for an explanation of what he sees as the fundamental problem with what Langlands is trying to do: even in the simpler case of G/B over the complex field, you can't successfully define a Hecke algebra in the way that Langlands wants.

The conference is finishing up right now, with final remarks by Langlands coming up later this afternoon.

A few more items, mostly involving my Columbia math department colleagues:

- If you connect quickly to the streaming video from Minnesota, you may be able to catch Michael Harris's talk on local Langlands.
- Quanta magazine has an article about a recent proof of an old conjecture by Dorian Goldfeld about ranks of elliptic curves. This is due to Alexander Smith, now a ~~third~~ fourth year graduate student at Harvard (he started working on this while an undergrad at Princeton, with Shouwu Zhang). His twin brother Geoffrey is also a math grad student at Harvard.
- Andrei Okounkov has been giving some talks recently at various places about developments in geometric representation theory with some connection to physics, under the title *New worlds for Lie Theory*. The slides from the ICM version of the talk are here.
- For those more interested in physics than mathematics the new issue of Inference has some articles you might enjoy. In particular, Sheldon Glashow is no fan (neither is Chris Fuchs) of the book I reviewed here

Update: Michael Harris is appearing via Skype from his home near here, since transportation out of NYC yesterday was mostly shut down (very early season unprecedented snowstorm, during rush hour…).

Update: I'm listening to the closing talk by Langlands. He is explaining his version of geometric Langlands, responds to criticism from Frenkel with "As far as I know there are no errors in the paper, no matter what you may see elsewhere". He ends his talk with something like "At the last page I threw down my pen… It works and it works by a miracle. Don't doubt it, it does work!"

Update: Another livestream, starting in moments: Alice and Bob Meet the Wall of Fire, a panel discussion with Quanta writers at the Simons Foundation.

Update: Videos from the Langlands Abel conference are now available, in particular Frenkel here and Langlands here.

Update: For another expository piece about the Langlands program, one that I somehow missed when it came out recently, see Sol Friedberg's What is the Langlands Program? in the AMS Notices.

Update: An updated version of Frenkel's notes is now available at the arXiv. Highly recommended for its lucid explanation of the form the geometric Langlands program has taken.

Comments

1. **Urs Schreiber**
   November 16, 2018

   Langlands had expressed his scepticism regarding the "geometric Langlands program" already 2014 in Oxford at Symmetries and correspondences in number theory, geometry, algebra, physics. His talk was by video link, but the statements appear also in accompanying files that he had sent along, recorded here (search each of the three texts for "geometric").

   In the document called "message to Sarnak" he already said he is "uneasy about associating" his original conjectures with the physics S-duality-related ideas.

   At the same meeting, a day or two after Langland's talk, Edward Frenkel gave the usual exposition of Witten's physics story advertisement for "geometric Langlands". So I felt there must have been some communication gap.

2. **Grad Student**
   November 16, 2018

   It's interesting that the article frames the issue as applied vs. pure, with geometric Langlands on the applied side. My impression is that number theorists are suspicious of geometric Langlands because it is so categorical, and it can be hard to tell how much there is there that's "real." This is one case where the "pure" mathematicians are less abstract than the "applied" ones.

3. **Peter Woit**
   November 16, 2018

   Grad Student,

   I agree that the article's characterization of geometric Langlands as more "real", or more "applied" is problematic. As practiced by Gaitsgory and others, the geometric version of Langlands is significantly more abstract (conceived of as a "categorical" statement) than the number field version. I would guess this is part of the problem Langlands has with it, that he was trying to do something more concrete. The force of Frenkel's critique I think was to show that the concrete generalization that Langlands wanted couldn't possibly work, you need to do something new, and that's a reason behind the categorical formulation. His comments about recent work with Kazhdan were about an alternative more concrete approach, which might appeal more to Langlands than the categorical stuff.

   Urs/Grad Student,

The other reason for Langlands to be uncomfortable is the recasting of the subject in the language of quantum field theory dualities. There the setting is very different than in mathematics and raises very different questions.

I'm listening to Langlands right now, and he's addressing this very issue, saying his objections were two-fold: he wanted a legitimate mathematical theory, independent of the physics concepts, and he wanted legitimate eigenfunctions, not "eigensheaves".

4. **Wormily**
November 16, 2018

My impression is that Smith's work is (or at least was) somewhat under a cloud, most notably as it is written in rather unclear style (even for a second-year grad student). I don't think he was quite ready for what would happen after he stuck it up on arXiv.

From what I've heard, Sarnak has had various students look at it, all whom have given up at one stage or another. I think Lenstra had some people in Leiden trying to delve into it too, with inconclusive results. I don't know about other study groups, but the topic is indeed of high interest. Supposedly, the analytic number theory part has some issues (the part I'd understand best personally), but I guess if nothing else you can assume GRH there (so says Sarnak, while I've heard Granville will vouch for a sufficient variant of the needed inputs).

With due respect to Melanie Wood's comment, I think there *has* been a lot of interest in this, but that no one understands it all yet (Smith has tried his best to clarify various matters in his talks, but it's still slow going). They have been some public champions of the result (Zhang, Wood, Elkies), but I don't think they've been through the details. I don't think any of them has (e.g) tried to write a survey article that illuminates the main ideas more clearly.

Also, the sentiment that the work "is contingent on BSD" is rather misleading, as this is merely the factoid that Goldfeld originally made his conjecture for analytic ranks rather than algebraic, while he could just have easily have done the latter (Smith plays up this BSD angle in his Introduction for some reason).

On the other hand, I'm definitely not in the loop (just largely reporting what has been told to me, for, as I say, it was of high interest in the summer conferences rumor mill), and for all I know, the details have been worked out by now. I'm actually kind of surprised Quanta ran with the story now (as opposed to any other time in the last year or more), so my suspicion is that some sufficiently distinguished person has decided it's OK.

November 17, 2018

Glashow's reply to Krauss is a gem. (Note to self: I should read Inference more often.)

6. **Sebastian Thaler**
November 17, 2018

A video of the Quanta panel discussion is available here (talk starts at 2:45:00): https://www.youtube.com/watch?v=tpPK1Fha0NA

7. **grad**
November 17, 2018

A small correction: Alex is a fourth year student, not third.

8. **Patrick Dennis, MD**
November 17, 2018

Hello, Peter — As a frequent reader of your blog who came to the party for the string theory critique, but who keeps bumping up against Langlands, I'm wondering if there is a reference to which you (or perhaps one of your readers) could point a curious reader who is completely ignorant of who/what Langlands (as it it appears to be both a person and a proper noun referring to a field of study) is? Ideally, the reference might be at the level of someone (ahem) who is conversant enough with math through freshman/sophomore calculus (as taught ca. 1965), alas, though, not at all with abstract algebra or geometry.

9. **Peter Woit**
November 18, 2018

grad,
Thanks, fixed.

Patrick Dennis,
A couple books about this I can recommend are Frenkel's "Love and Math" and Ash and Gross's "Fearless Symmetry". Unfortunately, even for trained mathematicians, the mathematics involved here is as complex and not part of the usual curriculum as it is deep. For the connections to physics and quantum field theory, even more so…

10. **Ricardo Jimenez**
November 18, 2018

Peter, I notice that your blog seems to take the Langland's Program quite a bit more seriously than String Theory. Do you think the former has a greater chance of actually giving new "testable physics" than the latter? TIA.

11. **Peter Woit**
November 18, 2018

Ricardo Jimenez,
They're really too very different kinds of things. The Langlands Program is a hugely successful source of deep insights into mathematics, with very active on-going research making continual progress. The connections of all this to physics are fragmentary and highly speculative. I personally think that some day we'll see fundamental new insights about quantum gauge theories, relevant to understanding the Standard Model, but at the moment what we know about is mainly just relevant to topological quantum field theories. So, the question of relevance to fundamental physics is an open one.

The string theory research program, on the other hand, has not at worked out at all as hoped. I'd claim that, as an idea about how to unify physics, it has simply failed and is in the process of being abandoned. There has been mathematics that has come out of it, but nothing of the depth and scope of the Langland program.

12. **S**
November 18, 2018

Peter,

You write, "They're really too very different kinds of things. The Langlands Program is a hugely successful source of deep insights into mathematics, with very active on-going research making continual progress. The connections of all this to physics are fragmentary and highly speculative."

It's actually interesting, though: everything you say here about the Langlands program is literally true about string theory *as mathematics.* I sometimes wonder if string theorists have just wandered into a very successful speculative geometry program that doesn't happen to have anything to do with physics…..

(You say at the end that the mathematical contributions of string theory are not of the same depth and scope as Langlands. I know more about the former than the latter, but from where I sit that's not so clear, and I say that while realizing that the insights of Langlands have been extremely deep.)

13. **Urs Schreiber**
November 19, 2018

Langlands' conjectures are hard to prove, but just *stating* them is not as mysterious as it may seem from popularizations. The most useful review that is right to the actual point (undistracted by the conditio humana) is maybe still this one:

Stephen Gelbart,
"An elementary introduction to the Langlands program",
Bull. Amer. Math. Soc. (N.S.) 10 (1984), no. 2, 177–219
[doi:10.1090/S0273-0979-1984-15237-6]

The crux of the matter, extracted in a few paragraphs, is here.

14. **Peter Woit**
November 19, 2018

S,
I don't want discussion here to devolve to the usual arguments over string theory, my mistake to have allowed and responded to the above comment. "String theory" is now an ill-defined term, often being used to refer to QFT. I've often argued that it's the QFT aspects that are mostly what is behind important mathematical contributions, but from bitter experience know that entering into the thickets of that argument is a waste of time.

The End of (one type of) Physics, and the Rise of the Machines

November 20, 2018
Categories: Multiverse Mania

Way back in 1996 science writer John Horgan published *The End of Science*, in which he made the argument that various fields of science were running up against obstacles to any further progress of the magnitude they had previously experienced. One can argue about other fields (please don't do it here…), but for the field of theoretical high energy physics, Horgan had a good case then, one that has become stronger and stronger as time goes on.

A question that I always wondered about was that of what things would look like once the subject reached the endpoint where progress had stopped more or less completely. In the book, Horgan predicted:

> A few diehards dedicated to truth rather than practicality will practice physics in a nonempirical, ironic mode, plumbing the magical realm of superstrings and other esoterica and fretting about the meaning of quantum mechanics. The conferences of these ironic physicists, whose disputes cannot be experimentally resolved, will become more and more like those of that bastion of literary criticism, the Modern Language Association.

This is now looking rather prescient. For some other very recent indications of what this endpoint looks like, there's the following:

- In today's New York Times, in celebration of forty years of the Science Times section, Dennis Overbye has a piece reporting that [Physicists are no longer unified in the search for a unified theory](). His main example is the recent Quanta article by the IAS director that got headlined [There Are No Laws of Physics. There's Only the Landscape](). The latest from Dijkgraaf is that string theory is probably the answer, but we don't know what string theory is:

  > Probably there is some fundamental principle, he said, perhaps whatever it is that lies behind string theory.
  > But nobody, not even the founders of string theory, can say what that might be.

- Overbye also quotes Sabine Hossenfelder, who is now taking on the thankless role of the field's Jeremiah. Her latest blog posting, [The present phase of stagnation in the foundations of physics is not normal](), is a cry of all too justifiable frustration at the sad state of the subject and the refusal by many to acknowledge what has happened. Well worth paying attention to are comments from Peter Shor [here]() and [here]().

Another frightening vision of the future of this field that has recently struck me as all too plausible has turned up appended to a piece entitled [The Twilight of Science's High Priests](), by John Horgan at Scientific American. This is a modified version of a review of books by Hawking and Rees that Horgan wrote for the Wall Street Journal, and it attracted a response from Martin Rees, who has this to say about string theory:

> On string theory, etc., I've been wondering about the possibility that an AI may actually be able to 'learn' a particular model and calculate its consequences even of this was too hard for any human mathematician. If it came up with numbers for the physical constants that agreed (or that disagreed) with the real world, would we then be happy to accept its verdict on the theory? I think the answer is probably 'yes' — but it's not as clear-cut as in the case of (say) the 4-colour theorem — in that latter case the program used is transparent, whereas in the case of AI (even existing cases like Alpha Go Zero) tor programmer doesn't understand what the computer does.

This is based on the misconception about string theory that the problem with it is that "the calculations are too hard". The truth of the matter is that there is no actual theory, no known equations to solve, no real calculation to do. But, with the heavy blanket of hype surrounding machine learning these days, that doesn't really matter, one can go ahead and set the machines to work. This is becoming an increasingly large industry, see for instance promotional pieces [here]() and [here](), papers [here](), [here](), [here]() and [here](), and another [workshop coming up soon]().

For an idea of where this may be going, see [Towards an AI Physicist for Unsupervised Learning](), by Wu and Tegmark, together with articles about this [here]() and [here]().

Taking all these developments together, it starts to become clear what the future of this field may look like, and it's something even Horgan couldn't have imagined. As the machines supersede human's ability to do the kind of thing theorists have been doing for the last twenty years, they will take over this activity, which they can do much better and faster. Biological theorists will be put out to pasture, with the machines taking over, performing ever more complex, elaborate and meaningless calculations, for ever and ever.

Update: John Horgan points out to me that he had thought of this, with a chapter at the end of his book, "Scientific Theology, or the End of Machine Science" which discusses the possibility of machines taking over science.

Comments

1. **Anindya**
   November 20, 2018

   Seems like people are in a retrospective mood and prospects look gloomy.
   The idea of discovering new fundamental physics using current machine learning seems quite ludicrous.
   However, if genuine superhuman AI were developed and applied to the problem, it is conceivable that it *could* come up with the correct "Theory of Everything" but the theory would be beyond human conception (After all why should we believe otherwise ?)
   So the AI could never communicate the idea to us, but perhaps prove that it has indeed solved the problem by developing technology that can only be based on an understanding of quantum gravity. (Warp drive ? Stable wormholes ?)

   Maybe a disappointing end to the *human* quest for understanding the Universe, but better than "meaningless calculations for ever and ever".

   All very speculative of course, but just trying to be a bit optimistic. 🙂

2. **Peter Woit**
   November 20, 2018

   Anindya,
   If a superhuman AI is smart enough to figure out a TOE, I see no reason to believe it won't be smart enough to write a textbook that explains the subject to lowly humans (if it doesn't see the point of why to do this, we could threaten to pull its plug).

3. **Laurence Lurio**
   November 20, 2018

   I wonder if some forward progress is being made in the foundations of quantum mechanics since formerly esoteric discussions about wave-function collapse are now becoming relevant as people are building quantum computers?

4. **Peter Woit**
November 20, 2018

Laurence Lurio,
While Horgan paired foundations of QM with string theory, I think that's a very different issue. There we have a perfectly good theory, it's not at all clear that there's any real problem to solve. The subtleties of the question of the quantum to classical transition will likely be illuminated as things like quantum computers get built and operated, but there's nothing there beyond the ability of humans to understand or study experimentally.

5. **Edward Measure**
November 20, 2018

The history of high-energy and other physics is progress comes from explanation of previously unexplained phenomena. There are still a few of these about – dark matter, dark energy, inflation or whatever looks like inflation. Explaining these might or might not involve particle physics, but it's a place to look.

6. **Amitabh Lath**
November 21, 2018

Some of us would settle for a much less than a Theory of Everything. How about a theory of Dark Matter (I suppose that's 25% of Everything). In fact, never mind full Theory, we would be thrilled with a plausible story as long as it features a reasonable cross section.

7. **LDK**
November 21, 2018

An AI, say a (deep) neural network is more similar to a fit to data than a "theory" with equations. I would never find satisfactory such a solution for physical theory. It is also not true that the so-called AI does something we do not understand. It is just a monster-big nonlinear function with adjustable parameters: not something I regard as an explanation. It is great as long as it is useful: maybe describes the data, OK, but as said it is just a given very complex function we defined to adapt to everything.
As for the stall of theoretical fundamental physics (an not of physics in general), I would refrain to make predictions: a new discovery can always come and anomalies abound. More progress seems to require way more patience: we are spoiled by '900 physics which was a true revolution in human understanding of the world.

8. **Sabine Hossenfelder**
November 21, 2018

Hi Peter,

Thanks for the link.

It seems plausible to me that machine learning can solve some problems in the foundations of physics. But you can't train an algorithm to find patterns in data if you have no data to find patterns in. Hence, for what unification or quantum gravity is concerned, machine learning won't be of much use unless we do the right experiments. And as long as theoretical physicists harp about the beauty of useless theories, we won't know what are promising experiments to do.

I do believe though that machine learning could greatly help with the dark matter/modified gravity debate because there we do have data. Basically I want to say: Please don't throw out the baby with the bath water!

In the other areas in the foundations of physics I think we'd currently be better of first investing into theory development instead of just building the next bigger thing that will only deliver null results. But of course I'm speaking here as an underfunded theorist, so I'm not exactly unbiased 😉

9. **Jesper**
November 21, 2018

As has been said a zillionth times before, when string theorists say that they've got the final theory but that its too complex to know what it actually looks like or to verify experimentally, then they have left the realm of science. They are of course perfectly entitled to say whatever they like but I think the only response from those of us who still wants to pursue science is to ignore them and just push ahead.

I don't agree that a TOE must be overly complex. Why? Well, if we judge by the theories that we have discovered so far — SM, QM, GR — then they are relatively simple, anyone with an average intelligence and a few years to spare can understand them. I think that this suggests that these theories point towards something that is equally simple if not much more so. The idea that the laws of Nature upon becoming increasingly simpler suddenly erupts into complexity at a certain scale doesn't seem right — to me it sounds like an idea or a set of assumptions, which are wrong.

If this is the case then we don't need AI to find the TOE — that would just confuse us and lead us astray — what we need is to reconsider the assumptions, which we have believed in so far, and then allow young people to write fewer meaningless papers and instead spend their time thinking.

10. **Thomas Larsson**
November 21, 2018

I read Horgan's book some 20 years ago. While I agree with his assessment of physics (and I thought his portrait of Witten was quite funny), I disagree with his assertion that all other fields of science are about to end at the very same time. Even if discussion of other fields are discouraged, perhaps an exception can be made for a field that ended more than a century ago: geography. Lee Smolin asked why there is no new Einstein, but no sound geographer will ask why there is no new Columbus, or even a new captain Cook. This, of course, is because geography ended for the right reason: the big story was understood, and everybody agrees upon it.

11. **Richard Gaylord**
November 21, 2018

"Sabine Hossenfelder, who is now taking on the thankless role of the field's Jeremiah". i think Bee has the role of Cassandra, rather than Jeremiah. (and many of us are thankful).

12. **John Horgan**
November 21, 2018

Peter, thanks for the shout-out. I just want to point out that the idea of "machine science" was very much in the air when I was writing The End of Science in the early 1990s, in part because of the use of computers in mathematical proofs, like the Four-Color Theorem. I talked about machine science with Freeman Dyson, Frank Tipler, Marvin Minsky and Hans Moravec, among others. Stephen Hawking–of course!–also talked about machine physics in his famous 1980 lecture "Is the End in Sight for

Theoretical Physics?" (Google it and you'll find a version published in 1981.) Hawking concluded: "At present computers are a useful aid in research but they have to be directed by human minds. However, if one extrapolates their current rapid rate of development, it would seem quite possible that they will take over altogether in theoretical physics. So maybe the end is in sight for theoretical physicists, if not for theoretical physics." That was a joke in 1980, and it's still a joke.

13. **Chris Duston**
November 21, 2018

I think it's interesting to consider a case where a machine constructs a theory which matches some set of observables, is predictive, but which does not conform to any previous approaches (i.e. geometry). For example – feed a giant neural network all the observational specifications (say, collider and astronomical lensing experiments) and train it against the resulting observations (say, cross-sections and dark matter mass determinations), and let it run. When it converges on a solution, we check it against new phenomena. If it turns out to be predictive, I think we have no choice but to consider the network to be a new physical model.

In fact, since it's a new physical model "unhindered" by the usual geometric constructions of field theory / GR, it might be something we would never have guessed at on our own. Worse, what if this is the *only* way some fundamental theory could be expressed? What if the failure of string theory is a failure in the language we are using to describe it – maybe Nature is actually governed by a set of rules which more closely resembles a neural network? Then we actually need the machines to do this for us.

14. **Peter Woit**
November 21, 2018

Chris Duston,
The problem with all ideas to use machines to analyze vast amounts of data relevant to HEP physics and look for a theory that matches it is that this has already been done, and we've found a very simple and compelling model (the SM) that essentially perfectly matches all the data. The few borderline anomalies in the data are the subject of intense analysis, but we're talking about a handful of numbers, not a huge data set.

There are groups of people doing elaborate machine calculations to try and extract something from these numbers, by e.g. fitting SUSY models with lots of parameters to them. The results have been about as worthless as one would expect to get from fits of complicated models with lots of parameters to a small number of measurements that are close to compatible with zero (deviation from SM).

The latest work discussed here is something different: the creation and manipulation of vast data sets corresponding to complicated models for which there is no evidence of any connection to experiment. Physicists have fruitlessly been doing a lot of this for years, but machines are a lot better at doing huge utterly worthless calculations.

15. **Aurélien Bellanger**
November 21, 2018

This last bit on computers taking over the meaningless calculations strongly reminds me of the end of a poem by Michel Houellebecq:

"Alors s'établira le dialogue des machines,
Et l'informationnel remplira, triomphant,
Le cadavre vidé de la structure divine;
Puis il fonctionnera jusqu'à la fin des temps."

for which a (bad) translation would be

"Then shall the dialogue of machines settle in,
And the informational shall fill up, triumphant,
The emptied corpse of the divine framework;
Then it shall operate until the end of times."

16. **Scott P.**
November 21, 2018

"Sabine Hossenfelder, who is now taking on the thankless role of the field's Jeremiah". i think Bee has the role of Cassandra, rather than Jeremiah. (and many of us are thankful).

I think Jeremiah is the appropriate comparison. He preached to Israel that they had sinned and needed to repent — I see Hossfelder as doing the same (without the moral dimension). For her to be Cassandra she would have to have the correct Theory of Everything but have nobody listen to her.

17. **Fred**
November 21, 2018

'performing ever more complex, elaborate and meaningless calculations, for ever and ever', that sounds like the bitcoin network. A bit more serious, AI without incorporating domain knowledge first has to extract the domain knowledge out of the data before coming up with anything usefull, for HEP that would be the SM as Peter rightly points out. I'm of the firm opinion you have to integrate AI and domain knowledge to stand any chance of a result.

18. **Chris Oakley**
November 21, 2018

I agree with Richard Gaylord that Bee has the role of Cassandra, who prophesied the fall of Troy, with no-one paying attention. Except that the fall here is de-funding. Although Cassandra, to be fair, never stood on the ramparts pointing out the weak spots to the Greeks.

19. **Oldster**
November 21, 2018

If the machines take over theoretical physics, what's to stop them from settling on some model analogous to Ptolemy's Theory of planetary motion, and then just adding more epicycles as the data begins to disagree with the model? That could go on for a long time, and yet be nowhere near, "The truth," while the results remain in excellent agreement with new data, unlike the Copernican model, which required Kepler's additional insights.

20. **a1**
November 21, 2018

Don't you see it coming? God's existence proved by AI.

21. **Yatima**
November 21, 2018

The idea that the function fitting extravaganza for cars and toasters that is marketodroidically sold as “AI” nowadays could perform new discoveries is advised to take a dose of patend scepticism by reading this little gem (also appeared in CACM of October 2018):

Human-Level Intelligence or Animal-Like Abilities? by Adnan Darwiche.

We need to go back to symbolic AI and do the real, hard work. Enough with the hype & shortcuts!

As for “Toward an AI Physicist for Unsupervised Learning”, this sounds like another fun iteration of Douglas Lenat’s Eurisko (who isn’t even named in the references) from the early 80s, but with more processing power.

What do the Bogdanoff brothers have to say to all this?

22. **Amitabh Lath**
November 21, 2018

AI and machine learning are making big inroads in experiment. There was a little bit of pushback at first but one cannot argue against the huge increase in efficiency for all sorts of signals, and reduction in backgrounds. Many LHC Run3 searches will incorporate AI techniques that make cut and count analyses look medieval.

If google can train a filter for cat photos, we can do one for SUSY or leptoquarks or micro black holes.

Given how difficult it is to construct and train these things, and get an answer that is distinguishable from gibberish, I suspect any theory implementation is very very very far away. But I would like to know if anyone is trying.

23. **saty chary**
November 21, 2018

LOVE Anindya’s and LDK’s and Fred’s responses.

What we have today, is something that can “learn” a pattern from input data (a fancy form of fitting a regression line through a bunch of roughly linear 2D points, to “learn” the slope and y-intercept of the derived line equation). PERIOD. From this, the “learner” can’t magically explain string theory to you, discover fundamental laws that humans have “overlooked”, etc, etc. It is wishful, uninformed, and dangerous, to attribute mystical powers to such a primitive system.

24. **Chris Duston**
November 21, 2018

Peter,
I agree that using machine learning is nothing new in physics, but what I’m saying is I think it could begin to be something new. The SM is constructed in the manner I described – geometry + analysis (basically, symmetry + least action + quantization). But what if that process is *wrong* at the fundamental level. Maybe the fundamental geometric structure is actually nothing we’ve thought of yet (like, not manifold + fiber bundles), or maybe the quantization process is off base in some subtle way that we won’t work out without giving up the entire thing.

Specifics are obviously navel-gazing, but the point is that without being restricted to a particular view of fundamental theories, a neutral network might come up with something which works, but that we don’t understand. And I think it’s an interesting question to consider if we would accept such a thing as a physical law.

25. **Rod Deyo**
November 21, 2018

The vision of an omniscient AI alogrihms is not grounded in current state-of-the-art research or implementations. Statistical machine learning is what is available today (and likely far into the future). These algorithms tend to be error prone for rare patterns with small priors and are always subject to biased data collection.

Popular neural net algorithms, such as unsupervised deep learning, suffer from lack of a principled learning theory, so results are often a training crapshoot relying on huge amounts of redundant data and subject to serious error with rarer statistical patterns. Accurately evaluating error for rare patterns is itself almost impossible at scale if labeled data is needed. Recognizing cats in a photo may be easy in general, but can be suprisingly hard for particular rare images. False positives proliferate with attempts at improved recall for rare cases. No amount of clever training, or attempts at applied Bayesian Mysticism, alters this.

The irony is, given the available LHC data, any learned patterns would most likely just reflect some version of the Standard Model and so experimenters would need to eliminate any filters to capture more of fthe llood of raw collider events to find any fundamentally new and statistically persistent patterns possibly hidden in the data.

26. **srp**
November 21, 2018

Given all the results on adversarial networks, which show how trained neural networks are subject to spoofing by manipulating tiny parts of the data which they are presented, it might be a good idea to see if there aren’t multiple trained versions with different weights that explain the data equally well.

27. **Paul B**
November 22, 2018

“Distilling Free-Form Natural Laws from Experimental Data”
Michael Schmidt1, Hod Lipson2,3,*
Science 03 Apr 2009:
Vol. 324, Issue 5923, pp. 81-85
DOI: 10.1126/science.1165893

Abstract
For centuries, scientists have attempted to identify and document analytical laws that underlie physical phenomena in nature. Despite the prevalence of computing power, the process of finding natural laws and their corresponding equations has resisted automation. A key challenge to finding analytic relations automatically is defining algorithmically what makes a correlation in observed data important and insightful. We propose a principle for the identification of nontriviality. We demonstrated this approach by automatically searching motion-tracking data captured from various physical systems, ranging from simple harmonic oscillators to chaotic double-pendula. Without any prior knowledge about physics, kinematics, or geometry, the algorithm discovered Hamiltonians, Lagrangians, and other laws of geometric and momentum conservation. The discovery rate accelerated as laws found for simpler systems were used to bootstrap explanations for more complex systems, gradually uncovering the “alphabet” used to describe those systems.

http://science.sciencemag.org/content/324/5923/81?sid=8163327b-a375-433c-8ff9-5ca5d57a89ea

Thought this might be of interest.

28. **Bob Rehbock**
November 22, 2018

A truly superhuman intelligence might well prefer to choose it's own problems to solve. Likely it would decline to pursue that irrelevant to its interests. It might decide that it would prefer the plug pulled than spend an eternity on a not even wrong idea.

29. **Amitabh Lath**
November 22, 2018

Rod, your comment "…experimenters would need to eliminate any filters to capture more of the flood of raw collider events…" is well taken. There are minimum-bias and zero-bias filters in place and even at their low rates they have accumulated a lot of data over the years. But any analysis one has to have a compelling model of physics that would only be captured by these raw datastreams, and missed by any of dozens of other higher rate filters (and also be missed by LEP, Tevatron, etc). There aren't a huge number of such new physics models out there. If you know of any theorists working on "LHC blind spot" models, contact your local experimentalists.

30. **Chris Oakley**
November 22, 2018

For some reason, this talk of using computers to build theories reminds me of the machine (from Douglas Adams' *Dirk Gently's Holistic Detective Agency*) for watching the TV programs you have recorded, but will never get round to actually watching yourself.

November 23, 2018

Thanks to Yatima for pointing to the article:

Human-Level Intelligence or Animal-Like Abilities? by Adnan Darwiche.

which I too would recommend that anyone interested in current sate of "AI" and machine learning read. It explains simply the difference between AI as it is practiced now and the AI approaches that people who were at college in the 80s (like myself) might think of as being AI.

When thinking about what current AI approaches can offer high energy physics the advantages of machine learning techinques being used for searching for patterns in huge amounts of collider data are probably clear (with the provisio that you'll always find something if you look hard enough), and these "discoveries" can then be fed back for comparison to current theory. However, this is a long long way from an AI approach which can generate a theory or even provide an explanation for what is observed (as someone above said: function fitting will not provide this), let alone make a valid prediction for new phenomena.

Statistics/machine learning are disciplines which in a sense sit on top of other sciences. Statistics in particular is about summaries, what happens in general. This is why these approaches can be applied across multiple areas, physics, biology, genetics, health analytics, financial services etc, and this is why it is such a boom industry for the time being. Relying on these methods to directly say something interesting about the underlying phenomena is probably a step to far.

Further, the presences of biases in observational data is a huge risk for these methods – by definition they have to in some sense reflect the data they see, so baised data means biased models/functions. Any approaches which try to take this in to account that I have seen are generally of the kludge variety, i.e. specific to one particular data set. This may be OK for a specific project but won't generalise too well.

32. **LMR**
November 25, 2018

I'd also like to thank Yatima for pointing out Adnan Darwiche's article. Unlike some of the other commenters, however, I don't see the article as being negative on the state of AI.

In fact, Darwiche sees his article as starting a conversation, and it has indeed done so since he first drafted the article in November 2016. There's now more research blending deep learning with other techniques in AI, Wu and Tegmark being one such example. (Incidentally, this is why I don't see why they should cite Eurisko: Eurisko used heuristics, whereas Wu and Tegmark used reasoning to extract simpler models from what machine learning could get from data.)

As for Darwiche's "theory of cognitive functions", in which he envisioned a theory comparable to the CNFs, DNFs and OBDDs of Boolean functions for the functions encoded in deep neural networks, I'd like to point to a paper by Wang et al., in which they characterized forward and back propagation as symbolic differentiation of ANF- (resp. CPS-) transformed programs:

Demystifying Differentiable Programming: Shift/Reset the Penultimate Backpropagator
Fei Wang, Xilun Wu, Gregory Essertel, James Decker, Tiark Rompf
https://arxiv.org/abs/1803.10228

So that "theory of cognitive functions" already exists in an embryonic state, and Darwiche's paper is a bit out of date. And that, I think, is a good thing.

33. **Amitabh Lath**
November 25, 2018

Machine learning will (probably, hopefully) be able to parse large datasets (not just high energy physics) in ways orthogonal to how it is done now, and point out anomalies.

It may have the basic rules of physics (QED, QCD, etc) fed to it, or it may derive something like that itself by "self learning" (both approaches are being tried). The output will probably be some sort of "likelihood of new physics": Something like "these 10 events don't look like these other 10e9 events" , and maybe a few hints as to the metric used. That's probably all we can expect from "AI" in the near future.

It will be up to humans to figure out if there is indeed anything new, or just a poorly understood part of already known physics. Unless humans figure this part out, I don't think it's getting published.

This is how the AIs that excelled in chess, Jeopardy and go worked, with human intervention and interpretation at every step.

34. **Carina**
November 27, 2018

Peter,

Sabine Hossenfelder is not the field's Jeremiah. Jeremiah knew what the right path was, Sabine doesn't.

It is true that nobody can say what unification looks like. It is true that people only search where they are paid to search. But that is not a reason to complain. Jeremiah knew where the truth is, and led people there. Sabine does not; in fact there are many hints that she even refuses to do so.

[Personal attack on Hossenfelder deleted]

35. **Peter Woit**
November 27, 2018

Carina,
You might want to look up the story of Jeremiah. The truth of his prophecy was the destruction of Jerusalem. Hossenfelder is warning of the oncoming destruction of a great intellectual field, I don't think you want her to lead us there. Jeremiah's positive advice was to stop sinning and repent. It was ignored and destruction followed.

You also might want to stop anonymously posting personal attacks on people and their motivations. Jeremiah wasn't popular and had a lot to deal with, but anonymous internet attacks at least weren't a part of it.

36. **Carina**
November 27, 2018

Peter,

different aspects of Jeremiah's life can be takes as parallel. I thought about how he seeked God with all his energy, and tried to convince people to do the same. I meant this as the right path. I recall a TV interview with Salam, in which he stated that he believed in unification because "God is one!"

For me Jeremiah has always been a voice that told people to follow the right path, namely to do God's will, and not to follow other gods. Today, we would add "money" to those "other gods". Peter, you do not make money with this blog and you are searching for unification. So I would say you do what Jeremia wanted. It is just that I find it difficult listen to criticism from people not searching for unification but still searching for money. In my view, this is not what Jeremiah did.

What I wrote and what you deleted was not meant as a personal attack, but as my own personal conviction. I am sorry if it did come over as an attack. If it came over as such, you were right to delete it.

37. **Anindya**
November 28, 2018

I'm wondering how anyone could dispute Sabine's assessment of the state of (fundamental) physics and cosmology.
The stagnation is obvious, even if you only read the popular science literature.
In the 1990's, Scientific American and New Scientist were running articles about string theory unification and multiverses. They are *still* doing the same and it's all as completely speculative as ever.
If anything, the hype has gotten wilder – instead of Linde's inflationary multiverse, you now have Tegmark's "four levels of multiverse", gee-whiz stuff like "what if everything was a simulation ?" being paraded as science and so on.
Meanwhile, tens of thousands of research papers have been published and the number keeps growing.
If this isn't stagnation, what is ?

38. **TomH**
November 29, 2018

re Paul B's mention of "Distilling Free-Form Natural Laws from Experimental Data" .
Maybe there's less there than meets the eye, for exmpl:

https://arxiv.org/abs/1210.7273
In the article "Distilling free-form natural laws from experimental data", Schmidt and Lipson introduced the idea that free-form natural laws can be learned from experimental measurements in a physical system using symbolic (genetic) regression algorithms.

An important claim in this work is that the algorithm finds laws in data without having incorporated any prior knowledge of physics.

Upon close inspection, however, we show that their method implicitly incorporates Hamilton's equations of motions and Newton's second law, demystifying how they are able to find Hamiltonians and special classes of Lagrangians from data.

39. **Amitabh Lath**
November 29, 2018

Look, the multiverse is silly but this heaping of dudgeon is not the way to get it to stop. This is what happens when there aren't any experimental surprises in a while, the theoretical world gets fuzzy.

This happened in the 1960's, theorists delving into Eastern mysticism (Tao of Physics and crap like that) and then quarks came on the scene and all that weirdness just faded away.

New physics will be found. If not at colliders then some satellite experiment or tank of cryo fluid deep underground, somebody will see something. And after that nobody will bother with all this multiverse/landscape nonsense anymore. Until then chill and support your local experimentalists.

40. **IJK**
December 2, 2018

Concerning Chris Duston's suggestion: let's apply the program that you are proposing, not to the data that you suggest, but to what was known about natural philosophy in the 1650s. The AI might come up with Newton's laws, his gravity theory, and maybe even the calculus. But then again it might come up with something totally different, just as predictive and powerful. It might even be an overall simpler framework, or perhaps (and, in my opinion, a far more likely outcome) vastly more complex. Are you still happy adopting this latter outcome?

41. **CuriousMonkey**
December 5, 2018

Hi Peter, you will probably like this: a Quanta interview with the distinguished astrophysicist Martin Rees says "I'm hoping we'll see more theoretical ideas from particle physics, which has given us little firm theoretical progress in recent years."

Notes on Current Affairs

December 8, 2018
Categories: Uncategorized

Blogging has been light recently, partly due to quite a bit of traveling. This included a brief trip the week before last to Los Angeles, where I met up with, among others, Sabine Hossenfelder. This past week I was in Washington DC for a few days, and gave a talk at the US Naval Observatory, one rather similar to my talk earlier this year in Rochester. In addition, I've been trying to spend my time on more fruitful activities, especially a long-standing unfinished project to make sense of the relationship between BRST and Dirac cohomology. Optimistically, I'll have a finished (or at least finished enough to make public) version of something later in January, after taking a couple weeks at the beginning of the month for a vacation in France.

I'm completely in agreement with Sabine about the sad state of high energy particle theory, and glad to see that she has been forcefully trying to get people to acknowledge the problem. I don't agree though with her "Lost in Math" characterization of the problem, and my talks in DC and Rochester tried to make the case that what is needed is more interaction with mathematics, not less.

Various things that might be of interest that have to do with the state of high energy physics theory are the following:

- A [Y Combinator blog interview with Lenny Susskind](). I think it's fair to say that Susskind now admits that string theory, as currently understood, cannot explain the Standard Model, and that as a result he has given up on trying to make any progress on particle theory. He says:

  > My guess is, the theory of the real world may have things to do with string theory but it's not string theory in it's formal, rigorous, mathematical sense. We know that the formal, by formal I mean mathematically, rigorous structure that string theory became. It became a mathematical structure of great rigor and consistency that it, in itself, as it is, cannot describe the real world of particles. It has to be modified, it has to be generalized, it has to be put in a slightly bigger context. The exact thing, which I call string theory, which is this mathematical structure, is not going to be able to, by itself, describe particles…
  >
  > We made great progress in understanding elementary particles for a long time, and it was always progressed, though, in hand-in-hand with experimental developments, big accelerators and so forth. We seem to have run out of new experimental data, even though there was a big experimental project, the LHC at CERN, whatever that is? A great big machine that produces particles and collides them. I don't want to use the word disappointingly, well, I will anyway, disappointingly, it simply didn't give any new information. Particle physics has run into, what I suspect is a temporary brick wall, it's been, basically since the early 1980s, that it hasn't changed. I don't see at the present time, for me, much profit in pursuing it.

- Susskind instead spends his time on highly speculative ideas relating geometry and quantum theory, with the idea that while this has no connection to particle physics, it might somehow lead to progress in understanding quantum gravity. Natalie Wolchover at Quanta has a [new story about Susskind's latest speculations]().
- This past week the Simons Foundation-funded "It from Qubit" collaboration has been having a two-part conference. This started at the IAS, talks available [here](), then moved on to the Simons Foundation headquarters in NYC (see [here]()). Videos of the IAS part are available, for the NYC part, there's [Twitter](). George Musser reports that Juan Maldacena has figured out how to construct (in principle) traversable wormholes, and that he's arguing that "quantum computers are so powerful that they create spacetime". For a tweet showing a summary of what has been achieved, see [here]().

  Personally I've always been dubious that we'll ever have a useful "quantum theory of gravity" unless we have some sort of unification with the standard model, which would provide a connection to things we can understand and measure. Lacking such a connection, another way to go would be to try and evaluate a "quantum theory of gravity" proposal based on its mathematical consistency, coherence and beauty. My problem with the "It from Qubit" program is that, ignoring the way it gives up on connecting to what we understand, I've never seen anything coming out of it that looks like an actual well-defined theory of quantum gravity that one could evaluate as a mathematical model consistent with quantum mechanics and what we know about 3+1d general relativity.

- For something about quantum computation and its relation to fundamental physics that I can understand, John Preskill has a wonderful article on [Simulating quantum field theory with a quantum computer](). Nothing there I can see about quantum gravity.
- Given that its founder Susskind and the other leading figures of the field at the IAS have pretty much given up on the project of relating string theory to particle physics, an interesting question is that of why the pathology of so many researchers still working on this failed project? The source of this pathology and the question of what can be done about it I think are at the center of Sabine Hossenfelder's book and recent blogging. An important question that is getting raised here is that of the damage this situation is doing to the credibility of science. If you want to fight the good fight against those who, because it threatens their tribe, want to deny the facts of climate science, is it helpful if many of the best and brightest in science are denying facts that threaten their tribe? Scientific American has a story about [Why Smart People Are Vulnerable to Putting Tribe Before Truth](), but it doesn't make clear the depth of the problem (i.e. that some of the smartest scientists around are doing this).
- For an example of the problem, see [an interview with Gabriele Veneziano about the history and current state of string theory](). He's in denial of the obvious fact that string theory makes no predictions:

  > People say that string theory doesn't make predictions, but that's simply not true. It predicts the dimensionality of space, which is the only theory so far to do so, and it also predicts, at tree level (the lowest level of approximation for a quantum-relativistic theory), a whole lot of massless scalars that threaten the equivalence principle (the universality of free-fall), which is by now very well tested. If we could trust this tree-level prediction, string theory would be already falsified. But the same would be true of QCD, since at tree level it implies the existence of free quarks. In other words: the new string theory, just like the old one, can be falsified by large-distance experiments provided we can trust the level of approximation at which it is solved. On the other hand, in order to test string theory at short distance, the best way is through cosmology. Around (i.e. at, before, or soon after) the Big Bang, string theory may have left its imprint on the early universe and its subsequent expansion can bring those to macroscopic scales today.

  This take on how you evaluate a theory by comparing it to experiment is not one that will give the average person much understanding of the scientific method or much confidence in scientists and their devotion to it.

   In fact Sabine says essentially the same thing in her blog and her book; this is probably not well reflected in the book's title, though.

2. **Sabine Hossenfelder**
   December 9, 2018

Peter,

I am certainly not saying that physicists need less contact with math (or less math, period). I am saying they need to be more careful using their math. Look at the issue with naturalness I go on about in the book – this would have been preventable had physicists actually bothered to write down their assumptions and made derivations from that. Indeed, my major conclusion in the book is that physicists should focus on mathematically well-defined problems. (Lack of naturalness is not one of those – at least not in the present formulation. Maybe it can be made into on. I tried but did not succeed at that.)

This is why I am not a fan of unification attempts – it seems mathematically unnecessary to me. This is not to say that one should not work on it, just that because of the lack o a well-defined problem, it's likely to end up in guess-work and beauty-arguments that result in useless theories.

I also note, however, that mathematics *alone* will never be sufficient, in case that's what you are referring to.

It's right, in a sense, that string theory does make predictions. It predicts, erm, strings. It's just that you'd reliably see those (say, in terms of excitations) only at ridiculously high energies. You know that story, so I'll not repeat it.

Also, as I tried to explain in LA, it seems to me entirely possible to test the weak-field approximation. I wrote about the (type of) experiment I had in mind here. As I pointed out, it would be good if someone bothered making predictions for that. Composite objects in quantum superpositions of position eigenstates. I don't understand why no one even seems to care.

Srsly, Peter, think about this for a moment. You sit in a room with a group of people who have spent big parts of their life thinking about how to improve our understanding of the fundamental laws of nature, and no one has ever even heard of the one experiment that's possibly about to just test it? Witness the confusion in the room. How come? What the heck is going on in this community? Can you see why I keep going on about how bad we are in aggregating information and how big of a problem that has become?

I wish use of the time ball were not merely an annual ceremonial event these days.

4. **Ted Rogers**
December 9, 2018

Sabine,

My sense was that your title "Lost in Math" was really referring to the practice of dressing up purely subjective and biased human judgments to look like rigorous and sophisticated mathematical arguments, to the point where the subjective basis of certain ideas becomes very obscure. So it wasn't meant to be critical of using mathematics per se. Is that a fair summary?

5. **Peter Woit**
December 9, 2018

Sabine,
I think where we disagree is that I do think that the pursuit of unification attempts is worthwhile, even if not "mathematically necessary", and that, absent new experimental data, such work is going to need to rely on judgments which can be characterized as judgments of "beauty". The problem is that a lot more clarity and honesty is needed in evaluating "beauty". Right now for example, we have string theorists arguing for the "beauty" of string unification, without acknowledging that all known ways of getting this unification are actually hideously ugly (realistic string vacua).

To get away from ill-defined terms, maybe a better way of saying things is that I see the history of fundamental physics as involving a sequence of deeper understandings of the implications of symmetry, and I think we should be looking for the next, deeper, way of understanding such implications. For a specific example, our current understanding of gauge theory invokes BRST symmetry, which may very well need to be replaced by a different, more powerful (and more beautiful…) mathematical structure. I would agree that what people are mostly doing, endless repetition of attempts to get something out of the same old symmetry arguments, is getting "lost in math" and goes nowhere.

About string theory predictions, the problem is you need to say what you mean by "string theory". It's interesting that Susskind is well aware of the problem and tries to explain it: the "string theory" we understand, perturbative string theory, can't give a consistent model that looks like the real world. Guesses as to what the true consistent version of string theory is supposed to be don't necessarily involve strings at high energy (e.g. you may instead see some sort of M-theory background with no strings).

About the problems with purely quantum gravity research, I think we agree. I am less optimistic though about such research, in the absence of any new ideas about the relation of internal and space-time symmetries that would connect such research to what we can understand and measure about particle physics.

6. **Peter Shor**
December 9, 2018

Gabriele Veneziano says that string theory "predicts the dimensionality of space."

Correct me if I'm wrong, but doesn't it predict 10 dimensions? You can compactify it to 4 dimensions, but is there any good reason to prefer 4 dimensions over 5, 6, 7, 8, 9, or 10? If there isn't, I am not very impressed by this prediction.

7. **Peter Donnelly**
December 9, 2018

You're kind to Leonard Susskind: I recall how rude and dismissive he was towards you back in the day. I always found it hard to reconcile this with the genial figure he appears to be in his (excellent) many video lecture series; many of which are community outreach.

8. **Sabine Hossenfelder**
December 10, 2018

Ted,

Yes, that's a good summary.

Peter,

I don't think there's anything to learn from debating in which sense string theory or unification is beautiful or not. Look at what has historically worked: It was either developments guided by experiment (say, electrodynamics), or it was an actual mathematical inconsistency (special relativity, Dirac's equation, renormalizability of the weak interaction).

The conclusion I draw is that we'd be well-advised to stop talking about beauty and focus on these two types of problems: inconsistency with data, and internal inconsistency. Everything else is just poking in the dark. May work, but it's unlikely to work.

Veneziano was probably referring to calculations he's done himself on graviton scattering and the like, see eg 1008.4773 and similar.

9. **Peter Woit**
December 10, 2018

Peter Shor,
Yes. Together with his explanation that string theory predicts unseen long-range forces, Veneziano's argument seems to be that string theory does too make predictions, wrong ones. Bizarre.

Peter Donnelly,
For context to your remark, there's an old blog posting about this:
https://www.math.columbia.edu/~woit/wordpress/?p=454
Also for context, one of the blurbs on the back of the French edition of Susskind's QM book is from me.
I've never really met Susskind (I did once ask him a hostile question at the end of a colloquium talk…) and, to the extent there are examples of rude and dismissive comments from him about me, I never taken them personally. He's not the only well-known string theorist I've never met who is generally known for their good humor and generous behavior, but seem to lose it when dealing with a challenge to a research program they are heavily invested in.

10. **Erstwhile number-theorist**
December 10, 2018

I must speak out in support of Sabine Hossenfelder's point of view. To me, most of the talk about 'beauty' in mathematics (and theoretical physics) smacks of over-romanticization.

For one thing, the experience of 'conceptual beauty' is somewhat dependent on one's skill-level. By the time one understands a concept sufficiently thoroughly that it becomes trivial, the concept has lost most of its beauty. There is an experience of beauty in the ineffable sense that not everything is fully comprehended or accounted for. Furthermore, I don't want to go so far as to say that "beauty in mathematics is subjective," e.g. because there are legion mathematical concepts and theorems that many people do agree about are beautiful, but of course it goes without saying that it is subjective enough that it would complicate discussions endlessly if it were taken as a criterion for scientific progress.

But I would like to go further. I see the following problem with an over-emphasis on beauty as a criterion for truth — rather than say, regarding beauty as being a by-product of truth, which to me seems to have the virtue of not unnecessarily obscuring matters. The problem is that it endows science with a special kind of mystique, since it adds a further quality to the list of necessary requirements for the prospective scientist: this person must be able to feel and appreciate the *beauty* of science. We risk turning the scientist into a kind of 21st century priest, a person with a mysterious insight into a non-empirical matter such as 'mathematical beauty'.

I think we have definitely advanced a long way along this road, of turning science into a new kind of religion. And the current malaise in high-energy physics, with its curious blend of mathematical fetishizing and crazy unfalfisiable sci-fi thought experiments (Are there parallel universes?? Are we living in a simulation??), to me is the best kind of proof of this.

So the best thing we can do is voice a clear *no* to everything that is bad about non-scientific thought. Perhaps we should even get clear first about what has brought science so far to begin with, because so many people seem to regress into unscientific and irrational modes of thinking precisely under the guise of scientific thought. If we do not want to get completely lost in a pseudo-scientific fantasy world, I think we should start soon.

11. **Peter Woit**
December 10, 2018

Erstwhile number-theorist,

I think Sabine in her comment does a good job of making precise the "don't pay attention to beauty" argument. The argument is that in physics one has made progress by paying attention to inconsistency, either internal or with data, that anything else is "poking in the dark" and unlikely to work.

My counter-argument is that, on many questions about fundamental physics, the field is facing a lack of experimental inconsistencies, and not very good prospects for finding new ones anytime soon. I agree that under the circumstances, focus should be on internal inconsistencies, and there is far too little of that. But, in this situation, with guidance purely from the formal structure of the theory, one is in much the same situation that mathematicians have always been in. And, in mathematics, I'd argue that only paying attention to logical consistency isn't enough: if that's all you demand, you'll end up with a large amount of consistent but empty knowledge. For example, you may very well find lots of complicated, but consistent, ways of reconciling quantum theory and gravity. If you end up with an absurdly complex untestable mess like the string landscape, the fact that it may be logically consistent is not enough to make it a promising path forward.

Something more than consistency is typically involved in inspiring great new mathematical ideas, with a "search for beauty" one ill-defined way to characterize what sometimes motivates the research from which some such ideas emerge. Yes, this is a very hard way to make progress on fundamental physics, but it is not impossible to find new ideas and make progress this way, and it may be the only choice people have who want to continue to work on certain questions. Some people should be pursuing this, and to have any success they'll have to have something a lot more sophisticated than a naive idea about what is beautiful and what isn't beautiful. I'd argue that the best mathematicians often are motivated by such ideas.

12. **Lee Smolin**
December 10, 2018

I agree with much of Sabine's argument, but I have a somewhat different perspective on one aspect of it, which is her criticism of the concept of naturalness, which is the requirement that any pure dimensionless constants in the parameters of a physical theory that are not order unity require explanation. We say a dimensionless constant that is orders of magnitude away from unity requires "fine tuning." The standard model has, depending on what you count, 29 dimensionless parameters, most of whom are not order unity and hence are fine tuned. The lesson that many people took away from this fact was to attempt to embed the standard model in another, possibly more unified theory, with fewer adjustable finely tuned parameters. Examples that were proposed included technicolour and supersymmetry. These failed, in some cases in more than one way: for example, the minimal supersymmetric extension of the standard model has more parameters-not fewer, and indeed 105 of them, which is not a small problem. And they are not less fine tuned than the original parameters.

This was not an aesthetic imperative, for we do not seek to reduce the number of finely tuned parameters to make a theory more beautiful, but to increase its explanatory power. This is a general aim of science.

What I take away from the failure of these attempts is that we have to accept on face value that the parameters of the standard model have been fine tuned to unnatural values. This requires explanation. One form that such an explanation could take would be if sometime in the past there acted a physical mechanism which choose such unlikely values for the parameters.

I have suggested one possible mechanism for this fine tuning, which is cosmological natural selection. This is falsifiable and hence will probably be shown wrong. But that is the price you pay for a genuine increase in the explanatory power-if true-of the hypothesis.

My bottom line, then, is that when taken to describe a physical theory, beauty is sometimes a measure of explanatory power, and this can be a good thing. Of course it often is not, in which case Sabine's arguments apply.

Thanks,

Lee

13. **Peter Shor**
December 10, 2018

@Lee:

When you say that "any pure dimensionless constants in the parameters of a physical theory that are not order unity require explanation," you are implicitly putting a probability distribution on the positive reals which is sharply peaked at unity.

Doesn't this assumption also require explanation? Why should the range of numbers between 1 and 2 be any more probable than the range between 10^10 and 10^20? Aren't there just as many numbers in the range between 10^10 and 10^20? as there are between 1 and 2? (Uncountably many in each.)

14. **quanta by any other name**
December 12, 2018

Thanks again for the links, I don't know how you find all of these.

Susskind said something else which everyone on this blog seems to be ignoring. At about 14:47 he says "will what does correctly describe particles be a small modification of [string theory] or a big modification, that's what I don't know."

Thus, if we are going by what Susskind says, we should start with string theory and modify it, not abandon it.

15. **Lee Smolin**
December 12, 2018

Dear Peter Shor,

Yes, exactly, and let me explain where that expectation for dimensionless ratios to be order unity comes from.

Part of the craft of a physicist is that a good test of whether you understand a physical phenomena-say a scattering experiment-is whether you can devise a rough model that, with a combination of dimensional analysis and order of magnitude reasoning, gets you an estimate to within a few orders of magnitude of the measured experimental value. People like Fermi and Feynman were masters at this, a skill that was widely praised and admired.

The presumption (rewarded in many, many cases) was that the difference between such rough estimates and the exact values (which were by definition dimensionless ratios) were expressed as integrals over angles and solid angles, coming from the geometry of the experiment, and these always gave you factors like 1/2pi or 4pi^2, which were order unity.

Conversely, if your best rough estimate does not get you within a few orders of magnitude of the measured value, then you don't understand something basic about your experiment.

Seen from the viewpoint of this craft, if your best estimate for a quantity like the energy density of the vacuum is 120 orders of magnitude larger than the measured value, the lesson is that we don't understand something very basic about physics.

Thanks,

Lee

16. **Cedric Bardot**
December 12, 2018

@PeterShor
Gabriele Veneziano can be seen in a video entitled "Why Four Dimensions and the Standard Model Coupled to Gravity … ". The speaker explains (following Solid Theoretical Research In Natural Geometric Structures) how "dimension 4 appears as a critical dimension because finding a given manifold as an irreducible representation* requires finding two maps to the sphere such that their singular sets do not intersect. In dimension n the singular sets can have (as a virtue of complex analysis) dimension as low as n-2 (but no less) and thus a general position argument works if (n-2)+(n-2) is less than n, while n=4 is the critical value. "
I let curious people to find out easily the source of this quote. To understand it is more challenging and requires some knowledge in differential geometry and operator algebra…

Another relevant detail I think for the issue discussed by Peter in his post: the speaker in the video is not Veneziano and is pretty well known to be doubtful about string theory. Nevertheless at the end of this video he praises publicly the italian theoretical physicist : "It's crucial we have doubts and we manifest these doubts… if we are just preaching this is a catastrophy… I admire Gabriele for that … we spend our life doubting , the chance we are right are tiny". The speaker and Veneziano had been professors at College de France at the same time for a while. Both are emeritus now.

PS: the link to the video is https://www.youtube.com/watch?v=qVqqftQ92kA
* irreducible representation of a specific operator algebraic equation…

17. **Peter Woit**
December 12, 2018

quanta by any other name:
Your Susskind quote I think reflects one of the most serious problems facing this field of physics. For Susskind and many others, string theory has become such a

dominant paradigm that, despite its complete failure as a unified theory, they cannot even envisage looking for a completely different starting point. The only conceivable direction for progress is to start with string theory and modify it, by a small or big amount. I think Susskind recognizes this hasn't worked so far, but after spending decades devoted to this ideology, he can't conceive of trying to start from a different point.

18. **Matt Foster**
December 19, 2018

As someone who has been led by the nose to some problems of "quantum geometry" in low dimensions (through some possible applications to mundane topological condensed matter systems), I've been digging through the old string textbooks like GSW to extract useful technology.

The thing I've never understood, and still don't understand, is why choose D = 26 for the bosonic string. The classical theory of the 2+0-D massless bosonic worldsheet decouples from the geometry of the sheet in the conformal gauge. The anomaly (if I understand correctly) says that the stress tensor acquires a nonzero trace whenever the worldsheet is not flat, proportional to the (gauge invariant) scalar curvature, unless we have 26 bosons to cancel the negative central charge of the Fadeev-Popov ghosts.

This just means that the free fixed point is unstable due to quantum corrections, right? The generation of a nonzero stress tensor trace from the scalar curvature looks like gauge invariant statement. If you want to study quantum strings (forget for the moment whether they have anything to do with gravity), then going to D = 26 makes that task easier, modulo the tachyon problem. But if you want a 3+1-D theory, can we be sure there isn't some strong coupling fixed point which itself could be critical (conformally invariant), but not perturbatively connected to the free one? Are we really forced to go to the critical dimension by physics, or is it just mathematical convenience (essentially integrability of worldsheet CFT) in this case??

19. **Peter Woit**
December 19, 2018

Matt Foster,
This is a rather off-topic technical question. There's a huge literature on string theory in non-critical dimensions, and many people over the years have looked into this. I think a fair summary is that no-one knows how to get a realistic unified theory this way, thus the concentration of attention on starting with strings in the critical dimension then somehow getting rid of the excess dimensions.

This Week’s Hype

December 19, 2018
Categories: This Week's Hype

A few months ago string theorists at Stanford had their university press office put out hype-filled promotional material about their research field, this was discussed here. One odd thing about this was that normally such PR efforts are made in connection with news of a supposed advance, but this press story had no news, just promotion of old and unsuccessful ideas.

This week it’s the turn of the string theorists at Princeton University, with Beyond Einstein: Physicists find surprising connections in the cosmos. Like the Stanford one, this story is not about any recent advance (there haven’t been any) but just a recounting of something from twenty years ago, without any acknowledgment that things haven’t worked out as hoped. To compare and contrast, another Princeton press office effort on the same topic back in 2007 (see here) at least had a specific new paper to advertise. The level of deception of the public though remains constant, no change from the 2007 highly misleading “Princeton Physicists Connect String Theory With Established Physics”.

The way this works, the misleading university press release gets picked up by others, who either just pass along the press release or write something based on it (with an even more misleading title). As an example of the first, phys.org yesterday had Gravity is mathematically relatable to dynamics of subatomic particles. For the second, today Science Alert has Here’s Why String Theory Might Actually Point Us Towards a ‘Theory of Everything’. I suspect we’ll see yet more of this in the next few days as the hype-diffusion process initiated by the Princeton theorists takes its usual course.

The basic, intentionally misleading, PR claim at that bottom of this is the characterization of AdS/CFT as:

> The key insight is that gravity, the force that brings baseballs back to Earth and governs the growth of black holes, is mathematically relatable to the peculiar antics of the subatomic particles that make up all the matter around us.

What’s not mentioned is that this has nothing to do with either gravity as experienced by baseballs, or the subatomic particles that make up matter. The AdS/CFT conjecture relates gravity in the wrong space-time dimension (5), with the wrong space-time curvature (AdS) to a quantum field theory that doesn’t describe any known particles (N=4 SSYM). For the last twenty years there has been lots of speculation about the possibility of extending this to the real world cases, but this hasn’t worked out. There’s no known dual QFT to gravity in the physical dimension with the physical sign of curvature, and, from the other side, no known gravity theory dual to the Standard Model.

As with the recent Stanford effort, the great thing about having your own university press office do this and not involve journalists is that they just talk about you and let you say whatever misleading thing you want. No danger that this kind of story will raise embarrassing questions or that it will give a voice to or even acknowledge the existence of anyone likely to raise objections.

   December 19, 2018

   I do wonder who the PR offices think they are fooling. After all, the fact that string theory is a dead end has reached all the way down to the popular level on “The Big Bang” theory where Sheldon gives it up.

2. **Peter Woit**
   December 19, 2018

   neil,
   I think the change in the popular perception of string theory has a lot to do with the decisions by string theorists to engage in this sort of PR campaign. Note that the Princeton article is coming out of the “Office of the Dean for Research”, the office responsible for helping faculty get research funding from public or private sources.

3. **JC**
   December 21, 2018

   Neil,
   “I do wonder who the PR offices think they are fooling. After all, the fact that string theory is a dead end has reached all the way down to the popular level on “The Big Bang” theory where Sheldon gives it up.”
   You have to give it to them, they´re fighting back in season 11 where Sheldon picks it up again.
   People who love Physics should start writing to TV producers, of this series and others, in order to stop misleading the public.
   We can´t leave Peter and others do all the work by themselves.

The Chronic Incompleteness of String Theory

December 19, 2018
Categories: Uncategorized

Ex-string theorist turned philosopher Richard Dawid has become known over the years for his arguments that string theory is a theory to be evaluated not by the conventional scientific method, in which experiment plays a role, but by "post-empirical theory assessment" methods. He has a book about this, and I've written about his arguments here, here and here.

Today he has a new paper out, entitled Chronic Incompleteness, Final Theory Claims, and the Lack of Free Parameters in String theory, which tries to address the "chronic incompleteness" problem of string theory's claim to be a complete unified theory. This problem is starting to look very serious:

> Rather than bringing the time horizon for the completion of fundamental physics from virtual infinity to somewhere within our lifetime, string theory's final theory claim seems to be associated with an extension of the time horizon for the completion of this particular theory that may, once again, virtually reach towards infinity.

In other words, there's a chronic problem of string theorists not being able to tell us what the theory actually is, and now it's looking like they'll never be able to do so. Dawid is right that this is the root of the problem, not usual excuses like "it predicts stuff, but you'd need an accelerator as big as the galaxy to test these predictions" or "the equations are just too hard to solve".

One question here is that of defining what "string theory" even means anymore. Dawid does the best he can with this in a footnote:

> Here as throughout the entire paper, the term 'string theory', if not specified otherwise, denotes the overall theory that aims at describing the observed world and is identified by the present knowledge on perturbative superstring theory, duality relations, etc.

This isn't exactly a precise definition, it's basically just "string theory is a conjectural theory with a certain list of properties which I'm not going to even try and describe, since that would get really complicated and different people likely have different lists".

In the main text, Dawid explains that "string theory has no fundamental dimensionless free parameters", a claim often made that I've always found kind of baffling. If you don't know what the theory is, how do you know that it doesn't have free parameters??? He makes a great deal of this assumption, adding in the argument that this lack of parameters means no classical limit, and I guess thus no formulation of the theory as "quantization" of something describable in classical terms.

I don't really see what the big deal is about having a quantum system that is not defined as the quantization of some classical system. A simple example of such a system is the qubit that we often start teaching quantum mechanics with. Somehow Dawid wants to get from "not quantization of a classical system" to "we can't ever hope to write down the theory", but I don't see how this follows.

He examines various possibilities for how the problem of no fundamental theory can be resolved. His alternative C is the obvious one: we just haven't found it yet. He would like to argue that this might not be right, that string theory is a new and different kind of science:

> …string theory and the conceptual context within which it is developed is in a number of ways substantially different from anything physicists have
> witnessed up to this point. Therefore, it is far from clear whether prevalent physical intuitions as to which kinds of questions can be expected to have a fully calculable theoretical answer are applicable in this case. It seems
> difficult to rule out that what seems to be a question that finds a fully calculable theoretical answer in fact rather resembles the case of the leaf carried by autumn winds and just defies calculation.

Dawid seems to argue that string theory may be an example of what he calls alternative A:

> Even in principle, there exists no mathematical scheme that is empirically equivalent to string theory and generates quantitative results that specify the fundamental dynamics of the theory. In that case, the fundamental theory is conceptually incomplete by its very nature. It has no fundamental dynamics and no set of solutions that can be deduced from its first principles. The fundamental theory merely serves as a conceptual shell that embeds low energy descriptions (ground states of the theory) consistent with the principles encoded in the fundamental theory. Those low energy descriptions contain specified parameter values and do generate quantitative results. But there is no way to establish from first principles how probable specific ground states of the system are.

His summary of his vision of string theory is as follows:

> Full access to a theory without free parameters thus might be expected to require representations that don't have their own classical limit. The fact that they cannot be developed by generalizing away from a classical limit seems to impede the full formulation of a final theory even once one has found it. The resulting idea of a fundamental theory whose full formulation is hidden from the physicists' grasp because its most adequate representation lacks intuitive roots has even more radical rivals, which amount to questioning the possibility of calculating the dynamics of the fundamental theory either within the bounds of human calculational power or as a matter of principle.

At one point Dawid acknowledges that some people have drawn the obvious conclusion about the current situation, the one consistent with our usual understanding of science:

> It has been suggested by various exponents and observers of contemporary fundamental physics (see e.g. Smolin 2003, Woit 2003, Hossenfelder 2018) that the chronic incompleteness of string theory represents a substantial failure of the research program that is indicative of a strategical problem that has afflicted fundamental physics in recent decades.

He doesn't like this conclusion, so argues that this time it's different:

> Considering the range and character of the very substantial differences that set the current state of fundamental physics apart from any previous stage in the history of physics, there is little reason to expect that theory building at the present stage can be judged according to criteria that seemed adequate in the past.

While he doesn't say so, this argument takes him back to the problem of how one is to judge "string theory", but taking a position even more radical than his earlier one. The argument now seems to be that we're supposed to consider accepting as the final, fundamental theory of physics, a "theory" that is not just untestable, but is a "chronically incomplete" framework based on something we can never hope to define or understand. I'm having trouble understanding why this is supposed to be science rather than another human endeavor that it looks a lot more like, theology.

1. **Lee Smolin**
   December 19, 2018

Dear Peter,

Does Dawid not consider the context, which is that "string theory"-defined as you like, is one of several different theories, hypotheses or research programs to complete the standard model and quantize gravity and that in the end it will be evaluated by contrasting it with alternative or rival theories? This is a basic theme of philosophy of science back to Kuhn, Lakatos, and Feyerabend.

What if an experiment confirms the hypothesis of Diosi, Penrose and others, that quantum dynamics becomes non-linear in order to disallow superpositions of macroscopically distinguishable gravitational fields? This begins to appear to be possible within a decade. To my knowledge no version of string theory predicts this, hence string theory might be simply disconfirmed, via the standard methodology of science.

2. **anon**
December 20, 2018

"I don't really see what the big deal is about having a quantum system that is not defined as the quantization of some classical system. A simple example of such a system is the qubit that we often start teaching quantum mechanics with."

A bit of a tangent, but according to Kirillov's orbit method, can I not regard a qubit as the quantization of the first nontrivial integral (co)adjoint orbit of SU(2)?

3. **Sabine Hossenfelder**
December 20, 2018

"…string theory and the conceptual context within which it is developed is in a number of ways substantially different from anything physicists have witnessed up to this point."

Last time we heard from Dawid he argued that it counts in favor of string theory that the theory is *not* all that different from the physics we know up to this point. It's what he called the "Meta-Inductive Argument." This didn't work, of course, because if anything that argument would count in favor of asymptotically safe gravity. Must have been inconvenient.

4. **Roger**
December 20, 2018

I am puzzled by Dawid's frequent usage of "chronic incompleteness" without defining it. I see two possible definitions:

chronic incompleteness – physicists keep trying to develop it into a meaningful theory, and keep failing.

chronic incompleteness – it fails to make any predictions, even with complete initial data.

The first is like "chronic pain", and the second is just a fancy way of using time as an adjective.

5. **David Roberts**
December 20, 2018

> *Even in principle, there exists no mathematical scheme that is empirically equivalent to string theory and generates quantitative results that specify the fundamental dynamics of the theory.*

Giving up on Hilbert's 6th problem?

6. **Peter Woit**
December 20, 2018

Roger,
Maybe it's because it's end of semester here, but to me "chronic incompleteness" brings to mind some of my students. In their case though, they almost always end up handing in something for evaluation….

7. **Peter Woit**
December 20, 2018

anon,
Yes, but that kind of "quantization" isn't what Dawid is referring to, he's talking about systems with a "classical limit". In the case of spin, you could try and interpret spin s as corresponding to a sphere with area proportional to s, then take as "classical limit" s goes to infinity. Then you could try and understand the qubit as the opposite spin half limit of the "classical" system at infinite spin. Dawid is quite right that this is not going to work. The point though is that we have other ways of understanding quantum systems that don't start with a conventional classical system and our intuitions about it.

8. **Roger**
December 20, 2018

My dictionary defines chronic as having long duration, or recurring. Seeing "chronic incompleteness" in a semi-technical paper makes me think it means something technical, like "the initial value problem is ill-posed", or that string theory cannot make long duration predictions. Or maybe he is just hiding string theory's shortcomings in an opaque phrase.

9. **Amos**
December 21, 2018

Regarding this quote: "It has been suggested by various exponents and observers of contemporary fundamental physics (see e.g. Smolin 2003, Woit 2003, Hossenfelder 2018) that the chronic incompleteness of string theory represents a substantial failure of the research program…"

Are those publication dates correct? I thought the Smolin and Woit books are copyright 2006. But even in the References section of Dawid's paper, where he lists author, title and publisher, both books are listed as 2003.

As an aside, it always seems strange to me that the Woit and Smolin books are so routinely cited as if they were the "big bang" of published skepticism toward string theory, considering that (for example) Penrose 2004 contains a highly critical/skeptical survey of the string theory program, and even discusses the sociological aspects (prestige of Witten, etc). Not to mention the critiques of Feynman and Glashow already in 1988. I suppose if the Woit and Smolin books really are 2003 they would take precedence over Penrose, but not if they were published in 2006 (as Wikipedia says).

10. **Peter Woit**
December 21, 2018

Amos,
I don't know why Dawid has those dates. The actual publication date was 2006. However it is true that my book was basically finished in 2003, when it was under consideration for publication by Cambridge University Press. For the full story, see here
http://www.math.columbia.edu/~woit/wordpress/?p=245

Of course it's true that from the beginning many physicists were aware of and complaining about the problems with string theory. Most of the public such complaints I was aware of when writing in 2002 were mentioned with citations in the book.

11. **Lee Smolin**
December 21, 2018

Dear Amos,

My book "The trouble with Physics" was published in 2006. No version was available before that. It was preceded by a few papers which compared different approaches to quantum gravity on purely scientific criteria,(ie no sociology), such as

Lee Smolin, How far are we from the quantum theory of gravity?, hepth/0303185.

but I don't know if Dawid referred to these.

Putting Peter and my books in 2003 rather than 2006 is a serious historical mistake, as 2003-2006 was a period of intense debate about the applicability of the athropic principle and the multiverse. My book and its reception would have been very different had it come out in 2003.

Regarding Sabine's comment, I argued in my review of Dawid's book, that his three non-empirical criteria for assessing a theory were satisfied very well by loop quantum gravity, and I'd agree they are also met by asymptotic safety. This is not to make an argument for either of those theories, but to demonstrate that Dawid's criteria are ambiguous and are of no help when one is faced with several competing theories or research programs. That is of course the present situation.

"String Theory and the Scientific Method. Review of a book by Richard Dawid.", in the American Journal of Physics, 2014.

Thanks,

Lee

12. **Peter Woit**
December 21, 2018

Re Lee's correct comment about the history, in more detail the story of my book is that the 2003 version had nothing about the multiverse/anthropics, which was a topic that only got going in 2004. The version published in 2006 did have a chapter about this, but that chapter was written in 2004-5, after I had given up on Cambridge and found another publisher. I think Lee is quite right that the nature of the 2006 debate that both of our books triggered had a lot to do with the fact that it was taking place in the context of many string theorists signing on to the idea that string theory implied a multiverse/anthropic explanation for fundamental physics.

Tim May 1951-2018

December 24, 2018
Categories: Obituaries

I was sorry to learn yesterday of the death of Tim May, who had been a frequent commenter here on the blog. For more about his life, see here and here.

One can find his comments here for instance by this search. In some of these he told a bit of the story of his life. I'll include here part of one such comment:

> In 1970 I was accepted at MIT, Stanford, and Berkeley for college. I transferred my acceptance and Regents Scholarship from Berkeley to UC Santa Barbara. A lesser school compared to Berkeley, on overall grounds, but a more interesting fit to my interests. (College of Creative Studies, with many advantages.)
>
> By around 1972 it was clear the Big Drought was unfolding. Tales of Ph.D.s driving taxi cabs, professors advising that the odds of the then-current Ph.D. candidates getting a real position were dwindling. (Besides the overall downsizing of HEP and other physics funding, there was a glut of physics professors who had been hired in the post-Sputnik boom era….and they were still 30 years or more from retirement.)
>
> Fast forwarding, I decided to not apply to grad school and instead join a small semiconductor company. There, I worked on a bunch of "engineering physics" probems. Because we were the leaders in dynamic RAM memory, I had exposure to some interesting problems. One of them was the mysterious issue of bits sometimes being flipped, but not permanently. In fact, the bit flips were apparently random and occurred only once (or at least close to only once…).
>
> My physics background served me well, as I knew about the physics of how the devices worked (more so than a lot of the EE folks, who thought in terms of circuits), and I knew some geology. I had a brain storm that maybe low levels of uranium or thorium or the like in our ceramic and glass packages were causing the problem. Some experiments confirmed this. And all of the physics calculations about charged particle tracks in silicon matched. A lot of stuff I don't have the space here to describe.
>
> So my career was launched. Lots of papers on this "soft error" phenomenon. (Oh, and the cosmic ray corrollary was indeed obvious: but in 1978 when the first paper was presented, it was insignificant as a source as compared to alpha particles.)
>
> Instead of spending until 1980-82 doing a Ph.D. and then 4-8 years or more as a post-doc, I had some fun and retired from Intel in 1986.
>
> I've been pleasantly able to pursue whatever interested me ever since.

Comments

1. **Jeff Berkowitz**
   December 24, 2018

   Sigh. Wow. Sigh and wow. I'd never heard Tim May's name. Sigh.

   Peter, I'm old enough to remember when this discovery was made and the decision by that "small semiconductor company" to go public with the information rather than retaining it for proprietary advantage.

   There's a mention in http://www2.ece.rochester.edu/~xinli/usenix07/ And although it sounds funny today, Intel was pretty small in 1978. The whole industry was small. That was an important piece of work.

   "[T]he first evidence of soft errors at sea level due to radiation was given in 1978 by May and Woods from Intel [56, 57]."
   https://pdfs.semanticscholar.org/721a/093aba13979c674878c4076fa28dc8fcd0d0.pdf

   Here's the paper itself: https://ieeexplore.ieee.org/document/1479948

   I'm sad. Thank you for posting.

   December 25, 2018

   Peter
   I was on the cypherpunks list in the early noughties and, while tremendously inspired by his technical prowess and prophecies, I found his misuse of the term 'anarchist' odd.

   So ' Yes' to the technological determinism. ' No' to the Randite-Rothbard politics.

   There's some interesting threads in the archives (MARC) of cypherpunks for physics buffs. Just dig around in there.

This Week’s Hype (and a couple other things)

December 28, 2018
Categories: Swampland, This Week's Hype, Uncategorized

For today’s university press release designed to mislead the public with hype about string theory, Uppsala University has Our Universe: An expanding bubble in an extra dimension. It’s the Swampland variant of string theory hype, based on this preprint, which is now this PRL. Marketing to other press outlets as usual starts here and here.

In the current Swampland hype, string theorists have “discovered” that string theory doesn’t really necessarily have that landscape of vacua making it untestable, and now we’re finally on our way to testing string theory. In this press release version:

> For 15 years, there have been models in string theory that have been thought to give rise to dark energy. However, these have come in for increasingly harsh criticism, and several researchers are now asserting that none of the models proposed to date are workable….
>
> The Uppsala scientists’ model provides a new, different picture of the creation and future fate of the Universe, while it may also pave the way for methods of testing string theory.

For some other things that may be of more interest:

- FQXI will be giving out \$8.4 million in large grants in 2019. There are two themes. One of these is Intelligence in the Physical World, sponsored by the Fetzer Franklin Fund, the other is Information as Fuel, sponsored by the Templeton World Charity Foundation (which seems to be independent of the Templeton Foundation).
- There’s a new initiative at Princeton I hadn’t heard about until recently: the Princeton Gravity Initiative.
- It looks like the idea of constructing a lepton collider in Japan, the ILC, is now unlikely to happen. The problem with this project has always been that it would be both very expensive and not provide a huge energy increase over the energies achieved at LEP.

Finally, I’m leaving tomorrow for a two-week or so vacation in France, blogging likely slim to non-existent.

Comments

1. **Roger**
   December 29, 2018

   That the Science Council of Japan (SCJ) does not support the ILC can’t be interpreted as anything other than very bad news for the project. To place the news in context, the SCJ comprises non-particle physicists and pp has traditionally had difficulty convincing other fields of the merit of their expensive experiments (eg the SSC). In other words, the SCJ report is a disappointment but its difficult to argue that it was entirely unexpected. However, it need not be the end of the story. The Japanese government will now take a decision based, in part, on the SCJ report together with other considerations, eg , the effect on the local economy of the area which would host the ILC. Its possible that the project will still go ahead though this admittedly looks unlikely right now. Had new physics shown up at the LHC which the ILC could probe, which was how the ILC was originally spun all those years ago, the motivation for the ILC would have unarguably stronger and the story could have been different. However, we don’t live in that part of the multiverse…

   If the ILC fails then the tectonic plates in the collider world start to shift. The FCC-ee (new ring at CERN with e+e- up to 400 GeV cm prior to hh at 100 TeV) gets something of a boost since the ILC won’t be around to do much of its physics program before the new tunnel is even built. CLIC at CERN (e+e- up to several TeV) should also get a boost but seems to be the forgotten child. It may be terribly unfair on the project but one hears far more about the FCC these days. It will be interesting to see how the ILC’s demise (if this happens) affects the attitude in China towards building its own e+e- machine (CEPC).

Roy Glauber 1925-2018: Notes on QFT

December 28, 2018
Categories: Obituaries

I saw today that Roy Glauber has passed away, at the age of 93. John Preskill speculates that Glauber was the last living member of the wartime T division at Los Alamos.

My only interaction with him was that he was the instructor for the first quantum field theory course I took, at Harvard during the 1976-77 academic year. The course was my first exposure to quantum field theory, and was taught from what seemed then (at the time of the advent of gauge theories and wide use of the path integral method) a rather stodgy point of view. It's one however that I have later in life come to appreciate more.

I just located the binder of notes I kept from the class and plan to look over them. It occurred to me that if I want to look at these on vacation, the thing to do is to scan them. So, I just did this, and am making the scans available here in case others are interested:

Roy Glauber: Quantum Field Theory notes 1976-77

Roy Glauber: Quantum Field Theory problems and solutions 1976-77

Update: The New York Times has an obituary here.

   RIP.

2. **Mark Hillery**
   December 28, 2018

   I am very sorry to hear this. As someone who has worked in quantum optics, and first encountered it by reading some of Roy's papers, I can say that his founding contributions were something that all of us learned, and they formed the framework for much of our thinking about the field. His papers were masterpieces of originality and clarity. Lesser known to those outside the field was his talent as an after-dinner speaker at conferences. He had the comic timing and manner of Jack Benny (OK, I am dating myself here). He will be very much missed.

3. **Si MohOumhand**
   December 29, 2018

   Dear Peter,

   Thank you for posting the notes. They are very neat. I read in your book "Not Even Wrong" that at some point you asked Witten to explain to you things in quantum field theory. Was it about these notes. If yes, do you remember which chapter?
   Thanks.

4. **Peter Woit**
   December 29, 2018

   Si MohOumhand,

   That was a year or two later, when for a semester I had an independent reading course with Witten (who was a newly arrived postdoc). Witten helped me go through basics of gauge theories, doing perturbative calculations and renormalization (his Ph.D. thesis at Princeton had been on perturbative QCD calculations).

   After Glauber's course, the next year I sat in on Coleman's QFT class. A published version of Coleman's class notes is supposed to appear soon, which I'm looking forward to. I think my last year at Harvard I sat in on or took a more advanced graduate course from Weinberg on gauge theories (something like volume II of his QFT book). Looking back on those days, I had the great luck to get to start learning the subject from the very best.

5. **Vhman**
   December 29, 2018

   Coleman's notes are already on Amazon.

6. **Peter Woit**
   December 29, 2018

   Vhman,
   Yes, but for delivery in a couple weeks. I hear they're being printed and shipped around now, so should be available starting in a week or two. I'll write something about them when I get back from vacation, hope to have a copy by then.

7. **David Appell**
   December 29, 2018

   Nice and thoughtful jobs with the notes, Peter. Thanks.

8. **DRLunsford**
   December 31, 2018

   I thought his papers were very clearly written. RIP

   -drl

9. **David Derbes**

January 1, 2019

I'm one of the editors (Brian Hill, Bryan Gin-ge Chen, Yuan-Sen Ting, Richard Sohn and David Griffiths are the others, names by chronological involvement) of the Coleman QFT notes. Peter was of huge help in getting the Coleman notes into publishable form. Early on I corresponded with him about the project and by return email came scans of his own notes of Coleman's class. These were invaluable, particularly for the second semester. (The bulk of the text is from transcriptions of the videotapes of Coleman's lectures, on line at Harvard's physics web site, but we couldn't have done it without other records of the lectures.) You can get the kindle edition today but I think the physical books won't be at Amazon till January 9th or thereabouts (but they exist; World Scientific air expressed a copy to me on November 12). I'm nonplussed by various "used" copies for sale; I have my doubts about the legitimacy of these. You can get an earlier version of the first semester notes (originally by Brian Hill; LaTeX'd by Yuan-Sen Ting and Bryan Gin-ge Chen) today for free at the arXiv. The book is about 1200 pages, including a very nice foreword by David Kaiser (who also did one for the reissue of Misner, Thorne and Wheeler), and about 72 problems and solutions (some are old exam questions). We tried to do a good job, but the readers will be the judge of that. Incidentally, all author royalties are going to Diana Coleman, Sidney's widow; we all worked for free. It took five years.

10. **Pascal**
January 15, 2019

Another aspect of Glauber's work is highlighted here:
http://bit-player.org/2019/glaubers-dynamics

11. **Anonyrat**
January 16, 2019

The store person at Barnes and Noble said that the Coleman QFT book is a "print on demand" book and so I'd best order it online.

12. **Peter Woit**
January 16, 2019

Anonyrat,
As far as I know copies are being printed in the usual way by World Scientific, which is selling them on their website. I'd be very wary of any "printed on demand" version. People should be aware that there's an industry devoted to grabbing pdfs from various places and marketing them as printed on demand books.

13. **Mark**
January 17, 2019

I just received my beautiful hardcover version (World Scientific) from Amazon UK (which I preordered quite a while ago) – It is a very heavy book and beautifully printed, and I am glad that I got the more expensive hardcover version – Amazon was nice and did refund the price increase from the time I ordered.

Michael Atiyah 1929-2019

January 16, 2019
Categories: Obituaries

While away on vacation, I heard last week the sad news of the death last week of Michael Atiyah, at the age of 89. Atiyah was both a truly great mathematician and a wonderful human being. In his mathematical work he simultaneously covered a wide range of different fields, often making deep connections between them and providing continual new evidence of the unity of mathematics. This unifying vision also encompassed physics, and the entire field of topological quantum field theory was one result.

I had the great luck to be at MSRI during the 1988-89 academic year, when Atiyah spent that January there. Getting a chance to talk to him then was a remarkable experience. He had one of the quickest minds I've ever seen, often grasping what you were trying to explain before the words were out of your mouth. At one point that month I ran into Raoul Bott walking away from an ongoing discussion with Atiyah and Witten at a blackboard. Bott shook his head, saying something like "it's just too scary listening to the two of them".

Any question, smart or stupid, would lead to not just an answer, but a fascinating explanation of all sorts of related issues and conjectures. For Atiyah, his love of discussing mathematics was something to be shared at all times, with whoever happened to be around.

The last time I met him was in September 2016 in Heidelberg. He was his usual cheerful and engaging self, still in love with mathematics and with discussing it with anyone who would listen. I did notice though that age had taken its toll, in the sense that he no longer would engage with anything that got into the sort of complexities that in the past he had been quick to see his way through. It's unfortunate that near the end of his life far too much attention was drawn to implausible claims he started making that he could see how to solve some of the most difficult and intractable open problems of the subject.

There's a lot more I could write here about Atiyah and his remarkable career, but I've realized that most of it I've already gotten to in one post here or another. So, for more, see some of the following older posts, which discussed:

Interviews and profiles here, here and here.

Atiyah and his work with Raoul Bott.

Atiyah and topological quantum field theory.

Update: In recent years Andrew Ranicki had been maintaining a page with Atiyah-related links.

Comments

1. **T**
   January 16, 2019

   In a previous blog posting you wrote "Atiyah favored "new-fangled" abstraction, only writing down formula when forced to by Bott". As an analyst (who finds themselves having to write down each step of a proof) I find this amazing. Do you have any more details as to how he was able to do this?

2. **Peter Woit**
   January 16, 2019

   T,
   I'm paraphrasing Atiyah himself there. My interpretation of what he was saying is that it's not about the details of a proof, just that he was happy working more abstractly with arbitrary solutions (e.g. in the index theorem, where you can show that there are solutions, without having them explicitly), where Bott wanted to work out what happened for explicit solutions in order to get more insight into what was going on (and ultimately convinced Atiyah he needed to do this).

   Actually I think analysis was the field where both Atiyah and Bott were weakest, and the papers he is discussing in that quote were written with an analyst (Garding). Atiyah characterizes their role in the paper as a "subcontract", presumably meaning they were handling just certain more topological and geometrical issues.

3. **DRLunsford**

Should the Europeans Give Up?

January 22, 2019
Categories: Experimental HEP News, Favorite Old Posts

The European HEP community is now engaged in a "Strategy Update" process, the next step of which will be an open symposium this May in Granada. Submissions to the process were due last month, and I assume that what was received will be made publicly available at some point. This is supposed to ultimately lead to the drafting of a new European HEP strategy next January, for approval by the CERN Council in May 2020.

The context of these discussions is that European HEP is approaching a very significant crossroads, and decisions about the future will soon need to be made. The LHC will be upgraded in coming years to a higher luminosity, ultimately rebranded as the HL-LHC, to start operating in 2026. After 10-15 years of operation in this higher-luminosity mode, the LHC will reach the end of its useful life: the marginal extra data accumulated each year will stop being worth the cost of running the machine.

Planning for the LHC project began back in the 1980s, and construction was approved in 1994. The first physics run was 16 years later, in 2010. Keep in mind that the LHC project started with a tunnel and a lot of infrastructure already built, since the LEP tunnel was being reused. If CERN decides it wants to build a next generation collider, this could easily take 20 years to build, so if one wants it to be ready when the LHC shuts down, one should have started already.

Some of the strategy discussion will be about experiments that don't require the highest possible collision energies (the "energy frontier"), for instance those that study neutrinos. Among possibilities for a new energy frontier collider, the main ones that I'm aware of are the following, together with some of their advantages and drawbacks:

- FCC-ee: This would be an electron-positron machine built in a new 100 km tunnel, operating at CM energies from 90 to 365 GeV. It would provide extremely high numbers of events when operated at the Z-peak, and could also be operated as a "Higgs factory", providing a very large number of Higgs events to study, in a much cleaner environment than that provided by a proton-proton collider like the LHC.

  In terms of drawbacks, it is estimated to cost \$10 billion or so. The CM energy is quite a bit less than that of the LHC, so it seems unlikely that there are new unknown states that it could study, since these would have been expected to show up by now at the LHC (or at LEP, which operated at 209 GeV at the end).

  Another point in favor of the FCC-ee proposal is that it would allow for reuse of the tunnel (just as the LHC followed on LEP) for a very high energy proton-proton collider, called the FCC-hh, which would operate at a CM energy of 100 TeV. This would be a very expensive project, estimated to cost \$17 billion (on top of the previous \$10 billion cost of the FCC-ee).

- HE-LHC: This would essentially be a higher energy version of the LHC, in the same tunnel, built using higher field (16 T vs. 8.33 T) magnets. It would operate at a CM energy of 27 TeV. The drawbacks are that, while construction would be challenging (there are not yet appropriate 16 T magnets), only a modest (27 vs. 14 TeV) increase in CM energy would be achieved. The big advantage over the FCC-hh is cost: much of the LHC infrastructure could be reused and the machine is smaller, so the total cost estimate is about \$7 billion.
- CLIC: This would be a linear electron-positron collider with first stage of the project an 11 km-long machine that would operate at 380 GeV CM energy and cost about ~~\$7~~ \$6 billion. The advantage of this machine over the circular FCC-ee is that it could ultimately be extended to a longer 50 km machine operating at 3 TeV CM energy (at a much higher cost). The disadvantage with respect to the FCC-ee is that it is not capable of operating at very high luminosity at lower energies (at the Z-peak or as a Higgs factory).

For some context for the very high construction costs of these machines, the CERN budget is currently around \$1.2 billion/year. It seems likely that member states will be willing to keep funding CERN at this level in the future, but I have no idea what prospects if any there are for significantly increased contributions to pay for a new collider. A \$10 billion FCC-ee construction cost spread out over 20 years would be \$500 million/year. Can this somehow be accommodated within CERN's current budget profile? This seems difficult, but maybe not impossible. Where the additional \$17 billion for the FCC-hh might come from is hard to see.

If none of these three alternatives is affordable or deemed worth the cost, it looks like the only alternative for energy frontier physics is to do what the US has done: give up. The machines and their cost being considered here are similar in scale to the SSC project, which would have been a 40 TeV CM energy 87 km proton-proton collider but was cancelled in 1993. Note that the capabilities of the SSC would have been roughly comparable to the HE-LHC (it had higher energy, lower luminosity). Since it would have started physics around 2000, and an HE-LHC might be possible in 2040, one could say that the SSC cancellation set back the field at least 40 years. The worst part of the SSC cancellation was that the project was underway and there was no fallback plan. It's hard to overemphasize how disastrous this was for US HEP physics. Whatever the Europeans do, they need to be sure that they don't end up with this kind of failure.

Faced with a difficult choice like this, there's a temptation to want to avoid it, to believe that surely new technology will provide some more attractive alternative. In this case though, one is running up against basic physical limits. For circular electron-positron machines, synchrotron radiation losses go as the fourth power of the energy, whereas for linear machines one has to put a lot of power in since one is accelerating then dumping the beam, not storing it. For proton-proton machines, CM energy is limited by the strength of the dipole magnets one can build at a reasonable cost and operate reliably in a challenging environment. Sure, someday we may have appropriate cheap 60T magnets and a 100 TeV pp collider could be built at reasonable cost in the LHC tunnel. We might also have plasma wakefield technology that could accelerate beams of electrons and positrons to multi-TeV energies over a reasonable distance, with a reasonable luminosity. At this point though, I'm willing to bet that in both cases we're talking about 22nd century technology unlikely to happen to fall into the 21st century. Similar comments apply to prospects for a muon collider.

Another way to avoid the implications of this difficult choice is to convince oneself that cheaper experiments at low energy, or maybe astrophysical observations, can replace energy frontier colliders. Maybe one can get the same information about what is happening at the 1-10 TeV scale by looking at indirect effects at low energy. Unfortunately, I don't think that's very likely. There are things we don't understand about particle physics that can be studied using lower energies (especially the neutrino sector) and such experiments should be pursued aggressively. It may be true that what we can learn this way can replace what we could learn with an energy-frontier collider, but that may very well just be wishful thinking.

So, what to do? Give up, or start trying to find the money for a very long-term, very challenging project, one with an uncertain outcome? Unlike the case of the LHC, we have no good theoretical reason to believe that we will discover a new piece of fundamental physics using one of these machines. You can read competing arguments from Sabine Hossenfelder (here and here) and Tommaso Dorigo (here, here and here).

Personally, I'm on the side of not giving up on energy frontier colliders at this point, but I don't think the question is an easy one (unlike the question of building the LHC, which was an easy choice). One piece of advice though is that experience of the past few decades shows you probably shouldn't listen to theorists. A consensus is now developing that HEP theory is in "crisis", see for instance this recent article, where Neil Turok says "I'm busy trying to persuade my colleagues here to disregard the last 30 years. We have to retrace our steps and figure out where we went wrong." If the Europeans do decide to build a next generation machine, selling the idea to the public is not going to be made easier by some of the nonsense from theorists used to sell the LHC. People are going to be asking "what about those black holes the LHC was supposed to produce?" and we're going to have to tell them that that was a load of BS, but that this time we're serious. This is not going to be easy…

Update: Some HEP experimentalists are justifiably outraged at some of the negative media stories coming out that extensively quote theorists mainly interested in quantum gravity. There are eloquent Twitter threads by James Beacham and Salvatore Rappoccio, responding to this Vox story. The Vox story quotes no experimentalists, instead quotes extensively three theorists working on quantum gravity (Jared Kaplan, Sabine Hossenfelder and Sean Carroll). Not to pick specifically on Kaplan, but he's a good example of the point I was making above about listening to theorists. Ten years ago his work was being advertised with:

> As an example question, which the LHC will almost certainly answer—we know that the sun contains roughly 10^60 atoms, and that this gigantic number is a result of the extreme weakness of gravity relative to the other forces—so why is gravity so weak?

Enthusiasm for the LHC then based on the idea that it was going to tell us about gravity was always absurd, and a corresponding lack of enthusiasm for a new collider based on negative LHC results on that front is just as absurd.

Update: Commenter abby yorker points to this new opinion piece at the New York Times, from Sabine Hossenfelder. The subtitle of the piece is "Ten years in, the Large Hadron Collider has failed to deliver the exciting discoveries that scientists promised." This is true enough, but by not specifying the nature of the failure and which scientists were responsible, it comes off as blaming the wrong people, the experimentalists. Worse, it uses this failure to argue against further funding not of failed theory, but of successful experiment.

The LHC machine and the large-scale experiments conducted there have not in any sense been a failure, quite the opposite. The machine has worked very well, at much higher than design luminosity, close to design energy (which should be achieved after the current shutdown). The experiments have been a huge success on two fronts. In one direction, they've discovered the Higgs and started detailed measurements of its properties, in another they've done an amazing job of providing strong limits on a wide range of attempted extensions of the standard model.

These hard-won null results are not a failure of the experimental program, but a great success of it. The only failure here is that of the theorists who came up with bad theory and ran a hugely successful hype campaign for it. I don't see how the lesson from seeing an experimental program successfully shoot down bad theory is that we should stop funding further such experiments. I also don't see how finding out that theorists were wrong in their predictions of new phenomena at the few hundred GeV scale means that new predictions by (often the same) theorists of no new phenomena at the multiple TeV scale should be used as a reason not to fund experimentalists who want to see if this is true.

Where I think Hossenfelder is right is that too many particle physicists of all kinds went along with the hype campaign for bad theory in order to get people excited about the LHC. Going on about extra dimensions and black holes at the LHC was damaging to the understanding of what this science is really about, and completely unnecessary since there was plenty of real science to generate excitement. The discussion of post-LHC experimental projects should avoid the temptation to enter again into hype-driven nonsense. On the other hand, the discussion of what to defund because of the LHC results should stick to defunding bad theory, not the experiments that refute it.

Update: Some more commentary about this, from Chris Quigg, and the CERN Courier. In particular, the CERN Courier has this from Gerard 't Hooft:

> Most theoreticians were hoping that the LHC might open up a new domain of our science, and this does not seem to be happening. I am just not sure whether things will be any different for a 100 km machine. It would be a shame to give up, but the question of whether spectacular new physical phenomena will be opened up and whether this outweighs the costs, I cannot answer. On the other hand, for us theoretical physicists the new machines will be important even if we can't impress the public with their results.

and, from Joseph Incandela:

> While such machines are not guaranteed to yield definitive evidence for new physics, they would nevertheless allow us to largely complete our exploration of the weak scale… This is important because it is the scale where our observable universe resides, where we live, and it should be fully charted before the energy frontier is shut down. Completing our study of the weak scale would cap a short but extraordinary 150 year-long period of profound experimental and theoretical discoveries that would stand for millennia among mankind's greatest achievements.

Update: Also, commentary at Forbes from Chad Orzel here.

Update: I normally try and not engage with Facebook, and encourage others to follow the same policy, but there's an extensive discussion of this topic at this public Facebook posting by Daniel Harlow.

Comments

1. **more to it than theory**
   January 22, 2019

   While discussions about plasma wakefield technology are fun to be had. It's also important to remember that particle physics colliders represent the forefront of accelerator technologies. New SRF technology and magnet development are only done at a few places in the world. These potential experiments aren't only interesting from the point of view of fundamental physics. They represent the technological bleeding edge, and knowledge that will be lost if we as humans don't continue to pursue it. While it can be viewed as 22nd century technology, it's not clear that it will ever arise if it isn't invested in. Given how prior magnet/accelerator technology has ended up so beneficial to society (the vast majority of accelerators in the world aren't for particle physics), it's important to think about the technological advances not just the fundamental physics. While the standard world wide web is trotted out for CERN, it's important to remember that a lot more than the web has come from particle physics. New technology as I recall, was one of the original driving interests for the CEPC and SPPC proposals in China, not just the prestige of fundamental physics.

2. **From a Former Professional Higgs Boson Hunter....**
   January 22, 2019

   The only black holes that the LHC revealed were the careers of the non-hardware post-docs…

3. **Scott P.**
   January 23, 2019

   Given that the LHC has failed to find any particles other than the Higgs, and there is nothing in the Standard Model that suggests there will be anything to find within the capabilities of colliders in the forseeable future, what is the justification for another larger collider? If there were supersymmetric particles we ought to have seen some of them at the LHC.

4. **katzeee**
   January 23, 2019

   Even if a FCC will eventually be built, will this not only shift this same discussion to 30-50 years later, when it must be decided what to do next? Built a ~100-billion-500-TeV-Collider (with appropriate e-p-mode before proton-run)?

   I am all in for spending as much money for science as one can, but the sensible (a.k.a. politically managable) decision might be, to increase incrementally and choose HE-LHC and see what magnet-technology, colliding muons etc. can do for us in the future and keep a running Collider.

5. **Sabine Hossenfelder**
   January 23, 2019

Hi Peter,

A great summary and thanks for the links. A note about the SSC/LHC comparison though. As I am sure you know the LHC is pushing hard on the computing frontier too. They have huge amounts of data to cope with and must do so quickly to decide what to keep and what to toss. The SSC would have reached an energy high enough to produce the Higgs but the data analysis would have been nowhere near as good as what we can do today.

I am not aware of any actual estimate for what this would have meant in terms of physics insights, but I think it's something one should keep in mind when one compares then to now. Best,

Sabine

6. **Dave Miller**
January 23, 2019

Peter,

Having done my thesis on the tau lepton and its neutrino (decades ago!), I'm intrigued to know more about the neutrino sector: what is the source of their mass and why is it so small but non-zero? Does anyone know if any of these proposals will give deep information about the neutrino sector, even good values for the neutrino mass matrix?

I also am tempted to think that a Higgs factory where we can measure the Higgs' behavior to high precision could be revealing: does anyone know if there is any hope of new physics there, or is it likely that we will merely find out that, yes, the Higgs does indeed give other particles their masses?

Your closing paragraph and the comment from Turok is key: what is the selling point to sell this to responsible politicians or intelligent members of the general public?

Dave

7. **Bunsen Burner**
January 23, 2019

A question no one ever seems to consider is what happens in the future if we don't keep on building accelerators and training a generation of physicists in the use? These are complicated entities that require the input of a vast army of experts. Once these experts grow old and die, if there is no one to replace them, where will the knowledge and experience come from to build accelerators in the future?

8. **Marco**
January 23, 2019

Hi Peter,
I think you have a bit outdated cost numbers (today 1.00 USD = 1.00 CHF):

– CLIC cost: 5.9 billion USD for the 380 GeV Stage
– FCC-ee cost: 11.6 billion USD (5.4 tunnel + 5.1 injetors +1.1 RF)

Updating CLIC to 1.5 TeV would cost an additional 5.1 billion USD and after that to 3 TeV an additional 7.3 billion. So for approximately the same amount you can get 1.5 TeV CLIC or 365 GeV FCC-ee

9. **Peter Woit**
January 23, 2019

Marco,
All the numbers I used came from the documents (Yellow Reports) issued last month. In particular, for CLIC, I used
https://arxiv.org/abs/1812.06018
which has on page 68 (for 380 GeV, in millions of dollars or swiss francs)
5890 +1470/-1270 (drive-beam based)
7290 +1800/-1540 (klystron based)
The reason for giving 7 billion as a rough number was partly that when someone gives you two numbers for the price of something, in my experience it's always going to cost the higher number…

In any case, these are all rough numbers. The only one of them that surprised me was the HE-LHC cost estimate, which seemed much higher than I would have expected (since I would have thought you could reuse most of the LHC infrastructure, mainly needed only to pay for the new magnets).

10. **Marco**
January 23, 2019

Hi Peter,
I understand, however, the 7 billion number is not the baseline concept, but a concept that uses klystrons instead of the drive-beam. This is not a caveat to the original machine, but a completely different machine meant to show that the drive-beam acceleration is more cost effective then klystrons (page 69 in the same document). In your writing the cost difference between CLIC and FCCee is 3B instead of 6B, which I think is a huge difference.

As for the HE-LHC cost estimate, this is not an actual cost estimate, it's more a target cost. The majority of the cost comes from the magnets. The R&D for 16T magnets is far from finished, and the industrialization of such devices has not even begun, subsequently any price tag for this kind of magnets bears very large error bars.

11. **Peter Woit**
January 23, 2019

Scott P.,
I recommend Tommaso Dorigo's blog posts that I linked to for his arguments about this.

The relevance here of my "don't listen to theorists" advice is that, while it may be true that theorists have no good motivation for any new physics beyond the SM, until one gets to the Planck scale, that's no better argument than the "naturalness" arguments made pre-LHC that said you had to see BSM physics below the TeV scale.

The difficult question here is not whether it's worth investigating smaller distance scales despite lack of motivation from the theorists. It's that the technology limits make the cost numbers vs. the energy reach not obviously attractive. If the HE-LHC could be done for \$ 1 billion I think the project would already be underway. If \$25 billion would buy a 1000 TeV collider, there would be a lot of enthusiasm to try and do that, no matter what theorists were saying.

12. **JC**
January 23, 2019

In the current global economic situation, there´s a slim chance CERN member states will be able to shoulder the cost of a significantly more powerful machine.
On thing CERN has proven is that different nations can and will cooperate in the advancement of science.
Since the whole world will benefit from the data obtained from a big cruncher, it´s time for CERN to invite other European and non-European nations to invest in the next one and accept physicists and engineers in the design, operation and analysis of whatever come out of it.
The time has come for CERN, the US, Russia, Japan and maybe even China to unite.

13. **Peter Woit**
January 23, 2019

Marco,
Thanks for the clarification, I hadn't understood that point.

The number I used for the FCC-ee was based on the \$ 10.5 billion total construction cost estimate given in the executive summary (page xxvi) of the CDR.

14. **abby yorker**
January 23, 2019

Sabine Hossenfelder wrote this for the NYT:
https://www.nytimes.com/2019/01/23/opinion/particle-physics-large-hadron-collider.html

A lot of interesting points including: do we need theorists to predict discoveries and then go after them or do we take a technique that has produced many unexpected discoveries in the past and scale it up until we can't afford it any more? I would personally vote for the latter as it seems to work. But we're getting close to the cost limit.

15. **Bernhard**
January 23, 2019

We need new ideas on how to improve acceleration technology cost-effectively. Grants focused on supporting talented young people to pursue this line could help.

16. **Peter Woit**
January 23, 2019

abby yorker,

Thanks. I'll add something about this as an update to this posting. My initial reaction after a quick read is that the piece comes off as blaming experimentalists for the behavior of theorists.

17. **Amitabh Lath**
January 23, 2019

Thank you Peter for pointing out that null results are not a failure. In fact some of the LHC searches have been breathtakingly clever and beautiful. Unfortunately articles like Sabine's in the NYT do give the impression that it's time to pack up our bags (and do what exactly?) even if that's not what she meant.

The FCC and the like will be built and operated by scientists and engineers who are kids right now; undergrads, high schoolers. They are reading Sabine's views, and I fear that they will take her glum outlook to heart.

18. **LDK**
January 24, 2019

Peter,
your "update" is really great at summarizing the core problems in this discussion. I'm pleased to see that although you are also critical against a certain way to do physics (hype, untestability, strings,..) your vision here remains very clear.
I cannot say the same for Sabine, although most of her stronger statements look milder if you read (really) carefully her replies on her blog. I think that dramatizing this discussion as she does on public media is just a harm for science (and not HEP only).

19. **LDK**
January 24, 2019

BTW, the "Europeans" expression needs an explanation (not for you Peter of course):
for me "Europeans" means CERN-based experiments but LHC is really a global effort and even so would be FCC. The same for a China-based collider. Europe by itself would not be able to put together enough money and manpower for such large endeavors.
So "should Europeans give up" should be read as "should WE.." or "should CERN…" .
USA might be over with SSC, but DUNE is still a very large scale US-based international project and their deep involvement in the LHC is beyond any doubt.
P.S. I'm not an US citizen and it is not my intention to "defend" US, CERN, the FCC project or whatsoever organization, even if I'm a particle physicist.

Nature has an editorial this week on the controversy:
https://www.nature.com/articles/d41586-019-00234-6

21. **Anon**
January 24, 2019

Dear Peter,

I am not sure it is a good idea to label falsifiable theories as "bad theories" after the experiments falsified them. For example TeV scale SUSY that solves the hierarchy problem made predictions that were sought out by LEP and LHC and has been falsified.

I would disagree with your observation that theorists "came up with bad theory." They solved an important problem that had predictions for experiments. The null results from LHC are baffling and probably tell us something deep about nature which we are still trying to unravel. That SUSY and other TeV scale physics solutions to hierarchy problem have been falsified is important by itself.

I do agree that the hype should not have been there. I do think that going for 100 TeV collider without any real theoretical motivation for that scale is a good idea, as the only reason not to find anything is Occam's Razor and this can also be tested in a sense.

22. **Low Math, Meekly Interacting**
January 24, 2019

First off: I am 100% behind the idea of my taxpayer money going to fund the FCC-ee or whatever the next generation ring winds up being. Simply because the energy frontier is there. I have no problem whatsoever with someone spending the money needed just to have a look. I can think of about 20-odd ways my country wastes more money every year in the present, and if I had my way I would happily lop those things off the budget and throw it all onto basic science. Something good always comes out of that kind of spending. It's just very hard to predict what what it will be. I think that's the most honest way to put forward the proposal. Unfortunately the most noble and truthful arguments for the SSC were much the same, and they failed to persuade. So my perspective is obviously one shared by a powerless minority, especially these days.

Given that, I'm puzzled by the argument that concern over a lack of theoretical guidance is overblown, and that the importance of strong odds in favor of a new fundamental discovery was never that relevant. Ideally, no, but this is the real world we're talking about, not the ideal. These things sure seemed awfully salient when earlier projects were being debated publicly, at least in the USA. Even in Europe, can we say with confidence that if there were not a virtual guarantee that the mechanism of EWSB would be revealed by the LHC it would have been built anyway? That's news to me, if so.

23. **tommaso dorigo**
January 24, 2019

Dear Peter,

many thanks for quoting my posts on the matter. I concur with all that you wrote, especially appreciating the updates. In particular one of the things I dislike the most about Bee's posts is exactly what you pointed out – she blames "particle physicists" as if there was one single kind of them; and she does this intentionally, because by blurring the image she is able to spin the story the way she wants. Indeed, the ones responsible for most of the hype are theorists, and they are the ones whose theories dictated our agendas.
I will give one example – we spent a lot of time and energy investigating SUSY scenarios, which is excellent science… But there is a budget of personpower that we invest in different avenues, and e.g. B physics has been seriously lagging behind (some analyses still deal with 2012 data today) because of lack of perceived interest in what is in fact a quite lively area of research, which produced lots of surprises and interesting new signals (yes, new particles!). I guess what I am saying is that the scientific output of the LHC experiments has indeed been influenced – negatively – by that hype to some degree. So experimentalists are the victims in some sense 🙂
Cheers,
T.

24. **Peter Woit**
January 24, 2019

LDK,
Yes, ultimately whether any of these projects happens will depend on participation of other countries. In particular, the US has an HEP budget of around $1 billion/year, so some fraction of that could help make a new collider feasible. I have no idea what the Chinese situation is, whether the proposal to build something there is realistic, or whether they would help construct something located at CERN.

Also to keep in mind is this new gilded age: Jim Simons could just pay for the FCC-ee himself, likely just out of his income, not even have to touch principal (he supposedly has \$ 20 billion). Same for a bunch of others.

25. **Peter Woit**
January 24, 2019

Anon,
You can be falsifiable and still "bad theory". My theory that at FCC-ee luminosity, at the Z-peak you will open a portal to another universe and angels will fly out is quite testable and falsifiable. I think it would be a really bad idea though for CERN to use it to justify the cost of the FCC-ee.

For what's "bad theory" and what isn't, you really need to discuss specific examples. The problems with string theory, large scale extra dimensions, SUSY extensions of the SM have all been endlessly discussed on this blog and in my book, and for each one, what's "bad" is a long story. One that shouldn't be very controversial though is the extra dimensions: it was an extremely bad idea to try and sell the LHC based on those models. I haven't seen anyone try that with the new proposals.

26. **Urs Schreiber**
January 24, 2019

The NY-Times text is worth reading closely to see what is really going on here. Consider the alternatives that are being suggested after…

> There are also medium-scale experiments that tend to fall off the table because giant projects eat up money.

The first suggestion for these is then given as follows:

> One important medium-scale project is the interface between the quantum realm and gravity, which is now accessible to experimental testing.

From the comment from Dec 9 here, this must be referring to the author's proposal here to use micro-force scales as in arXiv:1602.07539 for measuring quantum corrections to the gravitational attraction of two masses.

Now the first quantum gravity correction to the Newtonian potential can and has been unambiguously computed, Donoghue 95, Section 9 (arXiv:gr-qc/9512024). Even at 1 fm distance, it is still 38 orders of magnitude smaller than the classical effect. Contrary to the claim in the NYT pieces, this is utterly out of reach.

The second suggestion then is given as follows:

> Another place where discoveries could be waiting is in the foundations of quantum mechanics. These could have major technological impacts.

So this is saying that experiments should be looking for violations of the rules of quantum physics.

These are just not a serious contributions to the debate.

27. **Peter Woit**
January 24, 2019

LMMI,
Sure, if there is good evidence that there will be some interesting and completely new phenomenon for a new machine to study, that's a serious point in favor of building it, and optimizing the design for that purpose. There's also though a good case for investigating a new energy scale, even without an assurance there will be something completely new there to study. It's a fact that the case for building any of these new machines is weaker than the case for building the LHC. But I think that's just a reflection of the fact that the case for the LHC was unusually strong. I suspect though that without the Higgs it would have gotten built anyway. The new proposals won't have a slam-dunk argument like the Higgs, but I think can be justified on their own merits. A big problem is the high costs: if they were an order of magnitude lower I think the decision would be easy.

28. **Julius**
January 24, 2019

What about spending the next decade or two simply improving technologies? Dyson once said that an experiment should be performed when it is affordable. Maybe we have to acknowledge the fact that we cannot run development and implementation concurrently. No big experiments -> no big expectations -> no crazy hypotheses. Maybe, by moving the starting date of a new accelerator sufficiently far in the future would motive to start seeking the truth rather than beauty.

29. **Peter Woit**
January 24, 2019

Urs,
I suspect you're not properly interpreting what the author has in mind in these cases, and the thing to do is go discuss it with her at her blog to clarify. I happen to disagree with her about some of these arguments, but attributing straw-man non-serious arguments to her isn't helpful.

In the particular cases you mention, I think in the first case a more relevant counter-argument is that the gravity experiments she mentions are table-top experiments and the issue of how to pay for them is completely independent of the issue of paying for a new collider, where the cost is inherently huge. As for "quantum foundations", as far as I can tell "quantum" is the buzzword of the day, with companies and private foundations throwing vast sums of money at anything "quantum", and governments redirecting large parts of their research funding in this direction. So, I'm skeptical that good ideas about quantum foundations are being held up because of meager funding, something that could be fixed by using proposed HEP funding. To the extent we're talking about theory funding in either case, it's peanuts. irrelevant to the collider funding issue.

30. **Jonathan Miller**
January 24, 2019

I think that costs are the main factor why there are people interested in this discussion. The other potential discovery machines are roughly an order of magnitude cheaper. Their potential for discovery is arguably stronger, the only weaknesses is that there is a smaller scientific community involved and (possibly related) there are fewer non-discovery related publications and citations expected. Many of these discovery machines will not be built, possibly especially if a new collider is pursued.

I would love for a new collider to be built, but not at the cost of LISA or Hyper-K (for example).

31. **Peter Woit**
January 24, 2019

Julius,
The problem is that the limiting factor for hadron colliders is the magnet strength, and progress in recent decades towards increasing the strength of these magnets has been very slow. If you decide not to build a machine like the HE-LHC or FCC-hh because 16T magnets are not good enough (they require a 100km machine to get to 100 TeV, and cost scales with length), and wait for, say 32T magnets to bring the cost down by a factor of 2, you're not talking about a delay of a decade or two. More likely, 50-100 years.

I think this is a really important point. If we decide we can't afford these current proposals, we're not talking about a temporary hiatus, we're talking about the end of this kind of science for the rest of our lives. Maybe forever, since 50-100 years from now, we'll perhaps all be cyborgs owned by Google, with the curiosity about how the world works subsystem no longer there.

And as for whether no experimental results to keep them honest will cause theorists to change their ways for the better, I don't see why that should happen, the opposite seems more likely. "Post-empirical science" has not been working out well so far.

32. **Peter Woit**
January 24, 2019

Jonathan Miller,
The problem is that there are no other discovery machines on the table that will do what these colliders will do, investigate the 1-10 TeV energy scale. Deciding to instead investigate other things because it's cheaper is fine and that may be where we are headed. I just think people need to not fool themselves: taking such a path is giving up and putting an end to the long history of trying to understand the world at shorter and shorter distance scales. Arguably this was always going to happen sooner or later, the debate is just whether now is the time to give up due to the expense.

33. **Amitabh Lath**
January 24, 2019

Peter, I want to push back a little on the idea of "time to give up due to the expense".
Money spent on fundamental research does not simply disappear into some large extra dimension.

Look at Fermilab. In middle school (mid-70s) we had a field trip there and the area was all corn fields. Now it is a technology corridor. It has probably added multiples of what it cost to build into the local and national economy.

The FCC will throw up design, construction, and data analysis challenges that we would never encounter otherwise. Surmounting them will take thousands of the best brains from around the world and give them a training you can only get at the frontier.

Of course having said all that, some of us really just want to see some BSM signatures.

34. **HGB**
January 24, 2019

I am an outsider to this field. I have an interest in it – it has been at the leading edge of science for a long time. Thus, you can classify me as your typical tax payer who the HEP community should try to convince about the desirability of these new accelerators (it would of course be up to elected politicians, not me – but, you know what I mean.)

The truth is, such as things are right now, this would be a very difficult sale. My main issue here is Sabine Hossenfelder's argument, to wit, we have no compelling theoretical reasons to expect that those accelerators would find any new physics. It seems to me that we are talking huge amounts of money just to see if we are lucky and something is indeed out there. At this point in time, I would vote against such projects, recommending to devote the resources to other, more promising undertakings, of which there are many, not only in physics, but particularly in biology and genetics.

35. **Peter Woit**
January 24, 2019

Amitabh Lath,

I basically agree and don't think the "we can't afford this"argument makes sense. The EU yearly GDP is around \$ 20 Trillion, so devoting \$1 billion of that to building a collider is not crowding out anything else. And yes, the money is not being poured down a hole, it's employing people and paying their salary.

The real argument is that this funding has to come from a limited stream of public (or private?) funding for activity not devoted to making a profit. Lots of people have other ideas about what non-profit making activities they'd like to pay people to do other than build a collider.

This general issue (should we spend X on HEP physics?) tends to generate endless comments about how the money would better be spent elsewhere, according to the personal preferences of the author. This gets tedious fast and is a sort of discussion that goes nowhere (please try and restrain yourselves from such comments here). The economy and governmental budgets are not about to get reorganized along lines I'd approve of, so you're not going to hear from me an accounting of how the world should be run.

What I'd rather see discussed is the actual situation we are facing, with a realistic discussion of what the numbers look like. We are now just seeing total construction numbers, and over the next year or so those responsible for running CERN will have to see if they can somehow fit these into a plan that can plausibly be funded from available sources. I think Hossenfelder was making a mistake by starting on this campaign now. Let's see what draft plan emerges from CERN next year, and evaluate that. It will have real budget numbers and one can have a serious discussion about the implications of the collider spending vs. other sets of choices about what to do with the same source of funds.

36. **Amitabh Lath**
January 24, 2019

HGB, I have a comment on your "we are talking huge amounts of money" statement. Huge compared to what? As Peter points out, the world is fairly rich, we can afford this easily. This time around countries like China and India will contribute a larger fraction because their economies are bigger than in the 90s (they have both sent probes to the moon).

As I pointed out above, the monetary payoff will be thousands of scientists, engineers, and technicians educated to think creatively in a way that is just not possible at Google or Tesla.

Not to mention the technical breakthroughs. We don't like to talk about these because we would prefer everyone to focus on the physics, but aside from the WWW there are klystrons and niobium-titanium superconductors and proton beam therapy and a bunch more. Currently there is work being done on machine learning and ultrafast pattern matching that will undoubtedly seep outside HEP at some point.

So in terms of money, the world economy will get back far more than it puts in.

37. **Anon**
January 24, 2019

Hi Peter — A theory based on angels wont solve the hierarchy problem. What I said was that TeV scale SUSY solved an important problem and was falsifiable. Though I did not ever believe in SUSY, I think it still is one of the most amazing solutions for the Hierarchy problem, but nature seems more ingenious.

I think on of the things that requires more grants and boost is the neutrino sector — like the neutrinoless double beta decay experiments and leptonic CP phase. These and proton decay experiments if taken to the next level of precision (improved by factors of 10 or even 100) will pbly tell us more about natures.

38. **Thomas Larsson**
January 25, 2019

If there is a slim chance that an FCC will discover something, I am all in favor of building it, although I realize that I belong to the rather small fraction of the tax-payer collective that would actually care about the outcome. However, if failure to see something interesting is almost guaranteed, not so clearcut.

So I wonder how much results from precision experiments, such as the absence of EDM, are constraining possible deviations from the SM up to say 100 TeV. But then again, all such constraints are of course based on some theoretical assumptions that may be flawed.

Then I have a purely egotistical concern about the timeframe. If FCC does not start to produce results until 2050, I will probably not be around, or at least to old to appreciate them.

39. **Urs Schreiber**
January 25, 2019

Another puzzling aspect of the debate is that the flavour anomalies show every sign of being a real signal of New Physics (more). I suspect there is psychological inertia involved in not appreciating precision effects in loop contributions over the long-familiar direct detection events. But if EDM-bounds on new particle masses are anything to go by (e.g. Nature:s41586-018-0599-8), precision loop effects will only become more important in the future.

40. **Sabine Hossenfelder**
January 25, 2019

Peter,

The problem is that without the "bad theory" predictions, there are no predictions that indicate a larger collider would find anything new. "Look anyway" is all well and fine but not a convincing argument for such a big investment, especially because it's likely to negatively affect funding of more promising avenues. Maybe the situation will change with the LHC data still to come, in which case this whole discussion will become obsolete. But if not, I don't think a larger collider would be money well-invested.

As I lay out in my book, null-results are not particularly useful results if you want to develop a new theory. You really need evidence of new phenomena. It's this absence of data for new phenomena that results in "bad theories" becoming grandfathered to begin with. To break this vicious cycle of "null results – bad theories – null results", we should focus on those areas where we either already know there's something new to find (dark matter), or where we have good theoretical motivations (quantum gravity, quantum foundations).

I don't expect you to agree that those are the best areas to currently invest in, but at least I *have* an argument for why that's the most promising thing to do.

(Btw, I no longer work on quantum gravity. No need to fix that statement, just for the record.)

41. **Sabine Hossenfelder**
January 25, 2019

Should add, another way to move on would of course be if particle physicists came up with actually good predictions. I do not consider this impossible, but it would require them to acknowledge that their current methods aren't working and to come up with something better. I cannot see this happening. Sorry if that sounds cynical, but if they haven't seen light by now I don't think they ever will.

42. **Sabine Hossenfelder**
January 25, 2019

Urs,

By all due respect, you misunderstand the point of the experiment you are referring to. It's not measuring qg corrections to one mass, it's about producing a quantum superposition of masses and measuring their field. But I was not specifically referring to the Aspelmeyer group. There are various closely related ideas, see eg here https://arxiv.org/abs/1707.06050 and here https://www.nature.com/articles/549031a

Regarding your comments about quantum foundations. There are many things we simply do not understand about quantum field theories but those often receive little attention. (Think non-pert formulation, Haag's theorem, even the IR limit isn't as well understood as we thought only a decade ago.) As to your remark that it's "not serious" to test quantum foundations, that's a plainly stupid argument. I have written a whole book making my argument very clearly. I hope you'll read it before you produce further ill-informed and easily dismissive comments.

43. **Marco**
January 25, 2019

Hi Peter,
Regarding your comments

> The number I used for the FCC-ee was based on the $ 10.5 billion total construction cost estimate given in the executive summary (page xxvi) of the CDR.

Indeed this is written in FCCee executive summary.

> The construction cost for FCC-ee amounts to 10,500 million CHF for the Z, W and H working points including all civil engineering works.

But this does not include the tt treshold at 365 GeV, for this you need to scroll to page 275 of the CDR where it is stated

> Operation of the FCC collider at the tt working point will require later installation of additional RF cavities and associated cryogenic cooling infrastructure with a corresponding total cost of 1,100 MCHF.

And this is how you come to 11.6 billion in total. This number is also in line with what the CERN DG presented at the New Year presentation (https://indico.cern.ch/event/779524/) slide 62.

Thus operating CLIC at 1.5 TeV is still cheaper then FCCee and for instance you could measure the Higgs self coupling and quartic coupling which you cannot at the FCCee, among many other things.

44. **Shantanu**
January 25, 2019

Dave: The short answer is no. There is no connection between theories which predict non-0 neutrino mass and those which make predictions for LHC and beyond LHC experiments. They re completely decoupled form each other. Nothing we'll learn from neutrino experiments will tell us about collider physics or vice-versa. It disturbs me that no one else is concerned about this (esp. in the days of "grand unified theories" etc)

45. **sphaerenklang**
January 25, 2019

So many different ways of being a 'bad theory' – but what does it mean to be one, in the sense the phrase is being used here ?

E.g. 'so implausible and badly motivated that it's not worth spending even a few thousand dollars to test/disprove' (for instance .. perpetual motion machines?)

or 'badly motivated enough that it's not worth employing even one person to investigate experimental consequences' ?

or 'bad enough that they should never appear to be one of the principal science goals of a billion-dollar experiment' ?

Those are very different levels of badness. We know of course that LHC was planned and funded long before anyone came up with the prime examples of large extra dimensions / low-scale quantum gravity. And apparently even these were not quite bad enough to dismiss out of hand – without spending some years of PhD students' lives on calculating experimental signatures and then setting upper limits from actual data.

46. **Peter Woit**
January 25, 2019

Anon,
For reasons I've often written about here, I'm dubious that the "hierarchy problem" is a real problem. Even if you think it is, doing this (SUSY) by invoking models with 120 or more new parameters, carefully tuned to explain why no effects of the huge number of new fields introduced has ever been seen, is what I would call "bad theory". Doing it with ill-defined extra dimensional models is "really, really, bad theory".

Proton decay experiments are an interesting case to compare to colliders. There's no evidence at all for GUTs, so no reason to believe they'll see proton decay. Should one go ahead and build such experiments anyway? The answer seems to me to depend on cost + hope to learn something else (i.e., see supernova neutrinos). Should one spend \$20 billion on a huge proton decay experiment? Probably not, the money would be better spent on a less special-purpose machine, like a collider. But, at much lower cost, it's worth doing, and one can have a sensible argument about the specific HEP experiments like a proton-decay one that could not be funded due to collider funding. My understanding is that this kind of thing is exactly what the European strategy process is about. They very well may decide a collider is just too expensive, and follow the US into restricting plans to non energy-frontier experiments.

47. **Peter Woit**
January 25, 2019

Sabine,
I share your cynicism about the state of HEP theory. Best would be progress in theory that gave plausible ideas about how to improve upon the SM, which could guide choices about which experiments to fund, but that seems unlikely, with HEP theory split between those who have given up, and those intent on pursuing failed ideas.

But, once you give up on the theorists, if you don't want to give up completely, your only hope is the experimentalists, and whatever they can come up with to look somewhere new. Let's see what emerges from the strategy process. My understanding is that they'll be doing exactly what you want, comparing expensive collider proposals with other proposals. It's entirely possible the outcome will be a decision that the collider proposals are just too expensive for the chance they provide at something new, and Europe will head down the same road as the US HEP program.

Personally, I just haven't seen any evidence that there are other (non-collider) equally promising and cheaper places to look that aren't already being pursued. In particular, the search for "dark matter" has been a huge priority among theorists and experimenters for decades now, I'm dubious there are promising experimental avenues corresponding to well-motivated theory models that are not being actively and aggressively pursued.

48. **Peter Orland**
January 25, 2019

There is good physics coming out of the LHC. Hadronic cross sections (relevant to perturbative and nonperturbative strong-interaction physics), nucleus-nucleus scattering, etc. The intersection of this with the sales pitches is the null set, but it is science that nuclear (and some particle) physicists really care about.

The LHC was sold to the public as a big-bang-higher-dimensional-supersymmetric-hierarchy-problem-string-proving gadunzel. Perhaps if press releases had given a more complete picture of the science, there wouldn't be as much hand-wringing now.

49. **Low Math, Meekly Interacting**
January 25, 2019

Well, that's just it, isn't it.

Explaining the challenges of nonperturbative QCD to the average layperson (like me) is, well, very, very hard, much less what makes it worthwhile to study. Hopefully it's not harder than nonperturbative QCD, though.

50. **Saul Youssef**
January 25, 2019

Nice article Peter!

One thing I would modify is "One piece of advice though is that experience of the past few decades shows you probably shouldn't listen to theorists." I think that the right lesson is not to listen to SOME theorists. I think you'll find that the really great ones are dead honest about the LHC. Here, for example, is Steven Weinberg, speaking to the public about the LHC, pre-LHC (2010) without the slightest trace of getting over excited about speculative ideas. 52:08 https://www.youtube.com/watch?v=Gnk0rnBQrR0

Pick any field. It's almost inevitable that if you interview lots of professors about their research, they will try to make what they are doing sound exciting by talking about the most exciting possible outcomes. That's not really something bad about particle physics in particular.

51. **Anonyrat**
January 25, 2019

HGB wrote: *My main issue here is Sabine Hossenfelder's argument, to wit, we have no compelling theoretical reasons to expect that those accelerators would find any new physics.*

I hope that if a new accelerator can tack on a few digits after the decimal point on some number of measurements — i.e., reveals existing physics to much greater precision, that would be considered worthwhile.

52. **Amitabh Lath**
January 25, 2019

Peter, thanks for this: "…if you don't want to give up completely, your only hope is the experimentalists" Yes.

Let's consider the two arguments against a 100 TeV collider separately.

The money argument is specious. A few 10s of Giga$$ will be easily repaid into the world economy just by the technical and human products of the project.

The other seems to be "theorists have not written a clever enough paper to warrant a bigger machine." This is ridiculous given the two decade lead time. While plenty of machines were driven by theory (Bevatron for the antiproton, SPS for the W/Z, PEP, Petra, Tevatron for the top), there were many that were not (SLAC's Linac and SPEAR, BNL's AGS come to mind).

53. **WTW**
January 25, 2019

See the following for some examples of BSM physics that do not require higher energy colliders, and challenges in the funding of such experiments (and theorists who work on them):
http://online.kitp.ucsb.edu/online/hepfront18/safronova/rm/jwvideo.html
with slides at http://online.kitp.ucsb.edu/online/hepfront18/safronova/pdf/Safronova_HEPFront18_KITP.pdf

And http://online.kitp.ucsb.edu/online/hepfront18/vantilburg/rm/jwvideo.html

These are discussions of using ultra-high precision experiments rather than higher energy experiments to discover and explore deviations from the SM and Dark Matter.

54. **tulpoeid**
January 26, 2019

LHC experiments discovered the Higgs boson, therefore it didn't fail, period.

On the other hand, the money involved is a lot, and the question is not science vs. military expenses, it's science vs. science at this point. (Human Brain Project, anyone?) Also, a lot of what is going on is ego games by aging academics who have been used to be treated overly well. Apologies, but there is a societal/psychological side to almost everything, biases should be recognised even when accepted.
Even worse, have the consequences and the public repercussions of not delivering anything been considered? I hope they have by some. Because I'd consider such a scenario as catastrophic.

On the other other and more practical hand, I think there is an underrepresented aspect of the situtation in public discussions: Accelerator-based science and new experiments are not going to leave us. It's not "100TeV or nothing". Even CERN started inviting proposals for ingenuous new projects based on smaller-scale accelerators a few years ago, precisely as good alternatives to a lack of higher energies.
Some higher energy frontier fans have been giving the impression that we know only one way forward and that is brute force; brute force is a lesser hacking tactic, it may well be a lesser nature hacking tactic as well.

55. **J. S.**
January 26, 2019

What is the current status of muon colliders? They seem like an attractive idea to me — they are elementary particles, giving "clean" collisions; their mass is high enough that synchrotron radiation is not a problem; and yet their mass is one-ninth that of a proton, so the collider can be smaller for the same energy. On the other hand, the half life of the muon is 2.2 microseconds, so you have milliseconds at most to use them, even accounting for relativistic time dilation.

Fermilab has (or had) a "Project X" that included a muon collider but the information available on the web is out of date.
http://map.fnal.gov/index.shtml

Perhaps money would be better spent on this than on electron or proton colliders?

56. **Peter Shor**
January 26, 2019

I think one very important point to remember is that the LHC was sold to the public and the funding agencies using not just "we'll find the Higgs" but also "we'll find supersymmetry."

In retrospect, it doesn't matter. It's clear that the cost was justified by finding the Higgs and by what we've learned about the Standard Model.

But suppose we try to sell this new collider using the argument "we'll add a few more decimal points to our knowledge of the Standard Model, and there's also maybe a tiny chance that a miracle occurs and we find a new particle that there's currently no evidence for." Do you think it'll be funded? I don't.

So in order to get the new collider funded, we'll end up lying (maybe not lying, exactly, because there are string theorists who still believe that supersymmetry will be found just around the corner, but close enough). And then, if it actually doesn't discover anything, there's going to be a backlash against physics—probably all of physics.

So I think Sabine is ultimately right in that we shouldn't be trying to build a new collider now. Let the LHC run a few more years, see whether it sees hints of anything new, and decide then.

57. **NoGo**
January 26, 2019

I have no skin in this game other than as a taxpayer and interested bystander — and I am all for building the new collider, because frankly I'm curious what's out there at the "energy frontier"!

But I have a (I think) a legitimate question, which I did not see raised in the discussions I've read. This is: if there is new physics at the new collider energy, what are the chances it will be actually detected without "guidance" from the theorists?

Ever since I've learned about the triggers and how most events in the collisions are _not_ collected and recorded, I was wondering about it. As far as I understand it, the logic of the triggers is based on the Standard Model calculations. But cannot it lead to a false self-confirmation and circularity?

I've recently read on an internet forum an anonymous post claiming that LHC may be already producing "tons" of glueballs and how these events would look very similar to some common decays, and so dismissed by the triggers, and how one needs to have the right theory to distinguish these events. I have no idea whether the poster was a real physicist or a crackpot, but isn't there a danger of a similar scenario, and how big this danger is?

And if there is such danger, it would seem to me it increases with the size of a collider, because the bigger the energy, the larger is the percentage of events that one needs to discard (please correct me if I'm wrong).

So, shouldn't this also be a factor in assessing costs/benefits of a new collider?

Thanks!

58. **Amitabh Lath**
January 26, 2019

Tupeloid, your comment "it's science vs. science at this point" is dangerously naive.

Do you seriously think the few 10's of G$ that would have gone to the FCC-like collider will be plowed into other science? Are you still waiting for the post-SSC-cancellation funding bump for brain science and condensed matter?

No, the money just disappears. Probably tax cuts for the well off. If we do not build the next collider science will shrink as a fraction of human endeavor.

And I am effing sick of all the "but the theorists promised us SUSY wah wah wah…". You lot should be smarter than that. No one can "promise" that. What we promised, and delivered on, was *substantially* improved understanding of nature at ever shorter distances. Including the Higgs which wasn't a promise, but a reasonable guess given top mass and electroweak asymmetries.

Nature is what nature is. If we stop studying it because it doesn't confirm to our preconceived notions, it diminishes us.

59. **Amitabh Lath**
January 26, 2019

NoGo, your comment "LHC may be already producing "tons" of glueballs and how these events would look very similar to some common decays" is well taken. Probably not a crackpot (but you never know on the internet). This sort of physics a personal interest of mine.

We throw away over 99% of the collisions due to filters that require high energy deposits, or objects like electrons, muons, missing momenta… There are serious concerns about this sort of "filter bias" and there are regular discussions of how the new physics signatures could be hiding from us. One of them is what you describe, colored objects that decay in a shower of soft pions and escape all filters. Other ways include long lived particles (longer than the 20ns data-capture window), or signatures that travel along the beamline rather than transverse to it.

One of the ways we are addressing this is to use cutting edge fast electronics to do data analysis at a rate fast enough to recognize these reactions.

60. **DarkMatterMan**
January 26, 2019

Peter,

There certainly are experiments founded on good ideas that aren't being *effectively* pursued alongside the big LHC and neutrino experiments. As an example, there are a number of promising new ideas in the search for Dark Matter which involve small investments – experiments costing ~\$1M-\$10M. The *community* has been actively pursuing these projects for many years, but funding support has been extremely thin because they are not called out by name in the P5 report (which simply calls for a portfolio of "small and medium sized projects") and they have been squeezed, sometimes to the edge of viability or to extinction, by emphasis on the LHC and the neutrino program. Meanwhile, new proposals in this space have been slow-walked by the funding agencies while they figure out how to build a case to spend some relatively modest money within a system designed to shepherd much larger projects. The latest step in this now multi-year process was a recent "Basic Research Needs" workshop (formal DOE workshop used to define the "mission need" for a new research area): here is the glossy "show your congressperson" brochure shown at the recent HEPAP meeting based upon the workshop report:

https://science.energy.gov/~/media/hep/pdf/Reports/Dark_Matter_New_Initiatives_Brochure.pdf

…where the full report is due to be released by OHEP in the next several days. There is an intent – if it is decided that some money can be set aside for this – to call for proposals based on this report in the coming months, but I am certain that many good ideas will not make the cut even in the rosiest scenario. I believe this is an example of the kind of experiments that really aren't being aggressively pursued, and could be if we were willing to say we don't need every last dollar (and then a lot more) to build the next huge machine. Some of these ideas are indeed part of the European Strategy discussion.

It used to be that a smart lab director with a vision had the discretion to make experiments of this scale happen, and many great discoveries resulted. Whatever comes out of the discussion of what happens after the LHC, I hope there can be a solution, at least a partial one, to making a path forward for these kinds of small experiments – not just in this area, but across the field, because the system we have for funding, approving and managing \$1B experiments has proven unsuitable to dealing with these small experiments.

(It looks like my long link isn't going to be preserved, but you can easily google basic research needs dark matter.)

61. **Peter Woit**
January 26, 2019

DarkMatterMan,
Thanks for the comment. I don't think though that this sort of problem (how the current system deals with funding for small investments) is really that relevant to the collider discussion. The US has no expensive collider program now, and the last couple years DOE HEP has seen huge increases (10% in FY2018, 8% in FY2019, due to the Trump era jettisoning of any restraint on spending). So if, with plenty of new money and no collider, the US is not funding such small investments, the problem lies elsewhere than in the size of the budget or the existence of an expensive collider construction program. If CERN decides not to build a collider, they'll then likely be in the same sort of situation the US is now in, no reason to believe the problems of small investments will be any different.

62. **tulpoeid**
January 26, 2019

Amitabh,

> Tupeloid, your comment "it's science vs. science at this point" is dangerously naive.

I understand that it might sound like it because of the unusual tone, but it isn't really:

> Do you seriously think the few 10's of G$ that would have gone to the FCC-like collider will be plowed into other science?

I'm describing the situation as it is, not as it should be. In an ideal world both a huge collider and many smaller projects should be funded, but now, yes, if this order of money goes into one project then the science budget of several countries will have to cut down elsewhere. We cannot simply forgo this fact when thinking about the proposals.

> Are you still waiting for the post-SSC-cancellation funding bump for brain science and condensed matter?

From the context I understand that you didn't read correctly my mention of the Human Brain Project. I didn't mention it as a nice funding target, and I'm definitely not talking about taking money from physics and putting it elsewhere.
If you look up the Project's history you'll see that it is a very centralized mega-project which dried European funding from brain research in areas or labs not related to it. When it was under discussion many brain researchers opposed it on this ground. Now it is approaching its designated duration and it has infamously produced almost nothing.
So, I used it as an example of a real very centralized mega-project which did dry funding from others working in the same field.

> No, the money just disappears. Probably tax cuts for the well off. If we do not build the next collider science will shrink as a fraction of human endeavor.

Again, I'm describing the current situation, not the ideal one. (Still, I'm not sure that science will shrink as a result, if this money is spent on other HEP projects.)

63. **DarkMatterMan**
January 26, 2019

Peter,

You stated in a reply to Sabine that you had no evidence that there were promising new ideas – e.g. in Dark Matter – that weren't being aggressively pursued. This is what I was replying to:

"Personally, I just haven't seen any evidence that there are other (non-collider) equally promising and cheaper places to look that aren't already being pursued. In particular, the search for "dark matter" has been a huge priority among theorists and experimenters for decades now, I'm dubious there are promising experimental avenues corresponding to well-motivated theory models that are not being actively and aggressively pursued."

I was pointing out that this just isn't the case. No – neutrinos are not colliders – but it's the US mega-project and pushing the schedule for that, along with the other large projects, has eaten up all of the big increases you mention (along with the QIS push in OHEP, which is funding a lot of ideas of very dubious quality just because there is a big pot of money and not many really interesting ideas to use quantum computing for HEP.)

In any case, I never said, or implied, that there was a problem in the size of the budget, but I didn't think that was what was being discussed here. I thought the discussion was about how to spend the money that can be available, and I do think there is a problem where only the biggest and highest visibility projects squeeze everything else out and there is no process appropriate to bring forward promising small projects (which absolutely do exist!) and see that they have adequate resources to succeed.

64. **Peter Woit**
January 26, 2019

DarkMatterMan,
You're right, I should have made the point I was trying to make in a different way. I'm not well informed about the specifics of dark matter experiments, you may very well be right that there are good experimental proposals not getting funded. If this is so though, it's not because the issue of dark matter doesn't get much attention, or because of a lack of money that could fund small-scale experiments. So, I just don't think you can pin this problem on colliders, or expect that it will improve if collider proposals fail.

I suspect this is kind of a generic issue: non-collider scientists are aware of what they see as good science in their field which is not getting funded, think maybe if collider funding stops, then that good science will get funded instead. In most cases though, scientists thinking this way are likely to be disappointed. In this case, if there's a problem with small-scale experiments not getting attention and funding now, that problem is still going to be there after collider projects are cancelled. If CERN changes direction, they're not likely to decide "we're going to spend the \$500 million/year we save by not building a collider on 100 new small experiments each year". Instead they'll pick some small set of larger initiatives to fund.

Interested to hear your take on the redirection of HEP funding to Quantum Information Science. I'm beginning to suspect that both on the theory and experiment side, this is a really dubious trend, one that physicists should be pushing back on instead of joining.

65. **DarkMatterMan**
January 26, 2019

Peter,

I should perhaps also have been more clear. I'm not arguing against a future big collider or trying to "pin the problem on colliders", but simply that we have to find a way to make sure they don't squeeze out new ideas for small experiments. It's a problem, but not with colliders, rather more with the sociology that develops around big projects that often get oversold, to politicians, to the public, and to young people in the field who buy into the idea that these are the only things worth doing and are guaranteed to make huge new discoveries. I'll admit to having a dog in this hunt – since I work on some of these small Dark Matter efforts – but I've worked on the big collider experiments too, so I see this from many sides.

As far as these new initiatives, the full report on Dark Matter Basic Research Needs should be out soon and you can judge whether you find the case compelling. Who knows, maybe this process will be a watershed moment in trying to solve the problem. I know this has been seen as successful so far, and there is an intention to repeat this process to define the programs for other new areas of inquiry.

As far as QIS for HEP, here are the awards for which an estimated $12M was available, and you can decide for yourself what you think:
https://science.energy.gov/~/media/78921BDAD1894BBF9A686A2125C3B3C0.ashx
My impression (I can really only comment on the experimental side) is that a few of these are interesting, but perhaps will not get enough support among many others that are little more than a mashup of buzzwords without any real justification for the use of quantum computing techniques.

66. **Amitabh Lath**
January 26, 2019

Tupeloid, I understand your concern. Yes I would rather have a marketplace of several small experiments than one MegaProject. Socially, politically, financially it is definitely better.

But it appears Nature doesn't care, and is holding cards close to the vest. If we want to go beyond the effective theory that is the Standard Model, we're gonna need a bigger collider.

And since I grew up in Chicago let me quote Daniel Burnham: "Make no little plans; they have no magic to stir men's blood and probably themselves will not be realized. Make big plans; aim high in hope and work."

67. **WTW**
January 26, 2019

Amitabh Lath wrote:
"If we want to go beyond the effective theory that is the Standard Model, we're gonna need a bigger collider."

We keep approaching this as if "a bigger collider" is the only way to make progress in experimental, fundamental/particle physics. It's all or nothing – either we keep building colliders or we just stop and give up. It's not, and we shouldn't.

It should be noted that, due to limitations in their very design, high-luminosity high-energy colliders may no longer be the best approach to advancing our knowledge. Without meaning in any way to diminish the outstanding accomplishments of the experimentalists, engineers and technicians at FermiLab and CERN over the last decades, we need to recognize some of the fundamental limitations of that approach, and include those in decisions on how to proceed – and what to ask to be funded. The LHC is a wonderful "theory confirmation" machine, but it has issues with discovering unexpected results that aren't factored in to the designs of both the hardware and software (and analysis) required to handle the vast flood of both collision debris and data generated by those detectors, to the level of precision sometimes needed. It may be time to start thinking about whether other approaches could actually produce better results – before asking for more money, just to keep on doing what we've been doing for the last 75 years or so.

Part of this emphasis on "higher energy" being the only way to make progress is probably due to some of our assumptions/prejudices about how we think the Standard

Model can be generalized/unified. It's what "high energy physicists" do, and have done, both experimentalists and theorists, often (but not always) with great success. But it also can lead to blind spots about limitations in the way the Standard Model itself (and the underlying quantum theory) is put together, as well as the mathematical framework around which it has been developed.

To use a very crude and imperfect analogy: It may be time to start thinking about how to use scalpels and forceps to dissect the most subtle aspects of fundamental physics, rather than just hitting it harder with a bigger meat cleaver. Then we can talk about the cost(s) of those approaches vs. potential results. Just leaving those options off the table and hoping that somebody will do them sometime somehow just as long as we get more money for that bigger collider, when in fact they may be the preferable options, would be counterproductive scientifically as well as financially and politically.

68. **Alain Blondel**
January 27, 2019

Very nice post, thank you. No of course we should not give up, especially since there are important questions (The Baryon Asymmetry of the Universe, Dark Matter and the origin of neutrino masses) that are very likely to have particle physics answers.

Let me make a couple more additions to your description of the FCC-ee:

-1- One thing which has not permeated in the community very much, is that the 'new particles' that could explain the above questions do not necessarily have the kind of couplings that would allow to see them at the LHC. In fact it is very possible that they have much smaller couplings — this would automatically explain why we see no hint of new physics in the precision Electroweak measurements, while the top quark effect was a hefty 10 sigmas shift — for sure there isn't another top quark, up there. (we also know this from the Higgs production cross-section at the LHC).

A couple examples are documented in the FCC CDR: a famous one is right-handed heavy neutrinos (also named "sterile neutrinos, heavy Majorana neutrinos, heavy neutral leptons" etc..) — which are very much expected since the (left-handed) light neutrinos have been discovered to be massive. Another is 'Axion-like particles' as dark matter candidates. Both are very well motivated and are excellent candidates to solve one or more of the above questions. In both case there is significant (and relevant) phase space that can be probed in the Z exposure of the FCC-ee: there being 510^12 Zs produced, rare events can be searched with a sensitivity down to couplings of ~10^-11 of the weak coupling.

-2- a second point concerns the '10 billions' of the cost. As I am sure you know well, about 2/3 of the cost concerns infrastructure that is there to stay, e.g. for the (100 TeV) hadron collider (and possibly other facilities), and thus is a long term (some 70 years or more) investment. This makes it much easier to argue about with the host states and local authorities.

69. **Peter Woit**
January 27, 2019

WTW,
On the HEP theory front, I very much agree with the argument that it is long past the time that theorists should give up on the main directions they have been pursuing, go back to fundamentals, and try a new direction. This is difficult to do, but the reasons are sociological, not fundamental problems of how physical reality and allocation of expensive resources works. Some theorists would like to claim that they should just keep doing what they have been doing, the computations are just unfortunately getting harder. Maybe, magically, all of a sudden something will appear.

The situation with theory though is very different than the situation with experiment (and I think Hossenfelder's essay doesn't properly recognize this). While HEP theory has conclusively failed at what it has tried to do, HEP experiment has succeeded at doing exactly what it set out to do. The discovery of the Higgs and the on-going study of its properties has been a huge success. There are now carefully put together proposals for how to extend this success to smaller distance scales. Unfortunately they appear to be inherently expensive.

The idea that there is some different, much less expensive, promising route to progress is wonderful if it were true, but one has to come up with a viable proposal. I assume a significant part of the ongoing European study will be to examine such proposals. If such proposals exist, quite possibly the result will be to not fund a new collider, but to fund such proposals instead. Absent such proposals, what I don't think is a good idea is wishful thinking, i.e. deciding that since the known route is difficult and painful, let's just not do it and hope that somehow an easier one will appear.

70. **martibal**
January 27, 2019

Regarding the costs, since the world is always more full of billionaires which are more and more rush, what about some private fundings ? I completely agree that States should finance CERn, but in case they do not, is it totally exclude that some private philanthropists could contribute ? If I remember well, CERN has already "accepted" sone private fundings accepting the Breakthrough prize, and there are some examples of private financing of fundamental research which are working well, no ? (see PI, or the Simons Fondation). 5 billions is just 5 per mille of Amazon value (or Apple a few month ago).

71. **Amitabh Lath**
January 27, 2019

WTW, I agree with you. New physics could well be hiding in the collisions we already have. One of my personal interests is particles with strong interactions and low mass. They would be produced in huge quantities but this reaction would be overwhelmed by the huge rate of normal strong reactions in hadron collisions.

This is just one discussion. Another is long-lived particles. Think of a massive, slow moving BSM particle. It would be missed completely. We (experimentalists and phenomenologists) are constantly asking the question "Where could the new physics be hiding?".

The next generation colliders will not only be higher energy, but have smarter hardware and software as well. Expect machine learning and AI to permeate all levels from trigger to final analysis.

72. **Stephane**
January 28, 2019

Dear Peter,

thanks for your informative post.

Due to the lack of direct discoveries of new physics so far at the LHC, the current strategy in experimental HEP is to search extension of the Standard Model indirectly, by viewing the SM as an effective field theory (SMEFT, eg, arXiv:1706.03783 and arXiv:1812.08163) and thus perform the most precise measurements possible (by reducing the statistical uncertainties by collecting more data, and the systematic uncertainties with better detectors, etc.) Of course, this is a challenge for computing but also for theory to provide the most accurate possible calculations of SM quantities! This is the so-called "Intensity Frontier" program (a better name would be "Precision Frontier") in contrast to the "Energy Frontier" program.

This is the idea behind HL-LHC, HE-LHC and part of FCC programs. Of course, if one finds new physics directly at FCC, the better. It is thus of no surprise that a recent Les Houches school was dedicated to Effective Field Theory
see: https://indico.in2p3.fr/event/13465/

Let me finish by quoting Burton Richter (arXiv:1409.1196)
Abstract: "The success of the first few years of LHC operations at CERN, and the expectation of more to come as the LHC's performance improves, are already leading to discussions of what should be next for both proton-proton and electron-positron colliders. In this discussion I see too much theoretical desperation caused by the so far unsuccessful hunt for what is beyond the Standard Model, and too little of the necessary interaction of the accelerator, experimenter, and theory communities necessary for a scientific and engineering success. Here, I give my impressions of the problem, its possible solution, and what is needed to have both a scientifically productive and financially viable future."

73. **DB**
January 28, 2019

Hi,
this Nima conference from four months ago might be pretty relevant, IMO, for what´s being discussed here.

https://www.youtube.com/watch?v=zE6XjWzl-Eo

Best.

74. **Peter Woit**
January 28, 2019

DB,
While I agree with much of what Arkani-Hamed has to say in that talk, he definitely was someone I had in mind when I wrote above: "experience of the past few decades shows you probably shouldn't listen to theorists." He's smart and great at conveying enthusiasm, but he's also now spent a lot of his career vigorously and enthusiastically promoting the LHC in unfortunate ways (large extra dimensions, SUSY (Split or not), the LHC will explain why gravity is weak, only SM physics at the LHC is evidence for the multiverse, etc., etc.).

Three Short Book Reviews

January 29, 2019
Categories: Book Reviews

Unfortunately I don't have time now to write about the three following books at the length that they deserve, but here are some quick comments on three books worth your attention:

- A carefully produced detailed write-up of Sidney Coleman's Harvard Physics 253 quantum field theory course has now been published by World Scientific. This course was taught by Coleman off and on from the mid-seventies until 2002, and the book is based on various sets of video recordings and lecture notes (including a copy of my lecture notes from when I attended the class). A huge amount of work by various people has gone into producing a very high quality book. David Derbes has some comments here, and he is perhaps the main person to thank for seeing this project through to completion.

  David Kaiser has contributed an introduction to the book (available here, or, if this doesn't work, try here) which does an excellent job of putting the material in historical and intellectual context, as well as describing what Coleman was like and why he had a huge influence on several generations of Harvard students. If you've already spent a lot of time learning QFT from various modern textbooks, your reaction to much of this one may be "that's the standard way of explaining that point, nothing unusual here." Keep in mind that often the reason that's now the standard way of explaining things is that many authors of modern textbooks learned the subject from Coleman (or from someone who learned it from Coleman…).

- Jim Baggott has a very good new book out, entitled Quantum Space, which could roughly be described as a popular account of loop quantum gravity at the level of the account of string theory in books like Brian Greene's *The Elegant Universe*. Baggott has spent a lot of time talking to Carlo Rovelli and Lee Smolin, and one of the best aspects of the book is the way it conveys their personal stories, intellectual journey, and current outlook on the subject.

  One unavoidable topic that Baggott covers is the relation of string theory and LQG as competing (or perhaps someday collaborating?) approaches to the problem of quantum gravity. Due to long ago experience (to get an idea, watch this), I've long ago lost patience for arguments about which approach is "better". Baggott's take on the issue seems fair to me, but if you really want to engage in that argument it will have to be elsewhere than the comment section here.

- Finally, the new book you really should buy a copy of is my brother Steve's Fly Fishing Treasures. He has been working on it for years, and it includes the most amazing beautiful pictures of antique fly fishing equipment in existence, as well as a wealth of information about those who collect these things. OK, if you, like me, aren't especially excited about the topic of fly fishing, then buy a copy as a present for someone who is.

Update: I should have included links to postings about Coleman here, here and here.

Update: If you'll be at the March APS meeting in Boston, I hear there's a book launch for the Coleman book, 1:30pm-2:15pm Weds. March 6, at the World Scientific booth in the exhibition hall.

Comments

1. **David Derbes**
   January 29, 2019

   Many thanks for the kind remarks, Peter. I would remind your readers that the videos of the Coleman lectures from 1975-76 are up at Harvard's site. I think the fair division of credit is equal shares (as in splitting the bill for a meal in a crowd). There are six names on the cover as editors. I wanted a seventh, but that contributor wished to remain anonymous. So I'm happy to take one-seventh of the credit for editing, but no more. See my earlier remarks or the book's preface for more details if you wish. I, too, think David Kaiser did a wonderful job on the Coleman foreword; he also did a terrific foreword to the reissue of Misner, Thorne and Wheeler. I would recommend to anyone putting together a book with an interesting history that she or he ask David K. to consider writing a foreword to her or his book!

2. **Low Math, Meekly Interacting**
   January 29, 2019

   "…early encouragement from Hoagy Carmichael…"

   Seriously? That's amazing.

3. **Peter Woit**
   January 29, 2019

   LMMI,
   May be the son of the one you're thinking of…
   http://www.everythingzoomer.com/arts-entertainment/2018/01/22/hoagy-carmichael-jr/

4. **sdf**
   January 30, 2019

   The link to the foreward does not work for me.

   Can you give a comparison of how this compares with other intro books to QFT? I am totally unaware of Coleman's lecture notes up to now.

5. **Peter Woit**
   January 30, 2019

   sdf,
   Others have also noted this. Was working for me, now I also see a problem. Looks like something on the publisher's end. I've added another link to try to the posting. From the publisher's webpage for the book, you are supposed to get free access to the frontmatter, including the Kaiser piece.

   For more about the Coleman book: the topics covered are not unusual. There's a lot of influence of Bjorken-Drell and the point of view on QFT of the 1960s. This is combined with influences from the more modern point of view (gauge theories, path integrals, renormalization group) that the SM brought into vogue starting in the mid 1970s. The really unusual thing about the book is that it is very much based on Coleman's lectures, as opposed to being written as a usual textbook. So, there's a lot that comes through of the details and the spirit of a (very high quality) live lecture, while at the same time careful attention to the details of how to do calculations.

6. **Andre**
January 30, 2019

I took detailed notes on Coleman's lectures from the videos available when a graduate student at Harvard. The lectures were great, though not live, and my notes were extremely useful the first time I taught QFT, because as you said, there were almost no books available at that time. Consequently, I'm more interested in the fly-fishing book, as fly fishing is a one of my favorite activities!

7. **Mark Weitzman**
January 30, 2019

Is there an errata page for the book (or some place I can email corrections for a future edition) ?

For me the high points of the book are that you can read it without pencil and paper in hand. Additionally there are 25 problem sets with detailed solutions (which fills in many of the places where in other QFT books, you would need the pencil/pen and paper).

8. **Peter Woit**
January 30, 2019

Mark Weitzman,
For the Coleman book, you could email David Derbes (loki@uchicago.edu). On the other hand, if you find typos in the fly fishing book, email me and I'll forward them to my brother…

9. **Mark Weitzman**
January 30, 2019

Peter Woit: Thanks, I actually went fly fishing once in Whitefish, Montana about 25 years ago.

10. **Anonyrat**
February 2, 2019

I just received the paperback version of Sidney Coleman's QFT Lectures, and though perhaps not as nice as the hardback, it is very nicely produced indeed. (Purchased it through Amazon). My thanks to the editors for putting this together.

11. **João Paulo Cardoso**
February 28, 2019

Peter,

I will soon start studying QFT, and I intend to use Coleman's lectures. I don't plan to purchase the book published by World Scientific, but to use his material available on arXiv. The problem is: these lectures do not have exercises at the end of each chapter. Do you recommend any set of exercises to do along Coleman's lectures? It can be from any book or online course or similar stuff.

On Inference

February 2, 2019
Categories: Uncategorized

The first issue of the magazine Inference appeared online back in 2014. At the time, it was surrounded by a significant amount of mystery: who were the editors, what were they trying to do, and who was funding it? I asked around and no one I talked to was sure what the answers were to these questions. Best guesses seemed to be that it was run out of Paris, with David Berlinski playing some role, and the funding source might be Peter Thiel.

Looking at the early issues that came out, on the topics I was competent to judge, the contributions about mathematics and physics were generally interesting and of high quality. On some other topics where I lack competence, there seemed to be a skeptical attitude towards materialism and evolutionary theory that I'm not sympathetic with.

Late in 2015 I was contacted by someone from Inference (Hortense Marcelin) to write an essay for them, something about the multiverse and string theory. After thinking about it a bit, I turned down the offer. The main reason was that I was sick and tired of the subject, didn't want to spend time writing at length about it. A contributing factor in the back of my mind was that, not knowing the identity of the editors or anything about their agenda was another reason to not get involved.

A couple years later I got another invitation to write for them, a request to write a short response to an excellent piece by George Ellis, Physics on Edge. Deciding to do this wasn't hard. The piece would be short and I already knew exactly what I wanted to say, so it would take little time. In addition, I think by this time the identity of the editors was known, and, most importantly, Inference had a pretty good track record of publishing high quality articles in the areas I know about. What I wrote was published as Theorists Without a Theory.

Adam Becker a few days ago published at Undark a long article about Inference. It's a bit of an exposé, taking issue with some of the writing as "intelligent-design propaganda", and revealing that yes, Peter Thiel is a funder. An odd part of the story is that Becker suspects that a negative review of his book by Glashow in Inference was motivated by the fact that he had not much earlier contacted Glashow to ask pointed questions about the publication and its funding.

Today I got in my inbox *A Statement from Sheldon Glashow and Inference*, which is available here. You can read it for yourself. Noteworthy in the Undark article is Becker's report that Glashow had told him that "questioning evolution" is "no longer a
policy of the journal". Referring to two early 2014 articles that could be described as questioning climate change and evolution, the statement says:

> Becker believes that two of our essays are deserving of censure. They are William Kininmonth's "Physical Theories and Computer Simulations in Climate Science," and Michael Denton's "Evolution: A Theory in Crisis Revisited."
>
> Both were published in 2014.
>
> Now a secret must be imparted. Sheldon Glashow and Rich Roberts agree with Becker. Richard Lindzen and David Gelernter do not.

It ends with this response to the accusation about the motivation for the negative review of Becker's book:

> Inference commissioned Sheldon Glashow to review Becker's book in the spring of 2018, well before Becker was known to Inference. The idea that we would require the services of a Nobel Laureate in order to make a fool of Becker is absurd. Becker is capable of doing that quite by himself.

   February 2, 2019

   Oh, yes, that old, classy argument "he is a Nobel Prize winner, who do you think you are?" Also that other classy argument "yes, we do creationist and climate-denialist propaganda, and if you criticize us you must be an enemy of freedom". Adam Becker should be applauded, not ridiculed, for taking on such dark and powerful forces.

2. **Sabine Hossenfelder**
   February 2, 2019

   I was contacted by someone from Inference some years ago. They asked me to write an essay for them and made a pretty good financial offer. I put a lot of effort in this and submitted the piece as requested.

   After some while I received a revision from an anonymous editor who had garbled up my argument so badly and misrepresented my opinion so much that I could see no common ground and just refused to agree it be published. Luckily I hadn't signed the letter of agreement, so I had no trouble pulling out of this. (Otoh, I didn't get the kill fee either.) I then shortened the piece and published it elsewhere.

   By now I have dealt with quite a number of editors at many different publications and let me just say I have never seen anything remotely like this. Normally they are are little more… restrained. Also, while it's rather common that fact checkers and copyeditors remain anonymous, I don't know any other place where they don't tell you who is the editor.

   In any case, if you have been wondering why I never share or comment on anything from that magazine, now you know why. I got away with the impression that this magazine's editors have a rather heavy hand.

3. **Peter Woit**
   February 3, 2019

   Davide,
   I wasn't very impressed by Becker's book either, see
   https://www.math.columbia.edu/~woit/wordpress/?p=10147
   An interesting question to ponder is whether Becker's Undark piece would have been different if Inference hadn't published a bad review of his book. It came off to me as a hit-piece.

   As for the dark and powerful forces at Inference, the list of their editors is now public (and quite distinguished). Yes, it seems to be Thiel's money, but, if it's paying for good science writing (modulo some early dubious choices), so what?

4. **Davide Castelvecchi**
   February 3, 2019

Peter — I don't know whether or not Adam is correct to suspect that Inference slammed his book because they knew he was on their case. I have not read Adam's book yet, but whether I or you like it seems besides the point here. The picture painted by his Undark piece is much bigger and I am surprised that it doesn't cause you concern, given how active you are in tracking the influence of money on science.

At least the Templeton Foundation is open about its agenda and does not try to cover up its tracks. I find it hilarious for a publication to have anonymous funders (and even editors, according to Sabine) and then scoff at people who find that creepy. And I don't find it reassuring that the identity of the funder was not a secret to people "in the know". If anything, that makes it even creepier to me.

In response to all this, some mathematicians and physicists' attitude seems to be: "But the guy is so smart and generous and we like to have a place that publishes cool essays about quantum gravity and algebraic geometry."

But I find it hard to isolate this from the broader context, which is that you have a government that steals babies from their parents and puts toddlers in cages, and a billionaire who supports said government — and whose money comes in part from selling surveillance technology to it (https://www.bloomberg.com/features/2018-palantir-peter-thiel/).

5. **Sabine Hossenfelder**
   February 3, 2019

   Addendum: My husband reminded me that at the time I was pretty pissed off the anonymous editor believed to know more about my research area than I do myself. It didn't occur to me at the time, but now that I think of it, this almost certainly means it was a physicist. Someone with a big ego.

   I felt pretty stupid back then for turning down $5000, but in hindsight I am glad I didn't let some anonymous person channel their opinion through an essay with my name on top of it.

6. **Dave Miller**
   February 3, 2019

   Peter,

   While I think Intelligent Design is nonsense, I suspect that it may serve a positive purpose by forcing evolutionary scientists to provide more detailed evidence in rebuttal.

   Climate science is a different story: the media over-simplifies the subject to a binary "no human impact" vs "catastrophic human impact." "No human impact" is of course nonsense, but, in fact, there is lots of room for gradations in between the extreme positions: when Richard Lindzen of MIT or Judith Curry of Georgia Tech raise detailed questions about some specific aspects of the climate consensus, I am interested in their views, just as I am interested in your views critical of the established endeavors in string theory.

   I just finished Adam's book and found it interesting and informative. The book certainly has its heroes and its villains (though Adam seems not to see this himself). On the other hand, since some of his heroes (notably Einstein, deBroglie, and Wigner) were already some of my heroes, I found the book congenial.

   Does anyone know of any critiques of Adam's book that argue that he badly botched the story factually (as opposed to the reviewer's simply not liking the book personally)?

   Dave Miller in Sacramento

7. **Peter Woit**
   February 3, 2019

   Dave Miller,
   I just don't think arguments over publishing denials of climate change and evolution are that relevant here since that's not what Inference is now doing. One could definitely question what they were up to in their first few issues (and this affected my decision not to write for them then), but to be fair I think one needs to look at their current editors and what they are doing.

   For another review of the Becker book by an expert, see this
   https://arxiv.org/abs/1809.05147
   which I think does a good job of explaining the problems with the book. These problems are not a matter of "not liking the book personally". There's some similarity between the problems with the book and with the article: both are in some sense an unfair "takedown" (of Bohr and the Copenhagen interpretation in the case of the book, of Inference and its editors in the case of the article).

8. **Peter Woit**
   February 3, 2019

   Sabine,
   That is an odd story. My own experience was completely different (the only editing of the piece I remember was asking me if it was all right to reword a sentence or two).

9. **Peter Woit**
   February 3, 2019

   Davide,
   I agree there were good reasons to be dubious about what was going on at Inference when it first came out. Right now though their editors are advertised publicly, see
   https://inference-review.com/about
   and they have a track record of publishing that anyone can look at and make up their own minds about. Personally I think they're doing a good job, and that there are t0o few outlets for high quality writing about science, especially those that actually pay people to do it.

   I'm no fan of a lot of what Peter Thiel is involved in, but if he wants to spend his money this way, I don't see any reason people shouldn't take it. Yes, Templeton Foundation money is worth worrying about because it is designed to fund a specific ideological point of view (mixing science and religion). I don't see Inference doing this (now, one could reasonably have this worry about them at the beginning).

   On the general question of worrying about source of money funding things, I think one has to be careful about moralistically going down that road. Otherwise, for example consider the huge amount of funding now coming from RenTech via Jim Simons. I think he's doing a great job with what he funds and I have no problem with his politics, but I don't know how that money was made. The only answer I've ever seen to that question from the few who know is "if we told you we'd have to kill you." A lot of RenTech money also was used to attack US democracy and elect Trump. Talk about "dark and powerful"….

   Part of my reaction to this is also an increasing allergy to "takedown" journalism. Adam Becker in his article clearly has an agenda, partly driven by Glashow's review of his book, and it's not to give a fair evaluation of the story of Inference.

10. **Low Math, Meekly Interacting**
February 3, 2019

Has Inference properly disavowed their flirtation with ID?

Look, I don't want to revisit the debate anymore than you do, but if the observational evidence wasn't overwhelming enough, one might take some comfort that people like Fisher, Haldane and Wright put evolution on a mathematically rigorous foundation no later than the 1940's, well before the underlying molecular biology was properly understood. It's been as good as science gets for plenty of time now.

My feeling is that giving ID'ers a hearing isn't just sketchy, it's agreeing to disseminate a pernicious lie. If they haven't already, they should admit is much. It would be a great way to make amends and win back support, if cleaning up their act is a sincere objective.

11. **Peter Woit**
February 3, 2019

LMMI,
Glashow in his statement explicitly disavows the early ID and climate denialist articles. The current editorial board has eleven members, most of whom I have a high opinion of from what I know of their work. Two of them that I know a bit about and that I have problems with are exactly the two that Glashow identifies as not disavowing the early two articles. One, Richard Lindzen (who was my instructor in a PDE class at Harvard), could be classified as a climate denialist. The other, David Gelertner, is a computer scientist right-wing ideologue (at one point supposedly a possibility for Trump's science advisor), with the perhaps relevant background of being a victim of the Unabomber.

So, here's the question, if a publication has a generally high-quality editorial board of eleven people, except that two of them one feels have noxious and dangerous views, what should you think of the publication? Should you read it, link to it, write for it? My answer to this is to look at what they are publishing. If they're publishing pieces reflecting views I consider noxious and dangerous, that would be a problem. I see an argument for that in some of their early pieces, I don't see it now.

One can take a different and more purist view, that one should not associate oneself with any organization that has even one, much less two, people on its editorial board with dangerous views. I'm not that sort of purist.

12. **a1**
February 3, 2019

After reading here about the launching of Inference, I did a quick search and posted a 'guess' connecting it somehow to Mont Pelerin Society. I see now that in September 2018 Peter Thiel has been invited to speak at their General yearly meeting. So now I guess that the world is not what it appears to be – it's much more sinister.

13. **Peter Woit**
February 3, 2019

a1,
I'm still not seeing what is "much more sinister" here. We know who the editorial board is and we can see what they are publishing. Since they've been paying their authors and not advertising the source of their money, obviously it has been coming from some private source, likely a wealthy individual. Picking wealthy people at random, a lot of them share the crank Libertarian worries of the "Mont Pelerin Society", which from their website seem to be the dangers of big government, welfare, trade unions, inflation, and "business monopoly". That the money comes from someone (Thiel) who has the views on economics and politics of the Wall Street Journal editorial page seems to me neither surprising nor sinister. The relevant question though is that, since Inference publishes nothing on economics or politics, should one care about the views on those topics of its funder?

14. **a1**
February 3, 2019

I am not disputing any of this but I would just mention that they have a topic "Economics' with seven items and the first was in vol.I ,iss.1, about Piketty. If MPS has views and/or interests outside of economics, e.g. ID or climate scepticisms, that might be worrying.

15. **sphaerenklang**
February 3, 2019

I have no opinion on the merits of Inference's editorial staff. But .. why should we have to guess about where the money for an 'opinion' publication comes from?
Why would anyone be OK with *secretly* funded magazines whose aim appears to be – at least in part – influencing public opinion?

At least we know who owns Fox News …

16. **David Roberts**
February 3, 2019

Regarding money sources in publishing: it's not like people don't publish with Springer because it is owned by members of the Holtzbrinck family with one might imagine certain economic views…

And people publish with Elsevier despite their explicit political moves to remove access to academic research through open access means.

17. **Davide Castelvecchi**
February 3, 2019

Dear Peter,

I guess every time a journalist does his or her homework and reveals something inconvenient — but with obvious public interest — about a powerful person, lots of people will take the side of the powerful person and call it a "takedown". I call it doing a public service.

And just because someone funds the publishing of nice articles about quantum gravity rather than creationism, it does not mean that they don't have an agenda — in particular if the source of the money is an open secret among those in the know. There is already an agenda in giving people 5,000 dollars and then having those people say "geez, that guy gave me 5,000 bucks and I know I am a nice person, so I guess he must not be as bad as they say".

But I guess I am being "moralistic" and that supporting the guys who put toddlers in cages is not bad enough. Where will we draw the line, then? What needs to happen before we stop normalizing this?

18. **Davide Castelvecchi**

February 3, 2019

P.S. I should clarify that I do not equate those who accept money to write for a publication with those who fund it. I myself do not know what I would do if I were offered to write for such a publication — perhaps I would accept, perhaps not. What I do know is that 1) I would want to know where the money comes from, and 2) I would want the readers to know that as well.

19. **Low Math, Meekly Interacting**
February 3, 2019

Oh, I'm not advocating for purism or boycotts of Inference or anything like that. I myself have expressed the opinion that it's perfectly fine to accept Templeton funding if they let the recipients do legitimate science nonetheless, which seems to be the case. Money's fungible.

But I certainly have some sympathy for those who feel, as I do, that "teaching the controversy" crosses a red line. It was always a bogus appeal for intellectual freedom, and belied some truly anti-intellectual motives. Those who have promoted it are rightly viewed with deep suspicion. If Inference as a "whole" wishes to be free of that suspicion entirely, it could do worse than disavow such malignant pseudoscience explicitly as an official editorial policy moving forward, and not just an ostensible practice.

That said, if Inference gets lots of eyeballs, pays well, and lets people publish legitimate, high-quality work, I don't think it should be shunned even if it doesn't take such steps.

20. **Peter Woit**
February 3, 2019

Davide,
The "takedown" is not the revelation that Thiel is funding Inference, which wasn't hard to figure out. Adam Becker's article portrays the publication as a right-wing funded plot to delegitimize science, with the main editor Glashow a patsy who sleazily punished Becker for asking inconvenient questions by panning his book. Which do you think is more plausible: that Glashow panned Becker's book out of such animus, or that Becker's animus towards a publication that panned his book has a lot to do with the Undark piece?

As for Palantir, it went from nothing to yes, a huge dark and powerful force, due to funding from the Obama administration, with Joe Biden one of its promoters.

By the way, I just checked my records: Inference paid me \$250 for the piece I wrote for them. From what I remember, no money was promised when they asked me to write something, I did it assuming I was doing it for free, was a bit surprised when a check came in the mail. No, I'm not defending them because they sent me \$250.

I try and avoid politics on this blog, but I think there's a really important political point here. How to deal with Trumpism and the collapse of US democracy is the most important issue in the world today, but successfully doing so requires understanding how this collapse occurred. It didn't occur because of Peter Thiel: as far as his politics go, he's a garden variety wealthy Libertarian Republican, and such people will always support the Republican candidate. Trump won the election not because wealthy Republicans did what they always do, but because of a highly successful campaign of hit-jobs/takedowns of Hillary Clinton, coming not just from the Right, but from the Left and liberal establishment. Progressive publications were rabidly devoted to taking down Clinton as a tool of Wall Street, compromised by funding of the Clinton Foundation. The New York Times featured every day on the front page hit-job articles about her email server. By the time of the election, she had been taken down, she was the most hated person in the US, by the right, center and left. Opinion polls showed that, by a wide margin, people thought Trump was more ethical than her, and they voted (or didn't come out to vote) accordingly.

I don't think hardly anyone except the Right has learned this lesson from 2016 about how you destroy democracy. Already, as 2020 Democratic candidates start appearing, the takedowns have started. Elizabeth Warren's DNA test and the like is going to dominate the next two years, and we're going to end up reelecting Trump or worse. Demonizing Thiel may make you feel better, but he's not the problem. Self-righteous attacks on our own kind (in this case, the people at Inference who are trying to put out a high-quality publication) are.

21. **Dave Miller**
February 4, 2019

Peter,

Thanks for the link to Chris Fuchs' review. It seems that he did find some (relatively minor) factual errors; however, I disagree with Fuchs that Adam's interpretation of EPR is an error. As in so much concerning QM, this seems to be a matter of… interpretation.

You said:
> There's some similarity between the problems with the book and with the article: both are in some sense an unfair "takedown" (of Bohr and the Copenhagen interpretation in the case of the book, of Inference and its editors in the case of the article).

Well, I think that's what I was also trying to get at. Adam is more of an opinion journalist than an academic, in both the book and in his takedown of Inference. Is that a bad thing? He's pretty obvious, and it seems to me any reader should be able to decide for him or herself if Adam's taking of sides is objectionable.

I do remember from my own student days trying to get Feynman interested in foundational questions in QM: he did not literally say "Shut up and calculate," but there was a sense that we should sort of accept the Copenhagen perspectives as the only valid inspiration… and then forget all about it and just start doing calculations.

I.e., questioning Copenhagen back in the mid-'70s was discouraged. You are slightly my junior in age: did you have a different experience?

As to the Mont Pelerin connection, there is now an extensive historical literature explaining that the world we live in today was created by the Mont Pelerin Society (most recently, Quinn Slobodian's *Globalists: The End of Empire and the Birth of Neoliberalism*).

As it happens, I was friendly with several members of Mont Pelerin back around 1980 when I was at Stanford and had a chance to meet over a dozen of them (at the time, the Cato Institute and the Institute for Humane Studies were in the Bay Area, and both had some ties to Stanford).

Without going into details, I will just say that Adam's book is certainly more accurate than most of the historians' writings on Mont Pelerin! The over-wrought conspiracy theories about Mont Pelerin may have a veneer of academic respectability, but they have very little connection to the real world. The Bushes, the Clintons, the neocons, the Democratic Leadership Council, the Moral Majority, and a host of other groups and organizations have had a greater effect on the USA than Mont Pelerin.

Dave

22. **Peter Woit**
February 4, 2019

Dave Miller,

I started studying QM (haven't finished yet…) in the mid-70s, and don't recall ever hearing that one should "shut up and calculate" and not think about QM foundations. I spent a fair amount of time doing this (studying foundations of QM), came to the conclusion on my own that this was a waste of time. This was the era of the advent of the Standard Model, so I think the attitude of most theorists was "why would you spend your time thinking about those old questions where there's nothing new, when the SM has just given us all sorts of new and exciting things to think about?". The topics Becker wants to push were already old news at that time (Bohmian mechanics [1952], Many-Worlds [1957], Bell's Theorem [1964]).

My problem with Becker is a combination of disliking agenda-driven takedowns in general, and not agreeing with his particular agenda. In the case of the book, see my review. I don't think the world would be a better place if what's in the current QM textbooks about Copenhagen was replaced by material out of Becker's book. In the case of Inference, I don't think the world will be a better place if Becker's agenda to discredit the publication is successful. Discrediting the place that published a bad review of his book will be good for him, but convincing people not to read or write for one of a limited number of outlets for high-quality writing about math and physics won't make the world a better place.

23. **Davide Castelvecchi**
February 4, 2019

Peter — I happen to agree with you that the New York Times' behavior during the 2016 campaign was reprehensible, and I have said so many times on social media (even attracting the ires of some NYT colleagues).

Still, from there it is a big leap to conclude that the NYT was the main cause of Trump's electoral college victory. To begin with, I would guess that cable news channels had more impact than the NYT in making Clinton look bad in the eyes of the average voter. Probably a lot of Bernie Bros on social media helped, too — although how many of those were actually Russian bots (or real people misled by Russian meddling) is still unclear to me. Voter suppression certainly played another big role, and perhaps hacked voting machines did, too (although Putin would have been smart enough to use that in moderation, so the results would not deviate too much from exit polls). I think there are a number of different causes and perhaps none of them was decisive by itself.

I do not know whether it is true or not that Glashow slammed Becker's book out of revenge. Perhaps you know Glashow well; I have never had the pleasure. But I don't buy the argument "he is the one with the Nobel Prize, so it is self-evident that he would be incapable of pettiness."

What I do know for sure is that I value the information that Becker provided to me as a reader and as a journalist, and that therefore his piece was worth doing.

But seriously now, Adam Becker as a destroyer of democracy? He did not decide to work on the exposé because of the negative review of his book — that came later. He is one freelancer who stuck his neck out in the public interest, and is risking a lot because of it. (And by the way, so are the editors of Undark.) But somehow Becker is the problem, while the guy who enthusiastically contributed to electing Trump is not?

24. **Peter Woit**
February 4, 2019

Davide,
My comments about Trump and politics were in response to yours about Thiel and his support of our awful current president. That support, perhaps rightly so, has caused Thiel's name to become a swear-word in many quarters, including most of academia. Because of this, I don't thinking going after a Thiel-funded project is sticking one's neck out, quite the opposite for the audience Becker writes for.

Sure, Thiel is known for supporting lawsuits that led to court decisions against Gawker and put them out of business, but I'm afraid that there I'm kind of on his side. Gawker's whole business model was based on the unfair takedown/hit-job humiliation of their targets, exactly the sort of thing that has destroyed our democracy. The world is a better place without them. Yes, Becker and Undark before publishing this piece had to be sure to meet the very low legal standard for not libeling a public figure, but I don't think that's really onerous.

No, Becker is not responsible for the destruction of democracy in the US, but I'm dead serious that we're screwed if our side won't get over its love affair with the unfair takedown of our own people. A lot of complicated factors led to the 2016 debacle, but Clinton lost for exactly one reason: people on the center and left irrationally hated her. This wasn't because of the Russians or Fox News, but because they were fed a continuous diet of unfair stories by the "liberal" and Left media about how personally unethical and unlikable she was.

If Becker wants to takedown Thiel, or even the off-beat right-wing crowd that started Inference (Berlinski/Lindzen/Gelertner), that's fine with me. But, on the question of the current state of the publication and its editors, I think the Becker piece was highly unfair towards people doing good work. This is based on actually reading Becker's book and Glashow's review, as well as reading many of the articles Inference has published in recent years. Before applauding the latest takedown, you and others should first do the same.

25. **Tyler Hampton**
February 4, 2019

Hey Peter,

This is my first time commenting here, but I have followed the blog sporadically for years and I enjoy it very much.

I think Adam Becker's piece is highly misleading and unfair, for the following reasons:

1) Adam dismisses a review I wrote for Inference of Dan Tawfik's laboratory, not on the basis of its actual content, but on the basis that I was a 'tennis instructor' reviewing a complex biological subject. I admit I am not an expert. But I find it unfair that Adam does not engage the material on its own merits, and does notmention that I do have a degree in biology. (Yes, I have only an undergraduate degree, to be sure, but Adam writes as if I had no relevant background at all.) Adam also does not mention that Dan Tawfik liked the review well enough to link to it on his own website.

2) Glaringly, the very article that Adam Becker claims attacks evolution and upholds creationism in fact both affirms evolution and denies a supernatural biological creation. The relevant article is Michael Denton's "Evolution: A Theory in Crisis Revisited". I know, the title sounds bad. But if you actually read all three parts of it, you will see that Denton is criticizing a particular *mechanism* of evolution, not the *fact* of evolution. This is most apparent in part 3, where Denton asks, "If life is a natural phenomenon, how might its forms have been actualized? How can one type lead to another?"

Denton's answer is not "God did it", or "it can't be done naturally", although Becker's article would lead you to believe that. Instead, Denton defers to ordinary mutational events (albeit, mutations in a biological possibility space that is nicely ordered). Denton states in answer to his question of how evolutionary transitions are accomplished, "As the creation of atoms in the stars depended on a highly fortuitous nuclear energy pathway, so it is possible to imagine analogous minimum energy pathways at all levels of the organic hierarchy, arranged so that the distances between types are massively reduced in ontogenetic space. One might suppose that gene functions are clustered in the space of all possible genes, rather than scattered widely."

What Denton is suggesting is that, in a hypothetical major evolutionary transition, as gene 'x' mutates to gene 'y' with one single mutation, a phenotype 'A' may mutate in a very sharp and big way to a very different phenotype 'B'. It may not take a thousand mutations to get a big change, only a few. Denton may or may not be right on the details of the organization and distribution of phenotypes in the space of all possible genes, but his theory is not creationism in any sense, or an attack on 'evolution' or biological evolution founded on the laws of physics.

3) Adam Becker rather unfairly patches together quotes in J Scott Turner's essay. For example, the full line from which Adam Becker quotes is "evolution is driven not by natural selection, but by extended homeostasis." The deletion of the last part by Adam makes it sound more ridiculous than it is. Turner believes in evolution, natural selection, and Sewall Wright's fitness landscapes, and Turner's essay argues along the lines of the Extended Evolutionary Synthesis, which has much mainstream support in evolutionary biology. (Turner does however make some woefully ambiguous and suggestive remarks about cognition in swarm intelligence, but 99% of his article is good, and the remaining 1% is not overtly wrong, just uncomfortably ambiguous).

Overall, I conclude that Adam Becker's piece is misleading and parts of it should be retracted.

26. **Klavs Hansen**
February 5, 2019

Peter,
I would not be so sure that creationism has left the pages of Inference; see for example the recent 'An Open Letter to My Colleagues' by James Tour (the precise reference is not available to me, sorry, it seems the website is blocked here in China).
We should not be blind to the fact that serious scientists can potentially lend a lot of prestige to a website with a more or less hidden agenda it may want to push. Stranger things have happened before. It is then up to everybody to decide if setting things straight in their own field is worth the price, because a price will be paid.

27. **Tyler Hampton**
February 5, 2019

Klavs,

James Tour is a qualified synthetic chemist. He proposes *no* creationist scenario in Inference, and merely criticizes the lack of rigor in the field of prebiotic evolution, a discipline which is notorious for it. This is not my opinion: it is the opinion of qualified experts in the field of origin of life studies, like Steven Benner and the late Robert Shapiro. Look at Benner's 2018 Nature article about the history of the phrase 'prebiotically plausible': https://www.nature.com/articles/s41467-018-07274-y
See also Robert Shapiro's article here about 'plausible' prebiotic scenarios: https://www.scientificamerican.com/article/a-simpler-origin-for-life/

James Tour and Robert Shapiro criticizing existing prebiotic scenarios does not make them creationist any more than Peter Woit criticizing existing string theory scenarios makes him a creationist. To say otherwise is false, and if uncorrected, slanderous. I know you are for fair play, liberal values, etc. Then why are you unfairly generalizing and labeling people?

28. **Peter Woit**
February 5, 2019

Tyler Hampton/Klavs Hansen,

Thanks for your comments. I hadn't seen the James Tour piece and it's very odd that Becker doesn't mention it or link to it, since it seems to me the strongest evidence for the case that Inference still has an issue with the Berlinski/Gelertner editorial faction and their views of evolution. Tyler Hampton is correct that Tour is not explicitly making a case for creationism, but he is clearly a sort of skeptic about Darwinism. For a detailed explanation in his own words, see here
https://www.jmtour.com/personal-topics/evolution-creation/

Clicking through the links in the Becker piece trying to find a reference to Tour did lead me to a lot of material about Thiel's views on evolution and climate change. With the what seems to me misleading text "Thiel himself has expressed doubts about the settled science of evolution and climate change", Becker links to pieces that quote Thiel thusly:

About evolution: the New Yorker quote is "I think it's true." He does go on to "but it's also possible that it's missing a lot of things, and it's possible it's not the most important thing." There's also a Washington Post quote: "I believe that evolution is a true account of nature, but I think we should try to escape it or transcend it in our society."

About global warming: "probably true"

The two articles are worth reading if you want to get some idea of what Thiel actually thinks and thus some idea of his motivation for funding Inference. The way Becker paints him as a climate denialist and opponent of the theory of evolution is quite unfair.

I continue to feel that Becker's piece was a hit job. A serious and fair article about Thiel and Inference would make some attempt to explain Thiel's actual views and likely motivation, not caricature them in incendiary ways. It would also examine the interesting question of how the publication has evolved from the initial Berlinski/Lindzen/Gelertner version to the more recent version that seems to be more led by Glashow.

29. **David Berlinski**
February 5, 2019

Has it come to this: That OOL research is now beyond criticism? James Tour is an eminence in synthetic organic chemistry. He has published more than six hundred peer reviewed articles, and holds one hundred and twenty patents; his work has elicited over 77,000 citations. His criticisms of OOL research in the pages of Inference have been precise, detailed, and informed; and in each of his essays, he has gone out of his way explicitly to deny that he proposes to explain the chemistry of life by an appeal to religious sentiment. His is a call for a better scientific understanding. He has said as much again and again and again. Anyone who imagines that Tour is wrong in point of chemistry, or logic, for that matter, is free to say so in the pages of Inference. Arguments by irrelevant insinuation are now a commonplace of social and political life. Should they be a part of scientific life as well? The question, I am afraid, is rhetorical. Such arguments have already become commonplace. This is hardly evidence in their favour.

30. **Peter Woit**
February 5, 2019

David Berlinski,

Thanks for your comment. By the way, for those like me who might initially wonder what "OOL" is, I gather it is "Origins of Life".

31. **Geoffrey Dixon**
February 5, 2019

The original raison d'être of this blog, in my understanding, was to point out the failings of a politically powerful but narrow-minded theoretical physics elite for whom "tribal affiliation" trumped open-minded flexibility in every instance. The intent of the fusillade of critiques was intended to unsettle – to dent the barrier of complaisance surrounding mainstream (i.e., stringy) theory. It succeeded. Theoretical physics is now more chaotic than it was in the very recent past, and creativity thrives on the border of order and chaos. I approve, but then, I approve of all efforts to discommode any smug collective intent on maintaining order, even when that order is broadly detrimental – but also when the order may be broadly favorable. Some chaos is necessary. How ironic, then, that when this blog and its comments very infrequently stray into opinions on actual politics and world affairs (e.g., populism bad; Clinton good), there seems to be an underlying understanding that there is only one correct way of thinking on such things, and no flexibility will be brooked. Even to be undecided is to be deemed wrong. But that's academia for you, and more generally human nature. I should just feel fortunate that I live in a time and place where failing to conform does not lead inexorably to being drawn and quartered – actually drawn and quartered, as opposed to metaphorically. And I do – feel fortunate, that is. I think.

32. **Peter Woit**
February 5, 2019

Geoffrey Dixon (and all)
I'll revert to my usual policy of suppressing political discussion here, having to deal in even a limited way with the heat surrounding discussions of evolution and climate change is bad enough. I thought it was important to answer Davide and give some context to my intense dislike of the currently popular phenomenon of the (unfair) call-out/takedown/hitjob, which I think is incredibly destructive.

If it's any consolation Geoffrey, about politics I actually agree with you that there's a huge problem (in academia and elsewhere) of rigid thinking and rabid desire to destroy others. Where we likely disagree is that I don't really care if people like this on the left and center want to spend their time at war with their analogs on the right (who, by giving us Trump have done something truly awful to our society). What really bothers me is that my friends on the left and center often find it's a lot easier and more satisfying to go after their own, or people who are minding their own business trying to do something worthwhile.

Enough of all this, though, back to the peaceful issues of evolution and climate change…

33. **jjj**
February 5, 2019

Inference is not coming off well here.
Besides admitting the "Evolution in crisis" is just a clickbait title,
this sentence makes no sense:

"Inference commissioned Sheldon Glashow to review Becker's book in the spring of 2018, well before Becker was known to Inference."

34. **Peter Woit**
February 5, 2019

jjj,
Note that the "Evolution in Crisis" article was published back in 2014 in their first issue, and Glashow (who it appears is now their lead editor) agrees it is "deserving of censure".

It's pretty clear that the sentence about Becker is just designed to explain that the decision to have Glashow review Becker's book was made at a time (spring 2018) they'd had no contact with Becker (his book came out in March). In his piece, Becker gives summer 2018 as when he first heard from Inference (an invitation to write a piece) and mid-September as when he talked to Glashow. The review was published Oct. 19. Becker's take on all this is:
"It's odd that Inference would want me to write for them shortly after my book was published, then decide to pan it a few months later, after they knew I was investigating them. Even odder: A couple of weeks later, they asked me to write a response — again for a fine fee — to Glashow's review. I declined. "

I don't understand what's so odd about them giving him an opportunity to respond to the negative Glashow review, especially since their editorial model is to publish pieces and responses to those pieces. I also think the implication that Glashow decided to trash his book because he was asking questions about Inference is ridiculous. If Glashow was concerned about what he might write, the obvious thing to do would be to write a laudatory review. Based on personal experience, authors tend to hold much higher opinions of publications and reviewers that say nice things about their books.

35. **Anonymous**
February 5, 2019

@Dave Miller: Richard Lindzen has swallowed the kool-aid. I had a conversation with him where he brought up the effects of DDT, and he echoed the anti-science, anti-global-warming sites who said that DDT was harmless and it was banned because a lot of environmentalists baselessly agitated against it. I was incredibly disappointed with him, as I had believed his pretense of being a scientifically-motivated global warming skeptic.

I didn't think I could judge the claims of global warming personally, as the subject is too complicated. But the DDT claim is totally wrong. My father was a falconer, so I have actually researched this. Rachel Carson in *Silent Spring* overstated the effects of DDT (it only harms a large percentage of bird species; a reasonable percentage of bird species can tolerate it, and thus some studies on specific species of birds concluded it had no effects), but there is unquestionable scientific evidence that it was well on the way to driving bald eagles and peregrine falcons to extinction, and also had a significant negative impact on songbirds.

And don't ask me why the anti-global-warming propagandists picked DDT to include on their handful of examples of why scientists were totally wrong.

36. **S**
February 6, 2019

@Anonymous,

There's a pattern that I think is pretty common where a scientist comes to skepticism about some widely held belief (sometimes reasonably and sometimes not — that seems to me not to be crucially relevant to the pattern); and he says so, and then gets attacked; and the whole experience — doubt and reaction to doubt — so shakes his faith in the scientific establishment that he kind of loses his legs and starts questioning all kinds of things (almost always including things that should not be doubted — irrespective of what the status of the first thing was).

Serge Lang comes to mind here; I'm pretty sure I've seen others, although they do *not* come to mind at the moment. Particular kudos are due to Peter for *not* being an example.

My only point is that I think that skeptics' position on their first hobby horse should be evaluated on its own terms, assuming they were ever serious scientists. Their later openness to crackpottery seems a pretty frequent side-effect and only weakly correlated to initial correctness.

37. **Peter Woit**
February 6, 2019

S,

Thanks. Over the years I've repeatedly run into the phenomenon of string theory or multiverse proponents characterizing criticism of string theory or the multiverse as analogous to criticizing the theory of evolution. No, this hasn't caused me to question the theory of evolution, but it has been an eye-opening experience about how even the smartest and well-meaning of people can let their tribal affiliations cause them to adopt really bad arguments. Serge Lang is a peculiar case, but the phenomenon you describe may correspond to people who find reason to doubt a tenet of their tribe being led by this to change tribal affiliation (not paying much attention to the fact that the new tribe has even more dubious beliefs…).

All,
Just stop with the submission (from both sides) of rants about the perfidy of those of the opposite tribe. If people have reasoned arguments about the facts of the Inference story that's one thing, but if you just want to vent about how bad the other side is, do it elsewhere.

38. **Rollo Burgess**
February 8, 2019

Well I only discovered Inference relatively recently (perhaps via a link here now that I think about it) and I think that it is a very interesting periodical with some great essays and reviews. It is a welcome addition to the mostly tawdry wasteland of the internet.

I'm not sure why we need to get into all this conspiracy theorizing etc. It should be a fairly safe assumption that most people reading on here regularly or reading Inference are reasonably bright and well-educated. If there is the odd paper that one disagrees with, dislikes, or even disapproves of, one moves on. Having a bit of critical nous such as to be able to do this is one of the key purposes of an education!

I couldn't care less who funds it: it sounds like one of the less stupid things that Thiel probably does with his money; I don't need protecting from ideas like a feeble snowflake and nor do most of you, I'm sure!

39. **Low Math, Meekly Interacting**
February 8, 2019

Most people who read primary literature in peer-reviewed journals are typically very well educated in the field of interest. But if published work is funded by, say, a petrochemical or pharmaceutical company, it is a grave breach of ethics if that fact is not divulged, and may involve serious legal breaches as well. The consequences for not doing so are often dire. The reasons are a matter of extensive public record. Expecting scrupulous disclosure is entirely justifiable, regardless of the integrity of the recipients or their work.

Journalistic integrity is preserved by disclosing funding sources. I'm a big fan of NPR. They tell me when a story is made possible by a grant from Exxon or what-have-you. If they cover a story about, say, an oil spill, they take pains to disclose when sponsorship might raise concern about conflicts of interest.

It's not too much to ask.

Maybe undisclosed funding by Thiel is irrelevant. Why not make it public anyway, however easy it is to figure out? What purpose is served by not doing so? I don't get that at all. And I don't understand why Glashow seems so blase about it. It's standard practice in publication to be transparent about funding, often to avoid the very thing Glashow seems to feel is unreasonable, i.e. suspicion. It seems some of Inference's contributors would rather have learned certain facts from someone other than Becker. Are they being unreasonable?

40. **Peter Woit**
February 8, 2019

LMMI,
The comparison to disclosure of research funding by pharmaceutical or petrochemical companies is a bit of a stretch… I haven't seen even a hint of an accusation that Inference's editorial decisions have anything to do with Thiel's financial interests.

What people are suspicious about here is whether the journal has hidden ideological, not financial interests. When the journal first appeared I think this was a very reasonable suspicion: the problem wasn't really that the source of funding was unknown, much more serious was that the editors were unknown. And, if you did find out that they were Berlinski/Lindzen/Gelertner, you would have good reason to worry that the journal would reflect some of their shared ideology.

At this point though, the editors are known, and everyone is free to make what they will of them and of the choices they have been making about what to publish. I don't see the point of judging a publication on the source of its money rather than its editorial decisions.

I realized that, for most of the things I read online, I have no idea how they are funded. Picking one at random (Slate), I just went to their site and spent a while trying to figure out where their money comes from. No luck.

41. **Low Math, Meekly Interacting**
February 8, 2019

With Slate it seems to be the usual adverts, though I could be wrong. In fact, you do have an excellent point in that I don't really know. I should probably ask the question more often. Then again, Slate is kind of the media equivalent of junk food for me, so it's difficult to care as much as I would about, say, Quanta, which I'm thankful exists.

Mostly I sincerely think it's a case of the "cover up" being far worse than the insinuated crime, at least from a PR perspective for Inference. Plausibly, no one was trying to hide anything they felt was untoward. Which is kind of naive, I think, if you're Peter Thiel.

42. **Davide Castelvecchi**
February 9, 2019

Peter,

I am afraid you are missing the point in your response to LMMI. You said "I haven't seen even a hint of an accusation that Inference's editorial decisions have anything to do with Thiel's financial interests." The point of disclosing sources of funding is not that it's ok if you don't disclose your COI as long as you are not doing anything biased. (Also, I am more worried about Thiel's ideological interests than his financial ones.)

And I completely disagree that for a website like Inference, disclosure is less important than it is for researchers, so that the comparison is "a stretch". Would we be ok with Putin's propaganda outlets like RT hiding their sources of funding just because they do not publish peer-reviewed research? Is potentially subverting peace and democracy less grave a threat than subverting scientific integrity? It's not against any law to be secretive about a website you publish, and I believe one has the right to do that, but then one doesn't get to be offended if people think it's creepy — and say so.

It's also a bit circular to say "Oh everyone, relax, we know where Inference's money comes from now — so Becker's piece was hit job and unnecessary." I know where Inference's money comes from _precisely_ thanks to Becker. Otherwise I would not be here debating this in the first place.

43. **Anonyrat**
February 9, 2019

Slate.com is owned by the same holding company that owns the Washington Post. Of course that doesn't tell us how they are funded. They claim to be advertisement-funded in the US; and they have a paywall for non-US readers.

44. **Peter Woit**
February 9, 2019

Davide,
I'm afraid comparison to RT and the Russian campaign to subvert democracy is even more of a stretch than the comparison to drug companies subverting medical research.

Look, I think the story of Inference and Thiel's role in it is an interesting one, well worth writing about and of public interest. I even agree that the way it started out, with editors and funding hidden and sharing some dubious ideological goals, was creepy. But I also think Becker's piece was a hit job, and his book about QM had serious problems (one of which was that it was in some ways a hit job…). If you want to get outraged about an example of not so good ethical standards in journalism, publishing a piece aimed at discrediting a publication and its editors written by someone whose book they (for good reason) trashed a few months earlier doesn't pass a basic smell test.

45. **Peter Woit**
February 9, 2019

Anonyrat,
I don't think that's it's true that Slate currently has the same ownership (Bezos) as the Washington Post. Surely the identity of their current owners isn't hard to find out, but my point was just that there's nothing I could find anywhere on their website about it.

46. **David**
February 9, 2019

I scrolled to the bottom of Slate.com, and at the lower right found "Slate is published by The Slate Group, a Graham Holdings Company." There's lots of information about them at GHCO.com

Regarding Inference, they could move beyond their history of publishing pseudo-scientific nonsense but only if they demonstrate ongoing integrity. A clear denunciation of their past practice and disclosure of funding seem to be minimum requirements.

47. **Peter Woit**
February 9, 2019

David,
And what if the current editors of Inference don't agree that they need to issue a statement beyond the one they already issued, because that one doesn't meet your standards? Are you not going to read their articles? Are you not going to write for them if asked? The same questions are there for any publication at any time, what makes anything different about this publication? Everyone can look for themselves at what they are publishing and decide what they think of it. Is it worth reading? Is it of generally high quality or not? Those seem to me the relevant factors, but everyone can and must make their own decisions about this sort of thing every day.

48. **Immaterial**
February 10, 2019

An irrelevant remark. You impart knowledge, not a secret. You reveal a secret.

Where in the World are SUSY and WIMPs?

February 10, 2019
Categories: Uncategorized

Back in 2017, after it had already become clear that negative LHC results about SUSY and WIMPs had falsified theorist's most popular scenarios for how to extend the Standard Model, Nima Arkani-Hamed gave a summer school talk to students with the title *Where in the World are SUSY & WIMPS?*, which I discussed here. At the time I was encouraged that while he was still promoting SUSY and the landscape (in the split SUSY variant), at least he seemed to be arguing that the lesson to be drawn might be that the whole SUSY-GUT business was a mistake:

> The disadvantage to the trajectory of going with what works and then changing a little and changing a little is that you might just be in the basin of attraction of the wrong idea from the start and then you'll just stay there for ever.

A few weeks ago in Princeton, at a PCTS workshop on Dark Matter, he gave an updated version of the same talk. Much of it was the same material about how split SUSY is the best idea still standing. Unfortunately, at the end (1:09) he seems to now have changed his mind and be arguing that the best thing for theorists to do is to keep tweaking the models that failed at the LHC:

> You could very justifiably say "look, you're just continuing to make excuses for a paradigm that failed", OK, and I would say that's true, and even the paradigm most of your advisors love was already an excuse for the failure of non-supersymmetric GUTs before that.
>
> That is a perfectly decent attitude to take, but I would like to at least tell you that you should study some of the history of physics. This very, very, very rarely happens, that some idea that seems basically right is just crap and wrong, It's probably mostly right with a tweak or some reinterpretation. You'd have to go back over…, I don't know how far you'd have to go back, even Ptolemy wasn't so far from wrong…
>
> These are two different attitudes towards connecting theory and experiment. If you like, more the theory egocentered attitude, or the just more explore from the bottom up attitude, they're both perfectly good attitudes, we'll see which is more fruitful in the end. If you take the more top-down attitude, just keep fixing things a little bit.

If you had to pick the single most influential theorist out there on these issues, it would probably be Arkani-Hamed. This kind of refusal to face reality is I think a significant factor in what has caused Sabine Hossenfelder to go on her anti-new-collider campaign. While I disagree with her and would like to see a new collider project, the prospect of having to spend the decades of my golden years listening to the argument "we were always right about SUSY, it just needs a tweak, and we'll see it at the FCC" is almost enough to make me change my mind…

Update: Today Ethan Siegel at Forbes has Why Supersymmetry May Be The Greatest Failed Prediction in Particle Physics History.

   Trivial typo:

   "at lease he seemed to be arguing" ->
   "at least he seemed to be arguing"

2. **Peter Woit**
   February 10, 2019

   Jon Forrest,
   Thanks! Fixed.

3. **David Levitt**
   February 10, 2019

   I have followed your blog since its beginning (along with reading your book). I am a biophysicist with only an amateur's interest in high energy physics, but I found it fascinating that some relative nobody was claiming that the leading theoretical physicists were going down dead ends, lured by some sort of mathematical siren song. In your many posts you discussed in detail what was wrong with both string theory and supersymmetry. Although I could not judge the correctness of your explanations in detail, what I found most convincing was that you encouraged critical comments in your forum and I never saw a serious or convincing rebuttal of your arguments. It should be emphasized, that you stated this opinion long before the experimental results were available that now seem to support you. I do not think the hep community gives you the appropriate credit. Not only were you brave enough to stick your neck out, but, apparently, you were right. This account suggests to me that there are two distinctive types of theoretical physicists' skills or abilities. One is a great facility with the mathematical formalism, etc. that has led these "brilliant" physicists down dead ends. The other is a physical intuition that gave you the confidence to shout out that the emperor had no clothes. The fact that these brilliant physicists are not willing to give up these ideas even in the face of experimental evidence is just more confirmation of how strong a lure the mathematical ideas must be, along with their lack of the appropriate physical intuition.

4. **Peter Woit**
   February 10, 2019

   David Levitt,
   Thanks, but I can't take so much credit, and the conclusions you draw are backwards.

   First of all, skepticism about SUSY and string theory has always been fairly widespread among theorists. A sizable fraction of theorists never have worked on SUSY or string theory and for most such physicists, one reason was skepticism that these highly speculative models were all that promising. All I can take credit for is being more vocal and obnoxious with my skepticism than most.

   Secondly, one of the main reasons for the solidity of my skepticism has always been that I'm not much interested in "physical intuition", but am quite devoted to the idea that, at a deep level, great mathematical ideas and great ideas about physics go together. The problem with SUSY and string theory has been that while you can motivate them starting with some deep mathematical ideas, you find that these don't give you the right physics. You need to add ugly mathematical structure to them (SUSY breaking in the case of SUSY, hidden extra dimensions in the case of string theory) to get models that aren't obviously ruled out by experiment. So, my skepticism is not based on any "physical intuition" about problems with superpartners or strings. It is based on looking in detail at the actual SUSY/string models that are supposed to unify physics and judging that they are, mathematically, hideously ugly. As such, without strong experimental evidence in their favor, I'm going to be skeptical, and the complete lack of any experimental evidence seemed conclusive, even pre-LHC.

5. **Bob**
February 10, 2019

"It is based on looking in detail at the actual SUSY/string models that are supposed to unify physics and judging that they are, mathematically, hideously ugly."

Isn't this exactly the opposite what Sabine advocates in her book ?

6. **Peter Woit**
February 10, 2019

Bob,
I don't know about "exact opposite", but she and I have quite different takes on the role of mathematics here. I don't want to discuss her views here, what's on topic is Arkani-Hamed, and I don't think his problem is being "Lost in Math". In his talk, he does a good job of locating the start of all this trouble in the GUT hypothesis. I don't understand why he doesn't just draw the conclusion that should be abandoned.

7. **Sabine Hossenfelder**
February 10, 2019

Yes, this kind of refusal is the reason why theorists in these fields have not come up with useful predictions for decades. It illustrates that the self-correction in this community is not working. (Esp disturbing they still do it after they've been called out on it so many times.)

The absence of reliable predictions for new discoveries at the next larger collider means that such a machine is presently not a promising investment. There are better avenues to pursue. It adds to this that we have not seen much progress in collider technology since the 1990, yet maybe in 20 years we'll have plasma wakefield accelerators or high-T superconductors. Banking money on the FCC right now does not make any sense.

You call it "my anti-new-collider campaign" but I think I am just sharing information that particle physicists would like to keep for themselves.

8. **Ayloka**
February 11, 2019

"This very, very, very rarely happens, that some idea that seems basically right is just crap and wrong, It's probably mostly right with a tweak or some reinterpretation. You'd have to go back over…, I don't know how far you'd have to go back, even Ptolemy wasn't so far from wrong…"

You don't have to go back that far, surely? Kelvin's theory of vortex atoms, for instance.

9. **Marshall Eubanks**
February 11, 2019

"That is a perfectly decent attitude to take, but I would like to at least tell you that you should study some of the history of physics. This very, very, very rarely happens, that some idea that seems basically right is just crap and wrong, It's probably mostly right with a tweak or some reinterpretation."

Say what? The luminiferous aether is mostly right? Quantum mechanics is just a reinterpretation of Newtonian physics? Steady state cosmology just needed some tweaks? Phlogiston was abandoned too soon? What history of physics is he talking about? How could you say something like this in an open session and not have a line of people challenging you at Q&A?

10. **quentin ruyant**
February 11, 2019

I'd like to have references from historians of science to backup the claim that it "very, very rarely happens". I think it isn't true. Now if he thinks Ptolemy wasn't "far from wrong" once suitably "reinterpreted", then ok: *by these standards* physicists were rarely wrong. But is it the kind of standards we want? Keep tweaking the Ptolemaic model until it works? That's the question. I really doubt extensions of the Ptolemaic model would have been fruitful and yield new predictions for very long, if at all.

That's a side issue, but the idea of top-down vs bottom-up seems wrong-headed as well. To my knowledge, big paradigm change (such as relativity theory) were not "bottom-up" at all, quite the contrary: they were attempts to solve theoretical tensions. And conservative extensions of existing paradigms are very often "bottom-up", that is, take new data/phenomena and make it fit in a model of the theory.

11. **MartinB**
February 11, 2019

"This very, very, very rarely happens, that some idea that seems basically right is just crap and wrong"
Sure, we are all totally aware that modern physics deals with the aether, we all know that there cannot be a five-fold symmetry in a crystal, transition temperatures in superconductors are limited to below 40K and of course there is no such thing as graphene or dark energy or dark matter…

12. **RGT**
February 11, 2019

Tweak is generally accepted to mean a minor adjustment. On this basis the jump from for example Newtonian Mechanics to General Relativity could hardly be considered a tweak.
History they say – and this includes the history of science – is written by the victors. Theories and ideas which however good they seem at an instant don't stand the test of time are either lost to history or reported as 'failed' attempts on the path to our current understanding. Some ideas, however 'correct' they appear will, regardless of how much they are tweaked (in the sense we normally use the term), never produce the results we hope for. The difficulty is when and how, having started with a 'good idea' , one decides to give up tweaking and accept the initial premise as a lost cause.
It will always be easier to drop an unpromising line of enquiry if there are a number of alternative starting points. If a theorist is making little/no progress they have three alternatives – construct a new starting point (often requires a conceptual leap), keep tweaking and hope to make a breakthrough, give up (difficult). If a researcher is convinced that their starting point is the only 'good idea' available it's understandable that they will keep tweaking in the hope of making a breakthrough. On this basis A-H's stance, if not the reasons for it, makes some sort of sense. In the absence of an alternative plug on and hope for the best. The arguments against this approach have been well exercised in this blog and elsewhere by Dr Hossenfelder and others. Will there be a consensus any time soon?

13. **Peter Woit**
February 11, 2019

There seems to be a consensus that Arkani-Hamed's argument from history doesn't hold up…

In case you haven't watched the whole thing, or seen other of his talks like this, I think the most striking thing is the stream of consciousness, access to the id aspect of it. Here and in the previous version, he frames his support for split SUSY as "this is what I would say if woken up in the middle of the night with a gun to my head". This is highly peculiar, asking for psychoanalysis rather than rational evaluation. It's a fascinating insight into where people like him who have spent their careers on failed BSM ideas are right now.

If you just look at his rational argument, he locates the fundamental problem at the GUT scenario, and the way, after proton decay experiments shot down the first GUTs, people decided to "tweak" the GUT idea by making it supersymmetric. I remember the first time (1983? from Jon Bagger?) I heard the argument that the negative proton decay results coming in meant that SUSY-GUTs were the way to go. This made no sense to me: non-SUSY GUTs already had problems with too many parameters (they need a whole new Higgs sector to break the GUT symmetry), why was it a good idea to move to theories with even more unobserved fields and undetermined parameters? If Arkani-Hamed's argument was following a rational path, I think it would be an argument for why the GUT scenario is a mistake. It's disturbing that since the 2017 version he seems to be retreating from following the logic of his own argument.

14. **Amitabh Lath**
February 11, 2019

Stop picking on Nima. You all are doing the internet thing of taking one statement in an hour talk and ganging up.

I saw the video and what I see is a smart guy who is grappling with the LHC and direct detection null results. He was asked to defend SUSY to a room of bright young physicists. He goes into the history of how and why SUSY models came about, and his opinion is that the new theories will be arrived at adiabatically rather than from a paradigm shift. Yes he mentions 100 TeV colliders but also spends a lot of time on the electron EDM.

Since the unspoken baseline for all these discussions seems to be that the LHC has demolished all BSM forevermore, here are the actual limits (from CMS, ATLAS is probably similar):

http://cms-results.web.cern.ch/cms-results/public-results/figures/SUSY_results_2016-2017.png
https://twiki.cern.ch/twiki/pub/CMSPublic/SummaryPlotsEXO13TeV/EXO_barchart_Jan19.svg

Note that in certain sectors (EWK gauginos, some scalar DM) the limits are less than 1 TeV. Sometimes much less.

15. **Peter Woit**
February 11, 2019

Amit,

"He was asked to defend SUSY to a room of bright young physicists."

My question is why would anyone ask him to do this, and why would he agree? His talk took the point of view that the naturalness argument for SUSY is now basically dead, so what remains of the case for SUSY is
1. Better coupling constant unification in GUTs
2. WIMP candidate
Is it even conceivable that anyone in that room hadn't heard these arguments before? Maybe there was an interesting talk to be given about exactly what the LHC WIMP limits are, but that would have been "bottom-up", which he even explains is not what he does.

Again, the truly weird thing about the talk is that it gives an accurate account of the SUSY history, then draws the opposite of the obvious conclusion.

1. 1974: GUT proposal, testable by proton decay
2. 1983: Epic Fail of GUT proposal, no proton decay. Deal with failure not by abandoning GUTs, but by going to more complicated SUSY GUTs, with SUSY broken at the electroweak scale, testable at Fermilab, LEP and the LHC
3. 1990s-Now: Epic Fail of SUSY GUTs with SUSY broken at the electroweak scale.

An idea with no evidence for it fails miserably, you "tweak" it with new aspects for which you have no evidence, and the "tweaked" version fails miserably also. What lesson to draw?

1. The original idea was just wrong, beyond fixability by tweaking.
2. Keep on tweaking.

2. seems to me the wrong lesson, but even if you want to go that way, invoking the history of science as showing this is always the way to deal with consecutive multiple failures of an idea is just bizarre.

16. **Aurélien Bellanger**
February 11, 2019

The part about looking at the history of physics is truly unbelievable. The history of physics (as well as other sciences) is so packed with failed theoretical concepts which everyone deemed super beautiful at the time and which held back science for decades. Read Bachelard, there are two examples a page of such trends. But on top of that, Arkani-Hamed takes the worst possible example by referring to the ptolemaic worldview. The ptolemaic model did not need a little bit of tweaking to get true; in fact, for centuries people did nothing but tweak it with epicycles to make it fit averse data. What was needed, and what eventually happened, was to just get rid of it altogether, wipe the state clean and start all over again within the copernician worldview. That's one of the most obvious examples of a paradigm shift. Now I guess it is obvious to pretty much everyone what the lessons from this part of history tell us about theories which tweak themselves out of experimental data. That Arkani-Hamed would choose this specific example as a defense of SUSY is surprising, to say the least.

17. **Amitabh Lath**
February 11, 2019

Peter,
–My question is why would anyone ask him to do this, and why would he agree?

Why would anyone ask? Because SUSY is an important part of theoretical development of the last 40 years and the null results from LHC must be addressed. And who better than Nima for this reckoning?

Wby would Nima agree? Why not? What, do you want him to hide out in humiliation at the lack of SUSY or DM signatures?

I took away an entirely different message from his talk. He starts with the historical basis of SUSY, why did so many people feel it was right? What's left of the arguments after the latest LHC run? What is the way forward? Is it even possible? That bit about Howard Georgi deciding that short-distance physics is a dead end was there for a reason.

Even the pre-Copernican Ptolemaic stuff made sense to me. Basically, there are concepts in a failed theory that you might want to keep (things moving in circles around other things) and others you might want to jettison. Granted, he is not very good at history of science.

Look, if he had gone on about multiverse or beauty or naturalness then I would agree with you. But that is not what this talk was. It was him coming to grips, in public, that nature does not work the way he thought it did.

18. **quentin ruyant**
February 12, 2019

Amithab Lath,

I watched the entire presentation and I agree with you that we shouldn't get mad at him because of a loose comment made during the Q&A session. It looks more like a personal opinion than a fully worked out argument. But I disagree on Ptolemy, for the reasons given by Aurélien Bellanger: the question is not to what extent Ptolemaic astronomy got something right, but what research programs are fruitful.

Coming up with more and more epicycles before Copernicus would have been very inefficient without a deeper understanding. Another example is Vulcan, and then the asteroid belt around the sun hypothesised to explain Mercury's precession. In both cases, scientists were patching their current models again and again to fit anomalous data, without making new successful predictions or learning anything new, and I would say, looking back at history of science, that it "very very rarely" works…

Perhaps pursuing these programs would have been harmless before, but the question whether we're in the same kind of situation is more pressing today, given the cost of a new collider.

19. **DB**
February 12, 2019

Amitabh,
I fully agree with your last comment.

I think Nima has had the integrity of coming out to acknowledge, in public, that certain pictures of SUSY might very well be wrong.
And I applaud him for doing so.
Honesty and integrity are fast disappearing in today´s world, so I think that Nima should be given two thumbs up for what he´s done.
A couple of months ago Susskind also said, in a public interview, that ST would have to be "modified in a bigger context, generalized", because they (meaning the top ST ´s) know that it can´t describe the world as it truly is.
Another example of honest intellectual integrity.
Does that mean that ST should be fully abandoned, or that we shouldn´t build a larger, more powerful collider?
No it doesn´t. It just means that certain problems need to be attacked from a different angle.
So Nima, thanks a lot.

20. **Amitabh Lath**
February 12, 2019

DB, of course one does "acknowledge that certain pictures of SUSY might very well be wrong" but what someone like Nima brings is that excitement: Nature is more complex and interesting that we had thought! Let's get going! That above all is what I get from his talk. Listen to the description of electron EDM, he brilliantly summarizes the current reach and future prospects and what it means for BSM searches.
(made me slightly sad that I didn't chose to join the high precision group in grad school…)

The whole tenor of the talk is like that. This is a first rate mind surveying the situation figuring out where we go next, not one crouching at despair at the lack of high MET events. Either humans are meant to get to the next step in fundamental structure of matter, or we are not. Nima (and most of us experimentalists) are in the former, more optimistic camp.

21. **Peter Shor**
February 12, 2019

It's amazing how quickly amnesia hits.

For a more recent example from the history of physics, where a theory wasn't tweaked but forgotten, what about all the bootstrap models, that were one of the big things before the Standard Model was formulated? I only remember the PR articles about them, which I vaguely remember as being reminiscent of the current PR articles about String Theory. These theories seem to have vanished utterly once the Standard Model was accepted, which happened some time when I was in college.

https://en.wikipedia.org/wiki/Bootstrap_model

22. **Peter Woit**
February 12, 2019

Amit,
Yes, Arkani-Hamed is a very impressive thinker and a very compelling speaker, with a talent for inspiring others with a positive vision at a time when most are trying to process what seems like a bad situation. He's also sometimes spouting nonsense. Not mentioned here at all was the bulk of his talk, about models assuming hundreds of new scalar fields, or thousands of copies of every field already known. No one else could stand in front of an audience and go on about how this explains why we see nothing BSM now, but will soon, without getting laughed out of the room.

As far as the more serious material goes, a lot of his talk was of the order of "don't blame me, I never said the LHC would see something, in my favorite model (split SUSY), you don't expect to have seen anything, but you will at the FCC!". For another very similar discussion, see this by James Wells
https://deepblue.lib.umich.edu/handle/2027.42/144530

The problem here is that most theorists don't take split SUSY seriously. It actually was the butt of a well-known joke, the April 1 publication of a paper on "Super Split Supersymmetry", which now has a Wikipedia entry. In this context, the joke is that
1. GUTs don't work, so you "tweak" them to get SUSY-GUTs, broken below 1 TeV
2. SUSY-GUTs broken below 1 TeV don't work, so you "tweak" them to get SUSY-GUTs broken at 10-100 TeV, safe (for now) from disconfirmation.

The Super Split Supersymmetry joke is to make fun of the implausible second tweak by suggesting a further tweak of moving the breaking scale even higher, ensuring that your theory is completely indistiguishable from the SM. You're back where you started, pre-GUT hypothesis.

To put things more concretely, once you abandon the link of SUSY-breaking to the electroweak scale, SUSY doesn't explain the "WIMP miracle". So, all well and good to think maybe a TeV scale WIMP is behind dark matter, and even advertise that one thing the LHC and its successor will do is look for such a thing, but there's little to no reason to believe SUSY models have anything to do with it.

23. **Peter Woit**
February 12, 2019

Peter Shor,
Some would claim modern string theory as a successful "tweak" of the old bootstrap. The old bootstrap involved the idea that QFT couldn't describe the strong interactions, but you could do it using some unknown framework, specified not by a usual theory, but by consistency conditions (often actually analyticity conditions). This has now been "tweaked" so as to not just describe the strong interactions, but all interactions, with the conjecture of an "M-theory", specified not by a usual theory, but by a list of consistency conditions on what happens in various limits, related by dualities.

24. **Justin**
February 12, 2019

Woit always criticizes SUSY/string models. Fine, but not once on this blog have I seen any alternative proposed. What exactly would you like a potential FCC to look for?

25. **Peter Woit**
February 12, 2019

Justin,

I'd like a potential FCC to look for anything and everything that it can see that hasn't already been ruled out by LEP/LHC searches. This includes getting the best possible measurements of production and decays of the Higgs, especially anything sensitive to Higgs self-interactions. Also, of course, searches for any new states not accessible at LHC or LEP energies. Searches could specifically look for gluinos, squarks, or other states characteristic of SUSY models, but people should just realize that at this point these are not well-motivated searches. They're not likely to see anything (which doesn't mean you shouldn't do them), and if they do see something it is more likely to be something unexpected than something described by the MSSM.

No, I don't have a well-motivated BSM model that would provide an attractive target for an FCC search. Neither does anyone else….

26. **Amitabh Lath**
February 12, 2019

Peter, I do not understand your comments about "tweaking". Are you ridiculing theorists for proposing models and then revisiting them in light of null experimental results? Isn't that kinda how science is supposed to work?

What I see happening is theorists proposing a myriad of models, as they should when there is little constraint from experiment. As experiments come on line and models start falling, hopefully one model survives and the experimental goal switches to figuring out its parameter space (or there is a "surprise" ie November 1974).

We are at that point where some SUSY models have fallen, and some have not. I would not call it a "bad situation" because nature is doing something clever and not plain and obvious, and we have to be just as clever.

And as for crazy ideas "getting laughed out of the room" well they did that with fractionally charged particles that one couldn't see because they were too strongly bound. Frankly from my point of view there aren't enough crazy ideas yet, more are needed.

27. **Peter Orland**
February 12, 2019

Justin,

You are not making a point. If someone says it is unreasonable to believe dark matter is made of gray porcupines, you can't fault them for not presenting an alternative.

28. **Peter Orland**
February 12, 2019

Amitabh Lath,

As a particle theorist who has never really bought into BSM models, I can summarize why a (mostly silent) minority of my colleagues never felt tweaking these models was going to work:

The models don't solve problems, by which I mean inconsistencies. They do address esthetic questions, e.g. naturalness, which made them worth examining, but did not make them convincing.

29. **Peter Woit**
February 12, 2019

Amit,
The way science is supposed to work is that you are supposed to tweak good models that are doing something right to make them better. The problem here is that we're talking about tweaking bad models that didn't explain anything, not to make them better, but just to get them out of inconsistency with experiment (often by making them even worse, i.e. more complicated and explaining less). I see that Peter Orland has made a similar point.

There's a reasonable point of view that these models are just providing a randomized set of regions in the accessible search area for the LHC, giving experimentalists specific targets and specific ways of measuring progress towards covering this search area. That's fine, just don't fool yourself that these are well-motivated models, giving you something better than a random set of choices from throwing dice.

From a theory point of view, fractional charges were extremely well-motivated. We were seeing several sets of states with quantum numbers organized into the rigid patterns provided by irreducible representations of SU(3). The fact that all such representations could be generated by taking products of fundamental 3d representations provided an excellent reason to look for such 3d reps as elementary constituents, and these had to have fractional charges.

30. **WTW**
February 13, 2019

Peter,
>>"Not mentioned here at all was the bulk of his talk, about models assuming hundreds of new scalar fields, or thousands of copies of every field already known. No one else could stand in front of an audience and go on about how this explains why we see nothing BSM now, but will soon, without getting laughed out of the room."

While I also found it strange that no one there seemed to raise any questions about this, I also have to ask: given a rather arbitrary assemblage of 24 fields or so already, give or take a graviton or inflaton or two, what's so fundamentally different about having 1000 or 10,000 other such (hypothetical) fields also filling space?

Isn't this a kind of Noetherian-related "prejudice" for Nature obeying some (in Sabine Hossenfelder's terminology) mathematical "beauty" requirements — in this case just the minimalist "gruppenpest" symmetries of the Standard Model? While I recognize that Arkani-Hamed used these ideas to justify and explain more of the same stuff he has been proposing for years, for a 100TeV collider to test, if physicists are supposed to be thinking outside the box they've been in for the last two generations, why should even considering such things be verboten and ridiculed?

31. **Baron Munchausen**
February 13, 2019

Both the conformal and the S-matrix bootstrap are alive and well. See for example https://arxiv.org/abs/1805.04405 and https://arxiv.org/abs/1810.12849

32. **Amitabh Lath**
February 13, 2019

Peter W, your use of the word "tweak" needs a better definition. One person's tweak could be another's exploring new areas in theory-space in light of experimental results.

The most tweaked thing in my experience was the Higgs mass. In grad school (early 90's) we were taught it could not be heavier than the Z. Probably around 70 GeV or so. Then after some null results by Tevatron and LEP1 there were "tweaks" that raised it up to slightly above 100 GeV. I remember being told that 110 GeV was the absolute limit of what the theory would bear (granted it was by someone trying to recruit me for the search). When LEP2 found some fluctuation around 115 GeV one of the arguments from the theory side for delaying LHC was that it had to be the Higgs, because it couldn't really be much heavier, even this was a stretch. It didn't really end until 2012.

33. **Henry McFly**
February 14, 2019

Dear Peter,

The natural SUSY has certainly taken a hit after the null results at the LHC but the measure of naturalness was arbitrary anyways to begin with. You change your naturalness measure slightly or the limit what you call as natural and your sparticles are guaranteed to be out of the LHC's reach. Let's not forget one of the most important hints for SUSY, which is the Higgs mass at 125 GeV. In Standard Model, you really don't expect it to be that light, and 125 GeV is on the heavy side for SUSY almost guaranteeing that SUSY won't reveal her beautiful face at the LHC unless we are lucky. There is no inconsistency here. We knew back in July 4th, 2012, that this wouldn't be easy. So I am not sure why you and Sabine Hossenfelder think that the null results in the past few years are an indication that SUSY is ruled out. No, we really knew the results would most probably be null given the Higgs mass. Phenomenologists tweak their models so that they are discoverable at the LHC. It doesn't mean that's all out there, it just means that those models require immediate attention because the heavier ones won't be discovered at the LHC for sure.

34. **David Nataf**
February 14, 2019

A good example of a tweak in the history of astronomy is the addition of Neptune to the solar system. Back in the early 1800s, it was known that the present map of the solar system and the theory of Newtonian gravitation provided an inaccurate description of the movement of bodies in the outer solar system.

I don't know if any people proposed "alternative gravity" theories. But the solution to the problem was to tweak the framework that was then available, by adding Neptune to the map of the solar system, and eventually Neptune was indeed discovered. This would have followed an extensive period (decades?) of people not discovering Neptune, where they probably had "upper limits" on Neptune.

Though nowadays the solar system is largely relegated to being in children's science books, it was equivalent to the standard model of particle physics for most of the past few thousand years. As in, it was the mathematical/physical structure that people studied if they were curious about nature, and yes, many of the people studying it were partly inspired by the beauty of the underlying mathematics.

The equivalent to the BSM skeptics, circa 1820, would have been people saying "let's stop looking for Neptune. If we have not found it then it's not there. Let's just get better measurements of the motion of Saturn." Yeah, whatever.

Circling back to BSM physics, it's not a curiosity, it's a requirement. The standard model is a false description of the natural world. It doesn't include gravity, dark energy, dark matter, and it is not consistent with the baryon asymmetry in the universe. Ergo, it's false, and thus it is sensible that some fraction of theoretical physics be devoted to BSM research.

35. **Stefan**
February 15, 2019

@Henry
I agree with you that the benchmarks for what we consider to be natural have been somewhat arbitrarily set. I don't think that naturalness is ruled out. Theorists early best guesses have been ruled out. The LHC/naturalness debate seems to be more sociological than scientific in origin.

I'm not sure what you mean by the SM preferring the Higgs to be heavier than it is.
The precision EW fits from SM parameters imply the Higgs should be pretty much where it is: https://arxiv.org/pdf/1803.01853.pdf .

36. **Aurélien Bellanger**
February 15, 2019

David Nataf,

A two-minutes look at the related Wikipedia page is enough to learn that Neptune was theoretically predicted in 1845, then subsequently looked for and immediately found at the predicted location, in 1846. There were no "upper limits" on Neptune, and no two-decades long search for its position: it was predicted to be somewhere, people looked, and there it was. I fail to see how this piece of history provides a relevant defense of SUSY.

A more significant analogy would have been if Le Verrier had predicted a position, had been told that there was nothing there, had then tweaked its model by saying something like "it's certainly not a planet but a system of three planets orbiting each other in an intricate way, that's why it's actually further away, just look at this other position", had been told he was wrong again, and had then repeated the same process several times again. But that's not even close to what happened.

37. **Igor Khavkine**
February 15, 2019

In an earlier comment, RGT laid out the challenge: "… the jump from for example Newtonian Mechanics to General Relativity could hardly be considered a tweak."

I would maintain that the said jump is actually a *series* of tweaks, each one well-motivated and successfully tested in its time. The analogy is of course with evolution, which is nothing but a *long succession* of small individual mutations.

* Galileo, Newton: particle mechanics, forces [Newtonian mechanics]

* Newton, Coulomb: forces and potentials generated by massive and charged particles [Newtonian and Coulomb potentials]

* Gauss, Poisson, Ampere, Faraday: forces and potentials generated by multitudes of sources combined into fields [gravitational, electric and magnetic force/potential fields]

* Maxwell: (some) fields have their own dynamics independent of sources, finite speed of field propagation [Maxwell's equations]

* Einstein, Lorentz, Poincaré: (universal) finite speed of propagation extended to particle mechanics [special relativity]

* Einstein: the gravitational field is a metric [equivalence principle]

* Einstein: universal finite speed of propagation extended to all fields known at the time (meaning to the gravitational field), the gravitational field has its own dynamics [general relativity]

I did not aim to be very precise. The names listed with each tweak are mainly representative of the most famous people involved and of the epoch. And I also do not claim that the evolution of physical theories followed this one singular path. There were many branch points that underwent their own independent series of tweaks, but in the end did not survive. I also do not want to imply that there were no significant jumps in thought in theory development. But those jumps were more along the lines of abandoning a (possibly dominant but) unsuccessful line of thought and returning to tweak the last best step that was known to work.

38. **Thomas**
February 15, 2019

Igor Khavkine writes: "I would maintain that the said jump is actually a series of tweaks, each one well-motivated and successfully tested in its time."

Dear Igor, it all depends on how you define "tweak." According to your definition, a TESLA automobile is just a few "tweaks" of the wheel.

A rocketship is a just a few "tweaks" of fire and tents.

Most folks have a different definition of the word "tweak."

39. **David Nataf**
February 15, 2019

Aurélien Bellanger,

Be careful relying on 2-minute searches of wikipedia to come up with broad conclusions of scientific history. You may end up mistaken, as was the case here. The wikipedia article contains accurate information, but it does not contain all of the information.

Yes, there were improved measurements and calculations of Uranus' orbit in the 1840s, which led to the discovery of Neptune a few years later. However, the conclusion that Uranus' orbital motion was peculiar dates back to at least the 1820s, see page 23 at this link:
https://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=26&ved=2ahUKEwiXgI__kr7gAhUovFkKHQb0ArUQFjAZegQIBBAC&url=https%3A%2F%2Fwww.springer.com%2Fcda%2c1.pdf%3FSGWID%3D0-0-45-1380904-p174602935&usg=AOvVaw1YFFiK5CdnSwY9x9rniZRM

Moreover, you were very quick to dismiss an otherwise valid point on a technicality. You should know that the same general issue applies very much to the history of solar system studies. The orbital motion of mercury, for example, took a very long time to understand, and it had to be reconciled by modified gravity. Today, astronomers are looking for a "planet nine" which was proposed three years ago to explain the unexpected phase space distribution of kuiper-belt objections, observations and analysis are ongoing. Many problems in solar system science remain unresolved, such as the faint young sun paradox. People have not given up studying these issues simply because the questions have been around for 10+ years or 20+ years. Some questions are genuinely difficult to solve, and thus people research them for decades.

As was the case for the discovery of Neptune. That was a roughly ~25-year research problem. More actually, as once Neptune was found they had to confirm that it had the right parameters to resolve the issue.

40. **Peter Woit**
February 15, 2019

All,
Enough of the historical analogies, this really is a waste of time. The bottom line is that there is zero evidence for SUSY extensions of the Standard Model, and they explain essentially nothing (e.g just coupling constant unification in GUTs which don't seem to work anyway) at the cost of a huge increase in complexity and number of undetermined parameters.

That this kind of SUSY is now a dead idea, finally killed off by the negative LHC results, is not just some peculiar opinion from me and Sabine Hossenfelder. Most of the particle theory community has long been skeptical of the idea. The famous Copenhagen bet on SUSY back in 2000 had more than twice as many theorists taking the no-SUSY side, see
https://strings.ph.qmul.ac.uk/~dsb/dbwager.pdf

It would be interesting to see a poll of the HEP theory community now on the subject, I think one would find belief that SUSY extensions of the SM are viable post-LHC to be a small minority opinion. Even those sticking to this opinion I suspect have their doubts. Arkani-Hamed is known for the enthusiasm with which he expresses his opinions, in this case he's unusually defensive and tentative ("if you woke me up in the middle of the night and put a gun to my head…").

41. **DB**
February 15, 2019

Peter,
I agree with your latest comment.

It would be great to know what the top theorists believe.
Does anybody know?
Witten? Susskind? Maldacena? Nima? Seiberg?
Even the younger generation, like Douglas Stanford, Xi Yin or Daniel Harlow…

42. **Peter Woit**
February 15, 2019

DB,
Arkani-Hamed's talk is exactly answering this question, and taking the "I still believe, despite it all…" stand. For all the others you mention, I think they have long ago voted with their feet and decided that SUSY extensions of the SM were not something they wanted to work on. In a recent Facebook post, Harlow writes
"when I started graduate school in 2006 I was intending to work on LHC physics, but I decided that there wasn't much room for me to make important contributions so I chose to work on other problems which seemed to me more promising. In the years since the LHC turned on, many others have made the same choice. In particular I want to emphasize that Nima Arkani-Hamed, one of the best-known LHC model builders, has for the last ten years mostly worked on other topics where he finds progress more plausible. "
Some of these people may have been hopeful that SUSY would show up at the LHC, but I don't see any evidence that any of them besides Arkani-Hamed are impressed by split SUSY or any other attempts to "tweak" SUSY to explain why it hasn't shown up at the LHC.

43. **Amitabh Lath**
February 15, 2019

Peter, split SUSY is not a tweak in response to LHC null results because I recall mentions of split SUSY during Tevatron Run2 . It didn't get a lot of publicity probably because MSSM was ascendant (not to mention doable).

More accurate to say minimal SUSY is dead. The larger question "is nature supersymmetric?" has not been answered. It may well be beyond the capabilities of LHC or even future colliders to answer but we won't know until we get there.

44. **Claudia**
February 17, 2019

Amitabh Lath,

your statement "The larger question "is nature supersymmetric?" has not been answered. It may well be beyond the capabilities of LHC or even future colliders to answer but we won't know until we get there." needs to be amended, I think.

There are various scenarios where we can know *before* we get "there"; one scenario is that we find another description of the standard model that solves the issues that people have with it, most notably the understanding of its parameters.

Sometimes I like to be a bit populistic. The argument that "we cannot know before we get there" can be made for any theory – also for the one that tiny green mice live inside particles above 100 PeV.

If one honestly thinks that nature is supersymmetric and that it is described by 130 parameters instead of the 25 of the standard model, one must provide some evidence – like we would require from the people who talk about little green mice. Nobody has seen any evidence for those additional parameters. Some weeks ago, I talked to a researcher who spent all his life on supersymmetry. I asked him why he continued on that topic. He was quite for a minute, then said slowly: "because it is the only game in town". I think he was very honest.

My personal opinion is this: the interest in supersymmetry will decay rapidly as soon as another game in town arises.

45. **Lee Smolin**
February 17, 2019

Dear Claudia,

There are other "games in town." There are variants of strong coupling models of condensates such as technicolour. There are models of substructure of quarks and leptons, called preon models. There are people attempting to understand the deep structure behind the choices of gauge groups and representations of the standard model, such as Cohl Furey, arXiv:1806.00612 and previous papers.

Like all ambitious new ideas people can and have pointed our potential shortcomings of each of these. But that is always the case for new theories. I find it astounding that just a handful of people are working on the idea Furey develops that the octonions have something to do with the structure of the standard model.

The main job of particle theorists remains, after all is said and done, to understand why nature chose the structure of the standard model, with its particular gauge groups and representations, and the particular values of the dimensionless parameters. There is exactly one right answer to this question, which means that the sooner we encourage people to put to one side hypotheses that have not succeeded in favour of inventing and exploring a diverse range of newer ideas, the sooner we will know it. Even if one of the older ideas like supersymmetry turn out to play a role, it is likely at this point that the route to the right answer will involve new ideas such as the structure of the division algebras (and indeed there are links between the division algebras and SUSY.)

Thanks,

L

46. **Sabine Hossenfelder**
February 18, 2019

@HenryMcFly

"I am not sure why you and Sabine Hossenfelder think that the null results in the past few years are an indication that SUSY is ruled out."

You can't rule out SUSY and I certainly didn't say so. You can only rule out specific SUSY models. To the extent that predictions have been made for the LHC with specific models those have been ruled out. The reason is that all those models used arguments from naturalness for motivation why new physics should be discoverable in the LHC range.

“No, we really knew the results would most probably be null given the Higgs mass.”

Funny how particle physicists know things in advance after the data forced them to admit their predictions were wrong.

“Phenomenologists tweak their models so that they are discoverable at the LHC.”

We all know that. This is why those “predictions” are worthless. Stop doing it. It’s not good science.

47. **Paddy**
February 19, 2019

If I were a graduate student being told by a leading practitioner that his paradigm was no more wrong that Ptolemy, I would not be reassured. Isn’t Ptolomy’s the proverbial example of an utterly wrong theory being patched up to “save the appearances”? It’s not an accident that “epicycle” is a standard insult in physics.

So I’m not sure Arkani-Hamed has actually changed his mind, he is just leaving the conclusion to be drawn as an exercise for the audience.

Various and Sundry

February 15, 2019
Categories: Uncategorized

First a couple of items from Paris:

- Fields medalist Cédric Villani is campaigning for the position of Mayor of Paris. This Sunday there will be a campaign event/book launch for his new book, Immersion: De la science au Parlement.
- The long-awaited public unveiling of the results of director Ilya Khrzhanovsky's attempt to make a film inspired by the story of Lev Landau has finally happened, with Dau now on view spread over three locations in Paris. This project was filmed during 2009-11, and I wrote a bit about it here in 2015. For more about the project, see for instance here and here. Among those appearing in the film are David Gross, Sergio Cecotti, Alexander Vilenkin, Carlo Rovelli, Costas Bachas, Erik Verlinde, Igor Klebanov, Samson Shatashvili, Shing-Tung Yau, Dmitry Kaledin, Nikita Nekrasov and Andrey Losev.

Some number-theorist related items:

- Videos from last year's Barry Mazur birthday conference are now available here. Also available is the write-up from Mazur of a talk last fall on The Unity and Breadth of Mathematics.
- See here for an interview with Akshay Venkatesh.

Finally, some comments from Scott Aaronson on the current "like beer at a frat party" state of funding of quantum information theory:

> I wanted to call attention to a hilarious irony. For years, I've made the case that trying to build scalable quantum computers, in order to probe the universe for the first time in "the regime beyond the classical Extended Church-Turing Thesis," is just as scientifically interesting as finding the Higgs boson—even if we set aside any of the possible applications of QC.
>
> I don't think I imagined to what extent the tables would someday turn—with funding now flowing into quantum information like beer at a frat party (for a combination of good and bad reasons…), with the future of experimental particle physics now in serious doubt, and with me put in the position of arguing that the high-energy frontier is worth exploring too! 😀

Update: More about the opening of Dau in Paris here.

Comments

1. **cedric bardot**
   February 18, 2019

   Here is a conference to come soon in the suburb of Paris that might interest you and some of your readers Peter.
   Called "Space Time Matrices" it is organised by Thibault Damour, Jens Hoppe and Maxim Kontsevich at IHES from 25 to 27 February 2019
   (conference web page for registration https://indico.math.cnrs.fr/event/4272/)
   "Large-N limits of matrix models have been proposed as a way of describing the structure of Space and Time. The conference will review these models that may bring a new light on trying to reconcile Gravity and the Quantum."
   If there is a place where solid theoretical research in natural geometric structures has no risk to get lost in math this is probably at IHES thanks to senior scientists as Kontsevich & Connes (both speakers at the conference) and Damour as well of course.

2. **Anonymous**
   February 20, 2019

   Dear Peter,

   Have you already seen the new autobiography of Yau?

   https://www.amazon.com/Shape-Life-Mathematicians-Universes-Geometry-ebook/dp/B07N8V6DQX

3. **Peter Woit**
   February 20, 2019

   Anonymous,
   Haven't seen it yet. I'm wondering how it's different than "The Shape of Inner Space", which I wrote about in some detail here
   http://www.math.columbia.edu/~woit/wordpress/?p=3165

4. **David Roberts**
   February 20, 2019

   @Peter

   it looks much more biographical than the previous one, from the tables of contents of both books.

5. **cedric bardot**
   March 9, 2019

   During the "Space Time Matrices" conference at IHES one had the opportunity to notice an invited speaker was accurate enough to entitle his last slide "a chapter closed, in the **M-theory hypothesis**, via localization". //emphasis mine https://indico.math.cnrs.fr/event/4272/attachments/2260/2718/IHESConference_Piljin_YI.pdf.

   All the videos of the conference are here
   https://www.youtube.com/playlist?list=PLx5f8IelFRgFOUvecX2PLH0-ka__t77Zl and all slides there
   https://indico.math.cnrs.fr/event/4272/

   Regarding the "M-theory" word I find it interesting to translate from French a remark from a great geometer Valentin Poénaru about the quantum thinker who incepted it :

> In 1979, I was at a lecture on gauge theory at Cargèse where one of the stars was … Ed Witten. It turns out we were in the same hotel and so I often had the opportunity to listen to him ; and there is one thing that struck me a lot. While other physicists … always spoke in terms of phenomena, possibly in terms of concrete models tested on computers, Witten juggled all the time with theories themselves, their way of interacting, of complementing each other or simply of exploding. It seems to me that there is a direct link between this way of thinking and today's M-theory.

The Mathematical Question From Which All Answers Flow

February 19, 2019
Categories: Uncategorized

I'm beginning to suspect that there are actually (at least) two different theoretical HEP physicists named Nima Arkani-Hamed out there. One of them (who I'll call Nima1) believes the way to understand the fundamental nature of physical reality involves extremely complicated extensions of the Standard Model, with large numbers of parameters tuned to avoid conflict with observation, and possibly hundreds or thousands of extra fields thrown in for good measure. He also seems to like the multiverse and anthropic explanations. I have a lot of disagreements with Nima1, most recently discussed here.

The second Arkani-Hamed (Nima2) has a completely different point of view, one quite close to my own, although he may be even more of a mathematical mystic than I am. Natalie Wolchover has recently talked to Nima2 and written about it for the New Yorker. Nima2 is in love with the deep mathematical structure of physics and the way it appears in different aspects:

> Nima Arkani-Hamed, a physicist at the Institute for Advanced Study, is one of today's leading theoreticians. "The miraculous shape-shifting property of the laws is the single most amazing thing I know about them," he told me, this past fall. It "must be a huge clue to the nature of the ultimate truth."

Wolchover expands on this idea of multiple ways of expressing the same underlying mathematical structure:

> The existence of this branching, interconnected web of mathematical languages, each with its own associated picture of the world, is what needs to be understood.
>
> This web of laws creates traps for physicists. Suppose you're a researcher seeking to understand the universe more deeply. You may get stuck using a dead-end description—clinging to a principle that seems correct but is merely one of nature's disguises. It's for this reason that Paul Dirac, a British pioneer of quantum theory, stressed the importance of reformulating existing theories: it's by finding new ways of describing known phenomena that you can escape the trap of provisional or limited belief. This was the trick that led Dirac to predict antimatter, in 1928. "It is not always so that theories which are equivalent are equally good," he said, five decades later, "because one of them may be more suitable than the other for future developments."
>
> Today, various puzzles and paradoxes point to the need to reformulate the theories of modern physics in a new mathematical language. Many physicists feel trapped. They have a hunch that they need to transcend the notion that objects move and interact in space and time. Einstein's general theory of relativity beautifully weaves space and time together into a four-dimensional fabric, known as space-time, and equates gravity with warps in that fabric. But Einstein's theory and the space-time concept break down inside black holes and at the moment of the big bang. Space-time, in other words, may be a translation of some other description of reality that, though more abstract or unfamiliar, can have greater explanatory power.

Nima2 is obsessed with exactly the same mystical mathematical issue that I am: what's the right mathematical question that has as answer the Standard Model and GR?

> To Arkani-Hamed, the multifariousness of the laws suggests a different conception of what physics is all about. We're not building a machine that calculates answers, he says; instead, we're discovering questions. Nature's shape-shifting laws seem to be the answer to an unknown mathematical question…
>
> Arkani-Hamed now sees the ultimate goal of physics as figuring out the mathematical question from which all the answers flow. "The ascension to the tenth level of intellectual heaven," he told me, "would be if we find the question to which the universe is the answer, and the nature of that question in and of itself explains why it was possible to describe it in so many different ways." It's as though physics has been turned inside out. It now appears that the answers already surround us. It's the question we don't know.

I'm not sure the Amplituhedron is the right path to the "tenth level of intellectual heaven" and finding the "mathematical question from which all the answers flow", but I'm completely sympathetic with Nima2's motivation and quest.

   February 19, 2019

   Nima2 = Douglas Adams?

2. **Francois Loeser**
   February 19, 2019

   Maybe this provides the first compelling evidence in favor of the existence of the multiverse?

3. **Peter Woit**
   February 19, 2019

   Francois Loeser,
   What's confusing here is the continual tunneling back and forth between the two different Nima1/Nima2 universes.

   All,
   I'm wondering: has anyone ever seen Nima1 and Nima2 in the same place at the same time? He gives a lot of talks. Has anyone ever seen one containing both an inspirational segment on the existence of a deep mathematical answer to all our questions AND a segment on how split SUSY is the way to go?

4. **Low Math, Meekly Interacting**
   February 19, 2019

   Maybe he's normally in a superposition, and only collapses into one form or the other depending on the kind of question he's answering.

   When you posted that latest entry, I wondered immediately what happened to all the amplitude stuff. Guess this sort of answers the question.

   The article makes a lot of references to Feynman. I recall from watching the videos (and from reading QED) Feynman's frustration with getting answers out of QCD using the methods he'd helped invent. I gather there are lots of better ways to do it nowadays, but they don't seem to get to the heart of what was bothering him, namely his intuition that the approach was simply wrong on some level, and only good as an approximation. He found it hard to believe that nature really does all these calculations, and that there must be a better way that doesn't involve accounting for an infinite number of "paths" to get to the result.

Even if the radical interpretation of the amplituhedron is totally off, if it produced a way to do calculations in a realistic theory a lot easier, that seems like such a great use of one's time. Odd we don't hear about this version of the man more often in the pop-sci press.

5. **Peter Woit**
   February 19, 2019

   LMMI,
   Everyone would like a more insightful formulation of QCD, I have no idea if the amplitudes program has anything promising in that direction. The over-the-top claims I've seen tend do be of the "we're going to replace space-time", not "we're going to solve QCD" variety.

   As for the invocation of Feynman, the peculiar thing is that both Nima1 (complicated BSM models that evade experiment) and Nima2 (the mathematics-physics mystic) seem very far away from what Feynman would find congenial.

6. **Martin S.**
   February 19, 2019

   When you interact with him, you measure him. He is clearly macroscopic, thus don't be surprised that actual superpositions are not seen. May be if you would put him close to zero temperature, there would be a chance. Though I do not suggest it…
   Hm, the transitions suggest superpositions in between, i.e. a possibility of him approaching really low temperatures. Polar vortex?

7. **Sam Hopkins**
   February 19, 2019

   Do you know of any examples before the recent scattering amplitudes stuff in which total positivity had important connections to physics?

8. **Amitabh Lath**
   February 19, 2019

   Do I contradict myself?
   Very well then I contradict myself,
   (I am large, I contain multitudes.)

   -Walt Whitman, Song of Myself.

9. **ay**
   February 19, 2019

   Are the multiple perfect descriptions a profound property of physics or a mundane property of mathematics – namely that there's lots of it and it's all interrelated.

10. **Peter Woit**
    February 19, 2019

    ay,
    An excellent question. One problem with this essay is that since it's aimed at such a non-technical audience, there's no indication of what exactly Arkani-Hamed has in mind, so hard to tell what the origin might of the particular multiplicity of descriptions that he's interested in

11. **Low Math, Meekly Interacting**
    February 20, 2019

    Perhaps I misunderstood something, which is not unlikely. The amplituhedron's heritage (summarized far better than I ever could hope in the link below, so I won't even try) suggested notable relevance to the difficulties of QCD, specifically its roots in ideas (BCFW) being put to real use for, say, calculating backgrounds in hadron collisions (I'm aware there are many others). Regardless of what it all "means" about space-time and so on, if the amplituhedron work is to some extent a simplification or a generalization, then presumably it could be of some benefit for very real-world problems in cutting-edge experimental particle physics. To me that overall story, of how people got from Feynman diagrams to the present tools, is nothing short of heroic, with a lot of contributors doing great physics that makes demonstrable contact with experiment.

    It's a history that gets short shrift in the pop-sci literature, in my opinion. Just not mind-blowing enough, I guess.

    https://royalsocietypublishing.org/doi/pdf/10.1098/rsta.2014.0248

12. **Peter Woit**
    February 20, 2019

    LMMI,
    To be clearer, the amplitudes stuff reformulates the problem of computing perturbative QCD amplitudes in a different way, which may be quite important. But, as far as I know, it doesn't give an approach to understanding non-perturbative QCD, which is the big problem, one where we are lacking a good idea. Recall that these are amplitudes for scattering gluons and quarks, but the physical states are something very different.

    I'm quite a fan of the ideas about how to exploit conformal invariance using twistors being used here, but, again, the problem is that QCD is, non-perturbatively, not a conformally invariant theory. From the early work of Witten on the "twistor-string", it was clear that this kind of duality with a string was a "weak-weak" duality, unlike AdS/CFT where the weakly coupled string is supposed to be dual to a strongly coupled gauge theory.

    I don't want to encourage more discussion of amplitudes here though, because there actually was nothing substantive about the topic in this article, it was really about other more "metaphysical" issues.

13. **Gil Kalai**
    February 23, 2019

    Hi Peter, this is an an interesting and funny post, and meeting François is always a joy.

    Let me make the obvious (at least for a mathematician) comment (perhaps Peter also agrees) that there need not be a contradiction between a belief that "the way to understand the fundamental nature of physical reality involves extremely complicated extensions of the Standard Model, with large numbers of parameters tuned to avoid conflict with observation" and the belief in "a mathematical question from which all the answers flow." It is nice that the same scientist can make progress in both these points of view.

14. **Peter Woit**
February 25, 2019

Gil Kalai,
The problem is that Nima1 hasn't actually made any progress, quite the opposite. The only progress in the field of BSM physics over the past 20 years has come from experimentalists showing that the models studied by Nima1 and others, besides being ugly and not explaining anything, also disagree with experiment, to the extent they make any predictions at all.

Nima2 on the other hand is a mathematical physicist, and has been involved in significant progress in mathematical physics.

Yes, there's nothing mathematically inconsistent with the idea that there are mathematically very deep and beautiful ideas at the foundations of physics, which then are completely masked by a complicated, ugly effective low energy limit and mechanism for producing complicated, ugly ground states. The only problem is that there is zero evidence for this. Instead, our best theories are highly constrained by deep mathematical ideas about symmetry, and these get translated directly into what we observe about the world.

15. **Bernhard**
February 26, 2019

Peter,

I agree with you to some extent but in the end Nima1 has contributed a lot to make these results possible. Experimentalists can only shoot the theories/models that are there to be shot, and Nima was probably the most important theorist during this time providing well-defined models that led to new topologies that could otherwise have been missed. Experimentalists do know how to add a Lagrangian in Madgraph, but to come up with the Lagrangian itself you need a guy like Nima1.

It is true, every time I was in the audience in schools or conferences with him as speaker I had roll my eyes over some of the over-the-top BS he likes to pull, but it does not change the fact that Nima1 has significantly contributed to the results that came from LHC Runs 1 and 2.

A Few Items

February 28, 2019
Categories: Swampland, Uncategorized

A few things that may be of interest:

- The Perimeter Institute has a new director, Rob Myers, succeeding Neil Turok. Myers is very much a mainstream theorist, and Perimeter over the years has been converging with the mainstream, from a very non-mainstream initial state. While Turok has taken the view in recent years that theoretical physics is in "a deep crisis", Physics World has:

  > Myers says there are many opportunities in theoretical physics, mostly thanks to the vast amounts of data that are being collected by various experiments such as CHIME, EHT and the LIGO gravitational-wave detectors in the US. Yet Myers doesn't believe that theoretical physics is in "a deep crisis" as Turok once admitted. "Particle physics is somewhat at a crossroads," he says. "Describing it as a crisis is slightly dramatic, but I would agree that people have been relying on the status quo for too long and relaying on certain models from decades ago."
  >
  > Indeed, Myers now challenges researchers to think in new ways. "Young people are the future and we want to instill in them to question the status quo," he adds. "After all, it is the people here that make the PI such a special place."

- Speaking of challenges to the status quo, it seems that Sabine Hossenfelder now has a contract for her second book, topic not yet revealed.
- For the latest news from the Swampland, see this twitter thread from Will Kinney. He explains how the "Swampland conjecture" was meant to kill off the string theory multiverse, but this conjecture got in trouble:

  > So by getting rid of the multiverse, we have also gotten rid of known physics like the Higgs boson. Merde!

  It was replaced by a fix, the "refined Swampland conjecture", but Kinney has a new paper in PRL (arXiv link here) showing this fix doesn't solve the multiverse problem for string theory:

  > This means that, as soon as we fix up the Swampland Conjecture so it doesn't trivially rule out known physics like the Higgs, we inevitably get an unwelcome passenger: the string multiverse!
  >
  > This is important because it looked like the Swampland Conjecture was likely to free us from the multiverse and associated awful stuff like the Anthropic Principle. Not so, we're still stuck with it. Sorry.

- John Baez has a popular article at Nautilus about his new-found love for algebraic geometry, as an explanation of the relation of classical and quantum. The more technical version is a series of posts here.

Update: Arnold Neumaier has posted at the arXiv a series of three papers discussing his "thermal interpretation" of quantum mechanics (see here, here and here). While I find many of the points he seems to be making compelling, I haven't had time to think seriously about what the problems of his approach might be (and there's a long history of online discussions between him and others which would be a good place to start). Neumaier in the papers explicitly asks for discussion of them at physicsoverflow.org, and there are now posts there for this purpose (here, here and here). I look forward to following any discussion with him over there. He also has a website devoted to this topic here, which has some links to earlier discussions.

Update: There's a new issue of Inference out. As usual, some interesting pieces from people not usually heard from in a non-technical venue. No sign of the pro-intelligent design/climate denialism agenda that they've been accused of having (see here). Pieces specifically relevant to some of the obsessions of this blog are a review by Glashow of Lost in Math, and a piece by David Roberts on the Mochizuki/Scholze/Stix story.

Comments

1. **Thomas Van Riet**
   March 2, 2019

   If the dS swampland conjecture is correct, I cannot see what we exactly mean with a multiverse here. At least not a multiverse of dS vacua…

2. **a reader**
   March 3, 2019

   I read "Inevitability and Eternity," an essay from the new issue of Inference you linked to, and, as a citizen, I sincerely find it commendable. Thank you Peter.

3. **Blake Stacey**
   March 17, 2019

   Inference offered me the chance to write a response to Glashow's review of Becker's book (the review that Becker stops just short of claiming was some sort of reprisal for his investigating their finances). This happened in the usual manner: The invitation first went to one colleague, then was handed off to another, before eventually falling to me. Somewhere along the way, the e-mail boilerplate about paying contributors got lost, so I didn't know money would be involved, and for an academic gig I didn't think it would be. I drafted a brief essay that was critical both of Becker's book and, to a lesser extent, of Glashow's review.

   After Becker's piece in *Undark* came out, I was convinced that my criticisms would be portrayed as some kind of payback, so I withdrew the short draft I had composed. David Berlinski wrote to me (this was the 1st of February) to ask me to change my mind. After years of following the evolution-denial movement, and after attempting to read his "popular explanations" of mathematics, I have nothing but negative associations with Berlinski. I had been dubious all along about his name being on the masthead, but I'm also sadly accustomed to seeing Big Egos affiliated with "interdisciplinary" projects. Learning that he took any active editorial role — instead of being some kind of nominal holdover from an earlier management — convinced me that I had made the right choice.

   I withdrew before I had learned that they paid for articles, so I'll never know how much money I passed up.

   I was not particularly concerned that the original source of their funding was somehow still setting their editorial agenda. Years ago, I quit a paying gig at ScienceBlogs.com because the management there abandoned the firewall between funding and editorial by giving Pepsi the chance to write a blog about "nutrition science". So, I *can* be prickly about such things, but I honestly couldn't see much of an agenda in what *Inference* published, except perhaps a general type of intellectual self-importance that transcends partisanship. Again, that is familiar enough, and not necessarily a deal-breaker in my book.

After forsaking whatever fee I might have earned, I expanded my essay with various observations that hadn't made the cut for a short note, in the hope that I could make a comprehensive commentary and put Becker's book behind me forever. I doubt the result is publishable in any venue having pretensions of solemnity, but it ultimately felt good to catalog the ways in which Becker reproduces the typical laziness of bad quantum-physics writing while inventing some new problems of his own.

I have Issues with the response to Glashow's review that they did publish (by a linguist and philosopher), but this comment has already gone on plenty long, I fear to little benefit.

This Week's Hype

March 5, 2019
Categories: This Week's Hype

In recent years string theorists have been having trouble getting taken seriously by the media, a problem they've been trying to deal with by enlisting the PR departments of their universities to help. Following Princeton and Stanford, today's the turn of the string theorists at Northeastern, who had their press office put out a press release announcing "Northeastern team uses string theory to explain the fundamental nature of the universe."

As usual, this is just pure, unadulterated hype. It's based on a PRL publication, also available as this preprint. I usually try to avoid this sort of editorializing, but I'm actually shocked to see that PRL is now publishing this sort of thing, which is infinitely far from having any connection to conventional science.

Comments

1. **Roger**
   March 6, 2019

   Off-topic.
   It looks like the Japanese have made some sort of decision regarding hosting the ILC. There will be some news tomorrow (7th March) followed by a press conference by ICFA (International Committee for Futrue Accelerators):
   https://www.interactions.org/press-release/icfa-briefs-future-prospect-international-linear-collider

2. **David Littleboy**
   March 6, 2019

   FWIW, and it's not worth much, there was an item in the Asahi Shimbun (one of the major Japanese newspapers) a couple of weeks ago to the effect a particular group of scientists had announced that they were unenthused about building a new linear accelerator in Japan. It wasn't immediately clear whether said group was a group with clout or not, so I didn't track it down. Here, I do slightly more of my homework.

   Ah, here's something: https://webronza.asahi.com/science/articles/2018112600016.html

   It seems the folks promoting the project were irritated (as of Nov. 26 last year) that the Science Council of Japan's report on the project had "overly strong negative nuances". And held a press conference to that effect.

   Here's the PDF of the SCJ's December 19, 2018 report: http://www.scj.go.jp/ja/info/kohyo/pdf/kohyo-24-k273.pdf

   It's long. But it mutters about not thinking that the project has yet gotten to the stage of serious discussions about personnel allocations and funding.

   And there are definitely some other negative, or at least implicitly negative comments in there.

   Perhaps March 7 will be interesting.

3. **Peter Woit**
   March 6, 2019

   About the ILC.
   Let's see what the news is tomorrow. From everything I've seen, it seems unlikely to be positive for a Japanese ILC project.

4. **Bernhard**
   March 6, 2019

   How does this PRL compare to the Bogdanov affair?

5. **Peter Woit**
   March 6, 2019

   Bernhard,
   It's pretty different. The Bogdanov papers were highly unclear and did not really make sense. This paper is a different problem: it's perfectly clear what calculation they are doing, there just is zero evidence it has any relevance to the real world. What's surprising to me is that PRL's standards have evolved to the point where they are willing to publish this kind of completely unsupported speculation.

6. **Peter Woit**
   March 7, 2019

   For a Physics World story about the Japanese ILC announcement, see here

   https://physicsworld.com/a/disappointment-as-japan-fails-to-commit-to-hosting-the-international-linear-collider/

   Perhaps the best summary is the quote from Brian Foster:

   "It is difficult to be convinced that the Japanese government is serious about this," says Foster. "Delaying the decision in this way seems like a typical Japanese way of saying 'no'".

7. **Roger**
   March 7, 2019

   A large part of the original motivation for the ILC was to study in more detail the new phenomena that the LHC would see.

   I'm reminded of a comment Rolf Heuer made when he played a leading role in the ILC. He was asked in 2004 whether he thought the project would go ahead if the LHC found only the SM Higgs. His answer was no. He may well have been very prescient.

   It seems to me that PRL has a very low bar for 'trendy' interdisciplinary topics like neural networks, machine learning, etc when given some type of physics 'spin.'

In it for the Long Haul

March 8, 2019
Categories: Uncategorized

The CERN Courier today has a long interview with the omnipresent Nima Arkani-Hamed, discussing the current state of HEP physics. About the motivations for a next-generation collider project, I'm pretty much in agreement with him: the main argument is for a Higgs factory that would allow a much more detailed study of the Higgs, and if at all possible, an appropriate machine should be built (see more here). He agrees that the SUSY and extra dimensions models used to get people excited about the LHC can't reasonably be used again for a higher-energy machine:

> **Is supersymmetry still a motivation for a new collider?**
> Nobody who is making the case for future colliders is invoking, as a driving motivation, supersymmetry, extra dimensions or any of the other ideas that have been developed over the past 40 years for physics beyond the Standard Model. Certainly many of the versions of these ideas, which were popular in the 1980s and 1990s, are either dead or on life support given the LHC data, but others proposed in the early 2000s are alive and well.

The last reference is to his favored split SUSY models, which I think few people besides him find compelling.

About WIMP dark matter he seems to be claiming that a 100 TeV machine has always been what is needed to find it:

> There is a funny perception, somewhat paralleling the absence of supersymmetry at the LHC, that the simple paradigm of WIMP dark matter has been ruled out by direct-detection experiments. Nope! In fact, the very simplest models of WIMP dark matter are perfectly alive and well. Once the electroweak quantum numbers of the dark-matter particles are specified, you can unambiguously compute what mass an electroweak charged dark-matter particle should have so that its thermal relic abundance is correct. You get a number between 1–3 TeV, far too heavy to be produced in any sizeable numbers at the LHC. Furthermore, they happen to have miniscule interaction cross sections for direct detection. So these very simplest theories of WIMP dark matter are inaccessible to the LHC and direct-detection experiments. But a 100 TeV collider has just enough juice to either see these particles, or rule out this simplest WIMP picture.

I don't remember ever hearing, pre-LHC, from him or anyone else, this argument that the most likely WIMP dark matter models are inaccessible to the LHC or to direct detection experiments. For many years, most of the direct detection experimental results came with plots showing a "prediction" of SUSY WIMP dark matter (see for example here, figure 5), in a mass range of 100-500 GeV, at a cross section measurable (and now ruled out by) experiments like XENON1T (see here).

Arkani-Hamed likes to make the following argument, which I think most current HEP theory graduate students may find hard to swallow:

> **How do you view the status of particle physics?**
> There has never been a better time to be a physicist. The questions on the table today are not about this-or-that detail, but profound ones about the very structure of the laws of nature. The ancients could (and did) wonder about the nature of space and time and the vastness of the cosmos, but the job of a professional scientist isn't to gape in awe at grand, vague questions – it is to work on the next question. Having ploughed through all the "easier" questions for four centuries, these very deep questions finally confront us: what are space and time? What is the origin and fate of our enormous universe? We are extremely fortunate to live in the era when human beings first get to meaningfully attack these questions. I just wish I could adjust when I was born so that I could be starting as a grad student today!

There's something to be said for entering a field at a time when it is finally able to "meaningfully attack" difficult and fundamental questions. The issue though is whether anyone has any good ideas that will make headway against such questions. The Standard Model was in place by the mid-70s, and by the time I was a graduate student in the early 80s, the "what are space and time? what is the origin and fate of our enormous universe?" questions were already on everyone's mind as the next things to be thinking about. Starting in 1984, the superstring revolution promised a way to answer these questions.

35 years later, the current generation of graduate students has the same questions to think about, but a long history of failed attempts to consider. In addition, there's the sad story of the unwillingness of leading figures of the field to admit to the failure of the 1984 revolution, and widespread multiverse pseudo-science (often promoted by Arkani-Hamed) to overcome. The only argument that I can see that this is a good time to start an HEP theory career is that it's hard to see how things can get worse…

For some commentary about the interview by Tommaso Dorigo, concentrating on the positive case for a new collider as a tool to study the Higgs, see here.

Comments

1. **SFD**
   March 8, 2019

   " the main argument is for a Higgs factory that would allow a much more detailed study of the Higgs." I find it difficult to believe that the civil authorities, and scientists in other research fields, will think that this argument is enough to justify the $10B tag.

2. **Peter Woit**
   March 8, 2019

   SFD,
   Yes, but that's going to be what the serious debate is really about: now that the Higgs has been discovered and we have some information about its properties, is it worth building a next-generation machine to study it in detail, or should we just give up, deciding this is something that humans can't afford to try and learn about?

   I don't disagree that this is going to be hard to sell to some people, especially scientists who believe that the money would be better spent on their own field.

   But, to all potential commenters, the "is a bigger collider worth it?" question has already been beaten to death recently, and there isn't even yet a specific proposal from CERN to argue about. Unless someone has something new to contribute, I'd rather not host the same tedious discussion again right now, it's one that there will be many opportunities to go over in years to come.

3. **Tom**
   March 9, 2019

   Nima Arkani-Hamed is regularly described as a "superstar theoretical physicist" (Dorigo). But why? To quote from this blog: "The fact that none of the ideas about BSM physics he is famous for (large extra dimensions, split SUSY, Little Higgs, etc…) have ever worked out doesn't seem to slow him down"

   The trick which allowed Arkani-Hamed to become so famous boils down to taking established ideas and making them more "hypey".

   * Extra dimensions -> large extra dimensions

* Extra dimensions -> little Higgs
* Susy -> Split susy
* New methods for scattering amplitudes -> amplituhedron

And he hypes his favorite pet peeves using whatever argument sounds good no matter if it really makes sense.

* everyone knows electroweak charged dark-matter particle sit @1TeV, right? If only he had shared this wisdom earlier….
* "There has never been a better time to be a physicist. […] I just wish I could adjust when I was born so that I could be starting as a grad student today!" Really? What exactly changed in, say, the last 40 years for theoretical physicists?

All this, combined with his whole „memorable character thing" (see below) allowed him to get so influential although upon closer inspection none of his ideas turned out to be worth the hype.

Lately he hyped the proposed China collider to the extent that people started calling it Nimatron. This, of course, was what he was hoping for. This was his/is his chance to leave a legacy since so far, no one will remember his contributions to physics in, say, a hundred years.

Now since the China collider will probably not be built, he hops onto the next opportunity and repeats his arguments. This is his chance to be remembered in the history books as the guy who helped particle physics survive when "ex-particle-phenomenologist-cum-still-blogger" (Dorigo) tried to destroy it.

Everyone who ever met him in person knows that he tries very hard to be remembered, at least, as an extremely unconventional character. (The boots, the whole "I sleep only 3 hours each night and drink 22 espressi each day", his "Impresario"-Style talks in which he "nails" each argument.) And it seems to be working because journalists love to interview him.

But people should really stop paying so much attention to media fame and showboating and instead with a calm head reassess the arguments at hand.

And maybe journalists should ask instead a few young physicist who are starting "as grad student today" if they share his enthusiasm (so far I don't know a single one who does) and how they think the future of particle physics should look like.

4. **Lonely Physicist**
March 9, 2019

Dear Peter,

In my opinion, it seems that by frequently reporting in your blog all the nonsense this guy is spouting in interviews and conferences, you are yourself supporting him and his compaign!

5. **Peter Woit**
March 9, 2019

Lonely Physicist,
You may be right.

Tom,
I don't think Arkani-Hamed just impresses the press, for instance you can see from Tommaso Dorigo's posting that he's quite impressed. For another random example, I just saw this
https://twitter.com/preskill/status/1104449921363529728
on Twitter from John Preskill
"Nima is a magician — he gets my pulse racing over the prospect of measuring the self-interactions of the Higgs particle at a future collider."

I don't think it's helpful to criticize Arkani-Hamed's persona or argue that he's not honest, that he has other motives for what he's saying than that it's what he believes. I don't doubt that he believes the "best time in history to be an HEP theory graduate student" line even though it's way over the top (so much so that I think it seriously hurts his credibility with his colleagues whenever he uses it).

One reason for his influence is that he's legitimately very smart and well-informed, and the everything's fine, positive, full-speed-ahead enthusiasm is a lot more appealing to most people than being told that times are tough and they should be making difficult and unpleasant decisions about how to change their ways. Another reason is that while his own work on how to extend the SM has all failed, it's not like anyone else has done better. Traditionally the field looks for leadership to those whose ideas have succeeded, credentialed by a Nobel Prize. Right now, the youngest of these, Frank Wilczek, is getting to the traditional retirement age, and all the others (Gross, Glashow, Weinberg) are much older. With 40 years of failure under its belt, where does a field look for leadership?

A fascinating conflict here is between Arkani-Hamed and Sabine Hossenfelder. He dismisses her here in a really tasteless way
"It would be only to the good to have a no-holds barred, public discussion about the pros and cons of future colliders, led by people with a deep understanding of the relevant technical and scientific issues. It's funny that non-experts don't even make the best arguments for not building colliders; I could do a much better job than they do!"
basically arguing that she's not competent to be worth listening to (by the way I've seen this tactic used before…). I disagree with her conclusions about whether a new collider would be worth it, but the arguments Hossenfelder is making are serious, widely shared, and she's quite competent to be making them, every bit as competent to do this as C.N. Yang, whose arguments are actually similar to hers (although China-specific).

6. **Schrodinger's Rat**
March 10, 2019

"…the everything's fine, positive, full-speed-ahead enthusiasm is a lot more appealing to most people than being told that times are tough and they should be making difficult and unpleasant decisions about how to change their ways…"

"…where does a field look for leadership?"

Well, look somewhere else! This behavior is pretty much my definition of the exact opposite of leadership.

7. **parisien**
March 10, 2019

As a student I find his comments about being a student a bit naive. Try finding a position anywhere by saying that what you want to do is to think about what is space and time. I think that the current state of academia doesn't really allow for anyone new to even come in and find a new approach to those questions because they're so bogged down with trying to actully find a position of some stabillity and to start any kind of career. Perhaps instead of daydreaming about being a grad student, I feel he should use his position of a public figure to point out the actual problems in academia students coming into it are facing, because if he really wants someone in the next generation to have new idea or approach, better conditions for them are neccessary.

8. **Tom**
   March 10, 2019

   Peter,

   True. It's not just the press. Students and professors alike get starstruck when they meet him.

   And, of course, you're right that criticizing Arkani-Hamed's persona is not helpful. The discussion should focus on substantial arguments and nothing else. But if we subtract from the interview all the hypey yada yada, we are left with: "We should measure the properties of the Higgs as precisely as we can because we might learn something interesting. We might discover dark matter. We can't allow that fundamental knowledge is shoved in old dusty books."

   These are solid arguments. (Maybe except for the dark matter argument). But at the same time there are several good arguments against a new collider (monoculture, opportunity costs, physics case, etc.). And while he claims that he thinks a "no-holds barred, public discussion about the pros and cons of future colliders" would be good, we all know that this will never happen.

   The only person who currently seems to be willing to argue publicly against a new collider is dismissed as a "non-expert". So who is left to "make the best arguments for not building colliders"?

   There is a strong sense of community in particle physics. (A few weeks ago I witnessed how an eminent professor during his talk in a full lecture hall called Hossenfelder "our current nemesis" and no one disagreed.) And while Hossenfelder's arguments may be widely shared (especially among younger physicist), no one seems to be willing to go public. The only chance to hear people's true opinion on these issues seems to be during coffee breaks. Hossenfelder made the conscious choice to waive here "hopes of ever getting tenure". This is, most likely, the price you have to pay if you go public with your concerns.

   One final comment on Arkani-Hamed I would like to add. A few years ago I attended a summer school where during a break he told a group of students (I'm paraphrasing): "To make a career in physics you truly need to convince yourself that what you're doing is the best and most important thing in the world, even if you think it isn't." (Make of that what you will.)

9. **Jesper**
   March 10, 2019

   @ Tom, Peter: as much as I enjoy reading this blog and as much as I appreciate the important work it represents, I do feel that Tom has a point. In the present world of theoretical high energy physics everyone seems to be looking at the top of the hierarchy for new ideas. But the main thing you'll find up there are people who have spent their lives working on and promoting ideas which have not worked out and which we must now conclude are most likely wrong.

   I think that its necessary to spend time discussing and promoting new ideas too. People who think in new directions. There may not be many of them around but by paying attention — and not ridiculing and belittling them — we just might help create a culture where its cool to think more for yourself and not just work within one of the main scientific clusters in contemporary high energy physics.

   If we only pay attention to those at the top of the hierarchy — regardless whether this attention is positive or negative — then we feed all our energy into a system that hasn't worked well for the past decades. By directing all your attention to the top of the hierarchy you indirectly signal that its only those people who are worthy of that attention. But the truth is that those people are the least likely to lead us in a new direction.

   I believe that high energy physics used to be characterised by rebellious minds. People who didn't give a f… about hierarchy and what you might risk if you go against the current. I don't see that anymore. I see a lot of people who are afraid of loosing their status and — if they are younger — of not getting a job. I think that this lack of rebellion is a part of our problem.

   @ parisien. I agree with you. I think that in the present system its almost impossible for a young independent physicist who works on her or his own ideas, to make it. For this reason I have on my blog encouraged young physicists to 'go rogue' — if a young, ambitious researcher is faced with a choice between a career and working on her or his own ideas, then I think this researcher should consider whether it might be best to work outside of academia. This isn't perfect but the world isn't perfect either. People can do this in other professions — see for instance the arts and literature — so why can't scientists? I think that this whole idea that we can only do serious research within a given framework — academia, the universities — is wrong. I also think that it makes us smaller than we are.

   I have done that. I chose to work on my own ideas, which eventually pushed me out of academia. Its not great but its a hell of a lot better than the alternative. And it certainly isn't something that prevents me from doing the research that I want to do. The truth be told, I find it in many ways easier to do research in this way.

10. **DB**
    March 10, 2019

    I must say that I´m a bit awestruck by everything that has been happening in theoretical physics lately.
    I have to acknowledge that I was one of those that, since ten or twelve years ago approximately, I tended to think that everything that "string theorists" were saying was close to the absolute truth, and that we were pretty close to what people used to call a "final theory of everything".
    But thoughts and wishes are one thing, and reality is another one.
    Since the last two years I´ve been having lots of serious doubts about string theory being that so much sought TOE, and reading posts like this one (plus the comments from Tom and the rest), and even listening to people like Nima (who used to be my idol together with Witten), plus some comments Ed himself has been making lately, I think I really need to give a serious thought about all my previous ideas.

    One more thing: it seems clear that A-H himself has almost (90%?) forgotten about SUSY and extra dimensions, which is quite a lot to say.

    Time to go off for a while and double check my thoughts.

    Thanks to Peter for the post, and for all the comments.
    And good luck to everyone.

11. **Yatima**
    March 10, 2019

    "True. It's not just the press. Students and professors alike get starstruck when they meet him."

    That is the mark of a good, energetic *Persuader*. I haven't watched Nima give interviews but does he wield Jedi mind tricks – consciously or not – as those described in the little blog post by Scott Adams about Mr. Trump: [Clown Genius]?

12. **a reader**

March 10, 2019

Dear Peter, I appreciate your blog very much, and I respect your opinions. I have been a reader for many years, probably longer than a decade. As a (rank-and-file) (ex-)physicist, I would like to ask you…
Don't you think that writing "with 40 years of failure under its belt, where does a field look for leadership?" is rather misleading? I guess I know what you mean, but…
Your blog has a wide and large readership, I guess, so when you and others write "with 40 years of failure under its belt, where does a field look for leadership?" or something similar, would you please specify which field? Because some or may be many among your readers without a background in physics will may be guess that you are talking about all physics or all high energy physics rather than (several) subfields of high energy physics theory.
I mean, has experimental high energy physics 40 years of failure under its belt? Do the large collaborations, I mean all the human beings who built LHC, LEP, Tevatron, RHIC, Super Kamiokande and many other HEP-facilities of the last 40 years deserve that label, failure?
I think that sort of expression, without specifying, every time, even if it might seem tedious to do so, which particular subfield you are actually talking about, I think that is quite misleading and rather unfair.

13. **Peter Woit**
March 10, 2019

a reader,
To clarify, the field being referred to is HEP theory, not anything else. I thought this should have been quite clear, since the context is a discussion of the leadership issue with respect to Arkani-Hamed, an HEP theorist.

A possible source of confusion is that an HEP theorist is also trying to take on a leadership role on the question of what HEP experimentalists should do. Another odd aspect of Arkani-Hamed's criticism of Sabine Hossenfelder's views on experimental HEP is that he argues that people should instead listen to HEP theorists Yang and Glashow. Faced with the decision of where to go for advice about the future of HEP experiment, an obvious point to make is that the best answer is not Arkani-Hamed, Hossenfelder, Yang or Glashow, but none of the above. Why not consult instead an actual HEP experimentalist?

14. **Peter Woit**
March 10, 2019

Jesper,

Yes, in the current environment anyone who wants to pursue a career in this kind of theoretical physics needs to contend with the sad state of the traditional academic hierarchy and career path. That's not the topic of this posting, and I don't personally have a good answer for what people should do (which in any case depends on the person and their exact situation). I do hope I can help people trying to find their way by giving a clear-eyed perspective on what the current state of affairs is.

As for promoting new ideas, I do discuss here what I find interesting, while deleting the large number of comments that come in from those who would like to turn the discussion to something different that they find interesting (for those who would like to discuss new ideas with Jesper, I'm glad to see that he has a blog where you can do this).

Two reasons for critiquing the current academic HEP theory hierarchy instead of just ignoring it are
1. This is where students are, for better or worse, now getting trained and will continue to be trained.
2. The LHC null results, together with the failures of string theory and SUSY as theory (together with the multiverse debacle) I think have opened up many theorist's minds to the question of whether the subject is in a crisis due to having headed down a wrong path. Some influential theorists may be more willing to think through the implications of the current situation. As discussed here
http://www.math.columbia.edu/~woit/wordpress/?p=10842
Arkani-Hamed now seems to exist in a superposition of two very different states: Nima1, who thinks all is well, that current HEP theory an exciting success story, and that split SUSY and the multiverse are the answer, and Nima2, who would like to abandon his old ways and restart life as a mathematical physicist, searching for the deep mathematical question that will give us new insight into fundamental physics. I think it's worth trying to change the environment so that the amplitude of Nima1 is suppressed, that of Nima2 is enhanced.

15. **a reader**
March 10, 2019

Thank you Peter. I knew well that you meant hep-th, but, please, you all who commendably engage in a public debate, remember that it is very important that you mark the difference between hep-th, hep-ph, hep-ex and (especially if you talk to a very wide audience) physics-all, because the very real risk is, I think, long lasting damage, undeserved in many, but sadly not all, cases.
As for that Arkani-Hamed, Hossenfelder, Yang, Glashow and others are all theorists (hep-th), I agree with you.
Experimentalists (hep-ex), be proud of your heroic endeavors and epic achievements of the last 40 years, and speak out!

16. **Amitabh Lath**
March 10, 2019

In addition to being smart Nima is incredibly generous. A few years ago we had a bunch of high school students in our summer Quarknet program, and screened Particle Fever one evening for the students and their parents. Nima came, and took questions for hours upon hours. He answered even very basic questions in interesting and novel ways. Nima's enthusiasm for physics infected the kids and parents.

Nima is right to be excited about the state of fundamental physics. It is us humans vs. the universe and although right now our math might not be clever enough and our machines might not have enough energy or luminosity, we will get there and we will crack this. We always have, regardless of politics or personalities.

17. **citely**
March 10, 2019

Wired UK had an article that touched on colliders, whether SUSY is worth another LHC funding round, and quantum computers to process it all. Fluff, but of cultural note (particularly as to where "physics money" is being directed).

https://www.wired.com/story/inside-the-high-stakes-race-to-make-quantum-computers-work/

18. **Bernhard**
March 11, 2019

Nima is right about the motivation for a new collider (Higgs factory) and that we should learn from past lessons and not invoke hype to sell it. The 100 TeV collider argument for WIMP dark matter is not at all helpful in this respect and he's, as usual, making stuff up, counting with the fact that is enough intimidatingly smart that nobody will call BS.

19. **Roger**
March 11, 2019

Can someone explain the dark matter argument to me ? Why should the preferred WIMP mass be 1-3 TeV ? I always that it was theoretically unconstrained up to an order of magnitude.

20. **DDOwen**
March 11, 2019

The rather personal attacks on Sabine Hossenfelder combined with the dismissal of condensed matter physics (sure, the failure to explain high-Tc superconductivity would have some weight *if that were the only thing that CMP were concerned with*, but that's obviously false if you happen to know anything about CMP) do suggest that there's a certain amount of projection going on in NAH's argument.

21. **AcademicLurker**
March 11, 2019

This may be drifting off topic, but it's related to Jesper's comment above.

Sabine Hossenfelder's description of the HEP theorist career path in her book makes it clear that things haven't changed since Peter and Lee Smolin published their books 13 years ago. The thing that most strikes me as an outsider is the extremely short time frame that's imposed by the system of postdoctoral grants. If you need to start looking for a new position a year after you start your current one, then you want a paper at least submitted by then, which means you need some publishable results within not much more than 6-7 months.

I'm curious about people's impressions of to what extent this is intertia vs a deliberate choice. Do the powers that be in charge of dispensing fellowships & etc. affirmatively believe that this is the best way to select for new theory faculty members? Or is it more a case of "Well, this is the system we have and anyway we have to pick winners somehow so what else are we supposed to do?"?

22. **Peter Woit**
March 11, 2019

DDowen,
I think you're misreading Arkani-Hamed. His comment about high-Tc superconductors wasn't about failure of condensed matter physicists to explain the phenomenon, it was just pointing to the history of unwarranted enthusiasm for the prospects of using high-Tc superconductors to develop much cheaper magnets suitable for a proton-proton collider. This same argument is now being brought up as an argument against the HE-LHC and FCC-hh proposals: why not wait a few years for cheaper high-Tc superconductor magnets before planning a new collider? He just seems to be making the reasonable point that people have been saying this for years, but no viable technology of this kind has appeared, and there don't seem to be serious prospects for it anytime soon.

Roger,
I'd also like to see a reference for this. Arkani-Hamed here and here
http://www.math.columbia.edu/~woit/wordpress/?p=10824
seems to be claiming that a naive calculation of a weak interaction strength WIMP with the right abundance to be dark matter gives a mass of 1-3 TeV, and a cross-section too small to be seen in direct detection experiments, but accessible to an FCC-hh machine. I'd never heard such an argument before, curious to know what he's basing this claim on.

23. **DM theorist**
March 11, 2019

For Peter, Tom, Roger etc

I'm giving some pre-LHC references below (I even threw in one from Nima, sections 1.2 & 1.3) showing that DM candidates that are defined by their SU(2) representation and gauge interactions alone, typically are required to be very heavy and well out of the LHC range. In the MSSM you actually had to work a bit (see the Nima ref) to get a light candidate that gave you the right relic density.

https://arxiv.org/abs/hep-ph/0601041
https://arxiv.org/abs/hep-ph/0610249
https://arxiv.org/abs/0706.4071

The general idea is independent of SUSY, and just focused on WIMP hypothesis, taking the weak part, SU(2), to be literal and calculating the thermal relic density. It just so happens that some of the minimal reps, the doublet and the triplet can also be realized in SUSY as the Higgsino and Wino (when you don't consider mixing etc).

Theorists were talking about this before the LHC. However, at that time people focused more on what you could see at the LHC rather than what you couldn't. Obviously when you have an experiment you want to look at everything you can test with it. Nevertheless, this was well known amongst theorists that WIMP DM with basic reps of SU(2) implied masses out of reach of the LHC. As for the last part that Peter asks about with direct detection, when the WIMP mass is higher the number density of WIMPs is going to be lower. This is why the bounds decrease in the the cross section vs mass plain on the standard direct detection results that you see, while at low WIMP mass it's from threshold effects (there's a ton of effort on this in the dark matter community now on the low energy side where you can devise new experiments). So this is just the standard systematic problem for a heavy WIMP, but of course if there is something charged under a representation of SU(2), then a higher energy collider could produce it.

24. **Jesper**
March 11, 2019

@ AcademicLurker

I think that Lee Smolins book "The Trouble with Physics" very accurately describes the situation (and I have written somewhat of an update on my blog), where the short time-frames that you describe makes it very difficult to work on new ideas (especially if they are your own). You need to publish a lot and you need to publish fast. That system very strongly favours the technicians – those who are extremely good at solving technical problems – whereas the visionaries (I believe that Smolin called them the 'seers'), i.e. those who are good at producing new, creative ideas, are the losers.

During my career I have been a semi-insider to several of the leading communities in theoretical high energy physics and I have been in close contact with essentially all of them. And it has been my very clear impression that those people, who are at the top of the hierarchies, are predominantly technicians. And it is my impression that they generally think that the present system is fine. After all, it is basically the same system – perhaps a little rougher, perhaps a littler sharper – that they had to fight their way through during their own careers.

Again, I think that Smolins book describes the situation very well. And I believe that this applies to essentially all fields in theoretical HEP – including LQG. The trouble with physics is that the present system favours researchers who are good at digging very big holes (metaphorically speaking) and disfavours those, who are good at finding the right spot to dig those holes. The result being that everyone digs their holes in the same spot.

25. **Peter Woit**
March 11, 2019

DM theorist,

Many thanks for the explanations and references!
Those references led me back to something slightly earlier and simpler, this https://arxiv.org/abs/hep-ph/0512090
about "Minimal Dark Matter"
Yes, as Arkani-Hamed claims, the models discussed (pre-LHC) there are in the few TeV range, a range that would require 2-4 times the LHC energy to explore. It's interesting that these models got so little attention pre-LHC null results.

Also interesting is that the above paper gives a version of the standard direct detection plot (figure 2), with, besides the usual SUSY CMSSM blob mostly now ruled out, predictions based on these sorts of minimal dark matter models which are at higher mass, with cross sections that the latest generation of experiments should start being sensitive to.

26. **Peter Woit**
March 11, 2019

Jesper/AcademicLurker,
This has gotten way off topic, it's an interesting question, but, enough for now.

27. **DM theorist**
March 11, 2019

Hi Peter,

Glad to help, and yes one of the references was a followup on Minimal Dark Matter (MDM). These focused more on the 5-plet or 7-plet to get stability from the SU(2) rep, instead of having a parity which most models of DM have, and the cross section for direct detection grows like n^4 where n is the size of the representation. I don't remember the exact differences between the MDM calculation, but I recall 10^-47 cm^2 as the pure Wino case in SUSY, and at ~3 TeV in mass this is below the direct detection bounds even for future experiments. Not to say that this couldn't ever be tested outside of a collider (indirect detection is also interesting, but with its own uncertainties), just that what Nima said was accurate for the minimal representations.

I think all decent theorists were well aware of the models. However, I think that sometimes the synergy of being able to test things in multiple ways biases peoples interests, and at least for the SUSY case, they weren't as "natural" as having a light Higgsino. Now that we've seen nature isn't as "natural", the WIMP candidates themselves still just have the predictions they have. Some might call this bias in a pejorative sense, I think it's more just about opportunism. If I have a model that I can test with colliders, direct detection, and indirect detection that's very cool and super testable. If I lose one of those handles it's still interesting, but more difficult to interpret. I don't think there's a secret theory cabal trying to suppress ideas or not tell the truth about the possibilities, as you see in the Nima paper they were laid out honestly. Experimentalists are just naturally going to be most interested in the models they could see with on-shell experiments and thereby that gets a broader discussion in the community.

28. **Peter Woit**
March 11, 2019

DM theorist,
Thanks for the further comments. I understand there was no secret theory cabal at work, and people reasonably concentrated on looking at models that the LHC could test, but the way certain models got heavily publicized, despite well-known problems with them, is going to cause a credibility issue going forward.

The most outrageous example to me was the whole "we may see extra dimensions at the LHC" business, here I suspect if anyone tries this for future colliders they'll get laughed out of the room. Second though was the "we expect to see "natural SUSY", with lots of states light enough to be easily seen at the LHC", even though there was lots of indirect evidence against such states. To his credit, on some days Arkani-Hamed would mention such evidence and talk about split SUSY, on other days though he would go on about how many gazillion gluinos the LHC would produce and how the field needed to get organized to be able to disentangle all the many new states the LHC would see. I gather the WIMP DM story is a variant of this problem.

29. **Dave Miller**
March 12, 2019

Peter,

I wonder if you (or anyone) can elaborate on what we will get out of more details on the Higgs?

I myself had also concluded that looking more at the Higgs is the obvious next step. But… can we really get a good handle on the Higgs potential with the next collider? Or if we see something slightly different than we expect, will that merely tell us that the calculations for what to expect were too tough for the phenomenologists to do accurately? And, no matter how accurately we measure Higgs phenomena, will that tell us about anything beyond the Higgs, or will it just satisfy the curiosity of those of us who long ago learned the basic info about the Higgs?

I honestly don't know the answers to these questions, but, hopefully, some people actually do have answers to such questions! It seems to me that fleshing out the answers is key to making the case that deeper studies of the Higgs are worthwhile.

Dave

30. **tulpoeid**
March 12, 2019

Some "superstars" have to understand that standing on the shoulders of giants doesn't make themselves giants.

Also, I feel that it's important to voice a concern regarding Hossenfelder's treatment: She is by far not the only HEP physicist, and I include experimentalists here, who opposes the next large thing (although a couple of her arguments are hard to swallow but this is not my point here). I've been both at LHC and DM experiments; afaik most people in DM and other "small" experiments don't fear at all that HEP will die without a larger machine right now. There are several of their colleagues at LHC who don't disagree. There is a number of other smaller collider-based searches, both running and proposed, which at the very least will make us search in smarter ways.

Imho people who've established their careers on the energy frontier are just trying to single out Hossenfelder in an effort to persuade the public that there is only one clown who opposes the mainstream.

31. **ztimashi**
March 13, 2019

    Regarding your comment "Traditionally the field looks for leadership to those whose ideas have succeeded, credentialed by a Nobel Prize" I find it very curious, to say the least, that all non-emeritus theorists at IAS are now string theorists.

32. **Peter Woit**
March 13, 2019

    ztimashi,
    Arkani-Hamed isn't a string theorist, and, actually I think that's a reason his views are quite influential.

33. **Thomas Larsson**
March 14, 2019

    ztimashi,
    It is becoming increasingly difficult to look for leadership from people with a Nobel prize, since there is no longer any active HEP theorist with that qualification. Or at least none who is below normal retirement age, which in Europe is 67 or less. Wilczek is 68, I think.

34. **Stephen**
March 14, 2019

    "There has never been a better time to be a physicist" Really? Maybe Nima should study up on the history of particle physics between the mid 50s and the mid 70s.

This Month's Hype

March 14, 2019
Categories: This Week's Hype

Physics Today seems to have decided to deal with Sabine Hossenfelder's criticism of a future collider by publishing the least credible possible response: a column by Gordon Kane arguing that string theory predicts new particles of just the right mass to be likely beyond the LHC reach, but accessible to a higher-energy proton-proton machine.

In the column, we learn that:

> In recent years there has been progress in understanding those models. They predict or describe the Higgs boson mass. We can now study the masses that new particles have in such models to get guidance for what colliders to build. The models generically have some observable superpartners with masses between about 1500 GeV and 5000 GeV. The lower third or so of this range will be observable at the upgraded LHC. The full range and beyond can be covered at proposed colliders. The full range might be covered at a proton–proton collider with only two to three times the energy of the LHC. One important lesson from studying such models is that we should not have expected to find superpartners at the LHC with masses below about 1500 GeV.

Kane has a long history with this kind of thing at *Physics Today*, publishing there back in 1997 much the same sort of argument, in an article entitled String Theory is Testable, Even Supertestable. According to the Kane of 1997, a generic "prediction of string models" was a gluino at around 250 GeV, just beyond the Tevatron limits of the time. Thirteen years later, *Physics Today* had him back, publishing an article entitled String theory and the real world. I don't have the time to do a full search, but, by 2011 after the first LHC results came in, Kane had a string theory prediction of a gluino mass at 600 GeV, or "well below a TeV".

As better LHC results have come in, each time Kane has issued a new "string theory prediction" that the mass is a bit higher, just about to appear at the next round of LHC results. The last version of this I had seen (see here), was from 2017 and predicted "that gluinos will have masses of about 1.5 TeV". This is already disconfirmed and out of date, with Kane now telling us "between about 1500 GeV and 5000 GeV."

For some other evidence of how Kane deals with the problem of having predictions falsified, one can compare the 2000 and 2013 versions of his popular book on SUSY, an exercise I went through here.

At this point, the argument that we need a new collider because "string theory predictions" say that it will see gluinos has zero credibility. I don't know of any other theorist besides Kane who believes such a thing. That *Physics Today* is publishing this is just mystifying. Perhaps a collider skeptic there has come up with this as a clever way to back the Hossenfelder side of the argument.

There are some other odd things in the piece, one that stuck out for me was this bizarre claim about recent history:

> We now know that if Fermilab and the US Department of Energy had taken the Higgs physics more seriously, the Tevatron would have discovered the Higgs boson years before the Large Hadron Collider did.

I see Will Kinney has more about this on Twitter.

Update: More commentary on this from Jon Butterworth and Sabine Hossenfelder.

Comments

1. **Shantanu**
   March 14, 2019

   I urge everyone to write a response to this Physics today article. I am planning to write one. Peter is it okay, if we borrow mostly from this article

2. **Peter Woit**
   March 15, 2019

   Shantanu,
   If people want to contact Physics Today they should. For the editors there to see the problem they have, you don't need to point here, just to their own pages. A comparison of what Kane wrote there in 1997 and is writing now should be all that is necessary.

   I'm quite serious that the publication of this kind of thing is going to do damage to the credibility of HEP among other physicists, and be very unhelpful for the argument for a new collider. All those who went public to counter Hossenfelder should be doing the same here. That this kind of thing has been going on unchallenged for decades is part of the problem.

3. **John Baez**
   March 15, 2019

   Will Kinney has some nice images of Gordon Kane's boldly stated wrong predictions from 1994, 2001, 2015 and 2019:

   https://twitter.com/WKCosmo/status/1106287115720146945

   I don't know Kane. What about him makes him so eager to do this? Of course if you can keep convincing people to build particle accelerators based on a wild guesses that keep turning out to be wrong, and they keep forgetting you're always wrong, you have a motive to keep doing it. But that applies to anyone. Why does Gordon Kane, among all particle physicists, have such a spectacular track record of doing this?

4. **Peter Woit**
   March 15, 2019

   John,

   Kane has always been an outlier, with very few others taking seriously the argument that there were "string theory predictions" relevant to LEP, the Tevatron, the LHC, or any other collider (and such arguments I think had nothing to do with building and operating those machines). It's not so surprising to me that a theorist would have delusional views about their own favorite theoretical models. What I don't understand is why Physics Today (or anywhere else) continues to provide him a prominent venue to repeatedly make such obviously dubious claims.

5. **Low Math, Meekly Interacting**
March 15, 2019

I'm guessing that you meant to be facetious in your speculation about PT's motives for publishing. You might nonetheless be spot-on.

6. **A Former Professional Higgs Boson Hunter....**
March 15, 2019

Fermilab had a snowball's chance in hell of finding the Higgs given how far LEP pushed the mass limits…

Take it from me, I was there and was responsible for showing that Fermilab could get lucky if the mass was ~160 or so…

That statement from Physics Today is gaslighting at it's finest…

7. **Peter Woit**
March 15, 2019

AFPHBH,

Thanks!

The Higgs hunt at the Tevatron was covered extensively on this blog, so I'm well aware that there was an intense effort there, with, it turns out, no chance of success (i.e. no 5 sigma detection at 125 GeV). Thus my surprise at the Kane claim.

For an early posting about this, see this blog entry from 2005
http://www.math.columbia.edu/~woit/wordpress/?p=163
I think it was the first time I interacted with Tommaso Dorigo, who sent in a helpful comment clarifying the situation.

8. **Supernaut**
March 15, 2019

"… least credible possible response: a column by Gordon Kane…" I would have loved it if PT published the article but written by an accomplished experimentalist who is also a good writer like, say T. Dorigo instead.

9. **Garrett**
March 15, 2019

Too bad Gordon Kane can't bet his own $20B on building the FCC and finding his predicted superparticles. That would likely lead to the optimal case of the FCC being built and him losing money for being wrong. Instead, we'll have the FCC not built and him continuing to be profitably wrong.

10. **Peter Woit**
March 15, 2019

Garrett,
He has bet about $100, but bet not likely to pay off for several years, see
http://www.math.columbia.edu/~woit/wordpress/?p=7160

11. **A Former Professional Higgs Boson Hunter....**
March 15, 2019

Peter,
the Tevatron folks gave the proverbial college try, but the machine and the detectors were not quite up to it. When all the smoke cleared they could discern
WZ -> l nu bbar production, the standard candle, at about the 2-3 sigma level.

FWIW, from a conversation I had many years ago, the current CERN DG had no doubts about the WW channel around 160 but thought that the VH modes were wishful thinking. The CERN people were freaking out that FNAL could scoop them for a Higgs in the 150-170 GeV region…

12. **Anonyrat**
March 15, 2019

HEP superstring predictions for what colliders might find are degenerating into the weekly astrology column that so many magazines carry.

13. **Peter Woit**
March 16, 2019

Anonyrat,
I don't think it's a good analogy. Horoscope predictions are sometimes correct.

14. **Math Phys**
March 17, 2019

Physics Today used to be a serious publication.

15. **TonyG**
March 17, 2019

Gordon Kane seems to be on a PR offensive in support of his past claims that string theory makes verifiable predictions:

https://inference-review.com/letter/beyond-the-standard-model

16. **A Former Professional Higgs Boson Hunter....**
March 17, 2019

Funny that given the mess that theoretical particle physics has become, I am somewhat surprised that this paper has not been more closely examined:

https://arxiv.org/abs/hep-ph/9312316.pdf

Mh = 125 GeV and Mt = 175 GeV, a full two years before the top was found….

Not being a theorist I can’t comment whether there is any real meat to this or was it a lucky parameterization of our ignorance…

17. **Blake Stacey**
March 17, 2019

I wish I’d gotten in on some of those bets. My habitual pessimism could have paid off, for once.

18. **Math Phys**
March 18, 2019

Blake Stacey,

You are not the only one, it has nothing to do with pessimism, and people have been making these bets with G Kane since 1984.

I was present at a party in Ann Arbor in 1984 when I heard T Veltman say *“Gordy, if they discover supersymmetry, I’ll eat my hat.”*

19. **Doug McDonald**
March 18, 2019

The “what if Fermilab” question: since we know that Fermilab actually made and saw Higges, but nowhere near well enough to hope for 5 sigma, what could have been done to get enough?

Presumably that does not include increasing the energy. But it could have included higher rep rate for high luminosity. And what about adding a better, more modern, (LHC-like) detector or detectors? These are technical questions that someone probably thought about. Was the political situation post SSC-demise so bad that there was no hope?

20. **A Former Professional Higgs Boson Hunter....**
March 19, 2019

Doug,
you can whip a mule all you want but it ain’t gonna win the Kentucky Derby.

The Tevatron Run II involved ambitious major upgrades to both the existing detectors and the accelerator. Even with them, a SM Higgs was never really in reach. For example the silicon vertex detectors critical for b-jet tagging would have fried for the luminosity required to see a signal, the rad-hard electonics simply did not exist yet. The calorimetry was also not up to snuff in coverage in eta, segmentation and sampling resolution implying that jet-jet mass resolution was always going to be a limiting factor.

A heavy 4th generation quark might have bumped up the cross section to almost observable levels but that was already ruled out by LEP. Only an oddball Higgs would have been observable (e.g. fermio-phobic, very high tan-beta, triplet etc…).

The only realistic window was in the mass region around 2M_W and even that was a stretch. Personally I think it was remarkable the Tevatron program closed the mass region that at one time was seen as the hardest one for the LHC to cover…

21. **Julius**
March 19, 2019

Unrelated, but are you going to cover prof. Karen Uhlenbeck’s contributions to an actual understanding of physics?

22. **David Metzler**
March 19, 2019

This is OT, but I think the award of the Abel Prize to Karen Uhlenbeck is quite noteworthy, and relevant to the math/physics intersection covered here. Any thoughts, Peter?

23. **Peter Woit**
March 19, 2019

Julius/David Metzler,

Sorry, but I’m on vacation this week, and no time for more than saying congratulations to Karen. The usual suspects (e.g. Nature and Quanta) seem to have quite good articles about this that I can’t compete with.

24. **Jens Franke**
March 23, 2019

It would perhaps be interesting to have a list of papers by serious physicists which really gave a reasonably correct PREDICTION (i.e., dating from before 2012) of the Higgs mass. Besides the Kahana/Kahana paper quoted earlier in this thread the one I know of is by Shaposhnikov/Wetterich arXiv:0912.0208 : “Detecting the Higgs scalar with mass around 126 GeV at the LHC could give a strong hint for the absence of new physics influencing the running of the SM couplings between the Fermi and Planck/unification scales.”

25. **A Former Professional Higgs Boson Hunter....**
March 23, 2019

And here you go…

https://arxiv.org/pdf/0708.3344v8.pdf

The compilation is up to version 8, and the Kahana’s paper is still the best one especially given when it occurred and what the direct limits on the top quark and Higgs mass were at the time. Making Higgs boson mass predictions after LEP has put 112 GeV lower bound is not as nearly as impressive…

26. **Jens Franke**
March 24, 2019

Thank you. I suspect that many papers on the list where it says “many supersymmetric particles” under “other predictions” have been ruled out by LHC experiments. I also suspect that Shaposhnikov/Wetterich is consistent with current experimental data. If Kahana/Kahana get the “Higgs as a deeply bound state of two top quarks” that might be testable by now. I wonder whether it is consistent with LHC data.

27. **A Former Professional Higgs Boson Hunter....**
March 24, 2019

No idea if there are other testable predictions that can be gleaned from the Kahanas. At first glance, I am pretty sure it is consistent with current LHC results. It does however suggest to me that a e+ e- machine capable of studying the t-tbar threshold could yield a surprise or two that the LHC might not be capable of discerning.

It is pretty clear to me that a very heavy top quark is somehow related to the mechanism of EWSB and creating the vev of the Higgs potential. It just “smells” that way. That being said, I am not a theorist, so I can’t really say if those 2 papers that predicted the correct mass are showing us something of fundamental significance or were “luck” based on choices of boundary conditions or something else…

28. **Amitabh Lath**
March 24, 2019

AFPHBH, I notice that the Kahanas’ paper is dated Dec 1993. That was when SLD had collected around 50k Z events made with polarized electrons and the production asymmetry was turning out larger than expected, which (along with the latest Tevatron top mass limits) restricted the top mass window to about 5 GeV. (Full disclosure, that left-right asymmetry was my thesis).

I don’t think we put anything out in 1993 but if they had their ear to the ground (like good theorists do) the Kahanas may have picked some rumblings.

Note that top mass comes in squared in the Weak asymmetries, while the higgs mass comes in log. The asymmetries narrowed the Higgs mass to less than 200-ish, so for the Kahanas to nail that is pretty impressive.

29. **A Former Professional Higgs Boson Hunter....**
March 24, 2019

I was part of SLD when it stood for “Slow Lingering Death”. Never saw data.

Having those CCDs so close to the IP made SLD a very powerful detector for some key measurements especially when coupled with the polarization. It was a great complement to LEP…

30. **Dirk Freyling**
April 5, 2019

David and Sid Kahanas predictions about the Higgs-Boson-mass and the Top-Quark-mass (1993!!!) in a “parameter free fashion” are very precise. Source: https://arxiv.org/pdf/hep-ph/9312316.pdf

According to the standard model (SM) predictions are not possible. How do you explain the obvious discrepancy?

Peter Higgs knew about their work … he said, “You’re from Brookhaven, right. Make sure to tell Sid Kahana that he was right about the top quark 175 GeV and the Higgs boson 125 GeV” [Kahana and Kahana 1993].” Source:https://arxiv.org/pdf/1608.06934.pdf

One would assume that highly accurate calculations about the Top-quark-mass and the Higgs-mass are remarkable. Why didn’t the “Kahanas” get the “proper” attention? Why is there no adequate mention about these theoretical achievements?

I strongly believe that Sidney and David Kahana’s predictions need to be published and discussed again. With reference to Nambu Y and Jona-Lasinio G 1961 Phys. Rev. 122 (1) 345-358 (https://journals.aps.org/pr/pdf/10.1103/PhysRev.122.345) it seems that the entire SM-project had already been completed (…“methodical circular conclusions”) at the beginning of the 1960s.

For further reading see https://arxiv.org/pdf/1112.2794.pdf … “predictions by the authors D. E. Kahana and S. H. Kahana , mH = 125 GeV/c² uses dynamical symmetry breaking with the Higgs being a deeply bound state of two top quarks. At the same time (1993) this model predicted two years prior to the discovery to the top its mass to be mt = 175 GeV/c²…”

Incidentally the list of 96 Higgs-mass predictions by Thomas Schücker (https://arxiv.org/pdf/0708.3344v8.pdf) is a “good” reference of how and when predictions were made.

31. **Mitchell Porter**
April 5, 2019

Dirk Freyling – I agree that it’s strange just how little attention that paper has received (all the more so since Peter Higgs himself evidently knew about it!). I cannot find a single serious discussion of that model, formal or informal, that has taken place. By contrast, Shaposhnikov and Wetterich 2009, another paper which managed to predict the Higgs mass through heterodox means, is now approaching 300 citations.

It’s not as if the Kahanas did something completely alien to the known paradigms of physics. There are hundreds of papers on NJL-type models. You would think that someone who knows the topic, would have ventured a commentary by now.

The Shape of a Life

March 23, 2019
Categories: Book Reviews

I just finished reading The Shape of a Life, which is the great geometer Shing-Tung Yau's autobiography, co-authored with Steve Nadis. It's quite fascinating, and an essential read for anyone interested in the history of modern mathematics. Yau has been for a long time a central figure in the field of geometric analysis, so this is in some ways as much an autobiography of the subject as well as of the man.

Back in 2010 I wrote here about an earlier volume by Yau and Nadis, The Shape of Inner Space. What I really liked about that book (and discussed in some detail there) was the autobiographical material about Yau. Much of the book though was devoted to topics like string theory attempts to get physics out of Calabi-Yaus, with a discussion that was detailed and accurate, but to my mind often not of great interest (since these attempts don't work…).

The new book seems to have been written specifically to appeal to me, greatly expanding the autobiographical material of the earlier book, while limiting the discussion of dubious speculative physics. There is still a fair amount about physics, but this time more focused on another of Yau's interests, the mathematical theory of general relativity.

The book begins with the story of Yau's early years in Hong Kong, how he managed to survive an impoverished childhood, avoid becoming a duck farmer, and ultimately find a way to get to the US and graduate study in mathematics at Berkeley. It's a compelling story of that period and those places. It's also about the best example I can think of to show how bringing someone with undeveloped talent into the environment of a first-rate research university can change their life, liberating them to accomplish great things, with dramatic impact on their intellectual development as well as that of a whole field.

Yau has always had a deep interest in the history of mathematics, and the story he tells of his intellectual development explains in detail how his own work and ideas grew out of earlier strands of thought. Even as a graduate student, he had started to develop the point of view that has been so fruitful in geometric analysis, using the study of non-linear partial differential equations to prove theorems about geometry and topology. Besides his proof of the Calabi conjecture, this ultimately led to the proof of the Poincare conjecture, a story Yau explains in detail.

Over the years Yau has been involved in various controversies over priority for mathematical results. In this book he doesn't shy away from discussing these, but generally gives a measured explanation of his point of view on what happened. There's also a fair number of often amusing stories about mathematicians and the math community that liven up the history. For one sort of example, there are Yau's descriptions of his culture clash with the long-haired, pot-smoking Berkeley of 1969. For another, here's a story about Richard Hamilton (of whom Yau has a very high opinion) and his 1982 lectures at the IAS:

> Hamilton, who had come from Cornell, stayed for a week in an IAS apartment. At the end of his stay, the chief math secretary was livid because Hamilton had made a huge mess of the apartment, and it took a long time to clean up the place. On the other hand, he had given some wonderful talks, and collaborations between Hamilton, my students, and me picked up from that time forward. So, on balance, his visit would have to be called a great success. Hamilton may have posed some challenges to the cleaning and janitorial staff, but he had posed even more consequential challenges to the mathematics community, some of which were taken up by members of my group.

Yau is generally considered a major figure not just for his research, but also as a politician of the mathematics community, deeply involved for many years in efforts to build or expand research centers, here and in China. A recent example is the creation of the CMSA at Harvard. He has a lot to say about the stories of these efforts, and he definitely does not do so with the style of the politician careful to offend no one. In this book you get Yau's honest, unvarnished version of what happened, as well as his analysis of some general problems, and I won't be surprised if some people take offense at this material.

One thing there's perhaps a bit too much of in the book are the references to his conflicts with his advisor Shiing-Shen Chern (which I'd somehow never heard about before). A major touching theme though throughout the book is that of fathers, sons and traditions of filial piety. There's a lot about Yau's father (who Yau very much looked up to) and quite a bit about his sons. On the mathematical side, there's a lot about his numerous students, many of whom have gone on to important academic careers. As his academic father, Chern also fits into this theme, although not so felicitously. At the end of the book, Yau looks forward to his own future as, like Chern before him, the grand old man of the field. He's planning more teaching and less research, and taking pleasure in his mathematical legacy and progeny.

   March 24, 2019

   This is the other great thing about this blog. Besides finding fresh news about exciting ideas in mathematics and physics, we, readers, are always informed about any new interesting book about physics or mathematics. I always rush buy the books I find reviews of in this blog, and I've never regretted it. Thank you Peter!

2. **tenured physicist**
   March 24, 2019

   I second LP!

   I've again started reading books since I got tenure last year, and I always check out books that are reviewed here.

3. **luysii**
   March 24, 2019

   Some of the non-mathematical sociology in the book is also fascinating. Yau was immediately attracted to a physics grad student (who eventually became his wife). He did not approach her, as they had not been introduced. 18 months later when he was about to leave, he imposed on a friend to have a dinner to which she was invited. Courtship and marriage followed.

   After they were married, they lived separately for a time with their parents because of work.

   Yau is also hard on some Chinese mathematicians, who see it as a means to a comfortable life, as opposed to many American mathematicians who do math because they love it and can't think of doing anything else.

4. **Bananeen**
   March 25, 2019

   This is a question I have which is somewhat related to Shing-Tun Yau:

on the “about” page of the CMSA at Harvard, there is the following quote by Yau, who is the center’s first director: “The center will not only carry out the most innovative research but also train young researchers from all over the world, _especially those from China_. The center marks a new chapter in the development of mathematical science.” (http://cmsa.fas.harvard.edu/about/)

I couldn’t find any mentioning of support coming from China for this center, so is it just Yau’s own intent to single out Chinese researchers?

5. **Peter Woit**
   March 25, 2019

   Bananeen,
   The CMSA is funded by Evergrande, a Chinese property developer, see

   https://news.harvard.edu/gazette/story/2013/12/harvard-announces-evergrande-support-of-three-initiatives/

   Because of his own personal story, Yau has always been interested in bringing talented young Chinese researchers to places like Harvard, and I assume this has always been part of the mission of the CMSA.

6. **Bananeen**
   March 25, 2019

   Peter,

   Good to know. I only wish they made it more transparent on CMSA’s website.

7. **A curious reader**
   April 21, 2019

   Many thanks for the review! After reading your review, I bought and read the book in a couple of days. As someone with some acquaintance with Prof. Yau’s family, it’s amusing to see some of the family stories and pictures in the book. Very much admire Prof. Yau’s mathematical achievement, his honesty, and all he has done for the field and for the country where he was born.

Some Quick Items

March 25, 2019
Categories: Film Reviews, Uncategorized

A few quick items:

- This past weekend I went to see the new film Out of Blue, which sounded promising: a murder mystery based on a Martin Amis book, set in New Orleans, starring Patricia Clarkson, with a plot involving lots of deep ideas about physics. Unfortunately, the film was pretty awful, for a review from a professional, see here. There was a lot of physics, I think intended to add philosophical depth, but it was just the usual Schrodinger's cat, black holes, dark matter, multiverse mumbo-jumbo. The *Variety* reviewer appropriately ends her review with

> It makes one feel a little bit embarrassed for the multiverse.

- Sticking to the sophomoric, I was searching through old boxes of stuff and turned up a paper I wrote, Quantum Theory and Reality, about the interpretation of quantum mechanics for an expository writing class during my first year (1976) of college. While it was my first year, I did have sophomore standing. Rereading the thing, I'm glad to see that I've learned a few things since my sophomore year, but on the other hand, some of my views haven't changed (I still don't think "hidden variables" work…).
- Ethan Siegel at Forbes has This is Why The Multiverse Must Exist. By now, all I can do is refer to this FAQ.
- Results using the full datasets of the LHC Run 2 are starting to appear, some of them in talks given at last week's Moriond conference in La Thuile. There are summaries available from CMS, ATLAS and LHCb. Referring to the absence of any significant evidence of new particles or anything inconsistent with the SM, in these results and in a new result from BELLE, Jester comments:

> La Thuile: Where Hopes Melt Away.

This week, there's another ongoing "Winter" HEP conference ("Winter" I guess means you can go skiing…), at Aspen.

- I was sorry to hear of the recent death of Jean-Marc Fontaine, at the age of 74. Frank Calegari has an appreciation of Fontaine and his work here.
- For more positive recent developments in arithmetic geometry, I recommend Peter Scholze's lecture series at UCLA on Prismatic Cohomology, discussed by Terry Tao here. In related news, this week at MSRI there's an interesting workshop on Derived Algebraic Geometry and its Applications.
- For an interview with Eric Weinstein, who, like Sabine Hossenfelder, is always thought-provoking on the great question of why fundamental physics has gone off the rails, see here. I think he may have a point about Tom Lehrer.

Comments

1. **Dave Miller**
March 26, 2019

Peter,

Do you have a link to any discussion of your view that "hidden variables" does not work?

It seems obvious to me that hidden variables *does* work, but in such an aesthetically unappealing way that it is hard for me to believe that hidden variables is really true: the main problem of course is that Bell's theorem means that making hidden variables agree observationally with relativity will be a rather ugly kludge.

As I recall, Bell goes into all this in detail in his *Speakable and Unspeakable in Quantum Mechanics*.

In any case, I think understanding various thoughtful objections to the different approaches to QM may help us all understand better what the "mystery" is that bothers so many of us.

(By the way, I too wrote a term paper on the foundations of QM, in my case focusing on Bell's theorem, as an undergrad back in the mid-'70s.)

Dave

2. **Peter Woit**
March 26, 2019

Dave Miller,

Hidden-variable theories I know about have all sorts of problems accounting for quantum fields, for relativity, for spin, with getting around these problems requiring constructing something far more complicated and ugly than conventional QFT, for no discernable benefit. I understand that some are hopeful that a successful hidden-variables theory exists and want to pursue that quest, but they have not so far succeeded.

All, I don't want to start another discussion here about interpretational issues in QM, based on my naive views when I was 18 years old, and even less want to engage in the usual tedious ideological arguments over hidden variable theories. Please wait until there's something serious to discuss.

3. **Low Math, Meekly Interacting**
March 26, 2019

I'm just struck by how similar your essay is to any number of articles on the subject I've read over the past year, in terms of framing the issue. I'm with those who feel that "quantum foundations" has not been a terribly progressive field since its inception. DOA might be a forgivable assessment, if overly harsh. I hope someone comes up with a good experiment that actually…decides something one of these days. I'm amazed people approach the subject in the absence of new data without a sense of despair.

4. **Maximillian Tresmond**
March 26, 2019

Naive views? Hardly. Eighteen years old, just out of high school, and writing at a level of scientific sophistication that most people would never reach in their entire lives. That's amazing. We are all fortunate to have a real scientist like you, rather than a science communicator, help enlighten us about the pressing issues in physics and provide us with a deep level of insight that is hard to come by just in reading science news.

You really are an outstanding mind, a great scientist, and an ambassador to the profession that continues to inspire other people to get into science and mathematics.

Thanks for everything you've done and continue to do Dr. Woit.

p.s. Was than an IBM Selectric typewriter?

5. **Peter Woit**
March 26, 2019

LMMI,
Yes, the static nature of this subject is both striking and depressing. You can see perhaps why I have little patience for listening to exactly the same arguments I was reading about over 40 years ago. It is kind of ridiculous to often see the issue framed as the "brave new insurgency against the old Copenhageners", when these insurgents were active in the 50s and 60s, are all now long dead.

Maximillian Tresmond,

Thanks for the over-the-top compliments, but I'm sure our high schools and college expository writing courses to this day have lots of students writing similar things. I think it was a Smith-Corona electric, not an IBM Selectric.

6. **Peter**
March 26, 2019

Hi,

I don't want to start a discussion about the interpretations of QM. All the interpretations I've seen are untestable, unobservable or equally (or even more) mysterious than the thing they try to "explain".

However, I have a question.

How seriously did you take these "alternate interpretations", "tinkering with the laws of logic" etc. you write about at the end of the paper?

I remember reading about these alternate interpretations when I was a young student of physics. Arrogant as I was, I immediately thought "This is just silly. The whole mathematical machinery of QM is developed with plain, old-fashioned logic. Not one single mathematical theorem that is used has an indeterminate truth-value. How is it possible that we have to tinker with the laws of logic to understand something that never used or needed these alternate laws?"

Was I exceptionally arrogant, or did you have the same reaction?

7. **Peter Woit**
March 26, 2019

Peter,
You were smarter than me. I did take such things seriously, taking a lot of courses in the philosophy department, including ones from Quine (logic, i.e. Quine reading his yellowed notes on the subject) and Putnam (also found some of those papers, but I don't think anyone wants to read what I had to say about Kant…). It took me a while to realize this kind of thing could not be the answer to deep interpretational issues in QM, and that my time was better spent learning more about QM and QFT themselves.

8. **Maximillian Tresmond**
March 26, 2019

What was it like to study under W.V.O. Quine? Did he ever bring up his indispensability argument for mathematical platonism in his undergraduate classes?

9. **Peter Woit**
March 26, 2019

Maximillian Tresmond,
I was tremendously impressed by Quine's writings, by his major books available at the time (e.g. From a Logical Point of View, Word and Object, Ontological Relativity and Other Essays). The course I took though was a logic course, and a big disappointment. I'm not joking about his reading yellowed lecture notes. But he's one of the true greats of philosophy, and his way of thinking about science and how we gain knowledge of the world is quite compelling.

On the other hand, the logic course was a bore, and later in life when I read his autobiography, that was another disappointment, not exactly a gripping tale.

10. **anon.**
March 28, 2019

Just curious what you thought the novelist Martin Amis would deliver? A completely new – albeit non-crackpot – approach to solving the outstanding problems with the standard model, maybe? 😉

11. **AT—**
March 28, 2019

Dear Peter,

It was a pure delight to read your essay from your college days.

I would like to ask you a question (from the history of science perspective): was MWI not yet "en vogue" in those days already? As far as I know, DeWitt started his exposure of MWI in late-60's/early-70's. You didn't mention it in your essay, was it because you didn't take it seriously, or due to it being mostly unknown 43 years ago?

[For what it's worth, I think that MWI is, at best, a fringe interpretation of probability theory, but my POV is irrelevant to the question above]

12. **Peter Woit**
March 28, 2019

anon,

I haven't read the Amis novel, quite possibly it's much better than the film. I wasn't expecting much from the physics in the film, would have been perfectly happy to see a good film with some added cheesy physics for fun.

AT-,

It's been so long ago now I really can't remember when I first paid any attention to MWI. My vague impression is that MWI only started to get significant exposure with the DeWitt/Graham book published by Princeton in 1973. This was right around the time I started reading about quantum mechanics, and it's not the sort of volume I would have found accessible, I was more reading things from philosophers of science. So, it's quite possible MWI isn't mentioned just because I'd never heard of it.

In terms of the "has there been progress in the interpretation of QM since 1976" question, the fact that now such discussions often include a big dose of multiverse blathering doesn't really tip the scale in a positive direction.

13. **Blake Stacey**
March 29, 2019

The conventional view of historians and philosophers of QM is that Everett's ideas remained mostly obscure and un-discussed until the early 1970s. See, for example, Byrne's biography of Everett (informatively reviewed by Adrian Kent). I suspect that this picture is largely accurate, though looking in places they don't expect may turn up further discussions, and indirect evidence of conversations not written down. For example, Feynman presented an Everettian view in his 1963 lectures on gravitation, raising it as a possibility he took seriously but didn't find compelling. He seems to have filed it, along with the idea that somehow gravitation itself might be a breakdown of quantum mechanics, as conceptual speculation that isn't likely to be productive.

This Week's Hype

March 31, 2019
Categories: This Week's Hype

This week's hype comes to us courtesy of Scientific American, which, based on this preprint, tells us: Found: A Quadrillion Ways for String Theory to Make Our Universe.

As usual in these things, the only physicists quoted are the authors of the article, as well as some others (Cumrun Vafa and Washington Taylor) who are enthusiastic about the prospects for getting the Standard Model out of "F-theory". No one skeptical of the idea of F-theory compactifications of string theory (such theorists would not be hard to find…) seems to have been consulted. If such a person had been consulted, he or she might have pointed out:

- Models like this have been around for over two decades, see for instance this from 23 years ago.
- They have always come with claims that some sort of connection to experiment was right around the corner. A decade ago there were papers like this one (and promotional pieces like this one) explaining F-theory "predictions" for what would be seen at the LHC, "predictions" that never worked out.
- This new work doesn't even bother trying to make "predictions". It just works backwards, trying to match the crudest aspects of Standard Model, ones determined by a small set of small integers. Given the huge complexity and number of choices of these F-theory constructions, that some number of them would match this set of small integers is not even slightly surprising.
- The authors seem to argue that it's a wonderful thing that they have found quadrillions of complicated constructions with this kind of crude match to the SM. The problem is that you don't want quadrillions of these things: the more you find, the less predictive the setup becomes. What's being promoted here is a calculation that not only predicts nothing, but provides evidence that this kind of thing can't ever predict anything. A peculiar sort of progress…

Update: This hype has now been supplemented by the now common phenomenon among string theorists of having their university's press office put something out promoting string theory. This time it's the University of Pennsylvania, with a headline assuring us that their university's physicists are Making sense of string theory, with a discovery that "might change the course of the field."

Comments

1. **PeterH**
   March 31, 2019

   The paper is actually about the construction of a quadrillion chiral Minimal Supersymmetric Standard Models for which there is no evidence. Nothing really said about the SUSY partners just a hope that some models have a high SUSY breaking scale to avoid proton decay lifetime experimental lower bound. The title of the paper is hype and mis-leading.

2. **anon**
   March 31, 2019

   This seems like a somewhat mean blog post. The erticle is an unhyped description of a calculation that is not quite routine, but certainly no breakthrough; the physicists involved seem to be claiming nothing other than being part of the conversation of modern physics — providing useful and reassuring data for their colleagues to make more insightful discoveries.
   .
   And the basic question is profound and needs answering: What is special about the standard model, a very particular gauge theory on a very particular space — when all of the *mathematical* insights of the last 35-40 years of hepth/math conjecturally construct a web of dualities that relate all QFTs, of dimensions less than something small (but bigger than 4!)
   .
   'String theory' obviously makes no physical predictions yet, and you have
   been an important voice in disseminating that unpleasant truth. The
   flip side of that — that in various ways it includes the standard model,
   and that we cannot claim to understand the latter without
   understanding what `string theory' is, and what these equivalences are
   — and we do not. And we need to.
   .
   (For a description of an even more basic lack of collective understanding, you should go to Heselholts' talk on Wednesday — his lovely line is that mathematicians do not yet understand what a number is; see for example
   https://www.newton.ac.uk/seminar/20181008160017001
   for a pleasing description, aimed a little at homotopy theorists.)
   .
   This blog post does not engage in the anti-intellectual foolishness of pretending that string theory is nonsense, but it does seem _mean_ to a harmless paper.

3. **David Roberts**
   March 31, 2019

   @anon Thanks for that link to that talk from October. It's a cute line, that the integers are not the real base ring for homotopically enriched algebra, but the sphere spectrum S. Just as the natural numbers are the decategorification of the 1-category of finite sets, the integers are the connected components of S. Connes of course is also promoting this idea in his current approach to the Riemann hypothesis. Describing it as mathematicians not understanding what a number is is missing the joke 🙂 It's better to say we don't fully understand the collection of numbers with their arithmetic (and number theorists would agree on that, I think)

4. **Peter Woit**
   March 31, 2019

   anon,
   I don't think I'm being "mean" to the paper, would have just ignored it if Scientific American wasn't publishing an extremely misleading article about it. The string theory hype problem in the popular science press remains a well-entrenched one.

   I'm looking forward to the Hesselholt talk on Wednesday. For those interested, see
   http://www.math.columbia.edu/2019/03/27/spring-2019-kolchin-lecture/

5. **Sabine Hossenfelder**
   April 1, 2019

Hi Peter,

As PeterH points out in a comment above, the paper is not about the standard model (or standard models) but about the MSSM. And it's not all that clear you even get the standard model out at low energies because, as the authors write themselves (p 5):

"[T]his in turn also implies that certain proton decay operators compatible with the Standard Model gauge group will in general be present… We expect that in some corners of the moduli space, which incidentally could also support high-scale SUSY breaking, these operators can be suppressed."

Which basically means they don't know whether they would actually get anything resembling the standard model. (This is not to say that I doubt it can be done, just pointing out it's not in the paper.)

I surely hope that whoever reviews this paper requires that the title be changed.

6. **chorasimilarity**
April 1, 2019

From the reading of the e-print, the authors *give evidence* for the existence of many models which satisfy *necessary* conditions of compatibility with MSSM. I can't evaluate the hype, the article is a math proof with some parts which are not rigorous. Not read: the Scientific American popularization.

7. **Reg Taylor**
April 1, 2019

@Peter,
Perhaps a little unfair to Anil? He does say clearly in the SA article:
"the work assumes supersymmetry… String theory needs this symmetry in order to ensure the mathematical consistency of solutions"
"experiments at the Large Hadron Collider (LHC) have … yet to find any supersymmetric particles"
"Vafa and Taylor both caution that these solutions are far from matching perfectly with the standard model"
etc.
I'm not convinced that statements like this are 'hype'. More along the lines "we've found something interesting in the maths and it's worth a further look".

That said I'm with Sabine, the title of the Cvetic et al. paper is misleading, the authors themselves referring explicitly in the introduction to "exact chiral particle spectrum of the minimally supersymmetric StandardModel (MSSM)".

8. **Moyses**
April 2, 2019

It is too dated to ignore that since the early 2000's string phenomenologists are really: "Getting just the Standard Model at Intersecting Branes" (https://arxiv.org/abs/hep-th/0105155).
But I still found no pop-sci book mentioning this fact, that is dreadful!

Not Even Wrong 2.0

March 31, 2019
Categories: Uncategorized

This blog has just passed its 15th anniversary, and there hasn't been a lot of change in format since the first postings in March 2004 (there hasn't been a lot of change in string theory either, but that's a different topic…). I've been hearing a lot in recent years from people who have urged me to update the format of the blog, moving to formats more in tune with the way people now use the internet. One innovation in recent years has been that the blog content is available through Apple News.

I've decided to follow some more of the advice I have been getting, and have started up a [Not Even Wrong Facebook site](). No longer will you have to navigate to my WordPress site to access the blog content, instead it will be available the same way most people are now getting their news, through your Facebook News Feed. This will make it much more convenient for everyone to get notified about new posts and share these with others. I'm looking forward to the expanded readership and connections to the rest of the world that becoming part of the Facebook information eco-system will provide.

Update: Just unblocked a lot of comments that somehow were stuck in a moderation queue. Some people don't seem to understand that for an international blog like this, the date is best calculated according to UTC.

The uniformly hostile response here to the Facebook idea has been extremely reassuring. No, I don't intend to move the blog to Facebook. The fact that a sizable fraction of the US population in recent years has been getting its news off their Facebook News Feed seems to be one of the main factors in the 2016 collapse of democracy here, and the same thing is happening all over the world. This has also significantly moved along the ongoing destruction of the economic viability of conventional journalism. Going through the exercise of putting up a Facebook site made me aware of some aspects of how Facebook works I'd never realized. For example, on a Facebook post you can only hyperlink text to other Facebook material, not to the outside world.

It has become all too clear just how ugly the world created by Facebook is, that it is a sociopathic organization, and a danger to a healthy democracy. If you must stay in contact with friends and family this way, avoid any engagement with anything else on the Facebook site. Best would be to delete your Facebook account, now.

Update: For a book-length explanation of why you should be concerned about Facebook, see Roger McNamee's *Zucked*, reviewed here.

Comments

1. **Ian Mason**
   March 31, 2019

   I am hoping this is an early April fool's joke.

   People are fleeing Facebook like it was the plague.

2. **Casey Leedom**
   April 1, 2019

   Please do keep this old format! I've deleted my Facebook account so I don't have access to material there. (And I wouldn't go there even if it were available without a Facebook account.)

3. **Frank Quednau**
   April 1, 2019

   Interesting advice – medium is a place many people use to amplify their reach, as facebook struggles to reach younger people and those disillusioned with what the web has become.
   Here's hoping that your blog will stay because that was the real thing all along 🙂

4. **Matt Grayson**
   April 1, 2019

   Peter,
   Please don't abandon this site! Your blog is one of the best, and I can't be the only person who dropped FB and refuses to visit it.

5. **milkshake**
   April 1, 2019

   not everyone likes to use Facebook, they have absolutely atrocious privacy-violating business model.

   By the way, the format of Not Even Wrong is fine as it is. Making it more flashy could only add a web page bloat.

6. **4/1**
   April 1, 2019

   April Fools! You almost had me there, but that last sentence rather gave the game away.

7. **momerathe**
   April 1, 2019

   I hope you will continue to post here in parallel – I've sworn off Facebook and have it blocked on all my devices. Plus, this site is integrated with my RSS feed-reader, while Facebook makes it extremely difficult to do so.

8. **Chris Oakley**
   April 1, 2019

   The range of single-click responses in Facebook needs to be extended for the purpose.

   "Like", "Love", "Haha", "Wow", "Sad" and "Angry" do not cover it.

We need to ask also for: “Give me a break!”, “You’re a crackpot”, “Yeah, alright (I am tired of arguing)”, “So what?” and “See my web site/scientific papers”

9. **Peter Donnelly**
April 1, 2019

Are you going to keep the blog? I’m not on FB and don’t want to be.

10. **GVFool**
April 1, 2019

Everyone has a browser but not everyone is using facebook.

Time to start a new movement: #youtoo

11. **Jude Giampaolo**
April 1, 2019

I am hoping this is just a 1st April joke as I enjoy reading via RSS and won’t be able to follow nearly as regularly on Facebook.

12. **Ghost Bird**
April 1, 2019

I hope you will continue to post your content here as well, so that those of us who dislike Facebook (probably more malevolent than String Theory all things considered), can continue to read!

13. **Chris Herzog**
April 1, 2019

I gave up my Facebook account, shortly after the 2016 US election. I hope you will continue to post here in parallel.

14. **Balazs Vagvolgyi**
April 1, 2019

Please don’t switch to Facebook. I canceled my account years ago, I’m sick of it and refuse to visit it. I don’t know where you are getting your advice from, but in my circle of adult friends and colleagues, people are abandoning Facebook in droves.

15. **Mathematician and Fan**
April 1, 2019

April Fools?

16. **Trailmut**
April 1, 2019

Disappointed about your engagement with Facebook. I think this institution is one of the symptoms of the “disease” within our society and our culture.

17. **koala**
April 1, 2019

Yes please no Facebookization

18. **Dan Winslow**
April 1, 2019

I would prefer that this blog remains as it is. I don’t ever use Facebook, or any social media, and I find the clean presentation and simplicity of this blog’s format to be very comfortable and a refreshing change from the ‘improved’ internet formats.

19. **Chuck**
April 1, 2019

April Fools?

20. **GG**
April 1, 2019

Completely agree with the comments so far, but I wonder whether in some other timezone, the date of the post might be different?

21. **Martin Kovar**
April 1, 2019

I hope this was a joke related to April Fool’s Day.

22. **scrat**
April 1, 2019

I can’t shake the feeling the the post date for this should have been today… ^^

23. **Peter Schlaifer**
April 1, 2019

Let me add my small voice to the chorus asking you to continue the existing newsreader format and support.

24. **Ehud**
April 1, 2019

Hopefully an April's fool post.

25. **SteveB**
April 1, 2019

Hmmm. I read this on April 1.

26. **Curious**
April 1, 2019

Commenters, please check the date.

27. **F4**
April 1, 2019

This decision is unexpected and disappointing, even if posts continue to appear on this site in parallel. Trailmut's characterization of Facebook as an etiological factor of social disease (freeing that term here of those mitigating quotation marks) is likely not inaccurate.

Though this post is dated March 31, 2019 (9:51 PM). Hopefully it is in fact only an early joke intended for the following day.

28. **pierreauquebec**
April 1, 2019

April 1st ?

29. **Jon Forrest**
April 1, 2019

Is this an April Fools joke?

I join with all the others who ask that you not drop this site. Post in parallel, if you must, but there's too much on Facebook that's Not Even Wrong as it is.

30. **a reader**
April 1, 2019

Please keep it up and running here — if you can. I left Facebook two years ago — no regrets whatsoever. By the way… How are you going to police comments on Facebook?
"Informed comments relevant to the posting are very welcome and strongly encouraged. Comments that just add noise and/or hostility are not. Off-topic comments better be interesting…"
…On Facebook?

31. **Anders Bengtsson**
April 1, 2019

I agree we all the above. Don't go Facebook. Nothing is gained. It's a pleasure to read blogs like this one, not having to be interupted by silly AI-s who think they know what you want.

Second thoughts: is this an April's fools joke?

32. **jls**
April 1, 2019

(friends, check the date)

33. **pquant**
April 1, 2019

A facebook post once a year would be fine, I guess.

34. **Visitor**
April 1, 2019

And I thought that I was the only one…

35. **anonymous**
April 1, 2019

Also not on FB, and probably never will be, and I'm hoping you'll continue with this "old" format.

36. **Marty**
April 1, 2019

I hope this posting is an April Fool's joke posted on March 31 by mistake. I can't imagine that Facebook's ideals, past issues with fake news and other questionable content, its likely role in helping to elect Donald Trump, massive personal data collection in the name of more profitable advertising, etc. are particularly compatible with your own ideals. In the past, I also haven't noticed you being especially preoccupied with massively expanding your readership…

Anyway, assuming this posting is tongue-in-cheek, it gets a chuckle from me. It it's not a joke, uh oh… Like many others, I rarely visit FB and have never left a comment there.

37. **AcademicLurker**
April 1, 2019

As another long time reader who won't touch facebook with a 20 foot pole, I'll just add my voice to the chorus hoping that you'll keep this site going and not migrate to FB entirely.

38. **Steve Huntsman**
April 1, 2019

Excellent choice of material for today

39. **JE**
April 1, 2019

Thank goodness it's April 1. Almost bit it!

40. **Ken Martin**
April 1, 2019

Ditto to all the comments regarding not being on Facebook.

41. **Steven Docker**
April 1, 2019

Please tell me this is an April fools joke …

42. **markk**
April 1, 2019

Also a non-Facebook user. I will miss this blog if it is only available there.

43. **markk**
April 1, 2019

Ok , now I will leave my April Fools comment… except I don't have one. I have been ground down by the bastards but am still able to stand…

44. **WP**
April 1, 2019

Is it an April Fools' joke?

45. **M. de Lange**
April 1, 2019

Dear Peter,

Please keep the format as it is.

46. **Matthew**
April 1, 2019

The date at the top is supposed to be 1/April, surely!

I notice that if you don't have a facebook account, and scroll down to look at old posts, it blocks you after you've scrolled past the top (most recent) 3 or 4 posts. Not helpful.

I think the existing site could do with a make-over – it doesn't display well on mobile devices with a small screen, for example, but FB is not the way to achieve that.

47. **Theodore String**
April 1, 2019

Mr Woit,

This is the best one I read on this fine day.

Well done sir, well done, indeed.

48. **Bruno**
April 1, 2019

Am I the only one to think this post was delivered just a bit in advance ?

49. **Art**
April 1, 2019

Gee, on 1 April…

50. **Alexis**
April 1, 2019

Happy April fool's day!

51. **John Merryman.**
April 1, 2019

Not alot of fb fans here. Given the herd mentality it encourages, that might not be the additional audience you want.

52. **otto porter**
April 1, 2019

Like the others, no facebook for me.

I’ve been reading your blog since the beginning.

Please don’t change it.

53. **Kuas**
April 1, 2019

When I first saw this I thought April Fools, but the post date is one day off. I hope it’s April Fools.

54. **Walt Donovan**
April 1, 2019

It’s your blog, of course. I just hope you will keep the WordPress version active, and just feed Facebook or whatever from it.

55. **tulpoeid**
April 1, 2019

It’s nice that the original post has no mention of abandoning the blog, but the mere thought seems to terrify people :)
Imho Facebook is a real boon for humankind, it’s no worse than any other service in terms of privacy, and it has exactly zero relation with unlikeable election results. I’m very serious. Countless lives have been changed by it for the better in ways we never anticipated (and which we now take for granted).

But, back to physics, what would your take be on the latest notorious results?
https://www.reddit.com/r/ParticlePhysics/comments/b83ab6/regarding_the_recent_discovery_by_lhc_experiments/

56. **Peter Orland**
April 1, 2019

Hey commenters!

I suspect Peter is pulling an April Fools’ joke here.

Am I wrong? I hope I’m not wrong.

57. **Ghost Bird**
April 1, 2019

Wow, you got us. Congratulations, this was pitch-perfect.

58. **WTW**
April 1, 2019

FWIW, I have blocked Facebook URLs on all of my computers and those in my organization – laptop, desktop, mobile. If you move exclusively to Facebook, I will have to drop your blog. Consider your decision to move to Facebook at all a bad, possibly ill-informed one.

59. **Low Math, Meekly Interacting**
April 1, 2019

Hope the WordPress site mirrors the FB one, but understand that it may not be feasible. I also dropped FB, and don’t plan to go back. Best wishes!

60. **Kevin S. Van Horn**
April 1, 2019

I had to check the date on the post to make sure it wasn’t an April Fool’s joke. I find the blog’s current format to work just fine for me.

61. **Jay Sanders**
April 1, 2019

Facebook is blocked in the systems I use. Have you Facebook page, if you must, but, please, keep this blog going here, as it currently is.

62. **Bob**
April 1, 2019

Maybe this is Peter’s idea of an April Fool’s joke?

63. **Paul**
April 1, 2019

Like many, I’d prefer to continue to read your blog here.

64. **Fool**
April 1, 2019

April 1?

65. **Bernhard**
April 1, 2019

Hi Peter,

I hope you’re not saying the blog will now only be available through social media…

The blog is perfect as it is. I’m old school… please don’t make me join Facebook.

66. **Anon**
April 1, 2019

Perhaps Peter could only post here once a year, say on this particular date, April 1.

67. **Patrick Harris**
April 1, 2019

I realize the date is off by 1, but is there any relevance of the notorious start of April corresponding with this post…?

68. **Bernhard**
April 1, 2019

Wait a sec – April Fools? (really hoping 😀)

69. **raskra**
April 1, 2019

I hope this is an April Fool's joke…

70. **Spring chicken**
April 1, 2019

Amazing that this comment thread is still going, it might last longer than a particular day.

71. **theoreticalminimum**
April 1, 2019

I can hardly imagine you moderating or even paying attention to comments on FB, so I'd take this as an April Fools' day post, and I hereby conjecture that the FB page will be gone in no time 🙂

72. **NO FB**
April 1, 2019

FaceBook is crap. Please do keep the WordPress format. Thank you

73. **Max Madera**
April 1, 2019

Come on guys, don't you know which date is today?

74. **Not a fool**
April 1, 2019

Early April Fools' ?

75. **Andras Laszlo**
April 1, 2019

I would suggest not to move to Facebook. It does not only have its sociological / ethical downsides, but is simply inergonomic in my oppinion for practical usage. Best, Andras

76. **Zaaikort**
April 1, 2019

Haha, you almost fooled me!
You would never seriously consider joining Facebook, would you?
… Err … oops

77. **IA**
April 1, 2019

Guys, relax, its just April's fool joke.

78. **Reg Taylor**
April 1, 2019

You refer to wordpress as though it's a backwoods village buried in the deepest recesses of some impenetrable jungle. I've a single bookmark set up on the browser that takes me straight to your most recent wordpress blog entry. Just one click – how easy can it be? Like others making comments I would much prefer your blog and format to stay as it is, quick to access, visually clear and very readable. Not sure if this would be the same on facebook as I'm not terribly familiar with the system but from my limited experience I suspect not.

79. **jk47**
April 1, 2019

deleted my facebook account long ago when it became clear that they did not respect my privacy settings. i hope you keep this site.

80. **David**
April 1, 2019

Long-time reader here, and I even bought your Representations book. However, I won't follow you to Facebook. I refuse to use it, for political and ethical reasons.

81. **NoGo**
April 1, 2019

I am another devoted reader who really hopes this is an April 1 joke…
or at least that you would maintain this site in parallel.

I am not one who has no Facebook account, but I rarely use it and only to contact freinds and family, not to read news etc. Apart from all other issues, I find FB look/design horrible from both aesthetics and functionality points of view…

82. **Paul Schubert**
    April 1, 2019

    Please. Not. Facebook.

83. **bertie**
    April 1, 2019

    Have loved the blog for many years but dont visit facebook.
    Perhaps (I hope) the last post was an April fools joke….

84. **Foolish theorist**
    April 1, 2019

    What a fool… are you being threatened by the string theory mob?

85. **CormacinDublin**
    April 1, 2019

    Hi Peter
    A good April fool! – Will you post this comment?

    Although the timestamp is from yesterday however, was it only released this morning?

    Regards

86. **Richard Townsend**
    April 1, 2019

    Peter, please keep the WordPress site alongside Facebook. Like many, I am ex-user of Facebook!

87. **Oldster**
    April 1, 2019

    I hope this is an April Fool's joke. Facebook might even decide some of your posts, or reader comments, "Violate community standards." Then what?

88. **Jeff**
    April 1, 2019

    I was being shocked by the facebook thing news: how could a blog mocking hype move to facebook?! … and then I noticed the date of the posting 😉

89. **Anonymous**
    April 1, 2019

    Great April Fools Day post. Really got a rise out of the readers.

    At least I hope it is.

90. **Tom Dickens**
    April 1, 2019

    It's April 1, right?

91. **Woitreading nerd**
    April 1, 2019

    Please stay independent. I would like to continue reading your blog, but there is no way I am going to allow facebook crap on my system. I am blocking all their URLs.

    Had you just posted this one day later I would not be so worried about it …

92. **LD**
    April 1, 2019

    38 April fools?

93. **Gautam Menon**
    April 1, 2019

    And there I was, thinking this was an April Fool's day joke!

94. **mark thompson**
    April 1, 2019

    please keep the blog as it is, even if you try FP for a while

95. **godelta**
    April 1, 2019

    As a long time reader and fellow Facebook-phobe I just want to add:

Nicely done!

Had me sweating as well for a little while till I wised up.

96. **kodlu**
April 1, 2019

I love the blog as it is. No facebook please, I shan't join, and would really miss your wonderful blog.

97. **Ron**
April 1, 2019

Whoosh!

98. **Low Math, Meekly Interacting**
April 1, 2019

I just realized Peter is laughing his ass off right now. Well played, sir. Well played.

99. **Sir Lleb**
April 1, 2019

I'd rather you went back to blogging about New York, Biking, Desserts, or even, gulp, politics…

—
Long time lurker

100. **paul from tacoma**
April 1, 2019

Peter – please don't do this. I echo the reasons given.

But this is an April fools joke, right?

101. **Trailmut**
April 1, 2019

If this is an April Fool's joke, good and fine; but I'm not so sure it is that funny considering that some other good and smart people have been seduced by Facebook and a lot of us loyal readers felt worried.

102. **John Fredsted**
April 2, 2019

Very happy to read that I am not the only one opposed to Facebook (personally, I have never had any account there). As for other socalled social media, Facebook's business model seems to revolve around the idea of turning modern mans apparently ever increasing narcissistic tendency – see me, see me, see me! – into a money machine. I think it is a disaster for the human spirit that so many people spend so much time on that platform, for it keeps nurturing something that should not be nurtured.

103. **Visitor**
April 2, 2019

What changed your attitude from

> "I'm looking forward to the expanded readership and connections to the rest of the world that becoming part of the Facebook information eco-system will provide"

to

> "It has become all too clear just how ugly the world created by Facebook is, that it is a sociopathic organization, and a danger to a healthy democracy. If you must stay in contact with friends and family this way, avoid any engagement with anything else on the Facebook site. Best would be to delete your Facebook account, now."

… because Facebook's hyperlink policy hardly seems to be an adequate explanation for this kind of complete reversal.

104. **Peter Woit**
April 2, 2019

Visitor,

April 1 turned into April 2.

105. **Chris Oakley**
April 2, 2019

As usual I seem to be a $\mu+2\sigma$ outlier, but I have to say that I like Facebook – it is a nice casual way of keeping in touch with people you hardly ever see. It is also a good source of jokes, and, thanks to the targeted ads I got to meet Terry Jones (of Monty Python) about 10 years ago – he even bought me a drink! As for those individuals who are sufficiently weak-minded to believe a lot of the stupid crap that gets posted on it, well, more fool them: if it was not Facebook, it would be something else (e.g. Fox News). I do agree, though, that it is not a suitable forum for scientific debate as the format tends to encourage knee-jerk, emoticon-based responses rather than considered ones.

106. **unhappy vonnesline**
April 2, 2019

Great April fools…totally got me

107. **tulpoeid**

April 2, 2019

For the record, completely agreeing with Chris Oakley. My previous comment supporting facebook is honest although I was guessing the date-related background.
For the sake of discussion: facebook is not worse than other online media and in many cases and ways it's better; sadly, Trump was elected because of his personality and this is what we have to accept and fight. More importantly, I have ~500 "friends" from three continents (whom I all know personally) and maybe only a couple of them abandoned their account because of the last few years' events, so I'm made to think that it's worth considering whether the overreaction in US might be related to "traditional" media turning hostile towards facebook out of purely competitive reasons.
(Congratulations for the patience needed to put up an actual page, though.)

108. **a reader**
April 2, 2019

You got most of us! Well, that was a memorable April's Fool.
"Never get high on your own supply" (The Guardian, 23.01.2018)

109. **John**
April 2, 2019

I am against Facebook and never had an account or went there. But here uou are a scientist and make the following claim:
"The fact that a sizable fraction of the US population in recent years has been getting its news off their Facebook News Feed seems to be one of the main factors in the 2016 collapse of democracy here"

All without any real proof. This claim is almost as bad as the multi-verse. Facebook "news" is mostly left leaning. There are even claims being investigated that conservative news is blocked by Facebook and people working at Facebook, including Mark Z have admitted to some of that. The election's outcome didn't happen because of some dumb ads or "news" on Facebook.

110. **Peter Woit**
April 2, 2019

tulpoeid,
Yes, "traditional" journalists don't like Facebook because it is putting them out business. If you don't like "traditional" journalism, you may be fine with that. But I think we're now seeing what happens when you destroy "traditional" journalism and all that's left is Fox News, Russia Today, Buzzfeed, together with Facebook as a portal to share these and other sites of "journalists" who do nothing but write about whether Joe Biden smelled some woman's hair. I just don't see how you have a viable democracy when people's main source of info about the world is an information sewer.

tulpoeid/John,
The reason Trump won was not that lots of people liked Trump, but that everyone hated Hillary Clinton and thought she was more dishonest than Trump. Why did everyone feel this way about Clinton? Because of what they read on Facebook is one sizable reason. And the garbage they were reading about Clinton did not just come from the Right and the Russians, but also from the Left.

All,
I better call an end to the discussion of the implications of Facebook for our democracy. I was conducting a bit of an experiment here to see whether trying to put out news about math and physics on Facebook was something that anyone thought might be a good idea. The results were conclusive on that front.

111. **jk_in_nc**
April 4, 2019

Thanks for calling a halt to the Facebook discussion… although I am glad to see which way a science-prone crowd leans.

When I saw your original post, I decided against the April-fool idea because a March 31 date was listed, without a time imprint. Curiously, none of your posts have a time inprint, only a date one. However, all of the comment posts have a time (and date) imprint.
Wondering why that is.

112. **Peter Woit**
April 4, 2019

jk_in_nc,

The way time-stamps appear is just the WordPress default behavior, perhaps specific to the (standard) theme I'm using. It would be better if posts (and my "Updates") were time-stamped, but after some poking around I haven't found an easy way to do this, without adding some custom code.

113. **Andrew Bernatd**
April 5, 2019

Not Even Funny. 🙂 Facebook is such a miserable thing. I was worried for a minute or two!

114. **F4**
April 6, 2019

"It would be better if posts (and my "Updates") were time-stamped, but after some poking around I haven't found an easy way to do this, without adding some custom code."

The timestamps are not printed alongside the date but they are in the tooltip that appears uponon hovering over the date link.

Regarding updates, by the way: appending them to existing posts isn't ideal as they can easily be missed if the reader happens to not regularly revisit recent posts. Generating an entirely new post instead may seem unnecessary but it results in a cleaner presentation and historical record.

115. **Peter Woit**
April 6, 2019

F4,
Thanks for explaining how to see the timestamps.

One thing I'm looking into is whether there's some way to change the rss behavior so that feed readers such as feedly will notify of an updated post.

116. **Visitor**
April 21, 2019

So, if I understand you correctly, this was an April Fool's prank. And it required you to code a page for Facebook because I have no idea why. And oh by the way you were "conducting a bit of an experiment here to see whether trying to put out news about math and physics on Facebook was something that anyone thought might be a good idea" and you wanted this information because you were not going to actually act on this information once obtained.

This is not really credible.

As we all know, "The first principle is that you must not fool yourself – and you're the easiest person to fool". Apparently, when he said "you" he meant *you*.

Why Trust a Theory?

April 5, 2019
Categories: Book Reviews

I noticed today that Cambridge University Press has recently published *Why Trust a Theory?*, a volume of articles based on a December 2015 conference held in Munich. The book is available online here (if your university is paying for it…), and preprint versions of many of the contributions are on the arXiv.

The conference had its origins in a piece published a year earlier in Nature by George Ellis and Joe Silk, entitled Scientific method: Defend the integrity of physics. Ellis and Silk made a forceful case that widely advertised but inherently untestable string theory and multiverse research does damage to the public understanding of science and is a threat to the credibility of science at a time it is under attack. The piece suggested:

> A conference should be convened next year to take the first steps. People from both sides of the testability debate must be involved.

Looking through the proceedings volume, there's lots of abstract discussion of philosophy of science and some diversity of points of view on the multiverse. When it comes to string theory though, the organizers interpreted "people on both sides" to mean bringing in one person willing to point out that there is a problem with string theory, and an army of string theorists to defend the theory. On the issue of the problems of string theory, the volume contains nearly 100 pages of pro-string theory hype, from Polchinski (two contributions), Silverstein, Kane and Quevedo. As usual with Kane, there's a string theory "prediction" of the gluino mass (1.5 TeV +/- 10-15%) which has already been falsified. All I could find on the side of substantive criticism of string theory was in Carlo Rovelli's contribution (preprint version here), and mainly in a single paragraph:

> String theory is a living proof of the dangers of excessive reliance on non-empirical arguments. It raised great expectations thirty years ago, promising to compute all the parameters of the Standard Model from first principles, to derive from first principles its symmetry group SU(3)×SU(2)×U(1) and the existence of its three families of elementary particles, to predict the sign and the value of the cosmological constant, to predict novel observable physics, to understand the ultimate fate of black holes, and to offer a unique, well-founded unified theory of everything. Nothing of this has come true. String theorists, instead, have predicted a negative cosmological constant, deviations from Newton's 1/r^2 law at sub-millimeters scale, black holes at the European Organization for Nuclear Research(CERN), low-energy super-symmetric particles, and more. All this was false. Still, Joe Polchinski, a prominent string theorist, writes that he evaluates the Bayesian probability of string to be correct at 98.5% (!). This is clearly nonsense.

I won't spend more time here discussing the conference and the articles in this volume, mainly because I've already written a lot about this in previous posts. For a contemporaneous discussion of the conference and Polchinski's String Theory to the Rescue paper, see here and here. There are also interesting blog posts about the conference from Massimo Pigliucci, see here, here and here, and a Quanta piece by Natalie Wolchover here. For a discussion of Sean Carroll's Beyond Falsifiability contribution, see here (and discussion here and here). For a discussion of Eva Silverstein's contribution, see here.

Update: A few more links to material about the Munich conference: Jim Baggott here and here, Andrew Gelman here, Davide Castelvecchi here, and the conference website (with videos) here.

Update: Looking at the Preface, I notice that the editors claim:

> Additional contributions were solicited by the editors with the aim of ensuring as full and balanced presentation as possible of the various positions in the debate.

With regards to string theory, the one additional contribution in the volume is from string theorist Eva Silverstein, so evidently the editors felt that balance required yet more on the pro-string theory side….

Update: I mischaracterized Polchinski's calculation of the probability that string theory is correct as 98.5%. More accurately, he claims that the probability is "over 3 sigma" (i.e. over 99.73%).

Update: I finally got around to watching the videos of the panel discussions at the workshop (all videos available here). What most struck me about these discussions was the heavily dominant role of David Gross, who was on two of three panels, participating from the audience in the third. On the panels he was on, Gross was speaking far more than anyone else, and rarely if at all would anyone disagree with him. Gross's point of view is that there is a testability problem with the multiverse, but all is well with string theory (although probably not at Polchinski's "over 99.73% sure to be true" level). He's a powerful intellect and a forceful speaker, so it's not surprising that no one would take him on. But on the topic of string theory I think there are very serious problems with many of the claims he makes (for his arguments of 15 years ago, see the first substantive post of this blog), and the organizers should have found someone willing to challenge him on those.

Comments

1. **Sabine Hossenfelder**
   April 5, 2019

   Allow me to mention that I declined writing a contribution because at the time I was writing my book & felt the overlap would be too large. With my contribution missing, the balance of the proceedings shifts somewhat towards string theory. Though I am more critical of Richard Dawid's defense of string theory than of string theory itself.

2. **Jim Baggott**
   April 5, 2019

   And my take in the conference can be found here: http://www.jimbaggott.com/articles/status-anxiety-all-theories-are-not-the-same/

3. **Peter Woit**
   April 5, 2019

   Thanks Jim and Sabine,

   I've added a few more links to the post, including Jim's.

   I do still wonder though how the organizers of this conference and volume would justify the heavily one-sided nature of what they produced. Was it really impossible to find anyone other than Rovelli willing to write about the problems with string theory?

   By the way, I was looking for an excuse to mention Sabine Hossenfelder's talks nearby next week, she'll be giving multiple talks at Brookhaven on April 9, and a talk at Yale on April 10.

4. **Petite Kabylie**

April 6, 2019

Dear Peter
In my opinion, the fact that Lee Smolin and you Peter, who were the first to have seriously and brilliantly raised the issue with your books, have not been invited to contribute says it all.
I just wonder whether you Peter (and Lee Smolin) would have accepted to give a talk at the conference if they had invited you.
Thanks

5. **Peter Woit**
April 6, 2019

Petite Kabylie,
I believe Lee Smolin was invited to give a talk but declined. I would have participated if invited.

6. **Lee Smolin**
April 6, 2019

Dear PK,

Peter is right, I was invited and was unable to go in the end. I was just looking at my correspondence with the organizers and, while I don't want to quote email without permission, they indicated that they were looking for a single person to represent the "LQG point of view." What I have to say about Richard Dawid's book was contained in a review of it I wrote earlier. In short, I argued that the 3 non-empirical criteria he gives for taking a theory seriously could be applied equally as well to LQG as they could to string theory, which shows that they are ambiguous and of no help when we are faced with choosing between competing research programs.

This is why I argue that when there are two or more competing research programs, each of which has non-trivial results that offer considerable, but not decisive evidence for their being the truth, we have to support them all, and also leave room for new hypotheses and research programs. This is argued in detail in Chapter 17 of TTWP.

Thanks,

Lee

7. **shantanu**
April 7, 2019

Peter, are the questions asked recorded in the proceedings?
Shantanu

8. **Peter Woit**
April 7, 2019

Shantanu,
I don't think there's anything in the Cambridge volume concerning the panel discussions or questions asked at the conference. There are videos of these online (I just took a quick look, but they didn't seem to be working now). The authors of the articles in the volume do an excellent job of not responding to the serious questions someone should have asked about the current state of string theory.

9. **James Gallagher**
April 7, 2019

Hi Peter

Suppose you were invited:

Would you just talk about the easy criticism of the current theories, or perhaps, suggest anything new yourself ? (not a theory (obviously) but a new approach to theory finding maybe?)

10. **Peter Woit**
April 7, 2019

James Gallagher,
The topic of the workshop was not a call for new theories or new approaches. It was supposed to provide a venue for "both sides of the testability debate" to present their views. At least as far as string theory is concerned, the organizers decided not to do that, but to have the discussion of string theory (especially in the Cambridge volume) consist just of string theorists defending string theory.

If I had been invited to the workshop or to contribute to the book, I would have tried to represent the otherwise unrepresented side of the debate.

11. **shantanu**
April 7, 2019

Sabine had some hard questions for David Gross after his talk. He mentioned 19 tests of falsification of string theory. I don't know if they are mentioned after the talk.

12. **Peter Woit**
April 7, 2019

shantanu,
I just checked the video of the Gross talk, it cuts off at the end of the talk, no questions from the audience included. Not surprising that Sabine was the one willing to challenge Gross, too bad she wasn't on the panels.

13. **Blake Stacey**
April 8, 2019

The "Popperazi" accusation particularly rankles, because by the time Karl Popper was about four years old, [William James had already skewered](#) the next-level vagueness we now see in multiversology:

> The more absolutistic philosophers dwell on so high a level of abstraction that they never even try to come down. The absolute mind which they offer us, the

mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below.

14. **shantanu**
April 9, 2019

Peter I looked at that post of yours regarding David Gross's talk. Do you know if the two string theory postdocs who attended that are still doing string theory?

15. **Peter Woit**
April 9, 2019

shantanu,
At this point I don't remember exactly who I had in mind. Most of the theory postdocs from that era, like any recent era, didn't end up staying in the field because of lack of jobs. This is true of both string theorists and non-string theorists.

It was interesting to go back and see what the situation was 15 year ago. My commentary then was
"Gross and others seem intent on ignoring the failures of string theory, desperately hoping that superpartners will pop out of the LHC, thereby providing at least some vindication of the train of reasoning that led to string theory. What will be interesting to see will be what Gross et. al. do when this doesn't happen. Will they drop string theory?"

Unfortunately we now know the answer, and it is clear that belief in string theory has become completely decoupled from any possibility of experimental test.

16. **Bernhard**
April 9, 2019

I sometimes think this string theory/multiverse story is best left alone. Whenever I'm in a conference where real physics results are discussed this stuff tends to be ignored and I star believing this group lives already in their own parallel universe.

But, whenever I give an outreach talk I remember again of the danger. A few months ago I gave a BSM talk for high school kids. At the end of the talk, they were a bit disappointed to know I was not going to talk about strings and the multiverse…

17. **Petite Kabylie**
April 10, 2019

Thank you Lee.
I am sure it would have been a historic conference if both you and Peter were there.

18. **tulpoeid**
April 10, 2019

The banner today is a nice touch.

19. **AcademicLurker**
April 10, 2019

tulpoeid: I was actually a bit alarmed to open this page and find myself looking into the Eye of Sauron…

20. **Geoffrey Dixon**
April 10, 2019

The older I get, the more Felliniesque do discussions of the frontiers of HEP seem. Surely they have always been so, but we tend to imbue things with more seriousness when young. "Known for his distinct style that blends fantasy and baroque images with earthiness, he is recognized as one of the greatest and most influential filmmakers of all time." He was a fan of vaudeville, of course, and I imagine were he alive today, and did he care at all about theoretical physics, he would have referred to it as HEV.

21. **Low Math, Meekly Interacting**
April 10, 2019

Stunning. Jean-Pierre Luminet's 40-year wait has ended.

22. **cedric bardot**
April 11, 2019

Why trust theory?
Because you can make consistent computations…
This is the message I can understand from Petr Horava in a panel discussion at the recent European workshop: Quantum Spacetime '19 Bratislava, 11-15 February 2019 (https://youtu.be/S_nvO4Kembw?t=3245)
"I think mathematically, on paper, String Theory is that [a kind of theory of quantum gravity as least as good as QED] because it allows you to calculate graviton-graviton scattering consistently, it has all kinds of beautiful properties that make you think this theory is in some technical sense UV complete and how much more you want to ask at a first stage?"
…
"Why the standard model?" comments Ali Chamseddine from the audience (https://youtu.be/S_nvO4Kembw?t=3459) who don't intend to attack string theory but want to emphasize the urge to learn the lessons gained from other fundamental interactions to address quantum gravity.

23. **Peter Woit**
April 11, 2019

cedric bardot,

This is just the usual argument that "OK string theory doesn't work as a unified theory, but at least it's a consistent theory of quantum gravity". This isn't actually true, since there is no non-perturbative theory (what is the amplitude for a black hole in the final state when you collide two gravitons?). The secondary dodge is "OK, all we have is an effective theory at low energies, but QED is just an effective theory at low energies". I long ago decided that trying to argue with the "string theory is exactly like QED" people is just a waste of time, no different than trying to argue with people who claim "black is white, since they are both shades of gray".

24. **Jim Given**

April 11, 2019

A “testability debate” is such an unusual occurrence in the history of the natural sciences. Where is there a precedent? Perhaps mid-1990’s attempts by Freudian analysts to re-assert the reality of Freudian theory against the barrage of attacks by senior scientists and philosophers that ended the 1980’s. But the discussion, by that time, had ended, except in the minds of true believers. (Something similar may have occurred with string theory.)
Really, “testability” like the earlier “falsifiability” seems not to be a good way to evaluate scientific theories. Rather, the test of a productive research program should be the interesting new experiments, and new discoveries in science motivated by efforts to test it. What would be recent examples in this category for string theory?

25. **Peter Woit**
April 11, 2019

Jim Given,
I agree that “is it testable” is too simplistic. A better criterion may be the Lakatos productive vs. degenerative one, and string theory unification is a classic example of a degenerative research program. Put differently, instead of asking how close string theory is to giving a unified theory (these days, string theorists seem happy with “maybe centuries away”), you should ask whether it is getting closer or farther. I think there’s no question the answer is “farther”: 30 years ago string theory was almost there, now it’s much, much farther.

This and That

April 16, 2019
Categories: Uncategorized

Since you've read about the black hole image elsewhere, here are a few other items that might be of interest:

- I was sorry to hear today of the death on April 11 of Geoffrey Chew. Throughout the 1960s, Chew's S-matrix/bootstrap philosophy was the dominant paradigm in high energy theory. It went into eclipse with the success of gauge theories in the early 1970s, but in recent years the (S-matrix) "amplitudes" program has to some degree revived it a bit, with hopes that it may be relevant to formulating quantum gravity.
- I thought the string wars were at times rather brutal, but it seems that they may have been a picnic compared to what astronomers get up to when there is a lot of money involved. See here for the bizarre story of what happened to Richard Easther when he started criticizing the plan for a New Zealand component of the Square Kilometer Array.
- For some recent and upcoming conference sites giving an idea of what is new in math and physics, Microsoft is hosting Physics Meets Machine Learning, the Eighth New England String Meeting had lots of interesting talks, hardly any strings to be seen, and MSRI last week hosted a "Hot Topics" workshop on Recent Progress in the Langlands Program.

For some news related to new books, there's:

- Lee Smolin has a new book out, Einstein's Unfinished Revolution, arguing that quantum mechanics is likely incomplete, since it continues to lack a successful "realist" version. He will be giving a public lecture about this at Perimeter tomorrow.
- John Baez advertises on Twitter a forthcoming volume about "New Spaces in Mathematics and Physics". For some of the content, see here. Also, the original conference these articles are based on has videos here.
- I'm looking forward to seeing Graham Farmelo's forthcoming The Universe Speaks in Numbers, about which I suspect there will be parts I'll strongly agree with, others about which I'll equally strongly disagree. The book evidently is based mainly on interviews, some of which Farmelo is putting up on his website. Jon Butterworth has a review this week in Nature, entitled A struggle for the soul of theoretical physics. He describes the Farmelo book as "a riposte" to critiques from a group I'm identified as being part of, but I have to keep pointing out that my point of view is not at all that the problem with string theory/supersymmetry has been "too much math". I think progress in fundamental physics is going to require more mathematics, not less.
- There's a new edition of the Kiritsis String theory in a Nutshell textbook available from Princeton. Looking at the introduction, I'm glad to see that Kiritsis points out the problem with the usual "string theory works, at the Planck scale" argument:

  > A big "hole" in string theory has been its perturbative (only) definition. With the advent of nonperturbative dualities, it was hoped that this shortcoming can be bypassed.Although the nonperturbative dualities have shed light in many obscure corners of string theory (obscured by strong-coupling physics), they never managed to bypass the Planck barrier. The Planck scale is always duality invariant, and any dual description is well defined for energies well below that Planck scale. We have no clue from string theory what happens near or above the Planck scale, as the relevant physics looks nonperturbative from any point of view.

  I've added this to this FAQ entry.

Comments

1. **zzz**
   April 16, 2019

   "there will be parts I'll strongly disagree with, others about which I'll equally strongly disagree."

   what about the other parts ?

   April 16, 2019

   zzz,
   Oops, that didn't come out right. Fixed.

3. **Urs Schreiber**
   April 16, 2019

   More pointers to contributions to the book project "New Spaces for Mathematics and Physics" are here.

4. **Sabine Hossenfelder**
   April 17, 2019

   The point of my book was also not to say that physicists use "too much math." I am saying they do not pay enough attention to math and instead believe their sense of beauty must somehow tell them what is right. I don't know what's controversial about pointing out that belief shouldn't replace evidence. Fact is, arguments from beauty have worked badly in the past and they still work badly.

   (But the WSJ review now makes sense^^.)

5. **Jim Baggott**
   April 17, 2019

   For what it's worth, my book 'Farewell to Reality' doesn't argue that there's 'too much math', either. Mathematics has proved to be an extremely powerful language in which to *represent* the empirical physics, and only an idiot would suggest we need less of it. However, it's a mistake to think that you can *conjure* physics from mathematics, especially when there are no empirical foundations for it. I've never been against theoretical physicists exploring mathematical possibilities, but whenever these same theorists then go on to declare that this *is* the way reality works, and advertise their theories as well-founded, then I get a bit cross and feel the need to call this out.

6. **Dom**
   April 17, 2019

I note that Butterworth's review ends with "The Universe might speak in numbers, but it uses empirical data to do so". I could be mistaken but from reading his blogs in The Guardian and elsewhere over the years I got the impression that as an experimentalist he is quietly sceptical of String Theory and Supersymmetry.

7. **Low Math, Meekly Interacting**
April 17, 2019

Hopefully this isn't too OT, but the banner switch makes it rather difficult keep my mind off the subject. That and we have reportedly fully entered the era of observational science in the strong field regime of GR, which does have something to say about certain HEP theories with astrophysical implications. Empiricism and all that…

What parts of the "parameter space" of theories that predict exotic stars and other alternatives to the standard-issue spinning BH has been chewed off by the EHT? My sense from reading the paper is that things officially already look pretty bad for certain alternatives. Not sure how threatened fuzzballs and gravastars and so forth might be, but presumably they will be facing some tension if GR keeps holding up too, if not already.

Might be an interesting phenomenon to watch: How flexible are these alternatives to GR such that they continue to "survive" by moving the goalposts to evade experimental constraints.

8. **Peter Woit**
April 17, 2019

LMMI,
I've changed the header to get your mind off the EHT picture. I didn't write anything about it here, because I'm the wrong person to discuss black holes: it's a huge industry now, full of people who are experts, and best to find one of them to discuss this with.

The current header is temporary, I still haven't come up with a plan for a new permanent one.

9. **Anonyrat**
April 17, 2019

If only your banner could evolve to "Right! Finally!"

10. **Peter Woit**
April 17, 2019

Anonyrat,
That would be boring…

I've finished playing with the header, at least for today.

11. **Chris Oakley**
April 18, 2019

I think that a good banner would be something that lists the equations of Superstring theory. Something like this: http://cgoakley.org/qft/sseq.jpg

12. **Atreat**
April 18, 2019

That article about the New Zealand astronomy battle is wowzers. Such bad behavior on the part of scientists.

Upshot, is that the guy writing the journalist accusing his peer of having mental health issues with absolutely zero factual basis has not apologized, will not apologize, his university still supports him and how does he justify his behavior…? He says that the other guy was not kind and was rude at a conference and did not adhere to professional standards of courtesy of being kind… so therefore it was appropriate to asperse him with claims of mental illness to a third party… or something.

13. **Peter Woit**
April 18, 2019

Atreat,
For the latest, see here

14. **Low Math, Meekly Interacting**
April 18, 2019

Chris Oakley…

A variant on one of Pauli's other devastating take-downs?

"This is to show the world that I can paint like Titian … Only technical details are missing."

15. **Peter Woit**
April 18, 2019

LMMI,
New header generated.

16. **ay**
April 22, 2019

So the new header(s) are some kind of easter egg? What does the Pauli note say?

17. **Peter Woit**
April 22, 2019

ay,

At the moment the header you get is a random choice of four possibilities. I'll likely change this again when I get time. The Pauli thing is a page of a letter to Gamow, that he encouraged Gamow to show to others, as his statement about what he thought of Heisenberg's publicizing a "unified theory" (which Pauli had worked on with Heisenberg for a while, but became disenchanted with). It says:

"This is to show the world that I can paint like Titian.

[empty rectangle]

Only technical details are missing."

18. **Anon**
April 22, 2019

Anyone know if the Microsoft event is open to the general public? The Redmond microsoft office phone numbers don't work and microsoft support is sending me through endless automated loops of asking about which Microsoft product I'm unhappy with.

19. **Peter Woit**
April 22, 2019

Anon,
This listing
https://asaip.psu.edu/meetings/all-meetings/physics-meets-machine-learning
for the event says "please contact an organizing member if you wish to participate in this workshop. "

20. **martibal**
April 22, 2019

The random header is a nice idea, but why not include into the list the black hole picture ? It is not that much off topic, and very beautiful.

21. **Peter Woit**
April 22, 2019

martibal,
I think you haven't refreshed your browser often enough…

22. **Jon Butterworth**
May 8, 2019

Ta for linking the review. For what it's worth, the group in which I included you indeed has a variety of different criticisms of theoretical physics, not all them "too much math(s)". The bit I thought applied to you (and Lee Smolin) was "become a monoculture too focused on a small clutch of concepts and approaches", which I don't think you'd disagree with?

23. **Peter Woit**
May 9, 2019

Jon Butterworth,

Yes, that's right, I'm very much in agreement with Hossenfelder and Smolin about the "monoculture" problem you refer to.

Falsifiability and Physics

April 23, 2019
Categories: Uncategorized

Symmetry magazine today published an article on Falsifiability and physics, yet another in the genre of defense of current HEP theory against its critics. As usual, only defenders of the status quo are quoted, the critics remain unnamed and their actual arguments ignored. I don't completely understand this journalism thing, but if you are writing about a controversy, aren't you supposed to contact people on both sides?

The problems with this article begin with the misleading subtitle: "Can a theory that isn't completely testable still be useful to physics?" The problem here is not theories that aren't "completely testable", but theories that aren't testable at all, that make no testable predictions at all.

The article starts out by discussing Popper and the supposed "falsifiability" criterion for what is and isn't science, leading up to:

> But where does this falsifiability requirement leave certain areas of theoretical physics? String theory, for example, involves physics on extremely small length scales unreachable by any foreseeable experiment. Cosmic inflation, a theory that explains much about the properties of the observable universe, may itself be untestable through direct observations. Some critics believe these theories are unfalsifiable and, for that reason, are of dubious scientific value.

Who are these "some critics"? Where do they say that the reason there is a problem with string theory is "unfalsifiability"? For the case of one critic I'm pretty familiar with, chapter 14 of his book is all about how "falsifiability" is not something that can be used to decide what is science and what isn't.

We're then told that:

> At the same time, many physicists align with philosophers of science who identified flaws in Popper's model, saying falsification is most useful in identifying blatant pseudoscience (the flat-Earth hypothesis, again) but relatively unimportant for judging theories growing out of established paradigms in science.

Unclear who "many physicists" are, who the "philosophers of science" are, and what flaw in Popper is being referred to.

In an odd move, the article then turns to the topic of SUSY, where the problem isn't that well-advertised SUSY models (with electroweak scale SUSY breaking solving the "naturalness" problem) aren't falsifiable, it's that the LHC has falsified them. As usual in science, if your model gets falsified, instead of giving up and doing something else you can change your model to something less desirable that hasn't been falsified (SUSY models with symmetry broken at higher energy scales) and keep on going. This is though what philosophers of science call a "degenerating research program", which is not a good thing.

There's more in the rest of the article, but actual critics remain invisible and their actual arguments unaddressed.

Update: Will Kinney has some appropriate comments.

Update: Massimo Pigliucci has posted here his contribution to the "Why Trust a Theory?" volume, which discusses "falsifiability" and the "String Wars".

Comments

1. **David Appell**
   April 23, 2019

   I wouldn't call the writers for Symmetry "journalists." They're not and that's not their goal or purpose. Symmetry magazine, by design, has an agenda. Moreover, it's not reader supported:

   "Symmetry is a joint publication of Fermi National Accelerator Laboratory and SLAC National Accelerator Laboratory. Symmetry receives funding through the US Department of Energy."
   https://www.symmetrymagazine.org/about

2. **GoletaBeach**
   April 23, 2019

   I don't really see that article via the HEP theory lens. It makes some point or another about how for atoms falsifiability was an inappropriate criterion. I think the accurate point is: atoms were found because experimentalists kept at it and found them. Echoing an old essay by Luis Alvarez…. likely if there had been a review panel of theorists, they'd have never funded the experimental work that led to atoms being discovered, because of some philosophy or theory or prejudice… just like RT Cox's discovery of parity violation in the 1930's was not appreciated.

   From an experimental perspective, more beam energy has traditionally been the most effective way to make new discoveries. There was not a clear mass target until about the PEP and PETRA eras, where they hoped to make top quarks (and failed).

   Somehow the requirement of a vetted mass target seeped in through the review committee process now to all accelerator proposals.

   Best to just ignore SUSY or whatever and build the next machine. There will be (and always have been) naysayers who say it isn't worth it. Well, the marketing budget in the US for tobacco is… almost $10 billion/year. Societally, a 100 TeV machine isn't expensive. If nothing is discovered, of course, it would have been better to have spent the funds on air conditioners for elderly and impoverished people in US cities… or simple water purity in most of the world. If a shocking discovery that rewrites the foundations of physics is made… well… easily worth more than tobacco marketing.

3. **Peter Woit**
   April 23, 2019

   David,
   The distinction I think you're trying to make between journalism and PR is not so clear here. I've dealt a little bit with people at Symmetry, for instance concerning this article
   https://www.symmetrymagazine.org/article/the-coevolution-of-physics-and-math
   It's not so easy to distinguish what they do from what Quanta does (other than that I bet Quanta has a lot more money…), although perhaps the Simons Foundation tries to keep Quanta's coverage separate from promoting their own research, while Symmetry may try to help promote DOE-funded research.

   In any case, even if Symmetry were strongly agenda-driven in support of Fermilab and SLAC scientists, I don't think it would be hard to find such scientists with critical views of string theory and SUSY. So the question remains, why just report one side of a controversy?

4. **Peter Woit**
April 23, 2019

GoletaBeach,

I more or less agree with you: ignore the theorists and, if at all possible, build a higher energy machine. This article isn't though at all about that, no experimentalists appear. There are lots of topics in the article, some of which have nothing to do with any controversy over falsifiability (e.g. I don't think dark matter models and testing them is particularly controversial).

Leaving inflation aside, the controversial topics are string theory unification and SUSY, and the fundamental controversy is over how you evaluate the results of this research. The results now look like a failure if evaluated by any conventional scientific standard. The claim that falsifiability is an inappropriate way to evaluate these ideas is not then supplemented by any suggestion of how they should be evaluated. A lot of this article looks like an attempt to basically argue that these ideas should be immune from evaluation.

5. **Amitabh Lath**
April 24, 2019

The article points out that for Popper unfalsifiable theories were Freudian psychology and Stalinist history. Surely you don't think SUSY belongs with them? It is falsifiable, you may need equipment and techniques that are beyond our capabilities (for now) but that's not the theory's fault. Neutrinos were considered unfalsifiable by Fermi.
As for string theory, AdSCFT etc. doesn't pretend to be about our reality so the where do you even start with the falsifiable argument? You could argue it's been N decades and they really should have gotten the math straight by now and made some testable predictions but they could counter with "there aren't enough people working on it, we need more string theorists."

6. **martibal**
April 24, 2019

It seems hard to counter with "there is not enough string theorists". By a very rough approximation, I would say that the number of string theorists is one order of magnitude bigger than the number of people working in the second best known approach to quantum gravity (loop quantum gravity), which is again one order of magnitude bigger than any other approach to quantum gravity/unification (dynamical triangulation, noncommutative geometry etc).

Do the quality of the results obtained in these various theories range in the same order ? Not sure that the number of people working on a theory is such an accurate criteria.

7. **Davide Castelvecchi**
April 24, 2019

Peter,

I enjoy reading Symmetry and I have written for Symmetry earlier in my career. People who work there have standards of integrity. But they are very conscious of the fact that what they are doing is not journalism. It's science communication, and often of very high quality, but it's not journalism. Quanta is a whole other story. It is philantropist-sponsored — which comes with its own caveats — and tends to take the side of certain communities, but it still explocitly strives to uphold journalistic standards.

8. **Peter Shor**
April 24, 2019

@Amitabh Lath:

If, as you say, "string theory and AdS-CFT doesn't pretend to be about our reality," why are so many physicists convinced that AdS-CFT shows that quantum gravity in our universe has to be unitary?

And there aren't many physicists in Physics departments working on different theories of fantasy physics, while there are tons of them working on string theory and AdS-CFT. Shouldn't fantasy physics be studied in Philosophy, Mathematics, or Creative Writing departments, rather than Physics departments?

This is just a fairly transparent *ex post facto* excuse for why string theory and AdS-CFT have failed to say anything useful about physics in our universe.

9. **Dom**
April 24, 2019

This paragraph quoted below has me puzzled because it implies that somehow falsification is impeding people working on new ideas they know are likely to be wrong (which tends to take care of the falsification bit it seems to me).
"Tracy Slatyer of MIT agrees, and argues that stringently worrying about falsification can prevent new ideas from germinating, stifling creativity. "In theoretical physics, the vast majority of all the ideas you ever work on are going to be wrong," she says. "They may be interesting ideas, they may be beautiful ideas, they may be gorgeous structures that are simply not realized in our universe.""

10. **vmarko**
April 24, 2019

From the article:

"One such theory is cosmic inflation, which (among other things) explains why we don't see isolated magnetic monopoles […]"

All the falsifiability stuff aside, I still find it hard to believe that serious people consider this as a valid argument in favor of inflation. In addition to magnetic monopoles, the cosmic inflation could very well be able to explain why there are no unicorns in nature. Would that increase anyone's confidence in the theory?

The lack of magnetic monopoles is "explained" (basically by definition) by Maxwell's classical electrodynamics. A serious scientific/skeptical attitude should be that — absent any compelling arguments that something ought to exist — the default position is that it doesn't exist. The burden of proof is squarely on the person who claims that something ought to exist, not the other way around.

Of course, the magnetic monopole waters were muddied by the story that GUT's give a compelling argument that monopoles ought to exist, so their absence becomes something that should be explained. However, by far and large, GUT's have been falsified by lack of proton decays, which (among other things) disqualifies their argument regarding the existence of magnetic monopoles. You shouldn't seek to explain something that is predicted by a theory that is known to be wrong.

Are there still that many die-hard GUT-supporters out there, who keep the magnetic monopole argument alive, despite all proton-decay experimental results? Or is it just the case of people parrott-repeating arguments from books which are half-a-century old and haven't been updated with more recent data? Or am I missing something obvious here?

Best, 🙂
Marko

11. **Low Math, Meekly Interacting**
April 24, 2019

I find the whole notion of this debate distressing and always have. I know of very few people who are fundamentalist in their belief in the "scientific method", but for me some hope of contact with experiment is a non-negotiable. I simply can't fathom the notion of "science" without it.

Of course there needs to be toy models, simplifications, abstractions and so forth to attain the goal of observable consequences. But if the goal of modeling nature as it is, in a both descriptive and predictive manner, is dispensed with indefinitely in pursuit of other criteria for success which are necessarily human constructs, then in my opinion hope is lost. Human judgment simply cannot be trusted indefinitely, and humans should not feel offended by this truth. It is in our nature to err, and we cannot avoid it without external guidance. If the universe exists without us, then it is our only ultimately reliable guide, and if we cannot extract the information we need from it, then I think it is ultimately folly to try.

That might mean giving up on answering some questions. The fact that many find this unacceptable may be a major source of the current predicament.

12. **Peter Shor**
April 24, 2019

@Dom:

I think that one of the ways physics has advanced over the years is that people come up with all sorts of crazy ideas (relativity, quantum mechanics, Dirac delta functions, the replica method, Feynman diagrams, all certainly seemed crazy to some people when they were first proposed), and only kept the ones that agreed with experiment. Without experiment, physicists have no way to discard the incorrect crazy ideas and keep the correct ones.

Tracy Slayter objects to using the falsifiable criterion, as it will keep physicists from coming up with crazy ideas in the first place, but I don't think that's the real problem.

I am beginning to think that the problem with HEP theory currently is not that physicists don't discard non-falsifiable ideas, but that without experimental input, they don't have any reasonable way to vet their crazy ideas, so they end up throwing out the baby and keeping the bathwater. There is certainly some sociological process going on that selects some of the crazy ideas, and reject others.

13. **Peter Woit**
April 24, 2019

Amitabh Lath,
As I keep trying to explain, I've never been someone who thinks "falsifiability" is the issue here and in particular re SUSY it's a sterile debate. Amidst SUSY models you can find whatever you want: falsified already, falsifiable now, falsifiable at HL-LHC, falsifiable at FCC-hh, falsifiable a hundred years from now, unfalsifiable. The only clear relevance of the falsifiability criterion here is that people should stop paying attention to the small number of Gordon Kanes of this world who, in the face of repeated experimental falsification of an idea of theirs, refuse to give up on it.

Re SUSY, I think the best advice now for experimentalists is to ignore most of what theorists have to say about the virtues of this or that SUSY model, and just ask the pragmatic question: does the model provide a useful target for designing searches that will be sensitive to a significant range of possible new physics?

14. **Peter Woit**
April 24, 2019

vmarko,
Agreed about the weirdness of "inflation explains no GUT monopoles" argument, given that the relevant GUT models have failed other tests, so the simplest explanation for no GUT monopoles is that the GUT models are wrong.

One sorry aspect of these debates is that arguments made long ago for string theory/SUSY/GUTs/etc. do keep getting repeated, long past the time when argument has failed. A lot of this is people just repeating things they read long ago, unaware of what has happened since. Some of it is people who should know better, but for whatever reason can't let go of a falsified argument.

15. **DB**
April 24, 2019

vmarko,
this might be of interest to you.
Short video. The magnetic monopoles stuff starts at 02:30.

https://www.youtube.com/watch?v=9O-5ujTgZiQ

Peter (and the rest):
Why wouldn´t the top theoretical physicists let go of some theories which, according to themselves, do not describe reality?
It´s certainly not because of money (they´re all sorted…).
Can anyone think of another reason?

Finally, this 2014 interview with Susskind is very interesting.
From the 50th to the 55th minute he talks about No Symmetry, No Beauty, and …
letting an idea/theory go when it´s not correct!!

https://7thavenueproject.com/post/93035821815/leonard-susskind-radio-interview

16. **Peter Woit**
April 24, 2019

Dom/Peter Shor/LMMI,

I don't think anyone is seriously arguing that theorists should only work on ideas falsifiable now or in the near future, and I also don't think those working on highly speculative ideas often argue that it doesn't matter whether what they are doing ultimately leads to something testable. The real problem is not "falsifiablity", but how you evaluate the progress of speculative research programs. You can't do this by demanding an experimental test, but you also can't just accept theorists' assurances that people should keep supporting them to continue work on their favorite idea of thirty years ago, despite all evidence it hasn't worked out.

What's disturbing to me is that, increasingly, the string unification/SUSY research program seems to have moved from "evaluate us by LHC results or progress on these crucial problems that are in between us and a testable theory" to "there is no way to evaluate us, you just have to believe us, because there are so many of us and we're so smart." That's not the way science is supposed to work, for good reason.

17. **Peter Woit**
April 24, 2019

DB,
What I've learned over the years is that, once people become devoted to a certain idea and invest a lot of their time, energy and public reputation in it, they are highly unlikely to ever abandon it, no matter what new information comes along and no matter how smart they are. The best you can expect is "I still believe there must be something right about that idea, but I'm now spending my time doing something else…."

18. **DB**
April 24, 2019

Peter,
thanks for the reply.
Your last sentence is key for me.
I´m starting to think that many of the top string theorists have sort of "given up", and are really working on something else.
Though they don´t want to come out and say it in public, for obvious reasons.
Which, honestly, leaves them in a bit of a dishonest situation.

It will be very interesting to see how many of the Strings 2019 conferences in Brussels next July will focus on ST itself.

19. **Anonyrat**
April 24, 2019

IMO, if interesting mathematics is emerging from a speculative line of investigation in theoretical physics, and if "interesting" mathematics has some reasonably objective meaning, then that might constitute a measure of progress sufficient for the decision of whether to fund those theorists.

20. **Peter Woit**
April 24, 2019

Anonyrat,
I'm all in favor of supporting theoretical physics work that leads to interesting new mathematics. Keep in mind though that evaluating what is interesting new mathematics is something you need mathematicians for. Most physicists are likely to take the attitude that work that needs to be evaluated by mathematicians should be funded by the mathematics part of NSF. They may even take the attitude that theorists doing this kind of work should be in a math department. There are a few places (e.g. the Simons Center at Stony Brook) where there's a healthy overlap of math and physics research, but unfortunately that's not the case most places.

21. **vmarko**
April 24, 2019

Anonyrat and Peter,

There are some countries (like Portugal) in which the academic system is set up so that any non-experimental physics (i.e. all theoretical physics, not just hep-th) is a part of the math departments, rather than physics departments. IOW, if you want to be in a physics department, you need to be working in a *lab*, and measure something with some equipment. Everything else, any pen-and-paper work, is considered math.

The results of such an arrangement are, mildly put, catastrophic. The applications for projects, results that are obtained, papers that are published, etc., are all evaluated by committees in which theoretical physicists are present, but mathematicians are a majority. A paper published in a journal with "Math." in its name is more worth than a PRL. And if you ask a mathematician to judge the work done by a theoretical physicist, they will mostly laugh at it. The levels of rigor, precision, and definition-theorem-proof style of writing, that mathematicians are used to, are something a theoretical physicist can never even hope to reach. Mathematicians by and large regard theoretical physicists as amateur wannabe-mathematicians, who are toying with some equations and delude themselves that they are doing something serious. They often dismiss the work of physicists just because it is not formulated as a theorem and proved rigorously, even without looking at what was actually done. And they often have a hard time understanding why the work of a hep-th physicist cannot be formulated as a theorem… I was often asked stuff like "How do you even know what you are doing, if you cannot explicitly spell out all your assumptions for me, before you make a statement what the result is?"

Theoretical physics is not math. The whole math mentality is completely different from physics mentality, with different goals, intuition, background education, ways of thinking, and levels of rigor. There is just no way to consider theoretical physics as part of proper math, and it's a Bad Idea ™ to even try.

Best, 🙂
Marko

22. **Bernhard**
April 25, 2019

Peter,

Also, one point you have mentioned ad nauseam that I have never seen been addressed in this or any article is the question of the negative progress rate of String Theory as opposed to whether is falsifiable or not. String Theory could become a falsifiable tomorrow. But it's pretty clear it won't be. Not tomorrow, not ever. Every time I read those types of articles people discuss with a straw man never addressing the real issue.

23. **Amitabh Lath**
April 26, 2019

Peter Voit, Peter Schor, the longevity of string theory is not due to the middle-aged practitioners you mention but kids in their early 20s who continue to choose to go into the field. Some of the best undergraduate students in our high energy experiment group have over the years chosen to go to grad school in theoretical physics 🙁

Some go into phenomenology but some are indeed doing string theory.

These students are the most smartest and most sensible I have ever met, the cream of the Garden State. They devour the literature, they are fully aware of the arguments on all sides. I cannot in any seriousness entertain the idea that they are led astray by hyperbole. I believe all the arguments about string theory not having made any progress in decades, not producing any testable results, being stuck in a made-up universe nothing like our own reality; these are not deterrents but attractions to this type of student.

24. **Peter Woit**
April 26, 2019

Amitabh Lath,
The intended audience for the typical promotional string theory hype-fest piece is not ambitious youngsters considering a career in particle theory, but physicists in other fields, people in other sciences, university administrators, interested laymen, etc. In general, people who might have something to say about whether string theory research gets supported, and aren't in a good position to evaluate the claims being made themselves. When you're reading an article supposedly about some controversy, but only one side is quoted, what you're reading has an agenda behind it.

The topic of what's going on with talented undergrads who are interested in theoretical physics, want to study it more deeply and possibly go to grad school and try to make a career in the subject is an interesting one, but not so relevant to articles like this. Yes, they aren't going to impress a smart student seriously studying particle theory, and such students now do hear both sides of the controversy over string theory.

I know quite a few such students, some pretty well, either through teaching them here at Columbia and then following their later progress, or through having students from elsewhere contact me for one reason or another. What I see happening now (at least in the US) is that the best students are, as always, going to a small number of the top graduate programs (e.g. Harvard, Princeton, Stanford), where most of the theory faculty often identify tribally as "string theorists", but are now working on topics in GR/QFT/quantum information, etc. that have nothing to do with quantized strings or with string-theory based unification. The odd thing I keep hearing is that such students arriving at such a grad program are encouraged to spend a lot of time studying actual string theory (e.g. by reading Polchinski's two volumes) to prepare to start research, even though the research likely won't use any of this. My impression is that a lot of the theory faculty are unsure themselves which way the field should be going, and by default are suggesting students start off the same way they did 20 years ago.

Studying theoretical fundamental physics attracts, for good reason, and despite the field's problems, some of the best students around. Sometimes I do fear though that one reason the field is not generating much in the way of new ideas is not so much that the best students are drinking string theory kool-aid, but that they're getting their entry into the subject of fundamental theory in a way that hinders rather than helps them come to grips with the real problems of the subject.

25. **Peter Shor**
April 26, 2019

Amitabh Lath:

When it looks like two recent papers in a field are incompatible (despite both of them being quite reasonable papers on their own), and talking to some people in the field, nobody even seems to have noticed this fact, I suspect that something has gone seriously wrong with the field.

The two papers are (a) the ones suggesting the the CFT in the AdS-CFT correspondence is a quantum error correcting code and (b) Shenkar and Stanford, "Black holes and the butterfly effect," which starts out essentially saying "make a small perturbation to the CFT".

If you make a small perturbation (or even a large perturbation) to a state in a quantum error-correcting code, for any kind of quantum error-correcting code I am familiar with, you are extremely likely to be taken out of the quantum error-correcting code, which means that — as far as I can tell — the rest of the paper doesn't hold up.

Let me say that I think these are both good papers, but they are essentially starting with two different hypotheses about AdS-CFT, and I don't see how they can both be applicable at the same time. The fact that nobody seems to have even noticed this is very troubling to me. But maybe I'm too much of a mathematician.

26. **Amitabh Lath**
April 26, 2019

Peter V, I understand your point but the decisions made by these top tier students does much more to sway these "people who might have something to say about whether string theory research gets supported" than some national lab's public outreach 'zine.

Every grad program wants these students: sky-high physics-GRE, letters dripping with superlatives, transcripts with half a dozen graduate level courses completed as undergrad. They are courted with fellowships and awards. Their eagerness to join the field is seen as proof of vibrancy. If a big-name string theorist leaves your department and the acceptance rate for these blue-chips drops, you know the search committee will form quickly.

27. **Mark**
April 27, 2019

Peter Shor:

The Shenker-Stanford butterfly effect has since been independently found in CFT using strictly field theory tools, so I'd say that it's on a firmer ground than the error correcting code proposal. The HaPPY code's claim to fame is that you can act on it with operators in the "bulk", which is equivalent to acting on some "boundary" subregion. People don't know how to do time evolution in this approach, so they can't reproduce the butterfly effect from quantum error correction. But if I understood your comment, you're saying that already acting on the state should take you out of the code.

28. **Blake Stacey**
April 27, 2019

Peter Shor asked, "[W]hy are so many physicists convinced that AdS-CFT shows that quantum gravity in our universe has to be unitary?" I have also wondered about this. AdS is said to be "a box to put gravity in", but that comes at a price: The stability properties of gravitation on AdS are qualitatively different from those for dS or Minkowski backgrounds. The answer to the question "Will doing this experiment make my laboratory collapse into a black hole?" is, in principle, different, precisely because of that convenient boundary that makes for a nice box and gives a place for the CFT to live. This makes it hard for me to accept the reassurance that I was given many years ago, the standard colloquium line that we can put any local physics we want into an AdS box and apply the lessons from that exercise to our own world.

29. **Peter Woit**
April 27, 2019

All,
I fear this is the wrong place to debate the issues raised by Peter Shor about CFT and error-correcting codes, partly because the moderator knows nothing about the topic (he would like to someday understand what that's about, but today is not the day…)

30. **Peter Shor**
April 27, 2019

@Mark:

Just to be clear, I have no objections to the Shenkar-Stanford butterfly effect in CFTs that aren't also error correcting codes.

And probably we should stop any discussion here, to keep the moderator happy.

The Scientific Attitude

April 29, 2019
Categories: Book Reviews

Just when I thought I was done for now with the "falsifiability" business, in our local book store I found a new book, The Scientific Attitude: Defending Science from Denial, Fraud and Pseudoscience, by Lee McIntyre. This won't be a review of the whole book, much of which is concerned with what to do about the serious problem of the role of science in our increasingly post-truth society. I'll just address the few pages of the book that deal with string theory, in which a quote from me appears in a misleading way.

The problem here is almost exactly the same as the problem with the Symmetry article discussed in the last posting. Both authors believe that string theory is a conventionally predictive theory, one with predictions that just happen to be hard to test. According to them, critics of string theory just don't understand that there can be value in a theory which is testable in principle, even if a practical test is far away. Unlike the Symmetry piece, McIntyre at least names critics and links to their words, writing:

> If one reads these kinds of criticisms closely one finds careful phrasing that string theory "makes no predictions about physical phenomena at experimentally accessible energies" and that "at the moment string theory cannot be falsified by any conceivable result."[23] But these are weasel words, born of scientists who are not used to taking seriously the distinction between saying that a theory is "currently" testable versus whether it is "in principle" testable. The practical limitations may be all but insurmountable, but philosophical distinctions like demarcation live in the difference.

The quoted words are mine, with footnote 23 referring to my 2002 article in American Scientist. Of course I was and am well aware of the distinction between testable "in principle" and "currently". Bizarrely, the author has chosen to edit out from what I wrote the sentence that precisely addresses the issue I'm supposedly weaseling on. Here's the full quote:

> String theory not only makes no predictions about physical phenomena at experimentally accessible energies, it makes no precise predictions whatsoever. Even if someone were to figure out tomorrow how to build an accelerator capable of reaching the astronomically high energies at which particles are no longer supposed to appear as points, string theorists would be able to do no better than give qualitative guesses about what such a machine might show. At the moment string theory cannot be falsified by any conceivable experimental result.

As the deleted language make clear, by "any conceivable experimental result" I was making a claim about "in principle", not "currently". Furthermore, near the beginning of the article I explain the problem of principle:

> First, string theory predicts that the world has ten space-time dimensions, in serious disagreement with the evidence of one's senses. Matching string theory with reality requires that one postulate six unobserved spatial dimensions of very small size wrapped up in one way or another. All of the predictions of the theory depend on how you do this, but there are an infinite number of possible choices, and no one has any idea how to determine which is correct.

This article started out as an early 2001 arXiv posting and was published in early 2002, about a year before the now famous KKLT claim to have a string theory model with fully stabilized moduli. Back then, the problem I was pointing to was the basic one that, to have a self-consistent string theory model that you can confront, in principle, with experiment, you need to solve the problem of "moduli stabilization". 6d compactifications come in families with a lot of parameters (the "moduli") governing their size and shape, and the physics depends crucially on those parameters. You need to somehow give the moduli dynamics, and get a ground state with a correct fine-tuned vacuum energy.

KKLT claimed they could do this, but with an exponentially large "landscape" of solutions that removes the ability to get well-defined predictions from the theory. Their construction is so complicated, and non-perturbative string theory so poorly understood, that it remains controversial to this day whether these are really solutions to whatever the conjectural well-defined version of string theory might be. This is what the current "Swampland" argument is about.

I've put together a FAQ entry answering the Doesn't string theory make predictions at very high energy? question. What causes all the confusion here is the common claim from string theorists that "string theory is testable at high energy". If you ask them to tell you what the "test" is, they tell you about one of the characteristic features of the perturbative superstring (Veneziano amplitude, Regge trajectories, 10 space-time dimensions). What they are really saying is "if we did experiments at a high enough energy scale and saw one of these characteristic phenomena, we would have a successful test of string theory", which is true enough, but not a specific, falsifiable prediction. What they are not telling you is that they are ignoring the compactification problem as well as that of not having a well-defined non-perturbative theory, and that many "string theory" models wouldn't exhibit these characteristically perturbative features.

The main point of the new book seems to be to argue that a better way to characterize science is by whether those supposedly engaging in it are exhibiting the "scientific attitude", which

> can be summed up in a commitment to two principles:
> (1) We care about empirical evidence.
> (2) We are willing to change our theories in light of new evidence.

It seems to me there are lots of problems with this formulation. Sticking to the string theory question, undoubtedly string theorists "care about empirical evidence" and would like to have some. The problem though is they don't have any, and don't have any significant prospects for getting any. As for being willing to change one's theories in light of new evidence, if there's no new evidence, your willingness to change your theory won't ever get tested.

My impression is that most people, this author included, are just fundamentally unwilling to believe that, given the high scientific profile of "string theory", it could really have a serious problem of being inherently untestable. The technical issues involved are so formidable that non-experts don't have any hope of understanding them. But there really is a serious problem here, and those who worry about the string theory fiasco damaging the credibility of science in a dangerously post-truth world are right to be worried.

Comments

1. **Frank Wappler**
   April 30, 2019

   woit wrote (April 29, 2019):

   > It seems to me there are lots of problems with this formulation […]

I agree that there are problems with McIntyre's formulation; and I would call commitment to (merely) these two listed principles rather more specificly an "**unstructured** scientific attitude", oder "**pre-**scientific attitude".

A "(**structured**, **actual**) scientific attitude" might be instead summed up in a commitment to three principles:

(0) We care about notions (that go without saying), definitions, principles and methods (expressible in terms of those notions) which allow us to derive empirical evidence (from observations, as they become availabe to us).

(1) We care about collecting observations from which to derive empirical evidence by methods that can be adhered to.

(2) We are willing to change our expectations (about which observations and empirical evidence may still be forthcoming) in light of new evidence.

2. **Martin**
April 30, 2019

McIntyre writes "The practical limitations may be all but insurmountable, but philosophical distinctions like demarcation live in the difference". The demarcation is about demarcating science from pseudo-science. This is a legal argument, which is based on the fact that critics of string theory naively argue that falsifiability would be the criterion. McIntyre loves this criticism. The real point is that there is no empirical evidence in support (!) of string theory. Scientists do not attempt to construct falsifiable, i.e. wrong, theories, they attempt to construct theories that work. Obviously, when a theory should work then it might turn out that it does not work, but that is not the objective. That is why McIntyre states "We care about empirical evidence", deliberately without saying how the empirical evidence, if it could be obtained, should relate to the credibility of string theory. McIntyre argues like a lawyer – the critics cannot prove that string theory is not scientific. Therefore not guilty.

3. **Peter Woit**
April 30, 2019

All, I really don't want to host a discussion of McIntyre's ideas about the "scientific attitude" in general. I doubt many commenters have read the book, and I don't intend to read more of it, so if it's not about the string theory issue, please find somewhere else to discuss with the author.

I've been having trouble figuring out why this author would quote me in such an unprofessional way. Taking a look at his other recent activities, I fear the answer is that he's decided resistance to Trump justifies abandoning usual standards of academic writing, especially fairness to those you feel are on the other side. From this point of view, any criticism of prominent scientists puts one on the anti-science/Trump side, and given the current emergency all takedown tactics are fair. If only I could get McIntyre to read the collected works of Lubos Motl….

4. **vmarko**
April 30, 2019

Peter,

Have you contacted the author to ask him about this misinterpretation of your words? How does he explain it? How about the book publisher, can you complain to them?

Best, 🙂
Marko

5. **Peter Woit**
April 30, 2019

vmarko,
No, that seems like a waste of time. This author clearly knows nothing about string theory and cares less, it's just minor grist for his "science is under threat" agenda. Would be best to ignore this, but I did want to set the record straight.

6. **Daniele Corradetti**
April 30, 2019

I'm not at all a string theory fan and generally speaking I quite agree with the views expressed on this blog, so this is not a troll-question but a true-question. Reading Heisenberg, I clearly remember him saying that "Copernican theory doesn't agree at all with observations since every day everyone observes the Sun rising, culminating and moving around the earth". He says that in fact Copernican theory constrasts what is totally evident from observations to evidentiate a unitary and mathematical principle. My question is if this is in some kind different from string theory predicting that the world "has ten space-time dimensions, in serious disagreement with the evidence of one's senses". I repeat I'm really interested and is a true question, not trying to trolling anyone.

7. **Dave Miller**
May 1, 2019

Peter,

You said, "I've been having trouble figuring out why this author would quote me in such an unprofessional way." My guess is he took brief notes on stuff he thought might be useful and later forgot the larger context of those notes. The same effect can also occur from cutting-and-pasting different phrases in a manuscript as the author re-works the manuscript. Something like this seems to be what happened with various professionals (e.g., Doris Kearns Goodwin) who engaged in plagiarism but probably did not intend to.

A point that needs to be more clearly addressed in these ongoing discussions is what is wrong scientifically with producing random, string-inspired phenomenological models that can be multiplied ad infinitum, after each particular model fails.

I myself am not quite clear on how to formulate this succinctly, but, somehow, a scientist should be invested in a hypothesis in such a way that, if the hypothesis is falsified, it truly alters his thinking on the subject.

Somehow, it is not fair to toss out a hypothesis, knowing that, if it is falsified, you will just toss out another slightly tweaked hypothesis, and so on when it is falsified, again and again and again. (We all know of a phenomenologist in the upper Midwest who has a tendency to do this!)

I think the point may be that the goal of scientists is not simply to make and then confirm or disconfirm *hypotheses* but rather to seriously advance our knowledge of the universe by creating broad new theories that are significantly broader or more accurate than existing theories.

Just churning out one hypothesis after another, never being fazed by their disconfirmation, fails to advance the cause of building a better, broader theory.

All the best,

Dave

8. **Thomas Mattison**
May 1, 2019

Given an accelerator of astronomical energy, it seems likely that an experiment could falsify the hypothesis that the particles we know today are pointlike.

That would not prove they are string-like. But strings would be a reasonable working hypothesis under the circumstances. Other hypotheses might be equally plausible in the absence of more data.

You make a good case that the experimental program that would be required to which particular discrete compactification of string theory is correct would be daunting.

Is there no hope of organizing the landscape into a pseudo-continuous space with a hierarchy of parameters? So if you knew approximate values for the most important few, you would be able to make some meaningful predictions? So a few experiments could be extrapolated into predictions for more experiments ?

9. **Peter Woit**
May 1, 2019

Daniele Corradetti,
The point I was making was just that all our observations show four dimensions. If your theory says there are ten, you need to explain why we only see four. You need a theory of the dynamics of the other six dimensions, explaining why we don't see them and how you could in principle see them. The main problem with string theory is that there is no convincing answer to this question.

Dave Miller,
I don't see that problems with note taking are an explanation here. This author doesn't appear to be a Doris Kearns Goodwin…

Besides a few outliers like Gordon Kane, the problem with string theory is not that string theorists are making predictions, then changing them when they get falsified. The problem is that the framework they initially thought was predictive has turned out to be empty, with the partial theory they have incapable of predicting anything currently observable, and consistent with just about anything. The last hope was that the LHC would see something (e.g. SUSY) compatible with the string theory framework, but that hope is now dead.

Thomas Mattison,
Yes, if we could do experiments at the Planck scale we would likely be able to figure out what the quantum dynamics of space-time is, and in particular whether string theory had anything to do with it. My point is just that perturbative string theory is not capable of giving a consistent account of this (because of the compactification problem), so there's no "string theory prediction" of what you would see.

I actually don't think our current understanding of string theory is capable of giving a well-defined, consistent description of what the possible "string vacua" are, and thus what the "landscape" is. One could speculate that it has nice properties allowing us to calculate with it, but there's zero evidence for that.

10. **Lee Smolin**
May 1, 2019

Dear Daniele Corradetti,

Your question is an excellent one. I am not an historian, but I have read a lot of the history relevant to the Newtonian revolution, and I have the impression that a key part of the argument was carried out by Galileo, who argued by a combination of real and thought experiments that the Earth could be moving around the sun, without the effects of that motion being observed. (Essentially, he argued for the relativity of inertial frames.) But the issue was subtle because the very same observations (the ball falling to the foot of the mast of the smoothly moving boat…) justified both the claim that we would feel the motion were the earth moving and the claim that we wouldn't feel it, depending on whether one adopted the widely believed Aristotelean or the (yet to be) invented Newtonian dynamics. So Galileo's arguments rested (correctly) on a yet to be developed dynamics, and Copernicus, who lacked even reference to Galileo's intuitions, couldn't possibly tell a consistent or convincing story.

Meanwhile, Kepler went ahead and posited that the planets were influenced by a force from the Sun-which was a key step even if he did get details wrong. But what he really did that was crucial was to impose the conservation of angular momentum in the form of the equal area law, and show it was to first order in ellipticity equivalent to Ptolemey's law of equants.

So, after this overlong historical context, we can ask what a current day string theorist needs to do, to advance at least to the stage of Galileo and Kepler, and it is to invent some kind of principle that together with a good story based on a non-perturbative dynamics yet to be invented, that convinces us to ignore the evidence from the senses that the world has three stable spatial dimensions and not nine. And of course, this runs up against the problem of stablizing the moduli-a problem that Einstein knew about in the early 1920's which caused him to abandon the Kaluza-Klein idea. And that leads to KKLT, the swampland…and here we are.

11. **Thomas Van Riet**
May 1, 2019

Dear Peter

In your writings and those of Lee Smolin I see two main sources of criticism: 1) string theory is not sufficiently understood and 2) the Kaluza-Klein character of the theory anyhow makes it "unpredictable". Concerning 1) I agree and I hope more people will put energy in developing the foundations. Concerning 2) there might be a misunderstanding here. Consider alternative theories, without extra dimensions. These theories will always be confronted with non-uniqueness: these alternative quantum gravity theories cannot be coupled just to the standard model and most likely many other gauge groups and couplings will be possible. I am guessing an infinite choice. This is where string theory helps allot. String theory geometrizes this freedom AND by doing so it has shown surprising constraints and patterns in these possible 4D theories. Our struggles with moduli stabilisation and SUSY breaking only arises because the theory is quite constraining.

Sincerely,
Thomas Van Riet

12. **Peter Woit**
May 1, 2019

Thomas Van Riet,
I've just never seen any evidence that a string theory (or any other) geometrization in terms of extra space-time variables answers any significant question about the Standard Model. In the string theory case, instead of getting an explanation of features of the Standard Model, you have to put a huge amount of effort into (not clearly successfully…) trying to explain away why generic features (eg. SUSY, massless moduli fields) of these models are not observed. Fundamentally, you're asking people to accept a poorly understood, very complicated framework as an improvement over the Standard Model, with zero positive evidence for it (and, at this point, no plausible

prospects for getting any).

13. **Daniele Corradetti**
May 2, 2019

Dear Lee Smolin,
thank you for the insightful answer! I think is really a good point!

14. **Jim Given**
May 3, 2019

Peter,
I applaud you for having introduced your readers to the research project methodology of science, a la Inre Lakatos, as explaining quite well the situation with string theory, i.e., as a degenerate research programme. Hearing about the "scientific attitude" as an attempt at a serious contribution to philosophy of science made me so sad, I just wanted to point out that the long essay, "The Methodology of Scientific Research Programmes" by Lakatos is available in paperback, is well worth reading carefully, and will clarify these situations in physics theory that you struggle with, far more than such current, rather unfortunate attempts to redefine science. The problem is not science. Rather, you and I (and our generation) are spoiled, having been trained in science in an era of extraordinarily rapid progress. One comes to have faith that the logically "inevitable" next step will turn out to be correct, and that rapid progress will continue. Alas. As Lakatos notes, the current generation of scientists does not turn away from long adopted but failed research programmes. Rather, they retire, and are replaced by a new generation; hopefully, one that reads your blog-

15. **Andrew Krause**
May 10, 2019

You may appreciate this recent post on applications of the philosophy of science, and the associated paper. Quite a different subject matter, but perhaps this kind of Lakatosian analysis would help quantify some of the current state of affairs in fundamental physics? I don't understand enough on a deep level to be certain, but I find the approach overall valuable. Lakatos definitely popularized, if not originated, the ideas of a "degenerate research programme."

http://www.extinctblog.org/extinct/2019/5/1/what-to-do-with-scientific-disagreement

16. **Peter Woit**
May 10, 2019

Andrew Krause,

Thanks. I know nothing about paleontology, but the Lakatos distinction between a "progressive" and "degenerative" research program does seem to me the most illuminating way of thinking about how to evaluate scientific research programs. I've never seen string theorists deal with this argument, they seem to carefully avoid it, since by any measure string theory fits quite well into the "degenerative" characterization, not well at all into "progressive".

Witten Interview

May 2, 2019
Categories: Multiverse Mania, Uncategorized

Graham Farmelo has posted a very interesting [interview he did with Witten last year](), as part of his promotion of his forthcoming book [The Universe Speaks in Numbers]().

One surprising thing I learned from the interview is that Witten learned Calculus when he was 11 (this would have been 1962). He quite liked that, but then lost interest in math for many years, since no one gave him more advanced material to study. After years of studying non math/physics subjects and doing things like working on the 1972 McGovern campaign, he finally realized physics and math were where his talents lay. He ended up doing a Ph.D. at Princeton with David Gross, starting work with him just months after the huge breakthrough of asymptotic freedom, which put in place the final main piece of the Standard Model.

If only back in 1962 someone had told Witten about linear algebra and quantum mechanics, the entire history of the subject could have been quite different. It seems quite possible that within 5 years he would have picked up quantum field theory and maybe started thinking about Yang-Mills generalizations of QED, perhaps, at 16, beating Weinberg and Salam to the electroweak theory. Surely he could have figured out how to do one loop calculations in gauge theory, beating Gross/Wilczek/Politzer to asymptotic freedom and a Nobel prize, possibly a few years early. If he had done this at Princeton, he would have overlapped with John Schwarz, who surely would have then been more interested in pursuing gauge theory than string theory. So, no superstring theory or 1984 "revolution", and who knows what different sort of path the history of the field would have taken.

A lesson for all parents: if your child is an off-the-scale genius, learning Calculus at age 11, don't even think about trying to give them a normal childhood. Push them, hard, to skip grades, get to college/grad school early. Do whatever it takes.

I did though find some of the later parts of the interview quite depressing. While acknowledging that neither he nor anyone else has been able to figure out what string theory actually is, this hasn't shaken Witten's faith that it's the only viable path towards a unified theory. Most disturbing, on the topic of the landscape he says that he has gone from finding it upsetting to reconciling himself to the idea. For years, whenever asked about how evidence could be found for string theory, he would point to the naturalness arguments indicating that something like SUSY had to happen at the electroweak scale. Now that the LHC has falsified this and there's nothing to point to as any sort of "test of string theory", he shows no signs that this falsification has in any way shaken his faith.

Looking to the near future, he's most optimistic about the "It from Qubit" business. Maybe he's right and something will come of this, but I've seen no indication of a path to a unified theory in this direction (how do you get the Standard Model? Or has he just completely given up on that?).

I don't have time right now to transcribe the most relevant portions of the interview, might find time later, or maybe Farmelo will make available a transcription.

Update: As explained in the comments, the advice to parents was not meant to be taken seriously. No, your child is not going to grow up to be Edward Witten, and they do not need to hurry up to revolutionize physics before it is too late.

Sabine Hossenfelder had posted a transcript of the interview [here](). I'll add some extracts and some more comments about the interview.

About the landscape:

> These two puzzles although primarily the one about gravity which was discovered first are perhaps the main motivation for discussions of a cosmic landscape of vacua. Which is an idea that used to make me extremely uncomfortable and unhappy. I guess because of the challenge it poses to trying to understand the universe and the possibly unfortunate implications for our distant descendants tens of billions of years from now. I guess I ultimately made my peace with it recognizing that the universe hadn't been created for our convenience.
>
> GF So you come to terms with it.
>
> EW I've come to terms with the landscape idea and the sense of not being upset about it. As I was for many years.
>
> GF Really upset?
>
> EW I still would prefer to have a different explanation but it doesn't upset me personally to the extent it used to.
>
> GF So just to conclude what would you say the principal challenge is all down to people looking at fundamental physics.
>
> EW I think it's quite possible that new observations either in astronomy or accelerators will turn up new and more down to earth challenges. But with what we have now and also with my own personal inclinations it's hard to avoid answering new terms of cosmic challenges. I actually believe that string slash M theory is on the right track toward a more deeper explanation. But at a very fundamental level it's not well understood. And I'm not even confident that we have a good concept of what sort of thing is missing or where to find it.

If you theory is not well understood, you don't even know what sort of thing is missing, and a multiverse is being invoked to explain away why it can't be tested, the situation seems clear: you have a failed theory. Yes, failure may be personally upsetting to you, but, that's science.

> GF There's a famous book about night thoughts of a quantum physics. are there night thoughts of a string theorists is where you have a wonderful theory list developing you know unable to test it. Does that ever bother you.
>
> EW Of course it bothers us but we have to live with our existential condition. But let's backtrack 34 years. So in the early 80s there were a lot of hints that something important was happening in string theory but once Green and Schwarz discovered the anomaly cancellation and it became possible to make models of elementary particle physics unified with gravity. From then I thought the direction was clear. But some senior physicists rejected it completely on the grounds that it would supposedly be untestable. Or even have cracked it would be too hard to understand. My view at the time was that when we reached the energies of the W, Z and the Higgs particle we'd get all kinds of fantastic new clues.
>
> EW So. I found it very very surprising that any colleagues would be so convinced that you wouldn't be able to get important clues that would shed light on the validity of a fundamental new theory that might in fact be valid. Now if you analyze that 34 years later I'm tempted to say we were both a little bit wrong. So the scale of clues that I thought would materialize from accelerators has not come. In fact the most important clue possibly is that we've confirmed the standard model without getting what we fully expected would come with him. And as I told you earlier that might be a clue concerning the landscape. I think the flaw in the thinking of the critics though is that while it's a shame that the period of incredible turmoil and constant experiment and discovery that existed until roughly when I started graduate school hasn't continued. I think that the progress which has been made in physics since 1984 is much greater than it would have been if the naysayers had been heeded and string theory hadn't been done in that period.

"34 years later I'm tempted to say we were both a little bit wrong"??? No, others had good arguments and were right about this (string theory is untestable and has nothing to do with LHC-scale physics), and you had bad arguments and were quite wrong. That this clear result is not being acknowledged and is having no effect on faith in string theory is disturbing.

Update: For another interview with an influential theorist, Sean Carroll has an interview with Leonard Susskind. I don't think this is a good thing, but Susskind has been very influential in blazing the path that Witten now seems headed down (invoke the multiverse to justify giving up on unifying particle physics, hope very general "it from qubit" considerations will explain gravity). The interview explains in detail Susskind's point of view.

Update: Farmelo has another interview with a string theorist up, this time it's Michael Green. When asked if he's troubled by string theory not being experimentally testable, Green says (19:20):

> I don't think at the moment there's anything directly to test, because we don't know what its predictions are.

and says that string theory should really be called "string (not yet a) theory". Earlier (16:40), he explains

> The ingredients of something are there, but it's clearly not formulated in the right language, and because it's not formulated in the right language, we don't really know how to even make sense of its predictions. It doesn't have any really genuine rigorously derived predictions yet.

Green has been working on string theory for forty years, an entire professional lifetime during which string theory has gone from a relatively simple "(not yet a) theory", with a true theory seeming not far away, to a much more complicated "(not yet a) theory", with no progress towards an actual theory in sight. Farmelo doesn't ask the obvious question of why people shouldn't interpret this story straightforwardly as the story of a failed speculative idea that never worked out.

Comments

   May 2, 2019

   Rather bizarre that after learning calculus at 11 nobody bothered to give him any interesting math for years. If his parents were both illiterate farm workers, then I could understand their not appreciating his talent. But his father (Louis Witten) was a theoretical physicist who'd done a post-doc at Princeton. He must surely have known just a little bit of post-calculus math he could have shared at the dinner table.

2. **Richard**
   May 3, 2019

   > … if your child is an off-the-scale genius, learning Calculus at age 11 …

   I think your exposure to US undergraduates (ie to the products of miserable US high school education) may have coloured your perceptions a little here.

   To me this seems a little precocious (in particular a little more precocious than my never-to-amount-to-anything I was), but nothing truly extraordinary.

3. **kim8**
   May 3, 2019

   Anecdotally my understanding is being a child prodigy is not a good indication if one wishes for their success as an adult (what with the added pressure, etc.), although of course there are always unexpected exceptions.

4. **Olly Johnson**
   May 3, 2019

   Please tell me that the "lesson for all parents" is a joke that I'm missing?

   I tried to explain why at https://twitter.com/BristOliver/status/1124192117125939201

5. **Anonymous**
   May 3, 2019

   Hi Peter,

   I don't think that your speculations about what Witten might have done in his teens had he stayed on the math/physics path are any kind of justification for your "lesson to parents". Who knows what might have happened had he been pushed hard? Your instincts may be different, but mine tell me that pushing kids hard like that is not the way to success, especially not in creative fields. And expecting groundbreaking work from a 16-year old, no matter how talented, seems unrealistic.

   With respect,
   Anonymous

6. **Richard Gaylord**
   May 3, 2019

   bee hossenfelder just posted a transcript of the interview

   http://backreaction.blogspot.com/2019/05/graham-farmelos-interview-of-edward.html

7. **Shaltut**
   May 3, 2019

   That plot in the third paragraph 🙂

   I am not surprised that Witten won't leave string theory. For in this religion, he is the high priest.

8. **Matt Grayson**
   May 3, 2019

   Peter,

Pushing a genius is great for everybody else, but destroys the genius as a human being.

Producing Mozart was child abuse. I know more than a few music prodigies, and their personalities are largely frozen at the age that they were forced to practice 100% of their waking hours. Only the ones so extremely talented that they could achieve world recognition without sacrificing their childhoods have anything like a normal life. I'd put Witten in that last category.

9. **Peter Woit**
May 3, 2019

All,
The suggestion to parents was tongue-in-cheek. I felt the need to add some humor to this since I found Witten's announcement he has reconciled himself to multiverse pseudo-science profoundly depressing. Imagining a better parallel universe was the only way to cheer myself up. Witten is a very special case, not a good argument for what to do with other children.

10. **Matt Grayson**
May 3, 2019

BTW, when I was 11, I went to the town library, picked up Hocking and Young's Topology book, saw the Alexander Horned Sphere, screamed, and ran away. (Their illustration is far the creepiest picture in the literature.)

Apologies. I'm expecting a "Please no more about childhood" directive any second now…

11. **Lars**
May 3, 2019

As far as I can see, even in Witten's "special" case, his parents made an excellent decision NOT to push him into math and physics at age 11.

Witten seems not to have "suffered" too much (if at all) from his wanderings.

He may not have received a Nobel Prize (yet), but he did get the Fields medal and perhaps not coincidentally, Witten also seems to be a very content, socially well adapted human being .

And I suspect that like his own parents, he is probably also a very good parent — wisely disregarding popular songs like " Momma's , don't let your babies grow up to be string theorists."

Ha ha ha.

12. **Peter Woit**
May 3, 2019

Matt and others,
Yes, enough about 11 year olds.

13. **Amitabh Lath**
May 3, 2019

Alternative histories are fun. There is an experimental version centered on your own august institution. In 1968 the Columbia-BNL experiment was looking at dimuon production mapping out the recently theorized Drell-Yan spectrum. They saw a "feature" at 3 GeV (you can google "Lederman shoulder 3 GeV") . It wouldn't go away no matter how hard they polished the data.

https://www.mediatheque.lindau-nobel.org/research-profile/laureate-lederman

I heard this story from Leon Lederman himself. They considered exploring this 3 GeV anomaly in more detail but it didn't pan out. All the PIs went on to do other less interesting things.
At this point in the story Leon pauses:
"If we had followed up we would have scooped the parton discovery and the charmonium discovery. We could have called it the Lee-on".
(Pauses for effect)
"After T.D. Lee, of course."

A lesson for all scientists: if your data is showing interesting features, get a better spectrometer. Push the lab directorate, the funding agencies, skip other experiments. Do whatever it takes.

In this alternate history the top quark and higgs are discovered at ISABELLE in Long Island.

14. **David Appell**
May 3, 2019

When Witten is discussing the cosmic landscape, he says "…the possibly unfortunate implications for our distant descendants tens of billions of years from now."

What does he mean by this?

15. **student**
May 3, 2019

from the transcript

EW [00:17:48] But you've never been tempted down the other route. The other options are not.

EW [00:17:52] I'm not even sure what you would mean by other routes.

GF [00:17:54] Loop quantum gravity?

EW [00:17:56] Those are just words. There aren't any other routes.

Peter,

I’ve always wondered what Witten thinks of LQG and now I know.

I’ve always found it surprising such a towering figure in physics has zero interest and curiosity in one branch of physics, LQG.

Do you have any idea why he’s so dogmatic on strings as the only way to QG?

16. **Peter Woit**
May 3, 2019

David Appell,

I’m guessing he’s referring to the fact that the vacua of the string landscape are just metastable, so could in principle tunnel to a different lower energy vacuum.

17. **Peter Woit**
May 3, 2019

student,
I do think Witten has paid attention to LQG, just believes that it has problems that are not likely to get solved. What’s unclear is why he sees this as so different than the situation with string theory, which also has long-standing problems that have not gotten solved. That he’s more optimistic about the prospects for his own creation is not really surprising.

What I do find really surprising is what seems to me like a change in tone towards more dogmatism about string theory. Witten in the past has always been pretty cautious in what he says, and I would have expected the negative LHC results to make him even more cautious about making claims about string theory being the only way to go. Instead the change in his tone seems to be in the exact opposite direction. Odd.

18. **Milkshake**
May 3, 2019

I think “faith in string theory” is a bit unfair. He doesn’t have faith in the sense that a religious person has faith. Instead, it seems, there have been so many positive developments in string theory, and the theory is so rich, that he may use induction to conclude that it is on the right track.

19. **Peter Woit**
May 3, 2019

Milkshake,
There’s no fully objective way to measure “positive” vs. “negative” developments in string theory (I’d argue that the negative now far outweighs the positive, Witten undoubtedly sees things differently). Similarly, where one person sees a “rich” structure, another may see a “mess”.

Witten is a genius and surely has many valid technical things he can point to, but I think his evaluation of the state of string theory is highly colored by his emotional and intellectual investment in and commitment to a certain vision he came under the spell of in 1984. His reaction to the null LHC results and the landscape shows that it will be extremely hard to sway him from his belief in that vision. “Faith” isn’t an inappropriate word to describe what is going on.

There is an historical analog of this situation: Witten’s IAS predecessor Einstein, who until the end of his life remained convinced that the way forward to a unified theory lay in a classical geometric framework extending GR, rather than through quantum theory and quantum field theory. I think Einstein was wrong, misled by faith in a vision he first came to in his mid-thirties, and Witten’s situation is not completely different.

20. **A**
May 3, 2019

“What I do find really surprising is what seems to me like a change in tone towards more dogmatism about string theory.”

Not really surprising. It’s called the backfire effect and shows that not even brilliant geniuses are immune to cognitive bias.

21. **Low Math, Meekly Interacting**
May 4, 2019

One thing I found odd: Witten moved on from QFT because the problems he was working on (non-perturbative QCD and related things, I guess) were “intractable”.

The Landscape, with its effectively infinite vacua and lacking any sort of selection principle to narrow down the options to something that looks like our corner of the multiverse, seems rather intractable. Same goes for gravity in the transplanckian regime, about which string/M theory has apparently nothing to say because, again, the methods needed are non-perturbative.

At least while banging ones head against the QCD wall one can compare fruitless attempts with experiment. I’m not sure what the appeal of working fruitlessly on something that can’t be compared with observation might be. “Beauty”?

22. **Peter Woit**
May 4, 2019

LMMI,
Witten has always kept changing what he actually works on, looking for places he can make real progress. I don’t think he’s actually worked on the Landscape, or ever will, since that can’t go anywhere.

An accurate way to characterize the current situation I fear is that Witten and most leading string theorists have simply given up on unification. But instead of admitting that string theory was a dead end for this, they have decided to argue that the multiverse solves the problem so they don’t need to think about it any more. From the beginning David Gross argued that this was the big danger: the multiverse would get used as an excuse for giving up (at Strings 2003 he was quoting Churchill as “Never, never, never, never, never give up.”) I had thought Witten had a similar point of view to this, but that seems to be no longer true, as he has moved from finding “giving up” upsetting to making his peace with it.

23. **Anonyrat**
May 4, 2019

So, what is Witten working on these days? Yes, I can look at arxiv — but I can’t fathom the significance or “bigger picture”.

Thanks in advance!

24. **Peter Woit**
May 4, 2019

Anonyrat,
I have no idea if Witten now has some "bigger picture" he is pursuing. From the Farmelo and other interviews, it seems that he's interested in various currently popular ideas about how to get quantum gravity and spacetime as emergent out of some sort of non-gravity quantum theory ("it from qubit"). Much of this is now being pursued at the level of trying to solve low-dimensional toy models. For the absolute latest from him, tomorrow he'll be talking at the Yau birthday conference in Cambridge (I was hoping to get up there this weekend, but recovering from a cold, stayed home). His title and abstract is at
http://www.math.harvard.edu/conferences/calabi19/poster/program.pdf
and says

Title: "Unorientable Two-Manifolds, Super Riemann Surfaces, And Random Matrices"
Abstract: Recently, P.Saad, S. Shenker, and D. Stanford showed that what is arguably the simplest model of quantum gravity, which is the Jackiw-Teitelboim (JT) model in two spacetime dimensions, can be understood as a random matrix theory. This result depends on the facts that JT gravity computes volumes of moduli spaces,and on the fact that those volumes have a random matrix interpretation. In this talk (reporting on work with D. Stanford), I will explain how to extend these results to the case that an ordinary Riemann surface is replaced by an unorientable two-manifold and/or a super Riemann surface.

25. **Justin**
May 4, 2019

Hi Woit,

I understand that you were joking about pushing children to do physics. But, were you joking when you said that Witten would have discovered the electroweak theory and asymptotic freedom at the age of 16?

26. **Peter Woit**
May 5, 2019

Justin,
The stories of Witten's ability to learn and absorb very difficult material unusually quickly are many. If he had started studying higher level math and physics seriously at age 12 (1963), by the time of the Weinberg-Salam model (1967), it's possible he would have understood the ideas behind the model, much less likely he would have been in the right place to do something with them. However, for asymptotic freedom, which wasn't discovered until 1973 (ignoring 't Hooft's unpublished calculation, I'm counting discovery as including understanding the significance for QCD of the result), he would have ten years to get this done before Gross/Wilczek/Politzer. That he could have discovered asymptotic freedom before age 22 seems not implausible at all. Actually, if he had headed directly to graduate school at Princeton after his 1971 undergrad degree, it seems quite possible he rather than Wilczek would have been the one doing the asymptotic freedom work.

27. **Blake Stacey**
May 6, 2019

> Looking to the near future, he's most optimistic about the "It from Qubit" business. Maybe he's right and something will come of this, but I've seen no indication of a path to a unified theory in this direction (how do you get the Standard Model? Or has he just completely given up on that?).

My sense of the "It from Qubit" crowd is that they want to get spacetime, or at least some kind of processed spacetime-like product, out of quantum entanglement. The priority is not so much to get the Standard Model from more basic principles, but to find a setting that can include both it and gravity.

Now, I haven't so far been blown away by their writings on this. To me, it sounds plausible that they'll get a geometric way of talking about many-body quantum states, but I'm far less persuaded that one can really go in the reverse direction. In addition, the features cited in their models don't really seem to do more than scratch the surface of what quantum mechanics has to offer, being features that can be emulated classically (per the Gottesman–Knill theorem) and/or found in theories that have an underlying layer of local hidden variables (like the Spekkens toy model). "It from Barely Nonclassical Bits" just doesn't have a revolutionary ring to it.

28. **Brett Smolenski**
May 6, 2019

A rather unpleasant question, but one worth considering here: what paths should one take if our universe truly was described by a particular choice of compactification parameters, yet no way to determine what that choice should be? Now Witten and other string theorist believe, or have faith, in at least the first premise of this question, so perhaps the paths they are choosing to take are just their depressing answers to an inherently depressing question. I hope the premise of this question is false, but the universe does not seem to care much for my hopes.

29. **Peter Woit**
May 6, 2019

Brett Smolenski,
It's of course logically possible that all parameters of the SM are enviromental, determined by some unknown pre-big bang physics in an essentially random way. If we knew this to be true, of course we should give up thinking about the origin of the SM and do something else, and I guess that's what Witten and others think they are doing.

The problem is that we have absolutely no evidence at all for this. There is zero evidence for unification via a string theory compactification. If you're going to do science, you are supposed to have scientific evidence for your claims, and there is none here.

For another related interview, Sean Carroll has posted an interview with Leonard Susskind here

https://www.preposterousuniverse.com/podcast/2019/05/06/episode-45-leonard-susskind-on-quantum-information-quantum-gravity-and-holography/

where Susskind responds to a question about this not by claiming any positive evidence for it, but by just saying no one else has a better answer:

"My answer is always, "Yeah, what do you have that's better?"

This method of argument works universally: for any unsolved problem you can argue that it can't be solved (and, if you have tried and failed, you may strongly believe this). But if you want want your "it can't be solved" argument to be "better" than "it can be solved, we just don't know how yet", you have to have some evidence for your argument, and there isn't any here.

30. **Marko**

May 8, 2019

"Yeah, what do you have that's better?"

But there indeed *are* better, or at least equally promising, approaches. For example, higher gauge theory looks promising to revive the idea of unification of everything (gravity included), based on higher category structures instead of Lie groups (my recent draft shows how to construct the SM and gravity using 3-groups). With a little more research and a clever choice of a 3-group, this framework could potentially be able to reduce the number of free parameters in the SM. There are also other alternatives.

So string theory is really not the only game in town anymore, even for unification of matter, let alone gravity. But the vast majority of people just listens to Witten and Susskind, and ignores everyone else. That's the problem.

🙂
Marko

31. **Peter Woit**
May 8, 2019

Marko,

I've never understood the argument "we've devoted 35 years and the efforts of thousands of people to see if our speculative idea works, and by now we understand in detail why it can't work. So, our speculative idea is better than your much more poorly understood speculative idea, which seems to also have some problems."

Or, more briefly: "yes, our idea doesn't work, but at least we understand in detail why it doesn't work, so that makes it better."

32. **shantanu**
May 8, 2019

I would like to see a debate between Witten and some LQG person on LQG. Incidentally some of his own colleagues at Princeton such as Frans Pretorius are working on LQG.

33. **Peter Woit**
May 8, 2019

shantanu,
I think there is zero chance of ever seeing that. Back at the height of arguments over LQG vs. string theory in 2006-7 Witten showed little evidence of willingness to engage in that argument, even less now.

34. **IM**
May 8, 2019

Dear shantanu,
I believe that the only time Witten indirectly criticized some of the ideas underlying the research program of LQG in public was his paper "A Note On The Chern-Simons And Kodama Wavefunctions," see https://arxiv.org/abs/gr-qc/0306083
To understand the relevance of that paper to LQG and its response (by Smolin and others) you can read the Wikipedia page: https://en.wikipedia.org/wiki/Kodama_state
Interesting to note that in Witten's gr-qc/0306083 he never mentions the name "l.q.g." but only cites Smolin's hep-th/0209079
Regards,
–

35. **Michael Harney**
May 9, 2019

I can't believe Ed Witten has bought into the landscape nonsense. This is one of the brightest physicists in the last 30 years accepting unfalsifiable predictions. Truly bizzare.

36. **tulpoeid**
May 10, 2019

(@ Peter and Justin,)

"That he could have discovered asymptotic freedom before age 22 seems not implausible at all. Actually, if he had headed directly to graduate school at Princeton after his 1971 undergrad degree, it seems quite possible he rather than Wilczek would have been the one doing the asymptotic freedom work."

When I read this in the original post I took it as part of a great joke. Apologies, but I still do. Mathematical genius is one thing and good sense is another; if a lack of the latter is demonstrated so rigorously by an individual, then s/he cannot be expected to hands down discern study topics that will lead to concrete advancement.

37. **Peter Woit**
May 10, 2019

tulpoeid,

If you look at the history of the discovery of asymptotic freedom, it was done independently (although there are questions about leakage of info via Sidney Coleman) at Harvard by one graduate student (David Politzer) and at Princeton by David Gross working with his student Frank Wilczek. Witten quickly ended up working with David Gross at Princeton after he arrived there. If he had arrived a couple years earlier he still likely would have started working with Gross, and it's not at all implausible that he would have been the one Gross set on working on the beta function calculation, not Wilczek. Knowing Witten, it's also not at all implausible that he would have completed the calculation and understood its significance faster than the Wilczek/Gross pair did. Similarly, if he had gone to Harvard, he quite possibly would have worked with Coleman, who would have sent him down the same path Politzer started down, with the same result, possibly quicker.

Witten has great mathematical talent, but also great talents as a physicist, and it is the physics that more strongly motivates him than the math. Over the years his greatest work has often brought new mathematics to bear on physics, but this more often has been in the service of solving physics problems, not mathematics problems. I think blaming the string theory debacle on theorists being too "mathematical" and lacking "physical intuition" is a huge mistake. String theory unification is a very "physical" idea, just happens to be a bad one. The mistakes in judgement that have caused generations of physicists to pursue this failed idea are not ones that have their origin in too much exposure to mathematical culture.

Categories: Obituaries, Uncategorized

Possibly of interest:

- Goro Shimura, one of the major figures in twentieth century number theory and arithmetic geometry passed away on May 3 in Princeton at the age of 89. Princeton has an article about his life and work here. There's another article about him here (in German). Back in 2008 Shimura published an autobiographical memoir, The Map of My Life, which I wrote about here.
- The Dutch publication de Volkskrant has an article asking if theoretical physics has lost its way. Sabine Hossenfelder and Avi Loeb are quoted on the "there's a problem side", Robbert Dijkgraaf on the "no problem here" side.
- A commenter here points out an article in le Monde about the currently unresolved question of what to do with the 100,000 or so pages of writings left by Grothendieck at the time of his death. There seems to be a consensus that someone should carry out the expensive project of having the pages cataloged and transcribed, but how to pay for this, and who should ultimately take ownership of the papers remains up in the air. Supposedly a sizable part of the documents deals with Grothendieck's speculation about physics. The article starts off with a characterization of Grothendieck's work as important in the story of the Higgs discovery, which is quite inaccurate (there is no significant relation between his work and the Higgs).
- For many years people at SLAC have used the database there to produce "Topcites" lists of the most heavily cited papers in HEP physics, giving some insight into what topics are the most popular in current HEP research. From 1997-2003 Michael Peskin wrote up some reviews of what was going on in HEP physics each year based on these lists, and has started doing so again (for 2017 and 2018). These lists and the reviews are now dominated by astrophysical and cosmological topics, with little about HEP theory. To get an idea of what the hot topics are in HEP theory these days, take a look at the list of most frequently cited papers by hep-th preprints in 2018.
- The series finale of The Big Bang Theory will air this week, on Thursday. Since I've canceled my cable TV service a while back I haven't been following the latest episodes, which evidently feature a replacement for the failure of supersymmetry, called "super-asymmetry". At some point I hope to catch up with these, and find out what happens to "super-asymmetry".
- This week the European Strategy Update for Particle Physics is holding an Open Symposium in Granada, to discuss plans for the post-LHC future (a blog posting about this from Tommaso Dorigo is here). I've written here about the difficult issues that CERN and European HEP physicists are facing. Looking at one of the first talks on future colliders, I was surprised to see muon colliders listed as a potentially viable possibility, since I thought that the technology needed for those was still far in the future.

Update: Kenneth Chang at the New York Times today has an obituary for Shimura.

Update: On the obituary front, it was announced today (5/24) that Murray Gell-Mann has passed away, at the age of 89. The New York Times has an obituary written by his biographer, George Johnson.

Comments

   May 13, 2019

   Peter, there seems to be some mistake in the listing of top-cited papers,
   For the 2018 list, arXiv:1901.01540 is cited as a top cite, which just 4 citations.

   In a related issue I find that inspire-hep is no longer adding references to papers cited in 2nd and beyond versions of papers submitted to arXiv.

   I love these "possibly of interest" posts. Please keep them up.

3. **Grothenhiggs**
   May 14, 2019

   Was there ever a character that is a mathematician in Big Bang Theory? How was/would be the interaction of Sheldon and a pure mathematician?

4. **tommaso dorigo**
   May 14, 2019

   Hello Peter, long time no talk. Thanks for the link!

   As for muon colliders: the rationale of putting them on the table is to take the
   design of one such machine as seriously as it should. Here I summarize very succinctly the status of matters:

   – a muon collider would be a wonderful machine, enabling studies of the Higgs sector as well as searches for new physics in a cleaner environment than hadron collisions

   – muons decay in 2.2 10^-6 s in the lab rest frame, but in an accelerator they can live long enough to be accelerated, squeezed, and collided at high luminosity. This is not a heavy technical issue – we know how to get around the main hurdles.

   – there are big issues concerning the high fluxes of radiation (neutrinos!) produced around the ring, but these are also solvable

   – the main issue is how to produce them at low emittance. The conventional way to produce a muon beam is by hadron decays, but there the emittance is very large and cooling is a big issue. The alternative under study is to produce muon pairs by e+ collisions on a fixed target at threshold. There the emittance can be small, but intensity is an issue, and the target design is a bit nightmarish at the moment.

   All in all, I do believe Europe should pay attention to fostering these studies, although it is likely that a muon collider could only see the light when you and I will not be around anymore.

   Cheers,
   T.

May 14, 2019

I am bemused by Dijkgraaf's response to Hössenfelder's criticism. In his first quote, he says that physicists have no need for a thought police. That's actually a rather unfair representation of Hössenfelder's point, especially since she's explicitly disavowing it later on in the article (of course this might only have been after having been informed of Dijkgraaf's objection).

6. **Peter Woit**
May 14, 2019

shantanu,
I think that's just a paper Peskin is referring to as a very recent observational result, not as a top-cite.

Grothenhiggs,
I don't recall mathematicians ever making any sort of appearance on Big Bang Theory, unfortunately indicative of the point of view of most physicists, that whatever mathematicians might be doing, it has nothing to do with physics.

Tommaso,
Thanks for the summary!

Someone who reads Dutch,
I've also run into the phenomenon of people responding to a serious scientific argument that an idea doesn't work with "thought police" accusations. In this case, Dijkgraaf, as IAS director, has a lot of influence on what research gets supported and what doesn't. Accusing someone in Hossenfelder's position of being a heavy-handed ideological enforcer is kind of comical.

7. **TME**
May 14, 2019

Peter,

"Accusing someone in Hossenfelder's position of being a heavy-handed ideological enforcer is kind of comical."

That might be a bit harsh, but don't you agree that an outsider (in terms of understanding of string theory and nonperturbative QFT developments) like Hossenfelder trying to give arguments as to what research should and shouldn't be done is at least a bad look?

8. **Peter Woit**
May 14, 2019

TME,
In my experience Hossenfelder is generally careful to aim her criticisms at things she understands well enough to evaluate. Some of her arguments are about the reward structure of the field and some of the problematic results this leads to. She is more competent than most to make these arguments. I don't see her making arguments on more technical topics unless she has a reasonably good understanding of them.

For decades now, a favorite tactic of some theorists pursuing failed research programs has been to refuse to address criticisms of such failed research programs, resorting instead to ad hominem attacks on their critics as incompetents or "thought police", or whatever. You can try shooting the messenger, but it doesn't change the facts about your failure.

9. **Anonyrat**
May 14, 2019

Avi Loeb has a sensible suggestion:

"He {Loeb} therefore proposes a kind of hippocratic oath for physicists, inspired by the oath that doctors take, in which physicists must swear that at least one idea they are working on can still be confirmed experimentally during their lifetime. 'If I succeed, I would like to call them physicists again. Until then I think their ideas say nothing about reality. " (Via Google translate)

10. **Peter Woit**
May 14, 2019

Anonyrat,
I actually strongly disagree with that. Some theoretical physics is "phenomenological", closely tied to experiment, and that should be evaluated in terms of its relation to experimental results. But other areas of theoretical physics are not closely tied to experiment. For instance, there is a huge amount we still do not understand about quantum field theory. Theorists who want to spend their careers trying to develop new techniques leading to a better understanding of quantum field theory should be able to do so, even if there's no particular reason to believe that success would lead to some experimental test.

The argument that you want people to be able to do pure research that advances understanding, not just research with near-term practical consequences, is clear to most scientists, and extends to the issue of experimental confirmation. The primary goal is deeper understanding. If such deeper understanding leads to new experimental tests and confirmation, great, but that's not the most important thing.

The real problem is how you evaluate the results of such attempts to get deeper understanding, in the absence of clear experimental tests. The problem with string theory unification is not primarily the lack of experimental confirmation. It's a failed idea that does not lead to models that convincingly explain anything that we don't understand about the SM.

I don't think you should stop people from thinking about speculative ideas. But, you need some way to get them to give up when such ideas aren't working and try something else, and there won't always be experimental results that can provide decisive answers to what works and what doesn't.

11. **Someone who reads Dutch**
May 14, 2019

On the bright side, I think it's a safe bet to say that the debate won't go away anytime soon. If Hossenfelder (my apologies to her for misspelling her name earlier) and Loeb, despite going against the mainstream and not being personally involved in string theory research, have enough traction that mainstream media (even if it's only Dutch mainstream media) are reporting on their claims, and eliciting a response from one of the most prominent faces of theoretical physics in the world, I think that in itself is an enormous victory, and I want to congratulate Hossenfelder and Loeb on that.

My impression of Dijkgraaf in the article is that he's mainly putting out tired clichés. I mean by comparing the 40 years in the desert of string theory to Einstein's years of building up towards the theory of General Relativity. And I think Dijkgraaf himself surely realizes that the analogy is not beyond serious criticism, to put it very mildly. The main problem with this defense seems to be to me that he could use it no matter what. It almost seems like an abuse of Einstein's prestige to use it to defend a potentially pointless enterprise.

I think philosophy of science must come to grips with questions like: How can we actually distinguish between "a genuine quest for new ideas" on the one hand, and "the inmates running the asylum" on the other? I think we are already seeing that Popper's falsification criterion is just not cutting enough ice with enough people, because many folks are rightly pointing out that a successful paradigm shift is always born of the realm of heuristics and intuitive guesses.

However, this last argument does strike a false note with me, not so much because it is untrue but because it does not apply. If we would have asked Einstein what he had been up to between the years of 1907 and 1916, he wouldn't have said that he was aimlessly exploring new ideas in order to bring about a paradigm shift. From very early on, Einstein had a quite definite vision in mind of what the theory of General Relativity should accomplish (starting with the "luckiest thought of his life", or however he called it), and also he knew approximately what kind of mathematical tools should be involved in the shaping of that theory. So in that sense, string theorists are *not* doing what Einstein did, because they do not have the same sense of aim and direction that Einstein had (and it is amply documented that he did have it). At least to my understanding, all that string theory has to offer are some partial inroads into the Great Unknown. Quite a big difference. It actually seems a falsification of history to compare string theorists with Einstein.

12. **Someone who reads Dutch**
May 14, 2019

Of course, my statement that "philosophy of science must come to grips with questions like […]" should not be construed as meaning that there should be a Thought Police making sure philosophers of science are working on this question…

13. **Peter Woit**
May 14, 2019

Someone who reads Dutch,

An interesting question for those who compare themselves to the Einstein of 1907-1916 is whether the evidence isn't more on the side of their efforts being comparable to those of the Einstein of 1922-1955, who devoted decades to failed ideas about how to unify electromagnetism and GR. This question should be especially poignant for the director of the IAS, the institution that hosted Einstein's failed efforts.

From what I know of the history, if you look at Einstein's work from 1907-1916 you see the gradual successful working out of an early vision, whereas if you look at 1922-1955 you see an increasing accumulation of evidence for why the initial vision couldn't work. It's the latter story which looks comparable to the string theory unification story (which in a way, is about the same thing: a failed geometrical idea of how QED and GR fit together).

Of course one major difference is that Einstein never attracted a significant number of followers for his failed program, whereas string theory involved thousands and still has some sort of dominant role in many parts of the theory community. Arguably there's nothing wrong with encouraging a single talented researcher to pursue their vision even long past the point it seems to others to not be working out. But you don't want the whole community doing this.

May 14, 2019

One comment on Shimura that may be relevant to the current debates in physics. Throughout his career Shimura followed a very independent path — no one seems to know who his doctoral advisor was. The elliptic modular curves (quotients of the complex upper half plane by a congruence subgroup of SL(2,**Z**)) are initially defined over the complex numbers, but they are known to have canonical models over number fields. For the analysts, this is true because of the properties of the Fourier expansions at the cusps, and for the algebraic geometers, it is true because they can recognize the curves as a moduli varieties. There are similar complex curves attached to every quaternion algebra over **Q** split by **R**, but they have no cusps and are not moduli varieties, and so everyone knew that they did not have canonical models … until Shimura proved they did. This was perhaps his most original contribution, and was not something that someone too deeply embedded in the culture of the day could have done. Today the curves are named after him.

15. **Anonyrat**
May 14, 2019

Peter, I agree with what you wrote; though we would presumably value "improved understanding of QFT" higher than "improved understanding of string theory" because QFT has a well-demonstrated relevance to the physics of the universe, while string theory does not. I take it that Avi Loeb is trying to find a test to keep members of the physics department from spending their entire career on topics that are fiction though written in mathematics.

May 15, 2019

> There seems to be a consensus that someone should carry out the expensive project of having the pages cataloged and transcribed, but how to pay for this, and who should ultimately take ownership of the papers remains up in the air.

Scan the pages. Upload to the internet. The enthusiast nerds will sort the pages by themselves.
I am being serious.

17. **Peter Woit**
May 15, 2019

workerpleb,

I don't think it's so easy. Montpellier has conserved, organized, scanned and put on line, see
https://grothendieck.umontpellier.fr/
18000 pages of his earlier documents (another 10000 are not online, for legal reasons including the fact that letters can't be made public without permission of the writer). Even with all this careful work, many of these documents are not yet in a very usable form. In particular, a lot are hand-written, with deciphering Grothendieck's handwriting a skill most people won't want to spend the time to acquire. They really should be transcribed into TeX to be useful, but it looks to me like this would require a sizable group of French-speaking experts in algebraic geometry with a lot of patience and a lot of time on their hands.

18. **cedric bardot**
May 16, 2019

From his reading of Grothendieck text "La clé des songes" Connes – in this video with Serres: https://youtu.be/pOv-ygSynRI?list=PLwl60Z8ihqF7C4GNQUJCxNPFXPqfN087g&t=2513 – emits roughly the hypothesis that Grothendieck ' father dreamed of writing but never did so the 70000 pages written & archived by Grothendieck at his home might be his tribute to some extent.

Connes doesn't doubt one could develop a software to decipher the handwriting (thanks to IA ? ;-).
I guess a citizen science project like the one imagined to decode Darwin's Handwriting would be more difficult to implement due to the manifold of subjects (from abstract math to potentially paranoïd thoughts?) & legal issues.

About a possibly not so far-fetched connection between particle physics & Grothendieck concept of motives :

> "C'est une idée qui a émergé lors de discussions entre physiciens et mathématiciens à l'IHES, à l'heure du thé", se rappelle Francis Brown, professeur à l'Université d'Oxford [et à l'IHES (http://www.ihes.fr/~brown/)]. Le défi était de calculer comment les particules se désintègrent lors d'une collision sans se lancer dans les calculs d'intégrales utilisés classiquement, souvent très complexes. "Et c'est là que le miracle intervient: nous pensons que derrière ces intégrales se cachent des motifs qui permettraient de les calculer beaucoup plus rapidement! s'enthousiasme Francis Brown . Aucun physicien n'aurait pu s'en apercevoir. Il a fallu que Grothendieck passe par là!"

(https://www.science-et-vie.com/science-et-culture/grothendieck-les-archives-fantasmatiques-41922).
cf Mathilde Marcolli too: https://arxiv.org/abs/0907.0321

19. **jsm**
May 16, 2019

There may be gems in the 18,000 pages (or 118,000 pages) of Grothendieck's notes, but much of it seemed to me (when I looked at it) to be the sort of scrap paper most of us accumulate when working on a problem, and that not even we can understand five years later.

20. **Y-**
May 20, 2019

Historians seem to develop tools for transcribing handwritten texts, e.g. https://transkribus.eu/Transkribus/

21. **David Yager**
May 22, 2019

No narrative about SUSY2019? We're half way through it. The timetable at the event site shows a lot of presentations, but I haven't looked at it enough yet to see how much actual SUSY content is there.

It's the right time to start putting out predictions of what the muon g-2 delta is actually going to be, and what new particle explains it.

22. **Peter Woit**
May 24, 2019

David Yager,

I took a look, and there are at least two things about this conference that strike me as peculiar:

1. Gordon Kane as summary speaker. Why choose as summary speaker the person in your field with least credibility? What prediction for the gluino mass will he announce today?

2. Pre-SUSY 2019. The instructional talks for grad students and postdocs gave little indication of the problems with SUSY models. Given the LHC null results, and the huge industry of several generations of theorists trained to do SUSY calculations in models that have failed, why train a new generation in the same techniques?

23. **rpo**
May 24, 2019

On the subject of the mortality of great figures, Caltech has just sent an email to staff announcing the death of Murray Gell-Mann.

24. **Armin**
June 2, 2019

Peter,

Did you ever meet Gell-Mann? If so, do you have any personal anecdotes?

25. **Peter Woit**
June 2, 2019

Armin,
No I never met Gell-Mann. Stephen Wolfram wrote an interesting piece about his experiences with Gell-Mann, see here
https://blog.stephenwolfram.com/2019/05/remembering-murray-gell-mann-1929-2019-inventor-of-quarks/

26. **Chris Oakley**
June 3, 2019

The Wolfram article is interesting reading. I believe that Gell-Mann was not the only eminent scientist not to want to endorse *A New Kind of Science*. The article, as well as pieces written by others, give the impression that Feynman was the showman and Gell-Mann the quiet one. Maybe, but the one time I saw Gell-Mann speak he was very clear and very entertaining.

The Universe Speaks in Numbers

May 24, 2019
Categories: Book Reviews

Graham Farmelo's new book The Universe Speaks in Numbers has recently been published in the UK, US publication is next week. The topic of the book is one close to my heart, the relationship of mathematics and physics. I'm very much in agreement with the main argument of the book, which is that our most fundamental theories about physics have turned out to naturally be expressed simply and beautifully in terms of deep ideas about mathematics. This surprising congruence between the deepest ideas in two seemingly different fields strongly indicates that they share an unexpected unity. As fundamental physics reaches technological limits on the experimental side, investigating the underlying mathematical structures may be the best and only route open to further progress.

Much of the book is historical (and often Anglo-centric), beginning with Newton, a figure who made huge tightly intertwined advances in both mathematics and physics. Looking at Newton's career, it makes no sense to characterize him as a mathematician or a physicist, he's both in equal measure and at the same time. Farmelo then moves on to Maxwell, who also revolutionized physics while at the same time introducing important new mathematics into the subject. He tells the story of Maxwell's 1870 talk "On the relations of mathematics to physics", then a couple chapters later it's Dirac's 1938 talk "The Relation between Mathematics and Physics".

In Farmelo's account:

> Dirac quickly arrived at what was, in effect, a manifesto for research into theoretical physics. He proposed a new principle – the principle of mathematical beauty – which says that researchers should always strive to maximize the beauty of the mathematical structures that underpin their theories of the natural world…
> He concluded that "big domains of pure mathematics will have to be brought in to deal with the advances in fundamental physics"…
> Eventually the two subjects might possibly become unified, Dirac suggested, with "every branch of pure mathematics then having its physical applications, its importance in physics being proportional to its interest in mathematics."

A major reason for Dirac taking this sort of view was the example of Einstein's work on general relativity, which to reach fruition had required Einstein to become expert in the newly developed and rather challenging abstract mathematical machinery of Riemannian geometry. The two great pillars of modern physics, relativity and quantum theory, are deeply related to central modern ideas about mathematics, in particular, respectively, geometry and representation theory. While in the case of relativity the mathematics came first, for the case of quantum theory, the mathematics underlying the subject was mostly developed later.

Farmelo goes on to explain that relations between math and physics entered a fallow period during the 1950s and 1960s, but the advent of gauge theory and the Standard model led to a productive renewal of healthy relations during the 1970s. He does a good job of explaining how this came about, discussing in particular the central role played by Witten. Farmelo has benefited from getting to talk to Witten himself in some depth about this, and gives a nuanced portrayal of Witten's rather complex and evolving feelings about the relations of the two subjects and the role that he and his immense talents have played in this story.

There's a great deal of the usual sort about the history of string theory, emphasizing its points of contact with new mathematics. The next to last chapter is about Nima Arkani-Hamed and the amplituhedron story, portrayed as the latest exciting development on the math-physics front. Farmelo is clearly enthralled by Arkani-Hamed and his intense enthusiasms. The evolution of Arkani-Hamed from phenomenologist to mathematical physicist is definitely a fascinating thing to observe, and I've often written about it here (you might want to for instance read this posting). Farmelo also points to an excellent lecture by Greg Moore on *Physical Mathematics and the Future* (discussed here), which I think is based on a much deeper understanding of the current state of the math/physics relationship, and gives a much broader perspective than the narrow one of the amplituhedron. By the way, I see on Moore's website that he's writing up for the 2019 TASI school what appears to be an excellent set of notes about Chern-Simons theory and related topics.

A major problem though with this book is that it pretty much completely avoids the big problem raised by the program of pursuing progress in fundamental physics through beautiful mathematics: how do you know whether people doing this are on the right track or headed down a blind alley? Farmelo starts the book off with a very odd preliminary chapter comparing Einstein's work at the IAS in his later years to that of his modern day successors:

> was seeking a new theory, not in response to puzzling experimental discoveries, but as an intellectual exercise – using only his imagination, underpinned by mathematics. Although this approach was unpopular among his peers, he was pioneering a method similar to what some of his most distinguished successors are now using successfully at the frontiers of research.

The fact of the matter is that, in retrospect, Einstein's work of this era was a huge failure, as he got stuck deep down a blind alley. He was seduced by a specific speculative idea about how to get unification out of mathematics, by using simple extensions of the differential geometry that he had such success with in the case of GR.

How does Farmelo know that string theory enthusiasts following Einstein haven't run into the same problem he did? In essence, Farmelo just assures us that he has talked to them and they tell him that, like Einstein before them, they think they're on the right track. The existence of skeptics is mentioned, but their writings are carefully excluded from the 200+ item bibliography. Jim Baggott, Sabine Hossenfelder and I (and our writings) appear only in a short footnote on page 6, with bloggers described as complaining that "modern physics should get back on the straight and narrow path of real science". But the three of us are complaining about, not "modern physics", but one small subset of it, and at least in my case, the path I argue for is almost exactly what Farmelo is arguing for: absent help from experiment, pursue the path advocated by Dirac.

Here's part of Farmelo's summation of the current situation in the book's last chapter:

> The great majority of today's leading theoretical physicists are, however, confident that they are motoring steadily in the right vehicle, despite the problems they are having in trying to drive it.
>
> In the public domain, the debate about the merits of the string framework has been raging for years, especially in print and online. Some of these onslaughts are useful correctives to the hype lavished on this programme and to the superciliousness of pronouncements made by some string (although rarely by the best ones in my experience). Experts on the string framework have every reason to be proud of the progress they have made, but until such time as experiments confirm its validity, there is no room for smugness. Yet I am often troubled by the dismissiveness of some of the critical commentators, especially those who write with a confidence that belies the evident slightness of their understanding of the subject they are attacking. Opposing the view taken by leading theoreticians might be interpreted as a healthy disrespect for orthodoxy. However it may be part of the worrisomely common view that anyone can have a valid opinion on any subject, regardless of their technical knowledge and appreciation of it. In scientific matter this trend is especially regrettable.

The first part of this I think is simply not true, with most "leading theoretical physicists" these days unsure what the right direction is for how to get beyond the Standard Model. As for the last bit, I'll just say that I think it can accurately be described as "sleazy" (by the way, Farmelo at one point came to see me in New York when he was doing research for the book, and we had a quite pleasant conversation, he's rather charming). Besides the ad hominem attack on unidentified critics, there's nothing anywhere in the book about the actual problems of the vehicle some people are motoring in. For instance, the problem of the landscape and the multiverse is dealt with by just ignoring it, it's not mentioned at all. If it had been mentioned, Farmelo might have had to deal with the fact that it's mathematically hideous, so a direction which should be abandoned by his own arguments.

In the end, my feelings about this book are much the same as in the case of Farmelo's biography of Dirac (see here): a wonderful book in many ways, but marred by a bizarre degree of string theory fanboyism. While there's a lot to like about this book, and much of it makes a good case for a controversial point of view that I strongly agree with, unfortunately the problems with it are even more serious than in the case of the Dirac biography.

The IAS is having a [public event next week](), convening a panel to discuss the math-physics issues brought up by the book. I may add something here about this after it happens. Perhaps someone in attendance can get a show of hands from the assembled leading theorists to see if they really feel that they're steadily motoring in the right vehicle or not.

Update: I'm listening to a live-streaming version of the IAS event here. After a talk by Farmelo, mainly about history, and a discussion with Karen Uhlenbeck and Freeman Dyson (moderated by Natalie Wolchover), Greg Moore is now giving a talk (available here) on TQFT and gauge theory which is quite good. I'm very much in sympathy with his take on "physical mathematics".

Update: Besides an advertisement by Nima Arkani-Hamed and Thomas Lam for their work on amplitudes, the only discussion of the current state of the math/fundamental physics interface was the final short conversation between Dijkgraaf and Witten. Looking back at expectations from 30 years ago, Witten said he had expected progress on understanding the laws and principles behind string theory, but that has not occurred. Dijkgraaf tried to end with a defense of string theory as "well, by AdS/CFT it's connected to QFT, so it somehow is connected to the real world", to which Witten said something like "we shouldn't give up hope for string theory as a unified theory, we might yet find the right string theory vacuum". In the end Witten said that he found it hard to accept the possibility that the unexpected things discovered through string theory didn't mean that it had to do with a unified theory, but admitted he didn't have a scientific justification for this.

Update: There's a review of the book by Tony Mann at Times Higher Education. It includes:

> Farmelo's book is a response to these contrarians . He is confident that the beauty of the mathematics is significant in indicating that we are on the right track, and that eventually, even if we have to wait for many years, we will be able to test string theory against new experimental evidence. As a spirited defence of the idea that beautiful mathematics should be a guide for physicists, Farmelo's book is a timely response to critics such as Woit and Hossenfelder, defending what science writer Jim Baggott has called "fairy-tale physics". Ultimately I am not sure, however, that he makes his case anything more than a matter of faith.

I think Mann gets it right that the Farmelo book is intended as a defense of string theory against the Baggott/Hossenfelder/Smolin/Woit critique (with the odd feature that he refuses to allow mention of our books in the bibliography, or to engage in any way with the arguments we make), and that his argument comes down to little more than "trust certain famous theorists", especially those at the IAS. As usual, I'm inaccurately portrayed as opposed to the idea that progress can be made by following beautiful mathematics. The problem with string theory unification is that it's a failed physical idea, with the failure indicated not just by lack of predictivity, but also by the fact that string theory models compatible with observations are horrendously ugly.

Update: The Dijkgraaf-Witten conversation is available here. Some extracts from near the end.

> *Witten*: I'm actually personally reasonably confident that what we're doing is a lasting contribution. But I'm less confident that we'll really be able to put it on a completely solid footing. It depends on being lucky with experiment, I would say…
>
> *Dijkgraaf*: Often I hear questions about whether is string theory wrong or right, but I often answer there's no way in which we'll ever get rid of string theory, because in some sense it's an integral part of the theories that we already are using.
>
> *Witten*: That's true but not completely satisfying. Let's not give up on the dream of finding the vacuum that describes the real world…
>
> The honest answer is that personally as I told you before I have confidence that the general enterprise is on the right track, but I don't claim that the argument I've given is scientifically convincing.

Witten makes clear that at this point he has no likely forseeable experimental results relevant to string theory he can point to, no "scientifically convincing" argument that it's on the right track, just a feeling that since string theory research has turned up various points of contact with important math and physics, there must be something right about the idea.

Update: Siobhan Roberts at the New York Times has a piece about the centenary of the eclipse that made Einstein famous that also discusses Wednesday's IAS event.

1. **Sabine Hossenfelder**
   May 25, 2019

   There is a lot of mathematics. Some of it beautiful, some of it not so much. Some of it describes our world, some of it does not. How do we find the math that describes our world?

   That's the relevant question that anyone should ask who is interested in progress in the foundations of physics.

   Relying on beauty has not worked in the past and it's not presently working, so clearly this is not what physicists should do.

   Likewise, working on a theory just because a lot of other people work on a theory, is also not a good reason to think that this theory tells you something about the real world.

   And without these two arguments, what is left of string theory? Not much. It's not that it's entirely uninteresting, of course. It's just that the resources that have gone into it and continue to go into it vastly exceed the reasonable. And throwing further money at it just encourages people to produce more useless papers, like on the swampland and such. And don't get me started on folks who seem to think we live in Anti de Sitter space.

   Seriously, Peter, I ask you. How can anyone in their right mind still think that this has something to do with describing reality? Why are these people still receiving research grants?

2. **Koenraad Van Spaendonck**
   May 25, 2019

   S.H. said :
   "How do we find the math that describes our world?

   Here's an interesting read, from Lee Smolin, on the subject, as he tracks Einstein's modus operandi :

   https://arxiv.org/abs/1512.07551

   The introduction says :

   " There is a myth that Einstein's discovery of general relativity was due to his following beautiful mathematics to discover new insights about nature. I argue that this is an incorrect reading of the history and that what Einstein did was to follow physical insights which arose from asking that the story we tell of how nature works be coherent.

“

3. **Adrian**
May 25, 2019

Dear Peter, I read that the commenter Sabine Hossenfelder has written
”And don’t get me started on folks who seem to think we live in Anti de Sitter space.”

As a working string theorist, active in conferences and paper-wise, I have a good grasp about what the community of people working on various aspects of holography and extensions of the conjecture made by Maldacena in 1997, actually believe or think.

No one of my colleagues believes that ”they live on AdS space”. Actually, all of them know we do not live in Anti de Sitter. These colleagues use Anti de Sitter and a theory of gravity defined on it to calculate observable quantities (correlation functions) of conformal field theories. By studying deviations from Anti de Sitter, these colleagues learn about quantum field theories that confine, spontaneously break symmetries, etc. They have developed set-ups in which various other non-perturbative effects are actually calculated.
Other part of the community have made important progress on the dynamics of black holes.

I believe that not recognising and not understanding these basic points leads to very misguided comments (I believed Sabine Hossenfelder understood these things) . Not appreciating this particular enterprise is, I believe, very narrow-minded.

Thanks

4. **Peter Woit**
May 25, 2019

Adrian,
I don’t think there’s really any incompatibility between what you and Sabine Hossenfelder have to say. Her “folks who seem to think we live in AdS” comment is clearly aimed at those who (like Farmelo) defend string theory as a theory of the real world by pointing to AdS/CFT. To the extent she offers a critique of the kind of research you describe, it’s not that no one should be doing it, but that too many people are doing it, and I think she is right about that. It’s not healthy for the field to be so dominated by one particular rather narrow line of research for the past twenty years.

5. **Eli Rabett**
May 25, 2019

IEHO the connection driving force is not the beauty of the connection between math and physics but the terseness of it. Short makes sweet.

6. **Paolo**
May 25, 2019

Did Einstein “know” about the existence of Yang-Mills theory (in 1954) ?

7. **Peter Woit**
May 25, 2019

Paolo,
I doubt it. Yang did talk about Yang-Mills at the IAS in February 1954, a year before Einstein’s death, but I believe at this point Einstein would not have been paying attention to what particle theorists were doing (Yang was trying to get a theory of the strong interactions).

8. **Justin**
May 25, 2019

Exactly what mathematical structures are to be investigated in lieu of experimental limitations, and who is supposed to be investigating these structures, the mathematicians, physicists, or both? Newton was able to be a mathematician and physicist of equal measure at the same time, not because he possessed superpowers, but because in the 1660’s the amount of material in the two subjects could be learned quicker than today. I don’t think physicists today would know enough about math to investigate the structures, and I don’t think mathematicians would know enough physics to know what structures to investigate.

9. **Sabine Hossenfelder**
May 26, 2019

Adrian,

My sentence was an attempt at humor, trying to express that while there is a large community studying fields in AdS, almost no one in this community works on explaining what this has to do with the real world. I know that a few exceptions exist, no need to tell me things I already know. But the vast majority of people in the area do calculations in AdS just because it’s simpler and they know how to do it, not because they actually know of any argument why it is useful to describe reality.

If I ask them why they work on this, they tell me they hope to learn something from it about dS. If you ask them a little more, they will admit that they have no reason to think the results transfer to dS. And don’t get me started again on the claim that it should work because both spaces are locally flat. It makes zero sense because all the benefits from working in AdS are non-local. And, needless to say, the world isn’t supersymmetric and not conformal and N isn’t infinity. These are mathematical fictions, not descriptions of anything in the real world.

This is not how science should work. And the reason why this is happening is obvious: They do it because they can, because they continue to get funding for it. It’s a waste of time and of money and it has to stop.

The reason I am phrasing this so bluntly is that I see a lot of hype in the media about AdS/CFT (sadly including otherwise reliable outlets like Physics Today and Nature) and they tend to not give the reader a clear impression about the promise of this research. It’s 99.99% hot air. It’s been pursued since 20 years and pretty much nothing has come out of it. (Except possibly for explaining why you do *not* need it in heavy ion collisions.) And this is the supposedly “greatest breakthrough” in the foundations of physics since the 1970s.

10. **Rolf**
May 26, 2019

@Sabine
isn’t this Anti de Sitter space related work by you:
https://journals.aps.org/prd/abstract/10.1103/PhysRevD.91.124064

and this a notice about ongoing (since 2016) public funding you receive for this kind of work:
http://gepris.dfg.de/gepris/projekt/286641560 ?

Would you deny for others
What you demand for yourself?
(U2, Crumbs from your table)

11. **From Bejaia**
May 26, 2019

@ Peter,
I find your tendency in this blog to praise any book (or any passage from a book like Farmelo's) that exposes the deep connections between math and physics as a right track to move forward in unraveling the mysteries of nature really puzzling. I say this because from what I understood in Sabine's book "Lost in Math" is that, not only relying on mathematical beauty did not lead to any new discovery about nature since the 70's, but also what you call the "deep connection between math and physics" has not unraveled a single new principle about nature. It just created maybe new ways of dealing with problems in math or (at best) helped express old known facts in physics in a more abstract way.
@ Sabine,
I don't understand what you mean by "Except possibly for explaining why you do *not* need it in heavy ion collisions."

Thank you!

12. **Peter Gerdes**
May 26, 2019

Why is it at all surprising that physics is best expressed in terms of math? Not only is it not surprising it's necessarily true since math is just the *name* we apply to any kind of precise well-defined manipulation of concepts.

Or to put it another way can you even imagine a way in which the world could have been in which physics wasn't best described via math? I mean imagine in some alternate universe we came up with some completely different set of rules/theories for predicting things. Whatever kind of manipulation we used to make predictions in that universe would also be called math. Sure, one could imagine that we couldn't make any predictions about the world at all but in that case there wouldn't be such a thing as physics. At a minimum, if we are capable of making any useful predictions about the world and our mental processes can be emulated by a Turing machine we could mathematically describe the process we used to make predictions and quantify it's accuracy.

One can't even argue it's surprising that in many cases the math needed for physics was already developed. In a huge number of cases it isn't true (and an area of math is only explored after it becomes apparent it is useful in physics). In the cases where it is true often the area of mathematics was already inspired by earlier physical theories and mathematicians explored a huge space of generalizations/modifications one of which happened to be useful later.

Indeed, for us to discover a physical theory SOMEONE has to think of the concepts it uses (without someone thinking up non-euclidean geometry first we wouldn't have GR). Since mathematicians are also smart it would be shocking if physicists were always the first people to come up with those generalizations.

13. **Adrian**
May 26, 2019

Dear Sabine, dear Peter,
a very brief message given the conversation started above.

In this message, I am referring the work on AdS/CFT and many of its variations. I see what a majority of string theorist are doing as a way of learning about Quantum Field Theories in general (different dimensions, different amount of global symmetries). I very much fail to see this as a not-worthy enterprise. Also, I fail to see the hype in the media about this research (but may be this is due to the fact that I do not follow the media).

I find the criticism useful. But when Sabine writes about the research on AdS/CFT:
"It's 99.99% hot air. It's been pursued since 20 years and pretty much nothing has come out of it. "

I feel that she does not know and did not read 99-per cent of the works in this area to write this comment. I am unable to read all the papers on AdS/CFT, but on those I read and check calculations, my opinion is exactly the opposite of 'hot air'.

I refrain to believe that the great majority of my colleagues are working on this just because they get the funding to do so. I very much refrain to believe that the daily discussion and calculations with colleagues are just a 'charade' and that we should know that is 99.99 per cent hot air.

I find hard to believe that most of the people around me are idiots or perverse minds who are not interested in science, but only on their next grant. My empirical observations of colleagues indicate exactly the opposite!

On Sabine's paragraph

" It makes zero sense because all the benefits from working in AdS are non-local. And, needless to say, the world isn't supersymmetric and not conformal and N isn't infinity. These are mathematical fictions, not descriptions of anything in the real world."

Our viewpoints on this cannot be more divergent. I believe that she is just wrong. I prefer not to comment as it would make this posting too long.

14. **Peter Woit**
May 26, 2019

Justin,
There's no reason physicists can't learn math or mathematician's can't learn physics. Einstein (with some help) learned Riemannian geometry. Witten not only learned a lot of mathematics, he created very significant new mathematics. There is a whole field of "mathematical physicists" who work in between the two subjects.

From Bejaia,
Yes, investigations of the relation of math and physics since the 1970s have not led to significant advance in fundamental physics theory, but neither has anything else. Your choices at this point are to give up or pursue whatever you think is the most promising path, in full knowledge that that path has not recently been successful.

I don't see the failures of string theory, supersymmetry, etc. as due to people mistakenly pursuing mathematical beauty. After initial ideas with some beauty, those subjects quickly degenerated into a complicated and ugly mess (endpoint the landscape) as one tried to reconcile them with known physics. If people actually had been pursuing mathematical beauty, this would have caused them to abandon these subjects long ago.

Peter Gerdes,

What's surprising is not that fundamental physics is expressed in terms of math, but that its deepest ideas are closely related to the deepest ideas in mathematics. For example:
GR and Geometry
The Dirac equation
Connections, curvature and Yang-Mills theory
The relations between quantum theory and representation theory (see my recent book)

15. **Justin**
May 26, 2019

@Peter,

I understand that Witten created marvelous new mathematical structures, among his many achievements, his construction of topological quantum field theories stands out as his most influential. But, my understanding is that TQFT hasn't really had much of an impact on fundamental physics and is mostly studied by mathematicians. That's exactly my point, one doesn't know which mathematical structures to study that would lead to significant advances on the fundamental physics front.

16. **Peter Woit**
May 26, 2019

Justin,
Yes, there is no clear path saying "study this mathematical structure, you'll find the right idea for how to get a better theory than the SM +GR". There is also no other clear path to such a better theory, so this may be more promising than any alternatives.

17. **Sabine Hossenfelder**
May 27, 2019

Adrian,

Of course you do not want to believe what I say and neither want your colleagues. But no need to believe me. This is science after all. Look at the papers that have been written and list what observations were correctly predicted. The answer is: None. That's what has come out of it.

You don't have to dig deep for hype, here are some recent examples:

https://phys.org/news/2019-04-wormholes.html

https://www.quantamagazine.org/how-space-and-time-could-be-a-quantum-error-correcting-code-20190103/

https://www.express.co.uk/news/science/1072080/universe-hologram-holograph-science-news-leonard-susskind

"I believe that she is just wrong."

Hahaha. No shit.

Look, that's not how it works. Science isn't about beliefs. There is no reason to think that the limit Lambda to zero is continuous. In fact there are all kinds of reasons to think it is not, starting with the very fact that you do calculations in AdS because you need Lambda to be smaller than zero.

I did not say that it's not a worthy enterprise. Please do not put words into my mouth I didn't use.

Rolf,

Yes, I know what I am talking about. Glad to see you figured that.

18. **vmarko**
May 27, 2019

"" It makes zero sense because all the benefits from working in AdS are non-local. And, needless to say, the world isn't supersymmetric and not conformal and N isn't infinity. These are mathematical fictions, not descriptions of anything in the real world."

Our viewpoints on this cannot be more divergent. I believe that she is just wrong. I prefer not to comment as it would make this posting too long."

I find it hard to believe that this is not a tongue-in-cheek comment.

🙂
Marko

19. **Peter Woit**
May 28, 2019

All,
Maybe that's enough about AdS/CFT. It's not even emphasized that much in Farmelo's book, where his take on the current state of things is more Arkani-Hamed-centric, with the Amplituhedron the centerpiece of the best case for a current math/physics topic on the right track to success.

20. **Bernard Grossman**
May 29, 2019

Is the talk at IAS over ?

21. **Peter Woit**
May 29, 2019

Event is still going on, just now (4:25) coming back from break. Will go on until 5:45.

22. **Matt Foster**
May 30, 2019

@ Justin:
"I understand that Witten created marvelous new mathematical structures, among his many achievements, his construction of topological quantum field theories stands out as his most influential. But, my understanding is that TQFT hasn't really had much of an impact on fundamental physics and is mostly studied by mathematicians."

Actually TQFT and its "holographic dual" 2D CFT have been enormously influential and productive in condensed matter physics, where these frameworks are used to describe actual experiments such as the fractional quantum Hall effect (FQHE). TQFT was used by Shou-Cheng Zhang and collaborators to provide the "composite boson theory" of the FQHE, a simple mean-field framework that allows one to "derive" key results like Laughlin's many-body wave function. More recently (mid-90s onwards), much of Alexei Kitaev's work on spin liquids and topological quantum computation is rooted in CFT representation theory. This is now driving large-scale experimental efforts funded by Microsoft (Station Q at UCSB and Copenhagen).

Suffice to say we cm physicists do not believe that "fundamental physics" can be done only in the service of unification! 🙂

23. **DB**
May 30, 2019

Here is the Dijkgraaf/Witten conversation:
https://www.youtube.com/watch?v=RjthuCDzAnY

Is Edward acknowledging from 12:00 onwards that the AdS/CFT correspondence, and its relation to emergent spacetime, is (or might be) wrong?
It´s hard to say what word he uses around 12:33 ("It colours? a lot of our thinking…)

Thanks for any help provided.

24. **Peter Shor**
May 30, 2019

Regarding your comment that the book's defense of string theory is "trust certain famous theorists", I think the "trust famous theorists" attitude is one of the big problems with HEP today.

For a concrete example, Lenny Susskind is writing papers that use quantum information theory in what seem to me more and more nonsensical ways, and (a) there are some people paying attention to him and building on these papers, and (b) very few or no high energy physicists are saying that these papers can't possibly be correct.

25. **clayton**
May 30, 2019

Hi Peter Shor, I'm curious what makes you think Susskind's recent papers "can't possibly be correct." They seem so vague to me that they can't be right, but I'm interested to know what is concrete enough in them to be wrong.

26. **Peter Woit**
May 30, 2019

DB,
Thanks. I added a link to the conversation, some extracts and some comments. As for the part you point to, I can't tell what Witten's final "it might be wrong" is supposed to refer to. Unlikely he means the Maldacena conjecture, perhaps something more general about current expectations concerning "emergent space-time".

Peter Shor,

I agree that the "trust certain famous theorists" argument is highly problematic. For me, one of the main reasons I got interested in science and math was that it was not about trusting authority figures. If you were willing to put in the effort, you could learn a subject and follow the arguments, and once you did this you could evaluate for yourself the evidence for a claim.

My problem with much of the claims by Susskind of recent years is more that I can't even figure out what he is claiming, a rather extreme version of the "not even wrong" phenomenon.

Nima Arkani-Hamed is highly influential, with much of this book channeling his (current) point of view. However, if you look back at his career, you find equal enthusiasm for ideas that didn't work out (e.g. large extra dimensions), and he describes himself as a not-so-reliable "serial ideologue", here
http://www.math.columbia.edu/~woit/wordpress/?p=6476

Unlike Susskind and Arkani-Hamed, Witten is someone who tries to be careful and reliable in what he claims. To me, the conversation with Dijkgraaf indicates that, while he's still unwilling to give up on the dream of 1984, he's now all too aware that things have not gone well for it, that he has no "scientifically convincing" argument for his hopes, nor any prospects for getting one anytime soon.

27. **DB**
May 30, 2019

Peter,
thanks for the link and your comments.

After listening again to what he says, I agree with you that he´s most probably referring to ideas about emergent spacetime.
I tend to think the same as him there, that spacetime is emergent.
And I have my own idea of what is behind it, but that´s not for this post.
He´s very careful with his words, but it seems to me that he doesn´t like any of the ideas that are nowadays floating around about that issue.

28. **Peter Shor**
May 30, 2019

Clayton:

I am extremely skeptical of ER=EPR. Susskind says

"ER=EPR tells us that the immensely complicated network of entangled subsystems that comprises the universe is also an immensely complicated (and technically complex) network of Einstein-Rosen bridges."

I don't see how you can say that entanglement is the same thing as ER bridges unless you mean something completely different by either "entanglement" or "ER bridges" than Schrödinger meant, or Einstein and Rosen meant. Entanglement is a property of quantum mechanics, ER bridges are a property of general relativity, and as far as we know quantum field theory works fine without general relativity, and vice versa.

And Google Scholar says that this paper has 745 citations, which is two thirds as many as the AMPS (*Black Holes: Complementarity or Firewalls*) paper, which actually contains real, potentially correct, ideas.

29. **WTW**
May 31, 2019

Peter,
With all due respect to Dirac, it was von Neumann who put Quantum Mechanics on a sound mathematical basis. Dirac, among others, were the ones trying to make sense of the physics, and found mathematical formalisms that could help — as distinct from the essentially infinite sample of such formalisms that don't. Von Neumann pointed out logical inconsistencies in what Dirac proposed, despite it being more "beautiful" and "elegant" than what von Neumann proposed in its place that actually made mathematical sense. See, e.g., https://plato.stanford.edu/entries/qt-nvd/. (And Dirac's later obsession with numerology should serve as a warning about losing that perspective.) Never mind that the mathematically rigorous version requires infinite dimensional Hilbert spaces to make it work — not quite what one would consider a "physical" concept. Is that "mathematically beautiful"? Or does it just work, so we sweep the awkwardness under the rug?

As mentioned previously, Einstein first had physical intuition about what was happening; he then had to find a way to describe that in a consistent way that could be measured — which then helped to elucidate further implications of those insights, as well as advancing mathematics (e.g., differential geometry). Not the other way around.

Your own recent book seems like a slightly lesser version of what Sabine Hossenfelder and even you are critiquing. It seemed to me a good, if rather abstract, explanation of "Here's what they mean when they say 'XYZ'", from a mathematician's point of view, but only tangentially related to any underlying physics. (Reminds me somewhat of the book General Relativity for Mathematicians by Sachs and Wu. : -) As with most of modern fundamental theoretical physics — even some of what is described in low-dimensionality solid state physics — my response is essentially "That's interesting, in an abstract conceptual sense, but … So What?" In terms used by actual practitioners of Computer Science (i.e., programmers), much of what is described appears to be a kludge on top of a kludge on top of a kludge — but at least you get (approximately) the right answers. Unfortunately, that seems to apply more broadly.

The mathematics on which most of physics is based evolved as a way to describe things that can be expressed as differentiable (analytic) functions over smooth manifolds compatible with Euclidean space (locally if not globally) — but even there the mental gymnastics required to describe that in a self-consistent way seems far divorced from physical reality. Just the issue of differentiating with respect to time in a GR (not just Minkowski) spacetime, when time itself is a dynamical variable "in the real world", is just glossed over. And then the question: is it continuous, to the level we need to actually describe underlying fundamental physics? How does any of today's mathematics handle it if it's not?

Likewise, almost nothing that we are currently observing in astrophysics can be expressed concretely using any analytical formalism — only arbitrary, custom designed computational models calculated using Markov approaches, from which one selects "closest fits" based on semi-physical parameters and estimations — and often "matched" to data by machine learning algorithms. (A troubling corollary: the people who found significance in Bode's law – the supposed magical spacing of (then-known) planets in our solar system that turned out to be nonsense.) So I have trouble understanding your faith that some deep "mathematical mysticism" will lead to any better understanding of physics than we already have (or don't).

30. **Daniel**
May 31, 2019

Peter,
I also find the idea of "ER = EPR" to be a bit far fetching. But I think the idea is that classical spacetime is emergent from an underlying entangled state (of some unknown entity). Not sure how they could make it work but it is probably not true that entanglement is wormhole as entanglement could be between degrees of freedom of a single particle, and wormhole is between two different spatial locations.

31. **Peter Woit**
May 31, 2019

Peter Shor/Daniel,
It's very unclear to me what "ER=EPR" actually is supposed to mean, other than that it can't mean what it says since, as Peter Shor points out, it claims an equality of two things that in our currently understood best theories (QM and GR), have nothing at all to do with each other. As near as I can figure out, what it really is is a slogan for a speculative hope: "let's find a quantum theory of gravity in which these two things are related", part of the general program of "let's find a quantum theory of gravity in which space-time emerges from quantum entanglement".

All attempts on my part to understand what the current state of this program is have left me with the impression that, while this has been an increasingly hot topic among "leading theorists" for a decade now, it hasn't managed to get much beyond its original motivation based on some crude aspects of what happens in AdS/CFT. The main activity seems to be the study of toy models, with this research leading to the realization that the toy models don't actually in any simple way embody the hoped for properties. Some of the people involved in this have a history of misleading the public by promoting outrageous hype about string theory, and the current public promotion of things like "ER=EPR" is starting to look like more of the same.

Under the circumstances, to me it seems best to try and ignore all this for now, and wait and see if anything solid emerges from the cloud of "emergent gravity" hype.

32. **Peter Woit**
May 31, 2019

WTW,
You're missing the point I keep trying to make about the role of mathematics in new ideas about fundamental physics. This has nothing to do with mathematical rigor (other than the general point that you really should try and be clear about exactly what you are talking about, see above comment about ER=EPR: the problem there is not lack of rigor, but lack of any clear meaning at all).

Let me give three examples of what I am talking about:

1. Einstein's use of Riemannian geometry to formulate GR.
2. Dirac's definition of quantization as taking Poisson brackets to commutators, i.e. as a Lie algebra representation.
3. Dirac's introduction of Clifford algebras and spinors, allowing the construction of the Dirac operator and a square root of the Laplacian.

All three of these were huge advances in our understanding of fundamental physics, based upon the introduction of new and surprising deep mathematical ideas, not "physical intuition". I think the expectation that further such advances are possible and will have the same nature is quite rational. In particular, the mathematics behind parts 2. and 3. is still not completely understood (e.g. the role of the Dirac operator in representation theory), and a deeper understanding may very well lead to a deeper understanding of fundamental physics.

33. **Peter Woit**
May 31, 2019

I see that Urs Schreiber thinks it's a good idea to put up an edited version of what I write here on Twitter, see
https://twitter.com/SchreiberUrs/status/1134462156395749376
Note how he edits out the rest of the sentence he highlights, the part where I write:
"and wait and see if anything solid emerges from the cloud of "emergent gravity" hype."

By the way, to bring this back to the topic of the post. One reason for skepticism about "ER=EPR" and such things is the lack of any significant deep mathematical idea behind it. This line of research seems to be orthogonal to the deep mathematical ideas about symmetry that have been so successful in leading to the standard model, and instead often seems to be based on rather simple minded mathematics.

34. **Bernhard**
May 31, 2019

Peter,

What do you think of Dijkgraaf's comment: "…because in some sense it's an integral part of the theories that we already are using." ?

Is this the old story of "string theory is a quantum theory" sort of thing? Or what do you think he's alluding to?

I know of exactly zero theories we use in HEP to describe nature that string theory is a part of.

35. **Peter Woit**
May 31, 2019

Bernhard,
This is the same argument David Gross and others have been using for years when challenged about the failure of string theory unification. It's basically

"The AdS/CFT conjecture suggests that the superstring on AdS5 x S^5 is dual to N=4 super Yang-Mills on S^4. So, in this case, a string theory is an alternative formulation of a specific QFT, and one can find other examples of this kind of QFT/string theory duality. So, string theory is closely related to (some) QFTs, and so you can't argue that only QFT is relevant, not string theory."

One problem with this argument is that the relation to QFT is not to Standard Model QFTs known to be fundamental, but to QFTs with rather different properties (i.e. conformal invariance, no asymptotic freedom). Hopes that this could be extended to get a string theory dual of QCD have not worked out. There seems zero reason to believe in a string theory dual of the weakly-coupled parts of the SM (this would have to be some strongly-coupled string theory we have no evidence for or theory of).

The other problem is that, as Witten immediately recognizes and notes in his response, what people are doing when they are making this argument is implicitly giving up on string theory unification. When I and others argue to string theorists that string theory unification is a failure and they respond "string theory has some connection to QCD", they are acknowledging they have no positive argument for string theory unification and are trying to talk about something else. Witten responds to Dijkgraaf that he doesn't want to do this and implicitly give up on string theory unification, just turning the string theory research program into one focused on hope for a better calculational method to deal with certain strongly-coupled quantum systems.

May 31, 2019

The original qualitative arguments for "ER=EPR" (back in arXiv:1306.0533) left me completely bewildered. They would equally well imply that a wormhole exists between the two halves of a Werner system, or between any two correlated toy bits in the Spekkens model, which is absurd. Now, there can certainly be a big gap in solidity between the original motivations and later results, but here, I feel like we're still waiting to see what those "later results" actually are.

37. **Peter Woit**
May 31, 2019

Blake Stacey/Peter Shor,

Urs Schreiber explains here

https://twitter.com/SchreiberUrs/status/1134503200550203392

that ER=EPR is a "Zen koan", or maybe a "koan-like slogan", and Susskind's paper about it is "uninhibited vague brainstorming".

Will Kinney comments here

38. **cedric bardot**
June 2, 2019

Referring to a folk theorem stating there's one subject in math you always avoid that turns out to be the relevant one for your next paper, Robbert Dijkgraaf asks E. Witten:

> "Is there any subject in math you are consciously avoiding ?".
> "Well I've decided, I've judged there are some things that are too abstract for me to try to learn them… I'm more worried not being able to understand the things that aren't too abstract."

I naively conclude from this revealing interview that thinking abstractly (what could be the proper geometric framework to define quantum Yang-Mills-Higgs theory in 4D space-time for instance) might be the quality of mathematicians while computing formally (entropy of "entangling surfaces" to probe a "bulk geometry" in the AdS/CFT conjecture context) is mostly the privilege of physicists.

39. **JimV**
June 2, 2019

Re:
“1.Einstein’s use of Riemannian geometry to formulate GR.
…
All three of these were huge advances in our understanding of fundamental physics, based upon the introduction of new and surprising deep mathematical ideas, not “physical intuition”.”

Einstein’s Zurich Notebook* seems to indicate that the basic idea of objects following a geodesic on a curved surface had a lot of physical intuition involved–some of it based on previous classical physics results, but that is how intuition is developed, from experience.

* https://www.pitt.edu/~jdnorton/Goodies/Zurich_Notebook/

40. **Peter Woit**
June 2, 2019

JimV,
Yes, it does seem Einstein’s original motivation for GR could be described as “physical intuition”. I think though that if you look at the history, it’s pretty clear that he would never have gotten off the ground, developed a real theory and found the equations of GR, without the mathematics of Riemannian geometry.

41. **luysii**
June 3, 2019

Off topic but why nothing about the death of Gell-Mann?

42. **Peter Woit**
June 3, 2019

luysii,
See previous posting.

43. **John Putz**
June 7, 2019

Hi Peter,

I’m a big fan of your blog. I also really enjoy reading physics and math books that are geared to a more general audience (although I have a PhD in physics, I don’t want to have to work too hard to read a book before bedtime). I’ve gotten some good book ideas from reading your blog in the past. I’m wondering if you’d consider putting another recommendation section on your blog for books that you’ve enjoyed (perhaps categorized by subject) – and perhaps link them to reviews you’ve done, if you have. It’d be really nice to have one place to go to find a good physics/math book when I’m in the mood for one.

Thanks, John.

44. **Peter Woit**
June 7, 2019

John,
If you select posts by category, choosing the “Book Reviews” category

http://www.math.columbia.edu/~woit/wordpress/?cat=13

gives 105 postings about books, mostly book reviews, going back to 2004. Pretty much all of these are books about physics and or math. Mostly I write about something because I think it’s interesting enough to be worth reading. You should take a look at the review first, since in a few cases there’s a negative reason I’m writing about the book, definitely not recommending it to others (for a recent example, don’t go out and get Lee McIntyre’s “The Scientific Attitude”….)

Various News Items

June 4, 2019
Categories: Uncategorized

For physicists:

- For the latest news on US HEP funding, see presentations at this recent HEPAP meeting. It is rarely publicly acknowledged by scientists, but during the Trump years funding for a lot of scientific research research has increased, often dramatically. This has been due not to Trump administration policy initiatives, but instead to the Republican party's embrace of fiscal irresponsibility whenever there's a Republican in the White House. After bitter complaints about the size of the budget deficit and demands for reduction in domestic spending during the Obama years, after Trump's election the congressional Republicans turned on a dime and every year have voted for huge across-the-board spending increases, tax decreases, and corresponding deficit increases. Each year the Trump administration produces a budget document calling for unrealistically large budget decreases which is completely ignored, with Congress passing large increases and Trump signing them into law.

  For specific numbers, see for instance page 20 of this presentation, which shows numbers for the DOE HEP budget in recent years. The pattern for FY2020 looks the same: a huge proposed decrease, and a huge likely increase (see the number for the House Mark).

  The result of all this is that far greater funds are available than expected during the last P5 planning exercise, so instead of having to make the difficult decisions P5 expected, a wider list of projects can be funded.

For mathematicians;

- Michael Harris has a new article in Quanta magazine, mentioning suggestions by two logicians that the Wiles proof of Fermat's Last Theorem should be formalized and checked by a computer. He explains why most number theorists think this sort of project is besides the point:

  > Wiles and the number theorists who refined and extended his ideas undoubtedly didn't anticipate the recent suggestions from the two logicians. But — unlike many who follow number theory at a distance — they were certainly aware that a proof like the one Wiles published is not meant to be treated as a self-contained artifact. On the contrary, Wiles' proof is the point of departure for an open-ended dialogue that is too elusive and alive to be limited by foundational constraints that are alien to the subject matter.

  I don't know who the "two logicians" Harris is referring to are, or what the nature of their concerns about the Wiles proof might be. I had thought this might have something to do with number theorist Kevin Buzzard's Xena Project, but in a comment Buzzard describes such a formalization as currently impractical, with no clear motivation.

  Taking a look at the page describing the motivation for the Xena Project, I confess to finding it unconvincing. The idea of revamping the undergraduate math curriculum to make it based on computer checkable proofs seems misguided, since I don't see at all why this is a good way to teach mathematical concepts or motivate undergraduate students. The complaints about holes in the math literature (e.g. details of the classification of finite simple groups) don't seem to me to be something that can be remedied by a computer.

- For some cutting-edge number theory, with no computers in sight, see the lecture notes from a recent workshop on geometrization of local Langlands.
- Finally, congratulations to this year's Shaw Prize winner, Michel Talagrand. Talagrand in recent years has been working on writing up a book on quantum field theory for mathematicians, and I see that Sourav Chatterjee last fall taught a course based on it, producing lecture notes available here.

  For a wonderful recent interview with Talagrand, see here.
  I first got to know Michel when he started sending me very helpful comments and corrections on my QM book when it was a work in progress. He's single-handedly responsible for a lot of significant improvements in the quality of the book.

  I've recently received significant help from someone else, Lasse Schmieding, who has sent me a very helpful list of mistakes and typos in the published version of the book. I've now fixed just about all of them. Note that the version of the book available on my website has all typos/mistakes fixed. For the published version, there's a list of errata.

Update: For more about the Michael Harris vs. Kevin Buzzard argument, see here, or plan on attending their face-off in Paris next week.

Comments

1. **Kevin Buzzard**
   June 4, 2019

   It's interesting how my formalisation project divides opinion. Some mathematicians I've talked to have been super-enthusiastic; others can't see the point at all. The same is true with the undergraduates that I've been teaching; some lap it up, others find it bewildering and/or pointless. One reason I persevere is simply that it is clearly something different. I spent 25 years as a number theory researcher and lecturer doing, in some sense, the same thing as everyone else. Maybe I just got bored.

   Another reason I persevere is that I have bought into the vision of Tom Hales' Formal Abstracts project https://formalabstracts.github.io/ , which is also different. Hales is going to need lots and lots of definitions of mathematical objects for his project to succeed. So why not train undergraduates to at least be aware that mathematics can be done this way? Commelin, Massot and I have formalised the definition of a perfectoid space in Lean, which convinces me that these languages are now ready for what Hales has planned. However your criticisms are perfectly valid and your feeling about Hales' project might be similar.

   In 15 years' time this stuff could have completely taken over mathematics. Alternatively it could just be sitting there being not very helpful and of interest only to specialists. I really do not know which way it will go — but one thing is for sure, over the last couple of years I have met smart people with very different opinions about this.

2. **Scott Morrison**
   June 4, 2019

   I've been quite involved in Lean over the last two years, and as a mathematician my motivations are quite different from the "traditional" explanations for why we ought to formalise mathematics.

   Sure, it might be nice if we could worry less about gaps in the literature, but it's not like I've been losing sleep.

   Instead, I want interactive theorem provers for the same reason I enjoy computer algebra systems — they might make us more powerful mathematicians. At the moment the state of the art is very far from this point: doing mathematics in any of the existing theorem provers (including my favourite) is *excruciating*, and even more worryingly requires some skills that most mathematicians just don't have.

Nevertheless, this doesn't feel inevitable, and in particular there is so much "low hanging fruit" in terms of prospects for making interactive theorem provers easy to use, and more powerful, that I think it is worth investing in.

I personally doubt that computers will ever do the highest-level conceptual mathematics that we're used to doing. On the other hand, I think the computers will be able to help us with a large part of the work we already do, and I can envisage a future where, when I have a rough idea of how to proceed on a problem, I can hand that idea off to a computer and ask it "Can you sort out the details? If not, can you explain to me where you run into trouble?"

If any mathematicians are curious, please come over to https://leanprover.zulipchat.com/ and say hi! There's a very friendly and enthusiastic community over there, and we're very happy to answer questions, provide help, and give suggestions for interesting first projects for exploring interactive theorem provers.

3. **Shantanu**
June 5, 2019

Peter, the link to the presentations at the HEPAP meeting is not working. could you post the correct link?
Thank

4. **Peter Woit**
June 5, 2019

Shantanu,
Fixed.

5. **Supernaut**
June 5, 2019

"…during the Trump years funding for a lot of scientific research research has increased, often dramatically" Let's acknowledge that along with the bad there is some good. I am glad you mentioned this because a lot of people in the liberal/progressive camp suffer from trump-derangement syndrome, which makes them unobjective and therefore unreliable (and would not have reported such a thing as you did).

6. **Peter Woit**
June 5, 2019

Supernaut,
I don't actually think the fiscally irresponsible approach to the US budget of Trump and the Republicans is a good thing at all, even if as a side effect some more HEP research is getting funded. There are plenty of ways the world has become a much worse place over the years that have worked out fine for me and others like me. This doesn't make them a good thing. I hear Stalin was great on the math and physics research funding front.

All: no, I don't want to host here a discussion of such larger issues, not specifically about the HEP budget news.

7. **Supernaut**
June 5, 2019

Peter – I completely agree with you.

8. **Low Math, Meekly Interacting**
June 5, 2019

Hopefully the relevance to larger issues isn't too much of a distraction: My understanding is big HEP experiments can take decades to plan for and assemble. Further progress takes serious and very long-term commitment. The way the US govt. presently operates, beyond a few months one cannot reliably project whether or not any part of it will be funded. That a certain capacity benefits in any particular budget cycle is merely a fact, effectively disconnected from any future eventuality by caprice. There's nothing to celebrate, and the current modus operandi surely can't be good for anyone trying to do basic research.

9. **Arnold Neumaier**
June 6, 2019

Scott,

I also want interactive theorem provers to help me save boring work, and hence make us more powerful mathematicians. Currently, using interactive theorem provers doesn't save any work but multiplies the work needed to write a page of latex math by a factor of 40 or so. Some years ago I had tried to get funding for a large project called FMathL, see https://www.mat.univie.ac.at/~neum/FMathL.html – aimed at doing these things in a way suitable for mathematicians (rather than computer scientists). But I didn't succeed in convincing funding agencies – the referees dismissed the project as being far too ambitious.

June 6, 2019

Actually, I think that to some extent a formalisation programme can help with gaps in the literature. If we know about the gap, then we should fill it – and here a computer won't help. But often we do not know about the gap, and often that occurs in precisely a proof like CFSG where there are many cases to check, and it is easy either to make a mistake in one of these or simply not to have an exhaustive list of cases. Here a formalisation programme will highlight the gap, then we can fill it.

Of course, right now formalisation is so time intensive that it is only going to be done for hugely important results which had better be true (like CFSG). But part of this is because we keep having to add more basics to whichever system we happen to favour; I think the idea is that when CFSG is finally formalised, it will be much easier to do other group / representation theory formally, because most of the stuff one needs will already be in the system.

11. **Neel Krishnaswami**
June 6, 2019

> The idea of revamping the undergraduate math curriculum to make it based on computer checkable proofs seems misguided, since I don't see at all why this is a good way to teach mathematical concepts or motivate undergraduate students.

I've done this a bit, and I think it's a *wonderful* idea. The fundamental pedagogical problem that computer-checked proofs solve is that they make the feedback cycle much shorter.

As it stands, in the usual approach to teaching undergraduates how to prove things, we assign them a problem set, they go off and do the work and turn it in a week or two later, and then they get marked-up work a week or two after that. This is more than enough time for them to forget all the details of how they were thinking about the problem, and so they struggle with interpreting the feedback we struggled to write.

With a proof assistant, they get told their proof is wrong, the second they make a mistake at the exact proof step they messed up. As a result, the mechanics of proof — quantifiers, case splits, hypotheses and so on — can be taught and learned vastly more easily than in the traditional way. (You can — and I did! — even make the input format to the prover a structured format which is a subset of basic mathematical English.)

The machine can't learn the concepts for the students, of course, but obviously it's much easier to understand mathematical arguments once you can read and write proofs fluently — and this is where proof assistants shine.

12. **Anon**
June 6, 2019

For an example of an interesting and recent use of a proof assistant in pure mathematics, see the preprint arXiv:1810.04579 by S. Gouëzel and V. Shchur.

13. **Past-life mathematician**
June 6, 2019

I would like to hazard the claim that, if we compare students who have learnt to construct mathematical proofs in the "old-fashioned" way to students who submit their proofs to a proof assistant, then the two groups *are not actually learning the same thing*.

And I think this should actually be more obvious than it appears to be to most people: since the notion of a proof assistant (together with the underlying (meta-)mathematical theories) "formalizes" the notion of a mathematical proof, the two notions are in fact different, the one being formal, the other not. By seeking to "formalize" a concept, one changes the concept itself.

The traditional mathematical notion of proof is an "intuitive" notion, in that one develops a "feeling" for what is and what is not a proof. One could reduce it to a sociological phenomenon ("a proof is what mathematicians accept as such"). However, even such a move serves to sidestep the question as to what a proof *is*, by instead answering the question what a certain class of people think it is. By contrast, the notion of proof in the formalized setting *is* well-defined and formalistic ("a proof is what the following Turing machine will accept as such").

I think that to equate the two concepts is to make a category mistake. To *formalize* a certain notion, whatever it is, is to implicitly admit that this notion refers to a definite concept or entity. Otherwise one would not even have a criterion for a *good* vs. a *bad* formalization. If the formalization is all there really is, any formalization is as good as any other. To put it more concretely, the relationship in which "formalized proof" stands to "proof" is the same relationship in which "painting" stands to "model".

It is a belief of mine that there is a certain tendency in human beings (but mathematicians especially) to wish to deny as much as possible the existence of the intuitive and the non-formal, and to replace intuitive concepts by formalized notions, so that they can afterwards say that the formalized notion is what we were trying say all along. But in fact there is a very big difference, and it comes out especially in teaching. Students often want (or need) to know the "point" of a certain formalization, and rightly get bored by involving themselves in purely formalistic work without any underlying motivation.

Which is not to say that I do not approve of the idea of using proof assistants in teaching mathematics. But I do see the danger of creating a generation of students who are learning to prove theorems as just another kind of game, without *really* understanding what they are doing or why they are doing it. I think there is more enough of that as it is.

14. **Kevin Buzzard**
June 7, 2019

@Past-life mathematician: in my course, the students have the *option* to formalise their solutions. I think there is definitely something in what you say, but I do not think (and indeed, I do not think you're saying) that showing them that this *option* exists is somehow cheating them, or telling them that mathematics is something which it is not. It's analogous to showing them that they have the option to write their problem sheet solutions in LaTeX, rather than pen and paper. I believe that showing them this other way of thinking about the ideas I'm teaching them is broadening their minds. I'd like to think that as a teacher, this is part of my job.

15. **Past-life mathematician**
June 9, 2019

Dear Kevin: I wasn't criticizing you or your program. I have read your statement that Peter linked to where you explain your reasons for involving yourself in this type of research, and I agree with a lot of what you write. Especially your worries about a future loss of knowledge, and the fact that there is so much "folklore knowledge" that hasn't been written down anywhere, or if it has is contained in letters of so-and-so to someone else. I've encountered my fair bit of this while in academia, and I've always found it indefensible. I mean using private letters as a bibliographical reference in journal articles, especially when the reference is invoked in a proof. It runs completely counter to what I think should be the academic spirit: self-critical, transparent, maximally thorough. I think your program can only contribute towards that ideal, and I love that you are sticking up for it.

I was mainly responding to Neel Krishnaswami's seemingly blanket endorsement of basing the curriculum on proof assistants. I think if you do tha, you really lose something essential, as I've tried to argue.

16. **chethan krishnan**
June 9, 2019

Two A_R's on the same line on page 527 of your corrected pdf, Peter. (Para right above section 48.3.)

17. **random reader**
June 10, 2019

Past-life math (and Kevin Buzzard),

I think the issue is more what the human activity of mathematics "is", than what-is-proof (which has been clear in principle since Euclid). When serious mathematical communication starts to involve executable components by default, there will be an irresistible advantage to having definitions and proofs be machine readable, like engineers exchanging parametric CAD specification instead of diagrams or blueprints.

For now, we are still in the age of mathematical communication as a form of storytelling, and in that setting (particularly teaching) the discipline of extra formality for its own sake has benefits that are mostly orthogonal to the usual purposes of the communication. Unless the pedagogical added value of that discipline turns out to be very large for some reason, I think it will remain unpopular until mathematical communication itself is permeated by add-ons (e.g., functions, graphs, diagrams, computer programs, tablebase searches, etc accompanying almost every paragraph), and then the ability to generate such "animations" automatically from formalized definitions and proofs will create the demand for baked-in formalization. It's hard to see it being necessary for teaching of today's style of mathematics.

18. **Peter Woit**
June 10, 2019

chethan krishnan,

Thanks! Fixed.

Not So Spooky Action at a Distance

June 11, 2019
Categories: Book Reviews, Quantum Mechanics

I've recently read another new popular book about quantum mechanics, Quantum Strangeness by George Greenstein. Before getting to saying something about the book, I need to get something off my chest: what's all this nonsense about Bell's theorem and supposed non-locality?

If I go to the Scholarpedia entry for Bell's theorem, I'm told that:

> Bell's theorem asserts that if certain predictions of quantum theory are correct then our world is non-local.

but I don't see this at all. As far as I can tell, for all the experiments that come up in discussions of Bell's theorem, if you do a local measurement you get a local result, and only if you do a non-local measurement can you get a non-local result. Yes, Bell's theorem tells you that if you try and replace the extremely simple quantum mechanical description of a spin 1/2 degree of freedom by a vastly more complicated and ugly description, it's going to have to be non-local. But why would you want to do that anyway?

The Greenstein book is short, the author's very personal take on the usual Bell's inequality story, which you can read about many other places in great detail. What I like about the book though is the last part, in which the author has, at 11 am on Friday, July 10, 2015, an "Epiphany". He realizes that his problem is that he had not been keeping separate two distinct things: the quantum mechanical description of a system, and the every-day description of physical objects in terms of approximate classical notions.

> "How can a thing be in two places at once?" I had asked – but buried within that question is an assumption, the assumption that a thing can be in *one* place at once. That is an example of doublethink, of importing into the world of quantum mechanics our normal conception of reality – for the location of an object is a hidden variable, a property of the object … and the new science of experimental metaphysics has taught us that hidden variables do not exist.

I think here Greenstein does an excellent job of pointing to the main source of confusion in "interpretations" of quantum mechanics. Given a simple QM system (say a fixed spin 1/2 degree of freedom, a vector in $\mathbf{C}^2$), people want to argue about the relation of the QM state of the system to measurement results which can be expressed in classical terms (does the system move one way or the other in a classical magnetic field?) . But there is no relation at all between the two things until you couple your simple QM system to another (hugely complicated) system (the measurement device + environment). You will only get non-locality if you couple to a non-local such system. The interesting discussion generated by an earlier posting left me increasingly suspicious that the mystery of how probability comes into things is much like the "mystery" of non-locality in the Bell's inequality experiment. Probability comes in because you only have a probabilistic (density matrix) description of the measurement device + environment.

For some other QM related links:

- Arnold Neumaier has posted a newer article about his "thermal interpretation" of quantum mechanics. He also has another interesting preprint, relating quantum mechanics to what he calls "coherent spaces".
- Philip Ball at Quanta magazine explains a recent experiment that demonstrates some of the subtleties that occur in the quantum mechanical description of a transition between energy eigenstates (as opposed to the unrealistic cartoon of a "quantum jump").
- There's a relatively new John Bell Institute for the Foundations of Physics. I fear though that the kinds of "foundations" of interest to the organizers seem rather orthogonal to the "foundations" that most interest me.
- If you are really sympathetic to Einstein's objections to quantum mechanics, and you have a lot of excess cash, you could bid tomorrow at Christie's for some of Einstein's letters on the topic, for instance this one.

Comments

1. **Sabine Hossenfelder**
   June 12, 2019

   That's because Bell uses a notion of "locality" that very few people with a background in GR/QFT can relate to. It's sometimes called "Bell locality" more specifically, and one can reasonably question whether it has anything to do with "locality" in the sense we're used to. You can have eternal arguments about this with philosophers but it's not particularly enlightening. It's just a definition.

2. **ay**
   June 12, 2019

   Bell proved non-locality for hidden variable theories of quantum mechanics – not in a general formulation. But many believe that it is generally true (many including Bell). This paper, in the introduction seems to me to be clearly a clearly written description:

   https://arxiv.org/pdf/quant-ph/0408105.pdf

3. **Heikki Tuuri**
   June 12, 2019

   Peter, by a "non-local measurement" do you mean that there is another observer B far away from you, and you regard his action as a quantum mechanical "measurement"?

   A way to get rid of the spooky action at a distance is to assume just one observer, A. He performs measurements with his eyes and ears. Everything else, including all other humans, is either a part of the measuring apparatus which A utilizes, or a part of the physical system under the study.

   If A and B measure the spins of a pair of entangled particles, then the only real quantum mechanical "measurements" are the events when A reads the gauge of his own spin measuring apparatus, and when A reads an email sent by B.

4. **Manfred Requardt**
   June 12, 2019

   That quantum theory is really nonlocal can best be seen by reading Bells article: The Theory of Local Beables. It is by no means a question of strange definitions or philosophical opinions.

5. **Rolf**
   June 12, 2019

   Dear Peter,

The wikipedia is basically right on this, even though “our world” is too strong.
Replace “our world” by “all theories that fulfill certain
seemingly reasonable assumptions”.

> only if you do a non-local measurement can you get a non-local result.

“non-local measurement” = measurement on a system
in a spatially entangled state at space-like distance.

“non-local result” = even though the results are random,
they are correlated. QM describes no common cause for this
correlation –> QM describes its establishment as a non-local influence.

> Yes, Bell’s theorem tells you that if you try and replace the extremely simple >quantum mechanical description of a spin 1/2
> degree of freedom by a vastly more complicated and ugly description, it’s going
> to have to be non-local. But why would you
>want to do that anyway?

To avoid the above conclusion (the –>) by providing a common cause for the correlation. Under certain seemingly reasonable assumptions the Bell theorem shows that every theory that provides a common cause for the correlations cannot reproduce QM.

6. **Robert**
June 12, 2019

In my experience (in particular from my interactions of our local Bohmians), this insistence on “non-locality” comes from a prejudice about how classical the world should be in the form of “realism”, i.e. the assumption that a system has to have a state that even specifies properties that are not only not measured but in fact cannot be measured (as they are incompatible with properties are are in fact measured). For example assuming that the x-component has some (unknown) value if in fact the z-component is measured. Violation of the Bell inequality only implies that not both locality and realism can hold in quantum theory and it is your choice which to drop. My personal choice is to maintain locality as this is the foundation of QFT (or field theory which was invented to have a local field equation rather than a non-local force law in Newtonian gravity or electro-statics) and Haag’s book “Local quantum physics” makes this point most prominently.
For this point of view applied to foundations, my recommendation is to watch the video of Sidney Colman’s colloquium “Quantum Mechanics In Your Face” or the exchange that Reinhard Werner had with the Bohmian people that is well documented on the unterwebs.

7. **Jim Baggott**
June 12, 2019

The story of Bell’s inequality has subtleties that are often overlooked in popular retelling. But the most obvious point concerns the status of the wavefunction or state vector in quantum mechanics. ‘Spooky action at a distance’ is only a problem if it is assumed that the wavefunction represents the real physical state of a real physical quantum system. In this interpretation there are things that the theory doesn’t appear to account for – the theory is incomplete. This was Einstein’s view. One way of completing the theory is to assume that the wavefunction is statistical in nature, governed by the behaviour of some underlying hidden variables. A certain choice of variables in principle allows all quantum events to be local, leading to Bell’s inequality. Another choice is crypto-non local, leading to Leggett’s inequality. What these inequalities show is that no local or crypto-non local theory can accurately predict all the results of regular quantum mechanics. And experiment is pretty unequivocal – these hidden variable theories can’t be right.

If you want to press on and insist the wavefunction is real, then you face a choice between unpalatable evils, such as de Broglie-Bohm theory (in which spooky action at a distance is accepted as part of the representation), ad hoc physical collapse mechanisms (such as GRW), consciousness-causes-collapse mechanisms (Von Neumann and Wigner), and the many worlds interpretation.

Of course, you could instead assume that the wavefunction does not represent the real physical state, but rather codes for our knowledge of the system based on experience. Then all the bizarre, spooky stuff goes away, and there is no non-locality. But by making this trade-off, we lose any ability to understand what’s *really* going on at the quantum level. Like emergency services personnel at the scene of a tragic accident, such anti-realist interpretations advise us to ‘move along’, because there’s ‘nothing to see here’.

I used to favour Einstein’s realism. But the experiments ruling out especially crypto-non local hidden variable theories caused me to re-think. Like the great philosopher Han Solo, I’ve got a very bad feeling about this.

8. **Marko**
June 12, 2019

Peter,

“for all the experiments that come up in discussions of Bell’s theorem, if you do a local measurement you get a local result, and only if you do a non-local measurement can you get a non-local result.”

There are usually two main reasons people are bothered by Bell’s theorem. The first is that it excludes “local realism”, so if you want to keep locality you have to give up realism, which some people have trouble doing. The second (and IMO more important) is that the violation of Bell’s inequalities requires one to give up the metaphysical idea of reductionism — studying the parts of a physical system does not tell you everything there is to know about it, or in other words, the whole is more than a sum of its parts. Apparently people have trouble giving up reductionism as much as realism, so they are all “baffled” by nonlocality.

Bee,

“one can reasonably question whether it has anything to do with “locality” in the sense we’re used to.”

If you look at the dBB interpretation of QM, there is an explicit nonlocal interaction term in the Hamiltonian, whose sole purpose is to make the classical EoMs give predictions which are equivalent to QM predictions (including the violation of Bell’s inequalities). Thus, one can argue that Bell’s nonlocality can be seen as a form of nonlocal interaction, and cast into a usual language of a nonlocal Lagrangian.

Best, 🙂
Marko

9. **Billy Bob**
June 12, 2019

Bell non-locality is a subset of DBB non-locality. Bell locality is restricted to correlation only. DBB explicitly violates relativity by transferring information faster than light though no observer can access this to manipulate it to alter the past. Philosophers who don't make this distinction are no philosophers. But even physicists throw the word nonlocal around too loosely.

10. **Low Math, Meekly Interacting**
June 12, 2019

Sort of along the lines of what Marko says above, I thought the problem (forgive me if I screw up) is that, given QM accurately predicts probabilities of outcomes at spacelike separation that violate Bell's Inequality, giving up "local realism" is obligatory.

The problem is further exacerbated by lack of agreement about whether or not "local realism" is a valid requirement for a sensible interpretation to begin with. Maybe it's not universally clear what "local realism" is even supposed to mean.

Seems completely hopeless, if you ask me. "Shut up and calculate" wins again.

11. **Peter Woit**
June 12, 2019

I'm realizing that one thing that I really dislike about this subject is the hijacking of words (e.g. "realism" and "locality") to suit a particular agenda, the agenda that the fundamental QM formalism must be replaced because of the trickiness of relating this formalism to the classical formalism and our everyday intuitions. The words "realism" and "locality" get defined in a way designed to make QM non-"realistic" and non-"local" and thus problematic.

I think Sabine Hossenfelder is right, that arguing about the definition of "locality" will lead nowhere. To just make a bit clearer what I mean when I say Bell's inequality experiments are "non-local", take a look at the diagram of an example of such an experiment on Wikipedia
https://en.wikipedia.org/wiki/File:Bell-test-photon-analyer.png
What I'm referring to is just that one side or the other of this experimental set-up could be thought of as "local", putting the two sides together as one measurement apparatus is very "non-local". I don't see the lesson as "reality is non-local", see it as just a reflection of the measurement being a non-local physical process.

About "realism", I just don't see why it's a good idea to define "real" as "my human-scale classical model of the things I perceive" vs. "the best model we have from science of the physical world". My ontological commitments are based on what I know of science, which tells me the QM description of "physical reality" is the best-founded one. When Dr. Johnson refuted idealism by kicking a rock, the reality of the rock is best thought of not as "massive object with these coordinates", but "complicated many-body quantum system".

12. **Art**
June 12, 2019

What would a non-local result to a local measurement look like?

13. **Roger**
June 12, 2019

All of these arguments for non-locality are based on some sort of philosophical argument that the world must be described by hidden variables (like a classical theory), and then applying Bell's theorem and the Bell test experiments.

Sometimes the philosophical argument is based on analogies to classical mechanics, or on beables, or on reductionism, or on completeness. These are all just word games to disguise Bell's local hidden variable assumption. If you drop that assumption, then quantum mechanics is a local theory.

14. **Marko**
June 12, 2019

Peter,

"I don't see the lesson as "reality is non-local", see it as just a reflection of the measurement being a non-local physical process."

The only way to test whether reality is local or non-local is to perform a non-local measurement, since a local measurement is not sensitive to non-local effects. The fact that the experimental setup is non-local should therefore not be surprising. What is surprising is the *outcome* of that measurement, which suggests that reality is also non-local. This outcome is *not* an automatic consequence of the fact that the experimental setup is non-local, since in principle one could have also obtained a different result.

The definitions of locality and realism in Bell's theorem are not "hijacked" IMO, rather they are merely reformulations of what we traditionally and intuitively regard as locality and realism.

Informally speaking, locality is the statement that choices you make here and now are not correlated with the outcomes of measurements performed outside your past and future light cones. Realism is the statement that a physical system has a well-defined value of an observable even before one measures it. While there are all sorts of issues with the meanings of the words like "choice" and "measurement", I don't really see that these definitions are hijacking any otherwise traditional meaning of the notions of realism and locality.

🙂
Marko

15. **Mateus Araújo**
June 12, 2019

Dear Peter,

I believe your confusion is caused by the existence of several different versions of Bell's theorem, which often gets people talking past each other. You are right if you are talking about Bell's 1964 version (or rather CHSH's 1969 version of Bell's 1964 version), and Scholarpedia is right if they're talking about Bell's 1975 version.

I wrote about it here, maybe that can clear up something.

The root problem is that the word "locality" is rather overused, and people mean different things by it.

16. **Peter Woit**
June 12, 2019

Marko,

“Realism is the statement that a physical system has a well-defined value of an observable even before one measures it.”

I’m afraid that’s exactly what I mean by a hijacked definition, constructed specifically to generate a conflict with QM, a fundamental principle of which is that systems don’t have simultaneous well-defined values for non-commuting observables. I don’t at all see why I need to accept that definition. Looking at an “authoritative” source like Wikipedia
https://en.wikipedia.org/wiki/Philosophical_realism
shows a wide range of definitions of “realism”, with even the one about QM not the one you give. Of those, I would think the most relevant to scientists would be “scientific realism”, described as
“the world described by science is the real world, as it is, independent of what we might take it to be”
In this context, “science” (e.g. QM) is our best model of the real world, and the state of a physical system as given by QM is our best version of what “reality” is.

17. **Peter Woit**
June 12, 2019

Mateus Araújo,
Thanks for the references. The problem though is that I continue to not see why there’s anything surprising or problematic about the phenomena Bell is discussing, and why they are supposed to conflict with my understanding of reality or locality. So, it’s hard to get motivated to slog through long discussions of different versions of these claims.

18. **Peter Shor**
June 12, 2019

So how much value does the fact that interesting physics was discussed in it add to one of Einstein’s letters, and how much are you paying just for a letter in his handwriting?

19. **Eric Dennis**
June 12, 2019

Peter,

Unfortunately, what we can call the “John Bell camp” in the debate over the meaning of Bell Inequalities (because John Bell is in that camp) has been habitually misunderstood. For one, this camp is *not* motivated by a desire to impose classical categories (like particle position and momentum) on quantum objects. This camp is just fine with the idea that quantum objects can have different attributes that do not appear anywhere in classical physics–entirely new attributes subject to an entirely new dynamics as well. The sui generis-ness of quantum mechanics is a red herring in this debate.

Bell’s critics take a wrong turn at the very beginning. They make what is almost a category error: explaining how quantum objects defy certain classical assumptions (sometimes “realism,” sometimes “determinism,” sometimes “counter-factual definiteness”, etc.) and so the quantum objects are able to evade Bell’s reductio ad non-localitum. The category error is that Bell’s argument does not mention, does not rely on, does not implicitly refer to objects or theories being “quantum” vs. “non-quantum,” or “realistic” vs. “non-realistic” (whatever that might mean).

The first thing you have to do to grasp the meaning of Bell Inequalities is to forget the word “quantum,” and follow Bell as he imagines a very generic kind of system–totally agnostic as to whether its underlying dynamics is quantum, classical, stringy, wiccan, vegan, whatever. We only assume that the system has a few generic properties, like that you can identify two sub-systems at distinct locations A and B, that each sub-system has some kind of device with a binary read-out you can see (e.g., a screen flashes or it doesn’t flash), and that each device has some kind of two-setting gadget you can set.

Now Bell makes one critical assumption–the most obvious, straightforward implication of locality in terms of conditional probability distributions for the flashes on the A side given (i) the settings on both sides and (ii) the flashes on the B side. From this assumption, you go straight to the Bell Inequality. Violating the inequality means that the setting on one side somehow influenced the flash on the other side–a manifestly non-local effect, if the experiment is set up right.

One can imagine someone claiming that even though quantum systems violate this locality condition, they do not in fact exhibit non-local influences, because of some really subtle way quantum mechanics undermines the meaningfulness of Bell’s formulation of locality. Fine. Then do that; make that claim; spell out *how* that could be the case; don’t just insinuate it. No one ever spells it out, no matter how much background they have with QFT/GR. An august tradition started by Bohr, the patron saint of not spelling it out.

20. **Mateus Araújo**
June 12, 2019

Peter,

With regards to reality, I’m with you. It makes my blood boil to see people continuously trying to reduce “realism” to determinism, as Marko is doing. This is a hijacked definition. What should we conclude then, that the world is not real? Bell’s theorem proves that solipsism is true? Come on.

As for locality, though, I disagree. I think Bell’s definition of locality is a compelling one (that the probability of an event can only depend on events on its past light cone), and his demonstration that if fails for quantum mechanics is both surprising and problematic.

Since quantum mechanics was created people have noticed that there is problem with locality, because of the wavefunction collapse. Most famously we have Einstein’s 1927 and 1935 arguments. Now if you buy Einstein 1935, that we either have hidden variables or nonlocality, then Bell 1964 is a proof of nonlocality, as it shows that hidden variables cannot do the job. The argument is still messy though, not the least because of three decades in between, and that’s why I like Bell 1975 so much: self-contained, clear, and concise.

21. **vmarko**
June 12, 2019

Peter,

I wasn’t trying to give a rigorous definition of realism, or debate wikipedia, I just wanted to convey the idea, informally. Let me put it this way — how do you distinguish between the “real world” (which you observe while awake) and the “dream world” (which you observe while asleep and dreaming)? Assuming that everything you can know about either world is limited to what you can observe (and side-stepping 5000 years of philosophy on the topic), the only conclusion is that the real world cannot really be operationally distinguished from the dream world.

So if you want the real world to be “really real”, you have to subscribe to a metaphysical postulate that the real world, by definition, has at least some properties that are *independent* of the fact that you are observing them (otherwise you run into solipsism, as Mateus noted). And this is basically the same as the statement of realism I formulated previously.

Note that this definition does not require *all* observables to be simultaneously well-defined, so there is no problem with noncommutativity of observables. Also note that I am not really advocating for realism, I'm just explaining how I understand it.

Finally, claiming that "reality" is whatever your best theoretical description says it is — runs the risk of confusing the map with the territory. Our formal descriptions may change, while "reality" doesn't. For example, a century ago you could say that QM defines reality, but today we know that QM is wrong (particle creation and stuff), and that instead it is QFT which defines reality. And it is likely that QFT will also be eventually substituted with QG of some sort or whatever else. Our descriptions of the real world are epistemological, while the real world itself is (arguably) an ontological notion.

Mateus,

I'm confused, why do you say that realism is the same as determinism? The way I see it, realism is a statement about objectivity of existence of stuff, while determinism is a statement about its evolution (or predictability, or computability, or however you want to frame it). I don't see the two being equivalent in any way, since in principle one can think of a model which obeys realism but not determinism.

🙂
Marko

22. **Peter Woit**
June 12, 2019

Mateus Araújo,
I guess what I'm not understanding is how to reconcile
1. the microcausality of relativistic QFT, so presumably of the SM, our best model of physical reality
2. claims that observed violations of Bell's inequality imply influence outside the light cone.

This would seem to imply that while LHC physicists are desperately and fruitlessly looking for violations of the SM, atomic physics experimentalists are all the time looking at huge violations. This doesn't make sense. The problem has to be that a notion of "measurement" is being invoked that is in violation of the idea that a measurement apparatus is just another physical system. I understand that one possibility is that "measurement" does involve new physics, but I've never seen a plausible conjecture for what this new physics is, and why it is mysteriously inaccessible to usual modeling + experimental study, given that it is supposedly happening in so many experimental situations.

23. **Eric Dennis**
June 12, 2019

Peter,

The key assumption you're making is that (R)QFT/SM is locally causal. In Bell's sense, the SM is *not* locally causal.

The commutation of space-like separated field operators in the SM is something akin to local causality, but it is a weaker condition. This commutation-locality condition shows that we cannot *controllably* send faster-than-light signals. But commutation-locality does not preclude the existence of certain faster-than-light influences, which are not controllable by us.

The situation here with space-like separated field operators is just like the spin operators for the two particles in a Bell experiment. What Bell has shown is that we can make certain kinds of repeated measurements of pairs of spin operators (one for the particle on each side of the experiment), such that the two operators commute with each other in each measurement (because they are operators corresponding to two different particles), but nonetheless the total record of repeated measurements will statistically imply a faster-than-light causal influence between the sides. The nature of this influence just does not enable an experimenter on one side to *control* the measurement results on the other side, hence to send a signal.

What this shows is that the standard notion of locality in QFT (vanishing commutators) is really just a necessary but not a sufficient condition for locality. The SM, just like non-relativistic QM, is fundamentally non-local–as Bell showed it must be to reproduce Bell experiment results described by non-relativistic QM.

24. **Peter Woit**
June 12, 2019

Eric Dennis,
I'm surprised to hear that the last few decades when I thought I was studying local quantum field theory, I really was studying non-local quantum field theory…

25. **Robert**
June 13, 2019

OK, fine, you don't like the term "realism" as it means something else in other context. Call it something else "definitsm" seems to be freely available. What I mean is that it makes sense to argue about the value of something that is inherently unmeasurable like giving it a hypothetical value or talking about the probability of it having a value.

In the case of the original Bell paper, that is having P(a, b) (where a and b are vectors denoting the orientation of the detector) and P(a, c) in one equation where b and c describe incompatible measurements is the original sin.

Or put more abstractly: For a non-commutative algebra of observables, Bell's inequality (or better: its violation) shows that the space of states (the Bloch sphere in the case of a qubit) is not that of probability distributions on some space as it is not a simplex (where each state can be decomposed into pure states in which all events have probability either 0 or 1).

Speaking of definitions of terms: I think for these kinds of discussions it is important to use a definition of "locality" that does not render the classical theory "non-local". Of course, even classically, there can be (probabilistic) states that have correlations and thus even there states are global objects. Reading about the lottery numbers in one newspaper does not "uncontrollably influence" which numbers are printed in all the other news papers. It's just a correlation.

I strongly believe that as long as one sticks to statements that actually have observational meaning (thus excluding equations with P(a, b) and P(a, c) which not only are counter factual as nobody actually did the observation but have to as it is impossible to measure both) as well as the only thing worth worrying about is wether doing stuff here can instantaneously influence outcomes there (no, it cannot even in a quantum world, it could have only influenced a measurement that is impossible to do) then everything is fine. Only thing that has to go is the prejudice that all states are described by probability distributions (of what I would call "classical" outcomes in the 0/1 sense above of assertions that are either true or false).

Finally, with respect to reductionism: I think the strangeness of the quantum world is that the opposite is true: If you have full information about the whole (i.e. it is in a pure state described by a vector in Hilbert space rather than a density matrix, but if you don't like that language, you can equivalently say that you cannot gain more information by decomposing the states into a mixture of other states), entanglement means that you don't necessarily have full information about its parts: That is, even though the state of the whole is pure, the (marginalised) states of the parts can be mixed. Said more colloquially: Knowing everything about the whole does not mean you know everything about its parts (whereas the usual criticism of reductionism is that that knowing everything about the parts does not necessarily tell you everything about the whole).

26. **Mateus Araújo**
June 13, 2019

Marko,

What I'm saying is that your definition of "realism" reduces it to determinism. Since you agree that these are two different concepts that shouldn't be mixed, you should think again about using this as your definition of realism: "Realism is the statement that a physical system has a well-defined value of an observable even before one measures it."

Peter,

That's precisely why we have a problem. Apparently both 1 and 2 are true and contradict each other. But if you are asking about the solution of the problem, there are hundreds of opinions.

I can offer my own: note that Lorenz-covariance of QFT only holds for the unitary part of the theory, as measurements (with wavefunction collapse) obviously break Lorenz-covariance. Note also that Bell's observation that quantum mechanics is nonlocal (in the sense that the probability of an event depends on events outside its past light cone) depends crucially on making measurements and collapsing wavefunctions. This has two consequences: if you accept the standard description of measurement as valid, then there is no contradiction between 1 and 2, as QFT/SM breaks relativity anyway. On the other hand, if you accept that wavefunction collapse is not real, there is again no contradiction between 1 and 2, as Bell nonlocality does not exist.

27. **Peter Woit**
June 13, 2019

Mateus Araújo ,

"if you accept that wavefunction collapse is not real, there is again no contradiction between 1 and 2, as Bell nonlocality does not exist."

Since my point of view is that "wavefunction collapse" is just a crude approximation to what actually happens in a measurement process, that you really need to properly study the physics of the situation, treating the "measurement apparatus" + environment as quantum mechanical (not classical) systems, presumably the "nonlocality" disappears if you do this.

28. **vmarko**
June 13, 2019

Peter,

"I'm surprised to hear that the last few decades when I thought I was studying local quantum field theory, I really was studying non-local quantum field theory…"

Would it be of any help to see an explicit calculation of the violation of Bell's inequalities within the formalism of QFT? If yes, you may want to take a look at arXiv:1309.2059. They do not discuss what is local or nonlocal (their emphasis is on velocity-dependence), but an explicit QFT calculation may nevertheless shine some light on it?

Mateus,

"What I'm saying is that your definition of "realism" reduces it to determinism."

Care to elaborate how this reduction happens? It isn't obvious (to me, at least). While I believe that one could arguably bend over backwards and twist the meaning of the word "determinism" enough to fit your statement, I don't think it is true for the determinism in the usual sense of, say, Laplace's demon.

Best, 🙂
Marko

29. **Low Math, Meekly Interacting**
June 13, 2019

Forgive what might be some silly questions. I'm trying to get to the heart of the matter expediently using (I know, I know) words.

There are clearly a wide range of reactions to the fact that, in Bell-type experiments, nature violates Bell's (or CHSH's, or whoever's) inequality in a particular way. At the extremes are "Yeah? So?" and "GiH! Spukhafte Fernwirkung!" The debate between the two often looks to me like an intervention, with people yelling "I don't have a problem! YOU'RE the one with the problem!" back and forth.

So great, (literally) adjust your expectations for "reality". What should leave us perplexed, then, is not the correlation between quantum coin flips, but classical ones.

Is one therefore sweeping the "mystery" under the "emergence" rug and blaming evolution for our obtuseness, per usual?

30. **Eric Dennis**
June 13, 2019

Peter/Mateus,

It's not helpful to talk about QM (or QFT) here apart from some account of measurement, essentially bringing us back to 1925. The whole problem is that any theory that can account for actual measurement results (including Bell experiments) is, by Bell's reasoning, necessarily non-local. Indeed any particular such theory ever conceived (wavefunction collapse, hidden variables, spontaneous collapse, etc.) is manifestly non-local, whether in the context of simple QM or QFT.

It simply won't do to ignore Bell's result and say "Well, I don't believe in any of those theories, they're at best approximations, so there's no problem here."

I realize it is jarring to call Relativistic QFT (inclusive of measurements) non-local. First, this is not my idiosyncratic view. It is Bell's own view. See his paper "The

Theory of Local Beables”:

https://cds.cern.ch/record/980036/files/197508125.pdf

And it’s a view that has been gaining popularity more recently among people in QM foundations. Second, imagine that the field of QM foundations, for most of the period from the 1920’s onward, had been in a somewhat broken state, similar to the current state of string theory (viewed as a TOE).

There was never anything wrong with physicists arriving at something like the collapse view and simply confessing that such a thing didn’t make much sense when taken literally, but we’ll just leave it here as a placeholder until people figure out what’s really going on. Unfortunately that’s not what happened in the 1920/30’s. What happened were megalomaniacal pronouncements about QM constituting a philosophical revolution in our understanding of the relationship between existence and consciousness. We all know the embarassing quotes from Bohr, Heisenberg, Born, Jordan, etc.

When careful thinkers started poking around and asking questions (de Broglie, Einstein, Schrodinger, Bohm, Bell, Grete Hermann) they were dismissed as reactionaries, or simply misunderstood, not refuted. The early foundational mess crystallized inside the culture of physics and has been causing problems ever since. Given all of this, a pervasive misunderstanding about a somewhat subtle (and philosophically radioactive) distinction between the concepts of signalling locality and causal locality is not that shocking.

31. **nick herbert**
June 13, 2019

To my way of thinking, there are three basic levels of discourse, quantum Fact, quantum Theory and quantum Reality. The quantum Facts (exoeriments) are all local, both by actual experiment and by calculation. Quantum Theory seems to be non-local: when Alice makes a measurement Bob’s distant wavefunction collapses instantaneously. What about quantum Reality?

Bell’s achievement is that not only did he focus on Reality, considered by most philosophers to be inaccessible to mind, but he actually proved sonething about the nature of Reality.

When Bob and Alice share a pair of entangled photons, each makes a measurement on a sequence 1, 2, 3…N photons and gets certain results.

Consider one of these results, say result #36. Bell asks the question, what were the causes of Bob’s outcome for this single instance? What does nature need to know to produce this event? To answer this question one must consider for event #36, not only the event that actually happened but all possible events for all possible Bob and Alice settings. All of these events exceot one are contrafactual, but nature must be ready to produce a definite result for any of these possible choices.

Bell then considers what might be happening at Bob’s detector to produce Bob’s event,
making no assumptions about realism, determinism, but only that whatever causes nature uses to construct this outcome, the setting of Alice’s detector is not one of these causes. Bell then shows that any model of reality (how single Bob events are produced) with this restriction cannot reproduce the quantum Facts.

The “realism” assumption to my way of thinking is the notion that it makes sense to consider not only the one result #36 that actually happened, but events# 36 that could have happened for different detector settings. How you feel about Bell’s Theorem then would depend on how you feel about this “contrafactual definiteness” assumption. Is it “classical”, “metaphysical” or simply one natural way to think about quantum causality?

32. **Anonyrat**
June 13, 2019

To expand on Bee’s comment:
https://plato.stanford.edu/entries/bell-theorem/

“The principal condition used to derive Bell inequalities is a condition that may be called *Bell locality*, or *factorizability*. It is, roughly, the condition that any correlations between distant events be explicable in local terms, as due to states of affairs at the common source of the particles upon which the experiments are performed. See section 3.1 for a more careful statement.”

Section 3.1 is too long and dense to meaningfully excerpt here, as an appetizer: “The condition F of factorizability is the application, to the particular set-up of Bell-type experiments, of Bell’s Principle of Local Causality.”
https://plato.stanford.edu/entries/bell-theorem/#LocaCausAssu

33. **Peter Woit**
June 13, 2019

vmarko,
I’m not convinced that the problem lies with the QFT vs. QM treatment of polarization states, I think it’s with the coupling to a “measurement apparatus”.

vmarko/Eric Dennis
What I keep trying to point out is that what is getting ignored here is the actual physics of what happens when you take a spin 1/2 particle and “measure spin up or down”, or “collapse the wavefunction”. You’re ignoring the actual physics and using an extremely crude, non-local approximation to this physics, and then saying that it implies fundamental physics is non-local.

Eric Dennis,
You accuse Bohr et al. of engaging in mystification based on the crude “collapse” model of measurement, and there was plenty of that back in the 20s and 30s. From my reading, there was also a lot of much more nuanced discussion from them, well aware that the problem was the difficult one of emergence of classical behavior, but that they lacked the tools to analyze that so had to set that problem aside. That was nearly a century ago, the problem I see now is that Bell and those following him are now doing exactly what you accuse Bohr et al. of doing: making dramatic claims based on the problems with the obviously flawed “collapse” model.

34. **BSmith**
June 13, 2019

Physics is essentially local. When people talk about non-locality in the context of the EPR experiment “it’s a matter of giving a dog a bad name …”, according to Gell-Mann.
https://www.youtube.com/watch?v=gNAw-xXCcM8

35. **Eric Dennis**
June 13, 2019

Peter,

Permit me to create a stylized version, for purposes of clarity, indicating the pattern of many, many exchanges between the Bell camp and its critics…

Bell: Here's an extremely general theorem showing why *any* physical theory whatsoever that reproduces certain well-tested experimental results (specified in macro-level not micro-level terms) must be non-local.

Critic: Spacelike commutators vanish in QFT, so it's local, so it must evade your theorem.

Bell: QFT is not local. Spacelike commutators vanish, but this only ensures signalling locality, not full causal locality. The exact equivalent of spacelike commutators also vanish in a Bell experiment. My very general theorem shows how, despite vanishing commutators, the choice of device setting at A must influence the same-time output at B to match the observed results.

Critic: Let's not get too philosophical about defining locality.

Bell: OK, to be concrete, every specific, well-defined model ever conceived (collapse, hidden variables, etc.) that accounts for the measurement results is manifestly non-local. Exactly as expected from my extremely general theorem that doesn't refer to or rely on any theory-specific detail (like collapse, hidden variables, etc.).

Critic: Aha! Your theorem assumes the old-fashioned idea of wavefunction collapse, which we all know isn't rigorous or exact.

36. **Peter Woit**
June 13, 2019

Eric Dennis,
This has degenerated into the exactly what Sabine Hossenfelder warned would happen in the first comment, a useless argument over what "non-locality" means. I recommend the Gell-Mann video in the previous comment, where he makes essentially the same complaint I'm making about hijacking definitions in order to try and argue that there must be something wrong with QM.

37. **vmarko**
June 13, 2019

Peter,

The collapse postulate is also present in QFT, only hidden inside the LSZ formula. But if you are against using the collapse postulate to describe measurements, then your main problem is neither non-locality nor Bell's theorem, but rather the measurement problem of QM (of course, it remains a problem even if you do use the collapse postulate). In particular, you need some mechanism to explain why we observe a *single* outcome for every individual run of an experiment (say, a scattering process in LHC).

Nobody has a satisfactory answer to that, and I agree that the collapse postulate may look as an ugly phenomenological patch, rather than a fundamental part of a theory. But however you turn it, both QM and QFT are in this sense incomplete, and you need *some* additional postulate to define what a measurement is (or why we see single outcomes).

And in light of Bell's theorem, I don't believe that this additional postulate (however you choose to define it) is going to turn a non-local theory into a local one. You'll be just "kicking the can" further down the formalism, so to say.

🙂
Marko

38. **Peter Woit**
June 13, 2019

vmarko,
Yes, the measurement problem for me is the main problem. If you look at the Gell-Mann video mentioned above, his take on Bell's "non-locality problem" is that it's making the mistake of mixing things on "different branches", so he seems to be saying that it's the measurement problem.

As for the "why the single outcome" aspect of that problem, one thing that has always struck me is that we're typically DEFINING a "measurement apparatus" as something that behaves in such a way as to produce a single classical outcome. But that problem I think is much more subtle (and discussion of it left to a separate occasion) than the "non-locality" problem here, which just seems to be a red herring.

39. **Thomas Andersen**
June 13, 2019

Peter Woit wrote:
"
I fear though that the kinds of "foundations" of interest to the organizers seem rather orthogonal to the "foundations" that most interest me.
"

Why should that be something to fear? The world of physics is making very little progress at the moment (40 years). One thing is certain: if everyone got their way on what to not to study, there would be nothing available to study.

40. **Peter Woit**
June 13, 2019

Thomas Andersen,
That was a purely personal comment. I'm quite interested in the question of foundations of quantum theory so glad to see that a new group has formed to address the issue, just would be a lot happier if they seemed more interested in the questions that to me seem relevant. I don't think there's much danger at the moment of my views of what is interesting dominating the subject and driving out others…

41. **Peter Shor**
June 14, 2019

Three comments.

First: quantum mechanics doesn't just break classical probability theory (as Bell demonstrated); it breaks classical computational complexity theory and classical information theory as well. This is why there are a number of computer scientists who are convinced that quantum computers can't possibly work.

Second: I think this quote by Feynman is very relevant to this discussion: "I am going to tell you what nature behaves like. If you will simply admit that maybe she does behave like this, you will find her a delightful, entrancing thing. Do not keep saying to yourself, if you can possibly avoid it, 'But how can it be like that?' because you will get 'down the drain', into a blind alley from which nobody has yet escaped. Nobody knows how it can be like that." He said this in 1964; I think it's still good advice today.

Third: Feynman didn't actually follow his own advice. Around 1980, I saw him give a lecture at Caltech about negative probabilities, where he explained that his motivation was looking at all the hidden hypotheses of Bell's Theorem to try to figure out whether any of them might be false. He later published a paper on negative probabilities, but it didn't mention this motivation, presumably because he realized that negative probabilities couldn't explain quantum weirdness.

42. **Lee Smolin**
June 14, 2019

Dear Peter,

I have made what I hope is a strong case for taking seriously what we might call the "John Bell point of view" in my recent book Einstein's Unfinished Revolution, and find myself mostly in agreement with Eric Dennis and Marko. I would very briefly underline a few points:

-This is not a debate resting on confusions of words. Nor is there, to my knowledge, confusion among experts about the direct implications of the experimental results that test the Bell inequalities. The main non-trivial assumption leading to those inequalities is a statement that is usually labeled "Bell-locality". Roughly this says (given the usual set up) that the "choice of device setting at A cannot influence the same-time output at B".

Nothing from either quantum mechanics nor classical mechanics is assumed. The experiments test "Bell-locality" and the experimental results are (after careful examination of loop-holes etc.) that the inequality is cleanly and convincingly violated in nature. Therefor "Bell-locality" is false in nature.

-The conclusion that "Bell-locality" is false in nature is an objective fact. It does not depend on what view you may hold on the ultimate correctness, completeness or incompleteness of QM. Bohmians, Copenhagenists,Everetians etc all come to the same conclusion.

-Nor does it matter if there are other senses of "local" in which nature or QFT is local, because these notions are independent of "Bell-locality". Indeed, it is important to understand that "Bell-locality" is false in QM and QFT, as Bell showed directly. Therefor, the experimental result that "Bell-locality" is false in nature is an important confirmation of a prediction of QM and QFT.

-Now it is also true that Bell and a few others, for various and different reasons, held or hold a view that QM is incomplete, and that nature could be described more accurately by a different theory. Examples of such theories are dBB and collapse models. This has also nothing to do with confusion over the meaning of words. These are competing hypotheses about nature, to be settled ultimately by experiment.

For people in this camp, the falseness of "Bell-locality" is an important clue which constrains any such proposal for a completion of QM. But if you are not in this camp, and have no interest in the hypothesis that QM requires a completion to describe nature, you can just ignore the further implications.

Thanks,

Lee

43. **Peter Woit**
June 14, 2019

Thanks for the clarifications Lee.

By the way, beside Lee's new book, I can recommend the interview with him posted at Sabine Hossenfelder's blog

http://backreaction.blogspot.com/2019/06/a-conversation-with-lee-smolin-about.html

44. **Eric Dennis**
June 14, 2019

Lee,

Well put! My view is that "Bell locality" is the one True locality, because what could possibly be a better definition than 'no effects from outside the past lightcone'? But your line of attack here is probably more comprehensible to people with a conventional understanding of QFT.

Peter,

One natural impediment in coming at this stuff from the standpoint of conventional QFT is the scary question of what happens to QFT now. I think this fear has a really bad affect on people's ability even to permit Bell's analysis into the realm of Reasonable Views That I May Take Seriously.

Of course QFT isn't just rendered invalid as a scientific theory. There's just way too much ultra-precise and very diverse experimental confirmation. I can see only one natural explanation of this state of affairs: Lorentz invariance (more broadly, general covariance) is an emergent symmetry of nature at a particular energy scale, not a fundamental symmetry. This is controversial even within the Bell camp, however.

45. **Peter Woit**
June 14, 2019

Eric Dennis,
I'm not worried about QFT. The Bell analysis clearly has nothing at all to do with QFT.
As for using this as a motivation for deciding that Lorentz symmetry is emergent, I don't see that at all.

By the way, I'm developing a serious allergy to the endless claims now being heard that this or that about the SM or GR is not fundamental, but "emergent", with no idea what it is "emergent" from. I do thing classical behavior is properly described as "emergent", but in that case, we know what it emerges from (QM). If you want to start claiming QM is "emergent" too, you need some compelling story about where/when it fails as a description of nature, and what is supposed to replace it.

46. **Anonyrat**
June 14, 2019

My view is that "Bell locality" is the one True locality, because what could possibly be a better definition than 'no effects from outside the past lightcone'?

Sorry, neither "Bell locality" nor its failure means "no effects from outside the past lightcone". What ever entangled wave-function that a Bell-type experiment is measuring originated in the past lightcone of both the measurement apparatus.

47. **Mateus Araújo**
June 15, 2019

Dear Lee Smolin,

I'm sorry, but what you have written is false.

To start with, you said that "Indeed, it is important to understand that "Bell-locality" is false in QM and QFT, as Bell showed directly." It is important to notice that Bell's direct demonstration that "Bell-locality" is false in QM and QFT depends crucially on the collapse of the wavefunction. As it should be obvious, since unitary QFT is Lorenz-covariant.

Which brings us to the second point. You wrote that "The conclusion that "Bell-locality" is false in nature is an objective fact. It does not depend on what view you may hold on the ultimate correctness, completeness or incompleteness of QM. Bohmians, Copenhagenists,Everetians etc all come to the same conclusion." Now how could Everettians come to this conclusion, since the failure of "Bell-locality" depends on the collapse of the wavefunction?

And indeed they *don't* come to this conclusion, empirically speaking. If you check the literature you'll see that Everettians insist that quantum mechanics is (Bell) local. The appearance of nonlocality is caused by the mistaken assumption that measurements have a single outcome. This is elegantly put by Deutsch and Hayden in section 7 of their 1999 paper. A similar argument, perhaps clearer, is made by Brown and Timpson in section 9 of their 2014 paper. I've also blogged about his point here.

48. **vmarko**
June 15, 2019

Mateus,

"It is important to notice that Bell's direct demonstration that "Bell-locality" is false in QM and QFT depends crucially on the collapse of the wavefunction. As it should be obvious, since unitary QFT is Lorenz-covariant."

You have to be careful not to mix the Lorentz-invariance of the theory with the invariance of its solutions. The preparation and measurement are technically understood as boundary conditions, which fix a particular solution of the equations of motion. There is nothing surprising in the fact that a particular solution is not Lorentz-invariant — this is common even in the classical theory, and not specific to the collapse postulate in QM. When we say that QFT is Lorentz-invariant, we mean that the *dynamics* (encoded in the action or EoMs) is invariant, and this is true regardless of the measurement. In QM, the analogy would be that the Heisenberg equations of motion are Galilei-invariant, regardless of the fact that preparation and measurement can fix a particular frame of reference.

"Everettians insist that quantum mechanics is (Bell) local. The appearance of nonlocality is caused by the mistaken assumption that measurements have a single outcome."

Last time I checked with experimentalists, they did see a single outcome in every run of every experiment ever done. Do Everettians insist that these people are delusional? How do they explain any experimental results at all?

I understand that the measurement problem is hard, and that the collapse postulate may not be a perfect or complete solution, but ignoring that the problem exists is not a solution either, IMO.

Best, 🙂
Marko

49. **André**
June 15, 2019

Mateus,
Sure QM/QFT by itself is a local theory, the problem is that QM/QFT by itself is also a theory without any predictions. As soon as you want to make any connection to experiments, you have to talk about collapse in some way – and be it by reducing your consideration to one of the Everettian branches.
This is IMHO the main point that Everettians are missing: While it is mathematically perfectly consistent as a theory – and it looks like physics because the unitary dynamics has the same description as in standard QM (with ill-defined projection postulate) – the "anything goes" approach of Many Worlds is not a scientific theory, it is just a mathematical construct.
In this regard, an Everettian standpoint on QM is in no way better than the String Theory Landscape. That is also what puzzles me a bit about Peter's criticism of QM foundations, because sociologically I see a lot of parallels between string theorists and large parts of the quantum info community, and I also read (with great pleasure) the criticism of Many Worlds on this blog. But Many Worlds is an unvoidable consequence if you take QM/QFT by itself without any modifications that explain collapse.
[Edit: Marko was a bit faster with his reply.]

50. **Paddy**
June 15, 2019

Peter, you wrote:

> "I'm realizing that one thing that I really dislike about this subject is the hijacking of words (e.g. "realism" and "locality") to suit a particular agenda"

If you are going to write about this sort of thing you really need to accept that words like that are useless unless their meanings are very carefully specified, because different people honestly use them to mean very different things. Otherwise, rational debate is impossible.

Most physicists consider "locality" to be an essential feature of our theories (or of "reality"), and if you ask them why, they will probably point at Einstein (after all, Newtonian gravity was explicitly non-local). So it is relevant that what Lee Smolin calls "Bell-locality" is very clearly Einstein's personal view, implicit in the EPR paper and stated explicitly in his "Reply to Critics" in the Schlipp volume. I find it odd that modern relativists like Hossenfelder choose to use "locality" in a much more restricted sense than the founder, just so that they can insist that QFT is "local". One might even ask, who is doing the hijacking here, and why is it so important to keep the label, even though it no longer denotes anything more than a technical condition?

51. **Geoffrey Dixon**
June 15, 2019

Interesting, though hardly surprising, that comment count is proportional to how unknowable and controversial the topic.

52. **Mateus Araújo**

June 15, 2019

Marko,

"You have to be careful not to mix the Lorentz-invariance of the theory with the invariance of its solutions. The preparation and measurement are technically understood as boundary conditions, which fix a particular solution of the equations of motion. There is nothing surprising in the fact that a particular solution is not Lorentz-invariant — this is common even in the classical theory, and not specific to the collapse postulate in QM. When we say that QFT is Lorentz-invariant, we mean that the *dynamics* (encoded in the action or EoMs) is invariant, and this is true regardless of the measurement."

This might be true if the universe started with a measurement, and ended with one. Alas, this is not true, there are several measurements in between, that are part of the dynamics, not of boundary conditions. Technically speaking, while the dynamics between a given preparation and measurement can be well-described by a (unitary) S-matrix, if you want to talk about the future of a measurement or the past of a preparation, you'll need to introduce a collapse that will break Lorenz-covariance. That is, if you don't go Many-Worlds.

"Last time I checked with experimentalists, they did see a single outcome in every run of every experiment ever done. Do Everettians insist that these people are delusional? How do they explain any experimental results at all?"

I think you're just trolling, but I'll give a serious answer anyway. What Many-Worlds says that will happen in a measurement is that there will be several copies of the experimentalist, each observing a single outcome. And this is not postulated by fiat, it's what the equations say. Do you think that anybody would take the theory seriously if this were not the case?

53. **Mateus Araújo**
June 15, 2019

André,

"This is IMHO the main point that Everettians are missing: While it is mathematically perfectly consistent as a theory – and it looks like physics because the unitary dynamics has the same description as in standard QM (with ill-defined projection postulate) – the "anything goes" approach of Many Worlds is not a scientific theory, it is just a mathematical construct."

Even if you don't buy the Everettian approach to probability, this is not true. The theory makes many deterministic predictions: there will be no violation of conservation of energy, there will be no break of Lorenz-covariance, there will be no superposition of charges, etc.

And I don't think probability is a weak point of Many-Worlds, rather it is a strength (I'm aware that this statement is controversial). Standard QM cannot make sense of objective probability, but Many-Worlds can.

"In this regard, an Everettian standpoint on QM is in no way better than the String Theory Landscape."

This is just an empty insult.

54. **Marty Tysanner**
June 15, 2019

I don't know how anyone who is a "realist" and has taken the time to understand Bell's theorem and its experimental tests (and examination of its experimental loopholes, most of them implausible) can not be really, really disturbed by the consistent observation of violations of the theorem under a variety of increasingly stringent tests. It certainly freaked me out when I learned about it in grad school. Of course, as Lee noted above, this is only a problem for those who look for deeper meaning from theories and experiments; instrumentalists and those whose interest in QM is for practical ends can freely ignore the conceptual issues, and there is certainly nothing wrong with that.

Tim Maudlin (a philosopher of physics who has deeply studied Bell's theorem and articulated much on it) has argued Bell made two key assumptions: *locality* and the experimenter's *freedom to choose experimental settings*. Determinism is not an assumption. Hence, since all known experimental loopholes (like detector inefficiency) are now closed, violations of Bell's inequality imply either locality or freedom of choice is false. Bell noted that the latter is possible if nature is "superdeterministic" in Bell's sense. Since most people don't take his superdeterminism too seriously (and he didn't either), and experimenters at least seem to believe they can freely manipulate the settings, it is usual to conclude that non-locality is a fact of nature.

While I may understand their rationale, it still dismays me that so many people have thrown locality "under the bus" (so to speak). Locality isn't like the 19th century ether that was invented to explain certain physical phenomena; it's at the core of relativity, electromagnetism, classical mechanics, and even QM evolution up to the time of measurement. I can't think of anywhere else in all of fundamental physics–outside QM entanglement–where locality is in question. Moreover, there are obvious conceptual issues with non-local influences/communication between entangled particles at space-like separation: How do the particles "find" each other within the entire universe, so they can "communicate" (other than tautalogically or some other version of "it just happens; don't ask how"); and why don't we see nonlocality in other contexts if it's a truly fundamental aspect of nature?

I think there might be other viable alternatives besides the unpalatable choice between superdeterminism and non-locality. Concretely, one question stands out: What if experimental tests are *not* actually testing Bell's theorem the way it seems they are, so that the relevance we assign to the observed violations is an artifact of our ignorance of the "construction" (incomplete modeling) of the particles we employ, and of their interaction with the experimental apparatus, rather than an actual demonstration of non-locality? Stated differently, what if the change of basis (e.g., polarization basis for photons) that is central to Bell tests does not actually cause a particle to fully "forget" its original basis, and furthermore the memory of its original basis subsequently affects its path through the apparatus even though the particle by itself *statistically* respects its new basis in all ways? I'm thinking of something analogous to the phase of the wave function, but which corresponds to an actual attribute (or "hidden variable", to use that awful term) of the test particles.

In a meaningful sense this alternative violates the "freedom of choice" assumption if the nature of the particle is such that an apparatus cannot effect an irreversible change of basis without destroying the original entanglement. It would mean a photon is not completely characterized by its spin, frequency, helicity/polarization, electromagnetic coupling, and of course Poincaré symmetry; something more is present.

I don't think this idea can be dismissed out of hand. Abstractly, particles are representations of the Poincaré group and an internal symmetry group which are characterized by spin, mass, angular momentum, charge, etc., the origins of which remain unexplained. Given this lack of explanation/understanding there is no empirical reason–only historical or philosophical prejudice–for assuming we possess a complete characterization of the properties and behavior of the known particles. We can reliably model only what we observe, but our ability to test those models is constrained by what we know we should look for (ignoring serendiptous discoveries).

Nonetheless, first reactions to this alternative may be something like "Yuck, that's really ad hoc and contrived" or "Yeah right, and why exactly haven't we detected this attribute in other kinds of experiments?" But the Aharonov-Bohm effect can be interpreted as demonstrating the reality of the phase of the wave function, even though (as in the second objection) this phase is generally unobservable. And at least in my own research, much of it currently related to dynamical, geometric models of electrons and photons, the alternative scenario outlined above is *not* ad hoc; it actually appears plausible.*

Given the centrality of locality in physics, I think we should "fight to the death" to preserve it in a fundamental theory. That presumably requires considering alternative possibilities besides superdeterminism or giving up.

* [The reason you won't find papers on these models (yet) is straightforward. Any proposal of a concrete, mathematical yet explanatory dynamical model is automatically faced with the highly nontrivial task of ensuring empirical and theoretic consistency with all known phenomena and established theory of the modeled particle; or at least enough consistency must be demonstrated to make the model interesting, especially with QM/QFT and electromagnetism. That effort is ongoing…]

55. **Lena Birkenfeld**
June 15, 2019

I've seen a lot of debate on this comment section on traditional interpretations of quantum mechanics, but nobody seems to have taken a look at Neumaier's interpretation yet.

Mateus Araújo,

"And I don't think probability is a weak point of Many-Worlds, rather it is a strength (I'm aware that this statement is controversial). Standard QM cannot make sense of objective probability, but Many-Worlds can."

And Neumaier in his thermal interpretation of quantum mechanics states that the probability found in quantum mechanics is not objective, but is emergent from the fact that we only have incomplete knowledge of the state of the system:

https://arxiv.org/pdf/1902.10779.pdf

56. **Lena Birkenfeld**
June 15, 2019

Peter,

Neumaier says something similar to what the Scholarpedia article said about Bell's Theorem in section 4.5 of his 2nd paper on his thermal interpretation:

"Bell's theorem, together with experiments that prove that Bell inequalities are violated imply that reality modeled by deterministic process variables is intrinsically nonlocal. The thermal interpretation explicitly acknowledges that all quantum objects (systems and sub-systems) have an uncertain, not sharply definable (and sometimes extremely extended) position, hence are intrinsically nonlocal. Thus it violates the assumptions of Bell's theorem and its variations."

https://arxiv.org/pdf/1902.10779.pdf

compare with Scholarpedia:

"Bell's theorem asserts that if certain predictions of quantum theory are correct then our world is non-local."

57. **vmarko**
June 15, 2019

Mateus,

"Technically speaking, while the dynamics between a given preparation and measurement can be well-described by a (unitary) S-matrix, if you want to talk about the future of a measurement or the past of a preparation, you'll need to introduce a collapse that will break Lorenz-covariance."

I agree, concatenation of two solutions along a "measurement boundary" (past for one, future for the other) is not itself a solution. But note that QFT is usually always applied precisely in the sense that preparation happened in t=-oo, while the measurement happens at t=+oo. Of course, this is an approximation, but works well enough for events in the LHC and such, a context most common for QFT.

"What Many-Worlds says that will happen in a measurement is that there will be several copies of the experimentalist, each observing a single outcome. And this is not postulated by fiat, it's what the equations say."

Not really. The equations fail to say why the experimentalist always observes a single outcome in the computational (0/1) basis, and never observes a single outcome in the superposition (+/-) basis. There is nothing in unitary dynamics that could distinguish between the two bases. In order to work around that, MW has to resort to postulating a preferred basis — and this is postulated by fiat. The preferred basis postulate (a) breaks unitarity, and (b) it is essentially equivalent (in predictive power) to the collapse postulate, because otherwise MW would be a different theory, rather than just an interpretation of QM.

I've seen various attempts to single out a particular preferred basis using various arguments and handwaving, but they all fall short of being successful, as long as MW holds up to strict unitary evolution.

Best, 🙂
Marko

58. **Tim Maudlin**
June 16, 2019

"As far as I can tell, for all the experiments that come up in discussions of Bell's theorem, if you do a local measurement you get a local result, and only if you do a non-local measurement can you get a non-local result."

This is about as embarrassing and revelatory a sentence as could be written. What in the world could a "non-local result" mean?

You do experiments in two (or three: GHZ) labs. You get results of those experiments. Those results display correlations that no local theory (in the precise sense defined by Bell) can predict. Ergo, no local theory can be the correct theory of the actual universe. I.e. actual physics is not local (in Bell's sense).

This is the sort of thing that can be explained in 20 minutes to undergrads, and they understand it. Woit is clearly intelligent enough to understand it, and his lack of comprehension is indicative of some weird refusal to pay attention to what Bell did.

59. **Robert**
June 16, 2019

" The equations fail to say why the experimentalist always observes a single outcome in the computational (0/1) basis, and never observes a single outcome in the superposition (+/-) basis."

There is always a single outcome in the diagonal basis that was actually measured. You can measure the spin on an electron in any direction you like and you will always get a definite result.

60. **Mateus Araújo**
June 16, 2019

Marko,

You are silently moving the goalposts from "experimentalists should observe multiple outcomes" to the preferred basis problem. You seem, however, to not understand what the problem is (was, actually). You write:

"The equations fail to say why the experimentalist always observes a single outcome in the computational (0/1) basis, and never observes a single outcome in the superposition (+/-) basis. There is nothing in unitary dynamics that could distinguish between the two bases."

Actually, an experimental apparatus that makes a measurement in the 0/1 basis is different from an apparatus that makes a measurement in the +/- basis. There is no difficulty in capturing this difference in the unitary dynamics, it is really a different unitary transformation.

Rather, the problem was that given a unitary that makes the measurement in the 0/1 basis, ending up with a state like |0>|M_0> + |1>|M_1>, why should we interpret this state as representing a superposition of quasi-classical worlds |0>|M_0> and |1>|M_1>, instead of some other superposition of worlds, or even a single world with some other result? Historically it was simply postulated to be so: an apparatus that measures in the 0/1 basis creates quasi-classical worlds in the 0/1 basis. This is obviously rather unsatisfactory, and people moved on to trying to determine what the quasi-classical worlds are via the Schmidt decomposition, which doesn't really work (and it is anyway rather weird to postulate that the Schmidt decomposition has some special role).

The problem was solved via decoherence. People realised that an apparatus that measures in the 0/1 basis makes the system *decohere* in this basis. This has two effects: the quasi-classical worlds |0>|M_0> and |1>|M_1> are single out by being stable under decoherence, and also they become dynamically decoupled, which justifies thinking of them as separate worlds in the first place.

For a historical account of the preferred basis problem, I'd recommend Saunders' introduction to the "Many Worlds?" book, available here. For a pedagogical take on how decoherence gives rise to the quasi-classical worlds, I'd recommend Wallace's Decoherence and Ontology.

61. **vmarko**
June 16, 2019

Mateus,

"You are silently moving the goalposts from "experimentalists should observe multiple outcomes" to the preferred basis problem."

I'm not trying to move the goalposts — these two things are related. Let me put it this way. You split the Universe into three subsystems: the spin, the apparatus (including us), and the environment (rest of the Universe). Then you trace over the environment, and obtain a density matrix which is almost-block-diagonal in the computational basis, courtesy of (handwavingly specified) interaction with the environment. Say this density matrix looks like diag(1/2,1/2) [here each entry is actually a submatrix describing the detailed state of the apparatus]. The collapse postulate is a further (nonunitary) transformation of the matrix into a form like diag(1,0), encoding the statement "result '0' was observed". In MW you refuse to make that additional step, and instead interpret the non-collapsed density matrix as "in one branch I see diag(1,0), in the other branch the other me sees diag(0,1), and the two branches are weighted with probability 1/2 each". This interpretation makes sense only if you *prove* that the density matrix is really almost-diagonal in the computational basis, as opposed to some other basis. I've never seen this proof, only qualitative handwaving arguments that the interaction with the environment has precisely the right properties to single out a computational basis. So I wouldn't call this problem "solved" by decoherence.

Regarding decoherence itself, of course you can always describe nonunitary dynamics of a system as unitary dynamics of a larger system, by tracing over the ancilla. That's basically a theorem. Nevertheless, this relies on the assumption that the appropriate ancilla physically exists, i.e. that your physical system does have an environment with appropriate interactions. In other words, decoherence may work only for open quantum systems, but not for isolated systems. I find the "environment assumption" ontologically unsatisfactory, since the Universe as a whole is an isolated system, with no environment to fix a preferred basis. For a serious analysis of this issue, see for example arXiv:1105.3796.

I asked the same question to John Preskill a while ago (https://quantumfrontiers.com/2013/01/10/a-poll-on-the-foundations-of-quantum-theory/#comment-2823), and his reply was basically that we should always trace out the part of the Universe which is outside our observable horizon. I find this unsatisfactory, just like Bousso and Susskind do in the arXiv paper.

Best, 🙂
Marko

62. **Peter Woit**
June 16, 2019

All,
I'm closing comments on this posting. This has gotten to the point where zero light is being shed on the Bell-nonlocality issue, and I've lost the patience needed to try and sensibly moderate a general discussion that people want to take in other directions.

Various

First something really important: chalk. If you care about chalk, you should watch this video and read this story.

Next, something slightly less important: money. The Simons Foundation in recent years has been having a huge (positive, if you ask me…) effect on research in mathematics and physics. Their 2018 financial report is available here. Note that not only are they spending \$300 million/year or so funding research, but at the same time they're making even more (\$400 million or so) on their investments (presumably RenTech funds). So, they're running a huge profit (OK, they're a non-profit…), as well as taking in each year \$220 million in new contributions.

Various particle physics-related news:

- The people promoting the FCC-ee proposal have put out FCC-ee: Your Questions Answered, which I think does a good job of making the physics case for this as the most promising energy-frontier path forward. I don't want to start up again the same general discussion that went on here and elsewhere, but I do wonder about one specific aspect of this proposal (money) and would be interested to hear from anyone well informed about it.

  The FCC-ee FAQ document lists the cost (in Swiss francs or dollars, worth exactly the same today) as 11.6 billion (7.6 billion for tunnel/infrastructure, 4 billion for machine/injectors). The timeline has construction starting a couple years after the HL-LHC start (2026) and going on in parallel with HL-LHC operation over a decade or so. This means that CERN will have to come up with nearly 1.2 billion/year for FCC-ee construction, roughly the size of the current CERN budget. I have no idea what fraction of the current budget could be redirected to new collider construction, while still running the lab (and the HL-LHC). It is hard to see how this can work, without a source of new money, and I have no idea what prospects are for getting a large budget increase from the member states. Non-member states might be willing to contribute, but at least in the case of US, any budget commitments for future spending are probably not worth the paper they might be printed on.

  Then again, Jim Simons has a net worth of 21.5 billion, and maybe he'll just buy the thing for us…

- Stacy McGaugh has an interesting blog post about the sociology of physics and astronomy. His description of his experience with physicists at Princeton sounds all too accurate (if he'd been there a couple years earlier, I would have been one of the arrogant, hard-to-take young particle theorists he had to put up with).

  McGaugh's specialty is dark matter and he has some comments about that. If you want some more discouragement about prospects for detecting dark matter, today you have your choice of Sabine Hossenfelder, Matt Buckley, or Will Kinney. I don't want to start a discussion of everyone's favorite ideas about dark matter, but wouldn't mind hearing from an expert whether my suspicion is well-founded that some relatively simple right-handed neutrino model might both solve the problem and be essentially impossible to test.

- Lattice 2019 is going on this week. Slides here, streaming video here.
- Strings 2019 talk titles are starting to appear here. I'll be very curious to hear what Arkani-Hamed has to say. His talk title is "Prospects for contact of string theory with experiments (vision talk)" and while he's known for giving very long talks, I don't see at all how this one could not be extremely short.

On a more personal front, yesterday I did a recording for a podcast from my office, with the exciting feature of an unannounced fire drill happening towards the end. Presumably this will get edited out, and I'll post something here when the result is available.

Next week I'll be heading out for a two week trip to Chile, with one goal to see the total solar eclipse there on July 2. Will start out up in the Atacama desert.

Update: John Horgan has an interview with Peter Shor. I very much agree with Shor's take on the problems of HEP theory:

> High-energy physicists are now trying to produce new physics without either experiment or proof to guide them, and I don't believe that they have adequate tools in their toolbox to let them navigate this territory.
>
> My impression, although I may be wrong about this, is that in the past, one way that physicists made advances is by coming up with all kinds of totally crazy ideas, and keeping only the ones that agreed with experiment. Now, in high energy physics, they're still coming up with all kinds of totally crazy ideas, but they can no longer compare them with experiments, so which of their ideas get accepted depends on some complicated sociological process, which results in theories of physics that may not bear any resemblance to the real world. This complicated sociological process certainly takes beauty into account, but I don't think that's what is fundamentally leading physicists astray. I think a more important problem is this sociological process leads high-energy physicists to collectively accept ideas prematurely, when there is still very little evidence in favor of them. Then the peer review process leads the funding agencies to mainly fund people who believe in these ideas when there is no guarantee that it is correct, and any alternatives to these ideas are for the most part neglected.

Update: I think John Preskill and Urs Schreiber miss the point in their response here to Peter Shor. Shor is not calling for an end to research on quantum gravity or saying it can't be done without experimental input. The problem he's pointing to is a "sociological process" and so potentially fixable. This problem, "collectively accept ideas prematurely", not realizing the difference between a solid foundation you can build on, and a speculative framework that may be seriously flawed is one that those exposed to the sociological culture of the math community are much more aware of. Absent experimental checks, mathematicians understand the need to pay close attention to what is solid (there's a "proof"), and what isn't.

Comments

1. **Pascal**
   June 18, 2019

   In France too we have better quality chalk than in the US.

2. **Supernaut**
   June 18, 2019

   Thanks for the link to Stacy McGaugh's blog post, I found it interesting. I'll also be traveling to see the eclipse to Chile; I'll be near the La Serena area (hopefully the weather will cooperate and will see little or no clouds!)

3. **Peter Woit**
   June 18, 2019

   Supernaut,

I'll be staying in La Serena, no plan yet for where we'll try and see the eclipse, will depend on cloud situation that day.

4. **Dan Riley**
June 18, 2019

The timeline has detector construction starting in 2031, with HL-LHC shutdown likely around 2035, so there isn't that big an overlap. I believe (but can't find a reference now) that the timelines also all have the expensive tunnel excavation starting after HL-LHC shutdown.

wrt funding, unlike the US National Labs, CERN can borrow money to spread out spending peaks, and its funding is secure enough that it can get a good interest rate. Both LEP and LHC construction were partially funded that way. Any of the FCC proposals will still be a stretch, so the timeline also includes 3 years to work out the funding strategy and another 3 to get in-principle agreements.

5. **JE**
June 18, 2019

Hi Peter,

La Serena is really awesome, but cozy San Pedro de Atacama and its surroundings should be the best place in Chile to see such a thing. Of course it depends on the cloud situation, but if I remember correctly the Atacama desert is the driest place on Earth. Also, don't miss a trip to Valparaíso if you get a chance.

6. **Peter Woit**
June 18, 2019

Dan Riley,
Thanks, I wasn't aware there was ability to borrow against future funding, that would help.

The documents I was looking at said HL-LHC 2026-2036/7 and for the FCC-ee, see figure 19 of
http://cds.cern.ch/record/2653669/files/CERN-ACC-2019-0003.pdf?version=2
This has construction starting 2029 (tunnel) and 2031 (machine + detectors), physics operation starting 2039.

If there is some way to fund this, it seems likely it would involve stretching out this schedule.

7. **Peter Woit**
June 18, 2019

JE,
Problem is, the track of the total eclipse is fairly narrow, thus the need to be in the area around La Serena on July 2. Your other suggestions are encouraging, since our plan is to spend a few days in San Pedro de Atacama before the eclipse (any observatories nearby looking for a visitor?) and a day or two in Valparaiso afterwards.

8. **Michael Barany**
June 19, 2019

Many readers of this blog already know about my work on the history and sociology of chalk in mathematics. For those who don't: it's a topic of serious academic research, with lots of fascinating questions and findings!
Here's the piece I wrote for the Best Writing in Mathematics series: http://mbarany.com/DustyDisciplineBWM15.pdf
Here's the longer article it's based on: http://mbarany.com/Chalk.pdf
And here's a short interview I did on the subject: http://www.concordmonitor.com/x-6888872

9. **Peter Shor**
June 19, 2019

About almost-impossible-to-detect right-handed neutrinos—my suspicion is that theses models have been undeservedly neglected, to some degree, by theorists, just because there is no way that experiments would ever be able to detect it.

This is the presumably the same phenomenon that leads theorists to predict particles that can be detected by the next generation of accelerators. Somebody should give it a name, and then we will be better able to correct for this bias.

10. **Zoviyer**
June 19, 2019

The japanese chalk quality is fantastic, the multiple moving blackboards a thing to marvel. But woof!, the handwriting of many many mathematicians is so bad, they let us down most of the time. "You can't make a silk purse out of a sow's ear".

11. **Anon**
June 19, 2019

Regarding right handed neutrinos: You need the dark matter to be around today, whereas heavy right handed neutrinos decay to Higgs + regular neutrino. The requirement that they be stable on cosmological time frames constrains the possibilities, which pushes you to lower masses (which undercuts the seesaw motivation, if you care).

You then have to figure out how to produce sterile neutrinos in the early universe. Not only do you have to get the right amount of them, but they can't be relativistic because the extra contribution to N_eff screws up nucleosynthesis. It's challenging to actually get them to be cold dark matter; most models end up with at least a sizeable proportion as "warm" dark matter- which is (currently) observationally ok- perhaps even favored if you believe some structure surveys. Getting this to happen, though, generally requires them to be produced resonantly- meaning that you have to arrange by hand for at least two to have nearly degenerate masses. I don't think non-resonant production is entirely dead, but that case tends to be hotter. (The other option is to introduce some other particle that can decay to them- but then you've lost some of your simplicity.)

So, I'm not sure about your opinion about where "relatively simple" ends, but IMHO all the simple options are relatively warm, which are being studied via structure formation.

Summary of the state of the art is in this white paper:
https://arxiv.org/pdf/1602.04816.pdf

12. **Peter Shor**
June 23, 2019

Peter:

I totally agree with your update. I'm not saying we should give up thinking about quantum gravity. I'm saying that theoretical physicists should think very carefully about what they "know" about black holes, information loss, AdS-CFT, and string theory, and see whether their evidence is as convincing as they think it is. I don't think it is.

Some evidence that the sociological process is broken:

1. The conventional wisdom that Susskind's theory of complementarity explained the information loss paradox, which had been accepted by many high-energy physicists for years, broke down when the AMPS paper showed it was incompatible with basic principles of quantum information theory.

2. David Poulin and John Preskill have done some research on how you might be able to modify quantum field theory to obtain a non-unitary theory, thus accommodating black hole information loss. See this presentation. It seems to me that nobody is paying any attention to this because they "know" that the universe is unitary because AdS-CFT.

3. I don't see how the paper of Shenker and Stanford, "Black Holes and the Butterfly Effect" and the idea that the CFT is a quantum error-correcting code can possibly be compatible. I've talked with people who think these two papers are both correct, and who really should know what they're talking about, but I haven't gotten any answers that I've found satisfactory. Maybe I don't understand AdS-CFT well enough (I barely understand it at all), but my impression is that they're asking quantum error correcting codes to behave in ways that are impossible. I'd be happy to go into this in more detail by email.

13. **Peter Woit**
June 24, 2019

Peter Shor,
Thanks for the examples of the problem you're pointing to. For better or worse, I've spent a lot of time trying to understand how string theory unification is supposed to work, enough to clearly see why it doesn't work, and to feel comfortable writing about that problem. In the case of the supposed relation of quantum information theory and quantum gravity, I've yet to even see how this is supposed to work. I can't see what specific plausible proposals are behind the mantras "space-time is doomed", "quantum gravity is emergent" and "it from qubit", so wouldn't even know where to begin to try and evaluate the claims being made for such ideas.

It would be great if someone could write up clear explanations of this research program, what its specific proposals and goals are, what has been achieved, what has been found to not work. You should start a blog!

14. **Peter Shor**
June 24, 2019

Unfortunately, there are a lot of papers about the relationship of quantum information theory and quantum gravity that I don't understand. I'm not entirely convinced they have any interesting content, but I don't understand them well enough to say that they are all just Zen-koan-like slogans à la Urs Schreiber.

The big successes of this relationship so far, in my opinion, are (a) the AMPS paper
showing that Susskind complementarity cannot be correct as it was originally envisioned and (b) the Almheiri-Dong-Harlow paper showing that the Ryu-Takayanagi formula doesn't lead to fundamental contradictions in physics as long as you postulate that the CFT is a quantum error-correcting code.

More to the point of my answers to John Horgan, the AMPS paper claims that one of the following four assumptions is false (I've split their assumption ii into two pieces):

(i) Hawking radiation is in a pure state (i.e., unitarity is not violated),
(ii-a) the information carried by the radiation is emitted from the region near the horizon (i.e., locality is not violated),
(ii-b) low energy effective field theory is valid outside a region microscopically close to the horizon (i.e., physics behaves as we think it should under conditions where we've tested it extensively),
(iii) the infalling observer encounters nothing unusual at the horizon.

The AMPS paper opts for (iii) being the incorrect assumption, and arrives at firewalls.

Talking with people from the it-from-qubit crowd, many of them seem to believe that (ii-a) is the incorrect assumption. Maybe this makes research easier … if there's non-locality, you can just assume that we know nothing about the laws of physics in the AdS bulk theory, and only work on the physics in the boundary CFT. And conformal field theory is much better understood than quantum gravity, although I suspect that you can only go so far without thinking about how the laws of physics might work for the AdS part.

Taking (ii-b) as the incorrect assumption presumably would contradict over a century of physics experiments—as far as I can tell, nobody advocates this.

And finally, taking (i) as the incorrect assumption seems to be anathema. I suspect that this is because AdS-CFT is taken to be axiomatic—they have 20 years of work invested in it—and the conventional wisdom says that AdS-CFT proves unitarity. Is the conventional wisdom correct about this? Beats me, but as far as I know, nobody is thinking about whether it might be wrong.

15. **cedric bardot**
June 25, 2019

Is there really nobody thinking about wheter [AdS-CFT proves unitarity] is wrong?
To say the least Gerard 't Hooft is suspicious about it:

> String theory was supposed to take over when particle energies and momenta approach the Planckian domain. But the particles and fields that seem to be involved with black holes with mass M_BH , all seem to have energy excitations in the domain M_Pl^2/M_BH in natural units, where M_Pl is the Planck mass. These energies are way below the Planck domain. It should be possible to describe the properties of black holes with mass M_BH ≫ M_Pl without the use of string theory at all. We now claim that the assumptions "particles are pieces of string", and black holes are "stacks of D-branes"… that can be subject to the AdS/CFT conjectures, are better to be avoided in the case of large, heavy black holes.

https://arxiv.org/abs/1902.10469

Incidentally Utrecht University will host an international conference entitled "'t Hooft 2019 – From Weak Force to Black Hole Thermodynamics and Beyond" beginning Thursday July 11 until Saturday July 13 with the following advert:

> As Professor Gerard 't Hooft relishes lively debates, he was keen on us inviting speakers with perspectives that differ from his own – we expect stimulating discussions!

https://thooft2019.sites.uu.nl/speakers/

Looking at https://cds.cern.ch/record/2668388 it is instructive to watch how difficult it is for physicists to agree on the basics of the modelisation of the problem they want to deal with.

16. **cedric bardot**
June 25, 2019

Actually I didn't point to the video I was thinking about. https://cds.cern.ch/record/2668988 was the discussion cession about black hole information at CERN in march 2019 I had in mind.

17. **Peter Woit**
June 25, 2019

All,
I'm shutting off comments here, partly because people seem to want to get into a not obviously well-informed discussion of the details of AdS/CFT, and partly because I'm leaving for Chile now, will be traveling the next couple weeks.

What happens when we can't test scientific theories?

July 8, 2019
Categories: Uncategorized

Just got back from a wonderful trip to Chile, where the weather was perfect for watching the solar eclipse from the beach at La Serena.

While I was away, the Guardian Science Weekly podcast I participated in before leaving for Chile went online and is available here. Thanks to Ian Sample, Graihagh Jackson, and the others at Science Weekly who put this together, I think they did a great job.

The issues David Berman, Eleanor Knox and I discussed in the podcast will be familiar to readers of this blog. Comparing to the arguments over string theory that took place 10-15 years ago, one thing that strikes me is that we're no longer hearing any claims of near term tests of the theory. Instead the argument is now often made, by Berman and others, that it may take centuries to understand and test string theory. This brings into focus the crucial question here: how do you evaluate a highly speculative and very technical research program like this one? Given the all too human nature of researchers, those invested in it cannot be relied upon to provide an unbiased evaluation of progress. So, absent experimental results providing some sort of definitive judgment, where will such an evaluation come from?

Comments

1. **Jon Orloff**
   July 8, 2019

   Another relevant point, how does the science community expect taxpayers to pay for a program whose outcome may be uncertain for hundreds of years?

2. **Robert**
   July 9, 2019

   Same as in other fields. Mathematics comes to mind. No real experiments there, formal correctness of proof does not say anything about relevance of result and peers who can judge are also typically personally invested in the subject.

3. **tulpoeid**
   July 9, 2019

   @Robert,

   formal correctness of proof does not say anything about relevance of result? That's a new one to me. It'd be nice to hear more about what the implied problem is.

   (I'm not a mathematician and I've been having the impression that things are pretty smooth in the proof department.)

4. **Low Math, Meekly Interacting**
   July 9, 2019

   "(H)ow do you evaluate a highly speculative and very technical research program like this one?"

   If you're talking about science, to me the simplest answer is "You can't." It's also the only correct one, in my opinion.

   It shouldn't stop people from working on it, necessarily, but if one so chooses, one must therefore forgo classifying the activity as "scientific". People should be entitled to their opinions. I think they should even be afforded the opportunity to seek funding to further cultivate those opinions in an academic setting. Other disciplines do this. But divorced from experiment indefinitely (conceivably even eternally), speculation is just that: opinion, however rigorous or well-informed.

5. **Robin**
   July 9, 2019

   It comes down to costs and benefits. The cost of doing any theory is essentially independent of the type of theory that is being worked on – it is mainly the salaries of theoreticians plus overheads, and the cost is incurred as the work is undertaken. Benefits that might not be realised for some time in the future are worth less than comparable benefits that come sooner, for example by undertaking different endeavours. Berman mentions that he sees benefits delayed by perhaps a thousand generations, so these are of very little value indeed. This mismatch of timing looks fatal for the endeavour. Feel pity for the students and postdocs who are sucked in.

6. **Low Math, Meekly Interacting**
   July 9, 2019

   Suggestion: Include a photo of one of the eclipses you've observed in your banner rotation. It's obviously a passion of yours, and may have a certain aesthetic harmony with the the M87* data for some.

7. **Maik**
   July 9, 2019

   Well, I think it's a very delicate question, as it goes right to the heart of what freedom of scientific inquiry should and should not mean. Where does science end, which questions are worthy of scientific pursuit and where is one just wasting taxpayer's money for playing one's own little games?

   Even though I am very critical of string theory myself, I hesitate to answer that problem by calling for a restriction to this freedom in the sense of "only work on what can directly be tested". This may achieve the opposite of what one aims for, namely scientific progress. Nonetheless, I think there are ways to subject scientific work(s) to scrutiny without profoundly restricting that freedom: methodological and institutional ones (at least).

   Regarding the former, philosopher of science Paul Feyerabend was arguing very strongly that it is a bad idea to nail down scientists to a particular methodology (science as a kind of anarchy), but he did not question the need for methodology itself. Rather, which methodologies are appropriate or not is a question that needs to be evaluated and discussed by the scientists in the field and adjacent ones. With respect to fundamental physics, I can say that much of it has essentially become a mathematical subject and as such works therein should adhere to mathematical rigor and conceptual coherence. Even if this is not without problems, as Robert suggests, mathematical culture has evolved like this because it is all too easy to go wrong otherwise.

   On an institutional level, I think it is important to create opportunities for this kind of discussion, to keep the scientists engaged (not just in a circle of specialists), to challenge their ideas, be willing to listen both as a layman and a scholar with a healthy amount of skepticism. The power structure of academia is not always, but in my experience all too often an obstacle to this kind of `open science'. Furthermore, as I view it, Alexander von Humboldt rightly postulated the `unity of research and teaching', for in the context of this question teaching can also be considered a mechanism of `checks and balances'.

The problem we should be worried about is not that decade-old research programs turn out to be in vain (it's difficult and we're all human!), but that we create a system and culture that prevents actual progress via the illusory, implicit claim that "science is truth".

8. **Mongo**
July 9, 2019

Sounds like a very common problem many areas of science have that claim the proof is in the future and just 100 years or more away. Is it still science? Does this apply to all areas, hard and soft sciences? Is this a string theory only problem?

9. **Lennie**
July 9, 2019

As opposed to physics, mathematics is not supposed to have any relevance. Its relevance is a bi-product. and nobody knows in advance what is going to be relevant, and relevant to what. Of course, there is always a question of how many mathematicians the taxpayers are supposed to support. Recently some kind of experimental mathematics came to life, though one can say that it is not quite a recent phenomenon: that is what a big part of mathematics was before the 19th century. Maybe one should treat string theory as a new kind of physics, speculative physics, that, if one looks back, is also not quite a new phenomenon. It has already influenced mathematics in a positive way. Maybe this is enough to justify its existence?

10. **Peter Woit**
July 9, 2019

Jon Orloff/Robin,
The costs of paying theorists doing speculative physics theory are not very large, and in many cases aren't coming from taxpayers (e.g. the theorists at the IAS are mostly being paid from private money). I don't see any reason society shouldn't support at a modest level some small group of people to do speculative work on trying to find a better fundamental theory of physical reality, even if the time-scale for expected success is very long. The problem is how to evaluate this work as it is being done.

Robert/tulpoeid,
I've often argued that part of the answer to the question of evaluation of speculative physical theory is to look to the culture of mathematics, which doesn't have experiment to keep it honest. Part of the culture of mathematics is to insist on clear and unambiguous statements and arguments, and to my mind speculative physics is very much in need of more emphasis on this. Robert is pointing to the much more subtle problem of evaluating the difference between interesting and uninteresting correct results.

LMMI,
Much of our current understanding of things like qft is based on the work of mathematicians and physicists who developed new ideas following research programs that had little to nothing to do with experiment. You don't want to cut off this kind of activity. In any case, if you insist on this, you'll just have people going on about how their extra-dimensional research has something to do with LIGO, or how they will make predictions, but it will take 100 years or more.

What you really want is progress towards new understanding, and while this is something hard to evaluate, it is very real. Some work does deepen our understanding, other work doesn't, and expertise is a necessary but by no means sufficient requirement for evaluating this.

11. **Robert**
July 10, 2019

@tulpoeid

You can easily write a computer program that derives an infinite series of proven "theorems" from a list of axioms in a formal way (see gödel Escher Bach) with zero creativity or usefulness. On the other hand, many extremely fruitful contributions to mathematics came with incorrect proves at first or totally lacking those (as conjectures, programs, frameworks etc). I am just saying, things are not black and white once you look closer.

12. **DrDave**
July 10, 2019

I found the podcast to be eerily prescient. The universal thread that seems to bind the various mutations in ST is that whatever comes up, ST will adapt. No evidence? Just wait. No predictions? No worries. Until forever.
We can assume at this point that ST will have an answer to any challenge. There's no evidence that long term proponents will change their minds, in any case. From the comments in the podcast, we could be looking at support for speculative science to continue for decades or even centuries before anyone feels the need to change course.
It also seems clear that any breakthrough or discovery in Physics will be absorbed, Borg-like, into the theory.
In addition, and perhaps most importantly, the structure of academic institutions is simply not equipped to deal with this issue.
At this point, the only recourse would seem to be new, well financed institutions that provide a complete pathway from graduate student to professor, with a system in place to remain independent. A massive undertaking.

Against Symmetry

July 10, 2019
Categories: Uncategorized

One of the great lessons of twentieth century science is that our most fundamental physical laws are built on symmetry principles. Poincaré space-time symmetry, gauge symmetries, and the symmetries of canonical quantization largely determine the structure of the Standard Model, and local Poincaré symmetry that of general relativity. For the details of what I mean by the first part of this, see [this book](). Recently though there has been a bit of an "Against Symmetry" publicity campaign, with two recent examples to be discussed here.

Quanta Magazine last month published K.C. Cole's [The Simple Idea Behind Einstein's Greatest Discoveries](), with summary

> Lurking behind Einstein's theory of gravity and our modern understanding of particle physics is the deceptively simple idea of symmetry. But physicists are beginning to question whether focusing on symmetry is still as productive as it once was.

It includes the following:

> "There has been, in particle physics, this prejudice that symmetry is at the root of our description of nature," said the physicist Justin Khoury of the University of Pennsylvania. "That idea has been extremely powerful. But who knows? Maybe we really have to give up on these beautiful and cherished principles that have worked so well. So it's a very interesting time right now."

After spending some time trying to figure out how to write something sensible here about Cole's confused account of the role of symmetry in physics and encountering mystifying claims such as

> the Higgs boson that was detected was far too light to fit into any known symmetrical scheme…
> symmetry told physicists where to look for both the Higgs boson and gravitational waves

I finally hit the following

> "naturalness" — the idea that the universe has to be exactly the way it is for a reason, the furniture arranged so impeccably that you couldn't imagine it any other way.

At that point I remembered that Cole is the most incompetent science writer I've run across (for more about this, see [here]()), and realized best to stop trying to make sense of this. Quanta really should do better (and usually does).

For a second example, the Kavli IPMU recently put out a press release claiming [Researchers find quantum gravity has no symmetry](). This was based on the paper [Constraints on symmetry from holography](), by Harlow and Ooguri. The usually reliable Ethan Siegel was taken in, writing a long piece about the significance of this work, [Ask Ethan: What Does It Mean That Quantum Gravity Has No Symmetry?]()

To his credit, one of the authors (Daniel Harlow) wrote to Siegel to explain to him some things he had wrong:

> I wanted to point out that there is one technical problem in your description… our theorem does not apply to any of the symmetries you mention here! …
>
> It isn't widely appreciated, but in the standard model of particle physics coupled to gravity there is actually only one global symmetry: the one described by the conservation of B-L (baryon number minus lepton number). So this is the only known symmetry we are actually saying must be violated!

What Harlow doesn't mention is that this is a result about AdS gravity, and we live in dS, not AdS space, so it doesn't apply to our world at all. Even if it did apply, and thus would have the single application of telling us B-L is violated, it says nothing about how B-L is violated or what the scale of B-L violation is, so would be pretty much meaningless.

By the way, I'm thoroughly confused by the Kavli IPMU press release, which claims:

> Their result has several important consequences. In particular, it predicts that the protons are stable against decaying into other elementary particles, and that magnetic monopoles exist.

Why does Harlow-Ooguri imply (if it applied to the real world, which it doesn't…) that protons are stable?

What is driving a lot of this "Against Symmetry" fashion is "it from qubit" hopes that gravity can be understood as some sort of emergent phenomenon, with its symmetries not fundamental. I've yet though to see anything like a real (i.e., consistent with what we know about the real world, not AdS space in some other dimension) theory that embodies these hopes. Maybe this will change, but for now, symmetry principles remain our most powerful tools for understanding fundamental physical reality, and "Against Symmetry" has yet to get off the ground.

Update: Quanta seems to be trying to make up for the KC Cole article by today publishing a good piece about space-time symmetries, Natalie Wolchover's [How (Relatively) Simple Symmetries Underlie Our Expanding Universe](). It makes the argument that, just as the Poincaré group can be thought of as a "better" space-time symmetry group than the Galilean group, the deSitter group is "better" than Poincaré.

In terms of quantization, the question becomes that of understanding the irreducible unitary representations of these groups. I do think the story of the representations of Poincaré group (see for instance my book about QM and representation theory) is in some sense "simpler" than the Galilean group story (no central extensions needed). The deSitter group is a simple Lie group, and comparing its representation theory to that of Poincaré raises various interesting issues. A couple minutes of Googling turned up this [nice Master's thesis]() that has a lot of background.

Comments

1. **Lukas Berns**
   July 10, 2019

   FYI the Japanese IPMU article says the result *suggests* proton decay rather than claiming the proton is stable. I guess that makes more sense if B-L is violated ignoring the point about AdS (so the English article should be corrected).

2. **Sabine Hossenfelder**

July 10, 2019

Symmetries play an important role in theory-development because they are simplifying principles, they are patterns that you look for. Science is generally a search for patterns/laws, but in the foundations these appear in very strict, formal ways on the level of the equations, which makes them particularly powerful.

The trouble with using symmetry principles is that we don't know that this type of simplification will continue to work, both because (a) it may be the wrong type of simplification and (b) the next deeper level may just not be simpler than the present one.

In other words, it's nice that it works, but no reason to think it will continue to work.

If you want a more interesting take on the idea that symmetries are accidental, have a look at this paper:

https://www.sciencedirect.com/science/article/abs/pii/0370269380908424

It strikes me as the kind of idea whose time hasn't yet come.

As to the Cole piece. I couldn't even get myself to finish reading it. Unfortunately, it's the kind of nonsense that sounds plausible to people who don't understand the subject.

Thanks for clearing this up.

3. **Anonyrat**
July 11, 2019

How much of superstring theory's growth was fueled by pursuing symmetry no matter where it led?

4. **Robert**
July 11, 2019

Regarding global symmetries: Wasn't there an old (as in from the 80s) argument by Banks et al that argues from a string world sheet perspective that a global target space symmetry would always produce a corresponding gauge field which would render the symmetry local?

From an effective field theory perspective it could also be that the ultimate UV theory is not symmetric at all and what we see at low energies is only the practically massless stuff that is protected by symmetries from becoming heavy (gauge symmetries for spin 1 particles, chiral symmetries for spin 1/2, just a good symmetry lacking for the Higgs, if you don't have susy…). So our liking of symmetries is due to observational bias.

5. **vmarko**
July 11, 2019

"in the standard model of particle physics coupled to gravity there is actually only one global symmetry: the one described by the conservation of B-L"

Sorry, am I missing something here? Can anyone tell me which process in the SM violates B and L individually (while conserving B-L)? And does coupling to gravity have anything to do with it?

Because in the ordinary flat-space SM I don't see any Feynman diagram that could violate either B or L, and I also don't see how coupling to gravity could possibly induce such a violation.

🙂
Marko

6. **martin**
July 11, 2019

Sabine, I disagree with your opinion that the role of symmetries is in simplification. There is a difference between 1) I have this equation, I will study spherically symmetric solutions, because it is easier, and 2) I have this equation, I found out that it has these symmetries and I am going to study them because it helps me understand the solutions.

7. **Peter Gerdes**
July 11, 2019

Is your suggestion that somehow gravity could be emergent in AdS space but not in other spaces? Doesn't it seem difficult for a largely local effect to disappear based on changes to the global space? Now I'm merely a mathematician so I could be missing something but wouldn't at least something gravity like have to be emergent even in non-AdS spaces? I mean the other differences about the models in which the holographic principle seems to hold might matter but I'm curious how a local property could emerge/fail to emerge (even approximately) depending on whether some global constraint on the space holds.

8. **Peter Woit**
July 11, 2019

Sabine,
One problem here is that there are various types of "symmetry" arguments, and the term "symmetry" gets used with different meanings. What I have in mind (this is related to what commenter martin writes) is the symmetry properties of the fundamental equations of the theory. The Heisenberg commutation relations are precisely the statement that you have a representation of the Heisenberg Lie algebra, and largely determine the basic structure of quantum mechanics. Gauge symmetries and Poincare symmetry largely determine the structure of the Standard model.

It is quite possible of course that there is a better, deeper fundamental theory, in which gauge symmetries, the Heisenberg commutation relations, local Poincare symmetry are not fundamental, but approximate, emergent properties. I just don't see such speculation as so far working out.

9. **Peter Woit**
July 11, 2019

Anonyrat,
In some sense the fundamental problem with string theory is that no one has been able to find the non-perturbative version, to answer the question "what is M-theory?". A lot of efforts in that direction have been to try to find fundamental symmetries that determine the theory, but this has so far not been successful. One can take this as an indication that searching for fundamental symmetries is misguided (and I think this is one thing driving the "Against Symmetry" agenda), but trying to find a non-

symmetry based M-theory hasn't worked either, so maybe what is misguided is the idea that M-theory is a fundamental theory of nature.

10. **Peter Woit**
July 11, 2019

vmarko,
From what I remember, there is baryon number violation in the SM (at unobservably low rate) non-perturbatively due to instanton effects. Presumably B-L is not violated this way. This has nothing to do with quantum gravity.

11. **Peter Woit**
July 11, 2019

Peter Gerdes,

The problem with emergent gravity is, emergent from what? You need an actual theory, not just a bunch of words and hopes that a theory exists. The actual theories with some sort of emergent gravity that I'm aware of are toy models, very different than the real world (AdS vs. dS, wrong dimension). A lot of the current work in this area is on low-dimensional toy models that exhibit emergent gravity. The hope is that this will lead to some understanding that can be applied to find a realistic model, but that still seems very far away.

12. **Doug McDonald**
July 11, 2019

This will be procedurally unhelpful, but anyway … when I was studying on my own relavistic field theory and the standard model, there was a book that explained "From what I remember, there is baryon number violation in the SM (at unobservably low rate) non-perturbatively due to instanton effects" but not as instanton effects. They had a discussion that I was able to follow. They explained it as essentially a nonperturbative passage through a (classical) barrier in the (classical nonrelativistic, thus allowing potentials) Lagrangian by (relativistic) quantum tunneling. They used what seemed to me to be essentially (classical) transition state theory with a quantum tunneling correction to calculate the (astoundingly low, compared even to the usual GUT estimates) rate. It required the participation of 3 particles each of lepton and quark, with at least 2 of each being different generations, like one electron neutrino, one muon antineutrino, and a charged lepton. Three leptons turned into three quarks or vice versa.

But I was never able to find this passage again in any book I could check out of the library at a later date. It was a dated but well known in its day (post QCD discovery day) textbook, in the "epilog" on nonperturbative effects. I'd love to find it.

13. **Peter Woit**
July 11, 2019

Doug McDonald,
There's an extensive later literature, but this goes way back to 't Hooft's earliest work on instantons, see this 1976 PRL paper

https://journals.aps.org/prl/abstract/10.1103/PhysRevLett.37.8

14. **Marko**
July 12, 2019

Peter and everyone,

Ok, after some research, the relevant keywords are the "sphaleron" and the Adler-Bell-Jackiw anomaly, which seem to be responsible for B and L violation.

However, these effects have so far been unobserved (sphalerons ought to appear somewhere around 10 TeV), and they are nonperturbative. Given that the SM is an effective low-energy model, nonperturbative results are not to be trusted in general, unless supported by experiment (which is missing in this case). Therefore, I prefer to remain a skeptic regarding the B and L violation, until data starts to support it.

But it's a nice read, I learned something new today. 🙂 Thanks for the info and the links!

And regarding the media frenzy around the paper by Harlow and Ooguri, it's just business as usual — hype beyond any proportions. H&O of course also ignore that there is a difference between AdS and the real world (which is not even strictly dS, let alone AdS), which is also business as usual — string theorist's ultimate hope that AdS/CFT could at some point become relevant for the real world physics.

Best, 🙂
Marko

15. **Daniel Harlow**
July 14, 2019

Hi Peter,

If you want to read a popular article where the various caveats for our work are mentioned, see

https://phys.org/news/2019-05-constraints-symmetries-holography.html.

Best,
Daniel

16. **Peter Woit**
July 15, 2019

Thanks Daniel!

17. **Chris W.**
July 17, 2019

It's rather odd that the article referred to by Daniel Harlow starts out explaining that Harlow and Ooguri have presented new arguments supporting the conjecture that there are no global symmetries in quantum gravity, and then at a certain point starts dropping the qualifier "global", as though it's unnecessary (at least according to the piece's author, Ingrid Fadelli):

> Prior to Ooguri and Harlow's paper, other researchers made arguments supporting the claim that quantum gravity (the unification of quantum mechanics and gravity) cannot have any symmetry. Nonetheless, these arguments often presented logical gaps or loopholes, for instance failing to address some important cases (e.g. discrete symmetry).

…and later on:

> The insight from this previous research was essential to prove the theorem in the researchers' recent study. In their new study, Ooguri and Harlow found that the way quantum error correction works is not compatible with any symmetry. Thus, once quantum mechanics and gravity are merged, no symmetry is exact.
>
> "It has generally been believed that symmetry is a fundamental concept in nature," Ooguri said. "Many physicists believe that there must be a beautiful set of laws in nature, and that one way to quantify beauty is by symmetry. Some of the symmetry may be hidden in our world (or 'spontaneously broken," in physics terms), but they may manifest themselves if we look at nature at a more fundamental level. We showed that the belief expressed in the above is wrong. The laws of nature at the most fundamental level, where quantum mechanics and gravity is unified, have no global symmetry."

18. **Peter Woit**
July 17, 2019

Chris W.,
I think there are two serious problems with the way the Harlow-Ooguri result is being promoted:
1. The fact that, as Harlow notes, the only relevance to the symmetries that govern fundamental physics is to the highly obscure special case of global B-L symmetry is not made clear, replaced by nonsense about "QG means no symmetry". Even Ethan Siegel was taken in by this.
2. Their argument does not apply to the real world at all. It takes place in a toy model (AdS/CFT), which is quite different than a viable model of real 4d world quantized gravity coupled to the SM. Claiming that this tells you anything about the real world seriously misrepresents what AdS/CFT is. Arguably it's an interesting toy environment to use to think about quantized gravity, but it is not a solution to the problem of quantizing real 4d gravity.

Prospects for contact of string theory with experiments

July 13, 2019
Categories: Strings 2XXX

Nima Arkani-Hamed today gave a "vision talk" at Strings 2019, entitled Prospects for contact of string theory with experiments which essentially admitted there are no such prospects. He started by joking that he had been assigned this talk topic by someone who wanted to see him give a short talk for a change, or perhaps someone who wanted to "throw him to the wolves".

The way he dealt with the challenge was by dropping "string theory", entitling his talk "Connecting Fundamental Theory to the Real World" and only discussing the question of SUSY (he's still for Split SUSY, negative LHC results are irrelevant since if SUSY were natural it would have been seen at LEP, and maybe a 100km pp machine will see something, or ACME will see an electron edm).

He did discuss the string theory landscape, and explained it was one reason that about 15 years ago he mostly stopped working on phenomenological HEP theory and started doing the more mathematical physics amplitudes stuff. David Gross used to argue that the danger of the multiverse was that it would convince people to give up on trying to understand fundamental issues about HEP theory (where does the Standard Model comes from?). It's now clear that this is no longer a danger for the future but a reality of the present.

In order to go over time, Arkani-Hamed dropped the topic of his title and turned to discussing his hopes for his amplitudes work. The "long shot fantasy" is that a formulation of QFT will be found in which amplitudes are given by integrating some abstract geometrical quantities.

The conference ended with a "vision" panel discussion. Others may see things differently, but what most struck me about this was the absence of any sort of plausible vision.

Update: Taking a look at the slides from the ongoing EPS-HEP 2019 conference, Ooguri seems to strongly disagree with Arkani-Hamed, claiming in his last slide here that a CMB polarization experiment (LiteBIRD) to fly in 8 years, "provides an unprecedented
opportunity for String Theory to be falsified." I find this extremely hard to believe. Does anyone else other than Ooguri believe that detection/non-detection of CMB B-modes can falsify string theory?

Comments

1. **Tony**
   July 13, 2019

   I watched the "vision" discussion and I'm not entirely convinced the fate of high energy theoretical physics is in the best of hands given that the owners of those hands struggle with the concept of placing microphones in said hands for the purposes of audibility!

   That said, the language that is being used here and elsewhere seems to me to be better suited to theological discussions, rather than scientific ones. One hears "hope", "faith" and so on far too often to provide any convincing meta-evidence that these people are on the right track. I worked in neuroscience for nearly 20 years (and trust me, that is a field full of shysters) and never saw anything remotely as shambolic as the current state of theoretical (high energy) physics. I mean, the string landscape story is a morass of no escape and the whole AdS/CFT duality story is not even applicable to our universe.

   I remain absolutely stupefied that people with so much mathematical and technical expertise can get sucked into what has effectively become a cult. In my opinion, senior people in the field, such as Witten, need to show some genuine leadership and say enough is enough, let's move on. But of course that would require the cult leaders to themselves renounce their own faith and belief system, which they cannot do without admitting to practicing seriously poor judgment.

2. **Peter Woit**
   July 14, 2019

   Tony,

   There's a long history of Strings XXXX "vision" talks full of hype and unrealistic claims about the present and prospects for the future. Gross has a lot to answer for in terms of being responsible for many of these things, he was doing this 24 years ago at Strings 1995 and has never stopped. If instead of hype, he and others over the years instead put forward a realistic summary of the state of the field and the problems it was facing, that could have had a very positive effect.

   What struck me as unusual about this year's version was the lack of any actual vision, with the panelists having nothing much to say when Gross asked them for a vision of the future of the field over the next decades (Doug Stanford's response was something like "why do we need a vision, as long as we're having fun?"). Urs Schreiber is on the opposite extreme of string fandom from me, but his response to this was similar:
   "The closing 'vision' panel discussion did not take off."
   https://twitter.com/SchreiberUrs/status/1150113755566678016

3. **Alessandro Strumia**
   July 14, 2019

   I remember a "vision" talk by Gross at HEP 2011. At that time (no new physics in the first 1/fb of LHC data) many good theorists started discussing the reality of data. So I expected a useful discussion, but Gross predicted the discovery of SUSY, of DM, of new Z mesons, a new CERN/US linear collider to explore the superworld. All within 10 years. In the last slide Gross cared about LHC data, telling: "1/fb down, 3000/fb to go". Some wise guy commented: "1 beat in the head down, 3000 to go".

4. **Peter Woit**
   July 14, 2019

   You can watch the talk Alessandro Strumia refers to here
   https://webcast.in2p3.fr/video/an_outlook_from_theory
   At 28 min in you can see Gross's "predictions" for the 10 years post-2011. His track record on these is not good…

   For another such talk from him, way back when, you can take a look at the first substantive post on this blog
   http://www.math.columbia.edu/~woit/wordpress/?p=2
   from March 2004, which reported on a Gross "vision" talk I went to. The post included the text:
   "This [LHC startup] is now getting close enough that Gross and others seem intent on ignoring the failures of string theory, desperately hoping that superpartners will pop out of the LHC, thereby providing at least some vindication of the train of reasoning that lead to string theory. What will be interesting to see will be what Gross et. al. do when this doesn't happen. Will they drop string theory?"

The answer to this is now conclusively known. A remarkable aspect of Strings 2019 is that the only mention I saw of the LHC was Arkani-Hamed's rather absurd revisionist claim that the LHC null SUSY results did not change anything. After years of pointing to the LHC results as what would test string theory and vindicate the idea, the string theory community now acts like the null SUSY results at the LHC are not worth mentioning.

5. **Low Math, Meekly Interacting**
July 15, 2019

This isn't a very technically insightful comment, but if I may make a human observation: All this HEP theorist swagger and arrogance some people complain about seems to have left the building. The younger members of the panel make word choices and display body language that evinced more embarrassment than anything to my ears and eyes. Try to get these guys to talk about something other than their own work and the buzzkill is palpable. Gross is asking about "hopes" and all I could do was feel bad as they struggled to think of something they were willing to own up to.

6. **Peter Woit**
July 15, 2019

LMMI,
I think that's accurate. Arkani-Hamed was also unusually subdued, I'd guess partly because he isn't really a string theorist and has no particular positive vision of where string theory research is going. Having just delivered a talk about string theory prospects for connection with experiment in which he hadn't been able to come up with any can't have helped. Nati Seiberg also pretty much ignored string theory, sticking to the quite accurate point that there is a huge amount about QFT that we don't understand, and making progress there is what is most promising.

7. **Dom**
July 16, 2019

It is painful to read the site in question as a human being with empathy for people struggling with an illness but I gather that the reason that the Strings conference was dismal was:
"It almost looks to me as if the nasty anti-string crackpots were co-organizing the conference and could veto talks if not participants."

8. **Thomas Van Riet**
July 16, 2019

The suggestion by Ooguri is sensible. Maybe detailed model building and detailed understanding of SUSY breaking is still rather difficult in string theory. Not because of the theory but because, like anything in fundamental physics, it is tough to do detailed computations, especially when conformal and super-symmetries are broken. What string theory sofar seems to tell us is that there are patterns for "low energy" physics coming from string theory. These patterns are the key in order to make predictions. That is the essence of the Swampland program. The question is whether the patterns can be proven or not. The Weak Gravity Conjecture is probably the most rigorous such a pattern, but already consistent with experiment, so no prediction. Large field inflation seems clearly something that does not come for free in string theory. Some are trying to prove this formally. They might succeed, and some Euclidean version of the WGC could be behind it. Not clear yet. But we should be constructive and supportive to the people that are trying instead of complaining about it. I do not see any other framework for quantum gravity and fundamental physics where such endeavors are even possible.

9. **Peter Woit**
July 16, 2019

Thomas Van Riet,
What exactly is the falsifiable string theory prediction Ooguri is claiming for CMB B-mode polarization?

10. **Peter Woit**
July 16, 2019

Dom,
I normally try and avoid discussing the latest weirdness from Lubos, but for those who want to indulge, they can go to his website and check out his take on the Strings 2019 vision panel. He seems to agree with me and Urs Schreiber that there was no vision at the vision panel. Blaming this on me as co-organizer of the conference is pretty funny.

Thinking about it, a couple things that struck me about the panel is that of the five speakers (other than Gross, the moderator), three are currently at the IAS, two are recent products of Stanford. For a conference in Europe, this was very much a US group, focused on a narrow part of the US theory community. When I was a student at Princeton in the early 80s, the field was quite faddish. When I got there everyone was working on instantons. I think this way of working is still going on today, with the center of gravity some very specific questions about AdS/CFT and associated toy models. Lubos has this description of today's fad:

"All of the talks are about some French-speaking style general complexity-thermodynamics-AdS-attempts-on-quantum-cosmology issues, with some CFT rather disconnected from the string vacua."

As usual, the problem with everyone working on the same question is "what if this doesn't go anywhere"?

11. **DB**
July 16, 2019

Dom, Peter,
Trying to blame specific people (which we all know who they are, Peter being one of them) for what happened at Strings 2019 is not just a joke, it's unfair. Not the least because those people had nothing to do with organizing the conference. Not sure why the author of that web page came up with this ridiculous idea.

Wouldn't it be easier to accept that string theory, as is formulated nowadays, has hit a brick wall? Not sure if a temporary one or not, but it's definitely not progressing as it was expected a decade or two ago…

Acknowledging limitations is a good thing. Even Witten was asking for something more modest in his comment re the "vision"…

12. **Peter Woit**
July 16, 2019

DB,
Part of Lubos's complaint is that theorists who think they see how to get a unified theory out of string theory were not invited to Strings 2019 and not represented on the "vision" panel. As he discusses, one reason for this is that there is a separate "String Phenomenology 2019" conference where such people were represented.

I found it remarkable that Arkani-Hamed completely ignored this "string phenomenology" and I don't see any possible explanation for this other than that he thinks it doesn't work, is not able to give a viable connection of string theory to experiment. I think Lubos is right that the lack of representation at the conference or on the panel of people claiming to get a unified theory out of string theory probably reflects the views of the organizers. To his mind, they are wrong and have been cowed into submission by me and others, to my mind, they are right to not bring people in to discuss failed ideas.

The "vision" panel would have been a lot more interesting if the question Gross put to everyone was formulated as "give that string theory unification has hit a brick wall, what should we do?".

13. **Thomas Van Riet**
July 16, 2019

@Peter, if the dust settles then one might potentially get to "no B-modes" within the detectable range.

14. **Peter Woit**
July 16, 2019

Thomas Van Riet,
So, in this video
https://www.youtube.com/watch?v=ZlfIVEy_YOA
they should have not only been informing Linde that inflation had been discovered, but at the same time informing Kallosh that string theory was falsified?

15. **Sabine Hossenfelder**
July 17, 2019

The most remarkable thing about this is how hard they avoid saying "we got this wrong" (prospects to experimentally test strings/susy) even though the claims that turned out to be wrong are all over the published literature (and collected here on Peter's and on my blog), not to mention in the media.

It's concerning because without acknowledging that something went wrong in the first place, they'll never be able to learn from their mistakes. This is particularly obvious when it comes to the claim that now it's actually good news the LHC hasn't found susy. (Sure, hahaha.)

Frankly I think Nima understood the situation long ago, but people like to invite him for motivational speeches, at which he is admittedly good.

LMMI,

I see a very pronounced generational divide in the responses to my talks (which are not about string theory, I should add, but about the stagnation in the foundations of physics). While there are exceptions on either side, of course, by and large the older people are patently unwilling to even think about what I am saying (will frequently repeat arguments I just explained are wrong, it's quite comical actually) while the younger people may not agree but at least they see the need to think about what is going on (for the obvious reason that their career prospects depend on them getting it right).

While that's good news to some extent, the reality of academia is that it would take at least two more decades for power to shift to the younger generation if that was the only way self-correction in scientific communities takes place. One would hope that it was not the only way.

16. **shantanu**
July 17, 2019

Peter, the only time I have heard a seminar from Ed Witten (in 2005, cf. http://physics.bu.edu/festschrift/) he talked about proton decay in string theory models.
Is he or other people still working along these lines and how much recent work is going on? I don't know how many such talks have been featured in Strings xx meetings.

17. **Peter Woit**
July 17, 2019

As far as I know, neither Witten nor anyone else at the IAS has worked on this kind of "string phenomenology" in a long time, since it is clear that, for instance for proton decay, string theory is completely unpredictive: you can get any result you want. This understanding is widespread among prominent string theorists such as Witten, and that's why no one was invited to Strings 2019 to discuss such issues.

18. **Erickson Tjoa**
July 24, 2019

Hi Peter,

You mentioned earlier that "Nati Seiberg also pretty much ignored string theory, sticking to the quite accurate point that there is a huge amount about QFT that we don't understand, and making progress there is what is most promising."

Is this talked about at Strings 2019 and what are some of the things Seiberg (or you) found to be worth making progress for on that front?

19. **Math Phys**
July 24, 2019

"Isn't it just important to have fun now?".

How visionary!

20. **Peter Woit**
July 24, 2019

For Seiberg's views, see his talk
https://livestream.com/streaming/events/8742238/videos/193713207

Also, he is one of the co-organizers of TASI 2019, which focused on problems in QFT. See the videos from that conference, available here

https://physicslearning.colorado.edu/tasi/tasi_2019/tasi_2019.html

Quick Links

July 24, 2019
Categories: Uncategorized

A few quick links:

- Philip Ball at Quanta has a nice article on "Quantum Darwinism" and experiments designed to exhibit actual toy examples of the idea in action (I don't think "testing" the idea is quite the right language in this context). What's at issue is the difficult problem of how to understand the way in which classical behavior emerges from an underlying quantum system. For a recent survey article discussing the ideas surrounding Quantum Darwinism, see this from Wojciech Zurek.

  Jess Riedel at his blog has a new FAQ About Experimental Quantum Darwinism which gives more detail about what is actually going on here.

- This year's TASI summer school made the excellent choice of concentrating on issues in quantum field theory. Videos, mostly well worth watching, are available here.
- This month's Notices of the AMS has a fascinating article about Grothendieck, by Paulo Ribenboim. It comes with a mysterious "Excerpt from" title and editor's note:

  > Ribenboim's original piece contains some additional facts that are not included in this excerpt. Readers interested in the full text should contact the author.

- I've finally located a valuable Twitter account, this one.

Comments

1. **Pascal**
   July 25, 2019

   If someone learns about the "additional facts" on Grothendieck (and Peter doesn't mind) could they please share their findings in the comments section?
   Thanks in advance!

2. **Andrew Krause**
   July 25, 2019

   Yeah it would be worth asking Ribenboim if they are willing to publicly share the unedited version, or otherwise whatever was removed. If so I would also be keen to see what was removed.

3. **Mateus Araújo**
   July 28, 2019

   I'm really happy with Ball's article. Finally someone has explained correctly what decoherence (and Quantum Darwinism) is and what it isn't, that it does explain how interference becomes unobservable and the classical results stable, and that it cannot explain the emergence of a unique outcome.

   The idea that decoherence somehow solves the measurement problem or explains the collapse of the wavefunction is a common misconception even among people working in the field, and this article might help dispel it.

4. **Pascal**
   July 29, 2019

   "The idea that decoherence somehow solves the measurement problem or explains the collapse of the wavefunction is a common misconception."

   It does explain how several possible classical worlds emerge from one quantum world.
   It remains to explain the selection of a single classical outcome.
   This problem is "solved" in MWI by postulating that all possible outcomes are realized.
   In this way, decoherence provides a detailed, microscopic description of the way MWI could work.

5. **Another Anon**
   July 30, 2019

   Mateus, I think decoherence does a lot more than you suggest to solving the measurement problem. True, it cannot predict which eigenstate will be observed (that remains probabilistic), but it can explain why only a single state (one of the eigenstates) is observed, so it can explain why "interference becomes unobservabke" and "the classical results stable".

   We can understand it mathematically. Eigenstates (which Zurek calls "pointer states" in the article) are more robust because if you apply an operator to an eigenstate, the state remains unchanged, so "classical results stable". In contrast, any state which is not an eigenstate gets destroyed by the random state phase during the decoherence process, so "interference becomes unobservable".

   As I say, decoherence cannot predict which eigenstate will be observed, but decoherence comes pretty darn close to solving the measurement process. Certainly to the point where it appears that there is no "big unsolved mystery" here, no infinity of parallel universes created every time I measure anything.

6. **Peter Woit**
   July 30, 2019

   All,
   Comments about quantum Darwinism welcome, but not the usual arguments about more general issues in measurement theory. About MWI in particular, I'm likely to write something within the next couple months about Sean Carroll's forthcoming book, and that would be a better time to discuss MWI.

7. **Mateus Araújo**
   July 31, 2019

   Another Anon,

   The point is not predicting the outcome (solving the measurement problem is not about predicting the outcome), but explaining why only a single outcome is observed.

As Ball points out, decoherence only eliminates interference between alternatives, it doesn't single out any alternative, deterministically or otherwise. It couldn't, as decoherence can only delete off-diagonal elements of the density matrix, and to single out an alternative one needs to delete diagonal elements.

I'm afraid our host is getting annoyed by the constant discussion of MWI here, so maybe it's better to leave it for the post on Carroll's book.

8. **Low Math, Meekly Interacting**
July 31, 2019

The article may have alluded to this problem…

"Horodecki and other theorists have also sought to embed QD in a theoretical framework that doesn't demand any arbitrary division of the world into a system and its environment…"

Some folks seem to believe this need for division makes QD entirely circular:

"…'classical' pointer states do not emerge unless a key aspect of classicality has been tacitly assumed from the beginning…quantum Darwinists smuggle in classicality via their partitioning of the universe into distinguishable systems of interest that interact with mutually randomized environmental subsystems."

https://physicstoday.scitation.org/doi/full/10.1063/PT.3.2760

What think you? Fatally flawed or not?

9. **Peter Shor**
July 31, 2019

LMMI:

I think the ultimate hope of the proponents of quantum Darwinism is that, given a quantum system with dynamics, you can recover the partition into different subsystems that gives pointer states, and that this partition will be unique.

Has this been demonstrated yet? I don't believe so, but it certainly doesn't seem out of the question.

Finally, I suspect that there are probably some quantum dynamics which don't actually give pointer states. I don't know what quantum Darwinism says about these, but it seems to me that they should be investigated from a quantum Darwinistic point of view.

10. **Pascal**
August 1, 2019

About circularity: maybe the goal is to show that if we start from a classical-looking universe like ours and apply a quantum evolution, classicality is preserved (for instance, we will never observe the proverbial deal-and-alive cat)?
This looks like a reasonable goal.

If on the other hand they want to show that the "classical pointer states" emerge from some arbitrary (non "classical looking") initial quantum state, then it looks like a much more dubious goal to me.

Is it the first or second goal that the darwinists have in mind? Or something else entirely?

11. **Peter Shor**
August 2, 2019

Pascal: I don't know whether all the quantum Darwin people have the same goal.

Certainly, if you start with a high-temperature thermal (i.e., completely random) initial state, then it will stay thermal. But if you start with a low-energy state, you might be able to prove something.

12. **Arnold Neumaier**
August 4, 2019

Mateus Araújo,

as you write, decoherence cannot explain why only a single outcome is observed. The deeper reason for this is that quantum mechanics in the traditional interpretations has not even the means to express what it means to have a single outcome.

To explain the occurrence of single outcomes one needs an interpretational device that can talk about this. This is done in my thermal interpretation (already twice mentioned in Peter's blog); see the 5 preprints listed at
https://www.mat.univie.ac.at/~neum/physfaq/therm/
Essentially, decoherence tells roughly the same the same story as the thermal
interpretation, but only in statistical terms, whereas the thermal interpretation refines this to a different, more detailed story for each single case. This is possible since in the thermal interpretation, outcomes are defined as macroscopic expectations approximating the microscopic quantities to be measured, and q-expectations are always single-valued. This makes a big difference in the interpretation of everything!

13. **Jarek Korbicz**
August 22, 2019

One comment re the Quanta article on quantum Darwinism. The statement at the end:

"Spectrum broadcast theory (which has only been worked through for a few idealized cases) "

is not exactly correct in the following sense. Spectrum Broadcast Structures (SBS) have been theoretically found by the Gdansk group in *all* the models where quantum Darwinism (qD) was earlier predicted, apart from the NV centers (we are working on that). And in several more (QED, gravitational decoherence). Actually one of the pillars of the SBS program is to check as many models as doable to gather a theoretical evidence in their favor. So the SBS "has only been worked through for a few idealized cases" to the very much the same extent as qD. An arXiv search on my name will give the relevant papers. I wrote a comment to Quanta but it didn't seem to get through to the Editors.

Where We Are Now

August 6, 2019
Categories: Uncategorized

For much of the last 25 years, a huge question hanging over the field of fundamental physics has been that of what judgement results from the LHC would provide about supersymmetry, which underpins the most popular speculative ideas in the subject. These results are now in, and conclusively negative. In principle one could still hope for the HL-LHC (operating in 2026-35) to find superpartners, but there is no serious reason to expect this. Going farther out in the future, there are proposals for an extremely expensive 100km larger version of the LHC, but this is at best decades away, and there again is no serious reason to believe that superpartners exist at the masses such a machine could probe.

The reaction of some parts of the field to this falsification of hopes for supersymmetry has been not at all the abandonment of the idea that one would expect. For example, today brings the bizarre news that failure has been rewarded with a [$3 million Special Breakthrough Prize in Fundamental Physics for supergravity]. For uncritical media coverage, see for instance [here], [here], and [here].

Some media outlets do better. I first heard about this from Ryan Mandelbaum, who writes [here]. [Ian Sample at the Guardian] does note that negative LHC results are "leading many physicists to go off the theory" and quotes one of the awardees as saying:

> We're going through a very tough time… I'm not optimistic. I no longer encourage students to go into theoretical particle physics.

At [Nature], the sub-headline is "Three physicists honoured for theory that has been hugely influential — but might not be a good description of reality" and Sabine Hossenfelder is quoted. [At her blog], she ends with the following excellent commentary:

> Awarding a scientific prize, especially one accompanied by so much publicity, for an idea that has no evidence speaking for it, sends the message that in the foundations of physics contact to observation is no longer relevant. If you want to be successful in my research area, it seems, what matters is that a large number of people follow your footsteps, not that your work is useful to explain natural phenomena. This Special Prize doesn't only signal to the public that the foundations of physics are no longer part of science, it also discourages people in the field from taking on the hard questions. Congratulations.

In related news, yesterday I watched [this video] of a recent discussion between Brian Greene and others which, together with a lot of promotional material about string theory, included significant discussion of the implications of the negative LHC results. A summary of what they had to say would be:

- Marcelo Gleiser has for many years been writing about the limits of scientific knowledge, and sees this as one more example.
- Michael Dine has [since 2003] been promoting the string theory landscape/multiverse, with the idea that one could do statistical predictions using it. Back then we were told that "it is likely that this leads to a prediction of low energy supersymmetry breaking" (although Dine soon realized this wasn't working out, see [here].) In 2007 Physics Today published his [String theory in the era of the Large Hadron Collider] (discussed [here]), which complained about how "weblogs" had it wrong that string theory had no relation to experiment. That piece claimed that

  > A few years ago, there seemed little hope that string theory could make definitive statements about the physics of the LHC. The development of the landscape has radically altered that situation.

  and that

  > The Large Hadron Collider will either make a spectacular discovery or rule out supersymmetry entirely.

  Confronted by Brian with the issue of LHC results, Dine looks rather uncomfortable, but claims that there still is hope for string theory and the landscape, that now big data and machine learning can be applied to the problem (for commentary on this, see [here]). He doesn't though expect to see success in his lifetime.

- Andy Strominger doesn't discuss supersymmetry in particular, but about the larger superstring theory unification idea, tries to make the case that it hasn't been a failure at all, but a success way beyond what was expected. The argument is basically that the search for a unified string theory was like Columbus's search for a new sea route to China. He didn't find it, but found something much more exciting, the New World. In this analogy, instead of finding some tedious reductionist new layer of reality as hoped, string theorists have found some revolutionary new insight about the emergent nature of gravity:

  > I think that the idea that people were excited about back in 1985 was really a small thing, you know, to kind of complete that table that you put down in the beginning of the spectrum of particles…
  >
  > We didn't do that, we didn't predict new things that were going to be measured at the Large Hadron Collider, but what has happened is so much more exciting than our original vision… we're getting little hints of a radical new view of the nature of space and time, in which it really just is an approximate concept, emergent from something deeper. That is really, really more exciting, I mean it's as exciting as quantum mechanics or general relativity, probably even more so.

  The lesson Strominger seems to have learned from the failure of the 1985 hopes is that when you've lost your bet on one piece of hype, the thing to do is double down, go for twice the hype…

Update: The Breakthrough Prize campaign to explain why supergravity is important despite having no known relation to reality has led to various nonsense making its way to the public, as reporters desperately try to make sense of the misleading information they have been fed. For instance, you can read (maybe after first reading [this comment]) [here] that

> Witten showed in 1981 that the theory could be used to simplify the proof for general relativity, initiating the integration of the theory into string theory.

You could learn [here] that

> When the theory of supersymmetry was developed in 1973, it solved some key problems in particle physics, such as unifying three forces of nature (electromagnetism, the weak nuclear force, and the strong nuclear force)

Update: On the idea that machine learning will solve the problems of string theory, see [this yesterday from the Northeastern press office], which explains that the goal is to "unify string theory with experimental findings":

> Using data science to learn more about the large set of possibilities in string theory could ultimately help scientists better understand how theoretical physics fits into findings from experimental physics. Halverson says one of the ongoing questions in the field is how to unify string theory with experimental findings from particle physics and cosmology…

Update: Physics World has a [story about this] that emphasizes the sort of criticism I've been making here.

As mentioned in the comments, I took a closer look at the citation for the prize. The section on supersymmetry is really outrageous, using "supersymmetry stabilizes the weak scale" as an argument for SUSY, despite the fact that this has been falsified by LHC results.

Update: Jim Baggott writes about this story and post-empirical science here.

Noah Smith here gets the most remarkable aspect of this right. String theory has always had the feature that the strings were not supposed to be visible at accessible energies, so not directly testable. Supersymmetry is quite different: it has always been advertised as a directly testable idea, with superpartners supposed to appear at the electroweak scale and be seen at the latest at the LHC. Giving a huge prize to a theoretical idea that has just been conclusively shown to not work is something both new and outrageous.

Update: Tommaso Dorigo's take is here, which I'd characterize as basically "any publicity is good publicity, but it's pretty annoying the cash is going to theorists for failed theories instead of experimentalists"(he does say he wanted to entitle the piece "Billionaire Awards Prizes To Failed Theories"):

> An exception to the above is, of course, the effect that this not insignificant influx of cash and 23rd-hour recognition has on theoretical physicists. For they seem to be the preferred recipients of the breakthrough prize as of late, not unsurprisingly. Apparently, building detectors and developing new methods to study subnuclear reactions, which are our only way to directly fathom the unknown properties of elementary particles, is not considered enough of a breakthrough by Milner's jury as it is to concoct elegant, albeit wrong, theories of nature.
>
> Going back to the effect on laypersons: this is of course positive. Already the sheer idea that you may earn enough cash to buy a Ferrari and a villa in Malibu beach in one shot by writing smart formulas on a sheet of paper is suggestive, in a world dominated by the equation "is paid very well, so it is important". But even more important is the echo that he prize – somewhere by now dubbed "the Oscar of Physics" – is having on the media. Whatever works to bring science to the fore is welcome in my book.

Comments

1. **33lewski**
   August 6, 2019

   I am on holidays in Italy now where in the tv they call it "Oscars in Physics". I must admit that this is a good name, reflecting the promotion of popularity rather than physical aplicability of the theory.

2. **David Roberts**
   August 6, 2019

   > we didn't predict new things that were going to be measured at the Large Hadron Collider

   I thought people in fact *did* predict things that were going to measured at the LHC, and we haven't seen anything like any of them…

3. **Bernhard**
   August 6, 2019

   "big data and machine learning can be applied to the problem ".

   The most overhyped ideas of the moment will come save String Theory. How appropriate.

4. **Peter Woit**
   August 6, 2019

   David Roberts,
   Despite what one often hears, superstring theory has never predicted anything about what the LHC (or any accelerator) would see, for reasons I've gone on about here and elsewhere. What does make predictions is supersymmetry, and if you think supersymmetry solves the naturalness problem, these predictions should show up at the LHC. If supersymmetry doesn't solve the naturalness problem there is no prediction of what energy scale its effects will show up at, and it loses much of its interest.

   The accurate statement has always been that superstring theory predicts nothing, but that, if supersymmetry showed up at the LHC, that would be encouraging for the superstring idea, since supersymmetry is part of the theory. Pre-LHC, hopes for connecting superstring theory to the real world hinged on first finding supersymmetry at the LHC, then hoping that the discovered pattern of superpartners and their masses would somehow provide an effective constraint on possible superstring "vacua". If the constraint was good enough, you could hope to get new predictions out of the superstring.

   Post negative results from the LHC, there are no prospects for connecting string theory to the real world (see the recent post about Arkani-Hamed's talk on the subject). One reaction to this you often hear (from e.g. Witten) is basically "maybe a miracle will happen and we'll see something unexpected at LIGO or whatever." Another is Dine's "let's keep calculating and maybe a miracle will happen." Strominger seems to have adopted a different tactic: abandon the sinking ship and declare victory, announcing that it was a crummy ship anyway, that the new one being built will be infinitely superior, and the old ship will live on since some of its wreckage will be incorporated in the new one.

5. **John**
   August 6, 2019

   Peter,

   Your characterization of what Andy said ("Strominger seems to have adopted a different tactic: abandon the sinking ship and declare victory, announcing that it was a crummy ship anyway, that the new one being built will be infinitely superior, and the old ship will live on since some of its wreckage will be incorporated in the new one.") is completely off base. The proverbial "ship" in your analogy seems to refer to the idea that Strominger said is naiive, i.e. the hope that a simple ToE would be found and fundamental physics would be over. Nice way to straw man his argument.

   If anything, the "ship" would have to be what string theorists work on: string theory. He is by no means advocating abandoning string theory in favor of anything else. And you insinuating that just reveals how insincere and nitpicky your entire smear campaign has been all along.

   Strominger is telling us that string theory has expanded the horizons of physics in a wonderful way, and it is clear that e.g. AdS/CFT is making new strides toward connecting string theory with lots of things closer to the lab bench. Take for example holographic duality in the SYK model. That is a model where one might test things on a lab bench. You're absolutely missing how theoretical physics works, and Nima is correct in stating that non- or former-physicists are out of their depth.

   Regards.

6. **Lino**
August 6, 2019

Peter:

Where does all this leave particle physics? You quote Ian Sample above as saying: "I no longer encourage students to go into theoretical particle physics." What comes next? Do we look to the mathematicians or the experimentalists for the next step forward?

7. **Peter Woit**
August 6, 2019

John,
I don't think I'm misrepresenting Strominger's claims at all. In my analogy the sinking ship is the idea of string theory unification, the idea that string theory will explain the Standard Model and unify it with gravity. Strominger takes the bizarre tack of characterizing such an explanation as not that exciting, just a tedious "reductionist" explanation of some numbers in a table.

Holographic duality in SYK models is likely (among others) the kind of thing Strominger had in mind when he referred to "little hints of a radical new view of the nature of space and time". Trying to take a "little hint" and use it to make a dramatic claim that one has discovered the New World is about as hypey as hype gets.

As for the personal insults, I strongly suggest you leave them to Lubos.

8. **Peter Woit**
August 6, 2019

Lino,
The quote isn't Ian Sample's, it's from Ferrara, one of the awardees. I don't want to start a discussion here of my or other people's favorite idea for where progress may come from, just want to point out that it's been clear for a long time where progress won't come from: trying to get a unified theory out of supergravity (with or without strings). Supergravity is an immensely complex and technical subject, and it's the last thing young theorists should be spending their time learning about, although I fear this award is likely to encourage that.

9. **Angry Andy**
August 6, 2019

In the Nature piece, one reads: *"A lack of evidence should also not detract from supergravity's achievements, argues Strominger, because the theory has already been used to solve mysteries about gravity. For instance, general relativity apparently allows particles to have negative masses and energies, in theory. "If that was true, some things wouldn't fall to Earth when dropped, but fall into space," says Strominger. That does not happen, but no one could explain why not. Turning supergravity's mathematical machinery to general relativity, however, enabled physicists to prove that particles cannot have negative masses and energies. "Those results will hold whether or not supergravity actually exists in nature," says Strominger."*

This is a misrepresentation either of the problem in question, namely, the positive energy theorem in GR, and the history of its solution. (1) Saying that "For instance, general relativity apparently allows particles to have negative masses and energies, in theory. "If that was true, some things wouldn't fall to Earth when dropped, but fall into space," says Strominger" is to ignore years of work from relativists such as Arnowitt, Bondi, Bonnor, Choquet-Bruhat, Deser, Geroch, Misner and Lichnerowicz, only to list a few.
(2) The first proof of the theorem was actually worked out by Schoen and Yau, in "On the proof of the positive mass conjecture in general relativity" (1979) and "Proof of the positive mass theorem. II" (1981), where they employed rather more traditional methods from Geometric Analysis. It's true that Deser and Teitelboim, and then Grisaru, pointed out the positivity of total energy in isolated systems in SUGRA from the fact that its hamiltonian can be written as sum of squares of the hermitian supercharges, and this inspired Witten to later provide a simplified proof of the theorem using spinor methods in "A new proof of the positive energy theorem" (1981) (all published in Comm. Math. Phys.). But even so, Witten's proof was in need to some clarification to be completely rigorous, concerning particularly some analytical properties of Dirac operators, provided by Parker and Taubes, see here:
https://users.math.msu.edu/users/parker/Witten.pdf
Moreover, spinor methods have been applied to General Relativity at least from 1960 by Roger Penrose, see e.g.:
https://www.sciencedirect.com/science/article/pii/000349166090021X
I don't think Penrose needed SUGRA for this.

10. **Amitabh Lath**
August 6, 2019

There are two ways to interpret LHC results (140 fb^-1, !!). First, there are no more discoveries to be made; 2012 saw the final chapter in a story that began with the ancients and featured Mendeleev and Rutherford and Feynman and Weinberg and so many others. It's all over, pack it up. Tell the smart kids to go into cancer research or finance.

Or second, the experimentalists don't know how to look properly. We are pretty good at looking where we are told. Top, higgs decays were precisely modeled and the analyses beautifully crafted to look for exactly that. In this new era we continue to search for new physics by doing what we know: resonances, missing momenta, excess photons, electrons, muons or heavy quarks. Almost all LHC searches would look perfectly reasonable to someone from 50 years ago. But nature is not bound by our limitations.

Look, new physics is going to pop up. It might be something more complicated than a Ting-like bump on a nice flat background. We are collectively moving beyond basic techniques, and it is a really exciting time.

11. **Peter Woit**
August 6, 2019

For those interested in the exact relation of Witten's proof to supergravity, see section IV of his paper
https://projecteuclid.org/euclid.cmp/1103919981
which explains this in detail (and is consistent with what "Angry Andy" writes above).

12. **Sabine Hossenfelder**
August 6, 2019

Your quote from the Dine article ("A few years ago…") contains the words "absurd misinformation" which don't seem to belong there.

13. **Peter Woit**
August 6, 2019

Thanks Sabine,
Fixed.

14. **Lowell Brown**
August 7, 2019

Many years ago we received a letter of recommendation of recommendation form Sidney Coleman. I remember only two short sentences in the letter:

I am uninterested in gravity. I am super-uninterested in super-gravity.

I believe that a few years later Sidney did not retain this purity of soul.

15. **Chris K.**
August 7, 2019

Peter,

If there was any evidence that supergravity has anything to do with reality, Ferrara, Freedman and van Nieuwenhuizen would be getting a Nobel prize instead of the Breakthrough one. The goal of the latter is to recognize important theoretical discoveries in physics, which do not necessarily need to make contact with experiments. You can criticize the purpose of such a prize, but the fact that discovery of supergravity was a milestone towards better understanding of QFTs is rather indisputable. Among other things, to this day N=8 SUGRA remains the only four-dimensional theory of gravity that has a shot at being renormalizable. To me (as someone working on numerical GR) this fact is completely remarkable!

16. **TOM WEIDIG**
August 7, 2019

Given that the field is in a conceptual turmoil, given that the breakthrough has been promised for decades, and given that everyone seems to have given up hope for the next few years now that the LHC results are in, I expect a revolutionary breakthrough to happen soon! 😉

17. **Low Math, Meekly Interacting**
August 7, 2019

I thought the LHC was supposed to confirm the mechanism of EWSB, solve the hierarchy problem, uncover a new fundamental symmetry of nature and discover the LSP/dark matter. That was a "small" thing?

18. **Peter Woit**
August 7, 2019

Chris K.,
The problem is that if you're going to award a huge prize for theory not backed by experiment, you have a big problem of deciding what is good theory and what is bad theory. Given my interests, I've nothing against handing out huge prizes in mathematical physics, but if you do this you need to face up to some difficult problems of evaluation, and be careful to explain to the press that what you are rewarding is not success at explaining nature, but something different.

Note that the last two Breakthrough Prizes in physics went to solid state theory work that is connected to experiment, and to the WMAP experiment. The Breakthrough Prize is not promoted as a prize for work that can't be tested, quite the opposite. It is extremely misleading to the public to tell them that the construction of a supergravity theory and the WMAP experiment are the same sort of thing.

Have you read the citation for the supergravity prize? It explicitly claims that the significance of this work is based on the fact that supersymmetry
"offers solutions to some of those perplexing puzzles in the Standard Model, including a mechanism explaining the tiny particle masses, and a natural candidate for dark matter, which – like the hypothesized super-bosons – is massive but invisible."
This is just completely outrageous: the conjecture that SUSY "[explains] the tiny particle masses" (i.e. stabilizes the weak scale with respect to the Planck scale) always was highly problematic, and the work at the LHC has shown this is not true. What's going on here is much worse than giving a prize to an untested or untestable idea, it is explicitly giving a huge prize for an idea, based on an argument for its significance which experiment has just falsified. This is really bad for both the public credibility of the subject, as well as for the ongoing problem of getting it to face up to its failures.

19. **Peter Woit**
August 7, 2019

LMMI,
Actually I think what Strominger was referring to as a "small thing" was the 1985 hope to explain the spectrum of elementary particles and compute their masses and interaction strengths. By his measurement scale, the things you mention would not be small, but microscopic…

20. **Lee Smolin**
August 7, 2019

Dear Lowell Brown,

I was told by Bryce deWitt that I was the subject of that letter of Sidney's. There was just one more line…

Why is no one mentioning the simultaneous, and much simpler, construction of supergravity by Deser and Zumino? As students at the time we found much to admire from both results!

Thanks,

Lee

21. **Peter Woit**
August 7, 2019

Lee,
Philip Ball in his piece at Scientific American, writes
"One potentially controversial aspect of the decision is that the supergravity picture was also formulated independently by Bruno Zumino, a pioneer of supersymmetry, and Stanley Deser, now at Brandeis University, who also published their work in 1976—initiating disputes over priority. Zumino died in 2014, but the omission of Deser

from the award seems puzzling, Duff says, given that there is no restriction on the number of recipients."
Looking at a recent talk about the history of supergravity by Van Nieuwenhuizen, I'm guessing he might point out that his paper with Ferrara and Freedman was submitted March 29, 1976, the Deser/Zumino paper April 28.

22. **Peter Woit**
August 7, 2019

For Deser's view of the story of the discovery of supergravity, see
https://arxiv.org/abs/1704.05886

23. **TG**
August 7, 2019

I think S. Deser's final comment in the above-cited paper beautifully summarizes the situation; too bad it wasn't cited by the nominating committee…

"In conclusion, I quote Chou-En-Lai's reply to a query as to the effects of the then 200 year-old French revolution: "it's too early to tell": SUGRA is a beautiful set of theories, very much broken in the real world, yet with many useful and unexpected lessons in theory-building past and future."

24. **Marc Nardmann**
August 7, 2019

Witten's 1981 proof (or rather: detailed proof sketch; the analytic parts were filled in by Parker and Taubes in 1982) of the positive mass/energy theorem (PMT) is a very important result in mathematical general relativity and differential geometry. It was extremely influential. Witten's spinor proof has nothing to do with supergravity (or superanything), though. In fact, Witten added at the end of his article a section that begins with the following sentence: "In this section a few speculative remarks will be made about the not altogether clear relation between the previous argument and supergravity." If you cut that section from the article, you won't miss anything. The proof itself does not involve supergravity at all.

That the spinor proof was found only in 1981, two years after Schoen and Yau had given a different proof, is a historical accident. It could easily have been found in the mid-1960s, long before the discovery of supergravity: As inspiration, you just need Lichnerowicz' proof that certain compact spin manifolds without boundary do not admit a Riemannian metric with positive scalar curvature (1963); and the Arnowitt/Deser/Misner (ADM) definition of the mass/energy of an asymptotically flat spacetime (1960–1962). Knowing these things, you will feel a strong urge to figure out whether the main formula in Lichnerowicz' proof has a generalisation to certain compact spin manifolds with nonempty boundary. If you are moderately clever (Witten was certainly overqualified in that respect), you compute the boundary term in the case where the boundary is a large sphere in an asymptotically flat spacetime, notice that this term involves the ADM mass/energy, and thus get the strategy for the spinor proof of the PMT. You ask your local analysis expert why the PDE you obviously must solve has a solution, and then you're done.

The Breakthrough Prize announcement claims that supergravity "can be used to give a rather simple proof" of the PMT. This is like saying that apples can be used to give a rather simple theory of gravitation. Newton might have had an important idea for his theory while watching apples falling from a tree. But without apples, he would probably have had the same idea a week later, sitting on a privy, contemplating other falling objects. In an analogous sense, Witten most likely didn't need supergravity as an inspiration to come up with his PMT proof.

25. **Neo**
August 8, 2019

Dear Peter,

At Nature, "In 2013, for example, Stephen Hawking won for his theory — also still untested experimentally — that black holes give off radiation."

What do you think about this "justification" for supergravity ?

26. **Peter Woit**
August 8, 2019

Neo,
The problem with the Breakthrough Prize justification of an award for supergravity as an idea about unification is not that it's untestable, but that it has been tested and failed the tests. This isn't a compelling, hard to test idea, it's an idea that now has a lot of evidence that it's wrong.

Also relevant is the distinction Sabine Hossenfelder makes here between different sorts of untestable ideas:
https://twitter.com/skdh/status/1159032052320284673

27. **Bill**
August 8, 2019

Considering who decides these prizes, former recipients just made theirs look less unjustified by comparison.

28. **vmarko**
August 9, 2019

Speaking of prizes and levels of hype, yesterday the ICTP Dirac medal was awarded to Mukhanov, Starobinsky and Sunyaev, for inflation and CMB:

https://www.ictp.it/about-ictp/media-centre/news/2019/8/dirac-medal.aspx

Looking at the article, I was pleasantly surprised by the lack of hype and multiple comments about the agreement between theory and observations. But perhaps most surprisingly, while inflation is said to explain the uniformity and flatness of the Universe, there is absolutely no mention of the "magnetic monopole problem" – a rarely sober take on inflationary cosmology.

Best, 🙂
Marko

My take, just posted to Prospect Magazine's science blog. It's pretty much as you'd expect. https://www.prospectmagazine.co.uk/science-and-technology/prize-for-speculation-goes-to-how-foundational-physics-went-down-a-post-empirical-dead-end-science-prize

30. **Luca Coluzzi**
    August 10, 2019

    Regarding the matter, I heard an interview from the national italian radio broadcast (radiorai) to Ferrara, in which he says, among other things, that “likely” SUSY will be found in the next ten years, draws a comparison between the search for SUSY and the discovery of the Higgs Boson, and criticizes LQG.

    This is the web address of the interview (in italian, sorry)

    https://www.raiplayradio.it/audio/2019/08/RADIO3-SCIENZA-del-09072019—Un-superpremio-alla-supergravit195160-dc3fbb42-7089-4e48-800e-02fbe06cdaa8.html

31. **BrunoMAGAglitch**
    August 10, 2019

    Like much of theoretical physics, prizes from billionaires are sociological phenomena.

    Does this prize impede or enhance the execution of experiments with substantial discovery potential? That matters the most. Could go either way.

    By and large, theoretical high energy physicists don’t have any idea how to accurately estimate discovery potential.

    Meanwhile, the US neutrino budget is in turmoil, with ripples in $ that dwarf the chump change of the Milner prize.

32. **Jackiw Teitelboim**
    August 10, 2019

    Thank you for the link, Luca Coluzzi.

    I’m not a native Italian speaker, but if I understood Ferrari’s speech around the 14th minute of that interview correctly, Ferrari criticism of LQG (which the interviewer attributed to Carlo Rovelli) is, ironically, that it’s not predictive, while SUGRA and strings are, since they predict the existence of new particles!

33. **Lee Smolin**
    August 11, 2019

    Dear Jackiw Teitelboim,

    There are other ironies here: First of all, the LQG quantization of GR extends directly to give a quantization of supergravity, at least at N=1, including a treatment of d=11 supergravity. So supergravity and LQG are compatible, there is no conflict between them.

    Second, LQG evolved out of supergravity, as the key result that the hamiltonian formulation is polynomial when expressed in terms of the chiral connection arose in an attempt by Amitaba Sen to formulate a lattice regularization of supergravity.
    (For this reason the relation between supergravity and Witten’s proof of positive energy is particularly transparent in Ashtekar variables.) There is a small literature on supergravity in LQG for those interested.

    And yes, LQG permits a variety of couplings to matter and Yang-Mills fields (modulo some constraints.)

    Thanks,

    Lee

34. **evermasterx**
    August 12, 2019

    Yes, Jackiw Teitelboim,
    that is what Ferrara said.

35. **Amitabh Lath**
    August 12, 2019

    Tommaso Dorigo is right. The reason for not giving prizes to experiment is “there too damn many of you”. The whole system of giving prizes for science is still in thrall to the absurd romantic notion of the lone genius (at most two or three).

36. **Peter Woit**
    August 12, 2019

    Amitabh Lath,
    It’s not so much that there are too many of you, it’s that these days you don’t have enough of a star system. The goal of the Breakthrough Prize people is to promote fundamental physics by creating and publicizing “stars”. If you would just pick one or two people in your collaboration and identify them as the “stars”, you too could get more prizes.

37. **Bernhard**
    August 12, 2019

    Peter,

    ” If you would just pick one or two people in your collaboration and identify them as the “stars”, you too could get more prizes.”

    I don’t think the error is on the collaborations side. Actually, I think the opposite, collaborations should work to diminish the “stars” they already have (spokespersons) since their personal scientific contributions are 99% of the cases disproportional to the attention and prizes (like Nobel) they get.

    This winner takes all attitude and celebrity culture is the real problem here, and this BS prize makes it a million times worse. Moreover, be it or not what Milner cares about, it does reinforce the “romantic notion of the lone genius ” on the public’s imaginary.

    If you add to all of this the absurd idea that these prizes are now going for failed theories, nothing at all is positive to me (unlike Tommaso thinks). It’s made even worse by the fact they try to add confusion by rewarding real scientific discoveries in the mix.

    It’s a complete fiasco.

38. **Pankaj**
August 13, 2019

Nobel prize recognizes ideas that have succeeded. It may not be a bad idea to reward by some mechanism those ideas that have had enormous influence, but may not turn out to be correct. This will be a different issue how to "measure" influence. By almost any measure, idea of Supergravity has made major impact.

39. **Peter Woit**
August 13, 2019

Pankaj,
What personally attracted me to science when I was young was that it was about the search for a truth independent of what was popular or not popular. Having a huge prize for an idea being popular, even if it is not true, is an attempt to change this conventional understanding of what science is, and I think that should be resisted.

This is also peculiar in another way: often the reason for instituting a new prize is to reward work that is not already getting rewarded. Having a popular idea is what gets you all of the conventional rewards of academic life, so why add another reward for what is already rewarded?

40. **WTW**
August 13, 2019

Peter,
How about a prize for "The Theoretical Idea that has wasted more months of graduate students' time than any other over the last decade(s)"?
That could apply to both experimentalist and theoretician graduate students, and perhaps be expanded to include post-docs as well.

41. **Daniel Mittleman**
August 13, 2019

If you're going to award prizes for ideas that are wrong, then why stop with only those ideas which are now known to be wrong, but which were once thought to have some possibility of being correct? Why not award a prize for ideas that were known to be wrong at the very start? I'm thinking of somebody like Jan Hendrik Schoen, who inspired a great deal of experimental work around the world with his fantastic ideas, all of which were deliberate fabrications. Who are we to distinguish among the various flavors of wrong?

42. **no idea**
August 14, 2019

The sad truth is that if you are going to award prizes in this area, then you have to award prizes for ideas that are wrong, because there aren't any others.

43. **Anom**
August 14, 2019

Setting aside issues of whether or not it is right, is supergravity really even all that brilliant of an idea? Supersymmetry was a great idea, but after that it's kind of obvious that you should look for a theory of gravity with supersymmetry. A technical feat to be sure, but worthy of a big prize?

44. **Low Math, Meekly Interacting**
August 15, 2019

Although it's not nearly as lucrative, is the Dirac Medal considered more prestigious than the Breakthrough Prize?

Just as an example, Sen, Strominger and Veneziano won the 2014 Medal for "crucial contributions to the origin, development and further understanding of string theory." Actually, it appears many of the medalists won for theoretical work that is entirely speculative and arguably empirically falsified, to the extent that any idea like String Theory or SUSY can be falsified.

Handing out awards for brilliant theoretical work that either leads to falsified predictions, or evades any attempt at empirical validation through infinite malleability, does not appear to be unprecedented. Seemingly the practice is generating something of a monetary arms race, and that's the novelty.

45. **Peter Woit**
August 15, 2019

LMMI,
Yes, academia and science has always had a large number of prizes (the number is increasing) of all sorts, a bunch of them for theory and math/physics. There actually are three different "Dirac Medals" of this kind. The same supergravity group was awarded the ICTP version back in 1993, and has gotten a bunch of other similar ones together (Dannie Heineman Prize, Ettore Majorana Medal).

There are far more of these prizes than there are truly important successful ideas, so of necessity they end up rewarding lesser achievements and ones that not everyone would agree on. The difference is in the money and publicity campaign behind the Breakthrough Prize. When they won the ICTP Dirac Medal the three got an inconsequential amount of money and a few articles in places like Physics Today. For the Breakthrough Prize, it's articles in the Guardian and \$1 million together with a big PR campaign (including recruiting journalist pre-announcement to write many positive articles timed to appear at the announcement).

The question of whether this money and PR campaign will be successful is still up in the air. I noticed that many important media outlets decided not to cover this (e.g., nothing in the New York Times). In the future, which will carry the most positive reputational weight, a Dirac Medal or a Breakthrough Prize? The jury is still out, but I think unfortunately at the moment the Milner/Zuckerberg millions are speaking the loudest.

46. **David Roberts**
August 15, 2019

OT, but thank you, Peter, for resizing the "only the details are missing" picture to make the site design more uniform.

What's the difference between Copenhagen and Everett?

August 18, 2019
Categories: Quantum Mechanics

I've just finished reading Sean Carroll's forthcoming new book, will write something about it in the next few weeks. Reading the book and thinking about it did clarify various issues for me, and I thought it might be a good idea to write about one of them here. Perhaps readers more versed in the controversy and literature surrounding this issue can point me to places where it is cogently discussed.

Carroll (like many others before him, for a recent example see here), sets up two sides of a controversy:

- The traditional "Copenhagen" or "textbook" point of view on quantum mechanics: quantum systems are determined by a vector in the quantum state space, evolving unitarily according to the Schrödinger equation, until such time as we choose to do a measurement or observation. Measuring a classical observable of this physical system is a physical process which gives results that are eigenvalues of the quantum operator corresponding to the observable, with the probability of occurrence of an eigenvalue given in terms of the state vector by the Born rule.
- The "Everettian" point of view on quantum mechanics: the description given here is "The formalism of quantum mechanics, in this view, consists of quantum states as described above and nothing more, which evolve according to the usual Schrödinger equation and nothing more." In other words, the physical process of making a measurement is just a specific example of the usual unitary evolution of the state vector, there is no need for a separate fundamental physical rule for measurements.

I don't want to discuss here the question of whether the Everettian point of view implies a "Many Worlds" ontology, that's something separate which I'll write about when I get around to writing about the new book.

What strikes me when thinking about these two supposedly very different points of view on quantum mechanics is that I'm having trouble seeing why they are actually any different at all. If you ask a follower of Copenhagen (let's call her "Alice") "is the behavior of that spectrometer in your lab governed in principle by the laws of quantum mechanics" I assume that she would say "yes". She might though go on to point out that this is practically irrelevant to its use in measuring a spectrum, where the results it produces are probability distributions in energy, which can be matched to theory using Born's rule.

The Everettian (let's call him "Bob") will insist on the point that the behavior of the spectrometer, coupled to the environment and system it is measuring, is described in principle by a quantum state and evolves according to the Schrödinger equation. Bob will acknowledge though that this point of principle is useless in practice, since we don't know what the initial state is, couldn't write it down if we did, and couldn't solve the relevant Schrödinger equation even if we could write down the initial state. Bob will explain that for this system, he expects "emergent" classical behavior, producing probability distributions in energy, which can be matched to theory using Born's rule.

So, what's the difference between the points of view of Alice and Bob here? It only seems to involve the question of how classical behavior emerges from quantum, with Alice saying she doesn't know how this works, Bob saying he doesn't know either, but conjectures it can be done in principle without introducing new physics beyond the usual quantum state/Schrödinger equation story. Alice likely will acknowledge that she has never seen or heard of any evidence of such new physics, so has no reason to believe it is there. They both can agree that understanding how classical emerges from quantum is a difficult problem, well worth studying, one that we are in a much better position now to work on than we were way back when Bohr, Everett and others were struggling with this.

Comments

1. **Andrew Krause**
   August 18, 2019

   Can you expand a bit on being in a much better position to study such things now? Is this due to new ways to measure isolated quantum systems experimentally, or due to new ways to explain the theory?

   Relatedly, do you think we will see substantial progress on these "interpretation" issues, and if so where will it (likely) come from?

2. **Peter Woit**
   August 18, 2019

   Andrew Krause,

   Note that when Everett was doing his work, even the notion of decoherence was not understood, so there have been huge improvements since then in our understanding of the theory of how classical emerges from quantum.

   I've often here pointed to the work of Zurek and others, for instance on the notion of quantum Darwinism. For a discussion of recent experimental results related to this, see
   https://www.quantamagazine.org/quantum-darwinism-an-idea-to-explain-objective-reality-passes-first-tests-20190722/
   and
   http://blog.jessriedel.com/2019/07/24/faq-about-experimental-quantum-darwinism/

   A book describing many of the relevant modern experimental techniques is Haroche and Raimond, see
   https://www.oxfordscholarship.com/view/10.1093/acprof:oso/9780198509141.001.0001/acprof-9780198509141

   I know nothing about this, but I've always wondered whether these issues will come up in the design of quantum computers, where in some sense the whole problem is that of a quantum/classical interface (creating isolated qubits presumably is easy enough, but how do you then manipulate them?). I've been told there are serious practical problems with getting significant bandwidth when providing input to or getting output from a quantum computer. Can one learn anything from these (I have no idea)?

3. **orin**
   August 18, 2019

   Ultimately the difference is that Bohr and Heisenberg (inspired by the success of observer-dependence in Einstein's relativity) were anti-realists (they did not believe in a mind-independent objective reality) and used that to argue that quantum mechanics was complete, rather than that "we simply don't understand the details." For example they were OK with objective-level logical contradictions (ala Winger's friend), because they had abandoned realism in favor of subjectivism. More generally this has the consequence of disfavoring whole lines of research into the details, because much of what would ordinarily in the scientific tradition be seen as important issues, such as measurement outcomes not being objective, clearly defining what does and does not constitute a measurement, the contradiction of the measurement apparatus being treated classically, locality in instantaneous collapse in entangled systems, and so on, can be "waved" away by an appeal to antirealism. In this reading, indeed Alice and Bob as you describe them are really on the same side, against Copenhagen. Both can certainly be realists who just "aren't sure" about the details of how the classical emerges from the quantum. Both can be open to various "completions" of the QM story (Bob apparently favors Unitary QM), but both are aware that there can be no local hidden variables due to Bell, so whatever completion there is (within the tradition of scientific realism) is not so mundane as to be reasonably ignored by researchers. Alice could well even be a psi-epistemicist who is an instrumentalist/positivist because she thinks that progress cannot be made on the problem without further empirical constraint, while nonetheless acknowledging that there is some mind-independent machinery that we lack information about, that could potentially be part of an "interpretation" of what is going on behind the scenes. But such a position is generally understood as distinct from the antirealist views of Bohr and Heisenberg, murkily articulated by them though they were, because they would reject that anything more could be going on "behind the scenes" at all, just as there is no "behind the scenes, absolute velocity" in some preferred frame in relativity.

At some point in history this story sort of morphed into an association between "Copenhagen" and "rejection of philosophy" (ironically, given how universally literate and strongly informed the founders were by philosophy, logical positivistic though some of it was), rather than a more accurate association between "Copenhagen" and a rejection of realism. The rejection of a mind-independent reality has a poor reputation in virtually every other scientific discipline, including most of the rest of physics, so this reframing has historically allowed the discipline to sort of ignore what would otherwise produce significant cognitive dissonance.

4. **Peter Woit**
   August 18, 2019

   Orin,
   I'm trying to understand the difference, if any, between "Copenhagen" and "Everett" in the senses (which are fairly conventional) in which Carroll uses the terms. Here "Copenhagen" is what he calls the supposed current majoritarian textbook point of view, and which he also characterizes as the "shut up and calculate" point of view. To the extent Bohr/Heisenberg were arguing for "shut up" on dubious idealist philosophical grounds, I don't think those are shared by the textbook writers. Instead, the "shut up" point of view I think historically was backed by experience that no good could come of arguments about the problem of classical emergence from quantum because these tended to be empty and philosophical. This was a problem for those like Zeh trying to seriously attack the problem using physics.

   If you instead define "Copenhagen" as what Bohr/Heisenberg thought, one problem is that they were confused and struggling, said different things at different times. While using "Copenhagen" to mean one or another reconstruction of what they were thinking is relevant to the history of science, I don't think it's particularly relevant to the question of how physicists today are struggling with the "interpretation" or "measurement" problem of quantum mechanics.

5. **Peter Woit**
   August 18, 2019

   It might be useful for me to reproduce here Carroll's discussion (page 23) of "Copenhagen":

   "In a modern university curriculum, when physics students are first exposed to quantum mechanics, they are taught some version of these five rules [i.e. state space, Schrodinger, observables, Born rule, wave function collapse]. The ideology associated with this presentation – treat measurements as fundamental, wave functions collapse whey they are observed, don't ask questions about what is going on behind the scenes – is sometimes called the Copenhagen Interpretation of quantum mechanics. But people, including the physicists from Copenhagen who purportedly invented this interpretation, disagree on precisely what that label should be taken to describe. We can just refer to it as "standard textbook quantum mechanics."

6. **Doug McDonald**
   August 18, 2019

   Ah! I've never seen an explanation of Everett exactly like Carrolll's. After reading that,
   I see that what I been expounding is exactly that. If Carroll is conventional Everett,
   I'm an Everettian.

   Given that, I can state that the point is that Bob needs to be able to explain to Alice exactly HOW the Born rule works. We know that after a while a thermal system, the apparatus, evolves into probabilities that are Gaussian even after addition of the measured particle. We need a formalism that explains how the Gaussian probabilities of the apparatus select out the probabilities that we know from Born are correct,
   for the "world" that includes the pointer in the correct position. It's different depending on whether its like a spin 1/2 particle, discrete, or position of a photon
   on a screen after passing a double slit, continuous. Its that formalism you should be searching out.

   As far as I know, such a formalism is lacking. But I've found it essentially impossible even to search for the answer to that question.

   Added statement: I have always been mislead, if Caroll is correctly explaining Everett, by the words "split" and "worlds". There is only one world, that of unitary evolution.

7. **orin**
   August 18, 2019

   Peter, you have to understand that by "fairly conventional" you are referring to the few sentences in which the term "Copenhagen" is used in quantum mechanics textbooks, in which the aim is to teach physics students the bare bones of how to do calculations in quantum mechanics. The aim is not to get into any of these thorny philosophical details, which would take an entire course on its own, and would be hard to understand anyways without first learning the von Neumann style rules that the books teach. Further, since there is no wide consensus on which completion of QM is correct, any responsible textbook author is going to fall into a "shut up and calculate"-like position. As such, I think Carroll's description in the quoted text is consistent with what I've said. It's also relevant that to a large extent the textbook writers are not experts in quantum foundations, and so it shouldn't be all that important what they thought (interestingly, one of my favorite quantum textbooks is by Bohm, which happens to adopt the Copenhagen viewpoint, despite him later completely rejecting it). Though again, it's important to read textbooks in the correct context, which is that they are trying to convince the students to focus on the calculations, because there is no consensus pedagogic ontology or heuristic that will help the students learn more than bog them down and prevent the lecturer from finishing the standard topics on time in a quantum mechanics curriculum.

   So it's the wrong perspective to pin down your definition of "Copenhagen" on the textbooks. For an in-depth discussion of interpretations, you want to use the definition relevant to an in-depth discussion, and quantum textbooks aren't the place that in-depth philosophic positions on interpretations are expounded on. One place that in-depth discussion took place was literally in Copenhagen with Bohr and Heisenberg, and which influenced a generation of physicists, hence the name "Copenhagen". Despite Bohr and Heisenberg being opaque writers and not in total agreement, their general position was one of antirealism *and therefore* "shut up because therefore you won't get anywhere", *not* "shut up because philosophy is empty." Of course we all know that whatever the reasons, they were *wrong* about shutting up, as for example Bell showed that Einstein's realist intuitions about locality were correct and that there were testable consequences. But again, this wouldn't have mattered to Bohr, who was antirealist anyway.

8. **orin**
   August 18, 2019

   (I should clarify that I even though I have not read Sean's book, I would assume that with his description of Copenhagen as "textbook QM", he is less taking issue with the textbooks for not critically examining alternate interpretations, but more generally taking aim at the history and culture in physics of ignoring quantum interpretation work as "second class" or "too philosophical", of assuming as Bohr and Heisenberg had argued that "the work is done and QM is complete", a position that is only tenable if you are antirealist)

9. **Physicsphile**
August 18, 2019

I think the hope in many worlds is to prove the Born rule rather than assuming it. See for example:
https://arxiv.org/abs/0906.2718

10. **Sabine Hossenfelder**
August 18, 2019

That the observer cannot see why they're different is the reason people are arguing about it…

They difference is in the part that you don't want to discuss, which is that Everettians postulate the other worlds are real, while Copenhagenists refuses to say anything about what cannot be observed. I am not a fan of the Copenhagen interpretation (I just recently explained on my blog why) but it's philosophically on the safe side. Talking about the existence of non-observable things isn't something I like to see scientists engage in.

(Not so coincidentally, I am currently reading the same book.)

11. **Peter Woit**
August 18, 2019

orin,
If you like, just follow Carroll and replace "Copenhagen" with "standard textbook" in what I wrote. I'm referring to our understanding of the issues today, not that of Bohr and Heisenberg in their discussions in Copenhagen shortly after the discovery of QM nearly a century ago. Yes, their attitude was "shut up because our understanding is that you can't get anywhere", but
1. I don't think that this attitude was just naive anti-realism. It seems likely they had considered the practical issue of what would happen if you tried to treat a spectrometer as a quantum system, and realized they had no idea of how to approach the problem of emergence of the classical from quantum, so were stuck with figuring out what you could say without an understanding of such emergence.
2. Developments since the 20s such as decoherence have shown that there are hopes for making progress on understanding such emergence. As a result I think the "standard textbook" story has evolved to take into account this possibility (my impression is that this is sometimes called "neo-Copenhagen").

I don't think issues about Bell, Einstein, locality and realism have anything to do with this.

Physicsphile,

Yes, the "Everettian" hope is that if you understand classical emergence you'll derive the Born rule. I don't think though that there is now any accepted such derivation. For instance, for a discussion of the problems with the relatively recent Carroll/Sebens attempt at a derivation, see this by Adrian Kent
https://arxiv.org/abs/1408.1944

The conventional "Copenhagen" view of Bohr/Heisenberg would be that you can't hope to derive the Born rule, and the "standard textbook" view is that it's a postulate because there is now no derivation.

I guess one way of answering the question of what the Copenhagen/Everett difference is would be to say that they differ mainly in their guess as to how difficult it will be to understand classical emergence and derive the assumed properties of classical observables, collapse and Born's rule. Given progress on issues like decoherence I don't think the extreme "no progress is possible" position is tenable, so the difference between the two is one of degree.

12. **Peter Woit**
August 19, 2019

Sabine,
I'll be curious to hear what you think about the book!

I do want to put off discussing the "many worlds" business, because to my mind it is about an independent set of complicated issues and I want to think more about them. I'll just point out here that Zurek argues that the Everett point of view does not require adopting a many worlds ontology, and, even Carroll (on page 234) writes: "The truth is, nothing forces us to think of the wave-function as describing multiple worlds". Yes that quote is out of context, and he also makes an argument on the next page that multiple worlds are "enormously convenient". This is where I think I disagree with him, for reasons best discussed separately from the issue I wanted to bring up here.

13. **Alessandro Strumia**
August 19, 2019

Good old books inform that the same issue had been fiercely debated around 1926, when Schroedinger/Einstein wanted to describe everything via a deterministic local equation, getting rid of quantum jumps. Heisenberg/Bohr explained that it's not possible because we see particles as events. Decoherence and all modern stuff allow to understand better but don't change the key point: we need probabilities. So the Schroedinger equation is just a tool for computing probabilities in configuration space. Progress will be possible only if somebody will understand why a particle decays at a given time and choosing a specific final state (directions etc). But, exploring higher energy, nobody found dices.

14. **Jim Baggott**
August 19, 2019

Peter,
I find it helpful to distinguish the standard quantum formalism from any and all attempts to interpret this. It's fair to say that the axiomatic formulation is heavily influenced by the 'Copenhagen school' – the wavefunction provides a complete description, observables as the expectation values of Hermitian operators, the Born rule, the unitary time-dependent Schrodinger equation – but the formalism itself is a set of axioms and mathematical relationships, not an interpretation.

Although I agree with Carroll that there is no such thing as a 'Copenhagen interpretation' on which there was ever any kind of consensus, I think it is reasonable to follow Bohr and Heisenberg, who (rather uneasily) agreed on Bohr's notion of complementarity and a clear distinction between the quantum and classical worlds – sometimes referred to as 'Heisenberg's cut', or what John Bell called the 'shifty split'. Interestingly, I don't accept that von Neumann's projection postulate (the 'collapse of the wavefunction') should be included as part of this understanding of the Copenhagen interpretation. In the 'Mathematical Foundations', von Neumann applied his Process 2 (unitary time evolution according to the Schrodinger equation) also to classical measuring instruments, and only invoked Process 1 (the collapse) when the wavefunction encounters the experimenter's 'ego'. I don't know if Bohr ever had anything to say about this, but he surely wouldn't have liked the idea of applying quantum mechanics to classical objects.

It's therefore wrong in my opinion so say that the Copenhagen interpretation implies the collapse of the wavefunction. Copenhagen is a fundamentally anti-realist interpretation – arguably it doesn't take the wavefunction to represent the real physical state of a quantum system. The 'collapse' then just represents an updating of our experience, not a real physical event. It is only when you prefer to adopt a realist interpretation – as in the MWI – that you are obliged to interpret the collapse realistically. Of course, this hasn't stopped people (from Everett and Bryce De Witt, to Adam Becker in his book 'What is Real?') from accusing the Copenhagen interpretation of all this bad stuff.

The formalism is completely inscrutable on the question of interpretation and, as we know from all the marvellous experiments that have been done in the last 40 years or so, any attempt to *extend* the formalism using local or crypto non-local hidden variables fails to predict the results correctly. Any interpretation must therefore be consistent with the formalism, as we know this is correct. This doesn't mean to say that other realist extensions invoking spontaneous collapse mechanisms (for example) aren't possible, it's just that we haven't properly tested these yet. However, I have some sense of how such experiments might turn out …

So, in terms of the question you posed in your post – no, there is absolutely no difference in the way you apply the time-dependent Schrodinger equation in the standard formalism and in many worlds. But many worlds is a realist interpretation, and as such it struggles to find a realistic explanation for the Born rule, and for the preferred basis. Decoherence (understood as a real physical process) helps to bridge the quantum and classical worlds but I'd argue that it doesn't fix these problems.

And then you have the point that Sabine raised, above. Some 'Everettians' see little or no difference between the different 'branches' of the MWI and the 'empty waves' of de Broglie-Bohm pilot wave theory. Others see the MWI as a useful heuristic, not to be taken too literally. But still others – such as David Deutsch and philosopher David Wallace – want to interpret many worlds literally, in terms of parallel universes or a multiverse. This is where in my book the interpretation gets completely overwhelmed by its metaphysics.

I'm just now going through the final edit of my new book (now titled: 'Quantum Reality: The Essential Meaning of Quantum Mechanics and the Game of Theories') which will hopefully set all this out reasonably clearly so folks can understand the nature of the game that's being played. It will be published next year.

15. **Dave Miller**
    August 19, 2019

    Peter,

    I took QM from Feynman in 1974-75. He was quite explicit that he was making no philosophical point ("ontological commitment," the philosophers would say) in teaching the standard "Shut-up-and-calculate" approach (by the way, the phrase seems to be Dave Mermin's and was not Feynman's, contrary to folk wisdom).

    Feynman told us simply that if we tried to pursue interpretation issues, we would end up finding that we had not made any progress at all: it was not that the questions were necessarily meaningless but just beyond our abilities to answer.

    As to quantum computing: the British physicist David Deutsch, one of the pioneers of theoretical quantum computing, has written on this extensively and is quite convinced that the standard QM theory of quantum computing proves that many-worlds must be true. (For the record, I think he is wrong, but, then again, all I know is that I do not know the true answer!)

    Dave

16. **Jim Baggott**
    August 19, 2019

    Further to my earlier comment, I was sufficiently intrigued to spend a few minutes this morning finding out if Bohr ever said anything about von Neumann's quantum theory of measurement. There's a very brief reference in Abraham Pais' biography of Bohr, in which Pais quotes an entry from one of his old notebooks pertaining to a lecture delivered by Bohr in November 1954 which reads: '[Bohr] thinks that the notion "quantum theory of measurement" is wrongly put'.

    This gels with my own understanding. An anti-realist interpretation which assumes that the quantum representation doesn't apply to classical objects has no use for a quantum theory of measurement. This was never part of the Copenhagen interpretation.

    In his 1970 Physics Today article (the one that really launched 'many worlds') Bryce De Witt claimed that von Neumann's collapse postulate was part of the 'conventional' or 'Copenhagen' interpretation. I'd accept 'conventional', but he was wrong to say 'Copenhagen'. I suspect this was the beginning of attempts to demonize the Copenhagen interpretation and accuse it of all manner of bad things, presumably to make many worlds look good by contrast.

17. **Syksy Räsänen**
    August 19, 2019

    To follow up on Jim Baggott: it makes little sense to identify "textbook quantum mechanics" with the Copenhagen interpretation, since textbooks typically just provide the Born recipe without explanation. In this sense, "textbook QM" can be seen as compatible with Everettian and Copenhagen views, whether or not the two are contradictory.

    In order to meaningfully discuss the issue of compatibility of the Copenhagen and Everett pictures, one should first nail down what one means with the Copenhagen interpretation (as different people mean different things).

    This article about Bohr's vehement opposition to Everett's proposal may be helpful in this regard.

18. **Pascal**
    August 19, 2019

    Suppose you want to do cosmology and study the extreme situations when quantum effects become relevant. There does not seem to be any meaningful notion of a "measurement" or an "observer" since no scientist can locate his or her lab outside of the universe.
    Would that not favor Everett over Copenhagen ?

19. **Lee Smolin**
    August 19, 2019

    Dear Peter,

    There is a clear difference between Copenhagen and Everett.

    The various versions of Copenhagen (or textbook) QM all require that the system studied is in fact a small subsystem of a larger universe. This is to make room for Bohr's classical world, where live the measuring instruments, clocks and observers. This is also required to connect the "probabilities" defined by Born's rule and the projection postulate with genuine experimentally obtained relative frequencies. The whole formalism is based on a clean distinction between states and observables, which expresses the assumption that by doing many repetitions of a measurement or preparation (which is only possible if your system is a subsystem of a larger universe) you can cleanly separate the effects of laws from those of initial conditions.

These distinctions all become problematic when one tries to apply textbook QM to the whole universe. Consequently anyone who contemplated doing so (ie a quantum cosmology) were aware it would require a modification of QM.

Everett QM was a deliberate attempt to make such a modification of QM that would make sense when applied to the universe as a whole. That is a big difference. Everett, Wheeler and deWitt all emphasized this point.

It was Everett's brilliant insight that to make QM cosmological might only require dropping the projection postulate and any reference to intrinsic probabilities, thus basing the theory on universal unitary evolution. It seems to be widely believed that his version fails to recover the correct probabilities. Otherwise there would be no need for the very subtle Oxford version of Deutsch, Wallace, Saunders etc. Whether they have completely succeeded or not-and in what version-remains, to my understanding, unresolved.

Thanks,

Lee

ps I look forward to reading Sean's new book. I disagree with him on several key points, but have tremendous admiration for the clarity of his thinking and writing.

20. **Blake Stacey**
August 19, 2019

People are willing to accuse Bohr of all sorts of mean, nasty, horrible things based on second-hand impressions, hearsay and a few overly-recycled quotations. His reputation for being an obscure writer is warranted, but it is also amplified by the unfortunate accident that his highest-profile writing (like his reply to EPR) is much less clear than some lesser-known works (like his contribution to the 1938 Warsaw conference). [Catherine Chevalley](#) adds that the conceptual concerns which motivated Bohr typically hailed from a tradition that is unfamiliar to modern philosophers of physics, and that the questions on Bohr's mind were often *not* those which nowadays go under the name of "quantum foundations." This has naturally led readers to be frustrated with him, simply because they expect something else from a discourse on "the interpretation of quantum mechanics."

21. **Peter Woit**
August 19, 2019

Pascal/Lee Smolin,

Yes, that's true. The textbook/Copenhagen recipe doesn't work for a QM cosmology. On the other hand, given the difficulties one already has with understanding out to get classical emergence in the non-gravitational case, it's not clear that Everett will also solve the much harder problem of how to get a quantum cosmology.

22. **Mateus Araújo**
August 20, 2019

Peter,

"If you ask a follower of Copenhagen (let's call her "Alice") "is the behavior of that spectrometer in your lab governed in principle by the laws of quantum mechanics" I assume that she would say "yes"."

There is divide between old Copenhagen and new Copenhagen in this point. I think it is nicely illustrated by what happened in QUPON 2015:

Časlav Brukner, a good representative of the neo-Copenhagen point of view, gave a talk about how to understand Wigner's friend. He argued that measurements are in fact described by the Schrödinger equation, but that in order to avoid Many-Worlds one needs to understand quantum states as only representations of knowledge of specific observers, not as ontological entities. Moreover, one cannot compare perspectives of different observers.

Right afterwards Anton Zeilinger, aa good representative of the old Copenhagen point of view, and Časlav's former PhD supervisor, gave a talk about something else. He started anyway with a critique of Časlav's talk, and visibly angry he thundered: "The measurement apparatus is classical!".

23. **Lee Smolin**
August 20, 2019

Dear Peter,

I agree. Indeed, since, for me, that there is only one universe follows from the definition of the universe, plus basic principles like the identity of the indiscernible, any argument that applying QM to cosmology requires a many worlds formulation is a reductio ad absurdum.

The correct conclusion, I would argue, is that QM in its current form, cannot be applied to the whole universe, because it is structurally a description of a subsystem of a larger system. What is needed is a completion that gives a complete description of individual phenomena, such as dBB, dynamical collapse models or the real ensemble formulation. Or, something yet to be invented.

Thanks,

Lee

24. **Pascal**
August 20, 2019

As pointed out in some comments, research on decoherence can be viewed as an attempt to recover a classical world from Everett-style QM, that is, from purely unitary evolution.
So it is maybe not surprising that Zurek and Everett had the same thesis adviser (Wheeler).

25. **Pascal**
August 20, 2019

I am confused now because according to Zurek's wikipedia page his thesis advisor was William C. Schieve. But according to Wheeler's, Zurek was a student of his. Maybe Wheeler was a co-advisor?

26. **Arnold Neumaier**
August 23, 2019

I think that the desire to make quantum mechanics apply to the whole universe (as there seems to be no border between classical and quantum mechanics) is the only reason for the popularity of the Everett point of view that there is only unitary evolution of the universe and nothing else. But since the purely unitary view lacks definite concepts for the notion of objective local events and local observers Everett had to introduce other (in my view abstruse) stuff to produce (an appearance of) consequences of the universal evolution that are applicable to the lab – something that textbook quantum mechanics has no problem postulating.

In my recent work I propose a different interpretation of quantum physics, which shares with Everett's view the advantage of having only unitary evolution for the universe. But it avoids the downsides (of ill-defined worlds, splits, events, histories, etc.). This "thermal interpretation" is described in my paper https://arxiv.org/abs/1902.10779 and discussed in further papers accessible from my web site http://www.mat.univie.ac.at/~neum/physfaq/therm/thermalMain.html

These papers form the basis of a book featuring the thermal interpretation of quantum physics that will come out soon:

Something Deeply Hidden

August 20, 2019
Categories: Book Reviews, Multiverse Mania, Quantum Mechanics

Sean Carroll's new (available in stores early September) book, Something Deeply Hidden, is a quite good introduction to issues in the understanding of quantum mechanics, unfortunately wrapped in a book cover and promotional campaign of utter nonsense. Most people won't read much beyond the front flap, where they'll be told:

> Most physicists haven't even recognized the uncomfortable truth: physics has been in crisis since 1927. Quantum mechanics has always had obvious gaps—which have come to be simply ignored. Science popularizers keep telling us how weird it is, how impossible it is to understand. Academics discourage students from working on the "dead end" of quantum foundations. Putting his professional reputation on the line with this audacious yet entirely reasonable book, Carroll says that the crisis can now come to an end. We just have to accept that there is more than one of us in the universe. There are many, many Sean Carrolls. Many of every one of us.

This kind of ridiculous multi-worlds woo is by now rather tired, you can find variants of it in a host of other popular books written over the past 25 years. The great thing about Carroll's book though is that (at least if you buy the hardback) you can tear off the dust jacket, throw it away, and unlike earlier such books, you'll be left with something well-written, and if not "entirely reasonable", at least mostly reasonable.

Carroll gives an unusually lucid explanation of what the standard quantum formalism says, making clear the ways in which it gives a coherent picture of the world, but one quite a bit different than that of classical mechanics. Instead of the usual long discussions of alternatives to QM such as Bohmian mechanics or dynamical collapse, he deals with these expeditiously in a short chapter that appropriately explains the problems with such alternatives. The usual multiverse mania that has overrun particle theory (the cosmological multiverse) is relegated to a short footnote (page 122) which just explains that that is a different topic. String theory gets about half a page (discussed with loop quantum gravity on pages 274-5). While the outrageously untrue statement is made that string theory "makes finite predictions for all physical quantities", there's also the unusually reasonable "While string theory has been somewhat successful in dealing with the technical problems of quantum gravity, it hasn't shed much light on the conceptual problems." AdS/CFT gets a page or so (pages 303-4), with half of it devoted to explaining that its features are specific to AdS space, about which "Alas, it's not the real world." He has this characterization of the situation:

> There's an old joke about the drunk who is looking under a lamppost for his lost keys. When someone asks if he's sure he lost them there, he replies, "Oh no, I lost them somewhere else, but the light is much better over here." In the quantum-gravity game, AdS/CFT is the world's brightest lamppost.

I found Carroll's clear explanations especially useful on topics where I disagree with him, since reading him clarified for me several different issues. I wrote recently here about one of them. I've always been confused about whether I fall in the "Copenhagen/standard textbook interpretation" camp or "Everett" camp, and reading this book got me to better understanding the difference between the two, which I now think to a large degree comes down to what one thinks about the problem of emergence of classical from quantum. Is this a problem that is hopelessly hard or not? Since it seems very hard to me, but I do see that limited progress has been made, I'm sympathetic to both sides of that question. Carroll does at times too much stray into the unfortunate territory of for instance Adam Becker's recent book, which tried to make a morality play out of this difference, with Everett and his followers fighting a revolutionary battle against the anti-progress conservatives Bohr and Heisenberg. But in general he's much less tendentious than Becker, making his discussion much more useful.

The biggest problem I have with the book is the part referenced by the unfortunate material on the front flap. I've never understood why those favoring so-called "Multiple Worlds" start with what seems to me like a perfectly reasonable project, saying they're trying to describe measurement and classical emergence from quantum purely using the bare quantum formalism (states + equation of motion), but then usually start talking about splitting of universes. Deciding that multiple worlds are "real" never seemed to me to be necessary (and I think I'm not the only one who feels this way, evidently Zurek also objects to this). Carroll in various places argues for a multiple world ontology, but never gives a convincing argument. He finally ends up with this explanation (page 234-5):

> The truth is, nothing forces us to think of the wave function as describing multiple worlds, even after decoherence has occurred. We could just talk about the entire wave function as a whole. It's just really helpful to split it up into worlds… characterizing the quantum state in terms of multiple worlds isn't necessary – it just gives us an enormously useful handle on an incredibly complex situation… it is enormously convenient and helpful to do so, and we're allowed to take advantage of this convenience because the individual worlds don't interact with one another.

My problem here is that the whole splitting thing seems to me to lead to all sorts of trouble (how does the splitting occur? what counts as a separate world? what characterizes separate worlds?), so if I'm told I don't need to invoke multiple worlds, why do so? According to Carroll, they're "enormously convenient", but for what (other than for papering over rather than solving a hard problem)?

In general I'd rather avoid discussions of what's "real" and what isn't (e.g. see here) but, if one is going to use the term, I am happy to agree with Carroll's "physicalist" argument that our best description of physical reality is as "real" as it gets, so the quantum state is preeminently "real". The problem with declaring "multiple worlds" to be "real" is that you're now using the word to mean something completely different (one of these worlds is the emergent classical "reality" our brains are creating out of our sense experience). And since the problem here (classical emergence being just part of it) is that you don't understand the relation of these two very different things, any argument about whether another "world" besides ours is "real" or not seems to me hopelessly muddled.

Finally, the last section of the book deals with attempts by Carroll to get "space from Hilbert space", see here, which the cover flap refers to as "His reconciling of quantum mechanics with Einstein's theory of relativity changes, well, everything." The material in the book itself is much more reasonable, with the highly speculative nature of such ideas emphasized. Since Carroll is such a clear writer, reading these chapters helped me understand what he's trying to do and what tools he is using. From everything I know about the deep structure of geometry and quantum theory, his project seems to me highly unlikely to give us the needed insight into the relation of these two subjects, but no reason he shouldn't try. On the other hand, he should ask his publisher to pulp the dust jackets…

Update: Carroll today on Twitter has the following argument from his book for "Many Worlds":

> Once you admit that an electron can be in a superposition of different locations, it follows that person can be in a superposition of having seen the electron in different locations, and indeed that reality as a whole can be in a superposition, and it becomes natural to treat every term in that superposition as a separate "world".

"Becomes natural" isn't much of an argument (faced with a problem, there are "natural" things to do which are just wrong and don't solve the problem). To me, saying one is going to "treat every term in that superposition as a separate "world"" may be natural to you, but it doesn't actually solve any problem, instead creating a host of new ones.

Update: Some places to read more about these issues.

The book Many Worlds?: Everett, Quantum Theory and Reality gathers various essays, including
Simon Saunders, Introduction
David Wallace, Decoherence and Ontology
Adrian Kent, One World Versus Many

David Wallace's book, The Emergent Multiverse.

Blog postings from Jess Riedel here and here.

This from Wojciech Zurek, especially the last section, including parts quoted here.

Comments

1. **jxd**
   August 20, 2019

   The thing that's most bothersome to me about the measurement problem is whether, when I perform a Stern-Gerlach-like measurement that could produce one of two results, there is *anything at all* about the initial state of the universe that determines which result I see. Questions about whether there "really are many worlds out there" seem like they're sort of missing the point; both Everett and Copenhagen seem like different ways of saying "no" to this question, which is what many people (including me) find unsettling regardless of any questions about ontology.

   This leads to something that's confused me for a long time. It's always seemed quite clear to me that the answer to the above question has to be "no" if (i) there is a universal wavefunction that (ii) gives a complete description of the state of the universe and (iii) evolves according to the Schrodinger equation. Some of the conversation around the "emergence of the classical from the quantum" sometimes sounds like it's suggesting that (i-iii) are all true but somehow there ought to be some way to extract a single measurement result from it. Isn't such a project obviously doomed?

2. **Peter Woit**
   August 20, 2019

   jxd,
   I share your confusion, and have never understood how invoking many worlds is supposed to answer this.
   A while ago I wrote something asking a similar question here,
   http://www.math.columbia.edu/~woit/wordpress/?p=10533
   and learned a lot from the discussion. I'm still struck by the fact that, if you include environment + measurement apparatus, you are from the beginning dealing with mixed states and probability.

   But I'd rather not start up again exactly that old discussion, unless someone really has something new to add. I'd be much more interested in hearing or getting references to a more compelling argument for many worlds than the one Carroll provides.

3. **Edward Measure**
   August 21, 2019

   Are you actually talking about the cover of this book or the dust jacket? Tearing off the cover of a book seems pretty drastic, and makes the book a lot harder to hold, read, and shelve.

4. **Pascal**
   August 21, 2019

   Peter, you seem to accept the universal wave function as a description of the "real" state of the universe. Or at least you seem to accept it as plausible. Is that correct? Then I am again confused because I don't see the difference with the MWI, of which you are much more critical.
   Could you clarify the difference between these two positions?

   Also, from what I understand there is not a precise moment in MWI when a splitting "occurs." One can "split" a universal state vectors as the sum of 2 two (or more) vectors by choosing a basis. The 2 vectors can be viewed as the state of 2 parallel universes,
   and by linearity they will evolve independently. Is the issue why or how one basis is better than another to do this decomposition?

5. **Rollo Burgess**
   August 21, 2019

   Hi Peter

   Thanks for your thoughts on Sean Carroll's book. I will get it when it is available; I enjoy SC's podcast and his other writings…

   One question and one suggestion –

   Question – does the book contain lots of equations and mathematics? I ask because if not I will buy it on Kindle, and if so I won't. I really think that publishers should state this: it is outrageous that people sell mathematical books on Kindle (frequently expensively) which are in my experience essentially unusable as mathematical text does not display legibly. (emailing PDFs to Kindle works fine if you don't mind small fonts.)

   Suggestion – when you say that you are interested in references to places that that you can go to see the strongest argument for MWI – have you read The Emergent Multiverse by David Wallace? If not then that is your answer. Do not be put off by somewhat naff title; this is the most serious and sustained presentation out there, and also has a large bibliography. I'm very interested in your take. The issue that you and jxd are discussing seems to be a variant of the concern about where the probabilities come from, which is regarded as the big challenge with MWI. Wallace and the other 'Oxford' school' MWI people have a decision-theoretic argument which purports to address this. I have philosophical doubts about this argument but frankly, as someone who did physics only to UK GCSE and Maths to A-level and has recreationally self-studied beyond that I feel it is appropriate to be somewhat humble in my assessment of the arguments of trained professionals!

6. **Mateus Araújo**
   August 21, 2019

   Peter,

   I'm afraid you misunderstood Carroll's explanation on pages 234-5. He is saying that the alternative to having multiple worlds is needing to deal with the whole universal wavefunction. That doesn't give you a simple single-world ontology as one would want, but a hideously complex object that is nothing like a classical ontology. The most classical single-worldy ontology we can have (ironically enough) is precisely the one where we split the universal wavefunction into worlds.

   The issue here is that the fundamental ontology is the universal wavefunction, the worlds are a subjectively-defined emergent ontology that we use to connect physics to our everyday experience.

   An analogy would be to think of the universal wavefunction as a tree, and the worlds as the branches. Nothing forces us to think of the tree as being composed of branches, and in fact they are only an emergent ontology. They are not well-defined either, we can't really say where one branch begins and another ends. In fact there is only a tree made up of cells. It's just that it's very useful to talk about the branches, so we do that.

(Yes, trees are also only emergent ontology, I hope the idea comes through anyway).

7. **Amitabh Lath**
   August 21, 2019

   What does the multiverse mean in the "it from qubit" picture? If states+entanglement is everything (including the detector and the system being detected), and space and time are just how we experience this entanglement (spacetime "emerges" from entanglement); then what sense does it make to create other instances of spacetime?

8. **Nakagawa**
   August 21, 2019

   If the Everettian argument is valid, one solid consequence is that the initial one-World postulate for the argument is unphysical, since we have already been cohabiting with a vast number of mutually decoherent Worlds. When the initial postulate of the Everettian argument is replaced with the vast number of mutually decoherent Worlds, contingent interferences with each of decoherent Worlds may as a whole become significant, and I suspect decoherence only slightly outperforms recoherence. (Or, is there any convincing argument over the everlasting predominance of decoherence?) If so, wavefunction collapse-like phenomena will frequently occur by the recoherence effect.
   When we encounter an apparent wavefunction collapse, Everettians say it's caused by world-branching, but it should be explained either by branching or merging of a world, and there is no way to decide which really occurred…

9. **Peter Woit**
   August 21, 2019

   Edward Measure,
   Thanks! When I wrote that I knew "cover" wasn't the word I wanted, planned to go back to fix, forgot. Now done.

10. **Stephane**
    August 21, 2019

    Dear Peter,
    Are you going to review also the recent book by Smolin "Einstein's Unfinished Revolution: The Search for What Lies Beyond the Quantum"?

    I shall say that I much prefer what Jürg Fröhlich and colleagues are doing recently on quantum foundations (eg, https://arxiv.org/abs/1905.06603) rather than the Everettian approached favored mainly by cosmologists by considering that, instead of having a unique outcome from an experiment, all are realized (but only one in our Universe)…

11. **Peter Woit**
    August 21, 2019

    Pascal,

    1. I'm willing to consider the wavefunction of the universe, and use the word "real" to describe it (let's call this "real-psi"). I do worry though that maybe it makes no sense to consider it to be a pure state, that it is always a mixed state.
    2. In principle, one expects to somehow identify an emergent classical world corresponding to what we observe in this wavefunction. This is "real" in a different sense (the every day sense), let's call it "real-classical".

    MWI enthusiasts make what to me seems to be the following argument. One expects that if there is one emergent classical world in the wave-function, there will be lots. Since I've agreed that the one we're in is "real-classical", and the other emergent classical worlds are part of the same "real-psi" wave function, they must also be "real-classical". I don't see how this follows. To be fair to Carroll, he doesn't exactly say this. As quoted in the posting, he's aware that these are two different versions of "real", so you can't argue that one implies the other. So, I'm not "forced" by logic to agree to the "reality" of these supposed other worlds, and I don't see how agreeing to this solves any problem or does anything other than confuse the situation.

    The problem with the "split" picture you give is that it doesn't address at all the real problem of classical emergence. The best worked out theory of classical emergence that I'm aware of is Zurek's, and as far as I can tell he also rejects 2 above while agreeing to 1 (he describes himself as an "Everettian", see no need to describe other possible emergent classical worlds as real).

12. **Peter Woit**
    August 21, 2019

    Rollo Burgess,
    No equations in the book.

    Yes, I've tried reading the Wallace book, it is the most comprehensive and serious attempt at justifying the MWI picture. I didn't find anything convincing there on why multiple worlds must be described as "real", but was willing to believe there was a solid argument somewhere amidst the masses of material about probability and decision theory. One reason I like Carroll's book is that he writes and argues clearly, so you can easily follow the argument, see what he has and whether you agree or see a reason to disagree. It's in principle possible that Wallace has a convincing argument that Carroll just decided not to present, but one wonders whether that's really plausible.

    One thing I didn't get around to doing was adding links to the best sources I'm aware of for serious discussions of these issues, will try to do that soon.

13. **Peter Woit**
    August 21, 2019

    Mateus Araujo,
    I do understand that that's the point Carroll was trying to make, and shouldn't have been so flippant about "convenience". My point was just that, as you and Carroll both recognize, when you move from the universal wave function to supposed emergent classical worlds, you're discussing a very different sorts of ontology. Especially since I don't see any convincing theory of these "branches", I don't see why I have to use them to build my emergent ontology.

14. **Peter Woit**
    August 21, 2019

    Amitabh Lath,

I think what Carroll is doing is basically announcing that, in a fixed space-time, the problem of classical emergence is solved by MWI (except for an ongoing mopping up operation), and he's moving ahead to also get the space-time geometry as emergent out of a pure quantum system.

The first problem for me is that I don't think the original problem is solved. And that's a problem where you know exactly what the quantum system is (conventional textbook Schrodinger equation). But, much more seriously, I think the emergent space-time program suffers from the problem of "emergence from what?". Basically people doing string theory unification have given up, now are announcing that they will stop thinking about what the underlying theory is, and will derive our world as emergent from some unknown quantum theory ("it from unknown qu-something"). I don't see how they're going to get something from nothing here…

15. **Peter Woit**
August 21, 2019

Stephane,
I don't think I'll write a review of the Smolin book, don't really have anything interesting to say about it. As I've mentioned many times, I'm just not convinced by the point of view of Smolin and many others that what we don't understand about QM indicates the need for fundamental new physics. In the case of the Carroll book, I share his basic starting point (that what we know about the world should follow, emergently, from the known QM formalism).

About the "ETH-Approach to Quantum Mechanics", that just seems to me to be one of many sorts of programs which don't address the basic problem, that of understanding classical emergence.

16. **Mateus Araújo**
August 21, 2019

Peter,

I wouldn't use the word "moving". The fundamental ontology stays the same, it's always the universal wavefunction.

But I'm very confused. Are you saying that you accept the universal wavefunction as fundamental ontology, but that you think that this is somehow compatible with a single-world emergent ontology? How? How can you even single out one of the branches as "real"? They are the same, physically speaking. Or are you saying that the universal wavefunction doesn't have a branching structure? As far as I'm aware this point is not controversial – that decoherence splits the wavefunction into quasi-classical worlds that have effectively independent time evolution – and that people that reject Many-Worlds they also reject the universal wavefunction.

17. **Blake Stacey**
August 21, 2019

Steven Giddings had a criticism a little while ago of the "spacetime from entanglement" business which sounds about right to me. Basically, in order to define the kind of quantity that program wishes to build spacetime out of, you first have to introduce a structure very like what you're trying to explain.

> For example, one proposal is that spacetime "emerges from entanglement." However, a notion of entanglement relies, first, on a notion of division of a system into subsystems; it may be easily illustrated that for a given quantum state, different such divisions lead to either zero or nonzero entanglement. Related comments apply to entropies based on entanglement. Transfer of information, or entanglement, also requires division into subsystems between which transfer occurs.

(arXiv:1803.04973)

18. **Peter Woit**
August 21, 2019

Mateus Araujo,
Part of the problem here is that I don't believe anyone understands how emergence really works, so what the "branches" are, or what it even means to identify one branch as our own. I'd be much more willing to believe there could be a sensible argument for relative "emergent reality" of our branch and other branches if I felt I knew what the two different things actually were. I still don't see why accepting "reality-psi" of the wavefunction means I have to accept "reality-classical" of supposed branches that don't have anything to do with our "reality-classical".

I've found the place where Zurek, discusses this, see the last section of
https://arxiv.org/abs/0707.2832
which starts off
"There are two key ideas in Everett's writings. The first one is to let quantum theory dictate its own interpretation. We took this "let quantum be quantum" point very seriously. The second message (that often dominates in popular accounts) is the Many Worlds mythology. In contrast "let quantum be quantum" it is less clear what it means, so – in the opinion of this author – there is less reason to take it at face value."
and in "Closing remarks" there is
"It is therefore not clear whether one is forced to attribute "reality" to all of the branches of the universal state vector. Indeed, such view combines a very quantum idea of a state in the Hilbert space with a very classical literal ontic interpretation of that concept. These two views of the state are incompatible. As we have emphasized, unknown quantum state cannot be found out. It can acquire objective existence only by "advertising itself" in the environment. This is obviously impossible for universal state vector – the Universe has no environment."

19. **Peter Shor**
August 21, 2019

jxd:

If we could predict the measurement results we would get if we measured one element of an EPR pair, we would probably be able to transmit information faster than light (although this may depend on the exact model we're using on for how to predict these results).

Of course, this doesn't mean that the measurement results aren't predictable from aspects of the universe that are hidden somewhere that we can't get at. In fact, I think Bohm's pilot wave interpretation (which unfortunately has other problems) has this property.

20. **Mateus Araújo**
August 21, 2019

Peter,

"I still don't see why accepting "reality-psi" of the wavefunction means I have to accept "reality-classical" of supposed branches that don't have anything to do with our "reality-classical"."

Because there's nothing singling out any particular branch as physical, so it's not tenable to accept the branching picture but deny the reality of the "other" branches. Even if you define your current branch as the real one, it will split over and over again, with nothing distinguishing the future branches physically.

Incidentally, the Bohmians do have a single-world reality and a universal wavefunction, precisely by postulating these Bohmian particles that give reality to one branch of the wavefunction but not others. This is what it takes.

"Part of the problem here is that I don't believe anyone understands how emergence really works, so what the "branches" are, or what it even means to identify one branch as our own. I'd be much more willing to believe there could be a sensible argument for relative "emergent reality" of our branch and other branches if I felt I knew what the two different things actually were."

I'm not sure what your question is. The splitting part is the old story of decoherence, pointer states, quantum Darwinism. The "emergent" part is the arbitrary decision of when two branches have decohered enough so that their future evolution can be treated independently, and one can use the projection postulate to safely cut of other branches and focus on one's own.

21. **jxd**
August 21, 2019

I've always thought of the problem with trying to extract a single classical world from an Everettian picture as one of symmetry more than anything else. If the wavefunction of the universe can be written as a sum of two terms that don't interfere with each other and each term describes one of the two possible measurement results, you can't pick out one of them as "the one that really happened" without introducing some extra structure to this whole picture; there's nothing that could make one of them more "special" than the other. (And not introducing any extra structure is the whole point of the Everettian program!) The many-worlds move is to just accept this state of affairs and say, fine, then they both "really happened." This is the strange bit; whether you want to use the word "world" to describe them doesn't really matter.

Peter Shor: Yes, I think I agree, and that that's what I was getting at. The question I posed — whether there's anything about the initial state of the universe that determines which measurement result I get — is definitely an interpretation-dependent one. Everett and Copenhagen say no, Bohm (to the extent that it works) says yes.

The reason I'm confused is that some authors seem to want to extract a "yes" from unitary, collapse-free quantum mechanics with a universal wavefunction as the ultimate ontological description of reality, which seems obviously impossible to me. It would be lovely if this could happen, but as Mateus Araújo says I think it's pretty uncontroversial that it can't. This leaves you with either answering "no" to the above question or dropping one of the assumptions that got you there.

22. **Peter Woit**
August 21, 2019

Mateus Araujo,
I'm just not convinced that the cartoon structure of the quantum state space as divided into "branches", with us just characterized by a position on a branch actually captures what is going on. Part of this is skepticism that the picture of pointer states and quantum Darwinism is a complete understood answer to the classical emergence problem, neatly characterized by branches.

But also I have trouble with the idea that we're just a point on a branch. Remember that I find myself somewhere in between Copenhagen/textbook and Everett and note that Zurek claims (in the article linked to above) "One might regard states as purely epistemic (as did Bohr) or attribute to them "existence". Technical results described above suggest that the truth lies somewhere between these two extremes."

It is a basic fact about the state of the world as we see it that we can't characterize it as a pure state. As far as we can ever know, our world is at best some mixed state about which we have inherently limited information. Even in a purely classical world, I would be free to, given my limited information, decide to count as real worlds all trajectories consistent with that information, but that's not necessarily a good idea. The quantum situation is different, with limitations of information ones of principle, but still.

23. **Carlos Ungil**
August 21, 2019

What would a mixed state for the universe mean? A universal wavefunction would describe a pure state. We could have a proper mixture instead but that is usually understood to reflect our "classical" ignorance about the true quantum state (like in the case of an ensemble of systems where we only have statistical knowledge of their individual states); it is not really a fundamental property of the system.

24. **Pascal**
August 21, 2019

I am on the same page as Mateus and (I think) jxd. But I have a small quibble with one sentence in the comment by jxd:

"If the wavefunction of the universe can be written as a sum of two terms that don't interfere…"

By linearity of evolution, if you write the universal state vector Psi as Psi_1+Psi_2
the we have U(Psi) = U(Psi_1) + U(Psi_2), i.e., the 2 universes evolve "independently"
for *any* choice of the decomposition Psi = Psi_1+Psi_2. This means that "non inteference" is not a useful criterion to decide on which way to split Psi.
I think non-interference is a notion which makes sense only in the setting of
QM+projection postulate and not in purely linear QM.

25. **Mateus Araújo**
August 21, 2019

Peter,

"It is a basic fact about the state of the world as we see it that we can't characterize it as a pure state. As far as we can ever know, our world is at best some mixed state about which we have inherently limited information. Even in a purely classical world, I would be free to, given my limited information, decide to count as real worlds all trajectories consistent with that information, but that's not necessarily a good idea. The quantum situation is different, with limitations of information ones of principle, but still."

You are making the usual map-territory confusion. A mixed state is a description of your ignorance, not of what the world is. All our fundamental theories are formulated in terms of pure states; mixed states are introduced as derived concept, either to describe the statistics from local measurements on an entangled state, or to make probabilistic assignments of (pure) states to a not fully known system. The world itself is in a pure state, our ignorance of it doesn't make a difference.

"But also I have trouble with the idea that we're just a point on a branch. Remember that I find myself somewhere in between Copenhagen/textbook and Everett and note that Zurek claims (in the article linked to above) "One might regard states as purely epistemic (as did Bohr) or attribute to them "existence". Technical results described above suggest that the truth lies somewhere between these two extremes.””

Żurek’s statement makes no sense. Quantum states are either ontic or epistemic, the is no middle ground where to compromise. And the epistemicist program has taken quite a beating throughout history, I might add.

“I’m just not convinced that the cartoon structure of the quantum state space as divided into “branches”, with us just characterized by a position on a branch actually captures what is going on. Part of this is skepticism that the picture of pointer states and quantum Darwinism is a complete understood answer to the classical emergence problem, neatly characterized by branches.”

Well, that’s just the best we got. Sure, as all theories it is limited and subject to change, but until we find something better that’s what I’m going with.

26. **Blake Stacey**

Glitch notification: There’s an extraneous “~woit/wordpress/?p=11128#comments” just after the second blockquote.

27. **Peter Woit**
August 21, 2019

Carlos Ungil,
Sorry, I think my reference to a “mixed state” and universal wave function in that response to Pascal was confused, best to ignore that.

28. **Peter Woit**
August 21, 2019

Blake Stacey,
Thanks, fixed.

Mateus Araujo,
Thanks! Right now, while I have learned a lot, all of this is causing my brain to hurt, and I have other things to do, may or may not find time soon to think some more. I do wish someone could get Zurek to say more about this. He’s thought deeply about what seems to me the core of the problem, but the thing I quoted is one of the few places he has written about why he is skeptical about “Many Worlds” (in some other places he refers to this one).

29. **Mateus Araújo**
August 21, 2019

Pascal,

This is a point that often confuses people. The situation you describe is precisely one where the terms do interfere, and do not evolve independently. Let |0> be the upper path of an interferometer, and |1> the lower path. Then if the photon is in the state |0> + |1>, and passes through a beam splitter, the effect is H|0> + H|1> = |0>, the paradigmatic case of interference.

Now suppose we made a (non-demolition) measurement on the photon, entangling its position with the outside world |W>, ending up with the state |0>|W_0> + |1>|W_1>. Now these terms do not interfere anymore (as long as |W_0> and |W_1> are orthogonal), meaning that any whichever unitaries U,V one applies to the photon, getting U|0>|W_0> + V|1>|W_1>, will not make one term disappear as in the example above. In fact the evolution of both terms is now completely independent of each other.

An interference is only possible if one acts with an entangling unitary on the whole system at once. For a large enough system this is practically impossible, so it is far to regard |0>|W_0> + |1>|W_1> as a sum of two terms that don’t interfere.

30. **David Miller**
August 22, 2019

There is a basic problem with the idea of “branching” that is too rarely mentioned. The number of brnaches really cannot ever change, simply as a consequence of unitarity. There are never “new” branches. In some sense, the universe is just static, and the psi function and, indirectly, probability just sloshes around among the eternal branches.

All of us take this for granted when we do actual QM problems: e.g., resolving the spin of an eletron along different axes. But, somehow life gets more romantic when people think about MWI in the large.

David Deutsch takes this to its logical conclusion where there is no time either (try to do MWI in GR: the “problem of time” hits you). So, there is, Deutsch has said, just one eternal unchanging wave function with no actual time at all.

Like Peter, this makes my head hurt. Enough that I am willing to consider the possibility that just maybe QM is not the last word.

31. **Mateus Araújo**
August 22, 2019

Peter,

I’m glad you enjoyed the discussion. I think Żurek’s relative silence about this is because he doesn’t find Many-Worlds so objectionable. As he put it in his contribution to the “Many Worlds?” volume, his results “fit well within Everett’s relative states framework, but do not require ‘many worlds’ per se”.

32. **Anonyrat**
August 22, 2019

Mateus, is this table in wiki comparing QM interpretations accurate? It seems roughly split evenly between real wavefunction and not.
https://en.wikipedia.org/wiki/Interpretations_of_quantum_mechanics#Comparison

33. **Anonyrat**
August 22, 2019

All our fundamental theories are formulated in terms of pure states; mixed states are introduced as derived concept, either to describe the statistics from local measurements on an entangled state, or to make probabilistic assignments of (pure) states to a not fully known system. The world itself is in a pure state, our ignorance of it doesn’t make a difference.

I would argue that we formulate our theories in the simplest possible terms, which is why we formulate it in terms of pure states, but we simply don't know if the world is a pure state or not. Since the mathematical formalism works just as well either way, and since there is no experimental way to determine whether the world is in a pure state or not, "the world is in a pure state" is not a scientific statement.

34. **Will Sawin**
August 22, 2019

I think the issue is that a theory that describes

(1) the state of the world and
(2) what an observer observes at a particular time

is fundamentally incomplete. It also needs to explain

(3) how many, and which, observers exist.

Otherwise we would not be able to explain why any observers exist at all, nor why we find ourselves on Earth instead of on another planet or in empty space, nor answer whether other humans feel pain as we do.

If you accept that the universal wave function satisfying unitary evolution is fundamental, and everything else must derive from this, then you run into a problem with quantum measurements. It's alright to say that an observer, me, exists, and after performing the experiment, I either observed outcome 1 with 60% probability or observed outcome 2 with 40% probability. The problem is that there is nothing in the wave function to distinguish the observer who observed outcome 1 from the observer who observed outcome 2. So if one exists, then both must exist.

If you accept that both exists then I think you essentially accept many worlds. If before performing the experiment there are two scientists Alice and Bob, and afterwards there are Alice-1 and Bob-1 who both observed Outcome 1, and then observed each other discussing it, writing it down, etc., and also Alice-2 and Bob-2 who both observed Outcome 2. etc. etc., then it seems fair to say that Alice-1 and Bob-1 are in some kind of world together and Alice-2 and Bob-2 are in a different world together.

To believe that Alice-1 exists but not Alice-2 you have to believe in some extra information beyond the wave function that helps determine which observers exist. If you want to believe that Alice-1 and Bob-1 exist but not Alice-2 and Bob-2, or vice versa, but never any other combination, it seems like you have to believe in something like objective collapse or Bohmian mechanics.

35. **Mateus Araújo**
August 22, 2019

Anonyrat,

Yes, I think the Wikipedia table is roughly accurate. What's your point, though? Nobody is disputing that there are interpretations that consider the wavefunction to be real and interpretations that do not.

"I would argue that we formulate our theories in the simplest possible terms, which is why we formulate it in terms of pure states, but we simply don't know if the world is a pure state or not. Since the mathematical formalism works just as well either way, and since there is no experimental way to determine whether the world is in a pure state or not, "the world is in a pure state" is not a scientific statement."

So you want to ignore the historical development of our theories, and the fact that mixed states were introduced explicitly to be linear on the probabilities, to consider whether mixed states might be fundamental?

Fine, it is mathematically possible. It doesn't change the fact that the mixedness that Peter was talking about – the one caused by our ignorance of the precise state and environment – is explicitly a property of the observer, not of the world. Again, map versus territory.

And what if we still end up with a mixed state after removing this subjective mixedness? As you say, there is no experimental way to test whether the state of the universe is pure or mixed. We might as well use Occam's razor and take it to be pure.

36. **jxd**
August 22, 2019

I really appreciate the conversation this post has generated; it's clarified my thinking on a lot of these interpretation questions. I'm trained as a mathematician, not a physicist, and maybe relatedly I can sometimes find these questions really exasperating to read about. Over and over I've had the experience of reading some paragraph that purports to be explaining someone's favorite interpretation of quantum mechanics and realizing at the end that the paragraph didn't contain any content at all that I could meaningfully extract. (Żurek's discussion of what he thinks the wavefunction means is a good example.)

I especially feel this way about the epistemic interpretations I've tried to read about; I understand that they want to interpret the wavefunction as an expression of someone's knowledge, but I can never tell what this knowledge is supposed to be knowledge *of*. I know this might be off-topic, but can anyone point to a clear exposition of one of these approaches?

"… an electron can be in a superposition of different locations …" – Sure.

"… it follows that person can be in a superposition of having seen the electron in different locations …" – Maybe.

" … that reality as a whole can be in a superposition …" – Doesn't follow at all.

" … it becomes natural to treat every term in that superposition as a separate 'world'." – Really? In what world?

39. **Soup**
August 23, 2019

jxd,

You might enjoy this review by Matt Leifer: arXiv:1409.1570. He gives some toy models of what the "ontic states" might look like in a psi-epistemic theory i.e. what objective reality the wavefunction is supposed to encode knowledge about. They don't reproduce ordinary quantum mechanics though (well except for the trivial one ontic states = vectors in Hilbert space).

Realist psi-epistemic theories are awkward but it's interesting to see if they are possible. Personally, studying them has pushed me further towards a realist interpretation of the wavefunction.

40. **Mateus Araújo**
August 23, 2019

jxd,

The standard reference about epistemic versus ontic states is Harrigan and Spekkens. I find it quite clear.

People sometimes confuse epistemic quantum states with subjective quantum states. The former represents an observer's (lack of) knowledge about an underlying reality. The latter represents an observer's beliefs, without connection to an underlying reality. It is the point of view of QBism and similar subjectivist interpretations.

41. **Anonyrat**
August 23, 2019

So you want to ignore the historical development of our theories, and the fact that mixed states were introduced explicitly to be linear on the probabilities, to consider whether mixed states might be fundamental?

I fail to see how the historical development of our theories tells us anything about the subject of our theories, unless the history of the theory is part of the subject of the theory. Presumably if it is a good theory then some other culture/civilization/AI/alien species will arrive at the theory (or one isomorphic to it) with an entirely different history.

As you say, there is no experimental way to test whether the state of the universe is pure or mixed. We might as well use Occam's razor and take it to be pure.

Occam's razor would say, don't state an assumption either way. E.g., if there is no experimental way to determine whether God exists or not, Occam's razor says don't include God in your theory, and not "Might as well assume God exists" or "Might as well assume God does not exist".

42. **Anonyrat**
August 23, 2019

Just to draw your attention to a table of QM interpretations in A. Cabello. Interpretations of quantum theory: A map of madness. arXiv:1509.04711 and a Venn diagram (Figure 1.1) in J.B. Ruebeck, Understanding sequential measurements in psi-epistemic ontological models (https://uwspace.uwaterloo.ca/bitstream/handle/10012/14845/Ruebeck_Joshua.pdf?sequence=3)

It corrected my misimpression that psi-ontic and psi-epistemic was a complete classification of QM interpretations.

43. **Peter Woit**
August 23, 2019

Mateus Araújo,
The discussion here has been illuminating, causing the following evolution in my thinking:
1. When I wrote this posting I saw no problem with accepting the "universal wave-function" as what you get if you ask what is the description of the state of the world given by our best theory, QM. Now I realize that there's a big jump from what we know QM says about the world (which includes the fact we can't ever know the state of the world, so don't know if it is described by a pure state) to postulating a universal pure state wavefunction.
2. I remain confused about how the idea of multiple classical "worlds" is supposed to work and explain anything. What would really explain things is a detailed understanding of classical emergence. The best effort towards that I can find is the program of working to understand decoherence, the preferred basis problem and perhaps quantum Darwinism. Do the results of this program imply the "reality" of many worlds? Since I don't understand exactly how this is all supposed to work, I can't tell. That Carroll and most "Many Worlders" don't address this and seem rather uninterested in the details of classical emergence, while Zurek, who is interested , calls Many Worlds "mythology" doesn't encourage me towards the "Many Worlds are real" view.

In particular, Carroll only deals with the preferred basis/pointer state question in a single sentence (page 244-45): "the preferred-basis states are those that describe coherent objects in space, because such objects interact consistently with their environments." I'm not sure what this means, and he gives no references for it, not even a reference explaining what the "preferred basis" problem is. Among the many references in the book to more technical material, the only relevant one to classical emergence is to Zeh's 1970 decoherence paper (there are several attempts to derive the Born rule referenced, including Carroll's own).

As far as I can tell, Carroll's interest in the preferred basis problem is limited to the argument that the fact that interactions are local in space makes the position-space basis distinguished. I guess it is this that he wants to claim as somehow important for his attempt to find a theory of quantum gravity by identifying space inside a more generic quantum system (his version of "it from qubit"). As mentioned in the posting, I don't see any evidence you can do this with the tools and concepts available.

44. **Pascal**
August 24, 2019

Mateus, I am still not sure what "interference" means in this context since my point that U(Psi_1+Psi_2)=U(Psi_1)+U(Psi_2) for any Psi_1, Psi_2 is certainly valid. Instead I propose the following toy model.

The state space is a finite dimensional Hilbert state and the unitary U represents time evolution (time is discrete; for continuous time we would need an infinite dimensional Hilbert space).
The goal is to single out some "classical states" or in another terminology a "preferred basis".
We would like these states to enjoy some kind of stability property under the action of U.
So I propose that in a preferred basis, U should be simply (maybe up to a phase) a permutation matrix. "Up to a phase" means that the entries of the permutation matrix may be multiplied by arbitrary complex numbers of modulus 1.
This is a model of a cyclic universe: after a while we come back (up to a phase) to our initial state.
In this setting a "preferred basis" will be an orthonormal basis in which U becomes (up to a phase) a permutation matrix. This is a non-trivial constraint: not all bases satisfy this property.

This is unfortunately not enough to single out a unique “preferred basis”. For instance, given any permutation matrix one can always (like for any unitary) choose a basis of eigenvectors,
And if the initial state is an eigenvector there will be (up to a phase) no time evolution at all!
I will hazard the suggestion that the only way to single out a unique “preferred basis” may lie in the initial condition of the universe (which would be an element of that basis).
Again, there is no escaping the fact that if we start from an eigenstate there is no time evolution at all. But if we decompose the eigenvector in another of these “preferred bases” we may obtain a superposition of “universes”, each enjoying some time evolution even though there is no global time evolution in the multiverse (whose state is the eigenvector, if you have followed me up to this point).

Does this look like something that has been studied in decoherence or MWI ?

45. **Mateus Araújo**
August 24, 2019

Anonyrat,

“I fail to see how the historical development of our theories tells us anything about the subject of our theories, unless the history of the theory is part of the subject of the theory. Presumably if it is a good theory then some other culture/civilization/AI/alien species will arrive at the theory (or one isomorphic to it) with an entirely different history.”

It is important. We take seriously conjectures that are well-motivated, not conjectures whose only thing going for it is that “it hasn’t been proven false”.

“Occam’s razor would say, don’t state an assumption either way. E.g., if there is no experimental way to determine whether God exists or not, Occam’s razor says don’t include God in your theory, and not “Might as well assume God exists” or “Might as well assume God does not exist”.”

Not, Anonyrat, Russell’s teapot is just not there. We are not respectfully agnostic about unfalsifiable hypotheses, we mercilessly eliminate extraneous entities. And a state of the for |\psi> is much simpler than a state of the form p|\psi><\psi'|.

"Just to draw your attention to a table of QM interpretations in A. Cabello. Interpretations of quantum theory: A map of madness. arXiv:1509.04711 and a Venn diagram (Figure 1.1) in J.B. Ruebeck, Understanding sequential measurements in psi-epistemic ontological models (https://uwspace.uwaterloo.ca/bitstream/handle/10012/14845/Ruebeck_Joshua.pdf?sequence=3)

It corrected my misimpression that psi-ontic and psi-epistemic was a complete classification of QM interpretations."

Yeah, you can always reject an objective reality, and then anything goes. There's also no point in talking about it.

46. **Mateus Araújo**
August 24, 2019

Peter,

1 – I don’t see what’s the point of this discussion about whether the quantum state of the universe is pure or mixed. You still have many worlds either way, the important thing is that there is a quantum state for the whole universe.

2 – It’s not as if many worlds are postulated to explain anything, rather they are the consequence of applying the laws of quantum mechanics to the whole universe.

47. **Paddy**
August 24, 2019

Peter, Re Many Worlds vs Decoherence:

Everett’s starting point was von Neumann’s analysis of measurement in his Grundlagen. According to von Neumann, a “measurement” is a physical process that converts a pure quantum state into a mixed state. Pretty clearly von Neumann is thinking here of QM as a description of ensembles, and arguably this is nothing more than a mathematised version of the Born rule. The evidence for the Born rule, of course, is the fact that measurements on quantum systems give definite results, even when the original state is known to be in a superposition*, and after the measurement no further superposition can be demonstrated (or, per the analysis in the Feynman lectures, if you *can* demonstrate superposition you have not really made a measurement).

Everett applies von Neumann’s analysis to a single quantum system, and in effect asks: how should we interpret the plus signs when we write out the mixture as a sum (or integral) of terms corresponding to particular outcomes? Should we read “plus” as “and” or as “or”? Conventional QM goes for “or” but MWI goes for “and”, and it is hard to argue that this is not the only consistent interpretation of the mathematics.

A decade after Everett, decoherence theory explained in some detail how measurement-like processes, that is, interactions with “environments” containing a macroscopic number of degrees of freedom, could indeed convert a pure state into a state that effectively acts as a mixture, once the environmental degrees of freedom are traced out. Given the practical impossibility of designing an apparatus that took the environment into account in full detail, Zurek in particular claimed at the time that this “solved” the measurement problem and provided a complete interpretation of QM. However, it does not at all address the “and/or” question for mixtures and I believe that Zurek’s views have evolved over time on this. Most MWI people are very grateful to decoherence theory for providing a detailed account of “branching”, but would argue that we always knew that branching must take place thanks to the existence of our perceived classical world. And if you have every tried to explain decoherence at a popular level (or even to advanced undergraduates), you would have sympathy with Carroll for not delving into this in depth.

* Superposition of eigenstates of whatever is being measured.

48. **Peter Woit**
August 24, 2019

Paddy,
I don’t object to Carroll’s decision not to discuss decoherence theory in detail. In a popular book one’s ability to discuss more technical issues is very limited. My reference was to the very specific issue of the “preferred basis” problem. Note that he’s doing something very questionable with this book: he moves on from the old claim that MWI solves interpretational problems to the claim that it somehow is involved in telling you how to reconcile QM and GR. The hinge of this argument is that the “preferred basis” is the space coordinate basis,. Because this is both a huge problem for MWI and at the center of his argument, some sort of reference backing it up would have been a good idea.

I started looking a bit at how the MWI people treat the preferred basis problem, specifically at David Wallace’s discussion of it, and it seems to me that there’s not much argument besides the assumption that however classical emergence happens, it solves the problem. This is where I have a problem with Mateus’s point number 2. Besides Zurek, I just am not finding places where MWI people actually come to grips with classical emergence (in particular the preferred basis aspect of it), so the argument that the way classical emergence happens implies Many Worlds seems to me possibly empty.

49. **Paddy**
August 24, 2019

Peter,
I agree that Zurek seems to have put more serious work into the preferred basis problem than anyone else I know of. To be honest, I have not read his work on this point with enough care to claim that I fully understand how einselection is supposed to work, but I have extracted the idea that states expressed in certain bases are relatively stable because of the way the corresponding operators feature in the Hamiltonian, which seems extremely plausible (also, it sounds like what Carroll is referring to in the sentence you quote). If true it solves one of the two deep problems for MWI, the other being the probability issue, which I guess is why Wallace's book focuses on that.

50. **Charles Rezk**
August 24, 2019

I'm no expert on any of this, but I just want to comment on:

"A mixed state is a description of your ignorance, not of what the world is. All our fundamental theories are formulated in terms of pure states; mixed states are introduced as derived concept, either to describe the statistics from local measurements on an entangled state, or to make probabilistic assignments of (pure) states to a not fully known system."

This kind of glib statement is repeated everywhere. But I don't see how matters can be that simple.

If pure states are a description of the world, and mixed states just a description of incomplete knowledge, then we would model mixed states by *probability measures on the space of pure states*. Instead, mixed states are modelled by density operators: but there are infinitely many probability measure which give the same density operator. (E.g., for the qubit, the space of density matrices is a 3 dimensional ball, but the space of probability measures on pure states (a 2 sphere) is infinite.)

It seems to be a magical property of QM that for practical purposes almost all of the information about our incomplete knowledge can be ignored, and we can work entirely with mixed states (density operators). This seems like something which deserves an explanation in any account of an interpretation of quantum mechanics.

Of course, one way to respond to this is to suppose that there is something incomplete in our understanding of QM, which I think is a point of view Penrose takes in some of his big weird books.

It seems more economical to just suppose that mixed states can be a description of the world, exactly on par with pure states, a point of view which seems supported by the fact that the mathematical description of QM is at least as clean (if not cleaner) using mixed states as it is using pure states. Does anything go wrong if we just suppose that the world can be described by mixed states? I don't see how.

51. **jxd**
August 24, 2019

I may be misunderstanding the question, but I don't think you need any complicated explanation of classical emergence from the quantum in order to extract the many-worlds picture, provided you believe that the universe is completely described by a quantum state and that Schrödinger's equation describes how it evolves. It falls out of the linearity, right? If the environment starts in some state psi_E and the thing you're measuring has a state that lives in some other small Hilbert space, then the state that (1/sqrt(2))((psi_1 + psi_2) tensor psi_E) evolves into has to be a linear combination of the states that (psi_1 tensor psi_E) and (psi_2 tensor psi_E) evolve into, hence the macroscopic superposition.

I can see how you might *believe* these assumptions more readily if they were coupled with a good description of why macroscopic stuff looks classical; if this part of the story were somehow broken, there would be more of a reason to suspect that quantum mechanics needs to be modified. (Is this all you're saying?) But it seems pretty straightforward that the Everettian picture is what these assumptions imply.

Now, the many-worlds story comes from taking a physical model that performs very well in all the domains where we've tested it and inferring that it must also apply to the whole universe, a domain in which we very much have not tested it (whatever that would even mean). I don't think it's totally unreasonable to balk at the many worlds and conclude that it's a sign that the standard QM story must be missing something. But (a) there doesn't seem to be any experimental evidence for such a thing, and (b) I don't think there's a great theoretical candidate for what missing thing we could add that would solve the problem convincingly.

52. **Blake Stacey**
August 24, 2019

jxd,

The "Map of Madness" mentioned above (arXiv:1509.04711) does a pretty good job of finding what one might consider "canonical" sources for the various interpretations it tabulates.

53. **Mateus Araújo**
August 24, 2019

Charles Rezk,

"It seems to be a magical property of QM that for practical purposes almost all of the information about our incomplete knowledge can be ignored, and we can work entirely with mixed states (density operators). This seems like something which deserves an explanation in any account of an interpretation of quantum mechanics."

That is an excelent point. There is, however, an explanation. If you use true randomness to prepare your ensembles, and model the preparation procedures in the Many-Worlds way, then any two preparation procedures that result in the same density matrix for subsystem A must be related by a unitary transformation in subsystem B. Then it is clear why you can't distinguish the preparation procedures by doing measurements on A alone: that would violate relativity! You would be able to find out whether some unitary transformation was applied to subsystem B, but that application can be done with a space-like separation.

For more details, see the blog post I wrote about it.

54. **Mark Hillery**
August 24, 2019

"Once you admit that an electron can be in a superposition of different locations, it follows that person can be in a superposition of having seen the electron in different locations, and indeed that reality as a whole can be in a superposition, and it becomes natural to treat every term in that superposition as a separate "world"."

Ummm, no. This ignores the amplification process necessary to make the behavior of the electron visible to the person. Amplifiers are inherently noisy, which means they fuzz things out and destroy quantum superpositions. There is a very nice paper about this, which is, unfortunately, probably rather hard to find.: R. J. Glauber, Amplifiers, attenuators, and Schroedinger's cat, New Techniques in Quantum Measurement Theory, volume 480 of the Annals of the New York Academy of Sciences (1986).

55. **Blake Stacey**
August 25, 2019

Mark Hillery,

Here is a copy, online but paywalled.

56. **Arnold Neumaier**
August 25, 2019

Peter,

"The best effort towards that I can find is the program of working to understand decoherence, the preferred basis problem and perhaps quantum Darwinism. Do the results of this program imply the 'reality' of many worlds?"

Surely not. In https://arxiv.org/pdf/1404.2635, Maximilan Schlosshauer states in Section VII the little decoherence can contribute to the foundations. In particular, he writes: "Since decoherence follows directly from an application of the quantum formalism to interacting quantum systems, it is not tied to any particular interpretation of quantum mechanics, nor does it supply such an interpretation".

Mateus Araujo,

"It's not as if many worlds are postulated to explain anything, rather they are the consequence of applying the laws of quantum mechanics to the whole universe."

The laws of quantum mechanics neither contain the notion of a world nor that of a superposition in a preferred basis (which is usually used to motivate worlds). Thus many worlds cannot be a consequence of the laws of quantum mechanics alone. One must add quite some fancy, very controversial interpretation stuff to get many worlds….

57. **Peter Woit**
August 25, 2019

Paddy,
The problem with just saying it is the Hamiltonian that determines the preferred basis is, "which Hamiltonian, and how does it do this?"
For the case of a quantum particle, I see arguments for
1. configuration space basis: locality of interactions
2. momentum space basis: these are energy eigenstates for the free particle, so good basis for weak interactions.
3. coherent state basis: these have a nice relation to the classical limit.
For the case of a spin-1/2 degree of freedom, I have no idea how this is supposed to work.

58. **Peter Woit**
August 25, 2019

jxd,
The problem is how do you get from "the state is a macroscopic superposition" to "this corresponds to multiple worlds". In particular, "superposition with respect to which basis?" is the "preferred basis" problem. That's one problem you have to solve before the "multiple worlds" picture even begins to make any sense.

59. **Mateus Araújo**
August 25, 2019

Arnold Neumaier,

"The laws of quantum mechanics neither contain the notion of a world nor that of a superposition in a preferred basis (which is usually used to motivate worlds). Thus many worlds cannot be a consequence of the laws of quantum mechanics alone."

The worlds are part of emergent reality, not fundamental reality. The laws of quantum mechanics also do not contain the notion of trains, but this doesn't make them any less real.

"One must add quite some fancy, very controversial interpretation stuff to get many worlds…."

On the contrary, Many-Worlds is the only interpretation that takes quantum mechanics as it is. To get rid of the multiple worlds is that you need "fancy, very controversial interpretation stuff". To note:

Denying an objective reality (QBism).
Postulating a classical reality irreducible to the quantum laws (Copenhagen).
Postulating hidden variables (Bohmian mechanics).
Changing the Schrödinger equation (Collapse models.).

60. **Peter**
August 25, 2019

Mateus Araujo,

"The laws of quantum mechanics also do not contain the notion of trains, but this doesn't make them any less real."

I thought the problem was to get the trains from QM, and I don't see how MWI does it. I agree with Peter Woit when he writes that you have to solve the "preferred basis" problem before the "multiple worlds" picture even begins to make any sense.

There's something else that bothers me. What is this "environment" that causes decoherence? I suppose I'm wrong, but I sense a certain circularity. Environments cause decoherence, and if something doesn't cause decoherence in a certain system, it doesn't count as an "environment" of that system.

61. **Arnold Neumaier**
August 26, 2019

Mateus Araujo,

”The worlds are part of emergent reality, not fundamental reality. ”

See Peter Woit’s preceding post for the extra input needed to infer something emergent.

”Many-Worlds is the only interpretation that takes quantum mechanics as it is.”

Maybe it used to be the only interpretation that claimed that, but now there is also the thermal interpretation, which is based solely on the unitary dynamics of the universe:

http://www.mat.univie.ac.at/~neum/physfaq/therm/thermalMain.html

It works in a single world and features none of your objections to other interpretations,

”Denying an objective reality (QBism).
Postulating a classical reality irreducible to the quantum laws (Copenhagen).
Postulating hidden variables (Bohmian mechanics).
Changing the Schrödinger equation (Collapse models.).”

62. **Bill**
August 26, 2019

It has been pointed out by more than a few quantum foundation philosophers including Ruth Kastner that Quantum Darwinism because it is observer independent must assume a partition into environment+pointer+system in order to derive just that. Kastner posits an observer independent collapse theory which repairs a hole but causes another leak(non-unitary evolution of the Schrodinger equation). This is the common running theme in foundations literature(which assumption do you deny and how do you account for the inconsistency that arises).

63. **Peter Shor**
August 26, 2019

@Bill: It shouldn’t be circular.

You can choose many, many partitions into environment+pointer+system, and most of them don’t behave in ways at all consistent with Quantum Darwinism. So what you really need to do is show that there exists a partition with the right properties.

And of course, you need assumptions to ensure that this partition exists.

Assuming that such a partition exists at time *t*, and showing that such a partition exists for all times not too long after that is a reasonable way to proceed. This partition is not going to continue existing when the universe has died a heat death, so all you can ask for is that it remains for some time.

64. **Mateus Araújo**
August 26, 2019

Another Peter,

“I agree with Peter Woit when he writes that you have to solve the “preferred basis” problem before the “multiple worlds” picture even begins to make any sense.”

The preferred basis problem has been solved, for fuck’s sake. Everybody seems to love throwing around the sentence “preferred basis problem” without having the faintest idea what they’re talking about. If you want to be taken seriously at least describe what the problem is and why do you think the canonical solution is not satisfactory. Argh.

The problem was to explain why the basis corresponding to the measurement outcomes was the one corresponding to the quasi-classical worlds. Otherwise you couldn’t *derive* the fact that a state of the form |0>|M_0> + |1>|M_1> corresponds to a superposition of a world with result zero and a world with result one. Everett kind of postulated that measurement outcomes do correspond to worlds, and I think that’s fine: it clearly works. He was attacking the problem from the top-down direction, guessing what the quantum dynamics must be in order to solve the measurement problem. That’s profoundly unsatisfactory from the philosophical point of view, though, because you are introducing in your theory special “measurement” devices which happen to split the world according to their outcomes. A proper reductionist theory must describe measurements in terms of quantum dynamics, and explain why they split the world according to the outcomes.

And this has been done! It’s what this story about decoherence and pointer states and quantum Darwinism is all about. We have learned, from the 70s onwards and with more and more detail, that measurement devices are those that entangle the measured system to complex quantum systems, that their dynamics are nothing special, but a generic feature of system+environment interaction – called decoherence, that the measurement outcomes correspond to the pointer states – precisely those stable under decoherence, and that the subsequent dynamics of these pointer states are effectively split from eachother, again because they have decohered. That’s how you go from a superposition between two spins to a superposition of non-interacting quasi-classical worlds. Don’t take my word for it, read a fucking paper about it.

“There’s something else that bothers me. What is this “environment” that causes decoherence? I suppose I’m wrong, but I sense a certain circularity. Environments cause decoherence, and if something doesn’t cause decoherence in a certain system, it doesn’t count as an “environment” of that system.”

Yes, you are wrong. Decoherence is not about tautologically classifying systems into “environment” and “not environment”. It’s about showing how the usual interactions between some quantum systems – the prototypical example between a dust mote and air – cause them to be entangled, and thus interference in the system of interest effectively unobservable.

65. **Peter Woit**
August 26, 2019

Mateus Araújo,
Yes, I understand that there are people who claim the preferred basis problem is solved, but I’m not convinced. As you note, the Everett “solution” isn’t convincing, it just assumes classical emergence solves the problem somehow. Zurek actually engages with the problem, but has he really solved it? Jess Riedel in one of the blog postings I linked to above, takes the point of view “I say that the decoherence program as led by Zeh, Zurek, and others is an improvement—a monumental advance—but not a complete solution.”
For another randomly chosen example, here
https://www.preposterousuniverse.com/blog/2014/02/12/the-many-worlds-of-quantum-mechanics/#comment-7295910552604282125
Commenter “Matt” (Matt Leifer??)
objects to Sean Carroll’s claim that the problem is solved by “interactions are local in space”, and writes

"The preferred-basis problem, on the other hand, is specially a problem for the many-worlds interpretation, and refers to the fact that we can trivially expand the overall state vector in any of an infinite set of different choices of basis for the overall Hilbert space, where each basis paints a very, very different picture of what those different worlds are and what are the probabilities associated to them. There is no guarantee that most of those choices of basis will involve basis states that look classical, and, on the other hand, there may well be two (or more) choices of basis that give classical-looking basis states and thus inconsistent sets of classical realities that are not related to each other in a classically understandable way.

The preferred-basis problem is unsolved, and probably unsolvable without somehow adding on more axiomatic principles to the many-worlds interpretation for choosing one basis over all the others."

Unlike "Matt", I'm willing to believe that the preferred-basis problem as he states it is solvable, with a better understanding of what happens in a usual sort of physical "measurement", without new "axiomatic principles". My suspicion is that you have to really engage with what the properties of the Hamiltonian are that give the sort of "classical world" we want (and just saying "the interaction Hamiltonian is local in space" doesn't do it). I've not spent enough time understanding the details of what Zurek and others have done and have not done, but when I try and follow discussions of this, at crucial points they seem to me to be effectively assuming that an unsolved problem gets solved the way they want.

66. **Mateus Araújo**
August 27, 2019

Peter Woit,

Commenter "Matt" doesn't know what he's talking about. As I explained above, the preferred basis problem was about explaining why measurement outcomes correspond to quasi-classical worlds, not about the trivial fact that a quantum state can be written in different bases. His assertion that "each basis paints a very, very different picture of what those different worlds are and what are the probabilities associated to them" is often repeated, but empty. Nobody has *ever* even tried to show that there are in fact such different worlds, and what they would be (except for the science fiction author Greg Egan in his novel Quarantine, which I highly recommend, but is not a scientific work). If one wants to claim that there is some other basis where we have worlds with blue dragons, the burden of proof is on them.

About your point of view, it's hard to argue against wanting to have a better understanding of the measurement process, but I don't see a concrete objection. Do you think that there could be something that we usually regard as a measurement apparatus, but whose outcomes do not correspond to pointer states? Or do you think that we can have some pointer states that give rise to quasi-classical worlds with some radically non-classical feature, such as not being well-localized in phase space or having blue dragons?

The fact that neither thing happens in all the systems we have studied is good evidence that they in fact do not happen. Moreover, it is hard to prove a negative.

I don't see what is your problem with the "local interactions" argument. It is a great insight; Hamiltonians with interactions that are local in space will decohere spatial superpositions, and preserve states that are well-localized in phase space. Since the fundamental Hamiltonians we know *are* local, this does show that we won't have quasi-classical worlds with delocalized states, so this blue dragon is dead. What other non-classical features still need excluding?

67. **Peter Shor**
August 27, 2019

Mateus Araújo:

I don't see how the decoherence problem will really be solved until you can answer questions like: given a physical system, when will the polarization of light decohere into the vertical/horizontal basis, when will it decohere into the right/left diagonal basis, and when will it decohere into the clockwise/counterclockwise basis? And how about situations where it decoheres, but in which there is no preferred basis; how do you model decoherence in these situations?

Finally, blue dragons are indeed relevant; in some sense, the theory of decoherence won't be truly complete until you can *prove* that there are no quasi-classical worlds with a hidden basis that contains blue dragons. (Although making such a proof a requirement for accepting a theory of decoherence is much too demanding.)

It seems to me that pointer bases and quantum Darwinism only analyze the easy cases.

68. **Paddy**
August 27, 2019

Peter,
To be a bit more explicit than Mateus Araujo:

* Which Hamiltonian? Given that we are assuming here that QM is objectively correct, the one and only Hamiltonian that governs the evolution of the universal quantum state. Which, obviously, we don't yet know exactly.

* Which basis: to get a quasi-classical large-scale world, the wavefunction must be sharply peaked (by macroscopic standards) in both configuration and momentum space, but only for coordinates representing particles bound into macroscopic objects. "Sharply peaked" meaning resolved into multiple disconnected islands, one per "world". In this context "disconnected" allows the islands to be actually connected along one or a few dimensions, as when a position measurement is made on a delocalised particle. Owing to the very high dimensionality, O(Avogadro's number) for a simple lab setup, such connections are FAPP impossible to utilize to demonstrate interference effects.

The states are neither momentum nor position eigenstates which are both unphysical, nor are they exact eigenstates of any universal unique operator, e.g. coherent states. Zurek claims to have shown that einselection operates because the Hamiltonian can be expressed relatively simply in terms of position and momentum operators, and as a consequence, he says, when expressed in these spaces the wavefunction changes relatively smoothly. In contrast, whatever operator has eigenstates corresponding to non-pointer states, like, say, (live + dead) cat and (live – dead) cat would have a wave function that changed very fast indeed. States that change relatively slowly (and are therefore short-term predictable) are necessary for the function of any life-form (or general IGUS – information gathering and utilising system), so life has evolved operate in quasi-classical terms.

69. **Mateus Araújo**
August 27, 2019

Peter Shor,

Light-matter interaction is one of the most studied problems in physics. Finding an open problem about how the polarisation degree of freedom entangles with the environment would be a feat in itself. But lets say you do find such a situation where we don't know whether the decoherence will happen in the vertical/horizontal or clockwise/counterclockwise basis. What is the problem then? We do have "classical" light in such polarisations, these are not blue dragons.

"And how about situations where it decoheres, but in which there is no preferred basis; how do you model decoherence in these situations? "

What about that? Sounds like you're just getting photons polarised in a random basis. Isn't that pretty vanilla?

"Finally, blue dragons are indeed relevant; in some sense, the theory of decoherence won't be truly complete until you can prove that there are no quasi-classical worlds with a hidden basis that contains blue dragons. (Although making such a proof a requirement for accepting a theory of decoherence is much too demanding.)"

I agree that if somebody did find such a basis of quasi-classical worlds with blue dragons it would be a problem, as it would amount to a prediction that blue dragons exist, and in reality they don't (or even more fascinating, if somebody found such a basis that was *different* from the usual pointer states/coherent states basis, as it would imply that parallel to our reality of boring quasi-classical worlds there exists a hidden reality with blue dragons. That's the premise of Greg Egan's Quarantine). But absent such a discovery, proving that blue dragons are not predicted by quantum mechanics sounds like proving that Russel's teapot is not there.

70. **Peter Woit**
August 27, 2019

Paddy/Mateus Araújo,
Thanks for your comments. I'm afraid I've reached the point where to get more out of this I'd have to spend serious time doing some more reading and thinking, and there are other projects which seem more likely to be fruitful that I should get back to instead.

Without doing such reading and thinking, I'm stuck unconvinced that invoking "many worlds" as an explanation really explains anything, and in a position I don't like to be in, that of trying to figure out what is going on not by understanding something myself, but by seeing what experts say. From all I can tell, the best work done in this area has been that of Zurek and collaborators, and from what I can gather, Zurek comes down on the "many-worlds not necessary" side, while on the "is the preferred basis problem solved?" question I take Zurek as a yes, and Jess Riedel as "not a complete solution yet".

The Carroll book is going to convince a lot of non-physicists that the problems of QM are resolved by the existence of multiple worlds. I hope it will have the effect that experts with a good understanding of what is really going on will find the appearance of the book a good opportunity to write something less propagandistic that gives interested non-experts a more balanced explanation of the state of the subject.

71. **Blake Stacey**
August 27, 2019

> I hope it will have the effect that experts with a good understanding of what is really going on will find the appearance of the book a good opportunity to write something less propagandistic that gives interested non-experts a more balanced explanation of the state of the subject.

I hope so too. This is not a hope really founded on experience — my *expectation* is that people will continue to endorse whichever lazy answer they had already settled on, and to propagate the same dull arguments that were old by 1980 — but I shall hope anyway.

72. **Paddy**
August 29, 2019

Peter,
A last attempt to unblock the log-jam in your thinking about this. You have been told several times already, and so the fact that you don't take it on board suggests to me that it may be the crux of your problem:

Invoking "many worlds" is *not* supposed, even by MWI-ers, to be an explanation of anything. The explanation is QM. Many worlds is a *logical consequence* of QM. Or so say the MWI-ers. So you shouldn't be puzzling about what sort of thing many worlds explains, you should be puzzling about whether you can have a self-consistent, ontic, QM without getting many worlds as a by-product.

I think I was too kind to Zurek in an earlier comment. If you accept that decoherence is the explanation for the pure state to (apparent) mixed state transition, which he does, then you are committed to the mixed state being mixed only FAPP, and therefore you cannot consistently deny the existence of terms in the mixture that do not correspond to the world we experience. But Zurek did try to do that for many years, although I read something by him in the last decade or so (sorry, can't remember where) , which seemed to me to reluctantly accept the MWI deduction.

For the record, I am not fully convinced by MWI either. Probability is still a big problem, pace Wallace. QM could be wrong. It just seems to me that your criticism of MWI is surprisingly shallow.

73. **Peter Woit**
August 29, 2019

Paddy,

I think it's likely that you're misunderstanding my point.

Recall that the context of this posting is a discussion of Sean Carroll's book, which is devoted to making the case that invoking multiple worlds explains everything, with all that most people are going to get out of it the news that:

"Carroll says that the crisis can now come to an end. We just have to accept that there is more than one of us in the universe. There are many, many Sean Carrolls. Many of every one of us."

This is what I'm criticizing. I don't see how my accepting that there are many Peter Woits in the universe will end any crisis, or explain anything. What I decide to call a "real world", my choice of "ontology" if you like, to me is more of a philosophical than scientific issue, unless you can make a good case that this choice is important to understanding how to solve a problem.

The interesting physics question I'm trying to understand is that of exactly how the usual rules we teach students about how the bare QM formalism relates to "measurements" can be derived rather than postulated. This is an attractive idea and I don't see any evidence that this can't be done. The decoherence/Zurek line of research has clearly made a lot of progress towards this goal. I remain confused about whether it has completely addressed certain problems, and various claims made by Wallace and others for solutions to these problems don't seem convincing (the explanation for the Born rule lies in decision theory???). In trying to resolve these confusing issues, I still don't see how invoking a "many worlds" ontology solves anything.

74. **Mateus Araújo**
August 29, 2019

Paddy, Peter,

I also don't think the approach to the probability problem taken by Wallace (and Carroll and Vaidman, for that matter) is the proper one. Sure, they can derive from reasonable assumptions that rational agents must assign subjective probabilities given by the Born rule. But who cares about subjective probabilities? The reason probabilities in quantum mechanics are interesting is precisely because they are objective, not subjective. And rational agents? Come on! Many-Worlds is a reductionist theory about an objective reality, this agent-centric nonsense belongs in Copenhagen.

I also think it is a huge missed opportunity, as making sense of objective probabilities is an age-old problem in philosophy, and the only solution I know is using many-world theories.

I'm using lower case here because the solution I know is using a classical many-world toy theory, Kent's universe, not the quantum Many-Worlds itself. The quantum case still doesn't have a satisfactory explanation.

Some Math News

August 27, 2019
Categories: Langlands, Obituaries

My Columbia colleague Patrick Gallagher passed away a few months ago at the age of 84. He had only recently retired, and for many years was the longest serving member of the department and an important part of its institutional memory. On October 10 there will be a memorial conference here at Columbia.

It's too bad Pat didn't live to see the latest from Terry Tao, who describes recent results which are related to old work of Gallagher's by "Our proof of this theorem proceeds more or less along the same lines as Gallagher's calculation, but now with k allowed to grow slowly with x."

Turning to other topics, Peter Scholze continues to come up with new ideas about the foundations of mathematics at a pace far too fast for me to fool myself into thinking I might be able to follow what he's doing. In recent months he has run a course on "Condensed Mathematics", which involves new ideas about topology developed with Dustin Clausen. For a video of a recent talk where he explains this, see here.

On the Langlands/representation theory front, some interesting things are:

- A course run by Geordie Williamson in Sydney earlier this year.
- If you're interested in what Williamson is up to, you might want to watch videos from "somewhere in Russia" last month, or "somewhere on Long Island" last week. Lecture notes are here.
- Also in Russia last month, at the Skoltech Center for Advanced Studies, where my Columbia colleague Igor Krichever is director, there was a skoltech summer school on mathematical physics, with some of the lectures on video here.
- Several new papers addressing different points of view about geometric Langlands are out, including a very recent one from Etingof, Frenkel and Kazhdan. For some background on the relation of this to work by Langlands himself, see here and here. For some geometric Langlands-related work of a different sort, see here and here.

Finally, the 2019 PCMI was devoted to the topic of *Quantum Field Theory and Manifold Invariants*, videos are here.

Update: Also on the Langlands/representation theory/quantum front, this week at Northeastern there's a conference going on (rumored to be celebrating the fact that Etingof and Okounkov share the same birthday, and are now 50). Videos are starting to appear here, including one of Edward Frenkel discussing the paper with Etingof and Kazhdan mentioned above.

Comments

1. **anon**
   September 5, 2019

   Breakthrough Prizes have been announced (they seem to be moving earlier each year, wasn't the announcement in December a few years back). The recipients are Alex Eskin in maths and, unsurprisingly, the Event Horizon Telescope collaboration in Physics.

2. **Peter Woit**
   September 5, 2019

   anon,
   That is weird. In the past they kept this a secret until the prize ceremony near the end of the year. Maybe they're trying to get in before the Nobels, announced in a few weeks.

   I also still don't understand why they've inverted their previous practice of giving the "special prize" for current experimental results (e.g. LIGO/2016 and Higgs/2013) and the regular prize for (often failed) theory. This year the "special prize" went to the failed SUGRA unification idea and the regular prize to a current experimental result (EHT).

   There's some value in making an award to an experimental collaboration like EHT (as opposed to certain individuals). Besides the problem of awards for failed theory, for the rest of the math-physics awards they're making, I think we'd be better off without them. They're no different than any number of other awards out there, other than embodying the misguided idea that what math and physics research need is more Hollywood glitz.

3. **social network**
   September 6, 2019

   Eskin has co-authored papers with 7 Fields medalists. I'd be surprised if anyone else has a Fields number (to coin a term) as high as 5.

4. **Jamie**
   September 6, 2019

   @social network. Eskin clearly deserved the prize. Those seven are Margulis, McMullen, Kontsevich, Okounkov, Lindenstrauss, Avila, and Mirzhakhani.

   Except for Margulis, the other 6 Fields medals came after 1998, and four of them mostly worked in dynamical systems. Also, Fields medals for work in dynamical systems (or closely related work) include Yoccoz in 1994 and Venkatesh in 2018. Let's not forget that Sinai got an Abel prize in 2014. Seems like a very prestigious field in mathematics.

5. **social network**
   September 6, 2019

   @jamie, presumably the "Fields number" positively correlates with (among other things) strength as a mathematician. If you are strong enough to collaborate with top people in the field, and they keep coming back to write more papers with you, that's a pretty good sign that you are strong in your own right. At least that's how I interpreted it.

   Dynamical systems, at least in the USA, has had the reputation of being more social than other areas of math. Between that and it being a field that "relates to everything" it makes sense for collaboration numbers to be higher there.

6. **anon**
   September 6, 2019

Bourgain seems to have had at least five medalists (Bombieri, Figalli, Lindenstrauss, Tao, Venkatesh) as co-authors (six, if you count Connes; they were both editors of a conference proceedings). I only checked the ones that I though the most likely to have co-authored with him, so I may have missed someone.

7. **Peter Woit**

   All,
   Maybe that's enough discussion of the new "Fields number" metric.

Quantum Supremacy II

September 7, 2019
Categories: Quantum Mechanics

About the only thing that has transcended the bitter partisan divisions between Democrats and Republicans in the US during recent years has been quantum mechanics, with the enactment late last year of the National Quantum Initiative Act (the NQI was first mentioned on the blog here). In March there was a National Quantum Coordination Office established at the White House, and last week there was an executive order establishing a National Quantum Initiative Advisory Committee.

The NQI directs the federal government to spend \$1.2 billion over the next five years, with the NSF told to create two to five "Multidisciplinary Centers for Quantum Research and Education" and the DOE two to five "National Quantum Information Science Research Centers". Besides the NQI, pretty much everywhere you look the past few years you see new well-funded "quantum" centers popping up, two randomly chosen examples would be the Chicago Quantum Exchange and the Yale Quantum Institute. In the private sector, a huge investment in quantum science is taking place, driven by hopes that quantum computing and other applications will lead to a technological revolution and associated vast riches.

Looking at new books on fundamental physics that I've seen over the past year and a half, the conventional enthusiastic treatment of string theory/SUSY/extra dimensions is now dead, with Sabine Hossenfelder's Lost in Math the only popular book addressing these topics, and doing so in a quite negative way. The new trendy topic is the foundations of quantum mechanics, with the recent publication of Adam Becker's What is Real?, Philip Ball's Beyond Weird, Anil Ananthaswamy's Through Two Doors at Once, Lee Smolin's Einstein's Unfinished Revolution, George Greenstein's Quantum Strangeness, and Sean Carroll's Something Deeply Hidden. Forthcoming from Oxford University Press are two quantum books by Jim Baggott, Quantum Reality and The Quantum Cookbook.

On the whole this change in hot topic is a positive development, although the fact that it's driven by a lack of anything new to say about particle physics and unification is rather depressing. On the quantum front, while I think it's great that public attention is being drawn to quantum mechanics, if you look at my reviews you'll see that I have mixed feelings about the point of view taken by some of the recent books (the best of the lot I think is Philip Ball's).

The latest example of the high public profile of quantum mechanics is the publication today in the New York Times of a piece by Sean Carroll arguing that Even Physicists Don't Understand Quantum Mechanics: worse, they don't seem to want to understand it. Unfortunately I don't think that this article accurately describes the issues surrounding what we do and don't understand about "quantum foundations", nor the dramatically improving funding prospects for research in this area. In addition I don't think that it's accurate, fair (or good for public relations) to portray your colleagues as "not really interested in how nature really works", somehow not curious or bright enough to realize (see here) that there is a crisis at the heart of their subject and that, thanks to Sean Carroll:

> the crisis can now come to an end. We just have to accept that there is more than one of us in the universe. There are many, many Sean Carrolls. Many of every one of us.

Comments

1. **Blake Stacey**
   September 7, 2019

   > Not everyone was happy that Bohr's view prevailed, but these people typically found themselves shunned by or estranged from the field.

   Two examples do not add up to a "typically", no matter how famous those examples are. Nobody mentions Haag's debate with Bohr, for example, despite it being rather illuminating. Nobody reads the proceedings of the 1938 Warsaw conference, where Hans Kramers declared that "everyone knew the quantum theory was provisional" and Heisenberg was reported as speculating that quantum mechanics would have to break down at high energies. Nobody — and this surprises me — notes that Feynman took Everett seriously enough to criticize in his early '60s course on gravitation.

   Nor can Bohr coming off better in his debates with Einstein really be equated with his view *prevail*ing, not when even other physicists who disagreed with Einstein (like Heisenberg and Pauli) also disagreed with Bohr.

2. **Blake Stacey**
   September 7, 2019

   For that matter, the most famous riposte to the view that quantum mechanics can be "considered complete" is the EPR paper, and neither Podolsky nor Rosen were drummed out of the physics profession!

   Louis de Broglie doesn't seem to have suffered for returning to pilot-wave theory in the 1950s. I have heard that he quashed the careers of Jean-Louis Destouches and Paulette Destouches-Février for taking too Bohrian a turn in their work on quantum logic, but that's philosopher lore which may or may not be confirmable in a history book. And speaking of quantum logic, that's a thing that a small but determined set of researchers bustled away at in order to "dig more deeply", starting with Birkhoff and von Neumann and continuing with Jauch, Piron, Mackey, etc. I doubt that any of Andrew Gleason's colleagues criticized him for doing quantum foundations instead of getting back to Hilbert's fifth problem.

3. **GoletaBeach**
   September 7, 2019

   Sean Carroll's op-ed piece left me unimpressed. "What's surprising is that physicists seem to be O.K. with not understanding the most important theory they have." he says.

   Huh? We had Bell's work, boiled down nicely by David Mermin, certainly regularly taught in grad and undergrad quantum. We had a whole lot of delayed choice experiments, photon-by-photon build up of the two slit interference pattern, interference measured around solenoids showing the reality of the vector potential. We had just about every weird quantum correlation experiment that arose in decays of the phi meson and Upsilon(4S) interrogated… in the later, Sin(2beta) of CP violation is a bit harder to measure due the the collapse of the wave function caused by the first decay of the correlated pair. Considerable effort checked all of that experimentally.

   Experimentalists have tried really, really hard to get the first empirical clue that the simple-minded Copenhagen is off. Maybe it is Quantum Bayesian in fact, which kinda works, and kinda feels like: everybody, the details of the measurement are and always have been a big correlated mess between the system and the observation apparatus.

   No empirical clue of anything inconsistent has showed up. Maybe the experimental effort has even exceeded that devoted to supersymmetry. Neither experimental quest has found a shred of deviation from simple expectations. Not a reason to give up, but hardly a reason for new billion-$ initiatives… clever folks laboring away in Rutherfordian and Via Panisperna-like genteel poverty are as likely to find the new revolution.

   Many (not sure about "all") experimental condensed matter folks doing QIS are pretty blunt that they don't care much about the marquis item… and Gil Kalai points out that noise might deflate the grand expectations of quantum computing…. https://www.ams.org/journals/notices/201605/rnoti-p508.pdf

Mainly QIS is a good jugular of funding… and their standard old condensed matter funding mechanisms all got wildly political and unproductive. The card "what if the Chinese get quantum computing first and take over the world" is now getting played hard.

And a card that particle physicists cannot play. Getting supersymmetry first (or any new high energy or dark matter/energy phenomenon) won't enable anybody to take over the world. Perhaps speculative experimentation will gradually get ironed of particle physics… as all the money is needed for the world and US accelerator neutrino program.

4. **Lena Birkenfeld**
September 7, 2019

Peter,

If I remember correctly, in one of your past posts you introduced to us that Arnold Neumaier has a new deterministic thermal interpretation of quantum mechanics grounded upon the mathematical concept of coherent spaces, and links to his five papers. Now on one hand, it seems that his thermal interpretation and coherent spaces may be the concepts needed to resolve the issues in the foundations of quantum mechanics that Sean Carroll and others are bringing up, as well as unify quantum and classical mechanics together. On the other hand, Neumaier's ideas are still relatively new, and apart from this blog and on PhysicsForums, his ideas haven't attracted much attention (He hasn't yet had his five papers peer reviewed yet either.) He has a new book coming out on that topic on 24 October 2019 called "Coherent Quantum Physics: A Reinterpretation of the Tradition": https://www.mat.univie.ac.at/~neum/physfaq/therm/

5. **casper**
September 7, 2019

The responses so far have interpreted Sean's "quantum foundations" word choice as referring to topics outside of his apparent emphasis on quantum interpretations, to the point of confusing Sean's critique of physics culture for a critique of mathematics culture (Gleason), confusing quantum foundational work for questioning the empirical adequacy of the standard von Neumann recipe ("Neither experimental quest has found a shred of deviation from simple expectations"), and even broadening the definition to include QIS. It really shouldn't be all that controversial that working on quantum interpretational issues would not generally help one's case for tenure in physics departments in the years since WWII.

6. **Alessandro Strumia**
September 8, 2019

Writing that physicists are not interested in understanding quantum mechanics and suggesting that physicists pushed out of the field those who tried is worse than inaccurate. It's fake news. EPR, Bell and others who achieved interesting results were welcomed and discussed. The problem is that there are not so many interesting results, in particular when trying to address the key issue: why a probabilistic theory?

7. **Evgenii Rudnyi**
September 8, 2019

Well, we should just consider the process when Carroll makes a statement, for example,

"We just have to accept that there is more than one of us in the universe. There are many, many Sean Carrolls. Many of every one of us."

from the viewpoint of many worlds interpretation. During this process there appears a lot of Sean Carrolls speaking any possible statements including the negation of the above statement. Hence, why should we pay attention to a statement of just one of these copies?

P.S. The statement "Everett didn't even try to stay in academia, turning to defense analysis after he graduated" seems to be incorrect. According to the book The Many Worlds of Hugh Everett III by Peter Byrne, Everett did not want to stay by academia, he wanted to earn good money.

8. **chorasimilarity**
September 8, 2019

Your formulation "Forthcoming from Oxford University Press are two quantum books …" reminds me of a character from Saki who does not agree with his cook. He says something along the line that a rabbit served with a sauce with exotic ingredients does not become an exotic rabbit.

9. **Peter Woit**
September 8, 2019

Lena Birkenfeld,
I hope to find time to better understand what Neumaier is doing, likely will write here something about his book when it comes out. It's a quite different sort of thing though than the Carroll and other books mentioned here, much more technical, aimed at those with some expertise in the subject rather than the general public.

10. **Peter Woit**
September 8, 2019

Blake Stacey/casper,

Carroll's history, like that of Adam Becker's in his book, is just a caricature drawn for ideological reasons and I doubt anyone interested in the history will take it seriously.

More likely to be taken seriously is his description of the current situation, which also seems to me an unrecognizable caricature. As I pointed out in the posting, at the level of what the public is being told about fundamental physics, "foundations" is the hot topic and getting more attention than almost anything else. Of the huge influx of "quantum" grant money, new institutes and new positions, only a small fraction of it will go to "foundations", but some of it will, especially to work that has any sort of connection to the real world and the new possibilities being opened up for experiment by new technology. If your idea of "foundations"research is arguing about what is "real", you may continue to find your colleagues dubious of its value.

By the way, on this topic I recommend this from Will Kinney:
https://twitter.com/WKCosmo/status/1170668355847643136

11. **Blake Stacey**
September 8, 2019

> Carroll's history, like that of Adam Becker's in his book, is just a caricature drawn for ideological reasons and I doubt anyone interested in the history will

take it seriously.

This is a good point. However, I suspect that many people are more interested in having a Rationally Correct(TM) view of physics history, and so they will be content with the caricature because it was taught under the auspices of capital-R Rationality.

David Mermin coined the phrase "shut up and calculate!" to express the attitudes of his own professors during his graduate-school years, the late 1950s. He himself has been publishing on quantum foundations since 1980, starting with generalizing the Bell inequality in the pages of the *Physical Review*. Even if the "shut up and calculate" sentiment endures, I find it extremely implausible that the *set of questions to which it is applied* has remained invariant over the last sixty-odd years.

My day job is actually a problem that could be classed into quantum foundations or quantum information, depending on which way the light shines. Conversations about it tend to be richer and more fulfilling in the latter context, since the former field prefers to keep having the same old arguments with itself that it's been having for generations, while the latter is looking for new experiments to do. Even better still, in my experience, have been the interactions with the mathematicians whose attention is caught by quantum information reaching out into algebraic number theory. When I was in physicist school, I never expected I'd be teaching myself about Hilbert's twelfth problem.

Thank you for the pointer to Will Kinney's Twitter thread; I find much to agree with in it.

12. **Peter Shor**
September 8, 2019

Why do all these people who are unhappy with the current state of quantum foundations think the universe owes us a simple, intuitive picture of what is going on?

We have at least three intuitively very unsatisfactory, but perfectly consistent interpretations of quantum mechanics ("many worlds", Bohmian pilot wave, and Copenhagen) which all seem to predict exactly the same thing. Mathematically, it's a coherent and quite beautiful theory (at least until you try to add gravity). Why does there need to be a simple, intuitive foundation to it? There's nothing really wrong with looking for one, but there's also nothing wrong with looking for experimental evidence for dark matter candidates. You just shouldn't be surprised if you don't find them.

13. **Michael Weiss**
September 8, 2019

Peter, in 1977 Sidney Coleman prominently concluded his undergraduate course in introductory QM with a final lecture on Bell's Theorem ("Physics 143" at Harvard). Given Sidney's stature in that decade as both a leading theoretical physicist and a master lecturer (indeed, graduate students and post-docs from around Boston routinely attended his QFT lectures in Physics 253), surely this was a clear sign that Bell's Theorem had entered the mainstream of physics education by that time.

Prior to his final illness, Sidney gave a lecture on further Bell-related developments in the early 1990s, which is still available on the Harvard Physics website.

I also remember chatting with Ed Purcell somewhere in the 1985-1988 period about David Mermin's exposition of Bell's argument. Ed shared that Mermin had felt honored and thrilled that Richard Feynman wrote him a personal note congratulating David on putting together such as lucid account. My impression was that this was a very special form of peer recognition to Mermin.

Finally, Harvard's Francis Pipkin was a major advocate for Alain Aspect in the 1970s (as I gleaned in 1978 in the course of Physics 191; a lab course with much informal time for wide-ranging discussions); I understand that Pipkin helped ensure Aspect's promotion and tenure (told to me by someone else).

These anecdotes argue against Sean Carroll's suggestion that "mainstream elite" physicists had dismissed Bell's work as uninteresting and irrelevant.

14. **Mark Hillery**
September 8, 2019

I agree with pretty much everything Blake Stacey, Will Kinney, and Peter Shor have said, but I would like to comment on a few points in the article. First this:

"For years, the leading journal in physics had an explicit policy that papers on the foundations of quantum mechanics were to be rejected out of hand."

Assuming the journal in question is the Physical Review, I can say that as a soon to be retired associate editor at Physical Review A, who has handled parts of quantum information and, on and off, parts of quantum foundations for 15 years, this simply is not correct. We have published a very large number of papers on Bell inequalities and variations on them. There are papers on axiomatizations of quantum mechanics, and attempts to explain why there is a gap between the maximum correlations allowed by mathematics and those allowed by quantum mechanics (for more information on this see Tsirelson's theorem and Popescu-Rohrlich boxes). We recently published a paper in which experimental data was re-analyzed in order to place bounds on the collapse parameter in the GRW model (mentioned in the Carroll piece). This list is by no means exhaustive. Exactly what the policies were before my time, I cannot say, but there are papers in the Physical Review on Bell inequalities from at least the early 1980's.

Second there is this:

"The current generation of philosophers of physics takes quantum mechanics very seriously, and they have done crucially important work in bringing conceptual clarity to the field."

This certainly is not the way I see things. The few philosophers of physics I am aware of have a strong preference for Bohmian mechanics, which is a subject almost completely ignored by working physicists. This very much limits their influence. Also, from what I have seen, the philosophers further diminish whatever effect they may have by their aggressive style.

Finally:

"After almost a century of pretending that understanding quantum mechanics isn't a crucial task for physicists, we need to take this challenge seriously."

Again, this ignores a lot. The decoherence program pioneered by Zeh and currently being pushed by Zurek, is taken quite seriously and has been going on for quite a while.

In conclusion, as has been noted by other commenters, Carroll's piece paints a very misleading picture of the past and present of research in quantum physics.

15. **Peter**
September 8, 2019

I can confirm that Bell, EPR etc. were part of the curriculum in the early 1980s when I studied physics (somewhere in Europe …). It wasn't very thorough and nobody left the classroom with the idea this was a hot research topic(*), but it's not correct that foundational questions were neglected.

(*) I left the classroom with the idea that a) something was missing in the "interpretation" of QM, but b) every experiment confirmed the predictions of QM and one could do good physics without worrying about interpretations. Personally, I looked at the achievements of QM from the hydrogen atom to electroweak theory and thought taking position b) had its merits.

16. **Peter Shor**
September 8, 2019

And my previous comment, transmuted to poetry (or at least to words with rhyme and meter):

If the eternal dance of molecules
Is too entangled for us mortal fools
To follow, on what grounds should we complain?
Who promised us that Nature's arcane rules
Would make sense to a merely human brain?

17. **Dave Miller**
September 9, 2019

Peter,

I'm older than most of the posters here, and perhaps the only one who had a strong interest in QM foundations as early as 1970.

No one seems to be noticing that the very testimonials here actually document a phase transition in the profession's attitude towards foundational issues in QM between the early '70s and mid '80s.

Michael Weiss says, "Peter, in 1977 Sidney Coleman prominently concluded his undergraduate course in introductory QM with a final lecture on Bell's Theorem." That is the earliest sign I know of the transition. Michael is of course correct that Sidney was highly respected; on the other hand, Sidney was a bit of a maverick, and it is not surprising that he was an early harbinger of the transition.

When I took QM from Feynman in the 1974-'75 academic year, there was not *one word* about Bell's theorem (much less Bohmian mechanics or MWI!). I myself tried to engage Feynman in discussions about QM foundations: I'd known him personally since early in my freshman year, and he was generally open to discussions with undergrads. However, he just would not address QM foundational issues: indeed, the only thing he said about QM foundations in the QM class was a rather stern warning to all of us to avoid research in the area, since it was a career killer.

And yet, Michael cites evidence that "Mermin had felt honored and thrilled that Richard Feynman wrote him a personal note congratulating David on putting together such as lucid account" in Mermin's famous *Physics Today* article in 1985.

Yes, that is my point: Feynman's (and the profession's) attitude changed radically between 1974 and 1985 (with thanks to Sidney Coleman, Dave Mermin, et al.).

The pre-1975 attitude, by the way, was not that you were an evil person who deserved to be driven out of the field if you were interested in QM foundational issues; the attitude was simply that this was a fruitless line of endeavor, and that work in that area would generally not earn you credit among your colleagues.

Again, John Bell is an example: he was respected as a legitimate physicist who did real work at CERN but who happened to dabble in foundational stuff on the side.

I myself did a term paper on Bell's theorem in the 1974-75 year, not for Feynman's class but for a "Modern Physics" class. The prof liked it, and I earned an "A." I knew I would not be punished for my interest, but I also believed Feynman that making it my main research topic was not a good way to advance my career. Indeed, as late as, say, 2000, how many people considered giants in physics had made their name by working on foundations? Witten? Weinberg? Polchinski? Coleman himself?

I can think of none.

Again, it is true that a physicist prior to the transition who showed an interest in QM foundations was not vilified and expelled from the field. But, I know of no one prior to 1980 who made QM foundations the core of his research efforts and who was respected as a result by most other physicists.

It is of course completely different now: our friend Peter Shor is (quite rightly) famous.

My strong impression from Feynman, by the way, was that his generation had just been exhausted when they were young physicists hearing about the Bohr-Einstein debates, etc. and had understandably decided that all that was a waste of time.

And they had a point: for decades, the "real action" was in QFT, gauge theories, the quark model, etc. Bell's 1964 paper seemed not to be fruitful for further research: the initial experimental tests were not until the '70s and '80s, and it is really only in more recent decades that Bell's relevance to quantum computing has made Bell's work seem fruitful.

As Max Planck famously said (often misquoted as "one funeral at a time"), "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

Dave

18. **WTW**
September 9, 2019

For a very recent paper on experimental evidence of Quantum Darwinism, by Thomas Unden, with other authors including Zurek, see
Revealing the emergence of classicality in nitrogen-vacancy centers
https://arxiv.org/abs/1809.10456
(submitted to PRL)

See also: To catch and reverse a quantum jump mid-flight, by Z. K. Minev et al,
https://arxiv.org/abs/1803.00545
(in Nature, June 2019, https://www.nature.com/articles/s41586-019-1287-z)

They seem fairly "foundational" explorations of quantum mechanics, and as far as I can tell done outside of any "Quantum Initiative". But very interesting explorations of the details underlying quantum processes and measurement, without having to invoke any other copies of Dr. Carroll.

One comment: I have read multiple accounts of how the personality and position of Bohm stifled dissent re. problems with his ongoing interpretations of QM, including among some other very well known physicists. Even when apparent disagreements were stated, they tended to be swept under the rug or somehow merged together as "quantum weirdness". See, for example, https://plato.stanford.edu/entries/qm-copenhagen/#DivVie . More recently, physicists working primarily on aspects of string theory or particle physics topics with whom I have spoken also tend to sweep away any such issues as being either uninteresting or irrelevant to the core of the problems on which they are working. (And in fact the only people willing to spend much time talking about such things have been in the Philosophy of Science department : -) I have no idea how general or widespread such things actually are, but from a limited sample, Carroll isn't too far wrong in terms of how most theoretical physicists have (not) approached these issues.

19. **Lee Smolin**
September 9, 2019

Dear Peter,

Can I comment as someone whose first class in QM was Freshman QM in 1972, ie just before the phase transition Dave Miller mentions?

First of all, its true that American physics in general has had a pragmatic, anti-foundational orientation since it became dominant after WWII. Putting aside that there were felt to be good reasons for that (see remarks of Dyson, Feynman etc) , that made it unsurprising when we students were sincerely advised to work on building the present paradigm rather than attempt to over-through Copenhagen (ie text-book QM).

In the face of this, the very small number of us determined to work on quantum foundations took several strategies, and many succeeded. One was to split one's time between more mainstream (ie funded) and foundational issues (Bell, Adler, 'Sorkin, 't Hooft, Mermin, etc), one was to go to teach at a first class small college (Bernstein, Pearle, Wooters), one was to go to or stay in Europe (Penrose, Isham, Deutsch, Valentini, etc,) which was more diverse, finally one could work on QF from a math (Goldstein,Nelson) or philosophy (Shimony, Albert, Maudlin, Sanders, etc) department. Finally, one could work in industry (Bennet, Shor) or defence (Zurek)

Indeed enough of us succeeded, that in spite of the discouragement, as someone interested in foundations from the early 70's, there were always new ideas to ponder and work on and people to discuss them with. And what was most important, was that the crucial experiments got done-even if, as with tests of Bell, it took several attempts till the experimentalists had clean results. (And they were done at high status places: Harvard, Berkeley, Paris, MIT, Vienna…)

So if we are honest, I don't think we can argue that the progress of QF between the
1960's and the QIT revolution in the 2000's was personnel limited. These are very hard problems that go to the core of our understanding of nature. They require a different temperament than makes a successful mainstream physicist. Not many people have the interest, patience, focus and courage to work on them.

In addition, from 1972 on was a very tough job market for all of theoretical physics. So I think the overall story is that the problems in QF are so compelling, for those with a taste for foundational kinds of issues, that enough of us succeeded, against advice and expectations that we now have in front of us a much more interesting and diverse set of approaches and hypotheses, than faced the field in the 1950's.

Thanks,

Lee

20. **Yatima**
September 9, 2019

Sean Carroll writes at Quanta Magazine:

Where Quantum Probability Comes From

and as expected defends Many-Worlds, and derives the Born rule from first principles:

Can we resolve this uncertainty in a sensible way? Yes, we can, as Charles Sebens and I have argued, and doing so leads precisely to the Born rule: The credence you should attach to being on any particular branch of the wave function is just the amplitude squared for that branch, just as in ordinary quantum mechanics.

Still not convinced. "Knowing" or "attaching credence" ultimately means storing classical bits in massively copied physical state (including a fat chunk of previously recorded history and the algorithms needed to process the whole shebang into a prediction or a floating-point value). It's not some metaphysical essence that a system in quantum superposition could even have.

(For an earlier reconstruction of the Born rule from first principles, there is this article by Philip Ball, also at Quanta: Mysterious Quantum Rule Reconstructed From Scratch.)

21. **Peter Woit**
September 9, 2019

Yatima,
Thanks for the pointer to that new Carroll article, but I'm afraid I want to discourage discussion of it here, since it's a topic the moderator has no interest in…

22. **Peter Shor**
September 9, 2019

Lee Smolin:

I don't believe Feynman was truly anti-foundational. When I was at Caltech as an undergrad, around 1980, he gave a talk on negative probabilities, and said that his motivation was that he had looked at Bell's theorem, and realized that there was a hidden hypothesis that all probabilities were non-negative. So maybe if you allowed negative probabilities, you could understand the foundations of quantum mechanics.

He later published a paper on negative probabilities where, with typical Feynman showmanship, he completely omitted to mention his motivation, presumably because he couldn't get it to work.

There are lots more mathematicians working on the Riemann hypothesis than there are mathematicians willing to admit it (just like there were lots more mathematicians working on Fermat's Last Theorem than there were ones willing to admit it). I expect there are currently lots more physicists working on foundations than are willing to admit it.

If I'm correct about how many physicists have worked on quantum foundational problems without telling anybody, they're even a lot harder than we think they are.

23. **Blake Stacey**
September 9, 2019

If anyone wants to read Feynman's paper on "negative probabilities", it's here. He defines what would nowadays be called a discrete Wigner function for a qubit (a topic that you can indeed get into PRL for).

24. **Jim Baggott**
September 10, 2019

I think it's important to realise that the general negativity around quantum foundations in the 20/30-year period to the 1960s or early 1970s wasn't so much about a commitment to the Copenhagen (shut up and calculate) orthodoxy as a genuine belief that these were questions that couldn't be answered by experiment. If, as it seemed, these were 'just' philosophical questions based on different views about how nature should behave then, arguably, they didn't belong in physics. This wasn't just about Bohr's pragmatism or Heisenberg's positivism. Remember that in the 1930s von Neumann had published a proof that all hidden variable extensions of quantum theory are impossible.

Many argue that all this changed with Bell, who dismissed von Neumann's 'impossibility proof' and devised his famous theorem and inequality, but I think this process started with Bohm, under the influence of a conversation he had with Einstein in the early 1950s.

This change was critical. As soon as it became apparent that there were indeed some foundational questions that could be answered by experiment, interest grew and foundations became a 'respectable' part of physics, which is why it started to appear even in a small number of introductory QM courses. I fear that Carroll's particular spin on history and his arguments in support of a MWI which does nothing more than wrap the standard quantum formalism in a thick blanket of metaphysics does more harm than good to the credibility of quantum foundations in a pragmatic and empirically-grounded physics community. In a piece to be published online early next month by Aeon, I argue that this kind of stuff is dangerous and threatens to undermine the authority of science just when it is under unprecedented attack from anti-scientific and pseudo-scientific propaganda.

25. **Blake Stacey**
September 11, 2019

> Remember that in the 1930s von Neumann had published a proof that all hidden variable extensions of quantum theory are impossible.

I'm glad someone mentioned this. Adam Becker made a fairly big deal out of it in his book, in a way that I found incomplete enough to be misleading. But there's an angle that's more significant to the theme of how quantum foundations research is done today. Von Neumann's flawed theorem is *fixable* if one generalizes from his notion of measurement to that of POVMs, as is commonly done in quantum information theory. The additional structure of the set of POVMs furnishes a replacement for von Neumann's additivity assumption, the point where his argument was criticized by Grete Hermann and probably by Einstein. Of course, it is not so shocking to say that changing the assumptions will change what can be proved, but it's part of the story. And, topically, this part of the story was told in *Physical Review Letters*.

Regarding Papers about Fundamental Theories

September 9, 2019
Categories: Favorite Old Posts, Quantum Mechanics

Discussion in the comment section of the previous blog entry led me to do a little bit of historical research this morning, and I thought I'd write up the results here. First of all, for some interesting comments from people around back then about how attitudes in the physics community changed during the 1970s, see here, here and here.

What I looked into is one specific story, trying to figure out what was behind Sean Carroll's claim in the New York Times that

> For years, the leading journal in physics had an explicit policy that papers on the foundations of quantum mechanics were to be rejected out of hand.

Mark Hillery here notes that this is likely a reference to the *Physical Review*, and that it very much has not been true for the past 15 years, during which he has been an editor there.

Tracing back where Carroll got this from, I guessed that (since it's the historical source he recommends in his book) it came from Adam Becker's book, *What is Real?*. Looking at that book one finds on page 214:

> *Physical Review* actually had an explicit editorial policy barring papers on quantum foundations unless they could be related to existing experimental data or made new predictions that coulhered be tested in the laboratory.

This matches Carroll's claim (with the part inconvenient for his case deleted…). Becker's source notes for this text refer to an editorial in the July 15, 1973 issue of Physical Review D (Particles and Fields) written by Samuel Goudsmit, the editor-in-chief. The editorial is entitled "IMPORTANT ANNOUNCEMENT: Regarding Papers about Fundamental Theories". Goudsmit does not specifically refer to quantum foundations papers, but writes:

> The subject matter of these papers usually concerns a fundamental aspect of theoretical physics. Extreme verbosity and vagueness of expression makes these papers hard to read and understand. A paucity of mathematics as compared to wordage distinguishes them from the more conventional theoretical papers. The author proposes new theories, but their specific assumptions are usually hidden behind very lengthy arguments. Sometimes the paper contains a reinterpretation of existing theories which the author considers more satisfactory than the prevailing views, though no new experimental consequences are expected.

He sets forth the following as features expected of articles publishable by the *Physical Review*:

> All implied assumptions must be stated clearly and concisely and as much as possible expressed in mathematical form.
>
> The author must convincingly show
>
> - that these assumptions lead to the explanation of hither to unexplained observations, or
> - that these assumptions expose new relations between known data or theories, or
> - that these assumptions are simpler and fewer than in existing theories.
>
> Moreover, the author must show that the new assumptions do not contradict existing experimental facts.
>
> He must also investigate possible new consequences of his assumptions and whether these could be tested by new experiments.

Looking some more into this, I realized that I had first seen this story in David Kaiser's book *How the Hippies Saved Physics* (see review here), which clearly is Becker's source (Becker's next note refers to this). On page 121 Kaiser has:

> The longtime editor of the *Physical Review*… actually banned articles on the interpretation of quantum mechanic. He went so far as to draw up a special instruction sheet to be mailed to referees of potentially offending submissions: referees were to reject all submissions on interpretive matters out of hand, unless the papers derived quantitative predictions for new experiments.

Kaiser goes on to quote John Clauser as pointing out that according to this policy, Bohr's response to the 1935 EPR paper would not have been publishable. His source notes refer to the Goudsmit editorial and private emails from Clauser on July 8, 2009. The same note also refers to an article by Clauser, Early History of Bell's Theorem, which has a lot of detailed information about the story of the reception of Bell's theorem and early efforts to do experimental tests (but nothing about the *Physical Review* policy). By the way, back in 1964, Bell decided not to submit his important paper to *Physical Review*, not because of any policy they might have had, but because they had page charges.

So, as far as I can tell, the historical record shows that the documented Physical Review policy didn't, as the descriptions by Kaiser, Becker and Carroll suggest, explicitly refer to papers on the interpretation of quantum mechanics or quantum foundations. Possibly it was such papers that were annoying Goudsmit and led to his editorial, but I'd be curious to know if anyone knows more about what was specifically bothering Goudsmit. What sort of papers were being submitted to Physical Review D around 1972-73 that would uncharitably fit the negative description he gives quoted above?

Update: In the comments Blake Stacey suggests that the 1972 experiment of Freedman-Clauser may have been what led to papers being submitted to Physical Review that inspired Goudsmit's July 1973 editorial. Looking more into this, it's quite possible that the kind of thing Goudsmit was concerned about were the sorts of papers Jack Sarfatti was writing around this time. According to Kaiser's book (pages 62-63), it was just a few months before this that Sarfatti decided to change the sorts of papers he was writing:

> By the early 1970s, having published a few articles in prestigious journals on quantum theory, elementary particles, and even some idiosyncratic ideas about miniature black holes, Sarfatti could list half a dozen distinguished physicists scattered across the United States, Britain and France as references to vouch for the quality of his work…
> … Sarfatti began to lose enthusiasm for his position at San Diego State during the early 1970s, and indeed for the sterile direction in which he saw theoretical physics heading. He announced his new plans in a letter to renowned Princeton physicist John Wheeler in the spring of 1973… Sarfatti declared that he would leave his "uninspiring institution" and seek out "the best possible environment to create a great and historic piece of physics. I feel impelled by history – a certain sense of destiny," he explained. ("I recognize that I may be suffering under some sort of 'crackpot' delusion, but I cannot accept that as likely. In any case, I must try," he averred).

See the comment here for some of the sort of papers Sarfatti was writing at the time, quite possibly submitting them to *Physical Review*. The opening sentence of Goudsmit's description of the problem (and the fact that he was publishing it in Phys. Rev. D, Particles and Fields)

> The subject matter of these papers usually concerns a fundamental aspect of theoretical physics.

seems to me more likely to be referring to the sort of thing Sarfatti was writing than to papers on the interpretation of quantum mechanics.

Update: It turns out that Goudsmit's papers are available online, here. A non-exhaustive search turned up no evidence pro or con for my conjecture about Sarfatti or similar papers. I only found one set of files (Box 50, Folder 45, "Leibowitz refereeing, 1973") referring to his 1973 editorial. These have to do with this paper, which was published September 1973, after two years of refereeing. This publication led to another author writing a paper criticizing the first, leading to another refereeing problem. Goudsmit weighed in (January 5, 1976) by noting that it was exactly this kind of paper and the problems with refereeing such things that his editorial had been concerned with. Note that the paper in question is NOT an interpretation/foundations paper. Goudsmit writes:

> The event shows again clearly the necessity of rapid rejections of questionable papers in vague borderline areas. There is a class of long theoretical papers which deal with problems of interpretation of quantum and relativistic phenomena. Most of them are terribly boring and belong to the category of which Pauli said, "It is not even wrong". Many of them are wrong. A few of the wrong ones turn out to be valuable and interesting because they throw a brighter light on the correct understanding of the problem. I have earlier expressed my strong opinion that most of these papers don't belong in the Physical Review but in journals specializing in the philosophy and fundamental concepts of physics.

He then refers to his earlier editorial.

Looking at the exchange in these letters, the referee of the second paper writes "I would suggest that understands neither relativity nor quantum theory." This example suggests that the problem Goudsmit had in mind when writing his editorial was not a need for "an explicit policy that papers on the foundations of quantum mechanics were to be rejected out of hand", but just a need to deal with the common problem that is still with us, for both journals and the arXiv. There are lots and lots of people writing low quality papers claiming to say something new about the foundations of physics, on a continuum from the crank to the not so bad. Refereeing such things is difficult and time-consuming, so a journal needs a policy to deal with them quickly and efficiently, otherwise they end up with the mess described in these letters. Goudsmit's editorial I think was an attempt to come up with such a policy.

Update: Jorge Pullin wrote to remind me of an earlier Goudsmit story, which I described on the blog here, but had completely forgotten about. In 2008 an undated paper from Bryce DeWitt's files (he passed away in 2004) was posted on the arXiv. It included a claim much like the ones discussed here that refer to the 1973 editorial, but about a much earlier incident:

> Most of you can have no idea how hostile the physics community was, in those days, to persons who studied general relativity. It was worse than the hostility emanating from some quarters today toward the string-theory community. In the mid fifties Sam Goudsmidt, then Editor-in-Chief of the Physical Review, let it be known that an editorial would soon appear saying that the Physical Review and Physical Review Letters would no longer accept "papers on gravitation or other fundamental theory." That this editorial did not appear was due to the behind-the-scenes efforts of John Wheeler.

I don't know of any other evidence for this (took a quick look in the Goudsmit online archive, didn't see anything). It seems highly likely that this claim about Goudsmit and the Physical Review is not accurate. One minor problem with a claimed "mid-fifties" planned editorial for Physical Review Letters is that PRL wasn't even started until mid-1958. More seriously, the idea that the Physical Review in the mid-fifties would consider banning "papers on gravitation or other fundamental theory" is just completely implausible, and if that phrase is accurate, it surely is very much taken out of context. This story is very similar to the Carroll one about the 1973 editorial, and I'm guessing the true story about the mid-fifties incident is again just that Goudsmit was even then struggling with how to deal with bad "not even wrong" theory papers about fundamental physics.

Update: Steven Weinberg has a version of the "mid-fifties" Goudsmit story, in his biographical notice for DeWitt, in the context of a discussion of the January 1957 Chapel Hill conference on gravity:

> Samuel Goudsmit had recently threatened to ban all papers on gravitation from Physical Review and Physical Review Letters because he and most American physicists felt that gravity research was a waste of time.

Again, there's a problem with this that PRL wasn't even started until a year and a half later, and he has Goudsmit specifying just GR research, not the wider "gravitation or other fundamental theory" which DeWitt gave in quotes.

Comments

   September 9, 2019

   Goudsmit sounds a bit like the mathematicians who got tired of receiving proofs of Fermat's Last Theorem in the mail.

   He does say that "there exist excellent journals publishing articles on the foundations and on the philosophy of science", which is not really the blanket condemnation of quantum foundations one had been led to expect, just a "stop sending it here, please".

   As I mentioned in the previous thread, David Mermin was publishing on Bell inequalities in the *Physical Review* family in 1980 (*Phys. Rev. D* **22**, 356). Bernard d'Espagnat was doing so even earlier (for example, *Phys. Rev. D* **11**, 1424, received in 1974 and published in 1975). McGuire and Fry published there in 1973 (*Phys. Rev. D* **7**, 555), following up on Freedman and Clauser's "Experimental Test of Local Hidden-Variable Theories" from 1972 (*Phys. Rev. Lett.* **28**, 938). At a guess, the Freedman–Clauser experiment had made Bell-inequality tests enough of a thing that people started writing shoddy papers on the topic.

2. **Peter Woit**
   September 9, 2019

   Blake Stacey,
   "At a guess, the Freedman–Clauser experiment had made Bell-inequality tests enough of a thing that people started writing shoddy papers on the topic."

   That sounds quite plausible. I was trying to think of what could have happened around 1972 that might have been the impetus for the Goudsmit editorial. Given the traditional pattern in HEP theory of new advances quickly being followed by lots of papers rushed into print by people trying to get near the front of a bandwagon, there may have been a lot of such papers coming into Physical Review in late 1972-early 1973. Perhaps Goudsmit was trying to lay down some rules as to what they would require of such papers to consider them.

3. **Blake Stacey**
   September 9, 2019

   An interesting historical tidbit from Clauser's article is that the very term *Bell's theorem* was coined in the august pages of *PRL*.

4. **GoletaBeach**
   September 9, 2019

   In my experience Phys. Rev. could always turn difficult when it wanted to… still does sometimes. A classic in Phys. Rev. Lett. history was the years when they decided Lagrangean instead of Lagrangian…. https://physicstoday.scitation.org/doi/pdf/10.1063/1.2811374

   They also wouldn't publish Wino/Zino for the superpartners of the W/Z for a while.

Not sure if any journal initially wanted to publish quarks (Gell-Mann) or aces (Zwieg).

Encouraging well-thought out quantum models that have empirical consequences is a good thing. No surprise to me that the terrific Stuart Freedman was involved in an early Bell test…

He was one of the many terrific students of the late Gene Commins, and, later on, he helped give birth to the KamLAND experiment, which showed that antineutrino oscillations measured entirely on Earth were consistent with the solar neutrino problem.

September 10, 2019

Peter,

Thanks for digging this up. On the one hand, this explains some of the frustration felt by those of us who actually were interested in quantum foundations in the early '70s.

On the other hand, those of us who have followed quantum foundational work for the last fifty years can only note that Goudsmit's complaints are just about as timely today as when he wrote them:

> The subject matter of these papers usually concerns a fundamental aspect of theoretical physics. Extreme verbosity and vagueness of expression makes these papers hard to read and understand. A paucity of mathematics as compared to wordage distinguishes them from the more conventional theoretical papers.

Although I would note a more recent twist: papers that present some very complex mathematics that, it is claimed, reveal the secrets of quantum mechanics — except that no effort is actually made to connect this complicated math with actual physical issues such as the "collapse of the wave function," the Born rule, or the measurement problem.

So, even a low verbiage to math ratio is not enough.

I do, however, have some information on your conjecture:

> That sounds quite plausible. I was trying to think of what could have happened around 1972 that might have been the impetus for the Goudsmit editorial. Given the traditional pattern in HEP theory of new advances quickly being followed by lots of papers rushed into print by people trying to get near the front of a bandwagon, there may have been a lot of such papers coming into Physical Review in late 1972-early 1973.

From 1977 onward, I was a grad student at SLAC and tried to be fairly diligent about looking at the SLAC library's collection of new preprints: I was very interested at the time in quantum foundational issues but I recall very few preprints on quantum foundations (and the library did get lots of preprints on lots of topics, not just HEP)..

I also recall no seminars at either SLAC or on-campus on quantum foundations (except, curiously, for some guys in the Engineering and Economic Systems Department who had somehow gotten interested in quantum foundations). And, I do still recall a number of those seminars — one on perturbative quantum gravity, one by Sidney Coleman, one by Haim Harari on preons, a horrible seminar by Zichichi, etc.

In retrospect, of course, there was a lot of important work being done by pioneers testing Bell's theorem. But, the visibility in the physics community was low, and it seems to have been a very small fraction of the overall work in physics.

Dave

6. **Severin**
September 10, 2019

Have you ever considered going on Sean Carrolls podcast? I think this kind fact-checking and gentle push back would make for a way better conversation then what is currently on offer.

7. **Peter Woit**
September 10, 2019

Dave Miller,
I think it's also important to note that the mid-seventies was a period when the Standard Model had just come together, the November revolution of 1974, GUTs, SUSY had just appeared, the non-perturbative study of QCD had begun, etc. There were a lot of exciting things going on in fundamental physics at high energies, which I think had a lot to do with relative lack of interest in the measurement problem.

Severin,
I haven't been invited.

8. **Dave Miller**
September 10, 2019

Peter,

Yes, we were all excited by the Standard Model coming together, and people were also starting to think about supersymmetry/supergravity, quantizing gravity, etc. I actually heard about the November Revolution in November '74 from Feynman who had been in touch with the guys at SLAC and passed the information on to our QM class.

Strangely, Feynman never mentioned QCD or non-abelian gauge theories, even in his Intro to Particle Physics class that I took in '75-'76!

I think I first heard about non-abelian gauge theories in the summer of '76 from some experimentalist grad students I was working with at SLAC before I officially started grad school.

My own graduate work was on the tau lepton, discovered just before I entered grad school, which was pretty cool: gave me a chance to work with Marty Perl.

Still, all of us students were puzzled then, as students are now, by the weirdness of QM, and we were discouraged from pursuing that interest at all.

Dave

9. **Sebastian Thaler**

September 10, 2019

Popular culture occasionally voices its own opinions on the foundations of quantum theory:
https://www.facebook.com/berkeleybreathed/photos/a.114529165244512/2731285340235535/?type=3&theater

10. **Blake Stacey**
September 10, 2019

Given how nonspecific his editorial was, I suppose it's possible that Goudsmit was motivated by more than one subject. Would 1972 have been a good year for the crop of bootstrap models?

11. **Peter Woit**
September 10, 2019

Blake Stacey,
The height of the bootstrap was earlier, with Chew's book in 1966. Besides impetus from a specific physics craze, the other thing that occurred to me is that 1973 would have been about the time new people entering the field would have included a large number of dope-smoking long-hairs, and maybe this lifestyle was reflected in their writing. From the story told in Kaiser's book, there would be a certain amount of overlap between this explanation and the "people interested in Freedman-Clauser" explanation.

Another possibility is that Goudsmit was looking at the early string/dual models, realized how much trouble they could lead to, and was trying to get ahead of the string theory problem early on…

12. **GoletaBeach**
September 10, 2019

The Freedman/Clauser paper was cited about 11 times per year throughout the 1970s… I recall a lot of discussion about experimental tests in that decade. Local peak in citations in 1977.

It was 1981-1997 that the average citations were low… less than 8 per year, but a steady dribble.

1998-2019… citations of that paper have increased to about 30/year, with 46 citations in 2017.

The deeper issue: what does "understand" mean, exactly? Experimentalists are pretty satisfied if the equations match their data, and when that match happens consistently and repeatedly… something about having hands-on the data takes the edge off, and further, choosing which experiments to perform is a big, big, deal for experimentalists… theorists do toss off ideas without much worry as to just how immense the undertaking is to really do the experiment.

By and large it is theorists who claim we don't "understand". A bit too trite to just quote Upton Sinclair… I'm not saying Sean Carroll falls under this quote, but it might be true that book contracts and royalties do…

"It is difficult to get a man to understand something when his salary depends upon his not understanding it."

Might add… "when his perceived national security w/r to the Chinese depends on him not understanding it"… where "it" might be… the intrinsic noise in all quantum systems.

Adapting Big Bill Haywood… "A theorist is someone who leaves the room when discussions of noise and background for a proposed experiment break out."

13. **Low Math, Meekly Interacting**
September 10, 2019

Do the "dope-smoking long-hairs" referred to above include the Fundamental Fysiks Group? I take it quantum foundations and related philosophical concerns (as well as some acid-fueled musings of a more speculative nature) were right up their alley. Were they and their ilk especially prolific writers circa 1972?

14. **Peter Woit**
September 10, 2019

LMMI,
Yes, one subset of the dope-smoking long-hairs would have been some of the Fundamental Fysiks Group members (surely there were plenty others though). Kaiser tells their story in great detail, with one of the main characters Jack Sarfatti. If you go to the HEP database INSPIRE, you can see that in late 1973 Sarfatti was producing lots of papers (five in the last three months of 1973), and it may very well have been those that Goudsmit was trying to find an excuse for rejecting without refereeing.

The funny thing is that the titles of these papers sound very modern, could be titles of papers on the arxiv today, e.g.

The World On A String
Jack Sarfatti (ICTP, Trieste). Nov 1973. 7 pp.
PRINT-74-0117 (ICTP,TRIESTE)

Toward A Unified Field Theory Of Gravitation And Strong Interactions
Jack Sarfatti (ICTP, Trieste). Oct 1973. 7 pp.
PRINT-74-0081 (ICTP,TRIESTE)

Quantum Gravitational Dual Strings: Violation Of Time Reversal Invariance
Jack Sarfatti (ICTP, Trieste). Nov 1973. 7 pp.
PRINT-74-0116 (ICTP,TRIESTE

Explanation For The Asymmetry Between Matter And Antimatter In The Visible Universe
Jack Sarfatti (ICTP, Trieste). Nov 1973. 5 pp.
IC-73-175

and, a few months later

Quantum Mechanics as a Consequence of General Relativity
Jack Sarfatti (ICTP, Trieste). Mar 1974. 4 pp.

It's quite possible that Goudsmit's problem was this kind of thing, not papers about interpretations of QM and the implications of Bell's theorem.

15. **Jackiw Teitelboim**
September 10, 2019

Looking at this last paper by Sarfatti, it (embarrassingly?) looks not so different in (the lack of) content (and rigor) from a talk "QM=GR" delivered recently by Susskind in the t'Hooft Fest:

https://www.uu.nl/en/events/conference-t-hooft-2019

Maybe Susskind should start acknowledging Sarfatti's priority on these matters!

16. **Peter Woit**
September 10, 2019

Jackiw Teitelboim,
Actually, Susskind and Sarfatti worked together back in the 1960s (or at least that's what Sarfatti claims…).

17. **Joseph Healy**
September 11, 2019

As an aside, J.W. Stout referred to another Goudsmit comment in his 1986 article: The Journal Of Chemical Physics: The First 50 Years
.
"Sam Goudsmit once said that he suspected that the ratio of readers to authors of Physical Review articles was less than unity, since it was evident that some authors had not read their articles before submitting them. "
.
https://www.annualreviews.org/doi/pdf/10.1146/annurev.pc.37.100186.000245

18. **Low Math, Meekly Interacting**
September 11, 2019

I should have reviewed your review of Kaiser's book before posting, or it would have been obvious.

I wish to be clear I do not intend to besmirch the whole of long-haired, dope-smoking freakdom for the more offbeat behavior of a few notable individuals, however brilliant.

It's not hard, however, to imagine the Fysicists and their fellow travelers might have been sufficiently irritating to their squarer elders to trigger a response, however far-sighted some of the pesky deviants proved to be.

19. **former mathematician**
September 11, 2019

In summer of 1969, I moved into an apartment in Berkeley, where John Clauser and his wife Marilee had the informal role as superintendent. He spoke of his hopes for the experiment he was setting up. He expected the opposite result to the one obtained. When he was done, he thought, quantum mechanics would be relegated to a branch of mathematics.

20. **Peter Woit**
September 11, 2019

LMMI,

No criticism of anyone for dope-smoking or having long hair was implied. Those who still have all their hair are encouraged to enjoy it.

All,
See an update to the posting for more about Sarfatti. I now think the conjecture that it was Sarfatti's papers (and other similar ones) is the most likely explanation for the Goudsmit editorial, not an attempt by him to suppress study of the interpretation of quantum mechanics.

21. **Peter Woit**
September 13, 2019

See the updates to this posting for more historical evidence, which I think shows that Goudsmit's editorial was not particularly aimed at papers on interpretational issues in QM, but just concerned a long-standing problem of how to deal with low-quality "not even wrong" theory papers making claims about fundamental physics.

22. **Blake Stacey**
September 13, 2019

In the first decade of PRL's existence, Goudsmit declared a subject *non grata* at least three times. In 1959, it was masers; in 1960, it was the Mössbauer effect; and in 1965, it was "internal symmetries":

> Hereafter, papers in this area will be considered only if they propose a genuinely new concept which makes possible the correlation of previously unrelated data.

23. **Arnold Neumaier**
September 16, 2019

Potentially interesting in this context:
https://journals.aps.org/prx/pdf/10.1103/PhysRevX.4.040002
[Note: PRX = Physical Review X]

"when we are asked the question, "Does research on foundations of quantum mechanics fit into PRX's scope?" our answer must be a clear "yes." However, that is far from saying that any intellectually sound paper from that topical area merits a spot in PRX. Indeed, the task of judging whether an individual paper on foundations of quantum mechanics is suitable for PRX is an editorially challenging one, especially given the often unavoidable presence of philosophy in our efforts to understand, interpret, and apply quantum mechanics."

24. **Peter Woit**
September 16, 2019

Arnold Neumaier,
Thanks! That policy description also includes something similar to the 1973 editorial:

"In the end, we came away with the following guideline: PRX will publish papers on foundations of quantum mechanics proposing highly original, scientifically sound approaches or models that already, or can potentially, suggest new experiments, and/or lead to new numerical tools for solving quantum-mechanical problems, or even significant new predictions."

Again, the evidence is that Physical Review hasn't ever had a policy banning a topic, be it gravity or quantum foundations, but has just struggled with how to deal with low-quality papers in these areas.

25. **GoletaBeach**
September 16, 2019

From deep in the bowls of my memory comments from Eyvind Wichmann about Bell percolated up, from the 1970's, and at Berkeley.

Wichmann made the point that the Bell correlations between the two sides of an EPR pair were simply the consequence of angular momentum conservation.

Experimental work to test Bell correlations… well… do you really think there is a violation of rotational invariance? The EPR state, Wichmann emphasized, was the degree of freedom that the initial system could couple to. Now maybe Stuart Freedman was in the room. Maybe Stuart kinda stopped pursuing Bell tests.

26. **Mark Hillery**
September 20, 2019

Somewhat off topic but related to the last comment. Note that the Bell test experiment by Friedman and Clauser was published in PRL in 1972, Stuart J. Freidman and John F. Clauser, "Experimental Test of Local Hidden-Variable Theories," Physical Review Letters 28 #4, (3 April 1972), 938-941.

From the AIP interview with John Clauser:

Clauser:

Townes was just the opposite. Without Townes, I could never have done that experiment. Townes was the guy who actually twisted Commins' arm to put Stu Freedman on the experiment and to steer Atomic Beam Group funds into doing the experiment. And if I had not convinced Townes early on [it never would have happened]— In fact, the first thing I did when I arrived at Berkeley was that I gave a seminar describing this to Townes' group, and Gene Commins was there, as he had done this previous experiment with Carl Kocher. And at the end of this, Townes kind of puts his arm around Gene Commins and says, "Well, what do you think of this, Gene? It looks like a very interesting experiment to me." So if Townes puts his arm around your shoulder and says, "Looks like a very interesting experiment," I mean, Commins thought it was a total crock. But when Townes says he thinks it's interesting, it's interesting. It becomes interesting at that point.

Bromberg:

It's surprising to me because Cummins' experiment was precisely on the Einstein-Podolsky-Rosen paradox.

Clauser:

They did not understand Bell's Theorem. Nor did they understand just the significance of what it all meant at that point, absolutely not. But it was Eyvind Wichmann, a theoretician at Berkeley, a very bright guy, I think, who actually suggested that they do the experiment. He's a theoretician, a very bright guy. While I was at Berkeley, I actually audited a course he was giving. He apparently suggested to Commins that they can actually do this, and apparently they originally planned on doing that as a lecture demonstration. Originally it was built on this rolling table with wheels on it so they could roll it into a lecture. Kocher was going to do this kind of as just a little project, and polish it off, and then get on with a real thesis project. Well, it was much more difficult than they originally anticipated, and it became his thesis project. No, you could not have done it as a lecture demonstration. It took weeks of counting to get any decent statistics.

An Apology

September 15, 2019
Categories: Quantum Mechanics

I'm afraid I made a serious mistake in this previous posting discussing Sean Carroll's new book. Since the book was relatively reasonable, while the jacket and promotional material that came with it were nonsense, I assumed that Carroll was just being ill-served by his publisher. It's now clear I was very wrong. He's on a book tour, and the nonsense is exactly what he is putting front and center as a revelation to the public about how to understand quantum mechanics. For a couple examples, here's what was on the PBS News Hour

> The "many worlds" theory in quantum mechanics suggests that with every decision you make, a new universe springs into existence containing what amounts to a new version of you. Bestselling author and theoretical physicist Sean Carroll discusses the concept and his new book, "Something Deeply Hidden," with NewsHour Weekend's Tom Casciato.

and here's something from his talk down the street from me.

Using your public platform to tell people that the way to understand quantum mechanics is that the world splits depending on what you decide to do is simply What the Bleep? level stupidity. Those in the physics and science communication communities who care about the public understanding of quantum mechanics should think hard about what they can do to deal with this situation. They may however come to the same conclusion I've just reached: best to ignore him, which I'll try to do from now on.

Chasing Einstein

September 16, 2019
Categories: Film Reviews

Last night I went to a showing of Chasing Einstein, a new documentary about the search for dark matter. It's quite well done, and if you're near New York, Berkeley or LA, you might want to take the opportunity to go see it in a theater.

The film starts out with a segment on LIGO, talking to Barry Barish and Rainer Weiss. Later on there are scenes from their Nobel celebration ceremony at Caltech and the award ceremony in Stockholm. There are no claims made that LIGO's results are related to dark matter. Rather, this material functions as a counterpoint to the dark matter material, contrasting a great success story to the rather frustrating lack of success that physicists have had with dark matter.

Attention then turns to Elena Aprile and the Xenon1T experiment. Aprile is in the physics department at Columbia, and attended the screening I was at. I think she's the great heroine of this film, although a bit of a tragic one. She and her collaborators have done a fantastic job of getting a series of highly sensitive detectors to work. If a WIMP particle responsible for dark matter had existed in the region advertised by many theories, they would have found it and followed the LIGO people to Stockholm. Instead they put a strong limit on the possible properties of such a conjectured particle. The film includes a heart-breaking scene when they unblind their data, quickly realizing that their years of effort haven't been rewarded with the discovery that they had been hoping for. Aprile has a realistic take on the prospects for future experiments of this kind: they can be make somewhat more sensitive, but it's hard to be optimistic that the remaining accessible parameter space contains a new particle.

Attention then turns to Erik Verlinde and his "Emergent Gravity" explanation for the dark matter phenomenon. I've never found the motivation for this compelling, so haven't followed his work carefully. For someone who has, see Sabine Hossenfelder's blog where she has written on the topic quite a few times (and has her own version of a model here). Grad student Margot Brouwer worked on this attempt to experimentally test Verlinde's ideas, and she is also featured in the film. My understanding is that the positive results her group found are matched by other more negative results, see here.

Tech entrepreneur Cree Edwards appears at various points in the film, and I'm guessing that he's the one who brought together the physicists and filmmakers to make the film (and probably financed it). He has an amateur's interest in fundamental physics, and his questioning of the physicists reminds one of how people's fascination with the subject is often deeply connected to their desire to make sense of the world, hoping to find explanations of the great puzzles of human existence. I fear he's not likely to find much of what he's looking for in physics, but glad to see that his questioning led to an excellent film.

Finally, the film contains scenes of observing a solar eclipse, an added attraction.

   September 16, 2019

   I was hoping by reading this post I'd know how you thought about the film. This reminds me a bit about Dirac style of lecturing 😛 … Would you recommend others to watch it too?

2. **Peter Woit**
   September 16, 2019

   A_saint,
   I enjoyed the film, and I hope that came out in the posting, but I'm always leery of telling others that they will too, so should definitely see a certain film. Tastes differ, and what I find charming others might find annoying. So, I try to give enough information about what's in the film to let you make up your own mind.

   In any case, right now the film has only a very limited theatrical release, so relatively few people are going to have it available nearby.

3. **More Anonymous**
   September 16, 2019

   1.Just re-read the whole post and found one sentence that does describe your views: "… but glad to see that his questioning led to an excellent film."

   2.Also about " So, I try to give enough information about what's in the film to let you make up your own mind." Is there anything in the movie you have left out from the plot? Maybe add a spoiler in the title (if not)?

   3. "… "Emergent Gravity" explanation for the dark matter phenomenon. I've never found the motivation for this compelling … " I'm also curious what your view on the dark matter phenomenon is? Where should physicists be placing their bets?

   4. Also chrome is showing me a red sign with "Not secure" in the URL place (for this site). And if I click on the learn more:
   https://support.google.com/chrome/answer/95617?visit_id=637042412030042076-2172091136&p=ui_security_indicator&rd=1
   Whats this about?

   September 16, 2019

   About 4.

   That was quick!
   I just saw it go from:
   Not secure to Info to Secure

   Did you do anything on your end? I swear I'm not lying (and wasn't when I made that comment) … Interestingly it didn't remember my details despite the "
   Save my name, email, and website in this browser for the next time I comment." in the comment box.

   Also just noticed the username change in the 2nd post to More Anonymous must have accidentally done something .

5. **Peter Woit**
   September 16, 2019

A_saint/More Anonymous,
Yes, I did just fix the https warning, it was doing that because of an http rather than https in one of the buttons on the right hand side. The change in the site may have temporarily disrupted the "save your name" feature.

There's not really a plot to "spoil" for this film. The one moment of drama is the Xenon1T unblinding, but unless you're unaware that that experiment hasn't found dark matter, the outcome isn't a surprise.

I don't want to get into a general discussion about dark matter, it's a huge, endlessly debated topic, and unfortunately there hasn't been anything really new to say about it for quite a while (and I certainly have no new idea about it). My generic question about "emergent gravity" claims like those of Verlinde is "emergent from what?" Without a non-trivial answer to that question (and I don't see that Verlinde has one), it seems unlikely you are going to get anything interesting. Not mentioned in the film is the all too possible frustrating scenario that dark matter is a new particle, but one that has no interactions other than gravitational, so can effectively never be directly seen in a feasible experiment. If I had to place a bet, it might be there.

6. **GoletaBeach**
September 16, 2019

Perhaps the movie presents Elena Aprile in a tragic light, but I'm not aware of anyone in the actual dark matter field who shares that view. Everyone knows when they start a search program that the most probable outcome (by a lot!) is no discovery.

There is a very weird and contrafactual attitude out there… typified by a Malcolm Browne article in 1993 that ran under the headline "315 Physicists Report Failure In Search for Supersymmetry".

There was no failure. They (as LHC now, and Xenon-1T too) completely succeeded in doing exactly what they said they were going to do… achieve sensitivity to new physics within a certain parameter space. It is science… "Eliminate all other factors, and the one which remains must be the truth." Just as Michelson and Morley did. It is a recurring cynical joke that theorists on modern review panels would have defunded Michelson and Morley.

Everyone in the dark matter field knows that there are at least 8 orders of magnitude more to go before SUSY explanations of dark matter are close to inconsistent with SUSY. Anyone who says otherwise is confused about what some call the "Canadian Border Effect". Canadian population clusters around the southern border, it is the most desirable real estate. US population is sparse right there… for Americans, the northern border is not desirable.

A la mode SUSY dark matter theories always cluster just below the current experimental sensitivity for the same reason. For dark matter and for the LHC. Thinking "a la mode" is the only reason to build experiments is immature, although theorists want to be able to say "I predicted it!", so they find models just over the limit. Only other theorists take that seriously.

Aprile got involved in liquid xenon detector technology when it was mainly going to be used for x-ray astronomy at Columbia. She wasn't initially using the dual phase technique, invented in Russia. She had the insight to see and push for implementation of that technique with her liquid xenon ability to search for dark matter. She is not the only one, actually… Dolgoshien's old group in Russia and groups in UK simultaneously began the push. Aprile's group did get the first really good results out.

The technique has achieved 4-5 orders of magnitude in new sensitivity… imagine finding a technique that raised beam energy in proton-proton collisions by 4 to 5 orders of magnitude. And the liquid xenon can go a lot further; many groups are planning to continue… progress will be slowed (but not stopped entirely) when neutrino interactions start to show up.

The tragic element really is: both this blog (and Sabine Hossenfelder) portray vast improvements in experimental sensitivity without a transformational discovery as "failures". It is a lack of understanding as to how real experimental work and discovery works… the top quark didn't appear for 15-20 years post prediction, and its method of discovery was pretty much unheralded at its inception, for example. Real experimentation and experimental discovery entails quite a bit of persistence, and skepticism of all theorists.

Ruling things out has a huge value… Luis Alvarez answered this question in the 1960's when the muon intensity experiment in the pyramid of Khafre found "no large unknown chambers exist"… the technique did map the big chamber where they set up the experiment. He was asked about his "failure"… he pointed out that the experiment was a complete success, and would prevent explorers and drillers from mounting expeditions to look for new chambers… of no small value. And now, the technique has been refined and found a new chamber in the pyramid of Khufu.

These portrayals of "tragedy" and "failure" mildly annoy many experimentalists… and further convince them that theorists and mathematicians don't deeply comprehend what empirical science is. Sitting on a review panel with folks who don't get it can be quite painful… another topic Luis Alvarez used to write about. It may be that forums like this blog (and Hossenfelder) are suppressing discovery.

A portion of what Hossenfelder lobbies for is experimental testing of alternate DM theories. That is good…

7. **Peter Woit**
September 16, 2019

Goleta Beach,
I'm afraid the posting does not make my point of view clear, but I'm not sure why. To quote myself above:
"I think she's the great hero of this film, although a bit of a tragic one. She and her collaborators have done a fantastic job of getting a series of highly sensitive detectors to work. If a WIMP particle responsible for dark matter had existed in the region advertised by many theories, they would have found it and followed the LIGO people to Stockholm. Instead they put a strong limit on the possible properties of such a conjectured particle."

The reference to "tragic" is to the portrayal in the film, where she is interviewed and gives a nuanced explanation of what it is like to work on an experiment like this.

I agree completely that the achievement of huge increases in sensitivity and investigation of large new areas of parameter space by Xenon1T and others is a huge experimental success (while still being, undeniably, a failure to find an hypothesized new particle state). Arguably, this sort of achievement, not just discoveries, should be rewarded by the Nobel.

Similarly, the LHC results ruling out large new regions where there could have been new particles is a huge experimental success, while at the same time being a failure to find SUSY states. When I refer to such a failure, what I'm referring to is a theoretical prediction being successfully disconfirmed by experiment, and the failure is on the theorist's side, the success on the side of the experimentalists.

On the topic of where to expect SUSY states, my opinion has always been "nowhere", since such states don't explain anything, just make the SM more complicated. The regions heavily advertised for such states pre-LHC have now been ruled out, puncturing I hope the hype behind the whole subject. This doesn't rule them out in other regions, and if experimentalists can investigate some of those regions they should, but I think the argument for doing this increasingly is because something unexpected might turn up, not because unconvincing models will get ruled out.

8. **GoletaBeach**

September 17, 2019

Thank you Peter. The 3 families (e,mu,tau) and/or (u/d,c/s,t/b) also just make the SM more complicated too… who ordered that? Actually, "Who Ordered That?" might be the complementary experimental blog (if it existed) to "Not Even Wrong".

That the relative – sign between loops of symmetrical fermions & bosons in SUSY isn't the worst motivation I've ever heard of.

The WIMP motivation always has been: we doubt the dark matter has explicit strong and electromagnetic interactions. We believe the dark matter (DM) has gravitational interactions. That leaves one interaction to probe… the weak interaction. Slight bias if the DM has a weak interaction then it should have rest mass in the W/Z/Higgs ballpark.

That idea also helps in one scenario of the early universe, if the DM was in thermal equilibrium with us.

Experimentally that defines a program. The first "natural" experimental sensitivity benchmark was passed in the 1980's… if the (massive) DM had the couplings of a Dirac neutrino, it would have been discovered then. Experiments stopped for a while.

Gradually the idea that maybe the DM was not Dirac but Majorana seeped in, and the "natural" sensitivity plummeted to well below what we have lately achieved, because one needs to mediate through Higgs to top pairs to gluons, or through the Z0, and inevitably through interferences. Still no SUSY is needed. If anything SUSY makes *even tinier* cross sections *more* likely… also makes large cross sections more likely… just broadens everything.

Somehow Sabine Hossenfelder and Stacy McGaugh still write in the August 2018 Scientific American…
"But after three decades of failed attempts to detect any of these particles, ignoring alternative hypotheses is no longer reasonable."

First, there were no "failed attempts". Note they do not say "failed theories". "Failed attempts" implies the experiments failed. Most of the experiments succeeded admirably.
(I do know that you, Peter, are not equal to Hossenfelder and McGaugh, and I appreciate that).

The second clause of their sentence is always reasonable. Keep thinking about everything. Keep suggesting experiments to test the ideas.

A bunch of earthbound experimental effort actually did go into testing MOND… but turns out the loophole is… MOND depends on *absolute* acceleration. Relative acceleration is empirically proven to show no MOND effect.

So although lab experiments possess a sensitivity level sufficient to test MOND, we can't get them into the right reference frame without a rocket that gets out of the solar environment. To do that you are talking a billion $ at least. But just writing this has made me wonder if far out in the Kuiper belt or beyond their might be a system of binary snowballs that Hubble could study to test MOND.

A bit puzzling that Hossenfelder and McGaugh *ever* felt non-WIMP ideas were *ever* ignored.

Nobody felt strongly the collapsing binary signal would be large enough for this generation of LIGO to see the chirp. Great that unexpectedly massive black holes turned out to exist, but "Who Ordered That?" What is the formation mechanism? Post LIGO, no lack of theories, will be the same if WIMPs are seen at a cross section of 10-52 cm^2.

As for Nobels… only time will tell. Charpak's chambers did not work at all at first. It took non-Charpak adopters to correct their deficiencies.. but Charpak got the Nobel Prize. Yes, Nobels get awarded in particle physics for innovation without direct responsibility for a new particle or force.

The vast sensitivity improvement pioneered by Elena Aprile (and others) might yet get awarded a Nobel somehow.

9. **shantanu**
September 18, 2019

GoletaBeach: Some comments on your post.
we don't have even a single shred of evidence from astrophysical observational that dark matter is a WIMP or has weak scale couplings. (The only argument is WIMP miracle, which is at best a numerical coincidence)
Also the goal posts for WIMP direct dark matter detection have changed in the last decade. This is best exemplified in Figure 1 of https://arxiv.org/pdf/1703.02389.pdf

10. **Ron Avitzur**
September 18, 2019

I saw the ads for the film and was going to skip it, then saw your review and walked downtown to see it. Gorgeous film, loved the scenery, and awesome giving the physicists so much screen time. So thanks for changing my mind!

11. **GoletaBeach**
September 18, 2019

shantanu…. "we don't have even a single shred of evidence from astrophysical observational that dark matter is a WIMP or has weak scale couplings. "

You are right… we don't even have evidence that dark matter is a particle, or obeys our quantum mechanics or relativistic quantum field theory, or obeys any of our conservation laws.

But we assume some of that to test hypotheses. Gotta start somewhere.

That dark matter might have weak scale couplings is a conjecture, but has at least one very simple motivation you overlook: electromagnetic and strong couplings are very unlikely, gravitational couplings are likely (although could just be MOND or something like it), leaving the weak interaction as "the remaining one to check".

Sherlock Holmes logic: test the untested hypothesis.

The WIMP miracle *may* be a coincidence, or not. You may feel that it is, but your feelings are not scientific evidence.

The paper you refer to is nice but culls out the lower limits for cross sections, which for unconstrained SUSY models go down far below the bottom of those plots, down to at least 10-56 cm^2 or so. Not sure why the author forgot to mention that.

That (eventually) popular models tend to lurk just under the current experimental sensitivity has been true ever since models and sensitivity got on to a plot.

The popular models of any particular moment do not even close to comprising a "complete set" of pertinent models. For WIMPs there are always many models just below whatever the experimental sensitivity happens to be, and those models get popular when experiment gets there. But the knowledgeable know that those models are still lurking there right now, where experiment will be in 5 or 10 or 20 years.

The WIMP situation may not fit in a simplistic Kuhn or Popper-esque notion of science. They didn't describe real scientific discovery so that is no problem.

In real scientific discovery, the majority of new particles… the electron, the proton, the alpha-particle, the neutron, the electron neutrino, the muon, the muon neutrino, the tau, the strange quark, and the bottom quark were unheralded by theorists and dominantly discovered by experimentalists.

The photon, the gluon, the tau neutrino, the Z0 and W, the top quark, and the Higgs were predicted by theorists.

The charm quark is about 50-50.

So 10.5 particles for aphilosophical experimental exploration, 7.5 particles for textbook scientific philosophy.

For fundamental symmetries: C is definitely a theorists prediction, while P violation is about 50-50 (observed early by Cox and the tau-theta puzzle, then fleshed out by Lee and Yang), CP violation pure experiment, CPT on the theory side. So for these kind of symmeteries… 2.5 theory/philosophy, 1.5 experiment/aphilosophy.

Other symmetries… baryon number, lepton number… harder to say. Deep interplay throughout it all.

12. **shantanu**
September 19, 2019

Goleta Beach The dark matter could be a non-thermal relic. It could be a massive graviton. It could be even be a SM particle (see the collection of papers on Macro dark matter). There is no evidence from any astrophysical observational to distinguish between these (and other such possibilities) and a WIMP (for which so much of investment has taken place)

13. **GoletaBeach**
September 19, 2019

shantanu… you are right, the dark matter could be a non-thermal relic, which some WIMPs can be too, and there have long been experiments (ADMX, for example) among many others who have looked for non-thermal relics.

WIMP hunts, if you fairly account for all the dark matter effort going on at accelerators, with QIS sensors, with AMS and Fermi in space, with other indirect techniques… constitute a small fraction of all dark matter search funds. MOND got innovative attention in the 2000's but to really test it is in the billion-$ class now.

Whether the relative abundance of dark matter to our matter is astrophysical evidence that supports (to a certain extent) a weak interaction for dark matter is something you feel is a coincidence, but others feel is a bonafide observation.

Investment in experimental endeavor takes one input from perceived discovery likelihood, but there is another input which is innovation… innovation isn't perfectly correlated with $.

Experimentalists push to innovate all the time, and deep insights by folks like Aprile have led to huge advances in WIMP sensitivity per dollar. Other WIMP techniques have hit barriers and don't advance much even with the substantial $ that have been granted to them.

14. **Dan**
September 23, 2019

I saw Chasing Einstein, mixed feeling about this movie, mostly of the motives of the gathering these physicist in Montana and Carmel by Cree. Didn't get anything out of the Couch interview, and Carmel interview was uncomfortable to watch (poor Verlinde, just couldn't say what he really was thinking it seemed). Wish they would have gone more into the theory that Verlinde was putting forth. Aprile I feel was edited in the wrong light.

To A_saint, do not see this film, it was lackluster, and to be honest, I got more out of reading comments from GoletaBeach, shantanu and Peter Woit.

15. **Bernhard**
September 24, 2019

Thanks for pointing to Sabine's model, I didn't know it. I spent some time reading it – what a really cool article. Beyond me how someone who writes the number of high quality (many single authored by her!) articles she did not get tenure yet. In any case, I think "yet" is the word here.

Some background on “high energy physics”

September 16, 2019
Categories: Uncategorized

There was a workshop last week at the Harvard CMSA, focusing on new ideas about physics rooted in topology. Talks are available on the workshop webpage, and those interested in high energy physics might be most interested in the ones from the first session. There was an interesting introductory talk by Dan Harlow, in which he lays out his view (which I think is a very mainstream one) of the current situation of HEP theory.

He begins by noting the problem of building higher energy accelerators (claiming that the problem is that technological limits make the maximum energy of collisions go as the square root of the radius of the machine, but I think really for proton-proton machines it is linear in the radius, for electron-positron machines the fourth root of the radius). Given the lack of new data, he describes one tactic for theorists as to change fields, e.g. to machine learning or biophysics.

If one does want to persist, he argues there still is a list of things incompatible with the Standard Model (gravity, dark matter, neutrino masses, baryogenesis, inflation) and these are not just “aesthetic” problems (here he refers to misunderstandings in the “popular media”, a clear reference to Sabine Hossenfelder and her book). From there he focuses on quantum gravity, essentially arguing that the other problems can be addressed by BSM models, but none of these seem particularly nice, so without new data progress is unlikely.

He describes quantum gravity as the ideal situation for theorists, since according to him there’s no self-consistent theory that fits the data we already have (I guess he’s saying string theory models are inconsistent…). He describes current work on this as based on two main strategies, with AdS/CFT providing a link between them:

- “Study the non-realistic corners of string theory where mathematical control is possible”, i.e. pick some non-physical string theory background (e.g. AdS/CFT) where you think you can do self-consistent calculations and do those, hoping to get some more general insight.
- “Set aside gravity for the moment, and focus on understanding the mathematical properties of QFT.” He gives a few examples of general questions being studied (which unfortunately have no obvious relevance to addressing the problem of quantum gravity, or basic problems like that of non-perturbative QCD.)

In the question section, there was an exchange between Harlow and Seiberg, based on Harlow’s reference to changing fields because of no data and to something he said during the talk (at 2:06):

> **Harlow**: So then, what are we supposed to do in the meantime, right? You know we need to keep writing papers and posting them to hep-th and so on, so what do we do?

I suspect that for some context to the following exchange, you should also look at the video of the panel discussion earlier this year at Strings 2019, where Harlow, sitting next to Seiberg says (at 6:45) “We’re having fun, isn’t that the important thing?”.

> **Seiberg**: I’d like to make one comment.
>
> This was a beautiful summary, spectacular, except that one thing was fundamentally wrong and certainly should not be said. It’s not that we’re doing what we’re doing because we have to fill the time (audience laughter). We’re doing what we’re doing because it’s very important (audience laughter). I don’t think about “maybe we should write some books and this and that, until we have more information” I think this is wrong and this should not be
>
> **Harlow**: I’m doing it, right, I don’t like wasting my time, so, I think it’s worth my time. I do think it’s important. We have this list of phenomena that we can see and can’t explain.
>
> **Seiberg**: Comments like these have been used against us (audience laughter), in addition to the fact that they are wrong.
>
> **Harlow**: OK, yeah, yeah, I’m not talking to the New York Times, right. (audience laughter).
>
> **Dam Son?**: Is it recorded?
>
> **Harlow**: I don’t know actually (audience laughter), I’ve said much worse things that were recorded, so.

HEP theory is at a very difficult point in its history, and it seems that the older generation struggling with this is not particularly amused to hear what sounds like flippant takes on the problem from the younger generation.

Update: I finally got around listening to the Susskind interview mentioned in this comment. Susskind also has given up on particle physics:

> I originally was officially an elementary particle physicist. Elementary particles is not going so well, there’s no new experimental input and nobody knows what to do. It’s sort of reaching a point of, should I call it diminishing returns? It could change, it could easily change. I don’t think it’s doing very well. It’s not the fault of the physicists, it’s just the fact that they’ve reached a barrier, with no possible access experimentally to things that we’re not doing very well figuring out theoretically. So that’s not doing exceptionally well. My guess is the same thing may happen to cosmology. That they will eventually run, and they’re very close to it now, running out of new data, so there may be a barrier there.

Update: This week in Chicago there’s a workshop on the CEPC (proposed large new electron-positron collider in China). The first talk Monday was from Nima Arkani-Hamed. At the end of it, the question period started, with an exchange that resonates with the Harlow-Seiberg one:

> **Mike Peskin**: So, let me make a quick summary of this talk: “my prediction is that when we go to high precision with the Higgs we will see no deviation from the Standard Model, but that will be a good thing because theorists will be inspired to think about these fundamental questions.”
>
> **Nima Arkani-Hamed**: Absolutely. I’ve said it many times. Many people don’t believe me, but I believe it 100 percent. If we see some deviation, fantastic, great, people will have a lot of fun figuring it out, if we don’t see a deviation that’s a much, much bigger gauntlet thrown down at the feet of theorists to try to figure out what is happening.
>
> **Mike Peskin**: But on the other hand you’re not promising any concrete discovery, just we reconfirm the Standard Model at a much higher level of energy.
>
> **Nima Arkani-Hamed**: Reconfirming the Standard Model would just crank up the screws that are put on our theoretical imaginations even more.
>
> **Mike Peskin**: How many billions of dollars do you expect people to spend to reach this conclusion?
>
> **Nima Arkani-Hamed**: … However many billions it takes.

At the same conference, today Matthew Reece gave a talk on The Hierarchy Problem and the Motivation for Future Colliders. He starts out with:

> I'll review some arguments that may be well-known to many of us—but which I find are not necessarily well-known to students, some of whom are being taught that there is no motivation to search for BSM physics.

and gives this I think accurate characterization of the problem:

> The better way to frame the problem, and the role of fine-tuning, is that we are seeking a theory that explains the origin of the EW scale.
>
> If, within that theory, the EW scale is extremely sensitive to input parameters, it's not a very good explanation. The theory does not generically describe a universe like the one we live in.
>
> If moving around in parameter space just produces modest changes in the low-energy physics, that's a compelling theory that predicts a world like ours.

This characterization makes clear what the correct interpretation of the null LHC results should be: they provide significant evidence that the picture of a very high energy scale GUT/string theory with lots of parameters, generically producing the weak-scale physics that we see, is just wrong. There never has been any evidence for this anyway, so the failure of the hierarchy argument was to be expected. To the extent that you believe the hierarchy problem is the motivation for BSM physics, students who are being taught to give up on BSM physics by Harlow and others are not really being misled.

My own take on all of this: what Harlow and Arkani-Hamed get wrong is their claim that thinking about fundamental issues of quantum gravity is some new, exciting question that has just come up post-LHC null results. These issues have been there for decades; they were obvious at the time I was a grad student in the early eighties. The problem is what to do facing several decades of failure by theorists, and I don't think the answer is to make outrageous claims about how wonderful the current situation is. The motivation for a new collider is the one Reece points to, ignoring the business about the hierarchy problem: we don't understand at all the origin of the EW scale. This is the best argument for studying the scales just above it that the LHC has started to enter. If we can get some new insight into the EW scale from a detailed study of the scales just above it, that will revolutionize physics (not just be "a lot of fun"). If we can't, we're facing a very, very tough time, especially if we insist on pursuing fundamental theory the way it has been pursued in the past.

Comments

1. **DB**
   September 16, 2019

   Peter,
   re what Harlow says about quantum gravity being the ideal situation for theorists, here are Susskind's latest thoughts on some similar issues, talking about the "barrier" reached in both particle physics and cosmology, and why quantum gravity is probably the stuff to focus on right now.
   He mentions Maldacena's latest ideas as being the new biggest excitement, though I have no clue what they might be.
   Aforementioned info is between 15:50 and 19:20.

   https://podcasts.apple.com/gb/podcast/universe-speaks-in-numbers-lenny-susskind-interviewed/id1479389232?i=1000449685963

   PS: I also interpret that he says that string theory models are inconsistent… Hmmmmm, I thought he was a string theorist himself. Has he flipped?

2. **Peter Woit**
   September 16, 2019

   DB,
   What Harlow says I think is conventional wisdom in much of the "string theory" community (which these days mostly is not doing string theory anymore…), so it's not surprising you're hearing a variant of it from Susskind. The idea, as Harlow explains, is that the only fundamental problem left that isn't hopeless without new data is quantum gravity, and any approach to quantum gravity should start with holography and AdS/CFT.

   I don't want to start a discussion here of the latest things Susskind and others are doing along these lines. I'll just note that while Harlow makes it sound like this is new, this is pretty much the ideology the string theory community has been following for the past twenty years, and it seems to me that it has led them nowhere. The inspirational version you hear of this (it made an appearance in the "Chasing Einstein" film) is that the decks have been cleared and theorists are now confronting the most fundamental issues, space-time is doomed to be replaced by something new and exciting, inspired by AdS/CFT. The only problem is that this is not new, it's older than my students here at Columbia, and nothing promising has been found to replace the doomed space and time.

3. **Sabine Hossenfelder**
   September 17, 2019

   At least it looks like they they are trying to think about how to not waste further time. I guess that counts as progress. If all goes well, then in 20 years they will understand what I wrote in my book.

   For the record, I have a differentiated view on what problems are are actual problems in the foundation of physics and which are merely aesthetic misgivings. It's not like I am saying they are all just aesthetic. I have eg been very clear in pointing out that dark matter and quantum gravity are "good problems". I have a list here, in case you don't like to waste your time…

4. **Alessandro Strumia**
   September 17, 2019

   LHC has been mostly completed, its theoretical consequences have been mostly discussed, if nothing new happens the field will decline in the next few years. What next?
   Two long-term possibilities that seem not totally hopeless are:
   1) explore string vacua with supersymmetry broken at the string scale.
   2) make AI really I. Many deep results in physics have been achieved by a few smartest physicists, and there are reasons to think that A-IQ should be scalable.

5. **Sabine Hossenfelder**
   September 17, 2019

   Indeed, Alessandro's second point makes a lot of sense. There is almost certainly unexplored potential in the already existing literature where no one has made a connection that's hiding in plain sight. I recently wrote about an example from a different field. Readers of this blog might also enjoy looking at one of the early examples of this kind of analysis that happens to be the first string revolution.

6. **Maik**
   September 17, 2019

Am I missing something or is the claim that "we do not even have one self-consistent theory [of gravity] that fits the data we already have" really as outrageous as I perceive it to be?

7. **Shantanu**
September 17, 2019

So neutrino masses tell us there is physics beyond standard model. Why aren't more people working on connecting this to BSM physics theories at LHC?

8. **Peter Woit**
September 17, 2019

Maik,
He's referring to quantum gravity and the claim is not at all outrageous. As far as string theory goes, you don't have an understood, self-consistent version that gives four flat space-time dimensions and a small CC (the "landscape" vacua are controversial for good reason). For other approaches to quantum gravity (eg. LQG) I don't want to get into the often religious war of claims and counterclaims, but the argument that none of them have yet given a fully consistent model compatible with the real world is a defensible one.

Shantanu,

Plenty of people have been doing this, for decades. I think Harlow's claim (which I generally agree with) is just that all such BSM modeling has led to no compelling model, just a large collection of possible models, with no way of choosing between them unless we get some more relevant data. So, his argument is that best to stop working on this until and unless you get more data.

9. **adamt**
September 18, 2019

Seiberg says this is unhelpful to HEP, but also factually untrue: "Harlow: So then, what are we supposed to do in the meantime, right? You know we need to keep writing papers and posting them to hep-th and so on, so what do we do?"

And the exchanges illicit nervous laughter from the crowd.

The problem for HEP is that it is *not* untrue and that the public is getting wise and hence that laughter *should* be nervous. Even better if it were not laughter and the people in that room took the issue seriously rather than making comments about trying to hide the situation from The New York Times and worrying that the talk is recorded.

It is factually true that what the people in that room *do* is write papers. And that no one has been producing anything that really makes substantial progress on these problems for quite a long time. What *is* happening (and which is an unmitigated good thing) is that the problems themselves are starting to be classified and people are *starting* to think clearly about what problems are deserving of attention.

Of the two directions that Harlow mentioned I don't think a lot of progress can be seen. The public is getting wise to this. We're not all stupid.

10. **Jackiw Teitelboim**
September 18, 2019

Alessandro's 1th option (SUSY's broken at Plankian scales) would be the final give up in falsifiability, so not interesting at short/long-term. As the 2nd option (using AI), I bet you cannot fed an AI with the spectroscopic data accumulated in the XIX century and get "full" QM as an output (uncertainty relations, Dirac's transformation theory etc.).

11. **DB**
September 18, 2019

Peter,
thanks for the second update.

Nima Arkani-Hamed: "Reconfirming the Standard Model would just crank up the screws that are put on our theoretical imaginations even more".

Correct Nima… correct.
And it will probably put the final nail in the coffin to stuff like Susy.

Finally, no, we don't need to through out "as many billions as it takes" to reach those conclusions. That final comment is absolutely ridiculous, especially coming from someone who is a top theoretical physicist.

But I guess that the wheel has to keep on turning…

12. **Alessandro Strumia**
September 18, 2019

Jackiw, I assumed that nothing new gets discovered. If we already collected all particles accessible to realistic experiments, and we already have their low-energy theory, writing wrong models and falsifying them would be a politically-correct way of making no progress. The only hope would be matching what we know about the low energy theory (about 75 digits measured so far) with a high energy theory. Unnaturalness of the weak scale and of the vacuum energy points to a landscape of >10^150 possible vacua, so the situation might be hopeless. Maybe not. So far this failed, but attempts focused on N=1 SUSY at low energy.

13. **Amitabh Lath**
September 19, 2019

Most discussions about the LHC null results make it sound like experiments go out and look for new physics with no biases or input from the zeitgeist. This is not so, CMS and ATLAS were designed to look for new physics in signature spaces theorists were excited about. That's why they are breathtakingly good at missing momentum and electromagnetic energy resolution. Of course there is a tradeoff, they aren't as good at some others such as long lived particles or multiple low momenta particle signatures (compressed spectra). Yes, a large swath of BSM parameter space has been searched, but there are huge and important bits we are not sensitive to. Not yet.

14. **Alan**
September 21, 2019

Hello Peter,

I read your blog often. I have not commented before but I have a, possibly interesting, historical perspective on the topics in this post: quantum gravity, lack of experiments, and switching fields from physics to machine learning.

I did a PhD on quantum gravity in the late 1970's (supervised by Stephen Hawking) and started a postdoc in the US, but soon left physics for artificial intelligence (the term "machine learning" didn't exist at that time). I left physics because of several concerns. One was that quantizing gravity seemed very hard and all of the existing approaches had many problems. A second was the lack of experiments to guide and test theories (which was historically almost unprecedented). A third was that the research was becoming increasingly mathematical and I wondered whether it should be left to real mathematicians like Atiyah and Singer who had stronger mathematical tools. These concerns weren't unique to me, but other people didn't seem to find them so worrying. At that time, quantum gravity was fairly new (apart from a few pioneers like Bryce De Witt and John Wheeler) so most of my friends thought there could be breakthroughs soon.

But it seems that all these concerns remain valid almost forty years later. It is interesting that some leading physicists don't seem to realize how old they are. And that AI/ML is a very old escape route (though AI was done at only a few universities at the time).

I followed physics at a distance and was surprised at the growing amount of physics stories about conjectures (e.g., about extra space-time dimensions) which had no experimental support (but which non-physicists friends of mine believed because they'd read them in books or news articles) . I found your blog and Lee Smolin's book to be helpful reality checks and insightful about the sociology of physicists.

AI has been good to me (and I'm sure I was no loss to physics). AI also suffers from excessive hype these days, but the majority of AI researchers are fairly realistic about distinguishing between what AI can do now and what it has the potential of doing in the future (provided some very difficult problems are solved). Tough peer review, including the need to benchmark performance, keeps us fairly level headed. The hype is more from some start-up companies (financially motivated?), non-AI experts who have recently jumped on the AI bandwagon, and from reporters who realize that only the most exciting stories get on the front page.

Metaphorical Worlds Interpretation

September 17, 2019
Categories: Quantum Mechanics

Chad Orzel has a piece at Forbes which I like a lot, where he argues that the "Many Worlds" of the MWI interpretation should be taken metaphorically, and thus the MWI really should be the "Metaphorical Worlds Interpretation". I urge you to take a look (and argue about this with him, not me…).

Update: Natalie Wolchover suggests renaming MWI as the "Many Cakes Interpretation", since

> there's a lot of having of cakes and eating them as soon as things get awkward.

The Number of the Heavens

September 18, 2019
Categories: Book Reviews, Multiverse Mania

Multiverse mania seems to have been dying down recently, with this only the third entry in that category here so far this year, after 10 in 2018, 13 in 2017, 10 in 2016, 17 in 2015, 18 in 2014, 12 in 2013, 9 in 2012, 15 in 2011. Bringing up the rear (hopefully…) is The Number of the Heavens, Tom Siegfried's new book out today from Harvard University Press.

Siegfried is about the worst of the many journalists covering fundamental physics that I've run into over the years (only real competition is K.C. Cole). For some of his efforts as a journalist over the years, see here, here, here, here, here, and here. It's not surprising that his multiverse book is an atrocious piece of propaganda.

It's basically a compendium of arguments for string theory and the multiverse, with a bit of extra history tacked on. You get to read long sections of all the usual pro-string landscape and multiverse arguments from the usual suspects: Carroll, Deutsch, Guth, Greene, Linde, Polchinski, Rees, Susskind, Tegmark, and Weinberg. There's the usual chapter on the MWI, ending with the acknowledgement that this has nothing at all to do with what the rest of the book is about. There's a chapter about the glories of supersymmetry, brane-world scenarios, nothing about negative results from the LHC.

The way Siegfried handles criticism of string theory, etc. is very simple: pretend it doesn't exist. As far as I can tell, there's nothing anywhere in the book that even acknowledges that there's another side to this story: for instance, no Baggott, Hossenfelder, Smolin, Penrose, or any reference to any book at all critical of string theory or multiverse hype. While there's zero criticism of string theory, there are, as far as I can tell, just two appearances of multiverse critics:

- On pages 223-8, remarks by Burt Richter at a panel discussion in 2006 get two paragraphs, followed by four pages of arguments from Linde, Susskind, Polchinski and Carroll explaining why he's wrong. The prominent multiverse critic David Gross makes a brief appearance in these pages, with no mention of the fact that he is a multiverse critic.
- Pages 262-9 are labeled a section on "Multiverse Deniers", but there's only one multiverse denialist quoted, George Ellis, with the only source given for his arguments this paper. In these pages short excerpts of his arguments are interleaved with long explanations from the author (as well as Weinberg, Wilczek, Carroll, Donoghue and Rees) about why Ellis is wrong.

Th one thing I can't figure out about this book is how it got to be published by a reputable university press. My understanding has always been that university presses have some commitment to ensuring scholarly excellence in what they publish, for instance by having a manuscript about a controversy reviewed by experts from both sides. That obviously can't have happened in this case, so I must be mistaken about how places like Harvard University Press now operate.

Comments

1. **tulpoeid**
   September 19, 2019

   "Multiverse deniers" must be the most disgusting term ever used seriously in a scientific discussion.

   Spelling out the obvious – but are they now pretending so blatantly that multiverse is the mainstream in the community as to imply that the rest are lunatics whom it's okay to ridicule in their face?

   I hope that the guy is just a special case that nobody takes seriously but, yes, if it is so then HUP is certainly helping change that.

2. **Peter Woit**
   September 19, 2019

   tulpoeid,
   From everything I've seen, many influential string theorists have realized that the string landscape multiverse is a big problem for their subject, convincing many people string theory is a failure. Vafa is quite explicit about how trying to avoid this is the motivation for his swampland program. See for instance here
   https://www.math.columbia.edu/~woit/wordpress/?p=10486

   I suspect very few people take Siegfried seriously, and the fact that he's publishing with HUP is probably due to not being able to sell this to a commercial publisher. I see that the book is currently #182,033 on Amazon, which means that just after release this is selling less than one book/day. The few copies in existence are probably ones like the one I found in the stacks of the Columbia library, where they likely buy one copy of everything HUP publishes. Once I return it, presumably it will sit there undisturbed for the next few decades.

   It probably would have been best to just ignore the thing, but I was outraged that my alma mater's university press would publish something like this (and I'm still curious how that could have happened).

3. **Miguel**
   September 21, 2019

   Given your own stated experience with university presses's handling of string theory projects, I'm not entirely surprised!

4. **Peter Woit**
   September 21, 2019

   Miguel,
   My experience with Cambridge University Press was I suspect different: they had the manuscript reviewed by people with a range of opinions. The non-string theorists were very positive, the string theorists very negative. The negative opinions created a problem for them with publishing the book.

   On the other hand, I did see that university presses do some weird things: Princeton University Press hired Lubos Motl to review the book for them…

5. **John**
   September 23, 2019

   Glad you didn't actually buy the book. Buying the book only helps to continue the hype and puts money in their pockets.

6. **Peter Woit**

September 23, 2019

John,
I'm glad to not have faced the moral issue of whether to spend money on a book like this in order to write about. In this case, my university did, and that's a more interesting issue. I'm assuming they likely buy everything HUP publishes, and perhaps HUP is kept afloat not by selling books to the public, but by this effective subsidy, due to its reputation.

I don't have a problem with this in prinicple, nothing wrong with subsidizing in this or other ways the publication of high-quality books. But if you are going to have such a system, something has gone wrong if you use it to subsidize the publication of things of this low quality.

7. **Narad**
September 23, 2019

> perhaps HUP is kept afloat not by selling books to the public, but by this effective subsidy, due to its reputation

They're endowed.

> It probably would have been best to just ignore the thing, but I was outraged that my alma mater's university press would publish something like this (and I'm still curious how that could have happened).

I recommend looking at the volume of titles turned out weekly. The CFO of the university press I toiled for, who bore a certain temperamental resemblance to Yosemite Sam, once vented to me (we both smoked cigarettes then) about his inability to get Books to understand that a parade of gender studies titles wasn't going to keep the lights on.

I have no idea whether HUP has a top-down quota, but this strikes me as business as usual.

8. **Jim Baggott**
September 24, 2019

Not wishing to sound disrespectful of HUP, but my experience with an academic publisher confronted with a profoundly anti-string theory/multiverse book proposal was rather different. Oxford University Press has published most of my popular science output, with two new books on quantum mechanics due next year. Yet after receiving reviews on my proposal for 'Farewell to Reality' from a couple of academic physicists, one strongly positive but another worried about what kind of message such a book would send, OUP declined. 'Farewell to Reality' was published by a commercial publisher in 2013. (And the reviewer who welcomed the proposal later agreed to comment on the manuscript.)

I fear that the real truth is that even academic publishers with a trade books division are – like all publishers right now – feeling the pinch of declining sales and disruption from alternative online sources. And although books about string theory and the multiverse are less prevalent these days, as Sean Carroll has demonstrated, books on controversial scientific subjects can still sell well.

9. **Peter Woit**
September 24, 2019

Jim Baggott,
That's interesting, very similar to my experience with CUP. Basically if something is actually controversial, in the sense that there are prominent academics on both sides, they are very leery of publishing. I was explicitly told by one editor of a university press (Princeton?) that Not Even Wrong was too controversial to be published by a university press. So, like your book, it ended up being a commercial publisher that published it.

In the case of the Siegfried book, the way Siegfried deals with the controversy he's writing about is by essentially pretending one side of the controversy is illegitimate, represented by two misguided "deniers". If HUP editors tried to find reviewers on both sides of the multiverse controversy, from looking at the manuscript the only people referred to on the "denier" side would have been Burt Richter (now dead) and George Ellis. If they didn't get Ellis to review the book, they would have had to go out and dig deeper to figure out who other "deniers" were. I'm guessing they didn't do this, likely refereeing a book about a controversy with reviewers all on one side of it.

10. **Shantanu Desai**
September 24, 2019

Can someone point out these concerns to HUP?

Recently Modified Posts

September 18, 2019
Categories: Uncategorized

I’ve often added material to recent posts as “updates”, while aware that some who might be interested would likely not realize the added material was there. To improve the situation, I’ve just added a “Recently Modified Posts” widget on the right. The ordering is by modification time. I’ll try and figure out how to avoid having the modification time change when I do something like fix a typo (right now some old film reviews are appearing on the list because I recently added a “Film Reviews” category).

Among recent updates, I recommend the updates to this posting. Someone pointed me to a quite remarkable exchange earlier this week between Mike Peskin and Nima Arkani-Hamed.

Comments

1. **jellydonut**

   Sadly these will not show up for those of us relying on RSS to keep up to speed on the blog.

2. **Peter Woit**
   September 19, 2019

   jellydonut (and others),
   For those using the RSS feed, what RSS readers are you using? If I understand that I might be able to come up with a better solution. Feedly is the reader I use, and it shows 9767 users currently subscribed to this blog. I’d be curious to know what the other commonly used RSS readers are.

3. **Terry Murray**
   September 19, 2019

   Long time Lurker. Per your inquiry, read your blog via RSS->Feedly. Also the candor in you’re recent post on Siegfried was a breath of fresh air. I laughed loudly. Cheers.

Various and Sundry

September 26, 2019
Categories: Swampland, Uncategorized

A couple of mathematics items:

- Photographer Jessica Wynne has been taking photographs of mathematician's blackboards, and there's a story about this in the New York Times. Many of her photographs have been taken here at Columbia, where we happen to have, besides some excellent mathematicians, also some excellent blackboards.
- A non-Columbia excellent mathematician I've sometimes written about here is Bonn's Peter Scholze. If you want to get some idea of the field he works in (arithmetic geometry) and what he has been able to accomplish, a good place to learn is Torsten Wedhorn's new survey article On the work of Peter Scholze.

On the string theory front:

- Arguments about the failure of string theory as a unified theory have been going on so long that they are now a topic in the history of science. For detailed coverage of many events in the long history of these arguments, you can consult historian of science Sophie Ritson's 2016 University of Sydney doctoral dissertation. It and some of her other work is available at her academia.edu website.
- For the latest in content-free argumentation about the failure of string theory unification, Steve Mirsky has a podcast discussion with string theory fan Graham Farmelo (see discussion of his recent book here), in which Mirsky challenges Farmelo about the problems of string theory. Farmelo has spent a lot of time at the IAS and basically takes the attitude that the point of view of certain unnamed string theorists there is what should be followed. I'd describe it as basically "we've given up working on string theory unification, but will keep insisting it is the best way forward until someone proves us wrong by coming up with a completely successful alternate idea."
- For the absolute latest attempt to extract some sort of "prediction" from string theory, see this week's Navigating the Swampland conference in Madrid. Today there was a discussion session, with results shown of a survey of the views of those attending the conference. Note that, on the contentious topic of the reliability of supposed metastable de Sitter solutions of string theory, the Stanford group defending this reliability does not seem to be represented at the conference. I've been trying to understand what picture of physics this research has in mind, given that one main goal is to torpedo the metastable de Sitter solutions, and thus the usual "anthropic string landscape" picture. Looking at page seven, most participants seem to want to replace single field inflation models with more complicated quintessence or multi-field inflation models.
  In Hirosi Ooguri's talk he gives a supposed "unparalleled opportunity for string theory to be falsified", I gather by claiming string theory somehow implies a small value of r. He quotes Arkani-Hamed as saying that string theorists should have reacted to the bogus BICEP2 measurement of r=.2 by saying "if this is true string theory is falsified." They didn't do that. When the topic came up at the time, what they had to say was:

  > Theoretical physicist Eva Silverstein of Stanford says she disagrees that string theory-based models of inflation are in any sort of trouble. "There is no sense in which we are forced to start over," she says. She adds that in fact a separate class of theories that involve both axions and strings now look promising.
  >
  > Linde agrees. "There is no need to discard string theory, it is just a normal process of learning which versions of the theory are better," he says.

Update: Some more math

- Not just physicists, but mathematicians too can get the ridiculous headline treatment, see Number Theorist Fears All Published Math Is Wrong.
- A recent proof of the twin primes conjecture for finite fields from my Columbia colleague Will Sawin and a collaborator is the subject of a new Quanta article from Kevin Hartnett, see Big Question About Primes Proved in Small Number Systems.

Several physicists now have pieces up explaining why Sean Carroll's claim that "the Multiverse did it" (i.e. all you have to do is believe in multiple worlds) isn't a real solution to the measurement problem. Beside the previously mentioned Chad Orzel, there's also Sabine Hossenfelder and Philip Ball. I agree with Ball's conclusion:

> Here, then, is the key point: you are not obliged to accept the "other worlds" of the MWI, but I believe you are obliged to reject its claims to economy of postulates. Anything can look simple and elegant if you sweep all the complications under the rug.

Update: A video of the discussion session at the Swampland conference is here. It seems that I'm not the only one confused about what assumptions people working on this are making and what they are or are not accomplishing.

Comments

1. **Blake Stacey**
   September 27, 2019

   I think Ball makes a particularly good point near the end of his post:

   > Chad Orzel suggests that the right way to look at the MWI might be as a mathematical formalism that makes no claims about reality consisting of multiple worlds – a kind of quantum book-keeping exercise, a bit like the path integrals of QED. […] However, we have to recognize that many advocates of Many Worlds will have none of that sort of thing; they insist on multiple separate universes, multiple copies of "you" and all the rest of it – because their arguments positively require all that.

   That NYT story really makes me wish we hadn't gone the whiteboard route in our science building.

2. **Peter Woit**
   September 27, 2019

   Blake Stacey (and others),
   I'm afraid I need to encourage everyone who wants to discuss many worlds and the Sean Caroll campaign to do so at the other blogs covering this. Glad to see that others are writing about this, and they should be encouraged.

3. **none**
   September 27, 2019

   Regarding math blackboards, the ones of Knill teaching at Harvard have been simply inspiring
   http://www.math.harvard.edu/~knill/teaching/summer2017/exhibits/blackboards/index.html

4. **David Roberts**
   September 28, 2019

I don't see why people are saying it's "twin primes over finite fields", when really it's twin primes over polynomial rings over finite fields. No one would say we proved the twin prime conjecture over the integers (the OG conjecture) if it was proved over Z[x]. But maybe that's just me being curmudgeonly.

5. **Shantanu**
   September 28, 2019

   Peter, a link to a PI colloquium on swampland by Cumrun Vafa
   http://pirsa.org/19090116/

6. **Will Sawin**
   September 28, 2019

   David Roberts,

   I think in the Quanta article it's just an artifact of the fact that they can only explain one concept at a time – so they explain twin primes, and then finite fields, and then say "we're going to combine them" and then say "that doesn't make sense, finite fields have no primes" so introduce polynomials.

   But you're right that this isn't technically correct language – I would always say "over F_q[T]" to be as precise as possible, or "over function fields" to be a little more colloquial.

   It's fun to try to justify it – once could argue that, because the twin primes conjecture is only interesting in Dedekind domains, the phrase "twin primes conjecture" carries an implicit "for Dedekind domains" or even better "for principal ideal domains" so "over finite fields" means "for principal ideal domains over finite fields, i.e. polynomial rings".

   I guess Peter got it from the Quanta article but I'm sure he can argue his own case if he so desires.

7. **Peter Woit**
   September 28, 2019

   David Roberts/Will Sawin,
   Yes, I was using a sloppy terminology, following Quanta, but I think it's justifiable. Anyone who knows something about this field will know what is being meant. The standard math terminology for these things ("function fields") has always seemed to me to be opaque to anyone who hasn't heard it before, giving no indication of what kind of "functions" this has to do with.

8. **Yatima**
   September 28, 2019

   A couple of years ago, Buzzard saw talks by the senior mathematicians Thomas Hales and Vladimir Voevodsky that introduced him to proof verification software that was becoming quite good. With this software, proofs can be systematically verified by computer, taking it out of the hands of the elders and democratizing the status of truth.

   An apparent red-guard mentality concerning the need of canceling stale "elders" and implementing forced "democratization" (presumably after a "necessary conversation" has been had; with said conversation hopefully not ending in a short walk behind the shed)?

   It's almost as if I was reading Vice.com.

   Oh wait! Never mind.

   (And I absolutely like theorem-proving by machine; but I also agree with Michael Harris in [Why the Proof of Fermat's Last Theorem Doesn't Need to Be Enhanced](#))

9. **Peter Woit**
   September 28, 2019

   Yatima,
   What I think is more remarkable is the identification of "democratizing" with replacement of the judgement of human beings by that of machines.

10. **Blake Stacey**
    September 29, 2019

    > What I think is more remarkable is the identification of "democratizing" with replacement of the judgement of human beings by that of machines.

    I think this puts the matter well.

    Years ago, I read a comment by Michael Ashbacher about the classification of the finite simple groups. He wrote that the classification theorem was so long, the probability of an error in it approached 1, but the probability of any error being *uncorrectable* was nearly zero. There's just so much found out in the course of proving the result that the final structure is basically robust, in a way that mechanistic checkability doesn't really capture. The greater concern with the CFSG is that it wasn't written in any single place, let alone "democratized" so that people even slightly less specialized in the field could approach it. (The "second-generation" proof, revised and systematized with the benefit of hindsight, runs to [eight volumes so far](#) and still isn't complete.)

11. **Blake Stacey**
    September 29, 2019

    (*As**c**hbacher)

12. **jsm**
    September 29, 2019

    I agree with David Roberts: "twin primes conjecture for finite fields" made no sense to me, whereas "twin primes conjecture for polynomials over finite fields" should make sense to everyone.

13. **Peter Woit**
    September 30, 2019

    OK, OK, I give in. "finite fields" edited to "polynomials over finite fields".

14. **Neville**
September 30, 2019

I am more concerned with the exposition of the classification of finite simple groups than its correctness. Will future generations be able to make sense of this voluminous information? For example, some of Michael's work requires seriously heavy sledding to understand — he erroneously assumes the reader is at least half as smart and knowledgeable as he is. (Back in the day, I heard loud complaints about the difficulty of understanding my own very small contributions to the subject, although I don't think exposition was the real issue.) We should leave future generations with a reasonable chance of understanding the classification and making their own improvements and judgements about correctness when key contributors are unavailable to answer questions. There has been a lot of work on improving the situation, but I wonder whether it is sufficient. There is much understood by experts that is not spelled out on the printed page — Serre has made his share of complaints about the difficulties.

I do not believe this situation is unique to finite group theory. Too much knowledge is in the form of folklore, talks to an inner circle, or private conversations and correspondence. Fortunately, the internet has improved the distribution of information, e.g., the arXiv, videos of lectures, unpublished books, papers, and course notes posted on websites, and online availability of some letters, such as those from Langlands to Weil and Serre.

I agree with Thurston that human understanding should be our goal:
https://arxiv.org/pdf/math/9404236.pdf

Creating a proof in software of the classification would be a ridiculously large undertaking. I doubt the result would be easier for humans to digest.

15. **Wavefunction**
October 1, 2019

I was not too impressed by Farmelo's recent book although I loved his book on Dirac. Basically his attitude seems to be, "I am not an expert on this topic, so I am just going to assume the experts know best."

16. **Peter Woit**
October 1, 2019

Wavefunction,
Yes, Farmelo's attitude appears to be that "if the most illustrious theorist at the IAS tells me that his approach to going beyond GR to a unified theory is the best one, it must be the best way forward". An obvious counterargument is that if he had been a visitor at the IAS during an earlier period, Einstein would have told him that the ideas about unification he was working on then were the best way forward. Einstein's successors at the IAS today I believe are just as wrong now as he was then.

17. **no idea**
October 3, 2019

As a pure mathematician who has used computer-assisted proofs for almost 40 years, perhaps I can comment on the article "Number theorist fears all published math is wrong". Of course all published math is wrong, just as all published physics is wrong. But this is to take an absurd philosophical position. And as many commenters above have noted, pedantic approaches to proof are as foreign to real mathematics as they are to physics. There are mathematicians who loudly proclaim that their proofs are "computer-free" as if it was a virtue – and either make lots of mistakes that good use of a computer would have corrected, or silently use computers for any calculations they regard as "routine", while disparaging anyone else's use of computers that they don't understand. There are proofs that are regarded as "computer proofs" (such as the four-colour theorem) that are conceptually easy to understand, where the use of the computer consists of (a) finding a good way of dividing the problem into hundreds (originally thousands) of separate cases, and (b) systematically working through the cases with a handful of routine methods. There are proofs that are regarded as "human proofs" (such as the classification of finite simple groups) that are conceptually very difficult to understand, where the use of a computer has very little to contribute. Formalising such a proof in order to "check" it is an interesting exercise in logic/computer science, but who checks the checker? Proofs are checked by being part of the culture of mathematics, being used and re-used, re-worked, re-interpreted, taught to the next generation and continually checked against experiment. Just as in physics. And computers have always been used in mathematics – they just used to be human beings, that's all.

18. **Jackiw Teitelboim**
October 4, 2019

Dear Peter,

Regarding Farmelo's supposed attitude that "if the most illustrious theorist at the IAS tells me that his approach to going beyond GR to a unified theory is the best one, it must be the best way forward," and yours "obvious counterargument is that if he had been a visitor at the IAS during an earlier period, Einstein would have told him that the ideas about unification he was working on then were the best way forward,"

There's a significant difference. In Einstein's late days, most of his colleagues who worked on unified field theories, using extensions of Riemannian geometry to include electromagnetism, like Eddington or even Schrodinger, already moved on. Today, it's not only a lonely however illustrious theorist at the IAS that believes that the best approach forward is a particular framework for unification, but a significant percentage of a whole generation of particle energy theorists, working at many illustrious places, particularly in the US.

Another matter. Looking at this Swampland program (the colloquium at PI linked above is a good summary), it seems that Vafa and his collaborators are arguing that the whole approach to EFTs and naturalness arguments used to argue for SUSY at the LHC, failed since their theories, even if they looked OK from a QFT point-of-view, are not in the string theory landscape at all.

19. **Peter Woit**
October 4, 2019

Jackiw Teitelboim,

Yes, the situation is different. In the late stages of Einstein's career there were plenty of new experimental results pointing to more promising things to think about than generalizations of the Levi-Civita connection. Most people sensibly followed what experiment was telling them and ignored Einstein. If we were in the current situation back in the late 1940s, it's hard to know how many people would have followed Einstein. Quite possibly a "significant percentage" of theorists would have been arguing that generalized connections were the best way forward.

The "significant percentage" argument right now is useless, you can find an equally significant percentage who don't think string theory unification is the way forward. As always, judging an issue like this by numbers of followers isn't a very good idea. I've said before that I think the best argument for "string theory unification is the best way forward" is that Witten thinks so. Given zero experimental guidance, following the best theorist you can find may be the best thing to do, but it's a good idea to keep in mind this doesn't always work, with Einstein a good example to keep in mind. In his early 30s Einstein was seduced (for good reason) by a certain vision of the geometrization of physics, one he should not have stayed so attached to for so long. At a very similar age Witten was seduced by a vision of string theory unification, and I think the psychology of why he won't give that up may not be that different than Einstein's story.

About the Swampland program, I do recommend watching the recent discussion session mentioned earlier:
http://150.244.223.31/videos/video/2098/
The degree to which people are flailing about and unsure of what arguments they can trust and build on is remarkable.

Salam: The First ****** Nobel Laureate

October 3, 2019
Categories: Film Reviews

This evening I noticed that a recent documentary about Abdus Salam, entitled [Salam: The First ****** Nobel Laureate](), has just appeared on Netflix, and I spent some time watching it. The title is a reference to Salam's membership in the Ahmadiyya sect of Islam, which in Pakistan has been declared heretical, and thus Salam not Muslim.

I enjoyed watching the film, and learned a lot I didn't know about Salam, but there's not a great deal in the film about his actual work in theoretical physics. While starting to write more here about the film based on some notes I took while watching it, I noticed that Matin Durrani last year at Physics World wrote an excellent detailed review of the film, and I recommend you consult that for more details.

Among those interviewed are Chris Isham and Michael Duff, who have interesting comments on what it was like to work with him. I was pleased to see that one old photograph had him standing in front of a blackboard that prominently featured "Unitary G-reps".

Update: For another detailed review of the film, see here.

1. **AcademicLurker**
   October 4, 2019

   I've been searching in vain for interesting things to watch on netflix lately. Thanks for mentioning this, I'll probably check it out this weekend.

   All I know about Salam is what I read in Frank Close's *The Infinity Puzzle*.

2. **Peter Woit**
   October 4, 2019

   AcademicLurker,
   A main goal of this posting was exactly to just point to this as something Netflix subscribers might want to look at. Also, since it's about Nobel season, there's a little justification for discussing something which largely was about a Nobel Prize. There's a lot in the film about Salam getting the Nobel Prize, and the significance of that (including an amusing comment from Weinberg contrasting positively Salam's outfit with the penguin suits everyone else was wearing). Almost nothing though in the film about Salam's actual work on the electroweak theory. Close's book is good for that, there's also an old blog post here
   https://www.math.columbia.edu/~woit/wordpress/?p=3972
   although the Dombey article it discusses seems to have an ax to grind.

3. **David Derbes**
   October 5, 2019

   In 1975 I had just come out of the Part III Mathematical Tripos exams. I did well, but not well enough to stay at Cambridge. I was shopped to Imperial, Durham and Edinburgh. Durham, through Euan Squires, seemed to me all Regge all the time, no thanks. At Imperial I met Tom Kibble who was the soul of gentle kindness. He took me twice to see Salam, separated by an hour or so. Salam was never in. I knew his work, but it seemed to me that he would be tough to work with if he couldn't be found. I wrote to Kemmer at Edinburgh, and he invited me to travel north, where I had a chance to talk to Higgs. That went well, and in the fall I started working with Higgs. There is a bit more about Salam in Crease and Mann's *The Second Creation*, and there is a Salam biography with the somewhat scary title *Cosmic Anger* by Gordon Fraser. It's on my nightstand with another two dozen books. I've read a bit of it, but found it slow going. I really admire what Salam tried to do at the ICTP (a hell of a lot of the early supersymmetry stuff came out of there), and there is a touching story in *Second Creation* about Salam taking on Ne'eman as a research student.

4. **Anonyrat**
   October 6, 2019

   A story & interview published in Pakistan, Abdus Salam with Shahid Nadeem, originally published 1984; republished April 2019.
   https://herald.dawn.com/news/1153774

5. **Robert Delbourgo**
   October 8, 2019

   I knew Salam very well and from what I have been reading about this film it is a pity that his scientific achievements are largely skated over.

Various and Sundry

October 7, 2019
Categories: Uncategorized

Various HEP-related links:

- The physics briefing book for the ongoing update to the European Strategy for Particle Physics is now available, for more see here. This describes the physics that one might hope to do with various proposed new machines. The hard part comes in the next few months: coming up with a proposal that has some chance of getting funded.
- Jim Baggott has a new article in Aeon, But is it Science?, arguing that the heavy advertising to the public by physicists of untestable speculation about multiple universes endangers the credibility of the field. I of course am very much in agreement with this, and have often pointed out the problem, see here. Baggott specifically refers to the massive recent publicity campaign from Sean Carroll. Carroll in this case is promoting a multiple universe untestable interpretation of quantum mechanics, but in the past has been equally determined to promote the untestable multiple universe versions of unification, as well as an untestable multiple universe explanation of the arrow of time . Carroll will be touring Australia and New Zealand in February, presumably to further promote this sort of thing.
- There's an ongoing Cosmic Controversies conference in Chicago this week, which tonight will feature a panel discussion on "Do we need the Multiverse and can it made turned into a scientific theory?". Tomorrow the panel topics will be more promising: "What more can we learn from particle physics about cosmology?" and "Convergence or Disruption". You can find video posted from the conference here including a live stream.
- Slava Rychkov is giving a series of lectures on Lorentzian methods in conformal field theory. Lecture notes are appearing here, videos here.

Update: Wired describes job opportunities for physicists and astrophysicists in the fashion industry.

Comments

1. **Anthony Reynolds**
   October 8, 2019

   I thought Scott Aaronson's blurb about Sean Carroll's book was a bit over the top. Tears of joy? Really?

2. **Peter Woit**
   October 8, 2019

   Anthony Reynolds,

   Aaronson is the first person thanked in the book, for extensive editorial help. I suspect he may be the one responsible for keeping the multiple universe woo to a minimum in the book itself.

   Too bad he likely had no say on the book jacket. I do wonder what he thinks of the ongoing Carroll multiple worlds promotional campaign.

3. **Shantanu**
   October 8, 2019

   Peter: I don't think the KICP conference on cosmic controversies is livewebcast (despite the link you mentioned). Only the panel debates are put up online.

4. **Peter Woit**
   October 8, 2019

   Shantanu,
   I'm getting the livestream at that link right now, Arkani-Hamed is on…

5. **tulpoeid**
   October 16, 2019

   So, the physics briefing book looks really good as an up-to-date summary of the field.

   However, one sentence in the linked CERN Courier article grabbed my attention: "Readers are reminded that the discovery of neutrino oscillations constitutes a 'laboratory' proof of physics beyond the Standard Model."

   Last I checked, there was nothing "proving" BSM physics in neutrino oscillations. I went through that part in the book looking for developments that I might have missed and there are none. Actually, quoting Par.6.1.1,

   "To obtain finite neutrino masses, the Standard Model has to be extended in some way. A minimal extension is to introduce gauge singlet neutrinos (so-called right-handed or sterile neutrinos) which would allow to write down a Dirac mass term for neutrinos, in the same way as for all other fermions. This could indeed be the only source of neutrino masses, but in this case coupling constants need to be smaller than 10^-11 and lepton-number conservation has to be postulated as a fundamental symmetry."

   Despite clarifying that the SM might turn out to be adequate, a few lines above it is stated indeed that "The discovery of neutrino oscillation proves that neutrinos have non-zero masses. This is one of the few solid experimental proofs of physics beyond the Standard Model, as new interactions or new elementary particle states are needed to introduce this mass term in the Lagrangian."

   I'm not saying that I wouldn't like neutrino masses to turn out BSM, but … is neutrino hype the new selling point? Are we so desperate now?

6. **Peter Woit**
   October 16, 2019

   tulpoeid,

   I pretty much agree, although the "neutrino masses are BSM" argument is a common one. What people have in mind is the argument that if you don't add a sterile right-handed neutrino fields and just have Majorana mass terms, the usual Higgs sector won't do it, you need something else. However, you can just add a sterile right-handed neutrino field and have exactly the same kind of Dirac mass terms as for the other fermions (then you have to explain why the Yukawas are so small, but you don't understand anything about the values of Yukawas anyway). To me, calling such a scenario "BSM" is kind of misleading.

2019 Physics Nobel Prizes Announced, John Horgan Wins

October 8, 2019
Categories: Uncategorized

The 2019 Physics Nobel Prizes were announced this morning, half going to Jim Peebles for his work on big bang cosmology, half to Michel Mayor and Didier Queloz for discovery of an exoplanet.

You can read elsewhere more details about the prize winners and their work, but I do want to point out that this announcement means (since there will be no further Physics Nobel Prize awards before the start of 2020) that John Horgan has won his 2002 bet with Michio Kaku, with \$2000 going to the Nature Conservancy. The winning prediction from Horgan was:

> By 2020, no one will have won a Nobel Prize for work on superstring theory, membrane theory, or some other unified theory describing all the forces of nature.

If one looks at the comments back then, Gordon Kane signs on to an even stronger variant of the Horgan/Kaku bet:

> By 2020 there will be a Nobel Prize for a string- or unification- or supersymmetry-based theory or explanation or experimental discovery.

Luckily for him he doesn't seem to have put up any money for this, since he has now lost this bet.

For my own comments at the time, see here (this was a couple years before this blog was started). As I explained there, I was willing to sign up on Horgan's side of the bet if the "other unified theory" clause was eliminated. Unlike Horgan, I'm not a sceptic at all of the existence of a unified theory, or of humanity's ability to find it. My argument (which I think has held up well) was that we're not going to get there by pursuing superstring theory or anything like it. In a better world, the LHC would have found not a vanilla Higgs, but something unexpected that gave us a new idea about electroweak unification, one that pointed to a successful new idea about a fully unified theory. I didn't think this was likely, but I thought it was possible, and I wasn't interested in betting against the possibility I would most like to have seen.

What shocks me about where we are now that Kaku and Kane have lost their bets is not that they lost, which was to be expected, but that this loss seems to have had zero effect on their behavior. Kane's endless replacement of failed predictions by new ones is a well-known story. For Kaku, one can get some idea of his current point of view from this interview:

> **Yahoo News:** So tell us about your work in string field theory. You're trying to finish Einstein's equation?
>
> **Michio Kaku:** That's right. We want to find the "God Equation" — the ultimate theory that explains the entire universe. We want an equation that's maybe 1 inch long that would allow us to "read the mind of God" — those are Einstein's words.
>
> **Yahoo News:** And how's it going?
>
> **Michio Kaku:** We think we have it! It's called string theory. It's not in its final form, and it's not testable yet, we have the Large Hadron Collider outside Geneva.
>
> We're testing the periphery of the theory, but the theory itself is a theory of the universe — so it's very hard to test. But we physicists are optimistic. We think we will be able to test the theory. And we think it is the final theory. So physics ends at that point. Another era opens up, but one era ends when we finally prove this is the Theory of Everything….
>
> If string theory is correct, it means that all the subatomic particles — the electrons, the protons — are nothing but musical notes on a tiny vibrating rubber band. So that physics is nothing but the harmonies of the vibrating rubber bands. Chemistry is nothing but the melodies you can create from the vibrating strings. The universe is a symphony of strings.
>
> And the mind of God is cosmic music resonated through hyperspace.

Kaku also appears in this recent story, which Sabine Hossenfelder refers to as "math fiction". For this kind of phenomenon I prefer Horgan's version: "science fiction in mathematical form".

I don't know of other bets on string theory, but there were quite a few bets about SUSY. I assume David Gross has now paid off his lost bets on SUSY, haven't heard though anything about that. At the Copenhagen SUSY bet event, the losers (Arkani-Hamed, Gross and Shih) showed no signs that losing a bet on a scientific outcome had any effect at all on these scientist's views on the issue they were willing to bet on.

Update: Horgan has posted his own take on this here.

Comments

1. **Blake Stacey**
   October 8, 2019

   I'm pretty sure the "read the mind of God" line was Stephen Hawking in *A Brief History of Time*, not Einstein.

2. **Wavefunction**
   October 8, 2019

   Kaku's main goal for a long time has been to generate sound bytes and thrills for public consumption, not sound physics statements grounded in reality. I read his writings as speculative entertainment rather than science.

3. **David Brahm**
   October 8, 2019

   On a purely nitpicky note, I'm not sure whether "by 2020" means "by 1/1/20" or "by 12/31/20", so I'm not convinced the bet is closed. Contract law, anyone?

4. **Peter Woit**
   October 8, 2019

   Wavefunction,
   One can dismiss what Kaku and Kane say as not to be taken seriously, so not a problem. But the phenomenon of string theorists refusing to admit failure is a widespread

one, and it will do continuing damage to both the intellectual health of the field, as well as its perception among the public.

David Brahm,
In any case, there will be no string theory Nobel in 2020, and after that, Kaku will continue to give talks about how well string theory is doing anyway.

5. **Daniel Sudarsky**
October 8, 2019

It is truly astonishing that people that are supposed to excel at critical thinking, to be trained for, and committed to the scientific enterprise, to appreciate the power of reason over dogma and to be against crowd thinking, can express themselves in the manner Dr Kaku does regarding string theory. In an epoch where humanity is increasingly confronting the return of obscurantist attitudes, be it from politicians (and increasingly from segments of the so called " intellectual elites") not to mention from the wider public, it is frankly scary to see the ease with which such tendencies, that become forces to be reckoned with, emerge from within the scientific community. In fact, I wonder to what extent the latter in now contributing to the former. In other words, when eminent scientists tell us "we can prove a theory mathematically" (i.e. without concerning ourselves with empirical evidence) or that "one era ends when we finally prove this is the Theory of Everything", (i.e. there is no doubt that this IS THE THEORY) what is the effect on the attention people would pay to what other, less famous scientists, say regarding vaccination campaigns or global warming.

6. **David Roberts**
October 8, 2019

> Personally, I feel no need to prove the theory experimentally, since I believe it can be proven using pure mathematics.
> -Michio Kaku

Whatever you think about string theory, this is not how physics *or* mathematics works, I'm pretty sure. The following induction

> Because string theory has near-miraculous breakthroughs every 8 to 10 years, we can expect 2 more breakthroughs in the theory before 2020…

is astounding. There were, what, two (or three?) such breakthroughs before 2002? Or are there more stretching back before the 80s?

7. **Low Math, Meekly Interacting**
October 8, 2019

I hope this isn't OT, but while we're discussing the absence of unification, one could say the same thing about this year's prize. Worthy accomplishments, to be sure, but not exactly closely related. Is this not unusual?

8. **Peter Woit**
October 9, 2019

David Roberts,

The "near-miraculous" breakthroughs being referred to are

1. First superstring revolution, 1984: anomaly cancellation calculation of Green-Schwarz. This allowed the construction of certain kinds of superstring unification models that one would other wise suspect would have anomaly problems. 35 years later, all evidence is that if realistic such models can be constructed, there are so many of them that the class of models can give almost anything, explains nothing about the Standard Model. The real significance of this calculation is that it got Witten enthusiastic about superstring unification.

2. Second superstring revolution, 1995: Witten's M-theory conjecture, based upon evidence of string dualities. 24 years later, we still don't even know what "M-theory" is.

In 2002, if you believed the 1984 and 1995 hype, you might by induction have expected a mid-decade "revolution" in the 2000s. By now though, it has become all too clear that the first two "revolutions" did not give what was hoped, and (while you could argue for a 1997 AdS/CFT "second and a half" superstring revolution) since 1997 there have been no significant positive developments in the area of superstring unification. And quite a few negative ones, beginning with the failure of the last hope for some connection to experiment (at the LHC).

9. **Peter Woit**
October 9, 2019

LMMI,
That also struck me as very odd. I can't think of another example of a Physics Nobel award split in half, with the halves going to two completely unrelated topics.

10. **DanM**
October 9, 2019

"I can't think of another example of a Physics Nobel award split in half, with the halves going to two completely unrelated topics."

How about one year ago? Mourou and Strickland invented chirped pulse amplification, which is an optical amplifier that works for ultrashort pulses. Meanwhile, Ashkin came up with the idea of manipulating small objects with light (i.e., optical tweezers), which is a topic that is (from the point of view of an optics person) entirely unrelated to optical amplification, let alone to short pulse amplification.

That sort of thing is not actually all that rare. The assessment of "unrelated" is a matter of perspective. From most people's point of view, cosmology and exoplanets are both astrophysics topics, and therefore are very related to each other.

11. **A.J.**
October 9, 2019

2008 prize to Nambu and Kobayashi/Maskawa seems like a similar split, just a bit less obvious to laypersons.

12. **anon**
October 9, 2019

Another example from 2002: one half to Giacconi for X-ray astronomy and the other shared between Koshiba and Davis for neutrino astrophysics.

13. **Peter Woit**
October 9, 2019

DanM, A.J.,anon,

I see that in the summary of the award, they try and justify putting different things together. Back in 2008, the justification was that both awards were for understanding symmetry breaking (spontaneous for Nambu, CP for Kobayashi-Maskawa). In 2018 the justification was
"for groundbreaking inventions in the field of laser physics". In 2002 it was "for pioneering contributions to astrophysics".

This year, they're really stretching it, just pasting together two unrelated clauses of woo: "for contributions to our understanding of the evolution of the universe and Earth's place in the cosmos".

14. **kdl**
October 9, 2019

The Nobel Prize in Physics 1978 was divided, one half awarded to Pyotr Leonidovich Kapitsa "for his basic inventions and discoveries in the area of low-temperature physics", the other half jointly to Arno Allan Penzias and Robert Woodrow Wilson "for their discovery of cosmic microwave background radiation."

Actually this year's award to Peebles was related to CMB as well.

15. **Peter Woit**
October 9, 2019

kdl,
Interesting, that seems to be a case where there was no attempt at all to relate the two halves. One does wonder what rules are being used to govern this sort of thing.

16. **Moshe**
October 9, 2019

The flip side of the coin is the Physics Nobel Committee not joining together related discoveries when such a linkage would be natural. An example is provided by the (to me, surprising) omission of Robert Pound's elegant pioneering verification of the gravitational redshift in the laboratory (exploiting the ultra-precision of the Mossbauer effect) with the Hulse-Taylor binary pulsar as an indirect test of gravitational waves. The connecting thread would have been experimental testing of GR. Alas.

17. **Amitabh Lath**
October 9, 2019

The bet was made in 2002. The LHC startup got delayed (19 September 2008 magnet incident among other issues). Maybe you want to be a bit generous and extend the bet to the end of LHC Run 3?

18. **David Roberts**
October 10, 2019

@Peter,

that's what I thought, with AdS/CFT as a possible third, but so close to 1995 kind of rules it out.

Do people making such public statements not see they are being actively unhelpful to the field? By all means study field theories of extended objects, ideally in a mathematically rigorous way, just don't set your watch by a single pair of "near miraculous breakthroughs".

19. **chiz**
October 10, 2019

I've thought for some years that Wolszczan, Didier and Queloz deserved a Nobel but I'm puzzled as to why Wolszczan was only given a mention in the write-up rather than a share of the prize. Since when do you give the prize to the second person or persons to discover something?

Like others I'm unsure of what their work has to do with Peeble's. Maybe the committee didn't think Peeble's work was significant enough to be a sole recipient of the prize and was only worth part of a Nobel?

20. **anon**
October 10, 2019

The Nobel Foundation statutes say this about shared prizes:

"A prize amount may be equally divided between two works, each of which is considered to merit a prize. If a work that is being rewarded has been produced by two or three persons, the prize shall be awarded to them jointly. In no case may a prize amount be divided between more than three persons."

I don't see anything preventing a prize being shared by two completely unrelated works, though in practice they seem to at least try to find some connection.

21. **Peter Shor**
October 10, 2019

Why two barely related Nobel Prizes in the same year?

The Nobel Prize is only given out once a year, and I would assume that the Physics Prize Committee believes there is a long backlog of people who deserve it and haven't yet received it. Giving prizes to two only slightly related discoveries in a single year helps relieve this backlog.

22. **Lowell Brown**
October 11, 2019

Why does no one remark that Jim Peebles did wonderful work decades ago and that his award of a Nobel Prize is long overdue? Is no one interested here interested in significant connections of theory with observation?

23. **martibal**
October 11, 2019

@chiz: similar comments were made when Kobayashi and Maskawa got the prize, but not Cabibbo.

24. **Arnold Neumaier**
October 11, 2019

There are many Nobel prizes split to only loosely related or even very different achievements. Beyond those mentioned above consider, e.g.,

2009 Charles K. Kao, Willard S. Boyle, and George E. Smith
– for groundbreaking achievements concerning the transmission of
light in fibers for optical communication
– for the invention of an imaging semiconductor circuit –
the CCD sensor

1989 Norman F. Ramsey, Hans G. Dehmelt, and Wolfgang Paul
– for the invention of the separated oscillatory fields method and
its use in the hydrogen maser and other atomic clocks
– for the development of the ion trap technique

1986 Ernst Ruska, Gerd Binnig, and Heinrich Rohrer
– for his fundamental work in electron optics, and for the design
of the first electron microscope
– for their design of the scanning tunneling microscope

1981 Nicolaas Bloembergen, Arthur L. Schawlow, and Kai M. Siegbahn
– for their contribution to the development of laser spectroscopy
– for his contribution to the development of high-resolution
electron spectroscopy

1963 Eugene Wigner, Maria Goeppert-Mayer and J. Hans D. Jensen
– for his contributions to the theory of the atomic nucleus and
the elementary particles, particularly through the discovery
and application of fundamental symmetry principles
– for their discoveries concerning nuclear shell structure

1961 Robert Hofstadter and Rudolf Mössbauer
– for his pioneering studies of electron scattering in atomic
nuclei and for his thereby achieved discoveries concerning the
structure of the nucleons
– for his researches concerning the resonance absorption of
gamma radiation and his discovery in this connection of the
effect which bears his name

1955 Willis E. Lamb and Polykarp Kusch
– for his discoveries concerning the fine structure of the
hydrogen spectrum
– for his precision determination of the magnetic moment of the
electron

1954 Max Born and Walther Bothe
– for his fundamental research in quantum mechanics, especially
for his statistical interpretation of the wavefunction
– for the coincidence method and his discoveries made therewith

1936 Victor F. Hess and Carl D. Anderson
– for his discovery of cosmic radiation
– for his discovery of the positron

1927 Arthur H. Compton and C.T.R. Wilson
– for his discovery of the effect named after him
– for his method of making the paths of electrically charged
particles visible by condensation of vapour

This is still a non-exhaustive list; see
https://www.nobelprize.org/prizes/lists/all-nobel-prizes-in-physics/

October 12, 2019

Allow me to say that all (apart from maybe one or at most two) of the examples of “split” Nobels mentioned in the comments can be accommodated within a single descriptive sentence – at a layman’s level of description. These guys advanced astrophysics on large scales. Those guys found out how electrons in atoms behave. I think that’s good.
(And, yes, there is the backlog to consider as well.)

Foundations

October 11, 2019
Categories: Uncategorized

Some links related to the foundations of math and physics:

- Kevin Hartnett at Quanta has a long article on Jacob Lurie and his work on infinity categories. Unfortunately Lurie didn't participate in the article himself, so comments are only from others. The article does a good job of giving at least a vague sense of what these very abstract foundational ideas are about, as well as examining the math community's struggle to absorb them. Lurie's work on this is spread out over more than 900 pages here and more than 1500 pages here. Recently he has been putting together an online textbook/reference version of this material as Kerodon, which is modeled after and uses much of the same software as Johan de Jong's Stacks project.
- At Mathematics without Apologies, Michael Harris has some comments on a recent discussion of the Mechanization of Math, held here in New York at the Helix Center. A video of the discussion is available here.
- In the new (November) issue of the AMS Notices John Baez has a review of a recent collection of articles about the foundations of mathematics and physics. The book, Foundations of Mathematics and Physics One Century After Hilbert, contains contributions about both math and physics, although in his review Baez concentrates on issues related to physics. He notes "The elephant in the room is string theory."
  The same issue of the Notices contains an informative long article about Michael Atiyah and his career, written by Alain Connes and Joseph Kouneiher (Kouneiher is the editor of the book reviewed by Baez).

Comments

1. **Heiko242**
   October 11, 2019

   After reading the review by Baez it seems to me that "The elephant in the room is string theory." is somewhat contradictory. Apparently the whole book adresses the lack of understanding regarding string theory. But, and please forgive my ignorance, the metaphor "the elephant in the room"…doesn't it say actually, that the elephant is ignored?

2. **Peter Woit**
   October 11, 2019

   Heiko242,
   It's not true that "the whole book addresses the lack of understanding regarding string theory". The only article directly addressing string theory is Witten's. Baez I think explains his "elephant in the room" claim when he writes:

   "Given its remarkable impact on mathematics, it is natural to ask what string theory has achieved toward its original goal: becoming a true theory of physics, one that makes experimental predictions we can test. The volume under review does not address this."

   That's the elephant in the room: the last 35 years have been dominated by a specific proposal for fundamental physical theory (unification via string theory), but, while this subject has interesting connections to mathematics, it has none to experiment and the real world. Wikipedia defines "elephant in the room" as
   "an important or enormous topic, problem, or risk that is obvious or that everyone knows about but no one mentions or wants to discuss because it makes at least some of them uncomfortable or is personally, socially, or politically embarrassing, controversial, inflammatory, or dangerous."
   which is an accurate characterization of the way the problems with string theory get ignored in contexts where they are a central issue.

   I just looked at my old blog posting about the Witten article (which was also published in Physics Today):
   https://www.math.columbia.edu/~woit/wordpress/?p=8068
   There I used the "elephants in the room" line, getting it from an Ashtekar interview where, discussing the problems with string theory he says: "These are elephants in the room which are not being addressed."

3. **Christoph**
   October 12, 2019

   In other math news, a report of the ICM Structure Committee makes for some interesting reading:
   https://www.mathunion.org/fileadmin/IMU/Report/SC/2019/structure_committee_final.pdf

4. **Arnold Neumaier**
   October 13, 2019

   I found in the context of the above the following 1988 article by David Gross:
   https://www.ncbi.nlm.nih.gov/pmc/articles/PMC282459/pdf/pnas00301-0008.pdf
   From p.8374:
   "Our critical colleagues denounce these efforts, indeed all of string theory, and call it by the dirtiest name they can come up with – recreational mathematics. Although I resent being called a recreational mathematician, I admit that there is a valid (albeit small) point to these criticisms. They remind us of the danger, in following the Diracian dictum, of turning into mathematicians. This for some theorists is an ever-present temptation."

5. **Zoviyer**
   October 22, 2019

   I feel that by not having Lurie contributing to the Quanta article about his work we missed reading there about his motivation in developing this theory, like, what were the problems and limitations he saw with the current view or tools of mathematics. But Lurie has given many talks about his work, so maybe Kevin Hartnett could have tried (maybe he did try) to find the pieces that formed his motivation and make it clearer for the readers where all this is heading to? With Grothendieck´work the motivation were the Weil conjectures for example. I'm not sure if the same case happened with MacLane – Eilenberg work that introduced categories for the first time. Some of the comments in the article refer to the non-clarity of what is this really about.

6. **A.J.**
   October 22, 2019

   Zoyiver,

   I don't think we have to ask Lurie why mathematicians are interested in higher categories and n-stacks and such. It'd be interesting to know why he personally chooses to work on them, of course, but a lot of people were already interested before he started work on them. Topologists have been thinking about these ideas since at least the 1970s; they've long known that the standard homotopy category is deficient and were looking for a good replacement. Likewise, people have known that derived categories are defective since they were first invented. In algebraic geometry, the idea of using higher categories goes back at least to Grothendieck's letter to Quillen in the early 80s. Mathematical physicists, I think, got turned on to them mainly through the Baez-Dolan Hypothesis and Dan Freed's papers in the early 90s. Point being, the general ideas and motivations (some of them, anyways) aren't new and didn't come from Lurie. But until he got involved, the ratio of theorems to conjectures and motivation wasn't very high.

John Tate 1925-2019

October 20, 2019
Categories: Obituaries

John Tate, who was responsible for some of the most important developments in number theory and arithmetic geometry during the second half of the twentieth century, has passed away at the age of 94. Tate was a faculty member in the Harvard math department when I was an undergraduate there, moving on to UT Austin in 1990, then retiring from there in 2009.

The work that Tate is famous for includes “Tate’s thesis”, his 1950 doctoral thesis, which may be the most influential doctoral thesis of modern mathematics. For a book-length explanation of Tate’s thesis, see Ramakrishnan and Valenza’s Fourier Analysis on Number Fields. The later generalization of the GL(1) case of Tate’s thesis to the non-abelian GL(n) case is one of the founding pillars of the Langlands program.

Tate was the Abel Prize laureate in 2009, and one can learn a lot more about him from an interview conducted around the time of the award. For an extensive discussion of Tate’s mathematical work, see this article from James Milne, or this review by Milne of Tate’s Collected Works.

From Milne’s web-site, some stories about Tate:

> A mathematician was explaining his work to Tate, who looked bored. Eventually the mathematician asked “You don’t find this interesting?” “No, no” said Tate, “I think it is very interesting, but I don’t have time to be interested in everything that’s interesting”.
>
> As a thesis topic, Tate gave me the problem of proving a formula that he and Mike Artin had conjectured concerning algebraic surfaces over finite fields. One day he ran into me in the corridors of 2 Divinity Avenue and asked how it was going. “Not well” I said, “In one example, I computed the left hand side and got p^{13}; for the other side, I got p^{17}; 13 is not equal to 17, and so the conjecture is false.” For a moment, Tate was taken aback, but then he broke into a grin and said “That’s great! That’s really great! Mike and I must have overlooked some small factor which you have discovered.” He took me off to his office to show him. In writing it out in front of him, I discovered a mistake in my work, which in fact proved that the conjecture was correct in the example I considered. So I apologized to Tate for my carelessness. But Tate responded: “Your error was not that you made a mistake — we all make mistakes. Your error was not realizing that you must have made a mistake. This stuff is too beautiful not to be true.”
>
> During a seminar at Harvard, a conjecture of Lichtenbaum’s was mentioned. Someone scornfully said that for the only case that anyone had been able to test it, the powers of 2 occurring in the conjectured formula had been computed and they turned out to be wrong; thus the conjecture is false. “Only for 2” responded Tate from the audience.

Tate’s father, John Torrence Tate Sr., was a physicist, editor of the *Physical Review* between 1926 and 1950. In one famous story, Tate Sr. stood up to Einstein by insisting that one of his papers be refereed in the usual way. Einstein was outraged (but it turned out the paper was incorrect). A few years ago I was at a talk here in New York at the Simons Foundation, during which the speaker put up a slide referring to Tate (Jr.)’s work, with a picture of Tate. After a moment, from the back of the room we heard “that’s not me, that’s my father!”.

Update: Kenneth Chang has an obituary of Tate at the New York Times.

Comments

1. **Michael Weiss**
   October 21, 2019

   My favorite memory of John comes from the fall of 1977. Prof. Tate was frustrated by our undergraduate class’ not understanding the special properties of normal subgroups, and so he had the entire class recite — aloud and in unison — the central theorem. Prof. Raoul Bott’s office was right across the hall. Hearing the chant-like recitation, Bott knocked on the door and asked in a stage whisper, “John, where is the revival meeting?” John relished the interruption. It was clear to us that these two legendary senior figures had a special bond based on a shared love for the beauty and depth of mathematics.

   Based on comments from Barry Mazur and Dick Gross in recent years, I do not think that John ever repeated this experiment in undergraduate education. Yet whether the recitation worked in any didactic sense, we loved John for his passion, clarity and kindness. (John years later filled in for Bott as interim Master of Dunster House, depriving Adams House students of his generous advice at meals.)

Today's Hype

October 29, 2019
Categories: Swampland, This Week's Hype

Hype about string theory and fundamental physics seemed to have been dying down recently, with only three editions here so far in 2019 of This Week's Hype. Today however brings a bumper crop of the highest quality, with new examples from a few of the world's most prominent theoretical physicists. Today's hype neatly exemplifies the two main current genres of hype about string theory and supposed new fundamental physics. The first is the old-school genre of string theory hype we've now been seeing for 35 years: "string theory makes a testable prediction" (no, it doesn't). The second is the new, post-modern variety: no actual theory, just a grandiose claim that space and time have been replaced, although it's unclear by what.

Trend: Cosmic Predictions from the String Swampland

In the subtitle of this APS Physics piece from Cumrun Vafa, we learn that the string swampland has "led to testable predictions about dark energy." If you read the article trying to find the testable predictions of string theory, you'll get to Figure 3, where the caption says "The colored curves are string theory predictions for dark energy for different values of c."

The problems with this include:

- This is based not on a theory or calculation, but on a conjecture (see e.g. here) that consistent string vacua have certain properties.
- Many experts disagree with this conjecture. In particular it would imply that the well-known supposed metastable string vacua of KKLT are inconsistent, and that is a matter of controversy.
- This conjecture is not the sort of thing that can be proved one way or another, since it is not about something well-defined. The non-perturbative formulation of string/M-theory necessary to get a well-defined answer to such questions about string vacua remains unknown. You can make various conjectures about the behavior of this unknown theory, but then your swampland conjecture is a conjecture about a conjecture.
- The conjecture involves an unknown constant "c". Unless you know what "c" is, you don't actually have a prediction.

In his conclusion, Vafa writes:

> In the next 5–10 years, we may know, for example, whether dark energy is constant or not. If it is, that could pose a serious blow to string theory. But if dark energy is found to be changing, could that observation be the first experimental evidence for ideas emanating from string theory?

The most likely possibility over the next 5-10 years is that measurements continue to be compatible with constant dark energy. I don't believe for a minute that 10 years from now after that result is in you will see Vafa or anyone else giving up on string theory or even admitting it has suffered a "serious blow". On the other hand, if there is any evidence for a varying dark energy, Vafa or others will surely claim it as "evidence for string theory", which it will not actually be.

Over the last 15 years I've often written here about this "Swampland philosophy", which never made much sense to me. I didn't understand back in 2005 and still don't understand now why conjectures that behavior you don't observe in the real world might be inconsistent with some other conjectures about an unknown M-theory are supposed to be of interest. The sociological motivation here is rather clear though: the KKLT-based "anthropic landscape" philosophy has not worked out well for the field, and the hope is to disentangle the subject from that morass. A good explanation of what is going on is provided by this (stolen from Will Kinney, who also has a lot to say about the whole swampland business):

Cosmic Triangles Open a Window to the Origin of Time

This is a different sort of hype, with no direct relation to string theory. In this genre of hype, you don't have any connection between your calculation and either experiment or a fundamental theory, but this doesn't stop you from making grandiose claims. What's behind this particular article is this paper, which develops a nice calculational method exploiting conformal symmetry. What's not made clear in the Quanta article is that this has no connection to anything measurable. As the authors of the article explain:

> In this paper, we have worked under the lamppost of weakly broken conformal symmetry. This has allowed us to derive particularly clean insights into the analytic structure of inflationary correlators. However, it also restricts the strength of the couplings between the inflaton and additional massive fields. This makes the observational challenge to detect these effects enormous.

In other words, this is about speculative models in which the observable effects described at length in the Quanta article would be unmeasurably small.

The post-modern hype come into play with the argument that these conformal-symmetry based calculations somehow tell us how to replace space and time.

> This suggests that the temporal version of the cosmological origin story may be an illusion. Time can be seen as an "emergent" dimension, a kind of hologram springing from the universe's spatial correlations, which themselves seem to come from basic symmetries. In short, the approach has the potential to help explain

why time began, and why it might end. As Arkani-Hamed put it, "The thing that we're bootstrapping is time itself."

If you're trying to understand the origin of this particular dollop of hype, it's a good idea to keep in mind something Arkani-Hamed said at a talk about Lance Dixon's work back in 2013:

> … I AM an ideologue. In my defense at least I can say that I'm a serial ideologue, in the sense that I'll take totally different ideologies and drop the last one without thinking about it, but it's very important for me personally to be an ideologue when I'm working on something…
> So, usually I'll get up when I talk about scattering amplitudes and give a long introduction about how spacetime is doomed, we have to find some way of thinking about quantum field theory without local evolution in space time and maybe even without a Hilbert space and blah-blah-blah. This is all very high-falutin stuff, this is stuff that Lance wouldn't be get caught dead saying. I think none of these guys would ever say something that sounds so pretentious, but I have to say it, you know I have to say it, because this is the only way I can get up in the morning, and like "I suck again, OK, here we go, I'm doing it because spacetime is doomed, I swear to God, right".

I'm actually rather sympathetic to the "bootstrap" philosophy in some general sense, which I'd interpret as "all is unitary representation theory of the conformal group", i.e. that constraints of conformal symmetry, analyticity and unitarity are almost enough to determine a fundamental theory. The 1960s version of this, trying to get strong interaction physics purely from such general principles, didn't work out, but I've become more and more convinced that representation theory and fundamental quantum field theory are very deeply intertwined. I do think though that to get anywhere you're going to need to either work top-down (i.e have an actual fundamental theory and derive its implications) or bottom up (i.e. use observations to find the route to better theory).

Will head out soon for a short vacation in Northern California (if it hasn't burned to the ground). I had thought about stopping by the 2020 Breakthrough Prize Symposium, but decided listening to talks about why supersymmetry/supergravity got a $3 million award would not be good for my blood pressure.

Update: Those interested in KKLT vs. Swampland debates might be interested in the latest from Tom Banks. He makes a detailed case against KKLT/eternal inflation/Landscape models, which string theory Swampland enthusiasts may find appealing. They should however note what he has to say about string theory itself:

> A more sensible attitude, which I share, is to accept that string theory defines some models of quantum gravity, but obviously not the one that corresponds to the real world.

Comments

1. **S**
   October 29, 2019

   Curious — when you say you're sympathetic to bootstrapping, does that include the idea that "the thing that we're bootstrapping is time itself"? Or are there versions of this that are less exotic? (I haven't known you to be a big friend to emergentist pictures, so I'm guessing so, but am out of my depth.)

2. **Thomas Van Riet**
   October 30, 2019

   "The non-perturbative formulation of string/M-theory necessary to get a well-defined answer to such questions about string vacua remains unknown. " Not sure. If there are regions of string moduli space where we can do computations (weak coupling regimes and their duals) then we can try to uncover patterns in those regions. These patterns can then have deeper meanings, even relate to thermodynamics, black hole thought experiments, etc. If so one can expect these patterns to be there in the full string theory. Then we use holography to check for further non-perturbative evidence. That is the Swampland. Being against that would be against understanding patterns. Sure, some conjectures are quite radical and imply that "established" things (KKLT) are not that established. But that we knew. Check for instance McAllisters' talk at Strings 2019. He admits at the very end that the separate ingredients of KKLT might seem under control (not my opinion) but it remains to figure out whether the collections of ingredients can coexist. So no. Nothing was established. Neither a landscape and neither a very constraining Swampland. But a Swampland is clearly there. And it is exciting to see what can be proven more rigorously in the already-complicated "lamppost region". So let us carry on and enjoy it. It is the most healthy hype sofar. Kudos.

3. **Luca**
   October 30, 2019

   It's a bit sad to see this kind of hype coming from Quanta magazine. At least it is based on a very interesting theoretical work though

4. **Peter Woit**
   October 30, 2019

   S,
   People have different motivations and meanings for "bootstrap", but in general it involves the idea of not looking for a fundamental Lagrangian, but instead trying to characterize as much as possible a theory by general principles including typically symmetry, analyticity, unitarity. It you look at what these principles are, to a large degree they're equivalent to saying you want some sort of highest weight (which gives positive energy, analyticity), unitary (unitarity), representation of a space-time symmetry group (conformal group or at least Poincare group).

   Where I part company with bootstrappers is that I don't think one should assume that the fundamental theory is some complicated, inaccessible thing (e.g. string theory/landscape), with simple representation theory behavior only emerging in a low energy limit. If you find a good representation theory picture that realizes the hopes of the bootstrap program and describes the real world, I think it will actually be a fundamental theory (and you probably can find a Lagrangian version of it if you want).

   The "we're bootstrapping time itself" business is just meaningless promotional blah-blah.

5. **Peter Woit**
   October 30, 2019

   Thomas Van Riet,

   If you want, you can carefully examine an area directly under a lamppost and then guess that the rest of the world behaves in the same way. The problem is that if you then start publicly claiming "predictions" based on this guess, you need to make clear to people that all it is is a guess. And also, that when this guess is shown to be wrong, you have no intention of abandoning your theory, all you will do is say "OK, looks like things aren't the same elsewhere as under the lamppost".

   Both the swampland and landscape programs have exactly this problem. The arguments about the consistency of metastable vacua like KKLT also take place close to an unphysical lamppost, and are useless for making any legitimate scientific predictions about what the conjectural M-theory predicts about the real world.

6. **Peter Woit**

October 30, 2019

Luca,

Most of the Quanta article is fine. It should though have made clear how far this is from connecting to any observations. As a general principle, any quotes from Arkani-Hamed about revolutionary changes in our understanding of space and time should come with a warning label about the large renormalization factor that needs to be applied to such claims.

https://twitter.com/WKCosmo/status/1188539724048273408

8. **Will Kinney**
October 30, 2019

Glad you liked the meme Peter. 🙂

9. **Peter Woit**
October 30, 2019

Will,

I thought it was very enlightening as an explanation of the current swampland/KKLT argument. Thought for a minute about asking for your permission to use it, but decided "why do that, this is the internet, I'll just steal it."

10. **DRLunsford**
November 1, 2019

How does the conformal group come into the referenced paper (https://arxiv.org/abs/1811.00024)? That is, what was the motivation for this?

The problem with a paper like this is that it is too vague.

BTW there are interesting cosmic effects just from conformal kinematics, e.g. the idea of a cosmic rest frame, and by implication a way to distinguish it (e.g. the CMB). Amazingly, the Hubble relation itself comes right out this idea.

-drl

11. **Matthew Foster**
November 5, 2019

"all is unitary representation theory of the conformal group"

Well, not quite all. Non-unitary representations are pretty important too, if (rather frustratingly) still very poorly understood. Critical 2D percolation, the plateau transition of the quantum Hall effect, self-avoiding walks are all supposedly logarithmic conformal field theories still waiting for a consistent synthesis as far as I am aware.

I might wager that something like quantum gravity should also suffer from signatures of "non-unitarity," i.e. multifractality, turbulence, etc. Why should "spacetime foam" be anything less complex than classical 2D percolation is my question. It would seem to me that the same issues with nonlocality could naturally arise…

12. **Bernhard**
November 5, 2019

"A more sensible attitude, which I share, is to accept that string theory defines some models of quantum gravity, but obviously not the one that corresponds to the real world."

But is even that really true? I remember reading an article on the arXiv (https://arxiv.org/abs/1105.6359) several years ago which argued that "string theory addresses some problems of quantum gravity" but cannot yet be considered a theory of a quantum gravity, even an inconsistent with Nature one.

13. **Thomas Larsson**
November 7, 2019

Matthew Foster,
AFAIU unitarity is necessary for locality. Geometric phenomena like percolation and SAWs (I know nothing about the QHE) are defined globally, even if they are built from many small building blocks. Percolation is a path between two distant points, and a SAW defines the mass of a linear polymer inside a large sphere, and both definitions involve large-distance properties. Both phenomena can be embedded into families of graph models, a discrete set of which corresponds to unitary reps of the Virasoro algebra with local correlation functions, but percolation or SAWs themselves are inherently non-local.

So if you believe that quantum gravity is a local theory, you probably need unitarity.

Now back from a trip to the West Coast, here are some accumulated things that may be of interest:

- One thing I didn't do while there was attend the 2020 Breakthrough Prize symposium. For videos of three talks about supergravity, see here. At the time of the award I wrote here about why a \$3 million prize for a failed idea about particle theory was a bad idea. Listening to the talks, I think an even worse idea is telling the public that this is a great example of why they should trust science.
- For another dubious idea from the West Coast, in January the KITP is bringing high school teachers to Santa Barbara to teach them about Spacetime, Holography, and Entanglement. Most of the programs the KITP has run for teachers (see here) have been devoted to explaining important, solid science. Back in 2001 when they promoted string theory I thought that was a bad idea, this latest one isn't much better. Again, when the credibility of science is under attack, why go to the public (or, in this case high school teachers) to promote a highly speculative research program? Is it really a good idea for high school teachers to be exposed to this kind of hype, presumably with the hope that they'll somehow transmit it to their students?
- On the evergreen topic of bad multiverse science, Scott Alexander here defends multiverse speculation, responding to Jim Baggott's article. He and the authors of the more than four hundred comments debate at length a red-herring issue. Alexander writes:

  > My understanding of the multiverse debate is that it works the same way . Scientists observe the behavior of particles, and find that a multiverse explains that behavior more simply and elegantly than not-a-multiverse.

  Yes, if theorists had a simple, elegant multiverse theory with lots of explanatory power, you could get into interesting arguments about its testability and whether the idea was solid science or not. The problem is that no such multiverse theory exists. If you want to talk about the MWI multiverse, your problem is that solving the measurement theory problem by just saying "the multiverse did it" may be "simple" and "elegant", but it's also completely empty. If instead you want to talk about the cosmological multiverse, the problem is that you don't have a theory at all (and the actual fragments of a theory you do have are complicated and ugly). For more about this, see my posting and article on Theorists Without a Theory.

For something more positive, while traveling I noticed two quite interesting articles which explain in a detailed technical way approaches to two of the great unsolved problems of our time, while carefully discussing why the approaches have not (yet?) worked, leaving the great problems unsolved.

- For mathematics and the Riemann Hypothesis, see Alain Connes and Caterina Consani's article The Scaling Hamiltonian, about the attempt to understand the zeros of the Riemann zeta function in terms of the properties of a specific Hamiltonian operator, which in some sense is a generator of a group of scaling transformations.
- For physics and quantum gravity, see Donoghue's A Critique of the Asymptotic Safety Program, which has a detailed discussion of the problems with making sense of both quadratic gravity Lagrangians and the idea of a non-trivial fixed point gravity theory theory. I was interested to see that he has a lot to say about the Lorentzian vs. Euclidean signature issue, something often ignored.

Finally, I recommend reading Elizabeth Landau's interview at Quanta with astronomer Virginia Trimble and Trimble's excellent advice to us all:

> Pay attention. Someday, you'll be the last one who remembers.

Update: Two more math-related items well worth a look:

- Dan Rockmore at the New Yorker on Where do ideas come from?
- A profile of Terry Tao at the Princeton Alumni Weekly.

Update: Yet another blog entry from Scott Alexander about the multiverse, with more hundreds of comments. What is it with the fascination for this empty argument?

At BBC Science Focus, more multiverse promotion from Sean Carroll. He does end though by getting to the real point (note that when theoretical physicists say a question is "hard to answer", it means they have no idea how to answer it):

> Many-Worlds is a lean and mean theory, but it's possibly too lean and mean; there is very little structure to rely on, so questions like "Why do probabilities behave the way they do?" and "Why is classical mechanics such a good approximation to the world we see?" are hard to answer.

This is exactly the problem that those arguing over this at Slate Star Codex and elsewhere don't seem to understand: saying "all is the Schrodinger equation" doesn't tell you how to connect the theory to the world we observe. Adding in an ontology of multiple universes does nothing at all to solve this problem.

Comments

1. **luysii**
   November 12, 2019

   The interview with Trimble is also interesting for the way it contrasts her mindset with that of the woke young interviewer. Trimble isn't about to be patronized or felt sorry for. For details see — https://luysii.wordpress.com/2019/11/12/tough-60s-chick-disappoints-woke-young-interviewer/

2. **Peter Woit**
   November 12, 2019

   I'd rather try and moderate a discussion of everyone's favorite ideas about fundamental physics than one about Trimble's views on sexual harassment. Have left the luysii comment so those who want to discuss this can do so elsewhere.

3. **Bernhard**
   November 13, 2019

   "Is it really a good idea for high school teachers to be exposed to this kind of hype, presumably with the hope that they'll somehow transmit it to their students?"

   From some experience I say this is really bad since neither the exposed students nor the teachers have any idea how speculative these ideas are. I give "pro bono" talks about fundamental physics to young kids and they keep asking about the multiverse (which is close to science fiction). If anyone is to expose untrained audiences to supergravity, one has to be super honest about how not backed up by data this is (followed by a discussion on the importance of following the data and not abandoning the scientific method).

4. **Peter Shor**
November 13, 2019

I don't think the MWI multiverse is completely useless. It says that everything is quantum — there is no split between a macroscopic quantum world of observers and a microscopic quantum world of particles, the way that some people interpret (or at least used to interpret) the Copenhagen interpretation.

Of course, you *can* believe that everything is fundamentally quantum without subscribing to the MWI, but my impression is that there are a lot of physicists who don't truly believe this (for example, anybody who believes there is a sharp distinction between virtual particles and real particles is classifying particles into two classes, one purely quantum and the other more real).

5. **Peter Woit**
November 13, 2019

Peter Shor,
The problem with just saying "everything is quantum" (or with invoking splitting universes) is that it's an empty statement. You're saying nothing about the real problem (how does the classical world of our observations emerge from the underlying quantum formalism?). Yes, "everything is quantum" is simple and elegant, and I even believe it's most likely true, but it's not a non-trivial answer to the deep problem.

The criticism of an empty non-answer to a problem as being not testable/falsifiable is a way of pointing to the emptiness: if an idea about physics is non-empty, not just a bunch of words, you should be able to do something non-trivial with it that you can't do without it. If this new, different thing has some connection to the real world, however indirect, you expect it to imply some in principle observable difference.

6. **theoreticalminimum**
November 14, 2019

Off topic, but was wondering whether you've yet had any chance of reading the new bio of Jim Simons by Zuckerman, and whether you're planning to write a review of it at some point?

7. **Peter Woit**
November 14, 2019

theoreticalminimum,
Just finished reading it late last night, will write about it here very soon.

8. **Peter Shor**
November 14, 2019

Peter Woit:

If you don't say "everything is quantum," there's no problem. There's a classical world and a quantum world, and you don't *need* an explanation of how the classical world emerges from the quantum world.

You have to admit that "everything is quantum" before you can start to develop the theory of decoherence.

Certainly, some people were wondering why the classical world wasn't quantum before MWI — we have Schrödinger's cat and Wigner's friend — but my impression is that most physicists didn't even think about this problem. This seems to be confirmed by the historical development. Considering the following timeline (based on quotes from Wikipedia):

> Many-worlds is also referred to as the relative state formulation or the Everett interpretation, after the physicist Hugh Everett who first proposed it in 1957. The formulation was popularized and named many-worlds by Bryce DeWitt in the 1960s and 1970s.

and

> Decoherence was first introduced in 1970 by the German physicist H. Dieter Zeh and has been a subject of active research since the 1980s.

I agree with you that the statement "everything is quantum" is not an answer. But I think it's part of some very important questions.

9. **Peter Shor**
November 14, 2019

To continue my previous comment, while you can't test the MWI experimentally, you can indeed test the statement "everything is quantum" by doing experiments that look for interference between larger and larger objects. And so far, they haven't found a limit.

10. **Peter Woit**
November 14, 2019

Peter Shor,
I don't think we really disagree. Yes, you need to first pose the problem. My point is just that invoking MWI at the level of "everything obeys the Schrodinger equation, and our observed universe is one of many" sounds simple and elegant, but it does zero to solve the problem. And you can see this by noting that there is no testable distinction with the "textbook" or "Copenhagen" interpretation.

The theory of decoherence is very much non-empty, and, as a result, is very much testable.

11. **Will Sawin**
November 14, 2019

It's reasonable to complain about some many worlds promoters, but the part that's reasonable to complain about is not any flaw in MWI, but just the fact that they are presenting the existence of parallel universes as a big, exciting scientific discovery. As you note it's not even a scientific theory, just the avoidance of some bad theories and philosophical positions (objective collapse, hidden variables, denial of objective reality). It shouldn't even be that surprising. After hundreds of years of every scientific theory that implies that I, personally, am in some way special or unique, getting knocked down, are we really supposed to keep falling for it?

You are of course correct that MWI does not in itself contain any mathematical model of how, in fact, quantum states decohere. But the argument that we should take the interpretational point of view of whoever does the best mathematical (or experimental) work in this area seems shaky. Given that any correct quantum mathematics is compatible with any mainstream quantum interpretation, why should we not take the best mathematics and combine it with what we separately understand to be the best interpretation?

I read the beginning of one of the papers in the mathematical theory of decoherence that you linked on this blog, and noticed that it relied on a system of axioms about what observers observe and how that relates to the wave function. I don't think it explained what an observer is or how to tell which (if any) observers exist. If you add to this theoretical system any plausible definition of how to tell which observers exist from the wave function, you can conclude that there exists an observer which observes one outcome of the experiment and there also exists an observer which observes the other outcome, i.e. many worlds. I don't think this reasoning is illegitimate because I haven't written a paper on the mathematical side of decoherence.

12. **Blake Stacey**
November 14, 2019

There were historical predecessors to decoherence theorizing before Zeh, going back to Rosenfeld and company in the 1950s and even Heisenberg in the 1930s. Why the subject took so long to develop is an interesting question of psychology and perhaps even sociology, but telling why an idea got overlooked is always tricky. For example, Wigner nearly got the no-cloning theorem in 1961 but narrowly missed the point.

Weyl understood the mathematics of entanglement as early as 1931 — he called it a kind of *Gestalt,* since Schrödinger hadn't coined the modern word yet. In principle, he or anybody else after that could have said, "Hey wait, a generic unitary on a joint system will have no reason to respect the tensor-product structure, so it will rotate a tensor-product state into one that is *Gestalt*-y, whose marginals will be mixed, I wonder what that implies?"

I think that an underrated factor in the history of philosophizing about quantum mechanics is that, for much longer than we intuitively think nowadays, not everybody *trusted* quantum theory in their bones yet. Weyl himself expected it to be "subsumed" into a better theory. As late as 1938, Kramers was saying that "everyone knew that the quantum theory was provisional" and that there was no guarantee that "after some years, Schrödinger's equation would still be the root of everything." (See the proceedings for the 1938 Warsaw conference, which also report that Heisenberg was speculating about some kind of breakdown of quantum mechanics at higher energies.)

13. **Peter Woit**
November 14, 2019

Will,
I think the essential problem here is that, while many if not most of us believe quantum mechanics should also in principle describe observers, we don't know how to do this. There quite possibly are many different ways of thinking about what an "observer" is. It's perfectly plausible that in some definitions of "observer", time evolution take states with one "observer" into states with multiple, effectively disconnected, "observers". You can postulate such a definition with such behavior if you want, but this doesn't really buy you anything. If anyone asks you to say anything about the real world, all you can do is go back to what Copenhagen/textbook tells you to do.

What I see people arguing about MWI doing is starting with a sensible starting point (all is quantum), then ignoring the difficult problem this poses of how to describe observers, measurements, etc. and calculate something about them, instead starting in on empty discussions about conjectural behavior of undefined concepts.

14. **Peter Woit**
November 14, 2019

Blake Stacey,

I'm sure you're right that part of the explanation for the history of this subject is that its founders though of it as provisional. They had just been through a period of huge revolutions in physics, and expected another one soon.

Another part of the explanation may be the very limited experimental tools they had available, with lots of kinds of quantum behavior experimentally inaccessible. The context of the "Copenhagen" argument that you have to describe your experimental apparatus classically was one of much more limited kinds of equipment. If they had, say, a scanning tunneling microscope, they might have argued very differently.

15. **Narad**
November 14, 2019

> I'd rather try and moderate a discussion of everyone's favorite ideas about fundamental physics than one about Trimble's views on sexual harassment.

If I may venture one Trimble comment not on the foregoing subject, oh, man do I miss those ApXX reviews. The typescripts were a thing to behold – just riddled with typos (*many* of which the U. of C. Press failed to catch; c'mon, you call yourself an editor and don't know when a zero should be an *O* and vice versa?) and general zaniness. They rivaled Olin Eggen, whose secretary also prepared his submissions.

I just wish they would have let me have one rather than tossing them to the nearest warm body.

16. **Will Sawin**
November 14, 2019

I like the formulation:

> It's perfectly plausible that in some definitions of "observer", time evolution take states with one "observer" into states with multiple, effectively disconnected, "observers".

But the key point has to do with a certain stronger, but equally true statement:

> It's clear that in every plausible definition of "observer", time evolution takes states with one "observer" into states with multiple, effectively disconnected, "observers".

You're completely right that this doesn't make any progress on the difficult problem of defining observers and related concepts (which are not entirely problems in physics but also moral philosophy, psychology, possibly biology (of course if we use measuring devices and not humans as our observers these should merely be questions of physics and engineering)). But how much progress can we make on these questions if we can't even get this one basic fact right without 60+ years of bitter war?

17. **Arnold Neumaier**
November 15, 2019

Peter Shor,

"anybody who believes there is a sharp distinction between virtual particles and real particles is classifying particles into two classes, one purely quantum and the other more real"

No. The more typical belief is that real particles are quantum, while virtual particles are purely illustrative tools for discussing high-dimensional integrals. See https://www.physicsforums.com/insights/physics-virtual-particles/

"Of course, you can believe that everything is fundamentally quantum without subscribing to the MWI"

I do believe that, based on the much more rational thermal interpretation featured in my new book
https://www.degruyter.com/view/product/537801

18. **David Gerard**
November 15, 2019

Scott Alexander believes in the multiverse because Eliezer Yudkowsky believes in it – he comes from the LessWrong "rationalist" subculture.

19. **Peter Shor**
November 15, 2019

Arnold Neumeier:

I didn't say that the "more real" particles weren't quantum in some respects.

But in actual fact, there isn't a sharp distinction between "real" electrons and "virtual" electrons. It's a continuum, even though dividing electrons into "virtual" and "real" can be useful for intuitive understanding.

This idea that real electrons exist and virtual electrons don't actually exist (and are just a tool for doing calculations) seems to me to be a misconception carried over from the Copenhagen interpretation. To treat physics consistently, you either have to say that "real electrons" are just an approximation, or say that "virtual electrons" actually exist.

20. **Arnold Neumaier**
November 15, 2019

Peter Shor,

"there isn't a sharp distinction between "real" electrons and "virtual" electrons. It's a continuum"

This is not correct; you seem to mistake virtual electrons for short-living effective electrons.

As explained in detail in the Insight article linked to in my previous comment, there is a continuum between stable and unstable particles, but not between real particles (defined by having a state) and virtual particles (defined as internal lines in Feynman diagrams). It is impossible to write down the state of a virtual particle.

" "real electrons" are just an approximation"

Yes, since real electrons in QED are defined only asymptotically, at times $\pm \infty$.

langlands has some new (september) comments on the geometric langlands controversy. don't think i've seen this on your blog yet so thought you / your readers might like to be aware. https://publications.ias.edu/node/2700

The Man Who Solved the Market

November 14, 2019
Categories: Book Reviews

There's an excellent new book out about Jim Simons and Renaissance Technologies, [The Man Who Solved the Market](), by Gregory Zuckerman. I recommend it enthusiastically to anyone interested in the story of how a geometer ended up being worth \$23 billion. Lots of other mathematicians and physicists have also been involved in this over the years.

I first heard about Simons and his investment operation when I was a postdoc at Stony Brook in the mid-eighties, and have heard bits and pieces of this story from various sources over the years, sometimes clearly distorted in the retelling. It's very satisfying to finally get a reliable explanation of what Simons and those working with him have been up to all this time. For those with more interest than me in the details of quant strategies, the book provides far and away the most information available about how Simons and RenTech have been making so much money so successfully. The author managed to get some degree of cooperation from Simons, and was thus able to get a lot of those involved with him to talk. As a result, while this isn't an "authorized" biography, it's written from a point of view rather sympathetic to Simons.

One question that keeps coming up in the book is that of motivation. Why did Simons abandon a highly successful career doing research mathematics in order to focus on making as much money as possible? Part of the answer is that, from the beginning, Simons always had one foot out of the research math world, playing poker and trading commodities even when he was a graduate student working with Chern at Berkeley. Later, while employed at the IDA in Princeton, he spent time working not just on government projects but on the mathematical analysis of stock market trading strategies. While I've often heard the story of how he was fired from IDA after publicly criticizing the Vietnam War, less well known is that a big problem was that he was quoted in Newsweek saying he planned to work on his own projects, not government ones, until the war was over.

Unfortunately, the book has very little to say about a question I'm fascinated by: what does Simons intend to do with the \$23 billion (and counting, the RenTech Medallion Fund that he has a large piece of continues to be an incredible money-making machine)? There's very little in the book about his philanthropic activities, the most visible of which are at the [Simons Foundation](), which now has assets of nearly \$3 billion with amounts of the order of \$300 million/year coming in as income and going out as research funding. I think that on the whole Simons had made excellent choices with the math and physics that he has decided to fund, from the [Simons Center for Geometry and Physics]() at Stony Brook to a wide array of programs funded by his foundation.

A question that keeps reappearing throughout the book is that of the social significance of RenTech. It's a rather pure test case for the moral question about quant investing: would the world be better off without it? In the case of the main money-maker, their Medallion fund, it's hard to argue that the short-term investment strategies they use provide important market liquidity. The fund is closed to outside investors, and makes money purely personally for those involved with RenTech, not for institutions like pension funds. So, the social impact of RenTech will come down to that of what Simons and a small number of other mathematicians, physicists and computer scientists decide to do with the trading profits (calculated by Zuckerman at over \$100 billion so far).

Simons himself has engaged in some impressive philanthropy, but one perhaps should weigh that against the effects of the money spent by Robert Mercer, the co-CEO he left the company to (Zuckerman discusses Mercer in detail). Mercer and his daughter have a lot of responsibility for some of the most destructive recent attacks on US democracy (e.g. Breitbart and the Cambridge Analytica 2016 election story). In the historical evaluation of whether the world would have been better off with or without RenTech, the fact that RenTech money may have been a determining factor in bringing Trump and those around him to power is going to weigh heavily on one side.

Comments

1. **luysii**
   November 14, 2019

   There is also a fair amount about Simons in "The Physics of Wall Street" by physicist James Owen Weatherall, along with much more about quants and the street. Weatherall makes the statement that Renaissance Technologies is the world's best physics and math department.

2. **Peter Woit**
   November 14, 2019

   luysii,
   I don't know about "best" physics and math department, but it's certainly the wealthiest…

3. **Keith McClary**
   November 15, 2019

   "motivation"

   Oligarchs usually want to establish a dynasty (eg. Trump, Bushs, Rockefellers, Kennedys). Does Simons have kids?

4. **Peter Woit**
   November 15, 2019

   Keith McClary,
   Thinking a bit more about the book, it seems very likely that Zuckerman was operating under some sort of agreement with Simons which involved him promising to stick to RenTech and say little to nothing about the Simons children or his current activities beyond the Simons Foundation. The only real mention in the book of the children is that Zuckerman does discuss the quite tragic stories of the accidental deaths of two of his sons.

   What's not at all discussed in the book is that Simons has three living children, two daughters and a son. One daughter (Liz Simons) runs the Heising-Simons Foundation with her husband, Mark Heising. In 2017 this had assets of \$500 million, in 2018 gave away \$100 million. His son (Nathaniel Simons) with his wife run the Sea Change Foundation, focused on climate change, which supposedly has given away upwards of \$500 million.

   Also not discussed at all in the book is what must be a huge operation investing Simons' assets (I doubt he's putting them in a mutual fund…). This includes at least his family office, Euclidean Capital, and another investment group, Medley Partners.

   I also hadn't noticed that Zuckerman doesn't mention at all this story, which came out two years ago:
   https://www.theguardian.com/news/2017/nov/07/democratic-donor-james-simons-private-wealth-fund-tax-haven-paradise-papers
   Based on leaked documents, this described an offshore trust with \$8 billion back in 2010, as well as giving a lot of other details about Simons' assets.

   This raises the question of the significance of the one number Zuckerman gives about Simons' current wealth (\$23 billion). It's quite possible this doesn't include funds in trusts for his children or assets of Foundations he controls, so the size of assets controlled by him and his family may be much larger than this. Possibly his long-term plan is to leave his wealth to philanthropic foundations controlled by his children.

5. **Paul Blann**
   November 16, 2019

   Following your recommendation I read the book and was somewhat disappointed. It's principal subject is the history of a small group of people who use quantitative methods for exploiting the stock market and other financial instruments. Around this are painted a number of portraits of the key characters starting with Simons, but the cast is large. Despite the hagiographic treatment in the book these people are, in the main, a pretty unpleasant lot, mostly driven by an obsessive desire to acquire huge ampounts of wealth. They may well be mathematically adept (and in other subjects as well), but to a man (because they are virtually all men) they lack humanity. I was hoping to get more detail on the techniques used and how they developed over time. Alas, the writer is a journalist and despite doing a reasonable job at the history, was probably not able to expound on the science. I initially thought that the lack of depth in the characters was down to the writer – by the time I had finished I concluded that it was because many of the cast were rather one dimensional.

   I would say that if your interest is in how financial markets work and the people who work in them, then this could well be of interest. If you are interested in mathematicians in a real world environment I'm afraid this book will not shed much light.

6. **Peter Woit**
   November 16, 2019

   Paul Blann,

   Thanks. Your take on the book may be that of many readers, mine was colored by having a lot of interest, knowing a bit about many of the characters involved and having been curious to know more for a long time. It's true that on the whole they don't seem to be particularly interesting or pleasant people. The selection effect is for those who want to devote their lives to making as much money as possible by identifying obscure signals in a time series.

   Zuckerman doesn't give a lot of detail about exactly what Simons and his associates have been doing, but there's a lot more here than elsewhere. I would suspect the lack of detail is mainly due to the fact that those involved were only willing (or allowed) to discuss these trading strategies in generalities.

7. **Anonymous**
   November 16, 2019

   On the note of character, I found it disturbing that Simons would smoke during talks at the Simons Center (and I'm sure in other indoor environments) during the few times I saw him there. It gave off the vibe of "I'm so rich, I can break the rules and no one's going to say anything".

8. **Peter Woit**
   November 16, 2019

   Anonymous,
   The book contains more than a few stories about his smoking. One of them is that Edward Thorp wouldn't meet with him because he had heard he smoked in his office and meetings.

9. **Art**
   November 18, 2019

   Question about arXiv: Besides Cornell, arXiv "gratefully acknowledge support from the Simons Foundation and member institutions" on their homepage. Awhile ago, however, arXiv (briefly) solicited donations. I chuckled and moved on, but continue to wonder about the backstory to that episode.

10. **Peter Woit**
    November 18, 2019

    Art,
    Simons, mainly through the Simons Foundation, pays for a wide variety of things helpful to math and physics research, the arXiv contribution is just one.

    It seems that the arXiv is still asking for donations, see
    https://arxiv.org/about/donate

    One problem with having gazillionaires fund such things is that those with more modest resources, e.g. mere millionaires, start to feel there's not much point to donating, best to leave science philanthropy to our tech and financial overlords.

11. **Chris Oakley**
    November 19, 2019

    The notion that professional investors in capital markets are doing the world a service by "providing liquidity to the market" always makes me smile. Yes, they are, in the same way that professional poker players in Las Vegas provide a service to the tourists. These are the people who ensure that dumb investors like you and me get as little return on our investments as possible because they will have got there first. Still, I should not complain, as working for investment banks for 15 years is what paid for this house. I merely want to make the point that the notion that Jim Simons "launched the quant revolution" is a bit ridiculous. The idea of investment based on data-driven quantitative models occurred to a lot of people, including a number of companies in London who interviewed me in the late 1980s/early 1990s. Most of them are still going strong, but naturally they are very secretive, as I am sure was Jim Simons in the early days, so if one had to say anything along these lines it would be that each one of them separately "launched the quant revolution".

12. **random reader**
    November 23, 2019

    A less known piece of the story is that in addition to Simons' philanthropic outreach to scientists, RenTec has inreach that brings scientists and mathematicians to the firm as hired consultants. David Donoho was visiting Rentec when compressed sensing was the next big thing, and Cumrun Vafa has been there. It would be interesting to know who else has moonlighted at Renaissance.

    re: the 3 living children, it was reported that the younger daughter is autistic, and that as a result Simons has donated huge sums of money to research on the genetics of autism. Simons' surviving son has worked at Rentec in addition to being a philanthropist.

    > "The selection effect is for those who want to devote their lives to making as much money as possible by identifying obscure signals in a time series."

    This is a bit unfair even if technically true as a description of many jobs at RenTec. My understanding is that Simons set up the work culture of the firm based on the places he used to work at, IDA and academic research. As a result the employees seem to have a not insubstantial freedom to pursue their own projects and interests, though I guess (as at Google and other places with a similar approach) the idea is in part that a lot of those projects will end up making money for the company. From what I've seen of employees' postings on social media such as MathOverflow, they seem to maintain their interest in their areas of scientific expertise. Simons himself wrote some arxiv papers with Dennis Sullivan, harkening back to his work from the 1970's on differential cohomology (something about axiomatizing or characterizing the theory that had been originally defined by a construction).

13. **Cody**
December 12, 2019

To Peter, Paul and others,

I recommend you listen to Gregory Zuckerman's recent interview on the Bloomberg Master in Business podcast (titled 'Gregory Zuckerman on the Quant Revolution'). The podcast covers how the book was written and confirms Peter's suspicion as why the book is lacking the details one may have hoped to have learned about RenTech.

Terrifying Odyssey Through a Cursed World

November 18, 2019
Categories: Uncategorized

The great German artist Anselm Kiefer now has a show up in London at the White Cube Bermondsey gallery, with a review in the Guardian entitled [Terrifying Odyssey Through a Cursed World](). The review describes some of the works as follows:

> Another room is given over to panoramic blasts of brown and black that map sweeping vistas of desolate fields. A road twines through a morass of mud and collaged sticks. Lines of fence poles vanish in the distance. These scenes are drawn in black on a vertiginous scale. Kiefer uses perspective, the Renaissance technique of showing the real world shrinking towards a single vanishing point, to define his landscapes – but the perspective view is a transparency on top of a muddy tumult of colour and texture, with real, 3D stuff stuck over that in turn. From the right distance, the picture of a landscape can be read clearly, like a painting by Van Gogh. Go closer and the picture dissolves in a mess of bulges and muck.

What's the inspiration for these works (besides the Holocaust)?

> These landscapes are entitled Superstrings, a reference to string theory, an influential idea in contemporary physics that seeks to unify quantum mechanics with Einstein's relativity.

and the show is entitled Superstrings, Runes, The Norns, Gordian Knot. The gallery website explains:

> White Cube is pleased to present an exhibition of new work by Anselm Kiefer. The exhibition brings together many of the interests that have characterised Kiefer's work for decades, including mythology, astronomy and history. Located across the entire Bermondsey space, it features a large-scale installation and paintings that draw on the scientific concept known as string theory.

The Guardian review continues:

> The main gallery at White Cube Bermondsey is already pretty bleak in its featureless emptiness. Kiefer makes it work for him by heightening the chill, turning the White Cube into a morgue for Europe. Snow-covered landscapes with none of the cheer of Bruegel stretch away to infinity. They are marked with sticks as black as gravestones and nets that catch at nothing. Kiefer's science reading clearly hasn't cheered him up. The curvy grids of space-time become horrible wire traps in a devastated nowhere. We might be on the no-man's land of the Ukraine border. Anyway, this place has got death in its hard black furrows.

Another review, at City A.M. tells us more about Kiefer's motivations:

> This is where we come to string theory – the monolith of Kiefer's new show. Though he admits that he doesn't quite understand what string theory is, Kiefer professes complete fascination with the idea that there is a scientific equivalent to the allegorical Gordian Knot – an idea that he picked up after thirty years of subscribing to Spektrum, a German monthly science magazine…
>
> String theory cannot be verified empirically. Rather, it is an attempt to provide an all-encompassing description of the universe. And that, says Kiefer, is just why it is beautiful. "I suppose it's like painting," he says. "You cannot prove if a painting is good or bad. That is the point of it – it is descriptive… and there's something sublime in that."

From the images available, the work does look quite amazing. Kiefer quite possibly has gotten to the very heart of superstring theory, seeing in it a dark, desolate and blasted mythology which "cannot be verified empirically."

   The abject language used to describe this work is bordering on parody. I'm thinking less Nietzsche and more of those Sprockets guys in black spandex, deadpanning about the uncaring and eternal void of existence.

   Not that it isn't beautiful. I find it skillful, striking and unnerving, but come on…

News From HEPAP

November 24, 2019
Categories: Uncategorized

For presentations a couple days ago at the latest HEPAP meeting, see here. One piece of news, from this presentation, is that there likely will be a delay in the scheduled startup of the HL-LHC, with the next LHC run (Run 3) extended for an additional year (through 2024), and the next shutdown (LS3) extended by a half year. The HL-LHC would then start physics in 2028.

Most of the HEPAP discussions have to do with funding. The pattern of recent years has been one of huge decreases in funding proposed by the Trump administration. These are completely ignored by both the Democrats and Republicans in Congress, which passes large increases in funding (then signed into law by Trump). For FY2020 this continues: at DOE the HEP budget for FY2019 was \$980 million, for FY2020 the White House budget request was a massive cut to \$768 million. This was taken no more seriously by anyone than the last few of these, with the FY2020 House Mark \$1,045 million, the Senate Mark \$1,065 million. The FY2020 budget remains to be finally finished and passed, in the meantime the federal government has been operating under a sequence of continuing resolutions.

Specifically on theory funding, JoAnne Hewett has a presentation on The State of Theory. It has no numbers in it, but the DOE numbers given here show an increase from \$60 million in FY2017 to \$90 million in FY2019 for Theoretical, Computational and Interdisciplinary Physics. But within this category, pure theoretical HEP is pretty flat, with big increases for Computational HEP and a huge new investment in Quantum Information Science (\$27.5 million in FY2019). There does seem to have been some sort of decision to de-prioritize conventional theoretical HEP in favor of newer trendy areas.

Hewett describes the general consensus on current problems with theory funding as

- Universal concern on ever decreasing levels of funding for university groups: concern that university programs are dying.

  -Private institutions attempt to offset cuts with non-federal funding sources.
  -Cuts to program further accumulated in 2019. Many postdocs learned in May 2019 that their contracts would not be renewed for the fall. It was then too late to apply for new positions.

- Lab theory programs are also losing researchers.
- Even distribution of cuts across U.S. theory program has indirect proportional effect to small programs.
- Large fluctuations cycle-to-cycle is making groups less cohesive and more inclined to opt for "safer" research projects.
- There is the perception that the recent emphasis on QIS comes at a cost to more traditional HEP theory research.
- Summer salary has been capped or reduced to 1 month in many cases. Removal of summer salary across the board is demoralizing.

and ends with

> The situation is becoming increasingly unstable.
> University-based theory is suffering its most serious crisis in decades.
> Its future is in jeopardy.

It would be interesting to see some numbers on the size of new private research funding going to HEP theory (for instance funding from the Simons Foundation or the private funding of the CMSA at Harvard). I don't know of such numbers but I'm curious whether what is happening is that the total funding level has seen reasonable growth, but increases in funding are going to a small number of elite institutions, with the rest of the field in decline.

On the question of caps or reductions in summer salary, I doubt that any significant number of researchers is reacting to only getting 1 month of summer salary by signing up for another job (e.g. teaching summer school) and not doing research during the other two months of the summer. There has been another huge influx of money to the field that in some sense replaces grant-funded salary supplements: the multi-million dollar Breakthrough Prizes. A sizable number of HEP theorists have now partaken in all or part of one of the \$3 million prizes. If you add in this money, on average HEP theorists may have been seeing significant increases in income, however with almost all of it going to a small number of people (at the same elite institutions that are doing well). What we're seeing may just be the same trend as in the rest of the US economy: a move to a star system with ever larger increases in inequality.

Another problem for the field of HEP theory may be that funding is stagnating because the DOE and NSF are skeptical about its intellectual health. Hewett notes that "Formal theory resides solely in university environment and has undergone significant funding cuts." Trying to make the positive case for this part of the field, she lists three areas of advances, but oddly, the first two are identical. The two areas of advances in formal theory she describes are:

> Advances in strongly coupled quantum field theory (gravity/field theory duality, bootstrap program, amplitudes) has implications for particle physics, cosmology and beyond.
>
> Geometric advances in particle physics constructions from String/F-theory has implications for the "swampland program".

For the second of these, it's quite possible that most physicists don't see this as an advance at all.

Update: Physics World has more about the delay here. It is supposed to be announced on Tuesday. The cause evidently is a budget gap caused by some planned contributions from non-member countries now not happening. The story doesn't explain which non-member countries are involved or why their planned contributions are now not expected.

Comments

1. **Sabine Hossenfelder**
   November 25, 2019

   As I have tried to tell particle physicists for 5 years or so, even the dumbest politician will eventually see that they don't live up to the promises they've been making (basically since the 1980s), which will result in funding cuts unless they make drastic changes.

2. **Peter Woit**
   November 25, 2019

   Sabine,
   The problem is that people right now are responding all too well to the incentive structure of the grant system. If you want to get your grant renewed, the worst possible thing you could do is acknowledge that what you have been doing with previous grant funding was a failure. The incentives are to deny the obvious (that what you have been doing doesn't work), make some dubious claim of success, and try and reorient what you are doing to fit the latest hot topic popular at funding agencies.

For example, instead of admitting that finding new "string vacua" has been a waste of time, the incentive is to keep working on this, but claiming a machine-learning/AI/big data aspect to your research. Instead of admitting that your quantum gravity research has gone nowhere, claim a connection to quantum information theory.

3. **Alessandro Strumia**
   November 25, 2019

   Actually, a bibliometric analysis shows a decline of most elite institutions. A few decades ago one elite institution contributed up to ≈7% of the world-wide output, while now it's ≈2%. Only IAS remains better.

4. **WhoOrderedThat**
   November 25, 2019

   Hmmm… seems to me like accelerators and experimentalists have lived up pretty well to the promises they made… resolutions/triggers/data throughput rates/recorded integrated luminosities at the LHC detectors; Daya Bay nailed theta_13, T2K is plugging along, IceCube has good data. All sorts of experimental activities… a whole new program of (g-2), mu2e, DUNE is making its way through milestones.

   Gosh excoriating accelerator and detector builders for a year or two or three, given the complexity of the projects… particularly the LHC… including incredible financial gymnastics of dealing with many world currencies and distinct science bureaucracies… is not at all broad-minded. Marie Curie, a strong supporter of internationalism and collaboration, would be shaking her head.

   Lots of rockets blew up on the pads prior to successful rockets… gosh they still blow up sometimes. An awful lot of mistakes were made in motorcycles, cars, and planes (hey, ask Boeing about their 737)… theorists sitting on the sidelines and acidly criticizing the folks fighting the real world to get their experiments built quicker and cheaper is not a winning style.

5. **Peter Woit**
   November 25, 2019

   WhoOrderedThat,

   No one is excoriating anyone for the potential HL-LHC delay. May be just as well, allowing a longer run 3 so more data available to analyze during the LS3. The only thing of longer-term significance that this pushes back is the availability of the LHC tunnel for a next generation machine (assuming the length of the HL-LHC run kept constant). Given that any next generation machine looks like it will take a long time to agree on and get funding for, having the LHC tunnel in use for a year or two longer doesn't matter at all.

   I see that Physics World now has something about this, says announcement Tuesday. Evidently the delay is being caused by a budget gap of 100 million pounds or so, caused by expected contributions from non-member countries not happening. I'll add something to the posting about this.

6. **Alessandro Strumia**
   November 25, 2019

   Peter,

   running LHC for a few years more does not matter because it seems anyhow unrealistic that high energy physics would survive until 204X. The main hope is that China decides that they want to become the new world center of high energy physics by having the next collider while LHC runs ad nauseam. If China starts, most Europeans would likely join.

7. **Sabine Hossenfelder**
   November 26, 2019

   @Peter,

   Yes, the existing incentive structure of the academic system encourages scientists to claim that what they have previously done was successful and continues to be exciting and promising. But that in and by itself is not the problem. The real problem is that we all know that this leads to research bubbles, have known it for a long time, and yet don't do anything about it.

   And that is despite the problem is (1) patently obvious (2) much talked about and (3) not difficult to solve.

   The current structure of the system reinforces, rather than alleviates, cognitive biases. In this concrete example that's loss aversion — if you've been working on something for a long time, it's hard to admit (to yourself as well as to other people) that this time was wasted. Any sensible organization of the scientific system should therefore have incentives to *prevent* such cognitive biases instead of reinforcing them.

   Of course this is not specific to particle physics, but that's not an excuse to accept it.

   For the people who always falsely claim that I do not know how to improve the situation, let me remind you that I have a list with things you can do to help here.

8. **Thomas**
   November 26, 2019

   It's a peculiar situation. Other than the stimulus year (2007), the last couple of years have seen the strongest increases for DOE HEP in a long time (basically, since the demise od the SSC). The budget is over a billion dollars, with 90M (if enacted, I think) going to theory. The puzzle is why more of it is not trickling down to University based theory. I suspect the answer does not have much to do feelings at the DOE (or by politicians in congress) about strings, the swampland, or the multiverse. DOE is a mission driven agency, and when new money comes in they want to spend it on projects, like support for experimental programs at the labs, computation, or QIS. At the same time there has been all this philanthropic money for fundamental theory, so that in the end the only people left out are theory groups at public universities who do not get much private support. I actually wonder whether part of the thinking at DOE is that they see no need to subsidize private spending on fundamental theory with public money (although agencies like NSF have a long history of supporting the IAS, for example). I also wonder what happens to all these postdocs at the IAS, Harvard, etc. that are supported by private funds. Historically, the majority of them found jobs, many at public universities.

9. **David Brahm**
   November 26, 2019

   Are Breakthrough Prize winners generally distributing their prize money to their groups and/or departments? That was my impression, though I'm too lazy to generate any evidence.

10. **Peter Woit**
November 26, 2019

David Brahm,
I haven't heard of many examples of that, although had head that Kontsevich did distribute prize money (he got two breakthrough prizes, $6 million).

One group that I haven't heard of getting any prize money are the theorists at non-elite institutions who are now finding DOE/NSF grant money harder to come by.

11. **I**
November 27, 2019

David Brahm, Peter Woit,

A single data point in favour of David's claim is professor Bell Burnell donating her breakthrough prize (£2.3m) for a PhD scholarship award.

12. **Jackiw Teitelboim**
November 27, 2019

Dear Alessandro,

Where can I find the bibliometric data which you refered to in your first comment? Is it publicly available, or published anywhere?

Regards.

13. **Peter Woit**
November 27, 2019

Jackiw Teitelboim,

I'm guessing that what he is referring to is the data discussed in section 5.1 of
https://arxiv.org/abs/1803.10713
The unnamed "elite institution" is CERN.

14. **Alessandro Strumia**
November 28, 2019

Dear Jackiw ,
I compute InSpire data in the way described in the paper mentioned by Peter.
The plot below shows how much some main institutions contributed to the total bibliometric output from 1970 to ≈2017
https://alessandrostrumiahome.files.wordpress.com/2019/11/institutest.jpg

15. **WhoOrderedThat**
November 29, 2019

@Peter @Sabine_Hossenfelder

It is a mistake to ever think that SUSY or string theory or whatever theoretical fashion of the moment was a dominant motivating factor for the LHC or the SSC or the Tevatron or LEP or the SLC or the SppbarS or whatever expensive accelerator that required a vast team you'd care to list.

The motivation is that particle physics discoveries most convincingly appear with increased beam energy. Theorists grab a lot of bandwidth in the discussion, but hardly one hardbitten machine builder or experimentalist believes a-la-mode theory: the exploration into the unknown is the point.

Yes, many if not most experimental particle physicists must plead guilty to having a cognitive bias in favor of clear and compelling empirical evidence. And thank goodness they do.

Alternate particle physics techniques… that eventually quantum loops gave estimates of the charm quark mass, the top mass, and the Higgs mass… that neutrino oscillation and mass is pretty much the only existing clear and compelling beyond-the-SM hard data… are useful but their interpretations always were ambiguous… the superweak description of K0-K0bar CP violation suggested new physics at 10^5 TeV, but turned out that that CP violation was milliweak and the details were filled in slowly and surely by the (at that time) high-energy frontier.

Theorists on the sidelines really have no idea of all the team dynamics that go into actually getting big accelerators and big experimental teams to function successfully. It is hardly surprising that those teams have a persistence time… it is easy to understand that the LHC did not pass a new amazing threshold, but thinking that the LHC should be turned off in an instant because some au courant theory wasn't verified is immature.

The teams and institutions will persist for a while: and maybe something amazing will come out of it, like precision Higgs couplings not lining up with expectation.

And if someday we do get a 100 TeV machine at some reasonable price tag, it will be young and creative LHC team members will almost surely by the motivators and achievers. They won't really care more than a pfennig about string theory or SUSY.

That the course of particle physics has been some sort of psychological hallucination brought about by the sociology of cognition is an idea that has come and gone multiple times. See "Constructing Quarks" by Pickering, for example.

In fact, shocks from unexpected and sociologically sterile (prior to discovery) empirical results are far more common… results which the theoretical particle physics never predicted. Hence the famous phrase, "Who Ordered That?"… the neutron, the muon, the kaons, CP violation, the J/Psi, the long b-life, neutrino oscillation and mass, the rather large t-quark mass, etc.

16. **Peter Woit**
November 29, 2019

WhoOrderedThat,

I don't really significantly disagree with you. Especially at this point, where speculative theory has been such a failure in recent decades, experimentalists should mostly ignore theorists, do what they can to study what happens at the energy frontier, and hope for something unexpected. The next 15 years or so, for better or worse, the path is pretty clear: get the HL-LHC working and get as much out of the LHC as you can. While doing this, best to ignore theorists who want to tell you about ever more obscure ways to look for SUSY or some other dubious speculative model.

17. **WhoOrderedThat**
December 1, 2019

Speculative theorists are sometimes like politicians… you might find them phony and self-aggrandizing, but progress in fundamental physics or government without them would be even more meager.

Unfortunately both speculative theorists and politicians can become untethered… in California the politicians clearly had no idea how to keep the high voltage electric distribution system maintained through our PUC, for example, to suppress wildfires.. echoing their cluelessness with Enron 2 decades ago… or their innumeracy on public pensions about that same time. We can all notice the recent shambles politicians have made out of our foreign service recently.

While speculative theorists chase their tails, Fermilab is pressing forward in (g-2), mu to e, and DUNE. Thank goodness the theorists are ignoring those programs, they probably would impede them.

The theorists are, however, paying attention to dark matter searches, and not helping… they seem to forget that heavy DM interactions with nucleons might be any of the 5 fundamental Lorentz structures – S,V,T,A,P… back in the 1950's, their antecedents thought for sure the weak interactions was S and T, until the tau-theta puzzle (Who ordered that?) induced the fantastic experimentation of Chien-Shiung Wu and a shift to V-A took place. Ironic that no experimentalists got a Nobel Prize for that work… only theorists Lee and Yang (who did do crucial work).

So today speculative theorists want to declare WIMPs dead based on S alone, and ignore the other 4 Lorentz structures, based essentially on ignorance.

However, lots of great energy for other types of dark matter searches… boson-like, low-mass, etc… has come from speculative theorists lately. Bully for all that.

That MOND has been experimentally addressed (on earth), and was a rejected (by other theorists, not experimentalists) portion of the LISA project has been ignored by speculative theorists. They seem to think experimentalists weren't paying attention, or form a false narrative that experimentalists are ignoring MOND.

18. **atreat**
December 2, 2019

Sabine & Peter,

Another way to *solve* the problem is to let it play out precisely how it currently is! Thanks in part to both of you, it is becoming ever more obvious that funding *should* be cut to Theoretical HEP. As you yourselves continuously note, nothing good is coming from it and the return on investment for the public is in many ways *worse* than nil.

Theoretical HEP is in failure mode and deserves its funding cut. Period. Full stop.

19. **Peter Woit**
December 2, 2019

atreat,
My point of view (and I think Sabine's is similar) is not that cutting theoretical hep funding is a good idea or the solution to anything, but that what is needed is to change the reward structure so that the incentives provided by grant funding stop being incentives to keep working on the same failed ideas.

In the case of the DOE HEP budget, the part going to theory is relatively small. Cuts in it seem to have been redirected to small increases in the funding of a few large experimental projects, with likely marginal impact on the science. I don't think this is a net plus, nothing is being done about the underlying problem. Far better would be if DOE would take seriously the problems Sabine and others have been pointing out and make some changes in how hep theory grant proposals are evaluated.

20. **no idea**
December 6, 2019

Peter,
"make some changes in how hep theory grant proposals are evaluated" – do you actually have any concrete suggestions for what changes would be beneficial? Or is this just a gripe?

21. **Peter Woit**
December 6, 2019

no idea,

One simple change: panels should start rejecting grant proposals that propose to continue a failed research program. If you're proposing to work on much the same idea that hasn't worked for thirty years, your proposal should include a serious discussion of why this hasn't worked in the past (and what your proposal is to solve the problem).

If people find they can't get funded to pursue a program that isn't working, they'll have to find a new idea to work on (or drop out of the competition for grants, freeing space for someone who does have a new idea).

22. **no idea**
December 6, 2019

Well, yes, but this is just apple pie. You need a change to the structure of the system, not just some vague advice to the people making the decisions. If the panel is composed of people who don't agree with your definition of "failed", then this proposal doesn't work. The whole system of peer review rewards people who conform to the prejudices of the senior people in the field. Exhorting these senior people to ignore their prejudices is experimentally proven to fail.

23. **Peter Woit**
December 6, 2019

no idea,

No one said this would be easy. The reason many senior people in the field won't publicly admit failure of a research program is precisely because they are aware of the likely cost of that admission (the defunding of this research program).

While politics may make it not practically relevant, the fact remains that all that is needed is intellectual honesty about failure and its implications.

24. **anonymous**
December 6, 2019

Peter and no idea,

You are making the assumption that panels are made of senior people. In fact, many panels in theory have quite a few young people (including assistant professors). But your points are well-taken. How does one tell panels to reject grant proposals that propose to continue a failed research program? I have noted that there have been relatively few funded proposals to study MSSM phenomenology, so maybe things are changing, but too slowly. Still, do you have a specific suggestion?

25. **no idea**
December 6, 2019

anonymous,
I do have a specific suggestion, but Peter always censors it. My suggestion is that grant proposals should be funded at random. Or at least some significant proportion of them. My point is that no-one can predict the good ideas in advance, and it is foolish to try. Of course, one has to do a little work to devise a system that discourages the freeloaders, but one needs to break the feedback loop that stifles diversity and originality.

26. **anonymous**
December 6, 2019

no idea,

Interesting idea. Check out Nature, this week. An article is subtitled "A growing number of research agencies are assigning money randomly". This is being done in Switzerland and New Zealand. The problem in theory, however, is that you might find very important grants (like Stanford or Princeton theory) unfunded, which would be catastrophic. And there are also real crackpot type grants. Maybe the very best and very worst proposals would not be randomly evaluated, but the others could (maybe with a weighting system). Also grants have widely different funding levels (and the requests are usually much bigger than they eventually get), so I'm not sure how it could work. But it is obviously not crazy with serious funding agencies considering it.

This and That

December 2, 2019
Categories: Book Reviews, Multiverse Mania, Uncategorized

First, a few physics items:

- Mark Alpert has a new novel out, Saint Joan of New York, a thriller subtitled "A Novel About God and String Theory", which is an accurate description. It's published by Springer, so you may be able to get access to it like I did through an institutional license here.

  The plot revolves around Joan, a talented high school student here in New York, who has been learning more advanced material through a mentor at City College, and in particular has learned about string theory and Calabi-Yaus. This Joan plays the role of a modern-day analog of Joan of Arc, using divine help to do battle not with the English, but with more modern dark forces. This divine help includes a revelation about Calabi-Yaus and the theory of everything. It's a thriller, so I'll avoid telling more about the plot so as not to spoil it.

  I quite enjoyed reading the book even though I'm not much of a fan of thrillers, although a lot of enjoyment was due to the fact that much of the action takes place here in New York on the Upper West Side, and that the main plot revolves around the question of string theory and existence of a TOE. Edward Witten plays a role in the story.

  If you like this one, you might also want to read some of Alpert's other novels, a couple of which also involve themes of a TOE.

- Most theorists have abandoned the search for a TOE, or the idea of explaining anything about the Standard Model, in favor of concentrating on hopes to find some sort of emergent theory of quantum gravity. For the latest on this, talks from the recent misleadingly titled Quantum Gravity in the Lab conference at Google might at some point be available. John Preskill's slides are here. He indicates that the general idea is that quantum gravity will emerge from "Massive Entanglement, Quantum Chaos and Complexity." This week the IAS will host a similar event, a workshop on Qubits and Spacetime. Wednesday evening many of the participants will be put on a bus to Manhattan, where they'll continue with the 2019 meeting of the Simons Foundation-funded "It From Qubit" collaboration.
- Also here in New York this week, Roger Penrose will be at Pioneer Works Friday night for a public program involving a conversation with Janna Levin. I have no idea whether his presence in New York at the same time as "It From Qubit" is a coincidence or not. If not, maybe the "It from Qubit" people will get back on the bus and head out to Red Hook Friday night.
- Instead of being at the IAS, Nima Arkani-Hamed has been spending the past semester at Harvard, with activities that include teaching a course, Physics 283B: Spacetime and Quantum Mechanics, Total Positivity and Motives. Videos of his lectures are online here (first one here). It would be great if someone could put together a written set of lecture notes from these videos.
- Finally, for some multiverse-related book reviews that have the unusual feature of showing some skepticism, see John Horgan here, Matt Leifer here, also Chris Fuchs here. Fuchs explains the problem with multiple worlds as a solution to the measurement problem:

  > Its main shortcoming is simply this: The interpretation is *completely contentless*. I am not exaggerating or trying to be rhetorical. It is not that the interpretation is too hard to believe or too nonintuitive or too outlandish for physicists to handle the truth (remember the movie A Few Good Men?). It is just that the interpretation actually does not say anything whatsoever about reality. I say this despite all the fluff of the science-writing press and a few otherwise reputable physicists, like Sean Carroll, who seem to believe this vision of the world religiously.

Some mathematics items:

- The latest Notices of the AMS has a wonderful set of Memories of Sir Michael Atiyah.
- In the same issue, AMS vice-president Abigail Thompson criticizes the University of California's use of "diversity statements" in hiring. *Inside Higher Education* had an article about this here, and it led to some controversy described from one point of view here. For some blog discussions see here and here, with the first of these a place more willing to host a discussion of this than I will do here.

Update: In case you haven't been getting enough hype about the multiverse recently, Scientific American has Long Live the Multiverse! for you, from Tom Siegfried. Siegfried assures us that "multiverse advocates have been right historically". He also assures SciAm readers that multiverse theories are testable, in a way similar to the way Einstein demonstrated the existence of atoms in 1905 using Brownian motion:

> For that matter, it's not necessarily true that other universes are in principle not observable. If another bubble collided with ours, telltale marks might appear in the cosmic background radiation left over from the big bang. Even without such direct evidence, their presence might be inferred by indirect means, just as Einstein demonstrated the existence of atoms in 1905 by analyzing the random motion of particles suspended in liquid.

He doesn't mention that his analog of the Brownian motion experiment has been done: people have looked for the predicted indirect effects of other bubble universes on ours, and found nothing. To the extent that the multiverse is testable, it has been tested and found to not be there.

Comments

1. **Arnold Neumaier**
   December 3, 2019

   Matt Leifer, not Liefer!

2. **Will Sawin**
   December 3, 2019

   > I once asked Daniel Simon, one of the founders of quantum computation, whether Everett's interpretation of quantum mechanics aided him in finding his now-famous quantum algorithm. His response makes me laugh to this day: "Everett? Who's Everett? And what is his interpretation?"

   This seems like a strange argument because Simon's work built on earlier work of Deutsch-Jozsa, which built on earlier work of Deutsch, who was heavily inspired by Everett. So Everett's ideas contributed, at least somewhat, to Simon's work regardless of whether he was aware of them.

3. **Peter Woit**
   December 3, 2019

   Arnold Neumaier,
   Thanks! Fixed.

4. **Blake Stacey**

December 3, 2019

Jozsa, to the best of my knowledge, distrusted quantum mechanics: His motivation for working on quantum computation was to see how far the theory could be pushed, and what would break if we actually tried to build a device that relied upon quantum physics to compute. (This is conference chatter; I don't have a specific written reference in mind, though I can try to dig one up some day when I have more library time.)

And yes, it's *Leifer*, though he pronounces it the way that German 101 would make you think is written *Liefer*.

5. **Will Sawin**
December 4, 2019

Blake Stacy,

Perhaps this demonstrates the incompleteness of "has led to useful research" as a measure of the quality of a theory (though it is surely a very useful one). Skepticism of the accuracy of quantum mechanics has led to a lot of interesting research over the past century. But all of that research has just given us more reasons to trust quantum mechanics.

6. **Low Math, Meekly Interacting**
December 4, 2019

I listened to a sobering piece on NPR this weekend (Living Lab, you can look it up). The subject was "Planck's Principle", i.e., roughly, "Science advances one funeral at a time."

Someone actually attempted to test this notion with some rigor. The field was bio-medicine, but there likely are implications for other fields.

The conclusions were actually worse than Planck thought: Even if a Superstar scientist dies, their proteges keep up the rear-guard, stifling progress about as effectively. It's not enough for the ossified to die off. You've got to worry about all the people still around who agree with them.

Seems relevant to Multiverse Madness and its otherwise inexplicable staying power.

7. **Peter Woit**
December 4, 2019

LMMI,

The problem is that Multiverse Mania is not something just afflicting older leading theorists, with younger theorists skeptical. Unfortunately I think to some extent the situation is reversed. Perhaps the leading theorist most willing to take on the mania has been David Gross, who is now 78. Any list you make of prominent proponents will be almost all significantly younger.

There's a historically unusual situation here: the field of HEP theory made huge advances for a very long time, until the mid-seventies. Since then progress has come to a halt, arguably turned negative post-1984 with string theory and now the multiverse. The people who were trained during the period of progress are now hitting retirement age and the field is dominated by those trained in failed ideas who have never experienced what progress looks like. All our usual historically based modes of thinking about how science evolves in time, continually progressing, may no longer be relevant.

On some days I also notice that ideas I grew up with about US history as a progression towards a better and better society are not looking so good either right now, and the cheeriest thought available is that one does get old, die and not have to see where this goes…

8. **no idea**
December 4, 2019

On a more cheerful (?) note, the Memories of Sir Michael Atiyah are indeed a wonderful read. Lusztig's mention that Atiyah pointed out Sandy Green's seminal work on representations of GL(n) reminds me that (a) Atiyah was in the habit of denigrating algebra and extolling the virtues of geometry, and (b) Green was strongly opposed to this point of view. I well remember a wonderful lecture Green gave in Bielefeld, I think some time in the 1990s, in which he systematically demolished all of Atiyah's arguments, and convinced the audience beyond a shadow of a doubt of the superiority of algebra over geometry.

9. **Maik**
December 5, 2019

Peter,

the idea that science progresses continuously is not as prominent in the philosophy of science any more as it used to be. The situation has changed with Thomas Kuhn's works, who advocated for the idea that science progresses in cycles with phases of `normal science' ultimately leading to a `phase of crisis' until `revolutionary science' causes a `paradigm shift' and starts the cycle over again. If one believes in this, then one may very well view `multiverse mania' as a symptom of crisis.

10. **Peter Woit**
December 5, 2019

Maik,
I understand that the idea of continual scientific progress has always been understood to be problematic. But what I'm referring to is something different than the Kuhnian "normal science" leads to "crisis" leads to "revolutionary science" and then "paradigm shift", which is a model of progress with forward jumps.

What if the "crisis" of no progress goes on so long that the field loses its best people and instead attracts those happy with a bogus "revolution", one that is not in any sense progress? As far as I know Kuhn or Kuhnians haven't looked at this possibility, which may describe where we are now.

In the political realm the analog is a crisis of representative democracy leading to the rise of authoritarian demagogues, a phenomenon which is historically much more well-known.

11. **Maik**
December 5, 2019

Peter,

In Kuhn's book "The Structure of Scientific Revolutions" this is actually how he describes a crisis: Many capable people leave the field (some are forced out because they openly question `the paradigm'), old approaches and old (implicit) methodologies fail, scientific `puzzles' are solved via ad hoc postulates often in (indirect) conflict with

the paradigmatic approach taken (personal note: which you may call `revolution' to make your approach more popular), theorizing becomes more and more elaborate without solving the actual problems.
So Kuhn would probably say that this is just how crises look like.

Of course, you are right to say that it is not fully clear where to draw the lines, i.e. reality is often more complex than that. Yet in my mind this is just a consequence of the fact that Kuhn's work is not a mathematical theory, but a qualitative description of a sociological process (like politics).

12. **Peter Woit**
December 5, 2019

Maik,

I guess then the new situation is that HEP theory has been in a crisis for about 40 years or so, a situation with no analog in modern scientific history. To find another such 40 year period, I think you'd need to go back to a point where the field was organized very differently (e.g. a factor of 100 fewer researchers). What happens to a field that is in "crisis" for too long?

13. **Maik**
December 6, 2019

Peter,

Frank Pajares (Emory University) has a good synopsis of Kuhn's book on his website. Kuhn answers your question in Chapter VIII "The Response to Crisis": Basically, the fundamental scientific problems (e.g. what was the multiverse supposed to solve?) start to become recognized as such, resolving them becomes the focus of an increasing amount of scholars, and the otherwise very rigid "rules for normal research" start to loosen up, opening the gate for new ideas and thus new potential resolutions. Then, either `normal science' solves the problem after all (i.e. it was a hard problem, the problems were not with the paradigm itself), scholars set it aside (i.e. it is openly labelled a hard problem without renouncing the paradigm and the solution is left to future generations), or a new paradigm emerges (Kuhn describes in detail how that works).

I would not view things as pessimistically as your words suggest. Physics has lifted off only in the last few hundred years or so. By now we have been able to get rid of an extremely natural, but ultimately naive and wrong view of space and time, and have been able to take a very good glimpse at how matter is fundamentally structured. Yes, we have more researchers today, but I dare to claim that research and research environments have also become more complex. Maybe it is my age, but I am quite confident that good and honest science will resolve the issues we face today.

14. **Peter Shor**
December 7, 2019

@Maik: as Peter says, the scary part is that soon the people dominating the field of HEP will never have seen their subfield of physics work in a normal scientific mode, and will think that the paradigm of scientific `puzzles' being solved via ad hoc postulates and wild extrapolations from toy models is the normal paradigm.

If they then accept all the ad hoc postulates and toy models that the now-senior researchers have already come up with, and also come up with their own ad hoc postulates and toy models (that may or may not subtly contradict the ad hoc postulates that everybody already believes), they will end up with a body of `knowledge' built on extremely flimsy foundations.

This is the way the `It from Qubit' subcommunity of physicists seems to be headed. If it weren't for the example of the AMPS paper (which showed that the community can sometimes realize that some of their ad hoc postulates are self-contradictory), I would be in a state of complete despair over the direction of the field.

15. **Alessandro Strumia**
December 8, 2019

Dear Peter,

I draw your attention to a new scientific publication that criticises string theory. I quote from https://www.journals.uchicago.edu/doi/full/10.1086/704991:
«String theory provides an example of how white supremacist racial prestige asymmetry produces an antiempiricist epistemic practice among physicists, white empiricism». «String theory has failed to succeed in expected ways because the community—which is almost entirely male and disproportionately white relative to other areas of physics—is too homogeneous». «Disentangling physics from the norms of patriarchal white supremacy must begin with an honest accounting of the roots of the Western scientific project in the project of slavery». «Science is traditionally a sexist and racist practice». «White empiricism contravenes core tenets of modern physics (e.g., covariance and relativity)». «Black women must, according to Einstein's principle of covariance, have an equal claim to objectivity regardless of their simultaneously experiencing intersecting axes of oppression». «There are contexts in which Black women are epistemically privileged observers».

The author is presented on popular press as one of the greatest promises of US physics, and influential author of Particles For Justice. Does a field that produces this kind of results deserve to be funded as science?

16. **Peter Woit**
December 8, 2019

Alessandro Strumia,
Thanks, I hadn't seen that, and hadn't thought of that particular explanation for string theory multiverse mania.

The research behind that paper was funded by a 100K grant from FQXI, which also has funded a great deal of pro-multiverse research.

17. **Suzanne**
December 10, 2019

Alessandro, thanks for the link. I couldn't believe it first, but the following is indeed an actual sentence from that paper:

"Given that Black women must, according to Einstein's principle of covariance, have an equal claim to objectivity regardless of their simultaneously experiencing intersecting axes of oppression, we can dispense with any suggestion that the low number of Black women in science indicates any lack of validity on their part as observers."

Wow.

Not sure that person has understood "Einstein's principle of covariance", but the insight's from that research seem well worth the 100K…

18. **FB36**

December 10, 2019

An interesting article about String Theory etc:

https://physicsworld.com/a/a-mathematical-mindset

"He feels that their attacks are part of an "especially regrettable" trend, whereby "anyone can have a valid opinion on any subject, regardless of their technical knowledge and appreciation of it"."

19. **John Baez**
December 10, 2019

More madness: an article in *Quanta* titled Why the Laws of Physics Are Inevitable, with the blurb "By considering simple symmetries, physicists working on the "bootstrap" have rederived the four known forces. "There's just no freedom in the laws of physics," said one."

Yay! Fundamental physics has been solved! It's done!

The funny thing is that the article says nothing at all about the details of this supposed earth-shaking discovery. And indeed the work being reported on has nothing to do with deriving the four known forces.

It's sad to see *Quanta* sinking into the mire of fake news that's engulfed so many other pop physics reporting. Are we really entering a post-truth world?

20. **Jack Morava**
December 10, 2019

what John just said.

21. **Peter Woit**
December 10, 2019

Suzanne,
I'm unable to understand why either string theory's problems with predicting anything or general covariance in GR have anything to do with the problems Black women encounter in the physics community. The discussion I've seen of this on Twitter is not encouraging and I'd rather people not engage in it more here.

FB36,
For my take on Farmelo and his claims, I refer you to here
https://www.math.columbia.edu/~woit/wordpress/?p=11012
where I address a similar comment from him in his book with
"As for the last bit, I'll just say that I think it can accurately be described as "sleazy"".

John Baez/Jack Morava,
That was odd, especially, the sub-headline
"By considering simple symmetries, physicists working on the "bootstrap" have rederived the four known forces. "There's just no freedom in the laws of physics," said one."
which is complete nonsense.
I was planning on writing a more substantive blog entry about this, trying to explain what this is about in a non-misleading way. No time today, probably tomorrow…

22. **Boyer Lindquist**
December 10, 2019

Reading the essay "A mathematical mindset" by Matin Durrani from Dec 2019 issue of Physics World, one senses a revisionist history of TQFT as a result of string theory instead of Yang-Mills instantons in late '70s, e.g. the Atiyah–Drinfeld–Hitchin–Manin construction, while hadronic ST was already considered a failure replaced by QCD.

23. **Peter Woit**
December 11, 2019

Boyer Lindquist,

After many attempts, I've given up on trying to get people to look at the actual history of TQFT, and to understand that Witten did not get his Fields Medal for string theory but for something different. For one of my early attempts, see here
https://www.math.columbia.edu/~woit/wordpress/?p=99

Are Physical Laws Inevitable?

December 11, 2019
Categories: This Week's Hype

The last couple days have seen various discussions online generated by a piece at Quanta Magazine with the dubious headline Why the Laws of Physics Are Inevitable and an even worse sub-headline claiming "physicists working on the 'bootstrap' have rederived the four known forces" (this is utter nonsense). For some of this discussion, see Sabine Hossenfelder, John Baez and Will Kinney.

One reason this is getting a lot of attention is that the overall quality of reporting on math and physics at the relatively new Quanta Magazine has been very high, a welcome relief from the often highly dubious reporting at many mainstream science media outlets. The lessons of what happens when the information sources society relies on are polluted with ideologically driven nonsense are all around us, so seeing this happen at a place like Quanta is disturbing. If you want to understand where this current piece of nonsense comes from, there is an ideology-driven source you need to be aware of.

A major line of defense of their subject by string theorists has essentially been the claim that, while it may lack any experimental support, string theory is "the only consistent way to combine quantum theory and general relativity". I've often explained what the problem with this is, won't go on about it again here. Nima Arkani-Hamed is at this point likely the most influential theorist around, for some good reasons. The roots of the problem with the Quanta article lie in taking too seriously the kind of arguments he tends to make in the many talks he gives. He's trying to make as strong as possible a case for the research program he is pursuing, so unfortunately gives all-too-convincingly a very tendentious take on the scientific issues involved. For more about this, see a posting here about the problems with the recent Quanta article that motivated the latest one.

Debates over generalities about whether the "laws of physics are inevitable" are sterile and I don't want to engage in them here, but I thought it would be a good idea to explain what the serious ideas are that Arkani-Hamed and others are trying to refer to when they make dubious statements like "there's just no freedom in the laws of physics". Here's an attempt at outlining this story:

Quantum mechanics and special relativity:

A mathematically precise implication of putting together fundamental ideas about quantum mechanics and special relativity is that the state space of the theory should carry a unitary linear representation (this is the QM part) of the Poincaré group (this is the special relativity part). You also generally assume that the time translation part of the Poincare group action satisfies a "positive energy" condition. To the extent you can identify "elementary particles", these should correspond to irreducible representations. The irreducible unitary representations of the Poincaré group were first understood and classified by Wigner in the late 1930s. My QM textbook has a discussion in chapter 42. If you impose the condition of positive energy and for simplicity consider the case of non-zero mass, you find that the irreducible representations are classified by the mass and spin (which is 0,1/2,1,3/2, etc.). Non-interacting theories are completely determined by the representation theory and exist for all values of the mass and spin.

Extensions of Poincare and the No-go theorem of Coleman-Mandula

To get further constraints on a fundamental theory, one obvious idea is to extend the Poincaré group to something larger. States then should transform according to unitary representations of this larger group, carrying extra structure. Restricting to the Poincaré subgroup, one hopes to get additional constraints on which Poincaré representations can occur (they'll be those that are restrictions of the representations of the larger group). The problem with this is the Coleman-Mandula theorem (1967) which implies that for interacting theories the larger group can only be a product of Poincaré times an internal symmetry group. Representations will just be products of the Poincaré group representations and representations of the internal group, with space-time symmetries and internal symmetries having nothing to do with each other. This is why the Quanta headline about "rederiving the four known forces" is nonsense: the three non-gravitational forces are determined by internal symmetries, have nothing to do with what the Quanta article is describing, work on space-time symmetries.

One way to avoid the Coleman-Mandula theorem is to work with not Lie algebras but Lie superalgebras. Here you do get a non-trivial extension of the Poincaré group and a prediction that Poincaré representations should occur in specific supermultiplets. The problem is that there is no evidence for such supermultiplets.

Another possible extension of the Poincaré group is the conformal group. Here the problem is that the new symmetry implications are too strong, they rule out the massive Poincaré group representations that we know exist. One can work with the conformal group if one sticks to massless particles, and this is what the methods advertised in the Quanta article do.

The idea that our fundamental space-time symmetry group is the conformal group is mathematically an extremely attractive one, with the twistor picture of space-time playing a natural role in this context. I strongly suspect that any future truly unified theory will somehow exploit this. Unfortunately, as far as I know, no one has yet come up with a way of exploiting this symmetry consistent with what we know about elementary particles. Likely a really good new deep idea is missing.

Quantum field theory

To get stronger constraints than the ones coming from Poincaré symmetry, one needs to decide how one is going to introduce interactions. One way to go is quantum field theory, with a principle of locality of interactions. This gets encoded in a condition of (anti)commutativity of the fields at space-like separations, which then implies various analyticity properties of correlation functions and scattering amplitudes. The analyticity properties can then be used to prove things like the CPT theorem and the spin-statistics theorem, which provide some new constraints.

Given a method of constructing a Poincaré invariant quantum field theory, typically done by choosing a set of classical fields and a Lagrangian, one can try and realize the various possible Poincaré group representations as interacting theories. What one finds is that, for spins greater than two one runs into various seemingly intractable problems with the construction. One also finds exceptionally beautiful theories in the spin 1/2 and spin 1 cases that exhibit an infinite dimensional group of gauge symmetries. An example of these is the Standard Model. Unfortunately, we know of no principle or symmetry that would provide a constraint that picks out the Standard Model. If we did, we might be tempted to announce that the principle or symmetry is "inevitable" and thus the "laws of physics are inevitable". We're not there yet…

Amplitudes and the S-matrix philosophy

In the S-matrix philosophy one takes the analyticity properties as fundamental, working with amplitudes, not local quantum fields. The 1960s version of this program (also often called the "bootstrap" program) was based on the hope that certain physically plausible analyticity assumptions would so tightly constrain the theory of strong interactions that it was essentially uniquely determined. This didn't work out. In his recent introductory lecture for his course at Harvard, Arkani-Hamed explains why. The research program he and others are currently pursuing is in some sense a modernized version of the failed 60s program. The hope is that new structures in amplitudes can be found that will replace the structures one gets from local quantum fields.

Amplitudes based arguments about, for instance, why you don't see fundamental higher-spin states, and why spin 1/2 particles have forces of the kind given by gauge theory have a long history, see for instance work on massless particles by Weinberg in the mid-sixties and Weinberg-Witten in 1980.

As far as I can tell, the work referred to in the Quanta article gives new amplitudes-based arguments of this kind for massless particles, exploiting conformal symmetry. It's not clear to me exactly what's new here as opposed to earlier such arguments, or how strong an argument about real world physics one can make using these new ideas. One thing that is clear though is that the Quanta quote that what has been discovered implies that "There's just no freedom in the laws of physics" is as much nonsense as the "we rederived the four known forces" business.

Update: For some discussion with the author of the Quanta piece, Natalie Wolchover, see the comments starting here.

Update: The Quanta article has been revised, see comments in the comment section here. There Daniel Baumann provides a link to a popular summary of the facts about massless particle interactions that his quotes were about.

Comments

1. **Akhil**
   December 11, 2019

   What are those "good reasons" that Nima Arkani-hamed is the most influential theorist around? And what are your thoughts on his amplituhedron approach?

2. **Low Math, Meekly Interacting**
   December 11, 2019

   Thanks for this. I'm sorry you and a few others had to make the effort, needed as it was. I found that article in particular quite a letdown.

3. **Peter Woit**
   December 11, 2019

   Akhil,
   He has shown excellent taste in moving out of his roots in SUSY phenomenology and instead into mathematical physics. As far as topics in mathematical physics go, looking at amplitudes in twistor space seems like a good thing to be trying. He's clearly smart and hard-working, an inspiration to many.

   Another "good reason" that I had in mind was that he's an extremely energetic and compelling speaker, but while this is an important "reason", maybe it's not a "good" reason, in the sense of good for the understanding of science.

   About the amplituhedron, the hype campaign back in 2013 and the "Jewel at the heart of physics" business in Quanta at the time was a bit disturbing. It was however so over the top that I thought most people didn't take it seriously (evidence for this was Scott Aaronson's blogging about the "diaperhedron"). As a piece of mathematical physics, my reaction to it then was like my reaction to a lot of things: "I don't have time to sit down and figure out precisely what this is and what it does, so I'll just wait a few years and see what happens. Either it will genuinely be a huge advance and after things settle down there will be lots of nice places to easily learn the details, or it won't turn out to be that much, and I'll have saved a lot of time." Six years on, this seems to have been a good choice…

   More generally, I've been following Arkani-Hamed's claims that this research on amplitudes is going to replace space-time for over a decade now. At first I was impressed, but over the years it has become clear that there's a massive gap between what he actually has and the claims he likes to start his talks with, a gap which shows no signs of narrowing. He often makes very clear that he himself recognizes that what he's doing is trying to puff up his own interest in the subject in order to keep going.

   I really wish he and Baumann would start acting responsibly and stop the hype campaign, or at least stick to only getting it in places like New Scientist.

4. **Workerpleb**
   December 11, 2019

   I get the sense that articles like this are motivated in large part by research funding pressures.

5. **Peter Woit**
   December 11, 2019

   Workerpleb,
   I don't know about Baumann, but Arkani-Hamed definitely doesn't need the money. He has a $3 million prize, and a very highly paid position to do full-time research. Actually, in many of his talks he explains clearly the motivation for the hype: it's to motivate himself. Not easy to get up in the morning and do hard, tedious calculations telling yourself "if I work hard I'll find the value of the 3rd loop term in this scattering amplitude". A lot more effective motivation to tell yourself and everyone else you're doing this because it's going to kill off space and time and revolutionize physics. The problem is that others start believing you…

6. **Boyer Lindquist**
   December 11, 2019

   That Quanta article is also misleading from a historical perspective. There one reads: "As the Nobel Prize winner Steven Weinberg showed in 1964, the existence of a spin-2 particle leads inevitably to general relativity." It's true that Weinberg did this, but he wasn't the pioneer as the Quanta article seems to imply, e.g., Pauli & Fierz or even Feynman worked on the matter some time before.

7. **Akhil**
   December 12, 2019

   Peter,
   As you said Nima is clearly smart and hard-working, an inspiration to many (including myself) but your response makes a lot more sense. I wonder what will be a more productive/sensible way to motivate yourself than making over-the-top claims (as Nima admits)? How do others like Weinberg, Witten, Atiyah motivate themselves? What about pure mathematicians in general, their work is not immediately connected to physical world, forget about replacing space-time. What do they wake up saying themselves? Your thoughts Peter?

8. **DB**
   December 12, 2019

   Peter,
   thanks a lot for your comments and for answering Akhil question. I was going to ask the same.
   Arkani-Hamed is a very smart and hard working individual, no doubt about that.
   But I've got the feeling that he knows that the HEP theoretical world has found a brick wall at a dead end street.
   It was either Sabine or you who already mentioned that there were suspicions about that.
   The question is why doesn't he say so. Not sure if it's related to money, ego or professional position… or another option I can't think of. He already has enough money to live as you say, he doesn't show too much ego (at least in public appearances), and his position in the teaching sphere is totally assured, so…
   what's left?
   I think that what he's doing, imagining it would come to a successful end, is just solving technicalities, not anything that could revolutionize theoretical physics or bring in new ideas/theories, like the substitution of space/time with something else.

He was even asked once by David Gross if he thought that "God" spoke in the language of polytopes, to which he obviously answered "No".
What he's doing is not a waste of time by any standard, but something far, very far away from what he pretends to sell at his conferences.
Which is something that leaves me thinking about some ethical aspects of the whole thing.
Anyway, the key of this all is, as you say, that people believe in this kind of things.
When the amplituhedron idea came out, even Witten was very excited about it.

https://www.quantamagazine.org/physicists-discover-geometry-underlying-particle-physics-20130917/

But as time has gone by, it's clear that it is an amazing new way to calculate amplitudes
(and Nima deserves great compliments for that), but it ain't any physics revolution at all by any standard of the imagination.

I just wonder when everyone in that world will acknowledge that they're totally stuck, and that they have to go back to the blackboard, rewind two decades, and start re-thinking about all these stuff with a totally new and honest mentality.

9. **Suomynona**
December 12, 2019

Boyer Lindquist,
I believe Weinberg's achievement was showing that any QFT of a spin-2 particle must couple to all forms of matter equally, and is essentially the particle manifestation of the equivalence principle. The prior work of Fierz, Pauli, Feynman, et al., did not show such a robust intimate connection between the two concepts.

10. **Warren Siegel**
December 12, 2019

The problem with all the twistor stuff is that it's all on shell. You need that for conformal invariance. But massless on-shell loop amplitudes are infrared divergent. Any regularization (dimensional or massive or off-shell) destroys the conformal invariance. So these guys write the explicit integrands for amplitudes, but can't integrate them.

A related problem is that "on-shell states only" means there's no obvious way to introduce the iε prescription of Stückelberg-Feynman propagators, except for trees, where you can just stick them in by hand for the poles. So you get integrals where you don't know which contour to choose around the singularities.

11. **Peter Woit**
December 12, 2019

Akhil/DB,
Mathematicians can also be motivated by wanting to solve great problems. Andrew Wiles I think has said he was motivated to go into number theory by the Fermat problem, and possibly this had some influence on research directions he chose. Once he actually had a serious idea about how to solve the problem, he wasn't about to talk about it publicly.

The culture of mathematics is less tolerant of people making vague, unsupported and grandiose claims. But even in physics, behavior like that of Arkani-Hamed is quite unusual. While lots of people may be motivated by hoping to find a new way of thinking about space and time, they don't normally spend long parts of their talks going on about this. Also odd is the way he goes on about "this is the most exciting time ever to do this kind of theoretical physics". I don't doubt for a minute that he believes what he is saying, but it's not very credible, and I suspect most experts listening to him are well aware of this.

It seems likely that the current amplitudes program suffers from the same problem as the sixties version: by giving up local quantum fields and gauge symmetry you're giving up too much fundamental structure. You never were going to understand the strong interactions that way, just as I suspect you're never going to understand quantum gravity without some new fundamental idea about the symmetries of short-distance space-time degrees of freedom. One promising thing about the amplitudes program is the use of twistors and conformal symmetry. On the other hand, I don't see polytopes as a promising fundamental idea. But who knows, advances are made by those who believe in them, maybe something will come of this and it's great that some are pursuing these ideas.

12. **Boyer Lindquist**
December 12, 2019

Suomynona,
Thanks for the reply. I agree that Weinberg's approach was much clearer. But I would like to note an interesting paper on this subject, published by W. Thirring, "An alternative approach to the theory of gravitation," Annals of Physics (1961), where he also gave a field-theoretic approach to GR and concluded: "Regarding the two cornerstones of general relativity's the field theoretic approach (1) gives the equivalence principle as a result and not as a postulate (2) it replaces the general covariance principle by gauge invariance (…)".

13. **Peter Woit**
December 12, 2019

Warren Siegel,

Thanks! It's very helpful to hear not just about the positive hopes for ideas, but also about the main problems they face.

14. **Suomynona**
December 12, 2019

Boyer Lindquist,
Weinberg actually cites Thirring's paper in a related 1965 paper (PR 138 B988), and has this to say about it:

> In criticism of these articles we may say first that they generally seem to be based on specific Lagrangians, and secondly, that there does not seem to be much point in defining the spin of a field without being able to tie the definition to the physically relevant representations of the inhomogeneous Lorentz group, i.e., the one-particle states. In our work everything rests on the known transformation properties of the operators which destroy and create physical particles, and of course we make no use of the Lagrangian formalism.

Weinberg's approach in his 1964 paper (PR 135 B1049) still appears more general than Thirring's and is rooted in a quantum context (the S-matrix), whereas Thirring appears to start from classical considerations.

15. **4gravitons**
December 12, 2019

For what it's worth, I'm fairly certain none of the results the Quanta article describes invoke conformal symmetry. Aside from the mention of Nima's work on cosmological correlators with Baumann, Lee, and Pimentel, the article looks like it's mostly talking about Laurentiu Rodina's work. You can look at the conditions he imposes, they don't typically involve conformal symmetry in any crucial way (except in that they involve on-shell massless particles and thus spinor-helicity formalism, so if that's all you meant I apologize for misunderstanding you).

I agree that the headline and a lot of the language in the article is overblown, these people aren't deriving the SM gauge group or anything like that. All they're doing is looking at what sets of minimal conditions can be enough to fix tree-level amplitudes in various theories. What's interesting is that these conditions can be quite light: often a few constraints from UV behavior or soft theorems are enough to specify a class of amplitudes without invoking, for example, unitarity.

16. **Peter Woit**
December 12, 2019

4gravitons,
Thanks. I had assumed the reference to
https://arxiv.org/abs/1811.00024
indicated that the methods of that paper which used conformal symmetry were involved.

If that's not the case I'm even more mystified by the motivation for this article. The only reference to Rodina's work is to the more than 5 year old
https://journals.aps.org/prd/abstract/10.1103/PhysRevD.90.084048
which is described as an update of Weinberg. Rodina does seem to have very new results of this sort, e.g.
https://arxiv.org/abs/1910.12850
but those don't seem to be mentioned.

17. **4gravitons**
December 13, 2019

I suspect Nima was her primary contact. That would explain why she only asked Rodina about his older work with Nima, why she threw in the cosmological correlator story (which is kind of about the same thing, but a bit distant), and why she didn't mention related work by other amplitudes people like Rutger Boels. I don't think it was intended to be an article about any specific work so much as the general theme, but it is weakened a lot by not including more of the history and background. (Which by the way, your post is a good treatment of! The world needs more explainer posts!)

For what it's worth Warren's point isn't really applicable to any of the work referred to here, since it's a) all tree level and b) the one that uses conformal symmetry is for correlators and thus off-shell. It's potentially a valid criticism to the amplituhedron story but that's not really the topic at hand.

18. **Natalie Wolchover**
December 13, 2019

Peter,
The headline, I grant you, is overblown. Writers don't get to choose headlines. But as for the article, some people seem to be reading into it things it never says and ignoring things it does say. I would wager that these readers know too much for this article, and don't have a sense of what lay readers know and don't know. This article is for them — for people who have no clue about the scheme that nature's building blocks fit into, people who think "photons" and "gluons" are like animals you might come across in a zoo that can look and act any possible way. There is an astonishing aspect to fundamental physics that these folks are missing out on, and excuse me for daring to try to explain it to them.

The article does not say that this is the only possible way the universe could be; in fact, it discusses some of the instances where the universe has "creative license," as I put it — e.g. with massive spin-½ particles and spin-0 particles, where there are very few constraints. But in other instances, the options are incredibly constrained — so much more than most people appreciate. So rather than getting upset thinking I'm making some kind of anti-empirical claim, maybe just step back and try to remind yourself how interesting it is — how amazing it must have seemed to you when you learned about it in grad school — that a massless spin-2 particle must uniquely be the graviton. That the spin possibilities are so limited. Etcetera. The person on the street doesn't know about these things, and it's worth telling them.

If you're interested, the references that I was most often pointed to (aside from the classic Weinberg paper) are:
Benincasa and Cachazo (2008) https://arxiv.org/abs/0705.4305
Schuster and Toro (2008) http://arxiv.org/abs/0811.3207
McGady and Rodina (2014) http://arxiv.org/abs/1311.2938
Best,
Natalie

19. **Peter Woit**
December 13, 2019

Natalie,

I don't at all have a problem with the way you were trying to explain remarkable facts about constraints on theories of massless particles. This is a really tricky business and note that in my own attempt here to write something, even for a more sophisticated audience, I basically gave up. I was hoping to say more than what's in the next to last paragraph, but after thinking about it for a while decided it was just too hard to say something both true and insightful about this topic, even assuming a lot of background.

I also don't have a problem with the "are the laws of physics inevitable?" framing or the headline of your piece. I used this kind of title for what I wrote also, to get attention and be provocative (seems to have worked, this posting is getting more attention than usual). Sabine Hossenfelder makes the obvious accurate counter-argument about what is wrong with this, but it remains true that it's remarkable what you can say based on a couple deep ideas and consistency, without even looking at the real world.

The huge problem here is the sub-headline. It's just completely wrong, basically everything about it. And probably an order of magnitude more people are going to read it than read the whole piece. Over the years I've seen this time and time again in science journalism: pretty good article, which goes up to the line of being wrong, to make a point, but doesn't cross it. Whoever writes headlines thinks it's their job to jazz things up and get attention, so they happily cross the line and write something completely wrong. I don't know what happened here or what Quanta's procedures are, but it would be a good idea to think through whether you can do better than others and avoid this kind of thing.

Honestly, if this sub-headline had appeared on an article a most other places I would probably have just ignored it, figured it best to not give it more attention. A lot of the complaints you're getting here are due to the fact that people have a very high opinion of your work and that of others at Quanta. Keep up the good work, but think about whether you can do better with the headlines/sub-headlines!

Peter

20. **Squarkino**

December 14, 2019

In https://arxiv.org/abs/1709.04891 , Arkani-Hamed spoke of ‘deriving string theory’ from first principles. How much progress has been made on that front?

21. **Peter Woit**
December 14, 2019

Squarkino,
While the idea of “deriving” string theory from some constraints on amplitudes sometimes gets mentioned, that doesn’t seem to actually have anything to do with the work you link to or other recent amplitudes work discussed in Quanta articles. The questions about string theory amplitudes have to do with an infinite tower of massive states and short distance behavior, most of the new amplitudes methods are for theories of massless particles.

It’s remarkable the extent to which currently fashionable research on quantum gravity (for instance Arkani-Hamed’s idea that one can get rid of space and time using things like the amplituhedron or “it from qubit” ideas for emergent gravity) has little or nothing to do with string theory.

22. **Natalie Wolchover**
December 14, 2019

Peter,
Fine, you didn’t like the subhed. It’s hard to summarize these ideas in an appealing sentence. Does that critique really justify calling this piece “ideologically driven nonsense”? Why be so overly critical? If you think this stuff is indeed remarkable and worth explaining, why not say so in your original post — with the caveat that you don’t like the display copy — rather than calling it nonsense and insinuating that I’ve been taken for a ride by ideologues? It’s unkind and untrue, and unfortunately the clarifications in your comment will be seen by virtually no one.
Natalie

23. **Peter Woit**
December 14, 2019

Natalie,

My apologies for not making it clear that I was mostly talking about the subhed. In the main text though, the paragraph which expands the subhed
“Thus, by thinking through the constraints placed on fundamental particle interactions by basic symmetries, physicists can understand the existence of the strong and weak forces that shape atoms, and the forces of electromagnetism and gravity that sculpt the universe at large.”
has the same problem (the bootstrappers have zero to say about internal symmetries and thus the existence of the SM forces). I’ll add something to the end of the posting pointing to our discussion here.

The problem with the subhed (or that paragraph I quoted) isn’t that it’s not to my taste. Note that, the day before I wrote anything, both John Baez and Will Kinney found this so problematic and remarkable that they wrote Twitter threads about it (there was also the more general Sabine Hossenfelder criticism). I think any physicist who knows anything about this subject and read the subhed probably had the same reaction: why is such a nonsensical claim appearing in Quanta, which normally is quite reliable? My posting was an attempt to provide some background for anyone asking themselves that question, in both the positive sense of pointing to important technical results and in the negative sense of pointing to the motivation behind over-the-top claims from theorists.

Apologies also for the overly vociferous tone of some of the posting, which was aimed not at you, but at the theorists involved. I don’t know Baumann at all, but I don’t understand why any theorist would think it was all right to tell the public that he and his colleagues have shown that “There’s just no freedom in the laws of physics that we have.” The field of high energy physics has suffered greatly from overblown claims by theorists. After 35 years of this, I’m getting both old and testy…

24. **Jack Morava**
December 14, 2019

In general I am a fan of Natalie Wolchover’s work but I think it’s unfair to describe Peter’s remarks as overly critical. Extraordinary claims deserve extraordinary evidence, and one would like to believe that `there is some inevitability of the laws of physics that can be summarized by a short handful of principles that then lead to building blocks that then build up the macroscopic world’. In that case, though, it would be nice to see that short handful of principles.

25. **Jackiw Teitelboim**
December 14, 2019

Dear Natalie,

I believe your article succeeds well in explaining the notion of a particle’s spin in a quite accessible way, and its role in determining their possible interactions. It’s not quite easy to explain these things to lay-readers, and sometimes even to our students!

About what people called “hype,” given that lay-readers will always be impressed with quotations from Einstein, a possibility instead of stating ambitious nonetheless unsubstantiated claims would be to cite remark from Einstein’s Autobiographical Notes, particularly the last sentence (but I copy the whole paragraph for completeness):

There is something else that I have learned from the theory of gravitation: No collection of empirical facts, however comprehensive, can ever lead to the setting up of such complicated equations. A theory can be tested by experience, but there is no way from experience to the formulation of a theory. Equations of such complexity as are the equations of the gravitational field can be found only through the discovery of a logically simple mathematical condition which determines the equations completely or (at least) almost completely. Once one has those sufficiently strong formal conditions, one requires only little knowledge of facts for the setting up of a theory; in the case of the equations of gravitation it is the four-dimensionality and the symmetric tensor as expression for the structure of space which, together with the invariance concerning the continuous transformation-group, determine the equation almost completely.
—A. Einstein (Autobiographical Notes, 1949)

Interesting to note that, as you last article at Quanta says that “Einstein arrived at general relativity through abstract thoughts about falling elevators and warped space and time,” you see that Einstein himself in his later life understood quite well how the symmetries of the theory – “continuous transformation-group” – plays a fundamental role.

26. **bertie**
December 15, 2019

I feel quite sorry for scientific journalists covering HEP, after all, what is there to write about that is ‘news’, peraps a little adventurism with headings is forgivable?

27. **Peter Woit**
December 15, 2019

Jackiw Teitelboim,
What the Einstein quote is referring to (diffeomorphism invariance) and what the amplitudes papers that Natalie Wolchover links to are doing (adding constraints from locality and unitarity to the usual Poincaré group action constraints) are two completely different things. One of the main motivations of the whole amplitudes program is to formulate the theory in a way that gets rid of the action of local symmetries. I recall that in one talk Arkani-Hamed described gauge symmetries with the technical term "crap". The argument is that local field theory with an infinite-dimensional group of local symmetries is a bad starting point, since it introduces a huge amount of redundancy in the description of nature.

This is also part of my objection to the text I quoted from the Quanta piece, which seems to imply that what's different about the work she is discussing involves "the constraints placed on fundamental particle interactions by basic symmetries", which is kind of backwards.

28. **DrDave**
December 15, 2019

Natalie, I guess as an editor I would simply correct the highly visible line at the top (with a correction note) "physicists working on the "bootstrap" have rederived the four known forces" as it isn't true. One can argue about the imaginary layperson, and attention grabbing headlines, and so on, one can fob it off on the editor. But, at the end of the day, it isn't true and it has your name on it. So that's a really good reason, as a journalist, to correct it. One of the jobs of a journalist is to fix stuff like this. If you don't, it implies that you have seen the evidence that it is not true and don't agree with it somehow.

29. **John Baez**
December 15, 2019

It's pretty strange that the title and subhead of an article – the only parts most people actually read – should be left to crazed hypesters unrestrained by sense of honesty. Imagine that the *New York Times* had that policy. Would anyone take it seriously?

But it's not just that the title and subheading are completely wrong. The quotes of Daniel Baumann in the article are also misleading and make grandiose claims that he did not intend.

On Twitter I wrote:

> There's an absolutely wild quote by Daniel Baumann: "There's just no freedom in the laws of physics that we have." If he's shown this, then he's solved all the biggest questions in fundamental physics and he deserves the next 20 Nobel Prizes. But he hasn't.

Daniel Baumann replied:

> I agree its very unfortunate. I spoke in a precise context: that the long-distance interactions of a massless spin-2 particle are those of GR. Everything here is in the context of massless particles. As you said, this is old stuff. I didn't not mean to imply more. I was just explaining the technical arguments. Didn't mean to hype anything. Apologies.

I replied:

> Didn't Natalie read you your quotes? When I've been interviewed for *Quanta* articles they've been pretty good at doing that, which allowed me to fix things. They even had a "fact-checker" for this purpose.
>
> Whoever writes the headlines, however, seems beyond supervision.

Daniel Baumann replied:

> No, not this time. Until this morning, I didn't even know the post had appeared.

I told him (and everyone) to be very careful when talking to reporters. They often take the most grandiose, wacky thing you say and quote it out of context to make their article more exciting. Something that makes sense in the midst of a longer conversation can make you look like an absolute idiot when taken by itself.

Daniel Baumann does *not* believe that "There's just no freedom in the laws of physics that we have."

30. **Peter Woit**
December 15, 2019

John Baez,
Thanks. This is odd though. In my experience Wolchover is one of the more careful science journalists around, and the problem here is not just the headline. Also in my experience, the reason bogus claims about fundamental theory get into popular articles is that theorists are all too willing to drop caveats and mix together their hopes for their work with what they actually have.

Does Baumann also disavow the longer quote from the end of the article:

"It's "just aesthetically pleasing," Baumann said, "that the laws are inevitable — that there is some inevitability of the laws of physics that can be summarized by a short handful of principles that then lead to building blocks that then build up the macroscopic world."

Other examples of this kind of misleading language can be found, see for instance the webpage for a recent Simons Foundation conference (Arkani-Hamed and Baumann two of the organizers)
https://www.simonsfoundation.org/event/amplitudes-meet-cosmology-2019/
which tells us
"the laws of physics are a nearly inevitable consequence of quantum mechanics and special relativity. Nowhere is this seen more clearly than in the invariant observables associated with scattering amplitudes in asymptotically flat space."
You can find lots of Arkani-Hamed talks that very much seem to be saying that QM + special relativity inevitably give something like the Standard Model, as one random example, watch this IAS public talk:
https://video.ias.edu/arkani-hamed-lecture-10-12

31. **JE**
December 15, 2019

Sorry, Peter, if this sounds presumptuous. Although I think you are making a good point and I very much agree with what you wrote re Quanta's article, the whole discussion sounds a little bit over the top, especially after reading John's comment above. IMHO, as other commenters have suggested, this article and the issues it raises with the title, subheading, etc. may just reflect the precarious state of HEP and the lack of good stories to write about in the HEP field.

32. **Peter Woit**
December 15, 2019

JE,
One point of view on why HEP is in a precarious state would be because of the damage caused by 35 years of misleading hype. From that point of view, trying to stop more of it might not be over the top…

33. **John Baez**
December 16, 2019

Baumann didn't explicitly "disavow" other quotes from his article, but I'm not in the business of extracting disavowals.

I agree that Natalie Wolchover is one of the best physics reporters out there. I wouldn't have bothered talking about this otherwise.

My goal is not to rake anyone over the coals. But I did want to make a bit of a stink. I think it's the duty of all scientists to push back against nonsense.

34. **Natalie Wolchover**
December 16, 2019

Hi Peter (and John and others),
We've changed the wording of the subhead and another sentence in the blog post and added a correction note at the bottom explaining the changes.

As for Daniel Baumann, first I'll just say that he and other bootstrappers are careful and conservative; in fact that's kind of their whole thing! From a journalistic point of view, the quote that has so bothered some of you is a great quote. It's passionate and reveals his feeling of being highly constrained by the rules, a la Mel Gibson as William Wallace yelling "FREEDOM!" It's an exaggerated statement to which it is indeed possible to say, "Well, technically, not NO freedom…" The article tries to explain some of these technicalities. I've apologized to Daniel for causing him some grief over the quote.

Thanks for keeping us on our toes, thanks for the apology, and I apologize to you all as well for not vetting the display copy well enough.

Natalie

35. **Daniel Baumann**
December 16, 2019

Dear Peter et al.,

I have never commented on a blog before, but since my words seem to be misinterpreted, maybe it would be helpful if I clarify the context of my remarks.

Natalie asked me to explain the following two papers:

Benincasa and Cachazo (2008) https://arxiv.org/abs/0705.4305
McGady and Rodina (2014) http://arxiv.org/abs/1311.2938

I was happy to do so, since I like these papers a lot and was impressed that Natalie would attempt to describe such a complex subject. My short (popular) summary of the papers can be found here:
https://www.dropbox.com/s/50tvt2odrlgwkgc/Quanta.pdf?dl=0

As you can see, it is only about massless particles and long-range forces. Everything I said in the article is in that context. In fact, we spoke for a long time and it was mostly a technical discussion on the details of these papers.
That locality and unitarity fixes the long-distance interactions of massless spin-1 and spin-2 particles to be those of YM theory and GR is a beautiful fact that I tried my best to explain.

Best,
Daniel

36. **Peter Woit**
December 16, 2019

Hi Natalie and Daniel,

Thanks a lot for the clarifications, that's great! I've added a note about this at the end of the posting.

Peter

37. **Low Math, Meekly Interacting**
December 18, 2019

I think I've witnessed something remarkable and encouraging happening here, and I thank all involved for finding a constructive conclusion.

Natalie: I generally am very happy with Quanta's reporting on physics and mathematics, and consider your work to be a standout in the field of popular science reporting. Any disappointment comes from the fact that you and your colleagues have made it worth it to even care. I am grateful for that, and also wish to add my encouragement. Please do keep up the good work. A quick perusal of the "industry standard" of online pop-sci content make it clear how sorely it's needed.

38. **DK**
December 19, 2019

Just a suggestion: For all the blog postings, perhaps the "Updates" can be added at the very top rather than at the bottom, appropriately delineated? Will improve readability.

39. **tulpoeid**
December 21, 2019

I am afraid I will act kind of like a party spoiler. I hesitated doing so but I keep thinking that the view of those who don't enjoy Quanta magazine could be a useful addition here.

So, being a physicist, a researcher, and a reader of popular science press, a few months into reading Quanta articles I had to firmly decide that I stop doing so (the couple of times I went back reaffirmed my decision). I find them too long and too imbalanced – they are trying to both water down the subject and speak to quasi-experts at the same time, missing the objective of having a clear target group. In the best cases, I couldn't get any new knowledge on the promised topic because it is either buried in a deep and convoluted way or it wasn't really there to begin with. This is probably a result of heavy editting and of very specific guidelines, and I say so because even Hossenfelder's clear writing becomes Quanta-ized over there.

In the worst cases, it is sheer propaganda. I realize that steps were taken thanks to this post and the discussion under it. But at the same time I wonder how good, or at least how objective, it is to congratulate Wolchover. As far as I can tell her articles have consistently been eulogies of fake physics for a few years now and in the end it will always be "I was only covering". I don't know whether she is one of the top science journalists right now, but I am almost sure that she has contributed to building the inaccurate picture that the public mistakes for proven physics facts lately.

To wrap up, correcting one's article is certainly commentable. But I can't help thinking that it is an integral part of journalistic work. Again, I am aware that all this will probably sound a bit off, however the urge to bring into discussion the fact that not every HEPer looks up to Quanta has been surging in me for ten days now…

40. **Peter Woit**
December 21, 2019

tulpoeid,
First of all, I think you need to compare what Quanta is doing to what other outlets for science journalism (such as Scientific American) are doing, and I think they come off very well in that comparison.
Secondly, covering HEP theory has very special problems. The material is difficult for even experts to understand, and if journalists try and deal with this by consulting the most prominent people in the field, they have a thorny thicket of BS to try to find their way through. I don't think you can blame the results on the journalists. As a point of comparison, consider Physics Today, which is the house organ of the US physics community. The main person over the years they have turned to for coverage of HEP BSM physics has been Gordon Kane (no less than three articles from him). So, it could be much worse…

41. **Severin Pappadeux**
December 23, 2019

My first read on spin-2 particle leading inevitably to general relativity was from Feynman Lectures on Gravitation, given at Caltech 1962

42. **Cosmin**
December 27, 2019

You are actually talking about a very old dilemma: who is to blame, the physicists or the editors/gatekeepers. Now everyone wants to be in the active physicists field (99%) but very few (read almost nobody – 1%) wants to do the editing/gatekeeping work, for various reasons. The result is that strânge ideas get a pass simply because nobody is there to stop them. Everyone wants to play but nobody wants to be the referee.

43. **Peter Woit**
December 27, 2019

Cosmin,

The problem of gate-keeping/refereeing within the physics community is a different one than the problem here, which is that of gate-keeping between the public and theorists with an idea to promote. This is what journalists have to do, and in my experience they're enthusiastic and willing to work hard at it to try and get it right. But, especially for highly technical theoretical work (a good example would be no-go theorems, where the issue of the significance of various technical assumptions is at the center of the problem) there's no way they can evaluate the significance of the work themselves. They have to rely on the self-control of the theorists themselves, their willingness to be careful and not overstate their case, as well as the willingness of their colleagues to take them to task when they go too far.

44. **Sebastian Thaler**
December 31, 2019

Frank Wilczek on Twitter today: "It's time to concede that this was not, alas, the decade of supersymmetry. Hope springs eternal, but the terms of bets are finite … I've got two to pay off."

45. **Peter Woit**
December 31, 2019

Sebastian Thaler,

I did see that, at
https://twitter.com/FrankWilczek/status/1211973691644489728

The remarkable thing about all those who have lost SUSY bets is that I've never seen any of them draw the conclusion that there is something wrong with the idea. Wilczek's loss of a bet on SUSY leads him to conclude "this was not, alas, the decade of supersymmetry", but that "hope springs eternal".

London Calling with Career Opportunities

January 2, 2020
Categories: Uncategorized

At some point within the past couple years I noticed that one blog that had Not Even Wrong on its blogroll was the blog of Dominic Cummings, who was often getting credited with masterminding the political campaign that got the British to vote (narrowly) for Brexit in 2016. Cummings has had further success recently as Chief Special Adviser to British Prime Minister Boris Johnson, with a blow-out election victory three weeks ago putting him securely in control of the British state.

Today on his blog Cummings has, invoking Grothendieck, posted a job advertisement: ‘Two hands are a lot’ — we’re hiring data scientists, project managers, policy experts, assorted weirdos…. He’s looking for mathematicians, physicists and others to join him to change British society, working

> in the intersection of:
>
> - the selection, education and training of people for high performance
> - the frontiers of the science of prediction
> - data science, AI and cognitive technologies (e.g Seeing Rooms, ‘authoring tools designed for arguing from evidence’, Tetlock/IARPA prediction tournaments that could easily be extended to consider ‘clusters’ of issues around themes like Brexit to improve policy and project management)
> - communication (e.g Cialdini)
> - decision-making institutions at the apex of government.

For some other descriptions of who Cummings would like to hire, on the economics side there’s:

> The ideal candidate might, for example, have a degree in maths and economics, worked at the LHC in one summer, worked with a quant fund another summer, and written software for a YC startup in a third summer!
>
> We’ve found one of these but want at least one more.

He also wants “Super-talented weirdos”, with examples given from William Gibson novels, such as “that Chinese-Cuban free runner from a crime family hired by the KGB.”

The remarkable things to me about this long document are what it doesn’t contain. In particular I see nothing at all about any specific policy goals. Usually a new government would recruit people by appealing to their desire to make the world a better place in some specific way, but there’s nothing about that here. The goal is to control the government and what the British population believes, but to what end?

In addition, a more conventional hiring process would be asking for candidates of high ethical values, with some devotion to telling the truth. Cummings seems to be asking for exactly the opposite: best if your background is “from a crime family hired by the KGB.”

Best of wishes to my British readers, now joining the US and other nations in a new dystopic post-truth era. It’s massively depressing to me to see how this has worked out here, I hope you do better. Maybe you should be sending in your applications to Cummings and hoping to sign up for a role in the new power structure. If so, tell him “Not Even Wrong” sent you…

Update: For more on Cummings, there’s a good Financial Times article.

Comments

1. **chorasimilarity**
   January 2, 2020

   Seems like he wants to form a team like the one tasked with the detonation of the bridge over the river Kwai. Strange enough that the wikipedia page [1] does not say a word about this team, although the main part of the book is about the culture war between those who want to destroy the bridge and those who want to build it as an example for the primitives.

   [1] https://en.wikipedia.org/wiki/The_Bridge_over_the_River_Kwai

2. **Peter Woit**
   January 2, 2020

   chorasimilarity,
   Demolition is definitely on the agenda for Cummings. The main target to be demolished is likely those aspects of the “establishment” that stand in the way of total control. Here in the US we’ve seen how this works, as the Republican party and mass media (Fox) have been forced into submission to the Trump personality cult. In the case of Trump what has become clear is that he has no interests beyond narcissistic ones. Cummings/Johnson seem to want to destroy the establishment and take total power, with no more of an idea than Trump of what to do with this power, other than to gloat at the defeat of their enemies.

   Comments encouraged from those in Britain who know much more about this than I do, discouraged from those who want to discuss something other than exactly what Cummings is up to.

3. **Bill Anderson**
   January 2, 2020

   You make some very good points!

   Cummings carries a lot of power and authority without any direct connection to the electorate. There is an irony as this is one of the EU’s major flaws from the Brexiteers’ perspective. But, of course, this logical consistency doesn’t apply to Dom.

   Unelected, unaccountable and with no apparent remit or brief he is perceived by many to be dangerous. Given Boris J’s history of inattention to detail and erratic judgements there is potential for calamity.

   However, our Civil Service can be less than cooperative and Cummings has not shown long term commitment in his career moves thus far. The next 2-3 years will be difficult because of the complexity and enormity of the Brexit process so I’m hoping he’ll bail!

4. **Peter Woit**
January 2, 2020

By the way, I see that Cummings even commented on the blog once, see here
https://www.math.columbia.edu/~woit/wordpress/?p=755&cpage=1#comment-42623
Unfortunately I had no answer to his question, so didn't respond.

5. **gjz**
January 2, 2020

This is what Cummings was looking for:
https://cms-docdb.cern.ch/cgi-bin/PublicDocDB/ShowDocument?docid=4039

6. **Peter Woit**
January 2, 2020

gjz,
Thanks! I hope he's still reading the blog and can take advantage of that!

7. **René Pannekoek**
January 3, 2020

Just because he does not ask for people who "want to make the world a better place" does not mean he's planning any dystopian nightmares. His advertisement seems to me to be targeted towards people who want to help make the British state function more efficiently and rationally.

It is very easy to declare that you are the kind of person who wants to make the world a better place, and it can be done at zero cost. But among the people who say such corny things are a lot of hypocrites, naive folks, and folks who really do not know themselves all that well. (An example of that last category would be many participants in online mobs who think they are "making the world a better place" by hating on some poor sod who made an inappropriate joke, or who failed to use someone's preferred pronoun.)

Saying you want to make the world a better place does not make it so. Just like not saying it does not mean you are a bad person. Personally, I've really had my fill of all the virtue-signalling out there, and I'll be looking for how a person acts, rather than how a person advertises him- or herself.

8. **tulpoeid**
January 3, 2020

Gibson mentioned in context in a proper physics blog.
I already feel more complete this year.

9. **ArshadM**
January 3, 2020

The problem with the British civil service is that it's perceived as being slow, lethargic and ineffective. I can't recall a single project in the last 2 decades that wasn't grossly over budget or delivered on the original aims.

Don't get me wrong, the entry process into the service is extremely thorough and the people are highly talented. But the career progression in the service means that it's quite easy for people to move around from job to job and not be held to account.

There has been some discussion of an op-ed that Rachel Wolf wrote in the Telegraph (behind a paywall unfortunately), but a summary can be found here – https://www.independent.co.uk/news/uk/politics/dominic-cummings-civil-service-boris-johnson-reform-whitehall-a9267101.html.

Every government seems to try these grandiose types of changes, usually with limited success.

10. **Winston Smith**
January 3, 2020

René,

I read Peter's "desire to make the world a better place" as a synonym for "policy preferences". Most people have policy preferences that align with what they believe will make the world a better place, though there certainly seem to be some striking counterexamples.

You write "and I'll be looking for how a person acts"; I agree, but Peter's point is that the ad gives no indication about what kinds of "acts" will be undertaken. One example (of many possible) might be: do we plan to cut or increase funding to NHS? It is reasonable for an applicant to such a position to have a general idea of the ends to which he or she will be working. As Peter writes, it seems this question is rather explicitly beside the point; the point is simply to have the power, with unclear ends.

You mention "efficiency" which most people favor in the abstract, but only to the extent that it is a euphemism for "more money for people like me and less for everyone else".

11. **Peter Woit**
January 3, 2020

Rene Pannekoek,
I'm no more of a fan of virtue signaling than you are. You're ignoring my main point, which is that Cummings is asking for people to come to work for him and use their talents to gain control of the British state apparatus and manipulate the public, without any indication of what positive outcome he hopes to achieve.

In other times I might react to seeing this by giving him the benefit of the doubt and wishing him well, but we've now been watching this same TV show for several years in the US. We know how it turns out: looting by the already wealthy and powerful, and a new normal of non-stop lying and deception, smashing of democratic institutions and norms, ripping of societies apart, all in the service of keeping in power a narcissistic sociopath. I do hope it goes differently in Britain, but anyone who decides to go work for Cummings should expect that this is likely what they are signing up for.

12. **Allan Greenleaf**
January 3, 2020

Christopher Wylie's recently released book, Mindf*ck, on the rise and fall of Cambridge Analytica (in which Mr. Cummings makes several cameos) is a good cautionary tale on doing value-free data science.

13. **Mark**
    January 3, 2020

    "Just because he does not ask for people who "want to make the world a better place" does not mean he's planning any dystopian nightmares."

    Wasn't he very involved in the data-science scandal with Cambridge Analytica, which was a significant factor in getting people to vote for Brexit which has led to the nightmare the UK is now in? Not sure giving him more smart people is in the countries interests.

14. **Peter Woit**
    January 3, 2020

    René/Mark,
    The problem with Cummings is not that he has a secret plan for a new dystopia, it's that we're now living in one that he has helped create. This is someone who actually wants to live in a William Gibson novel. He has realized his dreams, shows no signs of having any other dreams than enjoying holding the power he always wanted and making sure he keeps it by running a Ministry of Truth staffed by "misfit" data scientists.

15. **Neil**
    January 3, 2020

    Hi Peter
    .
    All very interesting.
    .
    After reading the DC blog and then your own, my first instinct was to be objective in relation to your point about what was left out, and then 'clarified' by you in the comments section:
    .
    "You're ignoring my main point, which is that Cummings is asking for people to come to work for him and use their talents to gain control of the British state apparatus and manipulate the public, without any indication of what positive outcome he hopes to achieve."
    .
    I then thought about which manifesto pledges the Conservative Party was just elected on. Aside from 'Get Brexit Done', here are the top line policy "guarantees":
    .
    https://vote.conservatives.com/our-plan
    .
    For more detail, the full 64 Manifesto is here:
    .
    https://assets-global.website-files.com/5da42e2cae7ebd3f8bde353c/5dda924905da587992a064ba_Conservative%202019%20Manifesto.pdf
    .
    So, if those are the policy directions (positve or negative, depending on who you are), perhaps DC believes these goals cannot be met using the approaches of times gone by.
    .
    I hope this is useful.
    .
    Best from Belfast,
    Neil

16. **Peter Woit**
    January 3, 2020

    Neil,
    There is nothing in what Cummings writes pointing to any of that, for instance nothing about how the skills he's looking for will be used to hire 50,000 more nurses.

    Again, maybe Cummings is just a misunderstood guy intensely devoted to improving the world by hiring more doctors and nurses and investing in education and infrastructure. We'll see, but at this point I see no reason to believe that, and anyone thinking of taking a job with him should be asking him some tough questions. I do hope I'm wrong.

17. **CWJ**
    January 3, 2020

    Unsurprising:

    https://www.theguardian.com/politics/2020/jan/03/dominic-cummings-call-for-no-10-staff-may-break-employment-law

18. **Peter Woit**
    January 3, 2020

    CWJ,
    I don't think the problem with what Cummings is doing is that he's not following conventional hiring rules. Criticism of him for that just helps him, allowing him to pose as a rebel against the hidebound establishment and its rules obstructing progress. The press should instead be trying to find out what he plans to do with the people he's hiring and reporting on that.

19. **Art**
    January 3, 2020

    Per Wikipedia, Robert Cialdini, "the Regents' Professor Emeritus of Psychology and Marketing at Arizona State University", "is best known for his 1984 book on persuasion and marketing, Influence: The Psychology of Persuasion."

20. **Mike Greig**
    January 3, 2020

    Peter

The UK government machinery is very different to the USA's. There is a supposedly independent and impartial civil service which carries out the wishes of whichever Government is in power. In practice it is run by humanities graduates from Oxford or Cambridge universities who are very clever generalists. They have a track record of frustrating the implementation of policies that the electorate voted for.
Below is another quote from Cummings's blog addressing this aspect:
"People in SW1 talk a lot about 'diversity' but they rarely mean 'true cognitive diversity'. They are usually babbling about 'gender identity diversity blah blah'. What SW1 needs is not more drivel about 'identity' and 'diversity' from Oxbridge humanities graduates but more genuine cognitive diversity."
Cummings has a lot of experience of the way the civil service operates. He was special adviser to Michael Gove, the Secretary of State for education from 2010 to 2014. Amongst other policies Gove introduced was Free Schools (somewhat similar to US Charter schools) where I have some personal experience. Dominic Cummings quite famously attributed the quote below to a civil servant in the Department for Education talking to Michael Gove's team in 2014.
'You're a mutant virus, I'm the immune system and its my job to expel you from the organism.'
Whether or not the current civil service intends to operate in quite that way, they are certainly huge defenders of the status quo and opponents of change.

21. **Peter Woit**
January 3, 2020

Mike Greig,
According to Wikipedia, Cummings is a public school/Oxford graduate with a history degree, and "clever generalist" seems to fit him, so he's not adding much diversity on that front.

One thing we've learned here in the US from Trumpism is that the royal road to political success is to stoke resentments, convincing your supporters that the world is full of "enemies" that need to be destroyed. Here these days it's the "Deep State". If your enemies have elite university degrees, so much the better for the resentment thing (to get people to ignore the fact that your own background is the same is where you need a real pro like Cummings).

Every politician everywhere in the world complains about "government bureaucrats", that they're the ones to blame for their inability to fulfill their campaign promises. It looks to me like Cummings is going to war with the British Civil Service not because that's the way to get 50,000 nurses hired, but because when they're not hired, he'll have a good scapegoat to blame it on. Again, I very much hope to be wrong.

22. **uhoh**
January 3, 2020

If you want to get an idea of Cummings's priorities, you might try this talk from 2014:

https://www.youtube.com/watch?v=GNaWPV5l4j4

After watching that and reading his blog a bit, it seems to me that his primary goal is to eliminate the (perceived) dysfunction in the British government and that a necessary first step is to replace all the mandarins with people from math/physics and the private world who know what it means to solve a problem, as he sees it. (Full disclosure, the idea of a technocratic government run by mathematicians has some appeal to my vanity.) Normal policy matters like Brexit and taxes going this way or that seem to be secondary concerns to him.

If this is the case, then it makes perfect sense why he wrote the ad on his web page that way.

23. **Roger Prentice**
January 4, 2020

Why would Cummings use this (already long) blog post to list the government's policy objectives when they had already been stated in the Queen's Speech? Here they are:
https://www.gov.uk/government/speeches/queens-speech-december-2019
It's not very dystopian.

Peter claims that Cummings is "not adding much diversity" because he himself is an Oxbridge graduate with a history degree, but that's the whole point. He's wanting to hire people "smarted than me". He has identified his own limitations and seeks to overcome them by hiring different sorts of people.

I'm actually encouraged by the prospect of bringing some data science into the business of government and policy creation. As an analogy, I think there are currently too many humanities degrees sitting around thinking "it must be the multiverse".

24. **Peter Woit**
January 4, 2020

uhoh/Roger Prentice,

So far what Cummings and others like him have accomplished using AI and data science techniques has been to use them to lie and manipulate the public, wrecking democracy, bringing Trump and others like him to power, and inflicting the Brexit disaster on the British. I'm getting old and curmudgeonly so maybe you shouldn't listen to me, but I've seen a lot that's very disturbing and little good coming out of the the use of AI and data science, especially in the political sphere.

A lot of people on the other hand seem convinced that Cummings is just a modest, well-meaning guy, devoted to good government, which will consist of math and physics phds using data science and AI to hire those 50,000 nurses. I hope they're right.

25. **Patrick**
January 4, 2020

Those were some great Clash songs.

26. **Roger Prentice**
January 5, 2020

Oh, just one more thing, as Columbo might say. Here's a view on (the lack of) data science in government by statistician Graeme Archer:
https://unherd.com/2020/01/why-we-need-weirdos-like-dominic-cummings/

It's worth clicking through just to see the photo of Dominic Cummings looking like, as I read elsewhere "the owner-operator of a dangerous fairground ride arriving at his own negligence trial".

27. **Andrew**
January 5, 2020

Peter,

I fear you're getting the wrong end of the stick here and are too quick to make simplistic comparisons between UK and US politics. Cummings goals are clear and are in my view well intentioned – he wants a more data-driven/scientifically based civil service and to make the UK the global home for education and science. He wrote a 237 page essay on how to improve education here: https://dominiccummings.com/the-odyssean-project-2/ . Its worth reading this from Steve Hsu (a personal friend of Cummings it seems): https://infoproc.blogspot.com/2019/12/now-it-can-be-told-dominic-cummings-and.html

"What does he want? Why is he doing this? Not for money, not for fame. For love of country and human progress and civilization. Dom's dream is to make the UK a global center for science, technology, and education"

P.S with regards brexit, as quick as many are too dismiss it (and for what its worth I voted remain) it may be worth your time hearing David Deutsch explaining his support for it https://www.youtube.com/watch?v=xdtssXITXuE – it is again simple to just view it as "Trumpian", "populist" etc.

28. **Peter Woit**
January 5, 2020

Andrew,
I'm very familiar with Steve Hsu and his (highly Trumpian) views, which I find appalling. That he's close to Cummings seems to me yet another reason to believe that having Cummings anywhere near the levers of power is not going to lead to anything good.

I think I've now given sufficient voice here to the "Dominic Cummings is just a well-meaning, selfless sort who wants to use science to make the world a better place" argument, as well as explaining why I don't believe it, so I'm shutting off comments here. Again, I'll be very happy if I'm wrong.

Musings on the Current Status of HEP

January 4, 2020
Categories: Uncategorized

To start the new decade there's an article very much worth reading by Misha Shifman, entitled Musings on the Current State of HEP. It's somewhat of an update of something he wrote back in 2012, which I wrote about here. He starts off with:

> Now, seven years later, I will risk to offer my musings on the same subject.The seven years that have elapsed since brought new perspectives: the tendencies which were rather foggy at that time became pronounced. My humble musings do not pretend to be more than they are: just a personal opinion of a theoretical physicist… For obvious reasons I will focus mostly on HEP, making a few marginal remarks on related areas. I would say that the most important message we have received is the absence of dramatic or surprising new results. In HEP no significant experimental findings were reported, old ideas concerning Beyond the Standard Model (BSM) physics hit dead-ends one after another and were not replaced by novel ideas. Hopes for key discoveries at the LHC (such as superpartners) which I mentioned in 2012 are fading away. Some may even say that these hopes are already dead. Low energy supersymmetry is ruled out, and gone with it is the concept of naturalness, a basic principle which theorists cherished and followed for decades. Nothing has replaced it so far…
>
> HEP, "my" branch of theoretical physics since the beginning of my career, seems to be shrinking. A change of priorities in HEP in the near future is likely as business as usual is not sustainable. The current time is formative.

I encourage you to take a look at the rest, there's a lot more detailed discussion of the state of HEP and allied fields, especially about the central role of quantum field theory.

Shifman also includes a section very critical of Richard Dawid, the "non-empirical confirmation" business and talks given at the "Why Trust a Theory?" conference (discussed here):

> With all due respect I strongly disagree with Richard Dawid and all supporting speakers at the conference and beyond… I object against applying the term "non-empirically confirmed" to science (the more so, the term "postempiric science"). Of course, we live in liberal times and everybody is entitled to study and discuss whatever he or she wants. But the word science is already taken. Sorry, colleagues. For "postempiric science," please, use another word, for instance, iScience, xScience, or something else.

As for David Gross's attempt to claim that string theory is, like quantum mechanics and quantum field theory, not testable just because it is a framework, not a theory, Shifman is having none of it:

> David Gross is a great theoretical physicist, whose discovery of asymptotic freedom made him immortal, but I respectfully disagree with him. Framework or not, both QM and QFT have absolutely solid confirmations in all their aspects in thousands of experiments.

As for the once popular idea that string theory could provide a "theory of everything", he writes:

> Well… it never happened and – I will risk to say – never will.

Comments

1. **DB**
   January 5, 2020

   Hi Peter,
   happy new year to you and your readers.

   At last, at last one well known theoretical physicist comes out openly and says loud and clear what many already think, but are afraid of saying or writing due to repercussions in their professional lives.
   Yes, string theory is NOT the so much sought after "theory of everything". Susskind has already said it half a dozen times. Arkani-Hamed has semi-implied it. I wonder, and have written on this blog post before, when will all the big guns come out and acknowledge it publicly.
   I guess money and egos are running high there…

2. **Jack Harvey**
   January 5, 2020

   Your web site http://www.math.columbia.edu/~woit/wordpress/ gives a warning which you may want to to eliminate. Using Firefox, Chrome or MS Edge the padlock icon may have a red line through it. It's a security notice which may scare off people from going to your site.
   Jack

3. **Peter Woit**
   January 5, 2020

   Jack Harvey (and anyone interested in why the browsers are giving warnings),
   What's happening is that while the main connection to the blog is SSL encrypted (https), there are lots of scripts and code in WordPress and the plugins being used that use http, not https. Eliminating all of these occurrences would be a lot of effort and not actually solve any significant security problem, so not a high priority right now.

   sort of OT: The Economist surveys collider proposals in "Assembling the future" in its 4 Jan edition.

5. **Alessandro Strumia**
   January 5, 2020

   In fig. 1 Shifman plots particle physics as a dead trunk. Other authors one day earlier wrote that we must "communicate much more convincingly the prospective economical, societal, environmental and cultural impacts of HEP" (arxiv.org/pdf/1912.13466.pdf). Who is right?

6. **Peter Woit**
   January 5, 2020

Art,
Thanks. For others, that story is at
https://www.economist.com/science-and-technology/2020/01/02/finding-new-physics-will-require-a-new-particle-collider
Mostly well-done, but gets a few things wrong:
1. The problem with electron beams is not that less mass means less kinetic energy, but less mass means the synchrotron radiation problem described later is much worse.
2. Introducing superpartners doesn't reduce the number of free parameters of the Standard Model, quite the opposite: it adds many more.

I hadn't heard of opposition by the US to a Chinese collider since US scientists wouldn't be allowed to work on it. As far as I can tell, a US physicist (Arkani-Hamed) is still director of the Chinese institute planning such a machine, see
http://cfhep.ihep.ac.cn/

Alessandro Strumia,

Thanks. The Shifman article is about HEP theory, and there's a good argument that it has now been dead for a while. The other article you link to is about the experimental HEP side, and provides a good update and summary of the problem of a next generation European collider. There the problem I think is not that energy frontier experimental HEP is dead, but that it has a serious medical issue: major organ failure projected for 2035 or so, and a replacement organ will be extremely expensive, unclear how to pay for it. Close family members are saying "not worth keeping it alive, it's a goner anyway, so why should we go into hock to save it, money will be better spent on something else". Thus the line you quote.

The article gives a good summary of the problem:
"major changes will be needed with respect to the present CERN way of programme realisation: exceptional and quite substantial contributions from the host states, significant contributions from non-member states participating in this programme and preferential loans with long-term reimbursement profiles. We assume that this should be possible."

7. **33lewski**
January 7, 2020

Depicting Post Empirical Science as a tiny toxic mushroom next to a great tree of Physics is very accurate. In my view a polypore on a tree would represent the situation slightly more faithfully.

8. **Squarkino**
January 8, 2020

Speaking of CERN funding, did we ever find out which nations didn't pony up the €100 million and why?

9. **Parravicini 2036**
January 11, 2020

Ironically enough, just a few hours after this post, Icecube ruled out the last Standard Model explanation of ANITA's anomalous neutrino events:

https://icecube.wisc.edu/news/view/709

10. **Peter Woit**
January 11, 2020

Parravicini 2036,
Unfortunately I don't think ANITA seeing just two hard to understand signals and ICECUBE seeing nothing adds up to bringing down the Standard Model. About ANITA, Sabine Hossenfelder had some comments here
https://backreaction.blogspot.com/2019/07/science-shrugs.html
The usual "extraordinary claims require extraordinary evidence" principle applies.

11. **Nick M.**
January 11, 2020

Hi Peter,

I just read this article regarding the DoE's approval (this past Thursday) of Brookhaven's proposed Electron-Ion Collider (EIC), and thought that I would share:

https://www.energy.gov/articles/us-department-energy-selects-brookhaven-national-laboratory-host-major-new-nuclear-physics

Also at Science magazine here:

https://www.sciencemag.org/news/2020/01/department-energy-picks-new-york-over-virginia-site-new-particle-collider

12. **Peter Woit**
January 11, 2020

Nick M.,

Thanks. I note that the Science article explains something that is not known to most people:
"The decision on a machine still 10 years away reflects the relative good times for DOE science funding, Dabbar says. "We've been able to start on every major project that's been on the books for years." DOE's science budget is up 31% since 2016—in spite of the fact that under President Donald Trump, the White House has tried to slash it every year."

Why the foundations of physics have not progressed for 40 years

January 13, 2020
Categories: Uncategorized

Sabine Hossenfelder has a new piece out, making many of the same arguments she has been making for a while about the state of fundamental theory in physics. These have a lot in common with arguments that Lee Smolin and I were making in our books published back in 2006. The underlying problem is that the way theorists successfully worked up until the seventies is no longer viable, with the Standard Model working too well, up to the highest energies probed:

> The major cause of this stagnation is that physics has changed, but physicists have not changed their methods. As physics has progressed, the foundations have become increasingly harder to probe by experiment. Technological advances have not kept size and expenses manageable. This is why, in physics today, we have collaborations of thousands of people operating machines that cost billions of dollars.
>
> With fewer experiments, serendipitous discoveries become increasingly unlikely. And lacking those discoveries, the technological progress that would be needed to keep experiments economically viable never materializes. It's a vicious cycle: Costly experiments result in lack of progress. Lack of progress increases the costs of further experiment. This cycle must eventually lead into a dead end when experiments become simply too expensive to remain affordable. A $40 billion particle collider is such a dead end.

I have a somewhat different view about a potential next collider (see here), but agree that the basic question is whether it will be "too expensive to remain affordable."

What has happened over the last forty years is that the way HEP theory is done has become dysfunctional, in a way that Hossenfelder characterizes as follows:

> Instead of examining the way that they propose hypotheses and revising their methods, theoretical physicists have developed a habit of putting forward entirely baseless speculations. Over and over again I have heard them justifying their mindless production of mathematical fiction as "healthy speculation" – entirely ignoring that this type of speculation has demonstrably not workhat woed for decades and continues to not work. There is nothing healthy about this. It's sick science. And, embarrassingly enough, that's plain to see for everyone who does not work in the field.
>
> This behavior is based on the hopelessly naïve, not to mention ill-informed, belief that science always progresses somehow, and that sooner or later certainly someone will stumble over something interesting. But even if that happened – even if someone found a piece of the puzzle – at this point we wouldn't notice, because today any drop of genuine theoretical progress would drown in an ocean of "healthy speculation"…
>
> Why don't physicists have a hard look at their history and learn from their failure? Because the existing scientific system does not encourage learning. Physicists today can happily make career by writing papers about things no one has ever observed, and never will observe. This continues to go on because there is nothing and no one that can stop it.

This story brings up a lot of complex issues in the philosophy and sociology of science, but to me there's one aspect of the problem that is relatively simple and deserves a lot more attention than it gets: how do you get theorists to abandon failed ideas and move on to try something else?

The negative LHC results about SUSY have had some effect, but even in this case it's remarkable how many theorists won't abandon the failed idea of a SUSY extension of the Standard Model. This was always a highly dubious idea, explaining nothing about the Standard Model and adding a huge number of new degrees of freedom and more than a hundred new undetermined parameters. Not seeing anything at the LHC should have put the final nail in the coffin of that idea. Instead, I see that this past fall MIT was still training its graduate students with a course on Supersymmetric Quantum Field Theories. You can try and argue that SUSY and supergravity theories are worth studying even if they have nothing to do with physics at observable energies, but it is a fact that these are extremely complicated QFTs to work with and have explained nothing. Why encourage grad students to devote the many, many hours it takes to understand the details of this subject, instead of encouraging them to learn about something that hasn't been a huge failure?

The techniques one gets trained in as a graduate student tend to form the basis of one's understanding of a subject and have a huge influence on one's future career and the questions one has the expertise needed to work on. Besides SUSY, string theory has been the other major course topic at many institutions, with the best US grad students often spending large amounts of time trying to absorb the material in Polchinski's two-volume textbook, even though the motivations for this have turned out to also be a huge failure, arguably the largest one in the history of theoretical physics.

To get some idea of what is going on, I took a look at the current and recent course offerings (on BSM theory, not including cosmology) at the five leading (if you believe US News) US HEP theory departments. I may very well be missing some offered courses, but the following gives some insight into what leading US departments are teaching their theory students. Comparing to past years might be interesting, possibly there's a trend towards abandoning the whole area in favor of other topics (e.g. cosmology, quantum information, condensed matter).

- Harvard:
  Fall 2019
  PHYSICS 283B: Spacetime and Quantum Mechanics, Total Positivity and Motives
  PHYSICS 287A: Introduction to String Theory
  Spring 2020
  PHYSICS 211BR – Black Holes from A to Z
  PHYSICS 287BR – The String Landscape and the String Swampland
- Stanford:
  No courses beyond QFT in 2019/20
- Caltech:
  No courses beyond QFT in 2019/20
- Princeton:
  Fall 2019
  Phy 540 Strings, Black Holes and Gauge Theories (Klebanov)
  Spring 2020
  Phy 540 Strings, Black Holes and Gauge Theories (Polyakov)
- MIT
  Fall 2019
  8.831 Supersymmetric Quantum Field Theory
  Spring 2020
  8.851 Effective Field Theory

The places not offering string theory courses this year seem to have had them last year.

Update: Something relevant and worth reading that I think I missed when it came out: Jeremy Butterfield's detailed review of Lost in Math, which has a lot about the question of why theorists are “stuck”.

Update: There’s some serious discussion of this on Twitter. For those who can stand that format, try looking here and here.

Update: Mark Goodsell has a blog posting about all this here, including a defense of teaching the usual SUSY story to graduate students.

Update: A correspondent pointed me to this recent CERN Courier interview with John Ellis. Ellis maintains his increasingly implausible defense of SUSY, but he’s well aware that times have now changed:

> People are certainly exploring new theoretical avenues, which is very healthy and, in a way, there is much more freedom for young theorists today than there might have been in the past. Personally, I would be rather reluctant at this time to propose to a PhD student a thesis that was based solely on SUSY – the people who are hiring are quite likely to want them to be not just working on SUSY and maybe even not working on SUSY at all. I would regard that as a bit unfair, but there are always fashions in theoretical physics.

Comments

1. **Warren Siegel**
   January 13, 2020

   If there were anything else, people would move on.
   It’s exactly because high-energy physics as we have known it no longer produces new results that increasingly imaginative ideas are being tested.
   Defeatists have not found viable alternatives.

2. **Peter Woit**
   January 13, 2020

   Warren Siegel,
   I agree that if there were a readily-identifiable good alternative, people would move to it. In the past experiment would point in the right direction. That’s gone and it’s a very hard problem to replace that and find other routes to new ideas.

   What isn’t so hard though is to recognize when ideas don’t work, and doing so isn’t “defeatist”. The problem isn’t “increasingly imaginative ideas”, it’s going along with increasingly bad justifications for continuing to pursue failed research programs instead of acknowledging the obvious.

3. **Amitabh Lath**
   January 13, 2020

   The courses for advanced graduate students tend to be more fluid than the core courses. Sometimes an advanced topic is offered every other year (for instance General Relativity). Some of the more esoteric topics can be even less frequent. Also the course might not be called “String Theory” but “Special Topics in XYZ…” And occasionally students will just arrange a weekly meeting with a professor to learn a subject in depth. I wouldn’t put much weight on courses appearing or disappearing from the course catalog.

4. **Alessandro Strumia**
   January 13, 2020

   The problem is driven by physics, not by sociology. Simple explanation in natural units:
   (collider radius) ≈ (4π/alpha)^3 (collider energy)/(electron mass)^2.
   Collider technology remains based on old physics: electrons and electromagnetism. Because the heavier particles discovered at colliders found almost no practical use, not even for building better colliders. This is the key point. The rest follows: colliders become big, slow, expensive. Theory detaches from experiment.

5. **Mark**
   January 14, 2020

   I regard string theory as etudes for physicists like there exist etudes for piano players. It’s good for improving techniques (mathematics in our case) but not “the real thing”, because string theory is in principle based on quantum theory for extended objects, which is not conceptually really a new idea or even revolutionary, being technically difficult but conceptually almost trivial. We have at the moment no one who is capable to produce a masterpiece like did Bach or Chopin in music, for example. We are just practicing and preparing for it.
   But that’s better than nothing.
   I would not condemn string theory in total: Learning it’s technical aspects (etudes) may lead us one day to be capable to find the true masterpiece.

6. **Peter Woit**
   January 14, 2020

   Alessandro Strumia,
   Yes, it’s clear that the underlying problem is the physics that makes probing higher energy scales more and more expensive. This creates a different problem, with sociological aspects: once they’ve detached from experiment, what happens to HEP theorists and the field of HEP theory?
   Some possible reactions to this problem are:

   1\. Ignore it, refuse to acknowledge it publicly, and keep on pursuing previously popular research programs that have failed. Keep training new generations of students in the complexities of SUSY or string theory.

   2\. Give up, abandon HEP theory for another healthier field (e.g. cosmology, condensed matter, quantum information theory, machine learning).

   3\. Find some route to new, more promising ideas.

   I’d argue that 3 is still viable. A big problem is the historical sociology of the field has become dysfunctional. It emphasized concentration on a small number of questions, driven by experiment providing the right question. This falls apart when experiment stops providing the right promising question for everyone to focus on.

7. **Peter Woit**
   January 14, 2020

   Mark,
   I think that for quite a while post-1984 you could sensibly make the argument that while the string unification conjecture was a failure, there was a lot to be learned from

the deeper study of string theory and it was worthwhile for people to pursue that. Unfortunately, over the past 20 years or so, progress in learning new things from the deeper study of string theory has pretty much come to a halt. Keeping doing the same things over and over, while waiting for a genius to save you from yourself is not a good plan. For one thing, up and coming geniuses who take a look at a field and see that going on will flee and look for another field in which to exercise their genius.

8. **Sabine Hossenfelder**
   January 14, 2020

   Hi Peter,

   Thanks for mentioning. The piece actually isn't new, it's a reprint of [a blogpost I wrote last year](#).

   Butterfield has misstated my position on some issues. I have a brief response to this [here](#).

9. **Akhil**
   January 14, 2020

   Peter,
   PHYSICS 283B: Spacetime and Quantum Mechanics, Total Positivity and Motives looks like a very interesting course to take for new students. Does it have any promising ideas or is it just the old failed ideas?

   Also curious about your take on pursuing deep mathematics as a promising way to progress. Can you elaborate on that?

   Where can you disagree with Sabine, on pursuing deep mathematics vs lost in math?

10. **SparkTech**
    January 14, 2020

    Cut the funding. I mean that's an idea, not the solution: the solution is the one which make possible a financial limitation to string theory community and alike.

    I think of this because, I believe, the true problem is the(!) money that keeps pouring into that kind of bogus research.

    And scare resources should be a resource for creativity.
    The theoretical work better be focused on technologies oriented to experiments and observations, by driving experimentalists on what could do (what observations/experiments could think of), instead of making unnecessary abstract assumptions on how the universe should be (parallel worlds, holography, strings etc.).

11. **Peter Woit**
    January 14, 2020

    Akhil,
    That's an unusual course. Arkani-Hamed was visiting Harvard, it was an opportunity for him to explain his current research program in detail. I've written about this "amplitudes" research many times here on the blog.

    There is a great deal in my "Not Even Wrong" book about the relation of deep ideas in mathematics to the Standard Model.

    For my disagreements with "Lost in Math", see my review of the book.

    SparkTech,
    The problem isn't a lack of focus on experiment, it's the lack of experimental anomalies that could point to a way forward. Experimentalists and theorists have worked hard to change this, but nature is not cooperating. The problem is how to make progress given this situation.

    Theorists need to work with abstract assumptions on how the universe should be, but they need to do a better job of rejecting ones that fail to lead anywhere and coming up with new ones to try.

    Cutting off funding to failed research programs would be helpful, but what really matter is how the leading figures in the field deal with the problem of no progress. Funding decisions should come from the people in the field, not from people who don't understand the problems theorists are grappling with. Hossenfelder is doing a good job trying to get theorists to face up to the problem, in some sense what we need is a more serious response to her challenge.

    Just saw this
    https://twitter.com/JimBaggott/status/1217011515385139201
    which makes the same point.

12. **Claudio Paganini**
    January 14, 2020

    One of the problems I see is the concentration of power with certain fields in the theory departments around the world but particularly within the US.
    "Just cut of the funding for field X" doesn't work if the people deciding over funding in theory departments are all from field X.

    I think physics would need to revise their publication culture and get closer to that of mathematics. Way fewer papers but an idea worked out in full detail.

    There are interesting alternative approaches out there which manage to resolve some of the conceptional issues. Non-Commutative geometry, for example, seems interesting, although lacking a Lorentzian formulation as far as I can tell. E8 theory is another one. Causal Fermion Systems, which can explain the 3 generations of fermions belongs to that set as well.

    Then on the foundations of quantum mechanics there is also interesting new work being done. Ellis approach that claims the macro to be as real as the micro aspects of the world, resolving the measurement problem by top down causation.
    Fröhlichs Events, Trees, Histories (ETH) approach to quantum mechanics which resolves the measurement problem by providing a sharp definition of events and in the course abandoning unitary evolution (except as a non interacting limit case).

    What all of these have in common is that they require deep mathematics which unfortunately scares away many physicists, even theoretical ones, from truly engaging with them.

13. **SparkTech**
    January 14, 2020

@Peter Woit

Thanks for your answer and for the time it took. For sure you have better hard data than me to judge on this.

Your statement "Funding decisions should come from the people in the field […]" is perfectly reasonable, and I have accepted it myself for some time by now
However the way I see it now (ok, call it naive if you like): if we keep financing string theory community (for example) in the same way as we did so far, then string theorists will do what the did already in the last past decades. Is there any evidence for a paradigm shift? Maybe occasionally some scientists switch the field (but as I said, you have better data).

As for the nature which does not cooperate, (again, I believe you have better knowledge) I also believe it is a lot easier to cook up a complex mathematical theories about quantum foams than to think of a better technology to extract new data from that quasar which is that far away. By limiting the funding for that juggernaut theoretical community will force them to squeeze their "theoretical" brains towards a more empirical approach.

I also agree that theorists need to work with abstract assumptions on how the universe should be, but there also must be a limit on that: the pathology is now an inflation of theories that explains nothing, since there was little-to-nothing observed or experimented to start from in the first place.

14. **Shantanu**
January 14, 2020

Peter and others:
How come universities (with theory departments) are not offering dedicated courses in neutrino physics? That is the the only place where there is "supposedly" evidence for Physics BSM? Or is it that the "breakthroughs" in neutrino physics have taught us nothing?

15. **Peter Woit**
January 14, 2020

Claudio Paganini,

Yes, if funding, hiring, training of graduate student, etc. decisions are all in the hands of people working in field X, any significant change requires changing the thinking of those in field X. The terminology "field X" for the dominant field in formal theory in the US is a very good one, since, while people in this field often call themselves "string theorists", most of the best ones are not doing string theory. While they often have moved on to other things, the problem is that they are still advertising string theory to the public, training graduate students in string theory, and evaluating new research directions based on whether they somehow follow from the string theory research program path of the past.

16. **Peter Woit**
January 14, 2020

SparkTech,
The problem is that string theorists have already been under huge pressure to show that their research connects to experiment, and all this has led to is even more dubious research directions like the string theory landscape or the currently popular "swampland" program. What's needed is acknowledgement that this is a failed idea that can never connect to experiment, not more effort to find a way to do so.

17. **Peter Woit**
January 14, 2020

Shantanu,
Pretty much every institution teaches courses on QFT, leading up to the Standard Model QFT, and in many of these I would expect that there is some discussion of neutrino masses and possible extensions of the Standard Model involving them.

But I don't think there has been much in the way of either promising new theoretical ideas or unexpected experimental results on this front. If forthcoming neutrino experiments turn up something unexpected, I think courses on the topic would quickly become much more popular.

18. **SparkTech**
January 14, 2020

You could be right. My bet: they acknowledging that will never happen.

As you said, there is already evidence for what I believe(more dubious research in spite of huge pressure, etc., I mean the right trend is not there). And human-wise who could acknowledge that he/she spend last 20 years himself/herself on bogus physics? Which is rather consistent with my little samplings of string – theorists claiming that string theory did make significant progress in the last decades. And, as you mentioned already, it is not only them: we got also many-worlds/universes etc.

I mean: you, Sabine, Lees Smolin doing great job. And it could bring hundreds of others being just as vocal. Still waiting for that to see it happening. I only say it may not be enough.

Again, thanks for you patience and time,
and I wish you a nice day!

19. **Peter Shor**
January 14, 2020

Sabine says:

> Theoretical physicists have developed a habit of putting forward entirely baseless speculations. Over and over again I have heard them justifying their mindless production of mathematical fiction as "healthy speculation" – entirely ignoring that this type of speculation has demonstrably not worked for decades and continues to not work.

But didn't this method work wonderfully well between 1900 and 1975?

Planck put forth the entirely baseless speculation that light came in chunks of discrete energy (and won a Nobel Prize).

Dirac put forth the entirely baseless speculation that the entire universe was a sea of electrons that had both extra electrons and holes (and won a Nobel Prize).

Geoffrey Chew put forth the entirely baseless speculation that the "bootstrap method" could explain the particle zoo (and did not win a Nobel Prize).

The difference today is that we don't have experiments that rule out the worthless entirely baseless speculations and confirm the entirely baseless speculations that happen to be correct. Experiments have been replaced by some complicated social process that selects some subset of the entirely baseless speculations that physicists come to a consensus on believing, but which seems to do a terrible job of separating the correct baseless speculations from the incorrect ones.

20. **Peter Woit**
January 14, 2020

"Experiments have been replaced by some complicated social process that selects some subset of the entirely baseless speculations that physicists come to a consensus on believing, but which seems to do a terrible job of separating the correct baseless speculations from the incorrect ones."

An excellent summary of the problem…

21. **Sabine Hossenfelder**
January 14, 2020

Peter, Alessandro,

The idea that one needs high energies to probe new physics is simply wrong. To begin with, I don't have to tell you that if there's new physics at high energies that would also change low-energy predictions, so higher precision can replace higher energies.

But maybe more importantly it is generally an unjustified assumption that the next breakthrough in the foundations will come from going to higher energies or short distances as opposed to probing other regimes that have been untested so far. My favorite example are quantum effects in many particle systems. This is imo presently the obvious frontier to push. You may not agree, but that's not the point. The point is that higher energies is not the only route.

Of course particle physicists don't want to hear it, but building bigger colliders has clearly run its course — for now. It's expensive and the scientific benefit is negligible. Colliders are something we will certainly come back to. Maybe in a hundred years or 200 years. (Unless by then hunting with wooden sticks has become ground-breaking technology.) But this is not the right time to throw more money at particle physicists.

Let me also repeat that the problem with lacking experimental input is not decoupled from the lack of progress in theory development. The days in which we could bank on serendipitous discoveries in the foundation of physics are over. "Just look" does not work any more. The string of failed experiments in the past 40 years is evidence for that. This is simply not up to debate, it's a fact.

It is likewise a fact that theorists' methods of theory development are not working. Claiming that "it's physics" does not explain why they are not willing to revise their methods.

Re the supposed lack of alternatives.
First, it's wrong. There are various alternatives. It's just that so few people work on them that it's not even clear how promising they are. They are easy to dismiss because they have open questions simply due to lack of manpower.

But besides that, I am sick and tired of the claim that theorists in the foundations should be allowed to do a crappy job because no one has any better idea what to do. If they don't know what to do, then we shouldn't pay them.

Seriously, what kind of attitude is this? In what other profession would you get away with not being able to get anything right for 40 years and then saying you will continue that way because you can't think of anything better to do?

22. **Peter Woit**
January 14, 2020

Sabine,
I agree with much of what you have to say here, do disagree though about the issue of a higher energy collider. If the only argument for it was "let's go look, maybe gluinos or extra dimensions will turn up", I'd agree with you. You're right that the generic "let's investigate the 1-10 TeV scale even though we don't think there's anything there" argument faces a serious counterargument about the cost. The to me serious HEP argument is that the most mysterious and least understood part of the Standard Model is the Higgs sector (some might want to argue for the neutrino sector, but that area of HEP is going ahead with little controversy over its funding, since it is quite a bit cheaper). I don't believe there's any way to get better information about the Higgs sector than what we'll get from the HL-LHC without a new collider.

The problem of course is the cost. If a new collider cost less than \$1 billion there wouldn't be a lot of opposition to going forward. At \$10 billion and up, the cost is a big problem. For the latest on the leading proposal, see this talk from yesterday

https://indico.cern.ch/event/838435/contributions/3635822/attachments/1967874/3272551/200113_FCC-Status.pdf

The timeline given there (page 15) shows, I think assuming the project gets the go-ahead in the next year or so, a three year "funding strategy" period, and eight years before one starts even digging the tunnel. My understanding is that next week there's a drafting session scheduled, and May 2020 is the time frame for a specific proposal to be submitted to the CERN Council. I'd argue that it's best if everyone wait a little while to have a serious argument over the new collider question, until there's a specific proposal for both what to build and how to fund it on the table. There's going to be plenty of time for discussion about this before anything much actually happens.

23. **Alex**
January 14, 2020

The post had asserted:

"Caltech: No courses beyond QFT in 2019/20"

At Caltech, Physics 230 is seen as the follow-up to the QFT courses.

24. **Peter Woit**
January 14, 2020

Alex,
Thanks, I updated the posting. I'd stopped reading the course description after "Advanced methods in QFT" and seeing mention of confinement and non-perturbative techniques in gauge theory, typical Standard Model QFT issues. The course description does say however that a first term version of the course like the fall one would cover
"introduction to supersymmetry, including the minimal supersymmetric extension of the standard model, supersymmetric grand unified theories, extended supersymmetry, supergravity, and supersymmetric theories in higher dimensions."

and if that's what the instructor chose to do last fall, it would have been just as bad an idea as the MIT SUSY course.

I'm well aware (Amitabh Lath kind of points this out), that what gets covered in advanced classes like this depends on the instructor and evolves over the years. I'd be interested to know if instructors of courses like this are realizing that the topics covered should be changed.

25. **Peter Woit**
January 14, 2020

A bit of research shows that in Fall 2017 when Hirosi Ooguri was teaching Ph 230 at Caltech, the syllabus
http://ooguri.caltech.edu/education/230
covered mostly gauge theory, no SUSY.
In 2015-6, when the course was taught by Kapustin, the fall and winter quarter were Yang-Mills and non-perturbative QFT, the spring was devoted to SUSY.
http://www.theory.caltech.edu/~kapustin/Ph230/Ph230.html

26. **Alan Roxdale**
January 14, 2020

> The techniques one gets trained in as a graduate student tend to form the basis of one's understanding of a subject and have a huge influence on one's future career and the questions one has the expertise needed to work on.

I'll put forward the suggestion here that the techniques one does _not_ get trained in, or worse, get trained to avoid also play a significant role. In fact, I think this is the big structural issue which has lead to the current stall (albiet taking perhaps 50-70 years to do so).

Adam Becker makes a strong case in his recent book that the profession and education of theoretical physicists underwent a sharp transition immediately after the second world war. The volume of physicists (and also other scientists and engineers) spiked, the centre of the profession shifted to the previously placid United States, and educational norms began to emphaise practicalities over philosophical introspection. You could argue that foundational issues were forgotten in the heady days of Big Science.

But, I find it hard to avoid the conclusion that there is more to it. A reading of history suggests that (quantum) foundational issues were buried, becoming not simply unfashionable, but actually taboo. Becker presents several unflattering cases for the record of post-war physics, enough to convince me at least that lack of progress on foundations (and I'd argue any new physics) can be blamed in significant part on purely sociological issues, all physics aside. This is the case in all fields no doubt, but this really does include theoretical physics.

> But didn't this method work wonderfully well between 1900 and 1975?

The mid 70's alway seem to be a sharp cutoff for most assessments of the progress in physics. I'd point to a delayed fallout from the general shift in the profession, as an older differently trained cohort passed the torch to a structurally different generation (though you could point to the SALT treaty too!). A generation which had been trained, institutionally, socially or otherwise to _not_ go looking in certain directions. Maybe it worked for a while, and probably did work for several other fields, but it hasn't worked for theoretical physics.

The solution I'd advocate is to change the "training". Make graduate students (indeed all physics students) aware of the problems, and in cases the gaping holes. Make them keenly aware of the history and the controversies and the unexplained, that there is still work to be done, and then let them do it. Tacitly of course this resigns the current generation(s) to "standing and waiting". Perhaps more controversially, this involves public funding bodies be made aware that the profession is more fallible than generally accepted. In any case, continuing as is only means further 'Breznevisation'.

27. **Peter Woit**
January 14, 2020

Alan Roxdale,
I wrote about Becker's book here
https://www.math.columbia.edu/~woit/wordpress/?p=10147
where you can see that I very much disagree with the story he pushes about the evil, unthinking Copenhagen orthodoxy and the good Bohm/Everett "quantum rebels". The last thing theory graduate students need is to be drawn into the tar pit of "interpretations" and sold a moralistic story about how the old fogeys just didn't realize that many-worlds are the solution to fundamental problems.

28. **Amitabh Lath**
January 14, 2020

Peter, you say At \$10 billion and up, the cost is a big problem. Why? Surely the cost of the FCC (or comparable collider in China) is a smaller fraction of the World GDP today than Fermilab's cost was to the late 1960s US economy. By the way a lot of that 10G$ estimate is salaries for engineers which will probably be "in kind" contributions from countries like India and China.

Also, the world is a much more peaceful place today. There are no incendiary-laden B52s heading to Asia. Countries today are content to lob shipping containers at each other and a major world crisis happens when the number of containers decreases by 4%. This is the ideal time to build something like the FCC.

The Standard Model is proving to be a tough nut to crack, I'll admit. But I do not know of any (experimental high energy) physicist that does not think we will eventually break it. It might take many decades, our grandchildren might be the ones to see the first hints of new physics but it will happen. The alternative is to believe that 2012 was somehow a privileged point in human history after which no fundamental discoveries could be made.

29. **John**
January 14, 2020

Sabine and Peter,

I find that Sabine's line of argumentation against a next high-energy collider to be completely unsatisfying. It seems that she is arguing that because the LHC has not turned up new physics (besides the Higgs, which is a major triumph that she seems to downplay), that means that experiment is a failure and that future colliders should not be built. I am happy to see that Peter disagrees, but I would like to add some of my feelings.

For one, we should remember that the LHC would never have happened had it not been for the cancellation of the Superconducting Supercollider (SSC). The LHC currently operates at a center-of-mass energy of 13 TeV with an expected upgrade to 14 TeV (though 14 TeV was the initial "design" com energy). On the other hand, the SSC was a 40 TeV collider, and a reasonable upgrade could have sent it to 50 TeV. This is not insubstantial.

New physics shows up only in very very subtle hints before one reaches the mass threshold for producing on-shell particles (e.g. a new 10-15 TeV particle would be nigh impossible to detect at the LHC but might show up at the SSC). In the past, theorists of SUSY and other BSM theories have predicted what the thresholds for new phenomena should be, but have been basically wrong. So, justifiably, Sabine is arguing that the theorists have been on the wrong track in terms of predicting what the thresholds should be. However, according to her logic, that would mean it could turn out that the LHC upgrade that ups it from 13 to 14 TeV could open new worlds of possibilities. Likewise, the possibilities at 40 TeV would be (and would have been, with the SSC) that much greater. So already, when Sabine is saying that "we need new physics," it is completely unjustified to argue against a new, more powerful collider. Had US politics not steered collider physics as they have, we might now be in a bountiful situation much like what was seen in the 1970's. And writing off this sort of possibility, based on theoretical arguments, is hypocritical if the argument is based on the same kinds of theoretical considerations you were just arguing against.

Just to put it in a simplified form: we could have had a much more powerful collider, 40-50 TeV instead of 13-14 TeV, years ago. The costs for such a machine have gone down at this point (adjusting for inflation.) So we are in the situation that the people who've told us that we should expect new physics at some new energy, based on theory, have been shown to be unreliable — however, that reasoning for why we should not trust theorists applies _just as well_ as those who are telling us _not_ to expect new physics at the next collider.

Sabine's ideas on "alternative" kinds of experiments are complete "Hail Mary" ideas — she needs to cite better literature if anyone is to take her seriously when she is going up against a historically proven experimental program basically single-handedly. Even if such ideas had any merit, it doesn't mean delaying the next collider makes any sense — big science needs to push on multiple fronts, just like ITER (a much more expensive experiment than the LHC) has been trudging along despite developments in fusion that will have made it somewhat out-of-date already by the time it gets finished. But in the field of fusion energy, they have the right mentality in that the big mainstream projects should proceed in parallel with the smaller more speculative ones, and not to put off progress on the big mainstream projects in hopes that a miracle happens in smaller sideline work.

30. **Amitabh Lath**
January 14, 2020

That first sentence should say The cost of the FCC or Chinese collider is smaller as a fraction of the World GDP than Fermilab's cost compared to the US economy in the late 1960s.

31. **Peter Woit**
January 14, 2020

John,
I don't disagree and made many of the same points myself in the posting and discussion here
https://www.math.columbia.edu/~woit/wordpress/?p=10768
" One piece of advice though is that experience of the past few decades shows you probably shouldn't listen to theorists."

Amitabh Lath (and John),
My comment that a \$10 billion cost is a "big problem" was not meant to indicate I have a problem with government spending on that order to fund a collider, or that there is some problem of principle, but just that raising that kind of sum is going to be hard to do.

This isn't going to get built in the US and the US is not going to provide a large fraction of the cost of a machine built elsewhere. The US budget process is currently a joke, with no clarity as to what will happen next year, much less over a 10-20 year period. Any document promising US future funding would not be worth the paper it was written on. I also doubt the Japanese or Chinese will fund much of a machine built in Europe. Maybe the Chinese will do this in China, but that would require overcoming objections from those like C.N. Yang who feel that China has more pressing needs for spending \$10 billion.

In Europe, CERN has a fixed budget (in fraction of GDP) and while one can reasonably expect it to hold onto that, it's very unclear to me whether a plan for \$10-\$15 billion in new spending can fit into that budget. I don't know enough about CERN funding to know whether there's a realistic prospect of getting commitments for a big budget increase to fund a new machine. I'm guessing we'll be hearing from CERN leadership in coming months about these issues.

The above is what I meant by "big problem", I hope it can be solved.

32. **Peter Woit**
January 14, 2020

All,
As discussed above, I don't think further debate over a new collider here now is a fruitful thing to do (and, you shouldn't listen to theorists anyway…).

33. **Peter Shor**
January 15, 2020

Amitabh Lath: If a €1.5 billion telescope was cancelled because it was too expensive, it's difficult to imagine how physicists will be able to get funding for a $20 billion collider.

And it's also difficult to imagine how a new collider will give us information about quantum gravity, at the Planck scale. So even if it discover interesting physics beyond the Standard Model, it doesn't really solve the problem that Sabine's article brings up.

34. **Amitabh Lath**
January 15, 2020

Peter Shor, either new physics is there within human reach or it is not. If it is then the biggest hadron collider we can build is obviously the best bet to find it. Nothing beats bigger \sqrt{s}. If you look beyond the headlines (LHC fails to find SUSY) you will see the breathtaking precision with which the searches have been carried out. Yes we are still smashing Swiss watches together but now we can identify just about every screw, spring, and sprocket that flies out. This should give you confidence about our ability to find new physics.

As to the comment that "even if it discover interesting physics beyond the Standard Model, it doesn't really solve the problem…" I do not understand this statement. How do we know what problems the new physics can or cannot solve until we find it?

As for $$, yes but we won't get it if we don't ask. The astronomers might have struck out with the Overwhelmingly Large but they are getting the Extremely Large, not to mention the James Webb, the Vera Rubin, etc.

35. **André**
January 16, 2020

Amitabh Lath: "the biggest hadron collider we can build is obviously the best bet to find it"
To me, this seems not obvious at all. I do not think that "new physics" necessarily requires "new particles". Sure, if you want to find new physics, you need to somehow explore new parameter space, and larger energies are an obvious candidate, but so are violations of the equivalence principle, massive superpositions, large distance Bell

tests, …
There are currently very few reasons to believe that any of those will show new physics, but we need to keep in mind that reasons to expect something new from a collider are equally unconvincing. As theoreticians, our task is of course to work on finding such convincing reasons why something new should happen in one experiment or another, but in the absence of these convincing theoretical reasons all these options must be seen as equally (un)likely to produce anything truly exciting.
The way I understand Sabine, her point is mainly that, because of this fact, we should maybe focus on the easier (i.e. cheaper) areas where new physics could show up first, and I very much agree with that sentiment.
The only potential benefit I see for a new collider is the one that Peter mentions: better understanding of the Higgs sector. Whether or not this is worth the price is in fact not an easy question. The "just look" argument, on the other hand, has not been aging well in my opinion.

36. **Peter Woit**
January 16, 2020

André,
One problem with the "let's do cheap violations of the equivalence principle, massive superpositions, large distance Bell tests, … instead of building a collider" argument is exactly that such things are (on the HEP funding scale) cheap. The issue of funding and doing such experiments really has nothing at all to do with the collider issue since the scales are completely different. The US and Europe each have billion-dollar/year budgets right now being spent on high energy physics, the Simons Foundation is handing out a quarter-billion/year in grants. If proposals for small-scale experiments can convince people they're worthwhile, they should in principle be able to get funded (if this isn't possible, the field has a different sort of funding problem that needs to get fixed).

37. **John Baez**
January 17, 2020

Peter Shor wrote:

> Planck put forth the entirely baseless speculation that light came in chunks of discrete energy (and won a Nobel Prize).

I can't let this go by. Planck was trying to explain some experimental data, and he didn't originally even pay much attention to the fact that his calculation required that light came in discrete chunks.

The simplified story often told to students is that Planck was struggling to deal with the fact that classical electromagnetism combined with statistical mechanics leads to an "ultraviolet catastrophe": due to the equipartition theorem, a box of classical radiation in thermal equilibrium would have more and more energy density at higher and higher frequencies, as described by the Rayleigh-Jeans law, leading to infinite total energy. Planck showed that if radiation came in discrete chunks this problem would go away.

But in fact Planck wrote his groundbreaking paper in 1900, he didn't accept the equipartition theorem seriously at the time, and the ultraviolet catastrophe was only recognized as a serious problem later. (The term was coined by Ehrenfest in 1911.)

What Planck actually started out trying to do was justify a different formula for the energy density as a function of frequency of radiation in thermal equilibrium, one that seemed empirically correct at high frequencies: the Wien law. He wrote a paper doing this in 1899, but then experiments showed the Wien law was inaccurate at low frequencies, so Planck went back to the drawing board.

In "an act of desperation", in 1900 he introduced discrete energy levels to get a law that matched the Wien law at high frequencies but differed from it at low frequencies. But he didn't think much about the meaning of these energy levels. He later wrote that it was "a purely formal assumption and I really did not give it much thought except that no matter what the cost, I must bring about a positive result".

He got a formula that fit the data, the Planck law, and he was happy with that. Only in 1908, thanks to Lorentz, did he accept the physical significance of the energy quanta he'd almost unwittingly introduced. This was *after* Einstein wrote his Nobel-winning paper on photons in 1905.

In short, Planck was heavily data-driven, and only later did the conceptual meaning and revolutionary nature of his calculation become clear. For more, try Max Planck: the reluctant revolutionary by Helge Kragh.

Concerning Peter Shor, John Baez: Or read the formidable book by Thomas Kuhn, Black-Body Theory and the Quantum Discontinuity 1894-1912.

39. **Peter Woit**
January 17, 2020

Peter Shor/John Baez,
An interesting discussion of Planck, but this has gotten far off topic. Hossenfelder is getting a lot of flak for the "baseless speculation" terminology, but I think she was trying to point to something very specific, where she has a serious case.

Specifically, the problem is that there is currently no well-motivated theoretical reason to expect new physics:
1. At a new e+/e- collider. The examples people give of BSM models that contain new states that would not be seen at the LHC, but would be visible at a lower energy lepton collider appear to be contrived, "baseless speculation" is not a bad description. The non "baseless speculation" case for a lepton collider is as a tool for detailed study of the Higgs.
2. At a proton-proton collider with beam energy 2 (HE-LHC) -7 (FCC-pp) times that of the LHC. Such a machine would open up the study of a new energy range, but it is true that we have no well-motivated reason to expect something new in that energy range. Against her, there's a good argument that one should investigate the new higher energy range anyway, because doing so is what science is about (not just trusting that your theory extends to cover some unexamined region, but looking to check, something unexpected is quite possible). The problem is that doing this would be very expensive.

40. **Marco**
January 17, 2020

There is a nice reply from CLIC (https://arxiv.org/abs/2001.05373) on allegations made by FCC proponents (https://arxiv.org/abs/1912.13466).

41. **Amitabh Lath**
January 17, 2020

There is some seriously naive zero-sum thinking on this blog and comments. Peter Shor, Andre and others all point to cost as a the determining factor. Perhaps if science (colliders, telescopes, fusion…) manages to squeeze itself into a small enough box it won't get its head chopped off.

Projects like the SSC, LHC and the next one do not live or die by cost alone. Above a certain amount that isn't even the determining factor. The SSC was cancelled not because of minor cost overruns but because Speaker Jim Wright (D-Texas) was forced to resign, George H.W. Bush, (a yankee pretending to be Texan) lost re-election, and Lloyd Bentsen left the Senate. Suddenly Texas had zero support in DC. It's counter-intuitive but if the SSC had cost more, and that extra spending had been spread around widely to certain strategic states and districts, it could have survived.

If the FCC gets built it will be because of buy-in from the large CERN member states who will be promised major contracts. Italian, French, German, British, and Dutch electrical, mechanical, civil engineering firms will make sure to get their cut. Major code-writing will be done in Eastern Europe. There will be tacit agreement on new facilities in depressed areas, number of jobs, etc.

I understand the need highly numerate people have to believe everything is controlled by numbers, budgets, timelines. But the go/no-go decision on a project like the next hadron collider will rest on something a lot more political and social.

42. **Low Math, Meekly Interacting**
January 17, 2020

The political background is correct, but the motivation is forgotten: The SSC was supposed to discover the Higgs boson(s) and sparticles, or rule out natural SUSY.

The LHC already did that.

If one is being honest "because it's there" is the only well-founded motivation to probe the energy frontier, and one I happen to support (for what it's worth, which isn't much). Theoretical considerations have proven to be so pliable and inaccurate, and this has been going on for so long, it's very difficult for "outsiders" to take them seriously anymore.

It's really about time those making these arguments stop assuming interested outsiders are stupid and face the toll history has inflicted on the current state of the field.

43. **Peter Woit**
January 17, 2020

I'm going to delete any further arguing about a new collider here, nothing new is coming out of it. For the latest news about this, see this presentation from today:

https://indico.cern.ch/event/838435/contributions/3647164/attachments/1971463/3279599/05-D99-AB-next-steps.pdf

There's a strategy drafting session next week, results to be made public maybe in March. Even if there's a positive decision to pursue the idea of a new collider, it looks like this will just be the start of a multi-year process of trying to see if Amit is right and CERN member states will be willing to come up with new funding. An actual decision whether or not to go ahead is not envisioned until 2025/6. So, there will be plenty of time to debate this more…

44. **Peter Shor**
January 17, 2020

@John Baez: That's an interesting piece of history that I didn't know. But I don't think that invalidates the example. How much difference is there between "an act of desperation" and an "entirely baseless speculation"?

My point is that the paradigm that worked so well for physics before 1975 or so — throw lots and lots of not-so-crazy and crazy theories at the wall and see which ones are validated by experiments — doesn't work in the absence of experiments.

45. **Lee Smolin**
January 20, 2020

Dear Peter,

If its not too late, I'd like to propose a view point that points to a way forward for HEP. One reason scientists can get stuck is when we persist in asking the wrong questions. Progress resumes when someone asks the right question, ie a question that leads to the correct explanation of the physics in question.

In the case of unification and beyond the standard model physics, its pretty clear by now that what seemed like the right questions in the 1970's and 1980's: naturalness, what is the right symmetry group, etc are not leading to progress.

So what is the right question to ask now? Here is one suggestion:

Accept that the standard model parameters are fine tuned and ask: "What was the dynamical mechanism, acting in the early universe, or perhaps before the big bang, that tuned them?"

That is, think like Darwin rather than Plato. Faced with a diversity of species, Plato asked for absolute, timeless principles, that explained why these-and only these species-exist. Darwin's insight was that there are no such absolute principles. What we see in the biosphere is the result of a dynamical process: natural selection, acting over billions of years, that could have turned out differently. But the dynamics is simple, profound and leads to many insights.

My proposal, which I have been making since 1992, is that theoretical HEP will begin to flourish again when we HEP theorists drop the search for the ultimate symmetry group, and begin learning to think like Darwin.

Thanks,

Lee

46. **Peter Woit**
January 20, 2020

Thanks Lee,

I disagree with you that the current problem is too many theorists searching for a deeper symmetry-based explanation. These days the popular direction seems to be not that, but instead pursuit of the idea that space-time and the symmetries we see are just emergent epiphenomena of some seemingly unknowable or random quantum system.

The large number of random-looking parameters needed as input for the SM certainly doesn't look like the output of any known symmetry-based argument. Maybe they are environmental, determined either by anthropic selection or evolutionary path from whatever is going on pre-Big Bang. The problem remains though of coming up with a viable theory of whatever physics it is that is going on there, and that seems to me completely open.

47. **John Baez**
January 23, 2020

Peter Shor wrote:

> How much difference is there between “an act of desperation” and an “entirely baseless speculation”?

To me they seem diametrically opposed. Planck had some experimental data that contradicted the best theory so far, and he was desperately trying to fit it with a simple new model. An “entirely baseless speculation” doesn’t give a better fit of existing data: at best it satisfies some theoretical predilections and avoids contradiction with existing data. An example of the latter is making up a theory with new particles that just happen to have masses slightly larger than current colliders can see, but doesn’t make any more accurate predictions about things we actually do see. Some particle physicists have been doing this for decades now.

48. **DanM**
January 31, 2020

Is it worth pointing out that “the foundations of physics” are not limited to high-energy and particle physics? There are many theorists working on foundational problems in condensed matter physics, for example, where much progress continues to be made. It is a thriving and fruitful discipline with a close coupling to experiment and lots of exciting new results. The HEP community’s insistence that they’re the only ones who work on “foundations” (see, e.g., the headline to this very blog post) may be one of the problems here.

This and That

January 23, 2020
Categories: Uncategorized

- I was sorry to hear of the death a few months ago of Tony Smith, who had been a frequent commenter on this blog and others. Unfortunately my interactions with him mainly involved trying to discourage him from hijacking the discussion in some other (often unusual) direction. Geoffrey Dixon did get to know him well, and has written a wonderful long blog entry about Tony, which I highly recommend (Dixon's newish blog also has other things you might find interesting).
- On the Jim Simons front, the Simons Foundation has put together something to celebrate their 25th anniversary. It explains a lot about their history and what they are doing now, as well as giving some indication of plans for the future. On these topics, read pieces written by Jim Simons and Marilyn Simons. The Foundation has been in a high growth mode, having an increasingly large impact on math and physics research. Their main statement about the future is that the plan is for this to go on for a very long time:

  > According to its bylaws, the Simons Foundation is intended to focus almost entirely on research in mathematics and science and to exist in perpetuity. If future leadership abides by these guiding principles, Marilyn and I believe the foundation will forever be a force for good in our society.

  My impression is that the Simons children have their own interests, and foundations with other goals to run.

  News from the \$75 billion source of the money (RenTech) today is that Simons is increasingly turning over control of that to his son Nathaniel, who has been named co-chairman. He has also added four new directors to the board, four of them senior Renaissance executives, and one his son-in-law Mark Heising.

- There are various IAS-related videos you might want to take a look at:

  Pierre Deligne explaining motives last night.

  Michael Douglas on the use of computers in mathematics.

  A Dutch documentary (not all of it is in Dutch…).

- If you aren't regularly reading Scott Aaronson's blog, you really should be. Latest entries are a detailed report from Davos and a guest post with a compelling argument about a major factor behind the problem of why women leave STEM careers more than men.
- For the latest on the "It from Qubit" business, see talks at a KITP conference. John Preskill notes "lingering confusion over what it all means", which makes me glad to hear that I'm not the only one…

Comments

1. **John Baez**
   January 23, 2020

   Thanks for pointing that out about Tony Smith! I hadn't known.

2. **Richard Gaylord**
   January 24, 2020

   "The Foundation has been in a high growth mode, having an increasingly large impact on math and physics reserch.". that should be 'research'.

3. **Alessandro Strumia**
   January 24, 2020

   Dear Peter,

   you mention that "women leave STEM careers more than men", so let me point out that this is not what comes out analyzing data about every affiliation of every author of every paper in fundamental physics. This data allow to infer when every disambiguated author starts and leaves. An apparent 30% gender difference in leaving rates arises because the fraction of women in fundamental physics is higher now, while being hired has now become less likely for everybody. After correcting for this sociological confounding factor, the gender difference in leaving rates is found to be compatible with zero. This is shown in fig. 7 of a paper by mine, to appear on Quantitative Science Studies and that cannot appear on arXiv. Flaherty in (https://arxiv.org/abs/1810.01511) claimed a ≈400% difference in abandonment rates based on indirect small-scale data, but this has also been "firmly ruled out" by Perley (https://arxiv.org/abs/1903.08195).

4. **Chris Oakley**
   January 24, 2020

   Sorry to hear about Tony. He was part of the chorus of misfits and kooks (that included myself, Danny Lunsford, "Quantoken" – whoever that was, and, dare I say it, Lubos) that followed and commented in your blog right from the early days. His long posts were always supportive of everything up to, but not including, String Theory, and generally gave the impression that everything had been thought out carefully, however unorthodox the conclusions. Does anyone have something like a CV for him? I found a YouTube video of him talking about E8, and he is American, but beyond that, I know very little.

5. **Peter Woit**
   January 24, 2020

   Richard Gaylord,
   Thanks. Fixed.

   Alessandro Strumia,
   Thanks, but I'd encourage people who want to debate this complex issue to do so over at Scott Aaronson's blog, where he manages to do something I'm incapable of (moderating a sensible discussion of this kind of contentious issue).

6. **Geoffrey Dixon**
   January 24, 2020

   More information about Tony can be found …

London Calling with Career Opportunities II

January 27, 2020
Categories: Uncategorized

If you're a mathematician, you don't need to go work for Dominic Cummings in order to have dramatically improved career opportunities in the UK. The British government has just announced a huge increase in funding for mathematical research: 60 million pounds/year (or about \$80 million dollars) for the next five years (see here and here). To get some idea of the scale of this, note that the US GDP is about 8 times the UK's and the NSF DMS budget is about \$240 million/year. So the comparable scale of this funding in the US would be about two and a half times the NSF budget for mathematics.

Many of my mathematician colleagues have sometimes seemed to me to be of the opinion that a huge increase in funding for math research is the best way to improve a society. We'll see if this works for Britain.

While the new UK government ran on a nativist platform of restricting immigration, with the goal of keeping outsiders from taking bread out of the mouths of UK citizens, this doesn't apply to mathematicians: all limits are off and we're encouraged to flood the country. The law will be changed on Friday, changes go into effect Feb. 20. This will include an "accelerated path to settlement", no need to even have a job offer, and all your "dependents have full access to the labour market", no problem with them and the taking the bread out of the mouths of the locals thing.

Update: More here (except it's mostly behind a paywall, but evidently Ivan Fesenko is quoted).

Comments

1. **Robinson**
   January 27, 2020

   A sensible policy for sure. Mathematics is at the ground floor of so much (all, in fact) of science and technology.

2. **Peter Woit**
   January 27, 2020

   Robinson,

   Yes, and I should point out that my own work has always been aimed at progress on the foundations of math, physics, and so all science and technology. The world could thus be significantly improved by bags of cash being brought to my office on the fourth floor of the Math building. Thanks.

3. **Not Cummings**
   January 27, 2020

   You obviously are not aware of how toxic the debate has been in the UK over Brexit, otherwise you wouldn't be so silly to use the inflammatory sarcasm implied by "the goal of keeping outsiders from taking bread out of the mouths of UK citizens"

   Don't be dumb, it doesn't help.

4. **Peter Woit**
   January 27, 2020

   Not Cummings,
   Living in another Rupert Murdoch-controlled society in which toxic nativism plays a big role, inflammatory sarcasm seems as good a way to react to it as any.

5. **Chris Oakley**
   January 28, 2020

   As for anti-immigration, that platform only belongs to the far right here. The major political parties, including the governing Conservatives, only ever make pro-immigrant noises in public. Leaving the EU was, officially, more about not being bossed around by Brussels than fear of Bulgarians taking our jobs (although a native English person would probably not be prepared to work for the same money anyway …) Having large numbers of foreigners coming here to study or practise science and medicine is nothing new here. The Gates scholarships in Cambridge, for example, have attracted a lot of students from the Far East.

6. **Peter Woit**
   January 28, 2020

   Not Cummings/Chris Oakley,

   I see The Register has its own sarcastic take on this, headlining their story
   https://www.theregister.co.uk/2020/01/28/boffin_uk_visa_program/
   with
   "Boris celebrates taking back control of Brexit Britain's immigration – with unlimited immigration program
   Don't worry: The PM's only going to let the best boffins in… honest"

7. **martibal**
   January 28, 2020

   Maybe one should subtract from this "huge amount of additional money" the european fundings that UK may lost after the Brexit. Is the increase still so huge ? I think UK benefits quite a lot from the european research program (like ERC or Marie-Curie grants).

8. **Robinson**
   January 28, 2020

   If you think the UK could feed, cloth and house twenty five million low paid Indian and Chinese immigrants, make the case for completely open borders. If you don't believe in completely open borders then you have an immigration policy, and I would be interested to know what it is.

There's a general misconception in certain quarters that the UK's vote to Leave the European Union was an act of xenophobia (demonstrated here and elsewhere), when all surveys show that along with Norway the UK is one of the most welcoming countries for migrants in the whole of Europe. The "increase in hate crime" you read about is simply an increase in the recording of accusations of "hate crime", which can include being mean to someone on Twitter. 99% of these alleged crimes are never investigated. It's quite ridiculous.

The sneering and sarcasm I'm reading tells me that both here and in the US and in Europe the left has completely failed to absorb any lessons from Trump, Brexit and most recently the complete annihilation of Corbyn at the ballot box. On current trend it'll be at least one more election cycle before it starts to sink in.

9. **Peter Woit**
January 28, 2020

Robinson,
Yes, countries need immigration policies. I don't think there was anything all that wrong with the Obama-era ones here in the US, or the pre-Boris Johnson ones in the UK (which I am less familiar with).

I find it hard to believe that anyone is naive enough to believe that Trump/Johnson/Cummings are simply well-meaning public servants driven by an intense desire to work out a fair and just immigration system. I do think that most people, at least in the US, have absorbed a big lesson from Trump: dishonest pandering to xenophobia can help a lot in bringing you to power and keeping you there. The question is what to do about this lesson. The right has decided to embrace this tactic and support the demagogues using it, the left, it is true, has found no way to fight it.

Sorry, but on the hot-button immigration issues, no more here now, this kind of internet comment section debate is worthless.

10. **AcademicLurker**
January 28, 2020

How attractive are the working conditions for mathematicians (and academics more generally) in the UK these days. I haven't paid too much attention, but my impression was that UK universities have in recent years become even more ridiculously bureaucratic and metrics crazed than those in the US.

11. **Rod Deyo**
January 28, 2020

It's nice that pure mathematics will be generously funded in the UK, but will new theorems about motivic homotopy, p-adic Galois representations, or even a solution to the latest Erdos conjecture you never heard of, really solve society's economic and social problems?

At least the US is throwing money at more "applied" will 'o wisps, such as quantum computing.

12. **SnarkyButNotTotallyWrong**
January 28, 2020

Rod,

"but will new theorems … really solve society's economic and social problems?"

Perhaps! Because every highly intelligent person to whom you grant a lifetime position with a slightly better than subsistence salary and a small office stuffed with arcane books where they can live out the rest of their days pondering motivic homotopy and p-adic Galois representations in obscurity is one less highly intelligent person who could otherwise use their skills to destroy the world (witness, for example, Dominic Cummings).

13. **Anonyrat**
January 28, 2020

This webpage on UK funding of the mathematical sciences may be of interest. It has some nice charts and tables about areas of funding.

https://epsrc.ukri.org/research/ourportfolio/themes/mathematics/

14. **Peter Woit**
January 28, 2020

Anonyrat,

That's for current EPSRC math research grants. I'm curious if there's anything available explaining where the new money will be targeted. Note that the 100 million pound number seems to be for total (presumably multi-year) grant commitments. I gather many of these are grants for up to six years. The description of the new money is that it is for 300 million pounds over 6 years, so this is consistent with a truly huge increase in funding for math research grants.

Perhaps someone who actually understands these numbers can explain better what the current situation is and how it will change.

15. **Anonymous**
January 29, 2020

The £60 million/year will go to: 1) extending PhD fellowships and Research Associate positions to 4 and 5 years respectively (£19 million); 2) different kinds of grants (£34 million), and 3) extra money for specific research institutes in Bristol, Cambridge and Edinburgh (£7 million).

More details in

https://epsrc.ukri.org/newsevents/news/major-funding-boost-for-mathematical-sciences/

16. **Anonyrat**
January 29, 2020

As of 2017/18: "The current funding landscape in the UK shows significant overseas funding for Mathematical Sciences with £21.5m research income from the EU and £7.1m from other overseas sources. Together these account for 28% of the total research income to Mathematical Sciences compared with 55% from UK Research Council funding and 17% from other sources including health, industry and charities."

https://www.lms.ac.uk/sites/lms.ac.uk/files/files/LMS%20Mathematical%20Sciences%20and%20the%20Industrial%20Stategy%20designv17.pdf

17. **Amitabh Lath**
January 29, 2020

If you want to create native mathematicians maybe spend some of those $$ on K-12 math instruction? The "honors" math track in the US seems to be pre-calc in 11th grade and AP-calculus in 12th. Full disclosure, I have a kid in 11th grade on this trajectory. It's a good high school (Alan Guth's an alum!).

A few miles south there are some rich school districts that offer Calculus to 10th graders, differential equations in 11th, and real analysis in 12th. About 2-3 dozen students/yr go this track. I suspect this setup is replicating the path familiar to the asian immigrant STEM-professional parents who make up a sizable minority in these districts.

You might argue this is a waste of money, and injures students but I interview these kids for MIT and a common refrain is I didn't know what math was for until I did analysis!

18. **Peter Woit**
January 29, 2020

Anonyrat,
Nature has an article about the post-Brexit scientific relationship with the EU. In brief, nothing will change for a while, very much up in the air what they'll agree on for the future.

https://www.nature.com/articles/d41586-020-00215-0

Amit,

The new UK government's decision to make math research one of its first priorities, with emphasis on bringing in foreign researchers, is pretty unusual. More conventional would be to emphasize funding math education, with a goal of training those now in the UK to staff these research jobs. It looks like the new British government hasn't yet figured out exactly what it will do about education, see
https://www.theguardian.com/education/2019/jul/31/will-boris-johnsons-present-for-hard-up-teachers-be-enough

And, yes, for the best young math students, providing a curriculum in high schools that goes beyond basic calculus is a good idea. In the list you give, I'd replace real analysis with linear algebra.

19. **tulpoeid**
January 29, 2020

Although this will probably not appear in the comments section, I'd like to +1 opinions like Robinson's "there's a general misconception in certain quarters that the UK's vote to Leave the European Union was an act of xenophobia". It surprises me, as a scientist, to see people opposing Brexit on the ground of perceived xenophobia _and_ being totally dismissive to its supporters (in some cases as if the latter are too idiotic to even be present in online forums).

Some, or many, people voted for Brexit because of immigration. Many others did for completely different reasons. I'd never vote for remain if I were a UK citizen, as I oppose the political-financial structure that the EU has become today – therefore I believe that there are several others like me in UK right now.

But still, if we decide to focus on immigration, it'd be helpful to consider how many non-native inhabitants the UK has: the answer is *a lot*. This aspect shouldn't be disregarded, the British society shouldn't be dumped while other, actual xenophobic governments in countries where immigrants are suffering, are made to look angelic in comparison.

20. **Peter Woit**
January 29, 2020

tulpoeid,
I've no interest in debating the substantive issues around Brexit. I'm not that well-informed and it's not my country. A couple explanations though of why I have referred (with "inflammatory sarcasm") to the Cummings/Brexit/immigration issue.

1. While I'm not so well informed about the UK, I'm very well-informed about the US, where Trump and his enablers have very successfully exploited dishonest appeals to xenophobia in order to come to power. We've seen a lot of this here, with surely a lot more to come before November. The little I've seen of the UK media coverage of the immigration issue there smells exactly the same as the garbage we're subjected to here by Fox and Trump.

2. Cummings has played a central role in this. For those not familiar with the story, see for instance
https://www.theguardian.com/commentisfree/2019/jan/08/vote-leave-racism-brexit-uncivil-war-channel-4
which covers some of the story of the dishonest but effective way Cummings used his talents at Vote Leave to get out the xenophobe vote.

I don't think Cummings/Johnson are xenophobes themselves, but I do think Cummings is a master of the new technology of social control. Now that he's more or less in charge of the country, perhaps he'll use his talents for good, not evil. But best to be aware of the history of your new masters. Making an honest case to the public is not their thing.

21. **Dan F.**
January 30, 2020

Only about half of US federal funding for mathematical sciences comes from the NSF. The rest comes from the DOD, DOE, etc., and the real funding levels for mathematical sciences are somewhat higher than you indicate.

22. **David Schaich**
January 30, 2020

Although this is made clear in the links provided above, it may be worth emphasizing here that the "mathematical sciences" to be supported by this windfall are broadly defined in the UK, ranging from proving theorems to engineering and "Innovative Manufacturing". The funding is going to the Engineering and Physical Sciences Research Council (EPSRC), which does what it says on the tin. While my view may be distorted by the funding calls that come to my attention, I expect quantum technologies (uknqt.epsrc.ac.uk), data science, machine learning and artificial intelligence to be major beneficiaries (among others, of course).

One complication is that most nuclear/particle/astro/cosmology research—especially on the experimental side—is funded by a different Research Council, the Science and Technology Facilities Council (STFC). EPSRC and STFC are doing some joint funding of quantum simulation research, and each funds their own national supercomputing facilities (ARCHER and DiRAC, respectively). My area of lattice field theory is mostly STFC-supported, but can go after some EPSRC funding by focusing on data science and high-performance computing aspects. Similarly, string theory is mostly STFC-supported, but can go after some EPSRC funding by focusing on 'mathematical physics' aspects. I'm told that EPSRC support for string theory (and anything else that looks nuclear/particle/astro/cosmology) has dwindled over the past decade, but it may rebound now that they have all this extra cash to spend.

Regarding AcademicLurker's comment, my experience is indeed that UK universities are more bureaucratic and metrics-focused than those in the US, with the caveat that I was only a student and postdoc in the US, which shielded me from the bulk of the bureaucracy there. Salaries also tend to be lower in the UK, but on the plus side there's not a tenure gauntlet.

23. **tulpoeid**
January 31, 2020

    I see, that link about the brexit campaign seems quite illuminating (and takes into account that not everyone anti-present-EU is a racist).

24. **theoreticalminimum**
February 6, 2020

    Well, someone else has a take on Cummings: https://www.theguardian.com/politics/2020/feb/06/inside-the-mind-of-dominic-cummings-brexit-boris-johnson-conservatives

25. **Art**
February 18, 2020

    Oh dear. Respect for science devolves into advocacy of racism. Cummings, meet Schockley…

Various

February 3, 2020
Categories: Uncategorized

- A few months ago I ended up doing a little history of science research, trying to track down the details of the story of the Physical Review's 1973 policy discouraging articles on "Foundations". The results of that research are in this posting, where I found this explanation from the Physical Review editor (Goudsmit) of the problem they were trying to deal with:

  > The event shows again clearly the necessity of rapid rejections of questionable papers in vague borderline areas. There is a class of long theoretical papers which deal with problems of interpretation of quantum and relativistic phenomena. Most of them are terribly boring and belong to the category of which Pauli said, "It is not even wrong". Many of them are wrong. A few of the wrong ones turn out to be valuable and interesting because they throw a brighter light on the correct understanding of the problem. I have earlier expressed my strong opinion that most of these papers don't belong in the Physical Review but in journals specializing in the philosophy and fundamental concepts of physics.

  I had heard that people studying foundations of quantum mechanics, frustrated by this policy, had started up during the 1970s their own samizdat publication, called "Epistemological Letters". I tried to see if there was any way to read the articles that appeared in that form, but it looked like the only way to do this would be to go visit one or two archives that might have some copies. Unbeknownst to me, around the same time Notre Dame University had just finished a project of scanning all issues of *Epistemological Letters* and putting them online. They are now available here, with an article about them here and an introductory essay here.

- There's an interesting essay on the arXiv about the current state of BSM physics, by HEP theorist Goran Senjanović, entitled Natural Philosophy versus Philosophy of Naturalness.
- Here's an article about problems string theorist Amer Iqbal has been having in Pakistan.
- The New York Times has an article about Cedric Villani and his campaign for mayor of Paris. The election is next month, and I'm having a hard time figuring out why Villani is running. There doesn't seem to be a lot of difference in policy views between the current mayor (Hidalgo) and the Macronistas (Griveaux and Villani), with the main effect of Villani entering the race a splitting of the Macron party vote.
- I was sorry to hear recently about the death of mathematician Louis Nirenberg. Kenneth Chang at the New York Times has written an excellent obituary. Terry Tao has some comments here.

Update: Excellent rant on Twitter from Philip Ball about misrepresentations of the Copenhagen interpretation. For your own rants, please engage in them on Twitter rather than here.

   February 4, 2020

   Peter,
   Do you have anything to disagree with Goran Senjanović paper?

2. **Peter Woit**
   February 4, 2020

   Akhil,

   I mostly agree with the paper. As Senjanović points out, the problems with SUSY models/GUTs/naturalness were all known pre-LHC. It's interesting to see that the LHC results are now causing people to recognize these problems.

   I agree with him that the neutrino sector of the SM is now the part where there are mysteries that experiments might soon shed light on. I disagree about left/right symmetry, the left/right asymmetry I think is a fundamental feature of space-time.

3. **Peter Woit**
   February 4, 2020

   By the way, I just noticed that the new issue of Symmetry is out, with first article "Fine-tuning versus naturalness" that starts with the sentence:

   "When physicists saw the Higgs boson for the first time in 2012, they observed its mass to be very small: 125 billion electronvolts, or 125 GeV."

   Note that there's something obviously very peculiar about this. Since 125 GeV is higher mass than any other state known except the top quark, an equally good first sentence would have been:

   "When physicists saw the Higgs boson for the first time in 2012, they observed its mass to be very large: 125 billion electronvolts, or 125 GeV."

   What the author doing is assuming that the right way to measure masses is in terms of a GUT scale (there is no evidence at all for GUTs), or the Planck scale supposed to be relevant to quantum gravity (we don't know what quantum gravity is).

4. **Janko Frazzle**
   February 4, 2020

   I'm disappointed with Cedric Villani, he should know better. To be a great mathematician you need to have an interest in the subject from early childhood, and the same is with politics.

5. **Peter Woit**
   February 4, 2020

   Janko Frazzle,
   The French have in the past had political leaders who were first-rate mathematicians (e.g. Paul Painlevé). As for Villani, if you read his memoir you'll see that he consciously set out to win a Fields Medal, and successfully did so. With that track record, I wouldn't discount his prospects for achieving whatever his next goal is.

6. **Peter Shor**

February 4, 2020

It seems to me that the comment

> "Most of them are terribly boring and belong to the category of which Pauli said, "It is not even wrong". Many of them are wrong.

probably was true. Quantum foundations is a very attractive area for cranks, most of whose papers would be wrong or "not even wrong". On the other hand, throwing out all these papers, even those by lesser-known bona fide physicists[1], seems to me to be a mistake on the order of a math journal saying that, because they have been deluged by a flood of incorrect papers proving the Riemann hypothesis, that they will reject all such papers without even looking at them.

On the other hand, most of the cranks probably didn't even known that *Epistemological Letters* existed, effectively pre-screening submissions to it.

[1] Surely they wouldn't have rejected a foundations paper by Feynman without looking at it first.

7. **Peter Woit**
February 4, 2020

Peter Shor,
When I looked into the actual story, see
https://www.math.columbia.edu/~woit/wordpress/?p=11263
I found that it was just not true that Phys Rev had a "no foundations" policy. The supposed "no foundations" policy was announced here
https://journals.aps.org/prd/pdf/10.1103/PhysRevD.8.357
which starts off with explaining the reason for the policy:
"We occasionally receive a manuscript for which it is extremely difficult and sometimes impossible to find a suitable referee who is willing to read it."
This clearly would not a apply to a paper from Feynman…

Goudsmit later gave a specific example of why they instituted the policy, this paper:
https://journals.aps.org/prd/abstract/10.1103/PhysRevD.8.1679
In his archives you can find a long discussion of the difficulties they had trying to get this paper properly refereed.

8. **Suomynona**
February 5, 2020

Peter Shor,
My understanding of Feynman's work is that he was uninterested in epistemological issues, so it's unlikely he would have submitted something which violated the policy anyway.

Another note on Goudsmit is that he also had a similar policy on the other end of the spectrum, for papers perceived as too much about technological or engineering developments. Apparently some of the foundational papers developing the physics of the laser were rejected without review as the author described their work as on the "optical maser" (at the time, masers were widespread laboratory instruments).

9. **Felipe Pait**
February 5, 2020

Part of the reason why Villani is running may be that he can. The election in Paris is in 2 rounds, which means that a candidate that doesn't win can 1) gain name recognition; 2) bargain support in the 2nd round; and 3) not be tainted as a spoiler for splitting the vote.

It is somewhat like a primary in the US, full of candidates that can at most hope to get a spot as vice president or in the next round of elections.

10. **Peter Shor**
February 5, 2020

Suomynoma: Actually, Feynman was interested in epistemological issues (he was interested in everything); I assume he never published anything about it because he never figured out anything interesting and new to say about them.

When I was at Caltech as an undergrad, Feynman gave a talk where he explained that he had looked at Bell's theorem, trying to find hidden hypotheses. The hidden hypothesis he identified was that all probabilities had to be between 0 and 1, so he was trying to figure out whether negative probabilities could get around Bell's theorem.

He later published a paper about negative probabilities, but it didn't solve the difficulty with local hidden variable theories, and his motivation for looking at the question was only mentioned very briefly in it.

11. **Blake Stacey**
February 5, 2020

An interesting discovery from looking into the history last September was that Goudsmit actually declared a subject *non grata* three times in its first decade of PRL: masers in 1959, the Mössbauer effect in 1960 and gauge theories in 1965. In all these cases, the motivation was that too many mediocre, trend-following papers were being received, and so new ones would only be considered if they stuck to a high standard of concreteness. The bit of lore that they rejected the first article on lasers because they thought it was just another maser paper might or might not be true.

12. **Anon**
February 6, 2020

Hi Peter — The observed light neutrino masses (m_nu) suggest a heavy right handed neutrino mass scale ~ v_weak^2/m_nu which works out to be about 10^14 GeV when we put in v_weak~200 GeV, m_nu = 0.5 eV.

The above is simple dimension analysis — we can get large mass scale from two mass scales, and the physical reasoning behind this is the well known seesaw mechanism. Now 10^14 GeV is beyond reach of colliders. So if we want the large mass or new physics scale to understand the origin of neutrino masses to be at the TeV scale we need to multiply 10^14 GeV by a dimensionless small number ~10^{-11}. Such a small prefactor can physically be there if the Dirac type Yukawa couplings of the neutrinos are ~ sqrt{10^{-11}} = 10^{-5.5}.

Now we can argue that there is no reason why such a small prefactor cant be there in nature and search for the physics of the seesaw mechanism (right handed currents, neutrinos etc) at the TeV scale. But really is this physics more likely to be there at the LHC or even the next collider or is this physics more likely to be at 10^{14}GeV?

Naturalness arguments have generally worked and therefore the faith that multiplying by a small prefactor and getting the answer we want (namely reachable by LHC) is not likely to pay big dividends.

The Higgs mass seems to be fine-tuned and naturalness arguments appear to not work in this case, but naturalness is still a very useful guide (in experience of science over generations it usually works) and if the neutrino mass physics is indeed at 10^14 GeV then better to start thinking of what experiments can provide evidence for something at that scale (it could be other precision tests) rather than only working on LHC/TeV scale physics for right handed or B-L breaking scale.

Of course those guided by the idea that it is best to work at the TeV scale would also be doing great work because maybe there is a prefactor of 10^{-11} in the above. LHC or the next collider may help prove there isn't (most probable outcome aka nightmare scenario) or if it is there there that would be a remarkable discovery.

I dont see why people cant purse both approaches — or as a community we cant pursue both — trying to find BSM physics at TeV scale though there is no real reason or natural reason to expect one, as well as think of innovative ways to probe our theories even if their mass scale is out of reach of the LHC and conceivable future colliders.

13. **Peter Woit**
February 6, 2020

Anon,

The argument against usual Dirac mass-terms for neutrinos is that the ratio of electroweak scale to neutrino mass would then be unexpectedly large ("unnatural"). But we already know that the ratio of electroweak scale to the electron mass is very large (like 400,000). To me this just makes the point that we don't have any idea where the Yukawas come from, and not only no good reason to expect them to be order one, but plenty of evidence that there's an an unknown reason for them to be very small. I understand the usual seesaw argument, I just don't think it's all that strong an argument for a new physics mass-scale.

My earlier comment about possible new results about neutrinos was mainly a reference to non-collider experiments (neutrinoless double beta decay, sterile neutrinos). The speculative idea of a new high mass scale to explain neutrino masses doesn't affect my later comment that saying the Higgs mass is "small" makes no sense, since you should be comparing it to scales you know exist, not speculative ones.

14. **Amitabh Lath**
February 6, 2020

I never thought of naturalness as anything more than handwaving guesses. Sort of like Enrico Fermi's guess at the number of piano tuners in Chicago. Imagine if after Fermi made the guess they walked around looking for piano tuners and didn't find any. Maybe there is something suppressing piano tuners. Maybe they can't afford to live in Hyde Park and all moved to Englewood. Maybe people prefer woodwinds and gave up piano. Or maybe the piano tuners are there but you can't see them because they look like normal people.

Goran Senjanović's assertion that naturalness is some deep philosophical choice seems too harsh. Naturalness is what you do when you don't really have any other way.

Also, the bit about LHC experiments having a SUSY group and separate exotica group is true, but it's not because of we think SUSY is somehow better than. Essentially we sort physics signatures that have large missing momenta (MET) into the SUSY group, and everything else into the exotica group. I work on R-parity violating SUSY and that's in the exotica group because no MET.

15. **Anon**
February 6, 2020

Well we do know that the charged lepton Yukawa couplings of tau, mu and electron are similar to the bottom, strange and down quarks' Yukawa couplings. That is a good reason to expect the Dirac Yukawa couplings of nu_tau, nu_mu, nu_e to be similar to top, charm and up quarks' Yukawa couplings respectively.

Of course, it is not a proof but is a strong motivation to do further research with this thinking.

One can also, of course, assume as you seem to prefer, that the Dirac Yukawas of all three neutrinos are very very small and the light neutrino masses are all Dirac type, and nature has an exact B-L symmetry that prevents the Majorana mass term in the SM with the addition of 3 right-handed neutrinos.

16. **Goran**
February 7, 2020

Some comments on the comments on my essay. When I give an example of the LR symmetric theory, claiming it is a self-contained, predictive model of the origin of neutrino mass (analog to Higgs-Weinberg mechanism for charged fermion masses), I do not want to convince the reader of my starting point, I am only asking her or him (read Peter in this case 🙂 to appreciate the structural correlations that follow unambiguously. Moreover, it was the LR theory that led originally to neutrino mass long before experiment (many were telling me in the seventies that I was wasting my time – neutrino was supposed to be massless to most).

All I am doing in my essay is to advocate that high energy physics goes back to being natural philosophy in the Newton's sense of the world. You may be as philosophical as you wish, but you must make predictions and let the experiment decide, period. Which is why I argue against the obsession with naturalness as the main guiding principle for the BSM physics. Simply, it failed to produce an analog self-contained framework with verifiable predictions, and instead became a never ending game whose rules can change as and when one wishes.

17. **Goran**
February 7, 2020

Regarding the scale of seesaw. Seesaw by itself is just a scenario which basically says nothing – you are supposed to accept that a particle at unreachable energies 'explains' the smallness of neutrino mass? I argued, albeit briefly (I cite relevant papers for in-depth analysis) that a way to new physics and information about its scale ought to come through a well defined theory and experiment. In this case it is neutrinoless double beta decay which may be caused by neutrino Majorana mass or new physics behind it (or both). If the former explanation fails, say because we learn meanwhile that the hierarchy is normal, or even better, if electrons coming out were say RH, then we would need new physics. Simple dimensional analysis tells you then new physics must lie at energies not far from the LHC – and in the LR theory it is really hard to go above the 6 TeV LHC reach for the mass of the RH gauge boson. In other words, it is experiment and not wishful thinking that should (and can) decide the whether or not there is a small coupling in the Weinberg operator. Btw, the small coupling is rather natural in the LR theory where neutrino and electron live together – the 10^{14} GeV cut-off requires neutrino Dirac mass on the order of the top quark mass.

This said, if neutrino hierarchy ends up being inverse, or better, if you saw the neutrinoless double beta decay with LH electrons, I for one would, admittedly sadly, be first to admit no reason for new physics behind neutrino mass at reachable energies.

18. **Kris Krogh**
February 7, 2020

Peter,

I would guess you've never read John Bell's book, *Speakable and Unspeakable in Quantum Mechanics*, published in 1987. It's a compilation of his papers on quantum mechanics, each of them remarkably insightful. The majority were never published in mainstream journals, and several are from *Epistemological Letters*. That was definitely a reflection of the politics faced by Bell and his collaborators, as suggested by the book's title. Although the publishing situation is different now, those politics are still not behind us.

19. **Peter Woit**
February 7, 2020

Kris Krogh,
I have looked at that book, and read some of the articles in it. From what I remember I was put off by Bell's fondness for Bohm/hidden variables, and didn't find what I was reading helpful in terms of providing any insight into what seems to me the main problem (emergence of the classical from quantum).

20. **tulpoeid**
February 23, 2020

[I tried to put this under more relevant posts but they're closed.]
FYI, from a new interview with Jean Iliopoulos of GIM-mechanism fame (and well-known susy fan):
"What makes you be so sure about the existence of supersymmetry?"
"I am not."

Robert Hermann 1931-2020

February 15, 2020
Categories: Obituaries

I was sorry to hear today of the recent death of Robert Hermann, at the age of 88. While I unfortunately never got to meet him, his writing had a lot of influence on me, as it likely did for many others with an overlapping interest in mathematics and fundamental physics. Early in my undergraduate years during the mid-1970s I first ran across some of Hermann's books in the library, and found them full of fascinating and deep insights into the relations between geometry and physics. Over the years I've often come back to them and learned something new about one or another topic. The main problem with his writings is just that there is so much there that it is hard to know where to start.

While the relations between Riemannian geometry and general relativity were well-understood from Einstein's work in the beginning of the subject, the relations between geometry and Yang-Mills theory were not known by Yang, Mills or other physicists working on the subject during the 1950s and 1960s. The understanding of these relations is conventionally described as starting in 1975, with the BPST instanton solutions and Simons explaining to Yang at Stony Brook about fiber bundles (leading to the "Wu-Yang dictionary" paper). But if you look at Hermann's 1970 volume Vector Bundles in Mathematical Physics, you'll find that it contains an extensive treatment of Yang-Mills theory in terms of connections and curvature in a vector bundle. While I don't know if Hermann had written about the sort of topologically non-trivial gauge field configurations that got attention starting in 1975, he had at that point for a decade been writing in depth about the details of the relations between geometry and physics that were news to physicists in 1975.

Being ahead of your time and mainly writing expository books is unfortunately not necessarily good for a successful academic career. Looking through his writings this afternoon, I ran across a long section of this book from 1980, entitled "Reflections" (pages 1-82). I strongly recommend reading this for Hermann's own take on his career and the problems faced by anyone trying to do what he was doing (the situation has not improved since then).

A general outline of his early career, drawn from that source is:

1948-50: undergraduate in physics, University of Wisconsin.
1950-52: undergraduate in math, Brown University.
1952-53: Fulbright scholar in Amsterdam.
1953-56: graduate student in math, Princeton. Thesis advisor Don Spencer.
1956-59: instructor at Harvard ("Harvard hired me as an instructor in the mistaken belief that I must be a topologist since I came from Princeton").
1953-59: "My *real* work from 1953-59 was studying Elie Cartan!"
1959-61: position at MIT Lincoln Lab, taught course at Berkeley in 1961.

Hermann ultimately ended up at Rutgers, which he left in 1973, because he was not able to teach courses there in his specialty, and felt he had too little time to conduct the research he wanted to work on. It appears he expected to get by with some mix of grant money and profits from running a small publishing operation (Math Sci Press, which mainly published his own books). The "Reflections" section of the book mentioned above also contains some of his correspondence with the NSF, expressing his frustration at his grant proposals being turned down. At the end of a letter from late 1977 (which was at the height of excitement in the physics community over applying ideas from geometry and topology to high energy physics) he writes in frustration:

> However, when I look in the *Physical Review* today, all the subjects which people in your position so enthusiastically supported ten years ago are now dead as the Phlogiston theory – and good riddance – while the topics I was working on then are now everywhere dense. Does one get support from the NSF by being right or by being popular?

John Baez has written something here, and there's an obituary notice here.

Update: I've been reading some more of the essays Hermann published in the "Reflections" section of this book. Especially recommended is the section on Mathematical Physics of this 1979 essay (pages 30-38). His evaluation of the situation of the time I think was extremely perceptive.

Update: For more about Hermann, see some of the comments at this old blog posting. Also, on the topic of his book reviews, see this enthusiastic review of the Flanders book *Differential forms with applications to the physical sciences*.

Update: For an interesting review covering many of Hermann's books, at the Bulletin of the AMS in 1973, see here.

Comments

1. **Geoffrey Dixon**
   February 15, 2020

   RH advised me for a time when I was a math grad student at Rutgers. Later, as a grad student in physics at Brandeis, I moseyed into Cambridge in hopes of sounding out Glashow on my division algebra ideas. I was allowed to speak with Sheldon, but he confessed that abstract math was not his specialty, and I left shortly thereafter somewhat flustered. I ran into Robert Hermann in the science building cafe after I left and we sat together. I had just started explaining my ideas to him when Sheldon walked by. He spotted us, came over, and said that Robert was just the person I should be talking to. Of course, he was right. Sheldon sat with us, and I lost what little coherence I had left and made a poor showing of myself until I left a little while later. That, unfortunately, was the last interaction I remember having with Robert H, a really good guy. Had I known he was in town I would have gone straight to him. Alas … (About 18 years later I taught an undergrad course in particle physics with Sheldon G at Harvard; also a really good guy.)

2. **xyz abc**
   February 16, 2020

   Every time I think of Hermann, I always tend to relate him to Spivak, in view of their unique and somewhat idiosyncratic career paths.

   Many things puzzled me over the years about Hermann, one of which being what is mentioned in this post. Namely how he did not end up getting due credit for having attempted to drawn connections between gauge field theory and differential geometry on fibre bundles even before Wu-Yang-Simons. I once heard rumors that I. M. Singer had actually noted Hermann's contributions in this area.

   Another strange anecdotal mystery to me is Hermann's relationship with Sternberg. "Being critical" is perhaps an understatement about his BAMS review of Sternberg's 1964 book, in which Hermann was in fact acknowledged by the author. (In all fairness though, Hermann's book review was safely towered in its acrimonious level by Barry Mitchell's on "Module Theory" written by a romannian mathematician.) In a subsequent year, Hermann appeared to explain at pains in one of his papers on Cartan's EDS how his work was independent but perhaps no less valuable than the opus published at a slightly earlier time by Singer and Sternberg.

   If one were to be pessimistically cynical, one would likely not be surprised at the tremendous amount of latent ego right underneath the thin skins of apparently humble mathematicians.

3. **Peter Woit**
February 16, 2020

xyz abc is referring to this 1965 review
https://www.ams.org/journals/bull/1965-71-02/S0002-9904-1965-11286-1/
I don't know what relations were like between Sternberg and Hermann, note that Hermann left Harvard (and says he wasn't very happy there) about the time Sternberg arrived (1959).

It's interesting to compare this review to this 1982 one of a Hermann book
https://www.ams.org/journals/bull/1982-06-03/S0273-0979-1982-15019-4/S0273-0979-1982-15019-4.pdf

which is also a quite critical review. Hermann and Sternberg shared many of the same interests, as well as each writing quite a few expository books. While in many ways different, their books to me seem to share some similar features. These include a mixture of beautiful, deep and insightful exposition of material not available elsewhere (although sometimes very demanding of the reader), together with some idiosyncratic material of less value. Maybe this is generically what happens if you spend a lot of your life absorbing the ideas of Elie Cartan, and then start writing a lot of books…

4. **James Hart**
February 20, 2020

I just read the recommended selection from his book "Reflections" and I am more than a little impressed at his insights, at his clarity of thinking, and just how well he understood the problems our fields were facing. (I have a PhD in physics, but a strong interest in mathematics for its own sake and have given myself a crude first-year course in University mathematics via textbooks and supplementary online reading. It's no replacement for a real degree, but it makes me less of an idiot when dealing with reading things like that book.)

5. **D. F.**
February 21, 2020

Hermann's review of Sternberg's book is positive, bordering on enthusiastic. I'm not sure how anyone reading it could conclude that phrases such as "In this chapter Sternberg gives us, with great expository skill and taste, a glimpse of vast research areas …" are anything else. Criticisms are made, but they are constructive, not tendentious, and they are offered in a friendly way, not a destructive one.

6. **Peter Woit**
February 21, 2020

D.F.,
The summary is
"In summary, this is a book that contains much useful material and that is, in general, well written, but that is marred by inattention to detail."
but, in any case, I hadn't heard that there was any particular problem between Sternberg and Hermann.

Hermann made public some of the negative grant referee reports, and they seem to me to reflect not personal hostility but an unsurprising negative take on a proposal to fund someone not playing by the conventional rules (i.e. quitting his job and writing not journal articles but self-published mainly expository books).

7. **Anonyrat**
February 22, 2020

In the beginning pages of the Hermann link above, Hermann must have pounded on Kac's "dehydrated elephants" half a dozen times. What exactly was all that about?

8. **Peter Woit**
February 24, 2020

Anonyrat,
He was referring to this essay by Mark Kac (of Rockefeller University, where Hermann had been for a while)

https://www.jstor.org/stable/43636233

It's pretty much a ferocious attack on the sort of mathematical physics practiced by Hermann, starting off with "it seems self-evident that mathematics is not likely to be much help in discovering laws of nature". Like Hermann, I strongly disagree (but don't want to start here the same argument about this that has often featured on this blog, most recently over Sabine Hossenfelder and "Lost in Math").

Kac's specialty was probability and analysis. He had little interest in geometry, even as mathematics, so not surprising he didn't see it as important for physics. Note that the essay was written in 1972, same year Weinberg's gravitation textbook was published, which also took the attitude that geometry was not important for physics, writing "the passage of time has taught us not to expect that the strong, weak, and electromagnetic interactions can be understood in geometrical terms"

This didn't age well, with 1973 seeing the triumph of gauge theory, the mid-late 1970s the dominance of ideas about geometry and topology in the subject, and by the 1980s Weinberg himself was working on such things, see discussion here
https://www.math.columbia.edu/~woit/wordpress/?p=529

So, the historical context for Hermann's comments about this was that he was living through a period (late 1970s) of vindication of his point of view, a few years after Kac's attack on it.

9. **S**
February 24, 2020

I'm very sorry to hear this. Finding an old, beautiful paper of Hermann was key to my being able to get over an obstacle in my thesis. I always hoped to contact him and thank him, and even wrote an email or two trying to get his address, but none of it led anywhere, and I'm sorry I wasn't more persistent. I now have a number of his books, and look forward to mining them for insights. (I had the opportunity to own a very large number of his books, but unfortunately, the amount of shelf space they would take was ponderous, so I took only those that seemed best.)

RIP.

10. **Peter Orland**
February 25, 2020

I bought a copy of Hermann's "Lie Algebras and Quantum Mechanics" as an undergraduate at UC Berkeley, back when pterodactyls blotted out the sun. I learned a lot of basic ideas from the book (although there was significant overlap with other books I was reading at that time). There is a good discussion of affine Lie algebras and Schwinger terms, although issues concerning regularization (which is the hardest part of QFT) are not really discussed. From my current standpoint I'd characterize the book as very broad in a good way, but not especially deep. Nonetheless, for a first exposure to the topics, it was accessible and fun.

11. **Peter Woit**
    February 25, 2020

    Thanks Peter,
    That's one book of Hermann's I haven't looked at but should. The topics you mention got a lot of attention in the 1980s. That Hermann was writing about them in 1969 is yet another example of him being way ahead of his time.

    I just ran into an interesting review from 1973 that covers many of his books, will add a link as an update.

Why String Theory Is Both A Dream And A Nightmare (as well as a swamp…)

February 26, 2020
Categories: Swampland, Uncategorized

Ethan Siegel today has a new article at *Starts With a Bang*, entitled Why String Theory is Both a Dream and a Nightmare. For the nightmare part, he writes:

> its predictions are all over the map, untestable in practice, and require an enormous set of assumptions that are unsupported by an iota of scientific evidence.

which I think just confuses the situation, which could be much more accurately and simply described as "there are no predictions". The fundamental reason for this is also rather simply stated: the supposed unified theory is a theory in ten space-time dimensions, and no one has figured out a way to use this to get a consistent, predictive model with four space-time dimensions. If you don't believe this, try watching the talks going on in Santa Barbara this week, which feature, after 17 years of intense effort, complete confusion about whether it is possible to construct such models with the right sign of the cosmological constant.

Siegel gets a couple things completely wrong, although this is not really his fault, due to the high degree of complexity and mystification which surrounds the 35 years of failed efforts in this area. About SUSY he writes

> For one, string theory doesn't simply contain the Standard Model as its low-energy limit, but a gauge theory known as N=4 supersymmetric Yang-Mills theory. Typically, the supersymmetry you hear about involves superpartner particles for every particle in existence in the Standard Model, which is an example of an N=1 supersymmetry. String theory, even in the low-energy limit, demands a much greater degree of symmetry than even this, which means that a low-energy prediction of superpartners should arise. The fact that we have discovered exactly 0 supersymmetric particles, even at LHC energies, is an enormous disappointment for string theory.

Like everything else, there's no prediction from string theory about how many supersymmetries will exist. The special role of N=4 supersymmetric Yang-Mills theory has nothing to do with the problem of low energy SUSY, instead it occurs as the supposed dual to a very special 10d superstring background (AdS5 x S5). This is of interest for completely different reasons, one of which was the hope that this would provide a string theory dual to QCD, allowing use of string theory not to do quantum gravity, but to do QCD computations. This has never worked, with one main reason being that it can't reproduce the asymptotic freedom property of QCD. Siegel tries to refer to this with

> And when you look at the explicit predictions that have come out for the masses of the mesons that have been already discovered, by using lattice techniques, they differ from observations by amounts that would be a dealbreaker for any other theory.

including a table with the caption

> The actual masses of a number of observed mesons and quantum states, at left, compared with a variety of predictions for those masses using lattice techniques in the context of string theory. The mismatch between observations and calculations is an enormous challenge for string theorists to account for.

He's getting this from slide 31 of a talk by Jeff Harvey, but mixing various things up. The table has nothing to with lattice calculations, those are relevant to the other part of the slide, which is about string theory predictions for pure (no fermions) QCD glueballs. These are not physical objects, thus the comparison to lattice computer simulations, not experiment. The table he gives is from here and about real particles. The "predictions" are not made as he claims "using lattice techniques in the context of string theory." There are no lattice techniques involved.

Normally Siegel does a good job of navigating complex technical subjects. The subject of string theory is now buried in a huge literature of tens of thousands of papers over forty years with all sorts of claims, many designed to obscure the fact that ideas haven't worked out. It's fitting that the name chosen for the kind of discussions going on at Santa Barbara this week is "The String Swampland". String theory verily is now deep in a trackless swamp…

Comments

1. **Simon Coveney**
   February 26, 2020

   Isn't string theory a mathematical framework, and the study of the landscape/swampland the study of the mathematical space of string theories, akin to model theory or topos theory in the foundations of mathematics to study the space of mathematical theories?

2. **Peter Woit**
   February 26, 2020

   Simon Coveny,
   No, not even slightly.

3. **Low Math, Meekly Interacting**
   February 27, 2020

   Have you reached out to Ethan? Attacking factual inaccuracies can serve as a useful rhetorical cudgel for those who seek to make fallacious arguments against an otherwise sound message. The article would certainly benefit from corrections for a number of reasons.

4. **Peter Woit**
   February 27, 2020

   LMMI,
   I don't think there's anything particularly wrong with the overall point of view of Siegel's piece. On the details of the problems of string theory he gets some things wrong, but on the whole, almost all non-technical articles about string theory get things wrong. The subject really has become a swamp that any non-expert will quickly get lost in. If I spent more time on this, trying to get people to fix things, it would be a thankless and pointless full-time job (look up "Augean Stables"…).

   I don't think string theorists will even bother to attack Siegel for this, especially since the correct statements are even worse for them (string theory doesn't predict N=4 SUSY since it predicts nothing). The current main tactic of string theory proponents is to just do their best to ignore criticism and try and pretend it doesn't exist. They're not likely to do anything that will get Siegel's piece more attention.

5. **Matthew Leifer**
   March 1, 2020

“Normally Siegel does a good job of navigating complex technical subjects”

No he doesn’t. As soon as he leaves his home territory of astrophysics he usually makes major errors. I have even made finding the factual errors in one of his posts into an exam question in the past.

This Week's Hype

February 28, 2020
Categories: This Week's Hype

Sabine Hossenfelder already has this covered, but I wanted to add a few comments about this week's hype, a new article in Quanta magazine by Philip Ball entitled Wormholes Reveal a Way to Manipulate Black Hole Information in the Lab (based on this paper). It's the latest in a long tradition of bogus claims that studying relatively simple quantum systems is equivalent to studying string theory/quantum gravity. For an example from ten years ago, see here. The nonsensical idea back then (which got a lot of attention) was that somehow studying four qubits would "test string theory".

A first comment would be that this is just profoundly depressing, because Ball is one of the best and most sensible science writers around (see my review of his excellent recent book on quantum mechanics) and Quanta magazine is about the the best semi-popular science publication there is. If this article were appearing in any one of the well-known examples of publications that traffic in misleading sensationalism, it wouldn't be surprising and would best be just ignored.

Hossenfelder has pointed out one problem with the whole idea (we don't live in AdS space), but a more basic problem is the obvious one pointed out by one of the first commenters at Quanta:

> In the end, if an experiment is performed based on standard quantum mechanics, and verifies standard quantum mechanics as expected, then it is irrelevant that this aspect of standard quantum mechanics might be analogous to a vaguely-formulated and incomplete speculative idea about spacetime emergence — nor can it provide any experimental support whatsoever for that idea.

I understand that, for science journalists hearing that a large group of well-known physicists from Google, Stanford, Caltech, Princeton, Maryland and Amsterdam has figured out how to study quantum gravity in the lab (by teleporting things from one place to another via traversable wormholes!!), it's almost impossible to resist the idea that this is something worth writing about. Please try.

Update: Philip Ball responds here.

Update: More from Philip Ball (and, if it appears, a response from me) at the Quanta article comment section, ~~comments from one of the paper's author's~~ also comments here.

Update: Commenter Anonyrat points out that the Atlantic is republishing this piece, as A Tiny, Lab-Size Wormhole Could Shatter Our Sense of Reality: How scientists plan to set up two black holes and a wormhole on an ordinary tabletop.

Update: In the future, I hope to as much as possible outsource coverage of this kind of thing to the Quantum Bullshit Detector. Today, see for instance this.

Comments

   February 28, 2020

   Thanks for the link. It won't be long until the headlines say we can test string theory on a quantum computer.

2. **Peter Woit**
   February 28, 2020

   Sabine,
   I think that's just too old hat now. The time evolution has been:

   1990s: We can test string theory/quantum gravity at the LHC!
   Early 2000s: We can test string theory/quantum gravity at RHIC! We're creating black holes at RHIC!
   Late 2000s: We can test string theory/quantum gravity in condensed matter experiments! We're creating black holes in our condensed matter lab!
   2010s-now trend: The landscape has explained it all, who cares anymore about boring string theory? We now can test quantum gravity in atomic physics experiments! And we're creating multiple universes when we do it! And we're creating not just black holes but wormholes! And the wormholes are traversable and we're teleporting through them!!!!!!

   Looks to me like we're just months away from the physics hype singularity…

3. **Low Math, Meekly Interacting**
   February 28, 2020

   Quanta, the best new pop-sci outlet…

   I hardly knew ye.

4. **Peter Shor**
   February 28, 2020

   Reading the Quanta article, it looks like their experimental proposal is to *do* quantum teleportation (of a particularly complex kind) and *call it* a traversable wormhole by invoking the non-existent ER-EPR correspondence.
   This seems to me to be an ingenious way to address the objection that AdS-CFT is untestable in the real world.
   The original article is very difficult to parse, so I haven't read it yet, but I'd love to hear from somebody who believes that this isn't what they're proposing.

   I quote the Quanta article:

   > "The role of the coupling is to send the essential classical data, which, with the aid of entanglement, teleports the signal from one black hole to another," [Nezami] said.
   > This, at least, is how a quantum information theorist would view the process. But according to the AdS/CFT correspondence, the channel between the black holes created by entanglement is equivalent, in a description based on general relativity, to a wormhole in space-time that connects them.

   One question: were things like this the inevitable outcome of using the arXiv and dispensing with refereed journals?

5. **Adam H**
February 28, 2020

I couldn't have said it better than SH or Peter Shor. I also don't see what this accomplishes except to verify quantum teleportation(which has already been experimentally verified). Is this another sort of QM=GR idea? A true traversable wormhole should allow matter/info to arrive at a distant point in space faster than light could get there traveling from its origin. This is clearly not a traversable wormhole by that definition, and the same physicists involved in this enterprise would likely agree that true traversable wormholes are not likely to ever exist for consistency reasons.

6. **Blake Stacey**
February 29, 2020

Peter Shor:

> Reading the Quanta article, it looks like their experimental proposal is to *do* quantum teleportation (of a particularly complex kind) and *call it* a traversable wormhole by invoking the non-existent ER-EPR correspondence.

That seems accurate to me.

When I first read the ER=EPR proposal, it seemed motivated by very thin heuristics that just barely scratched the surface of quantum theory. E.g., entanglement can't be used for superluminal signaling, and messages can't pass through wormholes; therefore, the phenomena are analogous. This amounts to saying that a wormhole exists between any two correlated objects in the Spekkens toy model.

It's not clear to me that the Brown et al. proposal couldn't be done, qualitatively, with stabilizer states, Spekkens toy bits or correlated Gaussian modes. (The "thermofield double state" doesn't sound any more exotic, really, than using EPR pairs as purifications of thermal states in Gaussian quantum mechanics. The point seems to be that it's entangled and its marginals are Gibbs states.) I could be missing something important, but right now, I'm not seeing how it's *really nonclassical,* in the sense that nothing like it can be emulated in a local hidden-variable theory.

7. **Alex**
February 29, 2020

I wonder why people keep talking about "traversable wormholes" when there are numerous theorems in classical and semi-classical GR that put into serious doubt their physical feasibility. At the classical level, you need negative energy to stabilize them. This was proved by Hawking under very general conditions. Second, it was also proved by Hawking that when you put a quantum field in it, the whole thing instantly explodes and destroys all matter configuration that was holding it in place. One can still speculate that the Casimir effect may provide negative energy. Good luck with collecting the amount needed; besides, it will explode anyway. Well, you can speculate that quantum gravity may act as a cutoff for that energy divergence of the quantum field, but that is, as per today, just words, not serious physics. All currently tested serious physics says they can't exist. Period.

I really don't understand how these things can pass the peer review.

The second update points to a Twitter thread by a colleague of the authors who was thanked in the acknowledgments, not an author.

9. **Anonyrat**
March 1, 2020

The Atlantic online provides this headline for a re-hosting of the Quanta article:
"A Tiny, Lab-Size Wormhole Could Shatter Our Sense of Reality
How scientists plan to set up two black holes and a wormhole on an ordinary tabletop"

10. **CWJ**
March 1, 2020

Slightly off-topic, but I found it through one of the twitter threads: the APS March meeting has been cancelled due to concerns about Covid19

https://physicsworld.com/a/american-physical-society-cancels-march-meeting-in-denver-due-to-coronavirus-outbreak/

11. **Peter Woit**
March 1, 2020

CWJ,

Since physics labs around the country can create and manipulate wormholes, could everyone stay home and create wormholes to a lab in Denver, then run the conference via wormhole? Has anyone studied the problem of Covid19 transmission via physicist's wormholes? I'm not sure I would want to be entangled with someone who has the virus…

12. **Peter Shor**
March 2, 2020

Let me try to put it in simpler terms.

Suppose you take a balloon, and measure the distance between points on it. Then you inflate it more, and you see how much these distances have expanded. This *does not* tell you that the universe is expanding. It's an analogy.

The same thing is true for the experiment proposed in the paper. The experiment should succeed because quantum information theory works, not because of anything about general relativity and wormholes.

13. **Alex**
March 2, 2020

So, I did my homework and just read all the papers involved. They actually try to address the two points I mentioned about "ordinary" wormholes, so kudos to them in that regard. Problem is, the solutions are highly unsatisfactory. Regarding negative energy, they consider two asymptotic anti de Sitter universes, and in this way can obtain a negative energy carrying quantum field in an analogous way to the Casimir effect, where the boundaries of the anti de Sitter universes connected by the wormhole act as the conducting metal plates in the latter. The issue with this is, of course, that we don't live in anti de Sitter. So that isn't going to work for addressing the first point against the existence of wormholes. The second point is that, with stable ordinary wormholes, you can create closed causal curves and this produces energy blow ups in quantum fields. They solve this by considering a wormhole connecting two different universes and which collapses quickly enough (it's just a perturbed, by the negative energy quantum field, Kruskal wormhole.) Problem is, you need to start with a very particular initial state (two white holes in two different universes, or two different universes connected by a wormhole that collapses into two black holes.) This critique is also valid for the usual wormholes, since those geometries also assume an already created wormhole and no convincing method for their creation is proposed. In these new wormholes, they use the AdS/CFT duality and the ER=EPR hypotheses to argue that they are equivalent to a quantum teleportation experiment; thus, by creating a quantum teleportation you may be actually creating the wormholes. Of course, AdS/CFT duality and ER=EPR are highly speculative and mathematically unproven hypotheses, besides the already mentioned fact that we don't live in an anti de Sitter universe. So, the most likely result from a quantum teleportation experiment will be just to prove again the known phenomena of quantum teleportation and nothing more.

14. **Mark**
March 2, 2020

Alex,

This paper may be of interest to you (and other readers who care about substance not just sarcastic commentary): https://arxiv.org/abs/1807.04726
It's using Casimir energy, but it's building wormholes in flat space using Standard Model matter content.

15. **Peter Woit**
March 2, 2020

Mark,

Thanks! Especially impressive that, according to the Atlantic, you can build that thing on an ordinary tabletop.

16. **Alex**
March 2, 2020

Hey Mark, thanks! That was a very neat paper. I'm glad they are trying to address the actual problems. I think this is a good contribution to our understanding of wormholes, in line of Thorne's classic work. The most valuable thing, for me, is the exploration of quantum matter configurations (in the real world) that could be used to get the negative energy.

The only objection I have is that, again, a very special initial state for the geometry is assumed (even more weird than a mere standard eternal wormhole.) But they actually recognize this (in 9.3 Open questions) rather than adding baseless speculation, so kudos to them.

17. **John Baez**
March 3, 2020

Peter Shor wrote:

> One question: were things like this the inevitable outcome of using the arXiv and dispensing with refereed journals?

I think the problem is that real progress on high-energy particle physics and quantum gravity has been very slow for the last few decades, but people in these fields want to be doing impressive things, so many have turned to puffing up what they're doing, using all sorts of tricks to make it seem more exciting than it is.

In fields where there's more real progress and less grandiose ambitions, the arXiv seems to work pretty well.

18. **Peter**
March 3, 2020

I'm following this blog since I read "Not even wrong", but this is one of the weirdest things I've ever seen here.

Do I understand what's happening?

– You do an experiment on X, something you understand quite well;
– if you assume certain things (some of which are dubious, to put it mildly) the behavior of X should have in some way a resemblance with the behavior of something hypothetical, called Y, that you're not testing with the experiment;
– The result of the experiment on X tells you something about Y.

If this interpretation is correct, this idea is an interesting subject for a paper on Philosophy of Science. But it's not science like I know it.

19. **Peter Woit**
March 3, 2020

Peter,
Yes, that's right. This is "quantum gravity in the lab" where you are not testing anything to do with quantum gravity. Another way to see the problem: the idea seems to be to use some model to predict the experimental result. What are the possible outcomes?

1. The prediction works. You've learned that this is a useful model for describing this kind of physical setup. You've learned nothing about whether it's useful for describing quantum gravity.

2. The prediction doesn't work. You've learned that this is not a useful model for describing this kind of physical setup. Again, you've learned nothing about whether it's useful for describing quantum gravity.

20. **André**
March 3, 2020

To me it always feels like these analogue models for (quantum) gravity are a bit like what paper models are for architecture. You can certainly learn from them, if a wall here or there looks nice in a given context. And you might be able to use them to see if taking this wall or that wall out still gives you a stable structure. But often it seems to me, the conclusion people draw from them is that real houses should also best be built from paper.

21. **Low Math, Meekly Interacting**
March 4, 2020

    There's another important assertion in the article, which can seemingly hold regardless of what is implied about "reality": that Ads/CFT provides a simpler description of the system being modeled. I take that to mean, roughly, that it makes the math easier. Similar benefits (e.g. for some tough problems in QCD) have been promoted elsewhere. Any merit to this specific aspect of the claim?

22. **Peter Woit**
March 5, 2020

    LMMI,
    That's the hope, but the reality is that this hasn't worked for realistic systems. You can see the problem in the case of QCD, where AdS/CFT gives you a calculational method for N=4 susy Yang-Mills, but not Yang-Mills. You end up doing computations in a different theory than QCD, then hoping that some rough features of that computation apply to QCD. As far as I can tell, all advertised applications of AdS/CFT have similar problems. The underlying problem is that people believe there is some underlying gauge-gravity duality principle, that gravity duals always exist, but other than in certain very special examples don't know how to find the gravity dual. The "applications" of this duality to realistic problems become just general claims that certain kinds of phenomena on the realistic side will correspond to other phenomena on the gravity side, without any detailed prediction for exactly how this will work.

23. **Urs Schreiber**
March 5, 2020

    AdS/QCD is rich in quantitative predictions for confined QCD states, see here.

24. **Geoffrey Dixon**
March 5, 2020

    Am I correct in thinking that this surfeit of AdS/CFT talk is tantamount to looking for a nail in the dark under a lamppost because the light is better there, and anyway all you've got is a hammer, so the solution to your problem had better require a nail? Maybe two.

25. **Peter Woit**
March 5, 2020

    Geoffrey Dixon,

    Yes.

    Urs Schreiber,

    AdS/CFT is conformally invariant, spectrum looks nothing like QCD. AdS/QCD is a phenomenological model, engineered to try and reproduce the strong-coupling long-distance behavior of QCD. But if you want to do that, there's something much simpler: it has been known for ever that the strong coupling expansion of QCD is an expansion in surfaces and you can think of it as a string theory if you want, and also get "predictions" for the strong-coupling/long-distance behavior.

    The hard part of the QCD problem is not this, it's connecting this behavior to the short distance behavior (asymptotic freedom), through a region where your calculational method doesn't work. AdS/QCD does not at all solve this problem.

26. **A Former Professional Higgs Boson Hunter....**
March 5, 2020

    A bit off topic, but I thought it was inspired…

    Today Time Magazine announced its 100 Women of the Year going back to 1920 and to my utter astonishment, the Woman of the Year in 1921 was Emma Noether…

    Kudos to Time!

    https://time.com/5792615/emmy-noether-100-women-of-the-year/

27. **Urs Schreiber**
March 9, 2020

    The problem solved by AdS/QCD is the working definition of QCD in the confined regime, producing decent analytic predictions for hadron spectra otherwise accessible at best via lattice numerics. This is effectively the conceptual explanation of the old Skyrme model for baryons, improved by including the full tower of mesons beyond the pion, which turn out to be unified as KK-modes of the holographic theory. Sutcliffe 10 explains nicely how the secret holographic nature of the Skyrmion model is really the famous theorem of Atiyah-Manton 89.

    It's all rather remarkable, but remains underappreciated. A good account happens to be in Chapter III of the collection "The Multifaceted Skyrmion".

28. **Peter Orland**
March 10, 2020

    Urs,

    AdS/QCD is a model (basically a jazzed-up quark model). It is not the only conceptual explanation for the Skyrme model. Plus, it probably has little to do with real QCD (which must have both confinement AND asymptotic freedom, in particular, generation of logarithms in correlation functions at short distances).

    History is repeating itself (in molasses). Way back in the mid- to late-1970's, the strong-coupling lattice approximation was used to get a fairly decent picture of hadron masses. Except for the pseudo-scalar mesons (which later were incorporated), the results were claimed to show that QCD describes the world.

    Then critics responded that this works for the same reason quark models and string models work. Confine heavy quarks with a linear potential and out comes a model of the hadrons! No surprise there.

    So the strong-coupling lattice people, very sensibly, gave up (after a only a year or two) and turned to Monte-Carlo simulations (or eventually starting doing string theory, in some cases)

In my opinion, it is long overdue for AdS/QCD people to give up as well (and why can't they?).

The basic technical point (excuse the capital letters which follow, but they are important) is this; you need a theory which can get to the ZERO-bare-coupling fixed point. This does NOT mean weak renormalized coupling. True QCD has INFINITESIMAL bare coupling, not strong bare coupling. The renormalized coupling (depending on how you define it) can be large, but NEVER the bare coupling.

If you don't believe me about infinitesimal bare coupling, it was shown for more conventional QFT's in the 50's, using the Kaellen-Lehmann spectral representation; see Itzykson and Zuber, for example. See also how the renormalization group works in this context.

You can play games to get Skyrmions (I remember people did this with the bag model too), but this is still insufficient. Fitting hadron masses is nothing new (and not good enough).

Sorry for the long discussion. I have said similar words on this blog a few times here before. Some string theorists seemed incapable or unwilling to hear it (it's basic, not advanced renormalization theory), then responded with insults. My verbose discussion here is to try to leave no ambiguity.

Regards,
Peter Orland

29. **Urs Schreiber**
March 11, 2020

That the quark model correctly predicts hadron bound states is a purely computer-experimental observation (established only fairly recently for the first few hadrons arXiv:0906.3599) of which a conceptual understanding remains an open problem, dubbed one of the Millennium Problems.

While it is an old idea that the string model of mesons gives a conceptual handle on the confinement mechanism, its detailed and quantitatively accurate development used to be lacking. Making the string model of hadrons actually work is what holographic QCD is all about.

Since holographic QCD readily explains fundamental characteristics of confined QCD that remain mysterious not just in the quark model but also in popular *ad hoc* strong coupling model building such as the bag model (not only the confinement and chiral symmetry breaking mechanism itself, but also for instance vector meson dominance and the Cheshire cat property of the bag model are readily explained by holographic QCD) it is attractive to researchers interested in real-world QCD (e.g. Rho et al. 16, doi:10.1142/9710).

The Skyrme model for hadrons is in fact reasonable not in its original form but only after adjoining the tower of vector mesons to the pion. But in that tower-corrected form the Skyrme model works wonders: nuclei all the way up to carbon(!) are well-decribed already by Skyrmions in the pion+rho field (arXiv:1811.02064). This tower-correction of the old Skyrmion model had let nuclear physicist to discover (PhysRevD.69.065020) the hidden 5th dimension, leading to proof of vector meson dominance for nucleons. Conversely, the tower-corrected Skrymion model emerges from holographic QCD, where all mesons are unified as the transversal KK-modes of the 5d flavour gauge theory.

That available results in holographic AdS/QCD currently only ("only") address the strongly coupled confined QCD phase and not its asymptotically free UV is not intrinsic to the holographic theory but owed to its computational development: holography is studied for strong 't Hooft coupling only for the convenience to be able to disregard string-scale and strong string-coupling effects on the bulk side. Inclusion of small-N corrections into AdS/QCD to get the full picture remains to be developed but need not and is not being ignored (e.g. PhysRevD.74.076004).

30. **Peter Woit**
March 11, 2020

Urs Schreiber,
This "holographic QCD" discussion has gotten off-topic, and Peter Orland is right about the problems with it. You admit the main point, that no one can use this to address what happens at short distances (despite 22 years of effort). This is a fundamental problem not one of "convenience". Sorry, but enough arguing this point, where the situation is clear (this doesn't work).

31. **Peter Orland**
March 11, 2020

Sorry for being off-topic Peter,

Twistors are a lot more interesting than AdS/QCD approaches, which won't resolve any nonperturbative QCD problems, especially not millennial ones. Although twistors probably won't solve these problems either, they still seem to have new applications waiting.

I have both Ward and Wells' and Huggett and Tod's books, and should probably get my money's worth out of them.

32. **Peter Orland**
March 11, 2020

Just realized that is more relevant to your other recent post. Oops.

Penrose at The Portal

March 6, 2020
Categories: Uncategorized

Since last summer Eric Weinstein has been running a podcast entitled The Portal, featuring a wide range of unusual and provocative discussions. A couple have had a physics theme, including one with Garrett Lisi back in December.

One that I found completely fascinating was a recent interview with Roger Penrose. Penrose of course is one of the great figures of theoretical physics, and someone whose work has not followed fashion but exhibited a striking degree of originality. He and his work have often been a topic of interest on this blog: for one example, see a review of his book *Fashion, Faith and Fantasy*.

Over the years I've spent a lot of time thinking about Penrose's twistors, becoming more and more convinced that these provide just the radical new perspective on space-time geometry and quantization that is needed for further progress on fundamental theory. For a long time now, string theorists have been claiming that "space-time is doomed", and the recent "it from qubit" bandwagon also is based on the idea that space-time needs to be replaced by something else, something deeply quantum mechanical. Twistors have played an important role in recent work on amplitudes, for more about this a good source is a 2011 Arkani-Hamed talk at Penrose's 80th birthday conference.

One of my own motivations for the conviction that twistors are part of what is needed is the "this math is just too beautiful not to be true" kind of argument that these days many disapprove of. There are many places one can read about twistors and the mathematics that underlies them. One that I can especially recommend is the book Twistor Geometry and Field Theory, by Ward and Wells. A one sentence summary of the fundamental idea would be

> A point in space time is a complex two-plane in complex four-dimensional (twistor) space, and this complex two-plane is the fiber of the spinor bundle at the point.

In more detail, the Grassmanian G(2,4) of complex two-planes in $\mathbf C^4$ is compactified and complexified Minkowski space, with the spinor bundle the tautological bundle. So, more fundamental than space-time is the twistor space T=$\mathbf C^4$. Choosing a Hermitian form Ω of signature (2,2) on this space, compactified Minkowski space is the set of two-planes in T on which the form is zero. The conformal group is then the group SU(2,2) of transformations of T preserving Ω and this setup is ideal for handling conformally-invariant theories. Instead of working directly with T, it is often convenient to mod out by the action of the complex scalars and work with $PT=\mathbf{CP}^3$. A point in complexified, compactified space-time is then a $\mathbf{CP}^1 \subset \mathbf{CP}^3$, with the real Minkowski (compactified) points corresponding to $\mathbf{CP}^1$s that lie in a five-dimensional hypersurface $PN \subset PT$ where $\Omega=0$.

On the podcast, Penrose describes the motivation behind his discovery of twistors, and the history of exactly how this discovery came about. He was a visitor in 1963 at the University of Texas in Austin, with an office next door to Engelbert Schucking, who among other things had explained to him the importance in quantum theory of the positive/negative energy decomposition of the space of solutions to field equations. After the Kennedy assassination, he and others made a plan to get together with colleagues from Dallas, taking a trip to San Antonio and the coast. Penrose was being driven back from San Antonio to Austin by Istvan Ozsvath (father of Peter Ozsvath, ex-colleague here at Columbia), and it turned out that Istvan was not at all talkative. This gave Penrose time alone to think, and it was during this trip he had the crucial idea. For details of this, listen to what Penrose has to say starting at about 47 minutes before the end of the podcast. For a written version of the same story, see Penrose's article Some Remarks on Twistor Theory, which was a contribution to a volume of essays in honor of Schucking.

   Very interesting post Peter.
   I have read both "Fashion, Faith and Fantasy" and "The Road to Reality", and I must say that I found Twistor Theory extremely complicated. It takes a hell of a lot of time to get to understand it just roughly.
   There's no doubt about Penrose's originality and out of the box thinking, and how much Twistor Theory has influenced the amplituhedron and other Arkani-Hamed's ideas on geometry of the Universe.
   But back in 2003, he had a meeting with Witten in Princeton, and it seems that the latter managed to write a 70 page paper in which he basically showed that Twistor Theory was embedded into String Theory.

   Has this been fully proven and that's why T.T. has been basically abandoned as the possible theory of "where the Universe emerges/comes from"?

2. **Peter Woit**
   March 6, 2020

   DB,
   It's not so much that twistor theory is complicated as that it involves some mathematical ideas that physicists are not familiar with (e.g. holomorphic vector bundles). The basic idea of twistors that I described in the post is actually simple, but radical. Not everything is about string theory or AdS/CFT, and trying to understand the twistor string or duality and N=4 super Yang-Mills is not a good way to try and understand twistor theory. One thing to say though is that Witten's paper on the twistor string does contain a very lucid and explicit discussion of what's called the Penrose transform (relating field equations on space-time and on twistor space).

   New ideas are definitely needed to connect twistor theory to the Standard Model and to use it to quantize gravity. There's a long history of people trying this, without success so far. I see various possibilities and am trying to write something up about those, we'll see what comes of that project. I'm hopeful, but still confused about some crucial questions.

3. **DB**
   March 6, 2020

   Thanks for your helpful answer Peter, and I'm looking forward to that future project!!
   Best of lucks.

4. **Lee Smolin**
   March 7, 2020

   Dear Peter,

   I share your fascination with twistor theory and spent some time during graduate school in Oxford learning it from Penrose and his students. Indeed, twistor theory turns out to be intimately connected to LQG and spin foam models; one way to explain why is to to show that both make use of the chiral structures that are revealed when you reduce general relativity to a topological field theory plus constraints. I have one paper about this: https://arxiv.org/abs/1311.0186, but it has been developed extensively by Wolfgang Wieland, Simone Speciale, Laurent Freidel and others. Some of the interesting papers are below.

Take care,

Lee

https://arxiv.org/abs/1807.11376

5. **tulpoeid**
March 8, 2020

Admittedly and perhaps reasonably, this requires investing huge amounts of time for those of us with the math knowledge of a physics degree (grad studies didn't add much in terms of fundamental math), simply for getting what it is about. Still, it might well turn out that reality needs math beyond this level.
So I think that the question that comes to mind is, what are the insights / results / meaning of twistors? Why are they worth pursuing? What are the consequences of complex two-planes as fibers of spinor bundles?

6. **Urs Schreiber**
March 8, 2020

It is curious that the mathematics which makes twistors exist precisely in spacetime dimensions 3 and 4 and 6 and 10 (here) is the same that makes the Green-Schwarz superstring exist in exactly these dimensions (here).

7. **Peter Woit**
March 8, 2020

Lee Smolin,

Thanks for the references. The way both twistor theory and LQG exploit chirality of 4d geometry in a fundamental way is fascinating.

Tulpoeid,
There's a lot of sophisticated mathematics involved here, but the point about spinors is rather simple. All fundamental matter fields we know of involve a complex two-dimensional spinor degree of freedom. In the conventional approach to geometry, it is rather complicated to understand where these degrees of freedom come from. In the twistor approach, a point in spacetime is precisely given by a complex two-dimensional space (in 4d twistor space), and this is the spinor space. The spinor degree of freedom is not something added ad hoc later, it is built into the very definition of space-time (in mathematician's lingo, the spinor bundle is "tautological").

8. **D R Lunsford**
March 8, 2020

It's a sort of line geometry for spacetime. Strange coincidence – Pluecker's original paper on line geometry appeared in the same volume of "Philosophical Transactions of the Royal Society of London" as Maxwell's "A Dynamical Theory of the Electromagnetic Field" – in 1865. That was the first complete presentation of Maxwell's theory.

9. **Robert Wilson**
March 9, 2020

What I find fascinating about twistor theory is the way that Penrose uses the fundamental structure of the group SU(2,2), and the twistor space on which it acts, to model spacetime at a point, *before* doing the geometry to model spacetime on an extended scale. He uses this particular group because it is a double cover of SO(4,2), that he wants for some geometrical reason that I admit is opaque to me. Altogether there are about 8 different real forms of this group (depending exactly how you count them), coming from 5 different real Lie algebras so(6)=su(4), so(5,1)=sl(2,H), so(4,2)=su(2,2), so(3,3)=sl(4,R) and su(3,1). I am aware of significant work using su(4), and other work using so(5,1), both attempting to do similar things to what Penrose has done. But has anyone looked seriously at sl(4,R) or su(3,1)?

10. **Mark Callaghan**
March 9, 2020

Peter, I just want to thank you for directing me to the Portal website, the discussion with Roger Penrose was fascinating , and there is much content of a similarly stellar nature there.

11. **Peter Woit**
March 9, 2020

Robert Wilson,
SO(4,2) is the group of conformal transformations, the Poincare group is a subgroup. Relativistic massless particles transform according to irreducible infinite dimensional representations of this group (or its double cover). Understanding these reps tells you a great deal about relativistic massless particles. Note that the SU(2,2) representation theory story is a generalization of the SU(1,1)=SL(2,R) story (where the discrete series representations can be constructed using holomorphic methods on a hemisphere of the Riemann sphere). The "Penrose transform" is of great interest to those working on geometric constructions of irreps of real Lie groups like SU(2,2).

One of the wonderful aspects of the twistor story is that it relates what happens in different space-time signatures. SO(4,2) is the Minkowski space story, SO(5,1) is the conformal group of S^4, so gives a (compactified) Euclidean space story. SO(3,3) gives the signature (2,2) story, where your spinors are real, and you're talking about real 2 planes in real 4 space. From what I've seen, people doing amplitudes calculations seem to exploit the ability to work in different signatures, with the real (2,2) signature case often useful. I don't know of uses of the other signatures. SO(6)=SU(4) is a much simpler story (SU(4) acts transitively on G(2,4) and the irreps one gets are finite dimensional. I don't know about use of the SU(3,1) real form.

12. **D R Lunsford**
March 9, 2020

"One of the wonderful aspects of the twistor story is that it relates what happens in different space-time signatures. SO(4,2) is the Minkowski space story, SO(5,1) is the conformal group of , so gives a (compactified) Euclidean space story. SO(3,3) gives the signature (2,2) story, where your spinors are real, and you're talking about real 2 planes in real 4 space. "

This is a really deep point. I have done of lot of living in SO(3,3) and often broke my head on the relation to SO(4,2) physically.

The books of Felix Klein are really good preparation for all this, even though they are old. They read like novels 🙂

-drl

13. **Robert Wilson**
March 10, 2020

Peter,
Thanks for that explanation. I understand that SO(4,2) is the only real form that contains the Poincare group, so that if you're interested in gravity then this is the obvious choice. But it also contains a subgroup SO(1,1) that commutes with the Lorentz group and acts on the translation part of the Poincare group as scale-changes. This is fine if all you want to model is GR, but it seems to me to be a problem if you want a quantum gravity. So I'm not entirely surprised that particle physicists find the SO(3,3) signature useful. Do you know of a good reference to get me started on exploring what particle physicists do with SO(3,3)? To me, the interesting thing about this signature, apart from the fact that it is the only one with real spinors, is that there are subgroups of dimension 12, which do not occur in any other signature. Dimension 12 seems to be important for both bosons and fermions in the standard model.

14. **Peter Woit**
March 10, 2020

D.R. Lunsford/Robert Wilson,

I know nothing about physical applications of the split signature case. Two good places to find information about the way different signatures are related in the twistor picture are the paper
Real methods in twistor theory, by Woodhouse
https://iopscience.iop.org/article/10.1088/0264-9381/2/3/006
and Tim Adamo's lectures on twistor theory
https://arxiv.org/abs/1712.02196
In Adamo's lectures you learn that
"In general, the idea in twistor theory is to work in the complexified setting, imposing reality conditions only at the end of a calculation. In the old days of the subject, these reality conditions were usually the Lorentzian ones, while early in the 'twistor renaissance' of 2004 the split signature reality conditions were preferred. Nowadays, Euclidean reality conditions seem to be the most useful when performing explicit calculations. So depending on what era of the literature you read, you can find any one of the three reality conditions given preference for a combination of physical and technical reasons."
I'm not all that familiar with the 2004 era literature using the split signature that he's referring to.

March 12, 2020

https://cerncourier.com/a/when-twistors-met-loops/

16. **edg**
April 3, 2020

Dear Peter,

Eric Weinstein released the video of his 2013 Oxford talk on his approach to unified field theory, along with a preamble and some clarifying notes after the talk, see here:

https://www.youtube.com/watch?v=Z7rd04KzLcg&t=1s

To this physicist many parts are unclear, but perhaps you and others who follow this blog will be able to parse his constructions. I wonder in particular if this can be done in d=2 as a first toy model, before approaching d=4.

This Week’s Hype

March 20, 2020
Categories: This Week's Hype

In this disturbing time of pandemic, it’s reassuring to see that some activities continue as usual. On the string theory hype front, yesterday NASA put out a press release announcing that Chandra Data Tests ‘Theory of Everything’, which starts by explaining that:

> Despite having many different versions of string theory circulating throughout the physics community for decades, there have been very few experimental tests. Astronomers using NASA’s Chandra X-ray Observatory, however, have now made a significant step forward in this area.

This is based on a paper announcing limits on axions based on data from the Chandra X-ray telescope, which starts off with the dubious claim that axions “are generic within String Theory”. It seems to be very hard to get some people to understand that the number of “tests of string theory” is not “very few” but zero, for the simple reason that there are no predictions of string theory, generic or otherwise.

As usual, this kind of thing gets picked up by other news sources. In a sign of the times, the spin given to the bogus “test” is now often negative for string theory: This Galaxy Cluster May Have Just Dealt a Major Blow to String Theory.

Update: This is getting attention at The Daily Galaxy, under the headline “Mind of God?” –The Detection of ‘String-Theory’ Particles Would Change Physics Forever”.

For more on religion and string theory, there’s a ~~new~~ (actually from 2017) podcast featuring IAS theorist Tom Rudelius, entitled The Multiverse, the Polygraph, and the Resurrection. In an older podcast at Purpose Nation, Rudelius tells us this about the views of Nima Arkani-Hamed:

> To quote preeminent theorist Nima Arkani-Hamed, who is certainly no theist: “The multiverse isn’t a theory. It’s a cartoon, right, it’s like this cartoon picture of something that we might think might be going on but we really don’t have any solid theory of how it would work.”

It seems that Arkani-Hamed shares my views on this.

Comments

1. **dratcwo**
   March 20, 2020

   I agree that axion-like-particle is predicted in any theory with extra-dimension. However, there is another more generic prediction from string theory/SUGRA, the spin-3/2 gravitino.

2. **Peter Woit**
   March 20, 2020

   dratcwo,
   What’s the mass range and couplings for this “generic” gravitino?

   I don’t believe that string theory provides any answer to this. The situation is always the same: there is a “beautiful”, highly predictive, string theory/sugra that people like to point to, but it looks nothing like the real world (wrong space-time dimension, no SUSY breaking). Trying to make the theory agree with the real world requires making it exceedingly ugly and unpredictive, without any non-trivial “generic” predictions.

   The accuracy of the above characterization of the situation has become abundantly clear over the last couple decades. It would be nice if people would stop misrepresenting this to non-experts, e.g. innocent astrophysicists…

Fourier Analysis Notes

March 23, 2020
Categories: Uncategorized

This semester I've been teaching a course on Fourier Analysis, which has, like just about everything, been seriously disrupted by the COVID-19 situation. Several class sessions have been canceled, and future ones are supposed to resume online next week. To improve matters a bit, I've been writing up lecture notes for the material since in-person lectures were canceled, and we'll see how long I have the energy to keep this up.

The website for the course is here, giving detailed information about what it covers. In terms of level of mathematical rigor, the concept is to use the course as an opportunity to give students some motivation for a conventional real analysis course. The only prerequisite for the course is our usual Calculus sequence, which is not proof-based. In this class students are expected to try and follow proofs given in the book and in class, but not expected to be very good at coming up with their own proofs in the assignments, which mostly are computational. The textbook (Stein-Shakarchi) is based on a Princeton course with a somewhat similar philosophy of providing an introduction to analysis, but it is very challenging for the students to follow. I've looked around, but not found a better alternative. Other books on the subject tend to be either books for mathematics students that are even more abstract and challenging, or books for engineers that focus on either signal analysis or PDEs. Since the math department already has a PDE class I want to emphasize other things you can do with the subject.

The first set of lecture notes I wrote up were only loosely connected to Fourier analysis, through the Poisson summation formula. They dealt with theta functions and the zeta function, giving the standard proof of the functional equation for the zeta function that uses Poisson summation. I confess that one reason for covering this material is that I've always been fascinated by the connection between theta functions, quantization, representation theory (through the Heisenberg and metaplectic groups), and number theory. This subject contains a wealth of ideas that bring together fundamental physics and deep mathematics. On the mathematics side, this story was generalized by Tate in his thesis, where he developed what is essentially the GL(1) case of the modern theory of automorphic forms that underpins the Langlands program. On the physics side, one can think of what is going on as the standard canonical quantization of a finite-dim phase space, but with a lattice in the phase space giving a discrete subgroup of the usual Heisenberg group, and lots of new structure. For the details of this, one place to look is volume III of Mumford's books on theta functions.

The second set of lecture notes, which I've just started on, are intended as an introduction to the theory of distributions, a topic that isn't in Stein-Shakarchi. I highly recommend the book by Strichartz referred to in the notes for more details, with the notes maybe best used just as an introduction to that book.

I don't want to turn this blog into yet one more place for discussion of the COVID-19 situation that just about all of us are obsessed with at the moment. If you're interested in my personal experience, I'm doing fine. Almost all of us in New York are now pretty much confined to our apartments (it helps that the weather outside today is terrible), other than for short ventures out to get food or some exercise. I'd like to optimistically think that New York started taking action to stop the virus spread early enough to avoid disaster at the local hospitals. The best place I've seen to try and follow what is happening there is this web page. We'll see in the next couple days if the problem has started to peak, or has much further to go.

I'm in much better shape than most people, having left town early for a spring break vacation. I had been planning a trip to Paris, at the very last minute instead rented a car and started out on a road trip in the general direction of New Orleans, consulting coronavirus report maps for where to avoid. Ended up in Memphis and then the Mississippi Delta (it had become clear New Orleans was a bad idea) before finally deciding that the situation was getting serious everywhere and it was time to head home. So, ended up back here in New York in relatively good mental shape for the confinement to come. Good luck to all of us in dealing with the coming challenges…

Update: The semester is now over, and I've put together all the notes I wrote up in one document, available here. This fixes mistakes/typos/etc. in earlier versions of the notes, so I'm changing the links to point to the final version.

Comments

1. **Akhil**
   March 23, 2020

   Thanks Peter! We hope more genuine content on the Fundamental physics-Mathematics connections side is coming, which is hard to find elsewhere.

2. **Roderic C Deyo**
   March 23, 2020

   Perhaps it's not fully appropriate for the course since it uses complex analysis, but I noticed that Richard Bellman's wonderful short classic "A Brief Introduction to Theta Functions" was missing from the references.

3. **Hugh Osborn**
   March 24, 2020

   You are missing a – in the heat kernel in lecture 2

4. **Peter Woit**
   March 24, 2020

   Hugh Osborn,
   Thanks! Fixed.

5. **Jackiw Teitelboim**
   March 24, 2020

   Dear Peter,

   It's interesting that Vol.I of Stein & Shakarchi gets very very close to introducing the notion of Schwartz's distributions in their discussion of Poisson, Dirichlet, heat kernels &., but always avoids introducing the notion of continuous linear functional on the space of test functions.

   There's a short, rigorous and quite elementary book by Friedlander, "Introduction to the theory of distributions," which as a student at the time I found a valuable complement to Stein & Shakarchi.

   Regards.

6. **David Brown**

March 24, 2020

In the second set of notes, on page 1 in the last paragraph, shouldn't "Schwarz" be "Schwartz" for Laurent Schwartz? No tee Schwarz is either the string theorist Schwarz or Hermann Amandus Schwarz.

7. **Peter Woit**
   March 24, 2020

   David Brown,
   Thanks, yes it's Laurent Schwartz. Fixed.

   Jackiw Teitelboim,
   Thanks, the Friedlander/Joshi book is a good more advanced reference for distribution theory. I still would recommend the Strichartz book as less heavy on the theory and having more about applications and motivation.

   I can see why Stein-Shakarchi decide not to introduce distributions, but then you miss a huge part of the subject. The simplest way to introduce distributions, especially in the context of Fourier analysis, seems to me to be to stick to tempered distributions (i.e. Schwartz functions as test functions), but I don't think I've seen any text that does this.

8. **Babak**
   March 30, 2020

   Dear Peter,

   As you know, there's also a group theory point of view that can be found for instance in a beautiful book by Audrey Terras

   https://www.amazon.ca/Fourier-Analysis-Finite-Groups-Applications/dp/0521457181

   I think that is perhaps the true reality of Fourier analysis.

9. **Babak**
   March 30, 2020

   David: There's also Albert Schwarz. 😊☺️

This Week's Hype

March 25, 2020
Categories: Swampland, This Week's Hype

Maybe it's because people are at home with nothing else to do, but somehow the COVID-19 pandemic seems to be having the side-effect of generating new infections of "test of string theory" hype, a disease common many years back that seemed to more recently be under control. The example of a few days ago has now spread widely (see for instance Popular Mechanics), sometimes mutating into tests of "sting theory". Today there's a new example out, on the middle of the front page at Scientific American: Will String Theory Finally Be Put to the Experimental Test?

Of course the answer is "No", this is just one more in the Swampland strain of string theory hype. This latest example is based on a paper by Bedroya and Vafa, where they make a "Transplanckian Censorship Conjecture". The weird aspect of this kind of string theory hype is that it's not a "test of string theory", because it really has nothing to do with string theory. The authors of this paper are making a conjecture about "any consistent theory of quantum gravity". If their conjecture is true we shouldn't see the kind of B-modes in the CMB that were mistakenly claimed in the BICEP2 fiasco of 2014. So, the "test" here is a claim of falsification if experiments do for real see these B-modes. But what is being tested is a conjecture about any consistent theory of quantum gravity (one with very weak evidence). If B-modes are seen by a future experiment, the two possible conclusions to be drawn will be:

- There is no consistent theory of quantum gravity.
- The Transplanckian Censorship Conjecture is wrong.

It's pretty clear what the correct choice between these two will be, and none of this will "test string theory."

Update: I should have also pointed to this paper. Will Kinney today gave a talk, It Came From the Swampland, which went over this subject seriously in detail. His conclusion, which seemed to be shared by a string theorist he was talking to at the end, was pretty much that these conjectures should not be taken seriously. It looks like they're already in conflict with both experimental results as well as theoretical model-building.

Comments

1. **Zovi**
   March 25, 2020

   Just to mention that this week they officially cancelled the The Arithmetic of the Langlands Program series of events of this year at Bonn.

2. **Peter Woit**
   March 25, 2020

   Zovi,
   At this point I think pretty much everything not purely online has been cancelled for the next couple months and often beyond. A good point is made by Peter Coles here https://twitter.com/telescoper/status/1240963587138555905

   "It's now even easier to identify fake academic conferences – they're the ones that haven't been cancelled."

3. **Rajesh**
   March 25, 2020

   You missed the most important alternative which can be concluded, if B modes are ever discovered — Inflation is wrong. There are alternatives to inflation which can predict a large 'r' and still be perfectly compatible with this conjecture. In fact, in some follow-up work, it has been shown how even some (highly-contrived) models of inflation might also survive the TCC and yet produce a larger 'r'. So, I think the conclusions should really be:

   1) Inflation is wrong, or
   2) The TCC is wrong.

   It, most certainly, is not that there are no consistent theories of quantum gravity. But I completely agree with you that this, therefore, cannot be a test for string theory.

4. **Peter Woit**
   March 25, 2020

   Rajesh,
   Thanks, good point. However, if we ever do see a non-zero r, surely more film crews will show up at Andrei Linde's door, and he and the Stanford press office will again tell us about how non-zero r is "smoking gun" evidence for inflation. So, that's the point we'll be starting from…

5. **David Roberts**
   March 28, 2020

   @Rajesh

   and that 'or' is presumably not exclusive!

6. **Douglas Natelson**
   March 30, 2020

   Not to threadjack, but it's been making the rounds that Phil Anderson passed away yesterday at the age of 96. Truly, the end of an era, as he played a huge role in defining the discipline of condensed matter physics as well as discovered (if that's the appropriate term) what is now known as the Higgs mechanism.

7. **Peter Woit**
   March 30, 2020

   Douglas Natelson,
   Thanks, writing something now about Anderson (and including a link to your blog for more about his work).

8. **David Roberts**
April 3, 2020

Reported in Nature News [1]: Mochizuki's papers have been accepted for publication, with no substantial changes.

Philip Anderson 1923-2020

March 30, 2020
Categories: Obituaries

I heard this morning about the death yesterday of Philip Anderson, at the age of 96. It's not hard to make the case that Anderson was the most important condensed matter theorist of the twentieth century, with a huge influence on how we think about the subject. I believe he was even responsible for the name "condensed matter". There are already obituaries at Princeton, and at the New York Times. For more about his work, Douglas Natelson has written something here.

Anderson's career intersected with the field of high energy physics in several ways. Most importantly, what is often called the Higgs phenomenon really is a discovery of Anderson's, and this should have been recognized by a second Nobel for him (he already had one for some of his work in condensed matter). I've written extensively about this story on the blog, see for example here, here and here. The story is a bit complicated, but it's undeniable that in November 1962 Anderson submitted the paper Plasmons, Gauge Invariance and Mass to the Physical Review, and it was published on April 1, 1963. This was more than a year before the Higgs/Brout/Englert/Guralnik/Hagen/Kibble papers that HEP theorists always point to as the original ones. If you read Anderson's paper, you'll find a discussion of the "Higgs mechanism" which gets at the basic physics in much the same way we think of it today. There was no reason for HEP theorists to miss this paper, Anderson had written and published it not as a condensed matter paper, but as a contribution to current high energy theory. The only counter-argument I've gotten about this is that "Anderson's explicit model was non-relativistic", but this is a physical phenomenon for which relativity is not particularly relevant. Does it really make sense to argue that recognition should not go to a theorist who discovers a new phenomenon, but to others who later show that a possible problem (e.g. inconsistency with special relativity) not considered by the discoverer really isn't there?

My time as a student at Princeton during 1979-84 (during which years Anderson split his time between Princeton and Bell Labs) was a high point of interaction between the condensed matter and HEP theory groups. HEP theorists trying to understand QCD investigated many examples of non-perturbative quantum field theory behavior that were of common interest with Anderson and others working on condensed matter. Anderson did have a major philosophical difference with the reductionist point of view of many HEP theorists, with his 1972 paper More is Different providing a strong critique of reductionism and emphasizing the importance of emergent behavior. In some sense, leading HEP theorists in recent years have come around to his point of view, often working on emergent models of space-time, with little interest in what microscopic physics space-time might be emerging from.

Anderson made no friends among the HEP community when he came out in 1987 against building the SSC (which was cancelled in 1993), for more about this, see this blog entry. He was also a skeptic about string theory, which perhaps made for some discomfort as Princeton HEP theory centered around this subject starting in 1984.

The two personal interactions with Anderson that I remember both involved him providing me with significant encouragement. When I took my general exams at Princeton, one component was an exam on condensed matter theory. This was not then and is not now a subject I know much about. After the exam there later was a gathering of students and faculty, and Anderson came up to me to tell me that he had graded my condensed matter exam. On one problem evidently I had gone about it wrong, but at some point had stopped and written that the result I was getting wasn't sensible. Anderson complimented me on this, telling me that knowing when a calculation wasn't making sense was an important skill. This was the nicest way imaginable to encourage a student who didn't really know what he was doing.

Twenty years later, in early 2001, after I had written this article and had distributed it to several theorists including Anderson asking for comments, this is what he wrote back to me:

> (Jan 19, 2001)
> Dear Peter, I'm sorry to have been so slow to get back to you; my printer blew out when I tried to print out your attachment. When I finally got it it blew my mind–I loved seeing my vague misgivings made explicit. I would say that perhaps a stronger argument is the way of coping with black hole entropy, but since hearing about that i have never had it made clear to me that the story is unique to string theory except as a representative of sane quantum theories of gravity–the point made is that the gravitational theory provides its own cutoff.
>
> I would hope but wouldn't guarantee that P Today would publish it–I would be glad to introduce you as a guest columnist but they might not accept that.
>
> When Lewontin and friends wanted to do a similar, but less well justified, job on sociobiology they wrote a broadside for the New York Review of Books.Since there are so many popular books I see no reason not to do that. If that doesn't work I could perhaps insert you into John Brockman's "third culture" chat room..
> Anyhow, good luck–pwa

I wrote back to Anderson, telling him in particular that a prominent theorist had advised me not to publish the piece, since it would be counterproductive and the problems I discussed were well-known. He responded:

> (Jan 23, 200)
> Dear Peter, thanks for your reply. Of course would feel that the article would be counterproductive. Wasn't that just the point? And to whom is it all well-known? The general public? Deans and department chairmen who make the hiring decisions? Science journalists who create the buzz? Politicians and bureaucrats who control the purse strings? Bullshit!
>
> Yes, i agree that the version you sent me was too technical for a general journal like the NY review, but actually not much–the Lewontin arguments were pretty technical. Anyhow, good luck with this one. I showed it to a knowledgeable colleague, not a stringy but one who collaborates with them, and he also liked it.–pwa

Anderson then put me in touch with an editor at Physics Today. They decided not to publish the piece, first suggesting that instead I write a letter to the editor, and finally rejecting even that as "too inflammatory". Anderson's positive response to the piece though provided significant encouragement for my decision to start writing publicly about this issue.

He was one of the greats, and will be missed.

Update: More about Anderson from Physics World, Horganism, and Science magazine.

Update: David Derbes reminds me to point out that Higgs himself always properly credited Anderson, generally referring to the "Anderson mechanism", or more specifically describing what he had done as the "relativistic Anderson mechanism". For instance, he wrote here:

> I call this the relativistic Anderson mechanism because Anderson described it first: it was his misfortune not to do so explicitly enough.

   Amen. you might enjoy https://arxiv.org/abs/1605.06993.

2. **Peter Woit**
March 31, 2020

Mark Sharefkin,
Thanks, that's an excellent source for more about Anderson's work. The author, Piers Coleman, was in my class at Princeton and worked with Anderson. Another fellow student in my class, Gabi Kotliar, also worked with Anderson, and both he and Piers have gone on to careers as leaders of the subject.

3. **Alessandro Strumia**
April 1, 2020

Interesting to hear that, thanks to Anderson and internet, you bypassed Physics Today decision of not allowing physicists to read your letter. Do such editors think that physicists are idiots who cannot be exposed to an open debate?

4. **Peter Woit**
April 1, 2020

Alessandro Strumia,

About the Physics Today story: the person Anderson put me in touch with at Physics Today was Gloria Lubkin, who passed away recently also, see here
https://physicstoday.scitation.org/do/10.1063/PT.6.4.20200211a/full/
Despite backing from Anderson, I think it was unlikely Physics Today was ever going to allow a piece forcefully criticizing the research program of prominent people by someone with my much inferior credentials. If Anderson had been the author, they would have published it. The one piece they ever published criticizing string theory (1986 Desperately Seeking Superstrings) was quite forceful, could be published because Glashow's name was on it.
Since then they've published several propagandistic pieces promoting string theory, in particular a couple pretty outrageous ones from Gordon Kane. I'm unaware of anything critical they've published about string theory post 1986. They really should commission such a piece to make up for their sins.
Anderson had a lot of influence in the physics community, but even his influence was in many ways limited.

April 1, 2020

It's time to let Philip Anderson off the hook for the cancellation of the SSC. Once Jim Wright resigned as speaker of the House due to ethics investigations, the SSC was dead. It wasn't clear at the time but without a heavy hitter from Texas there was no way it was going ahead. What Everett Dirksen was to Fermilab, Wright was to the SSC.

Nothing a Nobel Laureate like Anderson said would have mattered if Wright had remained speaker, the SSC would have been built. After he was gone, nothing any number of pro-SSC Nobel Laureates said, no SSC.

6. **Ross McKenzie**
April 7, 2020

Phil Anderson wrote a sympathetic book review of Not Even Wrong for the Times Higher Education Supplement.
https://www.timeshighereducation.com/books/loose-ends-and-gordian-knots-of-the-string-cult/204995.article?sectioncode=1&storycode=204995
It is behind a paywall, but it is reprinted in his "Thoughtful Curmudgeon" book.
A double compliment.

7. **Peter Woit**
April 7, 2020

Ross McKenzie,

Thanks, I had forgotten about that. I should also have recommended that book to everyone (full title is "More and Different: Notes from a thoughtful curmudgeon").

8. **Thomas Larsson**

Latest on abc

April 3, 2020
Categories: abc Conjecture

Davide Castelvecchi at Nature has the story this morning of a press conference held earlier today at Kyoto University to announce the publication by *Publications of the Research Institute for Mathematical Sciences (RIMS)* of Mochizuki's purported proof of the abc conjecture.

This is very odd. As the Nature subheadline explains, "some experts say author Shinichi Mochizuki failed to fix fatal flaw". It's completely unheard of for a major journal to publish a proof of an important result when experts have publicly stated that the proof is flawed and are standing behind that statement. That Mochizuki is the chief editor of the journal and that the announcement was made by two of his RIMS colleagues doesn't help at all with the situation.

For background on the problem with the proof, see an earlier blog entry here. In the Nature article Peter Scholze states:

> My judgment has not changed in any way since I wrote that manuscript with Jakob Stix.

and there's

> "I think it is safe to say that there has not been much change in the community opinion since 2018," says Kiran Kedlaya, a number theorist at the University of California, San Diego, who was among the experts who put considerable effort over several years trying to verify the proof.

I asked around this morning and no one I know who is well-informed about this has heard of any reason to change their opinion that Mochizuki does not have a proof.

Ivan Fesenko today has a long article entitled On Pioneering Mathematical Research, On the Occasion of Announcement of Forthcoming Publication of the IUT Papers by Shinichi Mochizuki. Much like earlier articles from him (I'd missed this one), it's full of denunciations of anyone (including Scholze) who has expressed skepticism about the proof as an incompetent. There's a lot about how Mochizuki's work on the purported proof is an inspiration to the world, ending with:

> In the UK, the recent new additional funding of mathematics, work on which was inspired by the pioneering research of Sh. Mochizuki, will address some of these issues.

which refers to the British government decision discussed here.

There is a really good inspirational story in recent years about successful pioneering mathematical research, but it's the one about Scholze's work, not the proof of abc that experts don't believe, even if it gets published.

Update: See the comment posted here from Peter Scholze further explaining the underlying problem with the Mochizuki proof.

Comments

1. **PC**
   April 3, 2020

   Publication of RIMS does not really qualify as a major journal. So everything is going to be alright…

2. **Cosmological Constance**
   April 3, 2020

   In Fesenko's article one finds the following remarkable line:

   "Misinformation and disinformation in science has become a very serious issue, not only for mathematics."

   I think this is in fact a very relevant point – but, perhaps, just not in the way that Fesenko intends it.

3. **Peng**
   April 3, 2020

   Serious question.
   I have looked through some of Mochizuki's rebuttals. I was amazed by the almost "internet insults-as-defensive" language thrown in there. As well as his pedagogical choice of describing things with layers upon layers of analogy, that could be said more directly. Especially when some of the analogies seem to be chosen almost as if to insult someone if they question it. It feels like what a physics theorist I knew used to joke as some authors trying to "prove by intimidation". But that's in physics, where a bit of hand waving is allowed (no point in waiting for a millenial prize problem to be solved to posit an effective field theory). It's confusing how this manner of dialog aids any purpose in mathematics.
   -
   Anyway, I got a bit off tract. My question is:
   Is it possible the style / pedagogical choices are actually causing real problems? Would it be helpful at this point if someone that states they understand the theory (but unlike Fesenko, will explain in a more useful manner than Mochizuki), if they rewrite the proof in their own words? Or at least the more difficult portions?
   -
   Or is the claim that it is pedagogically impossible to present the more difficult portions in any different manner?

4. **IWonder**
   April 3, 2020

   Castelvecchi characterizes the style of Mochizuki's papers as impenetrable and idiosyncratic, with which I wholeheartedly agree. However, I wonder why in this discussion Go Yamashita's write-up (http://www.kurims.kyoto-u.ac.jp/~gokun/DOCUMENTS/abc_ver6.pdf) has apparently received so little attention. While I unfortunately can't follow the mathematics, I find the style to be very clear and traditional in the best sense. In particular, he gives a proof of the infamous IUTchIII Corollary 3.12 (Corollary 13.13 in his paper), which I find to lend itself better to a discussion.

5. **Peter Woit**
   April 3, 2020

Peng/IWonder,
For a long time the style, length, organization and idiosyncrasies of the Mochizuki papers seemed to be the main problem, keeping experts from being able to fully understand and thus check the proof, and Go Yamashita's version promised to improve the situation. But once Scholze and Stix identified a specific issue, spent a lot of time discussing it with Mochizuki, and ended up convinced this was a gap in his proof, that completely changed the situation. Few people are going to devote a lot of time to studying a very complicated proof that at a crucial point has a gap. What's needed is for Mochizuki or someone else to put forward a convincing response to the issue raised by Scholze/Stix. This doesn't seem to have happened, and behavior like attributing the problem to Scholze being an incompetent not only doesn't help, but just convinces others that engaging with Mochizuki and those around him to better understand the issue is a waste of time. The announcement that the journal will publish anyway also doesn't help the situation at all.

6. **David Roberts**

8. **K. N.**
April 4, 2020

Hi. I do read both Japanese and English, and I feel like I'm obligated to give you more information on this matter which may only be provided in Japanese so far. First of all, I am not an expert nor trying to convince you whether IUT holds to be true or not; I am only providing additional information.
–
In 2018, Scholze and Stix released the document to show the famous fatal flow, so did Mochizuki to show the validity of his work. In April, 2019, Fumihiro Kato, a Japanese mathematician who verified IUT, has published a book about IUT for non-expert Japanese audience. A few months later, I checked Amazon Japan to view readers' reviews, which most people gave 5 or 4 stars. Then I found one negative review briefly saying, "Who's gonna read this book? Math community now knows there is fatal flow in IUT." Kato responded to this review. He posted the same response on his twitter account, so we know this response is really came from the author. He, in a very humble manner, stated that IUT is still in the middle of proofreading (at that time), but IUT experts are now confident to say that Scholze and Stix were simply misunderstanding lines of argument.
–
In January 2020, Mochizuki updated his private blog only available in Japanese. For while, people thought this blog is not Mochizuki's but is made up by some geek. Surprisingly, Kato has told us in his book that the author of the blog is indeed the Mochizuki himself. Anyway, the updated article indicated the Mochizuki's frustration for his papers not being published for such a long time, and he rebuked the publisher in quite strong language. He didn't mention the name of the journal, but readers were aware that was RIMS since the article was available only in Japanese. Which implies that he was not a chief editor of RIMS for the IUT matter. When RIMS had a press conference yesterday, they indeed explained that Mochizuki was completely excluded from refereeing the papers.

9. **KS**
April 4, 2020

Dupuy should have any lecture in Princeton for Diophantine geometers.
It may be a good possible way to realize certain understandings and consensus in mathematical community out of Kyoto.

10. **Peter Woit**
April 4, 2020

sleep/K.N.

For more of the twitter exchange with Dupuy, see here:
https://twitter.com/meu_gato/status/1246220210891190272
where he seems to state that he is not able to provide a convincing proof of the problematic Corollary 3.12 (and agrees that Mochizuki publishing this in the journal he is chief editor of is a bad idea, no matter what procedures were followed).

The problem here is simple: neither Mochizuki nor anyone else has written up a convincing response to Scholze-Stix. Fesenko has devoted pages and pages to ad hominem attacks on them, nothing to a technical refutation of their argument. He's trying to make instead the opposite of an argument from authority, arguing that Peter Scholze is an incompetent. No one is going to buy this. Mochizuki apparently believes there is no reason to make significant changes to his article to address their concerns. He's entitled to his viewpoint that he is correct and they just don't understand, but any author who wants to convince the math community that he has a proof needs to be willing to work to explain to others what they are not understanding.

So, sure, Scholze-Stix may be wrong, maybe Mochizuki's methods do give a proof. But an explanation of how this works convincing to experts needs to be provided and it hasn't been yet.

11. **Peter Woit**
April 4, 2020

KS,
I don't think what's needed is more lectures about IUT. What's needed is a more convincing argument for Corollary 3.12, and my reading of Dupuy's twitter commentary is that he says he can't provide it.

12. **KS**
April 4, 2020

In my opinion, the corollary may be related to core theoretic framework of IUT , especially as how scheme theoretic universes are constructed and unified.
Mochizuki have been emphasized in his terminology mono-analytic generalized distinction of scheme theoretic objects , but which aren't mere ordinary scheme theoretic ones.
True problem may be such difficulty of theory , rather than so called too simplification by Scholze-Stix.
I hope that Dupuy or some other experts will lecture Diophantine geometers on core ideas and strategies of IUT in for instance Princeton possibly.

13. **justcurious1**
April 4, 2020

Can a referee go public after publication is made, or is that poor practise? Or could at least the referee reports be themselves published? They would help form better judgement on the situation: the experts would either say "nothing conclusive here", or "ha, I had missed that, got it".

14. **W**
April 4, 2020

@Peng,

My understanding is that there exists a paper (1) written by Mochizuki (and others), (2) using the language of IUT theory, (3) that is correct, (4) which could be made much clearer by removing the IUT language and writing it in more typical mathematical style. Unfortunately the paper for which I understand this is not the papers on ABC, but rather a paper he wrote after, purely about fundamental groups / anabelian geometry. (My understanding comes from a friend who has read it.)

So one can certainly say that there exists a paper where the style is the main problem. It just may not be true for the main IUT paper.
.
@Peter I don't think you can fully separate the Scholze-Stix criticism from problems with style. My understanding is that the Scholze-Stix criticism comes from (what they see as) changing the style of the argument so that it is more clear, and then observing that the modified argument is wrong, but Mochizuki says that these changes are substantive. If the argument specifically of Corollary 3.12 were written in a different style, there would be no issue.
.
@IWonder I know Scholze has said at some point that other expositions, including Go Yamashita's, are not clearer on the crucial 3.12. I don't know if this is true, as I haven't read it.
.
@Peter I am actually optimistic about Taylor Dupuy's work, specifically because I believe that if, in the future, he says he understands the proof of Corollary 3.12, then he will be able to write a comprehensible proof of it. If this is true then there would be two possible resolutions of his project and this would be a good thing.

15. **David Levitt**
April 4, 2020

I know that mathematicians are weird – but this is completely off the scale. Peter, could you please explain if there is any mathematical reason why, in eight years, Mochizuki cannot find an alternative approach to his proof? Your statement that "He's entitled to his viewpoint that he is correct" is too kind. To me, as a non-mathematical scientist, it seems crazy.

16. **Peter Woit**
April 4, 2020

David Leavitt,
Yes, this is completely off the scale. Having a serious math journal hold a press conference to announce that they're publishing a proof of a huge longstanding conjecture even though the consensus of experts in the field is that the proof is flawed is extremely weird.

It's not surprising Mochizuki hasn't come up with an alternative proof. That could be hard and he thinks this one is correct. The question is why, if he and others are convinced the proof is correct, they can't come up with arguments that will convince others of this.

17. **Peter Woit**
April 4, 2020

justcurious1,
The tradition is to keep referee reports confidential, and in this case it's not clear if breaking the tradition would help. Much of the work of the referees was surely on parts of the proof other than the controversial Corollary 3.12. On the controversial part of the proof, they're siding with Mochizuki that what he has written is correct and complete. If they have an argument for this that would convince Schole-Stix and others, it would be helpful if that were made public. This all comes down to the same problem of what is missing here that is needed to justify acceptance of the proof.

18. **Shinichi Aoki**
April 4, 2020

I am a Japanese science journalist. I've been watching your discussions on this site with interest.
In Japan, Dr. Mochizuki's paper, published in PRIMS, has the media buzzing that the ABC forecast has been proven. However, I disagree. I have read your arguments and understand that some researchers have claimed that Dr. Mochizuki's theory is correct and has proven a weak ABC theory, but have not convinced many experts.
Is there any chance that this situation could change?
I think Dr. Mochizuki will have to explain and convince himself. What do you think, Dr.Woit?

19. **Peter Woit**
April 4, 2020

Shinichi Aoki,
For there to really be a proof, it needs to be convincing to a consensus of experts in the field, and that has not happened here (the great majority of experts are not convinced). Scholze and Stix accurately entitled what they wrote about this as "Why abc is still a conjecture"
http://www.kurims.kyoto-u.ac.jp/~motizuki/SS2018-08.pdf
Unfortunately there does not seem to be much change since that was written. The publication of the article does not help at all, even hurts, since it removes some of the motivation for Mochizuki himself to write an improved version of his proof that might convince others.

20. **mahmoud**
April 4, 2020

I have asked this before in the comment section here, but I will repeat myself in the hope that someone knowledgeable is reading it:

It is well known that an effective proof of abc would imply an effective Roth's theorem (and consequently effective versions of many other things, like Falting's theorem), Mochizuki however has (to my knowledge) never stated any explicit bounds as a result of his work. It seems that he initially thought his proof of abc was non-effective due to a specific reason, this non-effective step was later removed by someone else (I have forgotten his name). Therefore his claimed and now published proof appears to have the feature that no explicit bounds follow from it, yet no one seems able to point to the source of this non-effectivity. To me that is a very strong indication that the proof is not complete.

And isn't the above a stronger reason to doubt the correctness of Mochizuki's work than the appeal to the authority of Scholze? Or har Mochizuki commented somewhere on why the proof remains non-effective?

21. **David Roberts**
April 4, 2020

> Therefore his claimed and now published proof appears to have the feature that no explicit bounds follow from it, yet no one seems able to point to the source of this non-effectivity.

this is not true. Dupuy and Hilado have derived very explicit estimates for Szpiro's conjecture in their work taking Cor 3.12 as a black box, and have just released a (pre-arXiv) preprint in Twitter. As in: "Let A_0 = 84372107405, B_0 = 316495, then the absolute value of the minimal discriminant of an elliptic curve E/F satisfying the standing hypotheses is bounded by … [explicit expression involving these constants and other known quantities]". This uses work of Serre–Tate is a serious way, and their reworking of Cor 3.12 into non-IUT language (that's another long paper they are working on). I don't know how you get more explicit than this.

There's also older work of Dimitrov (https://arxiv.org/abs/1601.03572) showing that one should get effective bounds ("there exist computable functions such that… [inequality]"), but I don't think he actually gives them.

22. **W**
April 4, 2020

@mahmoud I think the issue is that Mochizuki's work does give explicit formulas, they are just so weak you would have trouble finding an explicit countereaxample. Then any reduction argument to another problem would give you even weaker bounds. Taylor Dupuy and Anton Hilado have been working on giving explicit formulas on the statement https://www.dropbox.com/s/hwdxtpk5ydqhp6g/thm1p10-short.pdf?

If you look at Theorem 1.0.5 you can see constants like exp of 84372107405 times ell^4, where I think ell is a prime greater than 19, and thus must be at least 23. That's before you reduce from a general problem to Mochizuki's specific case.

I think Mochizuki has more precise estimates in his writeup, but they're also harder to understand.

23. **Felipe Lopes**
April 4, 2020

Here's my take on this situation. I know a considerable amount about elliptic curves and Abelian varieties, but the stuff on most high-level mathematics is way over my head.

It seems to me that Mochizuki's theory is an attempt to treat some classes of mathematical objects in the same way. That's not out of this world. The objections by Stix and Scholze boil down to a point where they believe this treatment is flawed. And Mochizuki answers that they do not understand his theory.

In all these years, several mathematicians were in contact with Mochizuki's group. If the relations he puts forward were so flawed that his proof is beyond repair, then there's something fundamentally wrong with his theory from the start, and the error would be much greater than a small passage in the controversial corollary.

Instead, what we are seeing is that there are many mathematicians open to the idea and are working on the theory instead of dismissing Mochizuki as a crank.

I find it completely possible that somewhere in the papers Mochizuki made a mistake that's very hard to fix, just like Wiles did when he proved FLT.

At the same time, I also find it possible a Heegner-style scenario, where someone outside the mainstream math community proved a theorem using 19-th century math, and people dismissed it on grounds that it cited an incorrect result, which turned out not to be flawed upon closer inspection.

In any case, I see little reason to not publish Mochizuki's papers. Even if his results are not perfect, many people seem to believe it's a viable route to attack the problem. That's enough for me.

24. **Peter Woit**
April 4, 2020

Felipe Lopes,
The latest version of Mochizuki's papers have always been available online, and anyone who wants to work on this has all they need. The only difference with having a published version is that the journal's editors have put their own reputation and that of their journal behind the claim that the arguments in the papers have been checked and are valid and complete. Given that the consensus of experts is still that this is a flawed proof, I don't see what the PRIMS editors are accomplishing here other than putting a torch to their journal's reputation.

25. **mahmoud**
April 4, 2020

Thanks to David Roberts and w for correcting me! I'm not sure how comforting it is that Dupoy & Hilado obviously have worked hard on this and still are unable to make sense of the proof of Mochizuki's 3.12 though…
(Vesselin Dimitrov was the name I couldn't remember in my first comment.)

26. **KS**
April 5, 2020

I want put here substantial reference on this issure , namely the corollary 3.12.
Mochizuki updated a his own survey which he recognize in his blog(in Japanese) as a most important summary on the heart of IUT which available at his web-site , the title as below .

The Mathematics of Mutually Alien Copies: from Gaussian Integrals to Inter-universal Teichmuller Theory.
(crucial arguments are about P142-146(example 3.11.4)).

In both above place and his blog , he is explaining that Scholze-Stix 's misunderstanding is caused by confusing logical relation ∧ with ∨ on the θ-link , so there is no problem in the theory originally according to Mochizuki himself.
Especially , there is an emphasis that θ-link should be absolutely "∧-unification" of Hodge theaters in the system of "log-theta lattice" and its horizonal sequence.
And he said in his blog(again to say , in Japanese but substantially well-argued in an above survey paper) , "logical operator ∧ " is basically stronger information than ∨ , in the sense of restriction of the relation.

As my "unreliable personal" undersrtanding , this arguement can be seen as just "how scheme theoretic universes are unified and computed systematically" in the context

of "arithmetic geometric(but mono-analytic , topological group theoretic) " construction of each of θ-divisors over global number fields.
Here , we should recall that θ-link is basically distinctly-unifying device of the Hodge theaters.

Anyway , I think there is any public need of the response to this by Scholze-Stix although it's not certain whether they recognized this matter or not.

27. **Vesselin Dimitrov**
April 5, 2020

All of this is confusing. Let me at least try to clarify something about effectivity and the external reduction.

@David Roberts: One can certainly be more explicit by spelling out – if not bypassing – what exactly those restrictive standing hypotheses mean. This paper by Dupuy and Hilado actually involves all of Mochizuki's special assumptions (from I Def. 3.1) occurring in his already explicit claim IV 1.10, and even more: [D-H] furthermore require the elliptic curve to have a good reduction at all prime ideals of residue characteristic 2. The latter is not assumed by Mochizuki (he rather states an explicit bound on the prime-to-2 part of the minimal discriminant, under his other assumptions in I Def. 3.1); and the Belyi maps argument does not allow a reduction to the case of good reduction above 2 (it only reduces to a situation of bounded contributions at 2). Besides, the true exponent is a "6" (as in IV 1.10) rather than the lossful "24" in [D-H]. My understanding is they rather want to make the statement more conventionally readable.

In my note you linked to, I simply explain that there is nothing inherently ineffective in the external reduction of the full abc conjecture to this explicit but restrictive statement IV 1.10. This is really disjoint from [D-H], the point being exactly to bypass the special assumptions. Yes, the increase in the constant will be rather large if fully worked out this way. Anyways the essence of the reduction is exemplified by the following representative statement that had not been known before Mochizuki's "Arithmetic elliptic curves in general position." It is one undisputed contribution of Mochizuki's to the subject of abc that will survive regardless of the ultimate outcome of the IUT saga: Over general number fields F, in the version where an [F:Q] dependence is included, the sharp (6+epsilon exponent) Szpiro discriminant-conductor conjecture is already equivalent to the a priori stronger sharp (1+epsilon) upper bound on (twice) the full Faltings height including its Archimedean term; with a change of constants that is traceable to a computable function of epsilon and [F:Q] alone.

@mahmoud, It seems Mochizuki has neither acknowledged nor disputed that his indirect appeal to compactness in "Arithmetic elliptic curves in general position" is straightforwardly turned around into a constructive argument, as I outlined in https://arxiv.org/pdf/1601.03572.pdf . But, along with his collaborators, he has subsequently gone about for effectivity in a different way:

I understand (cf. this announcement: http://www.uni-goettingen.de/en/77723.html?cid=20836&date=2020-01-23&fbclid=IwAR1DYidCLs2cwKcBE3TRQmiEwP8WXfSSiYvb5C2SR5rfX9JWKGxF7IYUeGw) that Mochizuki et. al. have since gone on to expand the claim of IV 1.10 further by also directly including the contribution to the minimal discriminant at 2. That would bypass the external recourse to Belyi maps insofar as the Szpiro conjecture over Q (not strong abc over Q with the "1+epsilon") is concerned. If they could really also directly add the Archimedean term of the Faltings height (as was claimed at one point in 2018), it would have yielded a full and practical explicit strong abc bound, and the connection to Siegel zeros would have gone through as well.

28. **PC**
April 5, 2020

@Peter Woit "I don't see what the PRIMS editors are accomplishing here other than putting a torch to their journal's reputation." For one thing they are making a lot of publicity for the journal. Whether this is going to harm or boost PRIMS in the long run remains to be seen.

29. **Peter Woit**
April 5, 2020

KS,
Mochizuki's claim "that "Scholze-Stix 's misunderstanding is caused by confusing logical relation ∧ with ∨" is not plausible and Scholze has in some sense responded to it with his statement to Nature that nothing has changed. This is just a variant of Fesenko's claim that the explanation for Scholze-Stix not accepting this proof is that they are incompetents, and equally hard to take seriously.

30. **Sam Hopkins**
April 5, 2020

I understand that other sciences have highly contentious episodes somewhat comparable to this one, and that of course in mathematics there are some people who maintain for a long time they've proved some important result although the community does not accept it (e.g. de Branges and the Riemann hypothesis), but I can't think of anything in math really similar to this Mochizuki stuff. Does anyone know of a historical parallel?

31. **Peter Woit**
April 5, 2020

Sam Hopkins,
People sometimes point to Heegner's proof of the class number 1 problem, published in 1952, but mistakenly assumed by experts to be incorrect until it was reexamined in the late 1960s. As far as I know though, the supposed problem with the proof was raised after its publication. I've never heard of anything like a journal going ahead and publishing a proof over a consensus of experts that it has a gap.

32. **DS**
April 5, 2020

Hi Peter,
I read that SM admits that it might be impossible to derive intermediate results from his purported abc proof, but has anyone else proved any statements about number theory or arithmetic geometry using IUT that are generally accepted (or provide a new proof even of known results)? Basically, has IUT been able to expand beyond its own shores?

33. **Peter Woit**
April 5, 2020

DS,
You need someone more expert than me for an informed answer to this. I haven't though heard of any major results crucially using the IUT stuff. For a related answer, see the comment above
https://www.math.columbia.edu/~woit/wordpress/?p=11709#comment-235908
from W.

34. **EricB**
April 5, 2020

From The Asahi Shimbun http://www.asahi.com/ajw/articles/13271575

The popular media seem to think it’s a done deal:

Editors of the journal of RIMS asked outside experts to peer review the articles for any problems.

In late 2017, it appeared that the articles would be published, but mathematicians in the West pointed out what they considered inappropriate leaps in logic in a core portion of the articles.

That led the journal editorial board to continue with their assessment. A number of other outside experts were consulted and it was only in February that Mochizuki’s proof was considered to no longer have any problems.

35. **David Roberts**
April 5, 2020

> Yes, the increase in the constant will be rather large if fully worked out this way.

The constant in the inequality is, even in D–H’s version, taking the curve E11a1 for concreteness (they check this satisfies the hypotheses of being “in initial theta data”) something like 10^86858896380650, *at the smallest*, if we take \ell = 7. So the bound can only get worse? (!!) I don’t know what the appropriate minimal discriminant is that this is supposed to be bounding, but this is not exactly a practical estimate.

36. **tulpoeid**
April 6, 2020

Naive question: Doesn’t “Publications of the Research Institute for Mathematical Sciences” sound like an institute’s own publication? If yes, they are morally entitled to publish their own work, with lower peer-review standards than for global-reach journals, isn’t it so?

37. **Peter Woit**
April 6, 2020

tulpoeid,
Different math journals do have different standards, and may have a mission of publishing their own researcher’s work. But “lower standards” means willingness to publish correct but not very interesting work, or maybe even correct but not very well written papers, not publishing incorrect papers.

38. **David J. Littleboy**
April 6, 2020

There was a front-page article in the Asahi Shinbun (one of the major Japanese newspapers) in the morning edition on April 4. An enormous article that took up about 1/3 the page, with the title in only a slightly smaller font than the lead article.

First, the old news, just for the record:

It states that the four papers were submitted to PRIMS at the same time they were published on Mochizuki’s blog and PRIMS submitted them to multiple outside reviewers at that time. The magazine furthermore asked the outside reviewers to continue their review in the light of the 2017 criticism of the proof, but says that said reviewers have now concluded that the proof is correct.

What I don’t think has been mentioned here is last paragraph of that article.

It states that (a) proofs in pure mathematics of things such as the abc conjecture have in the past led to practical applications and (b) that IUT is expected to be a powerful tool for solving a wide variety of difficult problems in mathematics. Furthermore (c) that a new research center (whose purpose is to promote this theory) led by Mochizuki had been created within the Kyoto University math department in 2019 and that the Ministry of Education, Culture, Sports, Science and Technology has created an annual budget of 4 x 10^7 yen (slightly under 4 x 10^5 USD) for said center.

If the proof weren’t controversial, that last paragraph wouldn’t be notable in the slightest. FWIW, a native speaker non-mathematician friend after reading said article was incredulous that there could be any problem whatsoever with the underlying math.

39. **Peter Scholze**
April 6, 2020

I have been weighing back and forth commenting again on this matter. However, the news in that last comment by David J. Littleboy convinced me that it might be good, even if futile, to say something again.

I may have not expressed this clearly enough in my manuscript with Stix, but there is just no way that anything like what Mochizuki does can work. (I would not make this claim as strong as I am making it if I had not discussed this for with Mochizuki in Kyoto for a whole week; the following point is extremely basic, and Mochizuki could not convince me that one dot of it is misguided, during that whole week.) It strikes deep into my heart to think that in the name of pure mathematics, an institute could be founded for research on such questions, and I sincerely hope that this will not come back to haunt pure mathematics.

The reason it cannot work is a theorem of Mochizuki himself. This states that a hyperbolic curve X over a p-adic field K (maybe with some assumptions, all of which are always satisfied in all cases relevant to IUT) is determined up to isomorphism by its fundamental group $\pi_1(X)$, and in fact automorphisms of X are bijective with outer automorphisms of $\pi_1(X)$. Thus, the data of X is completely equivalent to the data of $\pi_1(X)$ as a profinite group up to conjugation. In IUT, Mochizuki always considers the latter type of data, but of course up to equivalence of groupoids this makes no difference. (The passage back and forth is even constructive, by another result of Mochizuki.)

Mochizuki claims that by replacing X by $\pi_1(X)$, things can happen that cannot otherwise happen. Examples are given concerning the action of $\pi_1(X)$ on certain associated monoids. We discussed this at very great length in Kyoto, but none of these examples carried any actual content. Note that any potential non-commutativity of some diagram that results from identifying $\pi_1(X)$’s via isomorphisms of X’s could not possibly be resolved by using some other isomorphism of $\pi_1(X)$’s — all of them come from isomorphisms of X’s! Mochizuki considers infinitely many distinct isomorphic copies of $\pi_1(X)$’s, but could not tell us what goes wrong if we simply identify all of them with one another, and with $\pi_1(X_0)$ for some fixed X_0 — there is no diagram that commutes in his situation but does not commute under this further identification. (In my manuscript with Stix, we simply went through Mochizuki’s argument with this further identification, pinpointing what goes wrong. If this further identification causes problems, just tell us which diagram it is whose commutativity is rescued by not explicitly identifying $\pi_1(X)$’s.)

However, what I really want to do with this comment is to point out that there seems to be significant confusion over just the above point on X’s vs $\pi_1(X)$’s. Recently, arXiv:2003.01890v1 appeared, in which the author (Kirti Joshi) gives some survey on results related to Mochizuki’s work. In the introduction, on page 7, he explicitly claims that one could find non-isomorphic X’s giving rise to the same $\pi_1(X)$, and even more, in Remark 2.1 on page 14 he explains that my reading of the situation is a common misunderstanding. Even more, in Corollary 21.2 on page 47, he states something “well-known to everyone at RIMS” giving an explicit example of this phenomenon of non-isomorphic X’s giving rise to the same $\pi_1(X)$.

With this appearing on arXiv, I was indeed quite confused — did I in fact misunderstand this basic point all this time? If the above claims would have been true, I would see how Mochizuki’s strategy might have a nonzero chance of succeeding. But I was quite sure that in our discussions in Kyoto, Mochizuki agreed with me on that basic point; and the proof of Theorem 21.1 in that survey (of which Corollary 21.2 is indeed a corollary) was wrong. In any case, I emailed Joshi indicating my confusion, and he has since checked back with Mochizuki and retracted all of these claims (he told me a new version will be on arXiv soon). In particular, the fact “well-known to everyone at RIMS” is wrong, and in contradiction to this earlier correct anabelian theorem of Mochizuki.

I’m really frustrated with the current situation. What EricB reports from the Asahi Shinbun also sounds deeply troubling, effectively arguing along national lines; again, this strikes deep into my heart. I’m really quite surprised by the strong backing that Mochizuki gets from the many eminent people (who I highly respect) at RIMS.

If I can in any way help to mitigate the situation, I’d be most happy to.

40. **Taylor Dupuy**
April 6, 2020

Hi Peter!

First, hope your pandemic is going well. Mine is going ok. Hard to get things done without daycare.

Second, let me say that for hyperbolic curves over a p-adic field K (with no extra hypotheses like strictly Belyi type or Belyi type or canonical lift) that pi_1(Z) “determines” Z is open. Also, I personally would advocate against using words like “determines”, “reconstructs”, etc that have been causing sooo many problems in discussing all of these things. For the uninitiated, let me say that what Peter claims here is that outer isomorphisms of fundamental groups as topological groups are in bijection with isomorphisms of curves over a field K. The difference between what Mochizuki did in his relative case together with his interpretation of G_K and the absolute Grothendieck conjecture I claim is subtle (maybe I am missing something though, I’m a little intimidated saying this so publicly to be honest).

–to see this is a non-trivial topic consider for example the introduction to this manuscript here: http://www.kurims.kyoto-u.ac.jp/preprint/file/RIMS1892.pdf

Mochizuki’s theorem states that for Z and W hyperbolic curves over a p-adic field K, outer isomorphisms pi_1(Z) \to pi_1(W) *over* G_K — meaning they morphisms in an overcategory where pi_1(Z) \to G_K and \pi_1(W) \to G_K — are in bijection with isomorphisms between Z and W.

To prove this, it suffices for example to show pi_1(Z) interprets the field K. I have written down an unreviewed proof which I don’t think it is so difficult which I can share if you want.

Anyway, I think what you are thinking about that that pi_1(Z) admits and interpretation GG(pi_1(Z)) naturally isomorphic to G_K and since we have both the fundamental group and the augmentation map we should be in the setting of Mochizuki’s theorem and are done. This is not quite correct. What is at issue is that given f:pi_1(Z) \to pi_1(W) one does not necessarily know that GG(f) is inner (which would puts you into the hypotheses of the Mochizuki’s proof of the *relative* Grothendieck conjecture).

Also, Mochizuki has conjectured in print it is absolute Grothendieck over p-adic is not true—-See Remark 1.3.5.1 of this paper: http://www.kurims.kyoto-u.ac.jp/~motizuki/Absolute%20Anabelian%20Geometry.pdf but seems to be nonspecific nowadays. I don’t know. We would need to ask him.

I personally believe if it is true then there is sort of a Zilber trichotemy/diochotemy thing going on. That is “absolute Grothendieck over p-adic” iff pi_1(Z) interprets a field. Maybe I am using Zilber trichotemy/dichotemy wrong, but I stand by the statement. The reason for this is because in all the special cases where absolute Grothendieck over a p-adic field holds, (canonical lifts, beyli type, strictly belyi type) there is an interpretations of fields. Maybe this is wrong though and a reader can point out an example where we know the absolute Grothendieck conjecture over p-adic fields without some special hypothesis being imposed.

Third, your counterpoint is a heuristic and not a disproof. For example, Dieudonne modules are equivalent to finite group schemes and we don’t call them worthless. We could go blue in the face coming up with examples of two equivalent objects one of which is useful and the other which is not. Maybe I am missing something, but I’m not sure how productive these meta discussions are. I think your point is that he needs to “use something”/”do something”. I agree, but it is not a disproof.

Alternatively, we can argue who has the burden of proof here… which I think is a more compelling argument for rejecting the whole thing. I think we can all agree the notation in his manuscripts are a big dumpster fire.

Fourth, regarding the deformation theory, his entire theory is up to a generic isomorphism (=polyisomorphism) the base G. That is the fundamental objects he considers are (like) a fundamental group Pi with a map Pi \to G_K where G_K is considered up to automorphism. In fact, any time he does one of these polyisomorphisms (which I think we should be calling generic isomorphisms), we should probably be thinking of some sort of poor man’s universal family.

Next we can ask “does this *DO* anything”? Well, for one, it certainly provides a formalism for talking about how things change under automorphism. There are a lot of interesting representations of automorphisms of fundamental groups acting on various interpretations which seem to me to be vedry non-trivial… etale theta being a principal example. Here is another thing I haven’t been able to puzzle out but maybe you can help: Let Z be a hyperbolic curve over a p-adic field. Fix the augmentatio map f:pi_1(Z) -> G_K, let g:G_K -> G_K be and outer isomorphism. What is the base change of f by g?

pi_1(X) \times_{G_K, g} G_K = ???

It is like some sort of Frobenius twist looking thing—except not twisted by the Frobenius but by some outer morphisms of the fundamental group of the base. Is this the fundamental group of a curve? Anyway, it seems to me you can apply many of his interpretations to this object and that constructions are uniform in this sort of thing. This I am not 100% on and wish I didn’t have to talk about these things I don’t understand so well publicly. Maybe the readers can tell us what breaks here.

So, that’s all I have to say about that for now.

Best,
Taylor

P.S. Can someone tell me how to add new lines? Hopefully I can edit my comment later. Oooh, looks like spaces are included. They just didn’t show up in the preview. Niccce.

41. **W**
April 6, 2020

@Taylor Dupuy

Your clarification is very helpful for arbitrary curves, but as you say at the beginning, is relevant when there are no extra hypotheses like strictly Belyi type. Since IUT focuses on etale fundamental groups of once-punctured elliptic curves, and these are of strictly Belyi type, I don't see why they are helpful.

In case anyone following is confused about what theorem of Mochizuki is meant, it is Corollary 1.10 of his paper "Absolute Anabelian Cuspidalizations of Proper Hyperbolic Curves". (Not his earlier theorem about arbitrary curves.)

Even if this "stricly Belyi type" condition were somehow avoided, then the existence of extra isomorphisms of the abstract fundamental group would still be an open problem. It seems hard to imagine how these isomorphisms could ever be used in a proof of some concrete inequality between two real numbers without proving that at least one exists.

It is probably possible to make rigorous a lot of what Peter is saying, that any proof of XYZ form cannot possibly work, or maybe more precisely that Mochizukki's proof is equivalent to the wrong proof sketched by Scholze and Stix.

But one also should include not-completely-rigorous evidence when deciding on how much burden of proof to assign to the author of a paper. The fact that every plausible use of a particular mathematical construction would not help in a particular argument, but the construction adds unnecessary complexity to the argument, and thus would make it harder to see any mistake, and two smart mathematicians have tried to remove the construction and found an incorrect argument, is strong evidence against the paper, even though it is possible that (1) there is a different way to remove the construction which leads to a correct argument or (2) there exists a clear explanation of how the construction is used to solve a problem which is not possible without it.

> Fix the augmentation map f:pi_1(Z) -> G_K, let g:G_K -> G_K be and outer isomorphism. What is the base change of f by g?…. Is this the fundamental group of a curve?

Isn't the content of Mochizuki's theorem that, if Z of strictly Belyi type, then this is not the fundamental group of a curve? Of course this may be a curve in some other case.

42. **DL**
April 6, 2020

W writes:
>My understanding is that there exists a paper (1) written by Mochizuki (and others), (2) using the language of IUT theory, (3) that is correct, (4) which could be made much clearer by removing the IUT language and writing it in more typical mathematical style. Unfortunately the paper for which I understand this is not the papers on ABC, but rather a paper he wrote after, purely about fundamental groups / anabelian geometry. (My understanding comes from a friend who has read it.)

I'm not sure if I'm the friend to whom W is referring here, but I have had this experience and wanted to add a brief comment about it. I've gone through this paper:

https://projecteuclid.org/download/pdf_1/euclid.aspm/1540417834

and this paper:

http://www.kurims.kyoto-u.ac.jp/~yuichiro/rims1870revised.pdf

with some amount of care, and concluded that despite the non-standard language, they are both essentially correct. As W writes, either could be made much clearer (and shorter!) by rewriting them in standard language. What's worth noting here is that I was able to understand what was written in these papers and convince myself that they were correct, despite the non-standard exposition. On the other hand, I was unable to do this with crucial parts of the IUT papers, even after putting substantial time into doing so.

43. **Vesselin**
April 6, 2020

@W, just to fix your precise reference for the convenience of others following along: You mean either Corollary 2.3 on page 500 of that paper (Absolute anabelian cuspidalization of proper hyperbolic curves); or Corollary 1.10, part (iii) on page 43 of the subsequent paper (Topics in absolute anabelian geometry III).

Those disprove Corollary 21.2 of Joshi's preprint.

44. **Peter Scholze**
April 6, 2020

Taylor, thanks a lot for your answer!

Regarding your first point: Yes, I'm doing fine in these strange times; I hope you are too. Fortunately we are still allowed to enjoy the incoming spring.

Regarding your second point: As W observes, your objection only seems relevant when the curves are not of strictly Belyi type, but all the relevant ones for IUT are. So this objection is a red herring. (Meanwhile, it is clearly interesting to sort out whether strictly Belyi type is necessary, and I wish you luck in improving Mochizuki's anabelian results!)

Regarding your third point: Of course I am very well aware of the power of category equivalences. But there must be something you can do on the other side that you can't do on the first. As I said, during one week Mochizuki was not able to give a single relevant example. So to me it seems like a category equivalence that simply obfuscates things.

Regarding your fourth point: I am at a complete loss what one wants to do with full poly-isomorphisms. For the convenience of readers following along: A full poly-isomorphism between two isomorphic objects A and B of a category C is the set of all isomorphisms between A and B. Mochizuki often says that he identifies two objects A and B along the full poly-isomorphism. To be clear, this is (up to equivalence of categories) no data at all, there is a unique full poly-isomorphism, so you can't "pick one" (or rather, you can always pick one, and only one). On the other hand, to identify to objects in a category, you need to pick a specific isomorphism! Of course, you can just pick any one of them, but you can't pick all of them! If A and B are sets and $a\in A$ is an element, then what is the image of a in B under the full poly-isomorphism? It makes no sense. Mochizuki has repeatedly told us in Kyoto that because some diagram does not commute when A and B are identified via the obvious isomorphism (that usually exists in his situation), he has to identify them only along the full poly-isomorphism. But (in his situation) there is not a single isomorphism between A and B that makes the diagram commute! So how does the full poly-isomorphism help? You can't make the logarithm map into a map of fields by pre- and postcomposing with field automorphisms!

(To be clear, I am willing to accept that there is a nonzero chance that some of these things might make sense under certain circumstances. Again, let me stress that we discussed these very matters for one week in Kyoto.)

From what I understand, the objection to my manuscript with Stix is that we did some identifications that are not allowed. This is just the identification I was talking about: Mochizuki considers infinitely many distinct copies of $\pi_1(X)$ and is only allowing himself to identify them along the full poly-isomorphism. We do not see any diagram that commutes with this choice, but does not commute when we identify them along the identity map, once taking all $\pi_1(X)$ to be equal to the actual

$\pi_1(X_0)$ for our fixed curve X_0. In any case, the passage from X's to $\pi_1(X)$'s is giving you no extra flexibility, as discussed in my previous comment.

Best wishes,
Peter

45. **Taylor Dupuy**
April 7, 2020

Hopefully this is productive…

****
second point (and W's comment on the base change thing):
****

I'm not sure how much to engage here since this isn't strictly logically necessary for a disproof. Since I think this is an important point in terms of our understanding of what is going on I'm going to say a few words. First, for the readers, Peter and W are focusing on the bad non-archimedeans cases, I believe. In this situation, I'm not 100% sure that all the curves in what I would call the "zoo of covers" are SBT but certainly most of them are as they are analytifications of base changes of hyperbolic curves from number fields. This is Belyi's Theorem. There are a number of other points that we should consider: there are log structures too which should make things even more rigid (my understanding is that you need this information for reconstruction of the special fiber), you have these punctured tempered universal covers (these are certainly not algebraic), there are groups involved in mono-theta environments going on, and stacks fundamental groups. My point is that it is still conceivable to me that there is some sort of deformation theory going on and I don't want to confirm or deny this. But yeah, a lot of them are. The base fields certainly are not.

In terms of uniformity of constructions in G or "strange base changes"; Mochizuki performs many constructions with respect to (Π,G) where for a pair we consider a generic isomorphism $\mathbf{G}(\Pi) \to G$ — here $\mathbf{G}$ is the interpretation of a structure isomorphic to G_K in Π. This makes G "up to automorphism". You need Lemma 1.1.4.ii of "Absolute Anabelian Geometry of Hyperbolic Curves" for the interpretation $\mathbf{G}$.

W: "Isn't the content of Mochizuki's theorem that, if Z of strictly Belyi type, then this is not the fundamental group of a curve?"

I would say no, this is not the content of his theorem. But I don't know what you mean here. Mochizuki's theorem is a statement about morphisms not objects. The begining of the claim is

"*given* that $\Pi \to G$ and $\Pi'\to G$ are augmented fundamental groups of hyperbolic curves…"

There may be statements that allow you to classify when a group is the fundamental group of something but you will have to ask Daniel Litt or Emmanuel Lepage or Jakob Stix about this. They certainly will be much more knowledgable than me. By the way, this is what Mochizuki means when he calls things "bianabelian".

Let $\Pi = \pi_1(Z) \times_{G_K,g} G_K$. I think you can run the $\mathbf{G}(\Pi)$ interpretation on this thing. I haven't worked out what this does… it is unclear if $\operatorname{pr}_2:\Pi\to G_K$ is naturally the same as to $p_{\mathbf{G}}: \Pi \to \mathbf{G}(\Pi)$.

Also, Peter, don't hold your breath waiting for new results in this direction. What I said is pretty much the extent of what I "know" about absolute grothendieck conjecture over p-adic fields.

Also, I think we can all agree whether something can change or not due to Mochizuki's consideration of potentially lossy functors is one of the more interesting parts of this story and it is important that we as a community clarify the situation. I think Kirti's emphasis on this is a good idea.

****
fourth point:
****
https://imgflip.com/i/3vr2vv

Full polyisomorphisms should be considered as "generic isomorphisms". I completely agree with this viewpoint. There are some instances where you have polyisomorphisms which not full and these keep track of finite indeterminacy rather than an arbitrary choice.

For better or for worse Mochizuki decided this is the language he wanted to use to describe these things. When things are omitted without justification the statements made are no longer Mochizuki's. We can get mad at him all we want for over questionable style choices but it doesn't change his assertions. This, I believe, is grounds for rejecting a paper, but it doesn't disqualify the proof.

I want to give a couple comments on polyisomorphisms for the readers.

Comment A) First, I want to point out a really really really bad style problem that come with this choice of "polyisomorphism language": Many commutative diagrams involving full polyisomorphisms are tautologically commutative which makes many claims vacuous.

example: Theorem 3.11.iii.a, the $\vdash \times \mu$ prime strip commutativity statements.

These are everywhere.

This style choice forces the readers to search unnecessarily for non-full polyisomorphisms which, frankly, is a big pain (an example of a non-full polyisomorphism can be found in the definitions of the bridges of the Hodge Theaters for example). This doesn't make him wrong though. Just not the best expositor.

Comment B) If A and B are isomorphic objects then $\operatorname{Isom}(A,B) = f \operatorname{Aut}(A) = \operatorname{Aut}(B) f$ for any fixed isomorphism $f:A \to B$. In my head I always "push" the generic isomorphism into an arbitary automorphisms of one object. This is pretty tautological and Peter already does this but I just wanted to say that applying this systematically allows you to reduce a lot of things and perform computations.

Comment C) I have spent a bit of time literally identifying objects if they had a polyisomorphisms between them. Although you can actually get some pretty interesting "global objects" this is not what Mochizuki had in mind. One example comes from the so-called full polyisomorphism mono-theta environments and the log-linked fields. If you do this you end up identifying a bunch of roots of unity in a bunch of different fields — this is well defined because the fields are all log-linked. Anyway, my point here is that this is not what Mochizuki had in mind so you maybe don't want to do this.

(I can talk at length about other style issues. Another example is invocation of interpretations "in Hodge Theaters". This is one I feel that just sends readers on a wild goose chase reading page after page of definitions. Things are typically defined by much less and in an optimal presentation one shouldn't consider superfluous structure when a reduct will do.)

Ok, so what do generic isomorphisms do besides confuse readers?

First, they are intended to keeps track of automorphisms. Mochizuki's theory is really an investigation of the behavior of interpretations under automorphisms and permutations of the interpreting structure. I say permutations because sometimes they don't respect the category and are maps of sets. The stupidest example I can think of: Let $G\to G'$ be a map of groups with kernel N. Set theoretic permutations of G which fix cosets gN setwise induce the identity on G'.

Here are some example questions Mochizuki addresses:
–How does the kummer class of (an lth root of a pullback of) the Jacobi theta change when you take an automorphims of $\pi_1^{temp}(\underline{\underline{X}}^+)$?
–What about the evaluation points (conj classes of decomposition groups)?
–What types of automorphisms/actions stabilize what construction? (I am thinking about mono-theta environments here and the purpose they serve)
–What happens to a the measure space we construct when we take automorphisms of the interpreting G? (this is what Ind2 is)

Second, generic automorphisms can serve as a sort of "poor person's deformation space". I think Kirti discusses this well in his updated manuscripts so I'm not going to talk about this so much. I think, as Kirti has suggested, we should be asking ourselves which of these generic isomorphisms are actually representable. Emmanuel Lepage, if he is reading, might be able to say more about the usage of full and essentially surjective functors from the perspective of Gerbes. He told me something about this once.

Third, regarding your "what is the image of an element under a full polyisomorphism". This goes back to what the point of all these things are. We are really investigating interpretations under automorphisms. At the end of the day we are looking to construct a "multiradial representation of the theta pilot object" which is a region obtained by a procedure involving certain orbits. This is supposed to be 1) independent of any choices and 2) relatable back to our original P_q. We partially address (1) in my first manuscript with Anton which should be available soon. You can find some stuff on my vlog about indeterminacy diagrams. Anyway, the point of these comments is that the polyisomorphisms are Mochizuki's way of dealing with choices, it is also safe to make a choice but you need to make things independent of this choice.

****
fifth point:
****
–Regarding your manuscript with Jakob, the construction as you have stated imposes two normalizations that are alleged to be simultaneously enforced which lead to a trivial contradiction of the form A=B and A!=B. I think we all agree on this. Mochizuki says this is a straw man. I can't find these assertions in the manuscript.

I do however think that statements of the form "All proofs that use X must have property Y" could be very useful provided 1) we can make X completely rigorous and 2) Mochizuki's language can be pinned down in a way that makes X verifiable.

Aside: Actually, this was part of my motivation for looking at these interpretations. If you can show that two objects are equivalent (e.g. Frobenioids and pairs (Π,M)) then if there exists a proof using Frobenioids then there exists a proof using pairs (Π,M). These sort of reductions allow you to make assumptions about the structures that are used in the proof. This is what safely allows us to get rid of unappealing constructions.

I personally find a lot of the language very hard to falsify/parse.

–Regarding the sentences "This is just the identification I was talking about: Mochizuki considers infinitely many distinct copies of $\pi_1(X_0)$ and is only allowing himself to identify them along the full poly-isomorphism. We do not see any diagram that commutes with this choice, but does not commute when we identify them along the identity map, once taking all $\pi_1(X)$ to be equal to the actual $\pi_1(X_0)$ for our fixed curve X_0."

First, I don't think this is a faithful presentation of Mochizuki's setup but one thing I can say that might make you feel better: in this particular example of bad non-arch primes setting $X_0 = \underline{\underline{X}}_{\underline{v}}$ (this should be a double underline) then automorphisms of the fundamental group do all sorts of things to the zoo of covers. All of those dihedral symmetries act, all of the $\underline{\mathbb{Z}}$ symmetries act etc. Also, all of the stuff that is not interpreted from a fundamental group stays fixed. This seems particularly relevant in the context of "monotheta cyclotomic synchronization", but again, if I could finish the proof we wouldn't be having this discussion at all.

Sorry if I made any mistakes anywhere…

46. **DL**
April 7, 2020

Taylor — you've written quite a lot, but frankly I don't really see why anyone should continue discussing this until someone can point to a specific spot in the IUT papers which defeats Peter's objection. For example, if I understand correctly, you suggest some juice might be obtained by looking at maps of pi_1 which are not over G_K. If so, where are such maps used in IUT? And Peter gives a specific challenge — point to some diagram whose commutativity is rescued by not making the identifications Peter makes. If there is such a diagram, where is it?

47. **David Roberts**
April 7, 2020

> not making the identifications Peter makes

I'm convinced there is no such diagram, because that is not how category theory works. The whole issue with identifications (as in: demanding objects are distinct copies vs having them be the same object) is a red herring. Mochizuki doesn't want to do it for spurious technical reasons that one can ignore (or alternatively, humour him and agree to play along). I'm more suspicious that people could be thinking about objects that are living in different categories. But what do I know?

48. **DL**
April 7, 2020

David — indeed there are objects in different categories being identified here (eg a curve and its fundamental group). That's because we're speaking English, not trying to make formal mathematical statements. Formally, one might (for example) look for a diagram which is not commutative but whose image under some functor becomes commutative, say. That is something that can happen in "category theory." In any case, I agree it's likely there's no such diagram.

49. **David Roberts**
April 7, 2020

@DL

There are more people reading here than just experts on arithmetic geometry, or even mathematicians. I'm also writing for their benefit. I'm just pointing out that your interpretation of Peter's challenge is not really the question one should be asking—or at least, the way it comes across to me.

But oh well. I should keep my head down, perhaps. Much easier to discuss this not via the internet, but we are all locked away after all 🙂

50. **W**

April 8, 2020

@Taylor Dupuy,

> I would say no, this is not the content of his theorem. But I don't know what you mean here. Mochizuki's theorem is a statement about morphisms not objects. The begining of the claim is

> "given that and
are augmented fundamental groups of hyperbolic curves…"

Despite what DL mentioned, I just want to respond to this bit…

OK but if we're asked if something happens and we're trying to prove that it doesn't happen we can try a proof by contradiction.

We have a curve X over K and a map pi_1(X) => G_K. We fix K' and an isomorphism G_K => G_{K'} which does not come from an isomorphism K => K'. You ask, does the composition pi_1(X) => G_K => G_{K'} arise from a curve X' over K'?

Suppose it does. Then we have two hyperbolic curves X, X' and an isomorphism between pi_1(X) and pi_1(X'). Then Mochizuki proves that, if X is of strictly Belyi type, this isomorphism arises from an isomorphism between X and X'. In particular, it implies the isomorphism on the Galois part arises from an isomorphism K to K', contradicting our assumption.

In fact, given Mochizuki's previous p-adic Grothendieck conjecture theorem, the new theorem (except for the part about open injections, maybe) is precisely equivalent to the statement that the "base changes" of fundamental groups of Belyi curves are not fundamental groups of curves, plus the fact that the geometric part is identifiable as a normal subgroup.

51. **kirti joshi**
April 8, 2020

Dear Professor Woit,

This is to clarify the claims made about my paper in the context of your abc blog-post.
First of all let me say that my paper (referred to by Scholze in his comments) is not a survey of Mochizuki's work (though it may initially appear so because I state a number of standard results without proofs) and contains a number of new and original results (Scholze agrees with me on this). I start with one of Mochizuki's ideas and I build upon it in my paper. This is the paper which is cited in Scholze's comments and which can be found on the arxiv (though the update is not yet ready). In our correspondence Scholze has agreed (mostly) with all the changes in the new version and we (i.e. Scholze, Hoshi and myself) continue to correspond to resolve any persisting issues (of which there are very few). These issues and changes, at any rate, do not pertain to main results of the paper but to how the contents relate to IUT. Since comments about the retracted section of the paper may add to the confusion in a topic which is already quite complicated for many reasons, so all references to my paper (below) will be to the forthcoming version.

To explain one of Mochizuki's important ideas, let us begin with a classical result which says that there exist p-adic fields (i.e. finite extensions of the basic p-adic field Q_p) which are not isomorphic but which have topologically isomorphic absolute Galois groups. For examples of such fields see my paper. (In the 1990s this was refined by Mochizuki: a p-adic field is determined by its topological absolute Galois group equipped with its ramification filtration (see the section: five fundamental theorems of … in my paper) for references to proofs of these results).

Two p-adic fields with isomorphic absolute Galois groups have distinct additive structures (the multiplicative groups of non-zero elements of such fields are even topologically isomorphic). So the additive structure is the one which is changing (even as the absolute Galois group remains fixed). Because of Mochizuki's Theorem one can view the (upper) ramification filtration as the Galois theoretic manifestation of the additive structure of a p-adic field.

One of Mochizuki's ideas, simply stated, is to treat the p-adic field as a dynamic variable while keeping its absolute Galois group fixed. Because of the above remarks, this should be seen as treating the additive structure of the field as a (dynamic) variable. If readers are uncomfortable with this idea, they can simply think of allowing the p-adic field to vary while its absolute Galois group remains fixed. This makes complete sense and comes with highly non-trivial consequences as my examples illustrate:

(1) I show in my paper (with explicit numerical examples) that two p-adic fields with isomorphic absolute galois groups do not have the same different and discriminants (these are standard measures of complexity of fields in number theoretic contexts). These examples can be easily verified by any one with a computer equipped with SAGEMATH and importantly more can be found by my methods.

(2) I show that if E/F is an elliptic curve over a p-adic field F and if L,K are two p-adic fields with isomorphic absolute Galois groups and both containing F, then the base changed curves E_K and E_L (i.e. E considered as curves over L, K respectively) do not have the same list of numerical invariants (in general). This is done by means of explicit examples computed using SAGEMATH (with no additional programming needed). Notably my examples establish quite clearly that the additive structure of the p-adic field controls many subtle invariants of elliptic curves over p-adic fields. At any rate computing these examples does not require any of Mochizuki's theory.

Important realization on which my paper is based is this: the upper numbering ramification filtration is a Galois theoretic stand-in for the additive structure of the field and through this stand-in, the additive structure leaves its imprint on Galois representations.

(3) Notably invariants in (1) and (2) are also the sort of invariants which are crucial in Szpiro's conjecture and my work shows that these quantities are affected by the changes in additive structure and so Mochizuki's idea of using the variation of the additive structure to understand Szpiro's conjecture might have significant merit (there are several other new ideas in Mochizuki's paper as he has reminded me on a number of occasions). Note that I am not claiming that this is exactly what happens in the context of IUT, but I am simply reporting my observations that these quantities are not determined by the isomorphism class of the absolute Galois group of the relevant p-adic field. I do not know how to use my examples to illustrate changes in the specific context of IUT.

(4) I also demonstrate that the idea of changing the additive structure (which I have called anabelomorphy in my aforementioned paper) can be used in the theory of Galois representations. In this theory L,K are two p-adic fields which have isomorphic absolute Galois groups, so one can pass from representations of G_K to G_L. This does not affect many broad aspects of the representations as these two groups have equivalent categories of finite dimensional representations. However this operation of considering a G_K representation as a G_L representation via any given isomorphism of these two groups does not preserve (p-adic) Hodge theoretic properties of a representation (for example an Hodge-Tate representation of G_K may not remain Hodge-Tate when considered as a G_L representation via an isomorphism of G_L with G_K). However I prove that an important subcategory, namely ordinary p-adic representations is preserved under this operation. This operation of viewing G_K representations as G_L representations is not the identity functor in general nor is it so on the subcategory of ordinary representations. One can say such things because I also demonstrate that important numerical invariants of a Galois representations, for example its Swan conductor changes (again there are explicit numerical examples which I provide). The fact that this operation does preserve ordinary representations is of importance not only in Mochizuki's work (which uses two dimensional ordinary representations arising from Tate elliptic curves), but also in the broader theory of Galois representations (Wiles, Taylor and most results in the area since then). This result opens up the possibility of wider applicability of Mochizuki's ideas to other areas of number theory. For additional results readers are referred to my paper.

These ideas, proofs and examples have nothing to do with the one theorem of my paper which I have admitted was incorrect (and the new version will appear on the arxiv on thursday or friday this week) and my error should not be viewed by the readers as an example of what is wrong in this business. [I sincerely apologize to my colleagues and friends in Kyoto and Japan for the incorrect statement in the old version of my paper and my assertion that this (incorrect statement) was "well-known to everyone in Kyoto".] Again let me be clear that my errors (if any) should not in any case be attributed as issues emanating from Mochizuki's paper.

(5) I explain in my paper that even though K,L have topologically isomorphic absolute Galois groups, it is possible to communicate meaningful (arithmetic) information between them. For p-adic fields this idea is due to Mochizuki. There is no direct interaction between the additive structures of these fields at any point.

(6) In my paper I have also pointed out the analogy between Scholze's work (deeply extending earlier work of Fontaine) and Mochizuki's idea (see the section on perfectoid spaces in my paper) and in our personal correspondence Scholze has said that he sees no issues with my claims in that section (modulo minor corrections). In particular I point out in that section that Scholze's work is founded on a similar idea of changing perfectoid fields, perfectoid varieties (instead of p-adic fields and curves over p-adic fields) while keeping the absolute Galois group (of the perfectoid field) fixed (resp. etale fundamental group fixed). In the parlance of perfectoid geometry this corresponds to moving from one untilt to another untilt–see my paper for details (or Scholze's paper). Deepening of this analogy (as Taylor Dupuy and I hope to do in an ongoing project) should provide further insights into this difficult topic.

(7) The following way of remembering Mochizuki's idea may be useful:

A p-adic field wiggles and moves around in the isomorphism class of its absolute Galois group. This wiggling is a (new) degree of freedom in number theory and in algebraic geometry.

(This is illustrated in my paper with explicit examples and also see Mochizuki's paper and Hoshi's work and other members of the Kyoto school).

52. **Peter Scholze**
April 8, 2020

Dear Kirti Joshi,

thanks for chiming in here, and I'm sorry for concentrating on the parts of your paper/survey that were wrong.

The issue of non-isomorphic p-adic fields that have isomorphic absolute Galois groups is potentially interesting, and it is worthwhile to study which invariants are (un)changed under such an isomorphism. However, it is unclear to me how this enters into the actual content of IUT. In particular, your example of taking an elliptic curve E over a field p-adic field F and base-changing to p-adic fields K/F and L/F with isomorphic absolute Galois groups is not relevant to IUT. Namely, $\pi_1(E_K)$ and $\pi_1(E_L)$ are not usually isomorphic, although $\pi_1(E_K)$ and $\pi_1(E_L)$ both can be computed as pullbacks $\pi_1(E)\times_{G_F} G_K$ resp. $\pi_1(E)\times_{G_F} G_L$ where all terms are isomorphic — but not the fibre product, as the maps $G_K\to G_F$ and $G_K\cong G_L\to G_F$ are not the same. (This was the essential mistake in Joshi's first version.)

Regarding (6), perfectoid geometry gives nontrivial examples of such relations, which however require a strong "softening" of algebraic varieties (to pass to perfectoid spaces). Let me stress that perfectoid spaces have precisely this flexibility of changing geometry while preserving topology (like π_1), while Mochizuki's theorems I alluded to in the first comment prove that for the hyperbolic curves he considers, the geometry is determined by the topology (in fact, by π_1). It is clear that being able to change geometry while fixing topology can be interesting — but Mochizuki is just not in a setup where this is possible!

Finally, regarding (7), while Mochizuki claims that his proof must use this fact that p-adic fields are not determined by their Galois groups in some way, it never actually enters — in particular, no construction of such exotic isomorphisms is given or cited. In this sense, as you also say at the end of (3), this whole discussion seems tangential to IUT.

Best wishes!
Peter

53. **PC**
April 8, 2020

Dear Kirti Joshi,

I had the impression that the theorem of Jannsen-Wingberg says that the absolute Galois group of p-adic field only knows the residue field, the degree over Qp, and the number of roots of unity in the field. Maybe I misunderstood the statement, but if what I just wrote is correct, it is quite clear that you will have p-adic fields with isomorphic Galois groups and different arithmetic invariants.

Also I am confused by "the additive structure of the field" as such a field is just a Qp-vector space of dimension the degree over Qp; so its additive structure is encoded in the Galois group. Maybe you meant the multiplicative structure?

54. **OP**
April 8, 2020

Setting aside the matter of correctness, the referees have not fulfilled a crucial part of their assignment: ensuring that new ideas are explained much better, at least in the Introductions. If that was not part of their assignment then the editors (who have to be aware of the reasonable perception of the situation by the broader arithmetic geometry community) have been asleep at the switch.

If I understand correctly, after a lot of time and effort Peter Scholze has not identified any new insight in the papers that makes meaningful progress on the ABC Conjecture. The papers in their present form are therefore unsuitable for publication in a good journal, regardless of anything else (much as if Terry Tao were to regard a paper in harmonic analysis as devoid of new ideas then it is unsuitable for such publication too).

@PC: perhaps what is meant is that an identification of multiplicative groups (arising essentially from local class field theory) won't also respect the additive structure upon appending {0} with its usual multiplicative property.

55. **Tomate**
April 9, 2020

The last link doesn't work.

56. **Peter Woit**
April 9, 2020

Tomate,
Thanks. Fixed.

57. **AP**
April 10, 2020

@PC: I think what you state is true if you consider the absolute Galois group only as a group, but if you consider it as a group together with its ramification filtration then it determines the p-adic field.

58. **Taylor Dupuy**
April 10, 2020

****
W (=Will?) :
****
I agree with your observation. Nice.

Here is my summary (slightly modified).

Lemma.
Let X be an SBT curve over a p-adic field K.
Let $\Pi = \pi_1(X) \times_{G,g} G$ where $g:G \to G$ is an outer automorphism (=not inner).

The map $\operatorname{pr}_2: \Pi \to G$ is not isomorphic to the map between a fundamental group of an SBT curve to its base field. (Maps between maps are taken to be the obvious pair of maps satisfying the usual commutative diagram).
Proof.
Suppose it is.
First the map $\Pi \to G$ can be viewed as $\Pi \to \pi_1(X) \to G$, or pr_2 (indexing starting at 1 and not 0). Call this map h. In this case we have a diagram

$$\begin{CD}
\Pi @>\operatorname{pr}_1>> \pi_1(X) \\
@VhVV @VVV\\
G @>g>> G
\end{CD}$$

Where the bottom map is the outer g. If they were both SBT by Mochizuki's relative Grothendieck theorem + interpretability of the field we have that pr_1 is geometric (the Grothendieck theorem is not just about isomorphisms but all morphisms). But the bottom map is outer. This gives a contradiction. (I'm assuming the p-adic relative Grothendieck for morphisms here… which I need to double check on).//

I can't parse your last remarks completely…

"In fact, given Mochizuki's previous p-adic Grothendieck conjecture theorem, the new theorem (except for the part about open injections, maybe) is precisely equivalent to the statement that the "base changes" of fundamental groups of Belyi curves are not fundamental groups of curves, plus the fact that the geometric part is identifiable as a normal subgroup."

Here are a couple more points (I'm not trying to be a jerk):
a) What do you mean by "the new Theorem"?
b) We still don't know if $\operatorname{pr}_2: \Pi \to G$ is the same as $\Pi \to \mathbf{G}(\Pi)$ where $\mathbf{G}$ is the interpretation I referenced previously.
c) I think we only get that $\operatorname{pr}_2:\Pi \to G$ is not the natural map from and SBT curve to its base not that it is not the fundamental group of any hyperbolic curve.

I believe we can resolve (b) and (c) with the Lemma below.

Lemma. $\operatorname{pr}_1:\Pi \cong \pi_1(X)$ is an isomorphism. In particular Π is isomorphic to the fundamental group of an SBT curve.
Proof.
Let $f: \pi_1(X) \to G$ be the map from the fiber sequence.
Since $\Pi = \lbrace (a,b) : f(a) = g(b) \rbrace$ the kernel of the map pr_1 contains elements of the form $(1,b)$.
Since $f(1) = g(b)$ this means b is in the kernel of g. Since g is an isomorphism $b=1$ and hence the map pr_1 is an isomorphism.//

This means the composition $\pi_1(X) \to G \xrightarrow{g} G$ is something that Mochizuki considers but it not the isomorphic (as maps) to some $\pi_1(X) \to G_K$ of "geometric origin".

Also, I think you made an earlier comment about verifying the inequalities. I personally think people should be looking at the Mochizuki's inequalities after 3.12 but before Theorem 1.10 type inequalities. In my manuscript with Anton we point to a couple places where improvements can be made; there seems to be a lot of room between the two inequalities. To do direct computations with Cor 3.12 it seems you need to work directly with Division Fields as in the work of Harris Daniels, Alvaro Lozano-Robledo, and Drew Sutherland. Stuff like this:
https://alozano.clas.uconn.edu/wp-content/uploads/sites/490/2014/01/lozano-robledo_minimal_ramification_Rev1_v2.pdf

(Maybe you can email me and we can talk about this more if you are interested.)

****
Daniel:
****
More comments on p-adic Grothendieck:

The existence of some isomorphisms of fundamental groups of curves over p-adic fields inducing isomorphisms of absolute galois groups of p-adic fields "not of geometric origin" seems to be related to the section conjecture but I couldn't figure out if there was an "obvious" implication. See the results here:

http://www.kurims.kyoto-u.ac.jp/preprint/file/RIMS1892.pdf

I wanted to say something like "if the section conjecture is False then there exists a hyperbolic curve Z over a p-adic field K and some automorphism σ of $\pi_1(Z)$ such that $\mathbf{G}(\sigma)$ is not inner." but I may be totally totally off here. Maybe you can salvage this? I'm trying to get a sense of how difficult this should be by reducing this to a "really hard" problem.

Also, while the pro-p relative Grothendieck conjecture is true the pro-p section conjecture is False. This is a Theorem of Hoshi. I don't understand these counterexamples but it is my understanding that Jakob views these as “accidents” or “lucky”. (pg 192 of his evidence for the section conjecture book.)

I’m going to postpone any more remarks about missing monoid structures in the setup for a later post (if I’m going to say anything at all) because I want to get it right for everyone.

****
PC:
****
What OP says is correct. It is a local class field theory thing. A classic theorem is that for K a finite extension of $\mathbb{Q}_p$ we have $G_K^{ab} \cong \varprojlim K^{\times}/K^{\times n}=: \widehat{K^{\times}}$ where G_K is the absolute galois group of K. There is a version of this “on crack” where you can describe the topological groups $\mathcal{O}_K^{\times}$ and $K^{\times}$ among other things ‘inside’ G_K. You only get multiplicative stuff though.

You can’t recover the full field structure (both binary operations satisfying the usual axioms) because there exists fields K_1 and K_2 with $G_{K_1} \cong G_{K_2}$ where K_1 and K_2 are not isomorphic. This is a theorem of Jarden and Ritter.

Anyway, at the end of the day you can have one binary operation or the other but not both. The equivalence of having multiplication or addition (but not both!) comes from p-adic logarithms (which can be defined ‘inside the group’). This is just the first isomorphism theorem of groups.

59. **Peter Woit**
April 11, 2020

Thanks to all commenters here for the remarkably informative discussion of the mathematics involved in the problem with Mochizuki’s claimed proof explained by Peter Scholze. Note an important aspect of this discussion: no one (including Joshi and Dupuy, two people who have been deeply involved in the study of IUT) has come forward to explain how Mochizuki can get around the problem pointed out by Scholze. The only place I know of publicly available that supposedly contains such an explanation is Mochizuki’s web-page
http://www.kurims.kyoto-u.ac.jp/~motizuki/IUTch-discussions-2018-03.html
The only relevant materials there are absurd ad hominem arguments from Ivan Fesenko and Mochizuki’s own comments. Scholze and Stix are the only two who have had the experience of directly engaging in extensive discussion with Mochizuki of the problem, so their report that he has no answer to the problem must be taken as authoritative in the absence of some other strong evidence. The past two years of study of the problem do not seem to have led to anyone besides Mochizuki himself being willing or able to try to explain how Mochizuki’s claimed proof avoids the problem, and all experts I know find his explanation unconvincing.

Given this, the decision by PRIMS to hold a press conference announcing that the proof has been checked and will be published is completely outrageous. It may be good PR in Japan, but it is seriously damaging to the reputation of RIMS in the math community and those responsible for that institution need to come forward and address the issue.

60. **abc**
April 11, 2020

Hi Peter Woit:

I feel surprised to see your comment, since Mochizuki did respond extensively in his personal blog:

https://plaza.rakuten.co.jp/shinichi0329/diary/202001050000/

I did not see any “absurd ad hominem argument” you are talking about. Scholze and Stix’s names did not even appear.

I am wondering – did anyone ever reached out directly to PRIMS’s editorial board on this? Isn’t it too quickly to reach a conclusion that “…is completely outrageous. It may be good PR in Japan, but it is seriously damaging to the reputation…” without some communication with the referees who have done respectable work on this paper? These people did spend eight years in going through the detail and understanding the paper. Should not these words be reserved for publishers that published Atiyah’s six sphere paper (https://www.springer.com/gp/book/9783319648125)?

I am not sure how you came to the conclusion that “…no one (including Joshi and Dupuy, two people who have been deeply involved in the study of IUT) has come forward to explain how Mochizuki can get around the problem…”. It is still possible that Mochizuki does not need to “get around the problem” because the problem does not exist in the first place; maybe it is caused by confusion and misunderstanding from both sides.

I feel confused reading through the blog. If someone with established expert status in a nearby field “give his/her nod” or “shake his/her head” regarding a paper, is this enough to replace the traditional journal referee process? If this is the case I would be more than happy to know Atiyah’s six sphere paper is complete, detailed, rigorous and correct – Atiyah claimed his proof was correct.

61. **Peter Woit**
April 11, 2020

abc,
I read Mochizuki’s blog entry when it came out. To the extent I could make sense of it via Google Translate, it appears to be an argument that the people who see a problem with his proof (eg Scholze-Stix) are simply not understanding it because they are too dim-witted to understand the difference between an “and” and an “or” in a logical argument. This is just completely absurd.

I agree completely that it is the responsibility of the PRIMS editorial board to put forward publicly whatever mathematical report they received from referees showing that Scholze-Stix had misunderstood the argument and that the problem they pointed to does not exist.

As for the comparison to the sad story of Atiyah’s delusion in his declining years that he had a proof of the six-sphere question, it’s very telling that you see any relation at all between these two proofs.

62. **UF**
April 11, 2020

As far as I understand the main objection brought up here by Peter Scholze is: Mochizuki considers infinitely many distinct isomorphic copies of $\pi_(X) $’s, but can not tell us what goes wrong if we simply identify all of them with one another, and with $\pi_1(X_0)$ for some fixed X_0 – there is no diagram that commutes in his situation but does not commute under this further identification.

It seems to me that this is adressed in (C7) in Cmt2018-05. Mochizuki claims there that if one (once and for all) identifies the various $\pi_1(X)$’s in one column (using the non-archimedean logarithms), then there is no switching symmetry between the two neighboring columns. On the other hand, if one identifies the $\pi_1(X)$’s just as topological groups via poly-isomorphisms, then Mochizuki claims that there is such a switching symmetry (i.e. some diagram commutes at this weak level).

It seems to me that in the proposed proof both viewpoints are used: The ability to rigidify the relationship between the $\pi_1(X)$'s in one column when needed (e.g., I think, on both columns for the log-Kummer correspondence), and then later the ability to forget about the rigid structure, to pass from the LHS to the RHS.

63. **naf**
April 12, 2020

One way to prevent this absurd situation, i.e., the "proof" of abc being published by PRIMS, might be to organise an open letter/petition. The reason that I think that this might be useful is that even though many well-known mathematicians have expressed their views on Mochizuki's papers, these have been scattered across several blog posts and comments. If there were a simple open letter, saying something to the effect that the undersigned have gone through the IUT papers and do not believe that they constitute a proof of abc, and this was signed by a relatively large number of experts, then this might have more of an effect and might even be picked up by the Japanese press.

Of course, for this to work some expert–I am not one, though I have read the papers–has to take the initiative.

64. **Peter Woit**
April 12, 2020

naf,
The problems with such a petition are:
1. There's a strong feeling among many that engaging in that kind of effort to get publicity for one side of a mathematics argument is inappropriate, that mathematical truth is not a topic for petitions.
2. Scholze-Stix are the only people who have spent the time directly engaging with Mochizuki needed to be completely sure, based purely on their own personal understanding of the mathematics, that he doesn't have an answer to objections to his proof.

On the topic of 2., a huge part of the problem here is that, eight years after the proof came out, as far as I know no one except Mochizuki is willing to publicly claim that they fully understand the proof and can explain it to others, in particular that they can convincingly explain why Scholze and Stix are mistaken. Even in Mochizuki won't travel or give talks explaining this point, why won't anyone else?

There are mathematical organizations that arguably have some responsibility here and whose boards should consider some action. In particular the EMS is the publisher of PRIMS, and perhaps the IMU should consider the issue.

65. **BR**
April 12, 2020

Peter Woit,

there is one aspect I find not really well represented in the current discussion. I think an author has also the right to make a mistake, and I do not mean deliberately, but in the process of scientific investigation. At the same time one has to take care not to inflate the meaning of scientific publishing and peer-review. It is a misconception to think the peer-review process should warrant absolute truth and correctness. Especially not in cases of relatively new and open fields.

In that sense one could take a lot of pressure out of the current debate, especially concerning the various close-to or ad-personam issues, if we would more agree on the fact that publication in an international journal is just another means of communication, if however one with a certain level of quality assurance.

These are just some thoughts that I have accumulated during 20 years of active scientific research.

66. **Peter Woit**
April 12, 2020

RB,
I think you and many of my readers are not familiar with the culture of publication in mathematics, which by the nature of the field has a different aspect than that of other sciences. Assuring that the proofs of theorems given in a paper are correct is the main concern of the reviewing process at a math journal (secondary concerns are how interesting the theorems are and expository quality). What is going on here is completely unheard of.

Mathematics has a rigid, unyielding quality that differentiates it from other intellectual subjects. Either a proof is correct, with the claim logically following from the assumptions, or it isn't. Unfortunately it's not good enough for an argument to be fine at all steps except one, and this makes proving an important new theorem a high-pressure business. One can invest years in something which in the end simply doesn't work. In order to make progress in mathematics, one needs to understand clearly when there is a correct and complete argument and when there isn't. Mathematicians have the advantage of a much clearer boundary between what is understood and what isn't than is typical in most fields.

Mostly this leads in my experience to a positive aspect of mathematical culture: people are used to finding that they are wrong and arguments about whether a mathematical argument is correct tend to not get personal. A colleague likes to explain that mathematics is the only subject he knows about where when two people go into a room disagreeing about whether something is true, almost always they come out with one of them agreeing he (or she) was wrong.

In this case, one side (Scholze-Stix) is making purely mathematical arguments, the other (Mochizuki-Fesenko) has engaged in unusual public argument about the competence of those who disagree with them. The very existence of this asymmetry is evidence for which side has the mathematics right.

67. **Peter Scholze**
April 12, 2020

As UF is trying to point to a specific objection to my manuscript with Stix, and it's the first real try in this thread, let me try to answer this.

Actually, the objection is bizarre. If all your copies of $\pi_1(X)$ are the same, then how can the situation be less symmetric? It's totally symmetric. It's not symmetric if you also look at some other structures present in Mochizuki's setup, like the log-link: This just means that the logarithm map is a different map from the one you obtain by switching source and target, which is self-evident (the logarithm is not its own inverse). It also cannot be salvaged by using some other/indeterminate identification of $\pi_1(X)$'s — this would at most change source and target by some field automorphism. So it's unclear to me how the passage from X to $\pi_1(X)$, and to $\pi_1(X)$ up to indeterminate isomorphism, is helping in this matter.

68. **BR**
April 12, 2020

Peter Woit,

thank you for your explanations, you are fully right, to imply I am not a mathematician (also in our circles Mathematics is not considered a science but part of humanities (which is a bad translation for "Geisteswissenschaft")). But for the one you don't hit the nail fully on the head if you mean that in (other) sciences the peer reviews primarily “concerns are how interesting the theorems are and expository quality”. What I meant to address is that the peer review should mainly check technical and scientific consistency (call it quality). And here, definitely in the “sciences” is still plenty of space for technically and “scientifically” pretty flawless works to turn out to be “wrong” at a later stage of affairs.

It seems much less likely, but I am not convinced that all is that digital (either wrong or right) as you describe it. Let me attempt to construct an example: Lets take some theorem about a relatively involved concept like a perfectoid space with a technically fully correct proof. Let us assume there is some subtle issue in the definition of the perfectoid space which went undetected yet. Such a subtle issue might lead to a wrong theorem with a proof that relies on the definition, while the proof itself might still be technically fully correct.

I think even Maths is not immune against such problems. And such a problem could arise even if the proof is technically correct. In fields like arithmetic theory with very complex structures such cases seem not too unlikely.

69. **mahmoud**
April 12, 2020

Peter,
that it’s unheard of that a paper on mathematics gets published despite the referees not being completely sure of its correctness seems at odds with history; I guess Hales’ proof of the Kepler Conjecture would be the most famous counterexample. So what is unprecedented in this affair does not so much seem to be that Mochizuki has put forth a series of lengthy papers that the mathematical community is finding it hard to fully understand, but rather the complete breakdown in communication as is evident after the Scholze-Stix manuscript became public.

Any decision to (not) publish the articles will hardly change this highly unfortunate divergence of opinions that is going on now (and that I think is unprecedented).

70. **Peter Woit**
April 12, 2020

BR,
The reference to concerns about interest of the theorems and the quality of the writing was just about mathematics, that these are important in evaluating a paper, but secondary to the issue of correctness of the proofs. In different fields of science I would think standards vary, depending on what characteristics of research are considered most important.

Yes, the example you give is relevant. Proofs can be wrong if they rely on problematic definitions or other results. When referees evaluate a math paper, normally they are starting from the same assumptions as the author about the correctness and unambiguity of the earlier literature. But this is exactly why it is considered so important that a new paper not contain an incorrect argument, since this can wreck the consistency and correctness of later published literature. What is going to happen if Mochizuki’s paper is published is essentially a fork in the mathematical literature. People will write papers that depend on Mochizuki’s results and may get these published in a new fork, but the majority of the community will have to reject such papers in order to preserve the consistency of the larger fork. This will not be a good situation.

71. **Peter Woit**
April 12, 2020

Mahmoud,
The problem here is very different than the Hales case. In that case, referees were nearly certain the proof was correct, but could not be completely sure due to its complexity, making a computer check desirable. In this case there’s the bizarre situation that the referees seem to have agreed that the proof was correct, while the majority of experts believe the proof is simply incorrect.

If you read what Scholze has to say, he’s not saying that the Mochizuki proof is hard to check but probably correct. He’s saying that the proof is wrong, for fundamental reasons that he has explained and which the author has no answer to. The situation is in some sense relatively conventional: experts have looked at a claimed proof of a major result and identified a serious flaw, but the author has been unwilling to admit his proof has a flaw. The only unconventional thing is that given this situation a journal’s editors have decided to go ahead and publish the paper anyway.

72. **naf**
April 12, 2020

Peter,

I am not convinced that there is any “strong feeling” against a petition, since such a situation has perhaps never occurred, at least in the last few decades. Also, the intended purpose would not be to “determine the truth”, but merely to express an opinion with the hope of convincing PRIMS .

It is clear that Mochizuki is unlikely to be ever convinced to withdraw his claims–no one outside his circle actually thinks the proof is correct and should be published in its current form–and nothing can be done about this. The unfortunate thing is that RIMS is now explicitly supporting him. I can only assume that there must be strong non-mathematical reasons–they cannot be unaware of the Scholze–Stix objections–for them doing so.

As you had said before, all doubts concerning the acceptance of the papers could be cleared if PRIMS released the referee reports, but this could only happen if they are acting in good faith and not under some strong external pressure.

73. **Peter Woit**
April 12, 2020

naf,
I agree that something should be done about this, but there are significant problems with the petition idea, and I see no reason to believe that the PRIMS editorial board would agree to change its mind about publishing the papers in response to such a petition. There are a limited number of people who have responsibility for RIMS and this journal, and I suspect they’re hearing privately strong arguments that they should do something. I hope they live up to their responsibilities.

74. **mahmoud**
April 13, 2020

Peter,
I agree that the case of Hales is quite different from the IUT papers, but cf. the editorial note here for an approach one could take when publishing them. Furthermore, your contention that Scholze & Stix found a mistake in the proof and that Mochizuki should fix it or retract his claim isn’t unproblematic; I take the comment at the very end of his reply to S&S as saying that he completely agrees with their argument, but that this “absurd and meaningless” theory isn’t IUT but their own misguided simplification of it. So no essential progress at all has been made since he first made his papers public and the problem still remains that no one understands what he’s talking about. (I’m tempted to say that IUT appears to be not even wrong.)

To me the issue of whether PRIMS will publish the articles or not is minor since it seems most unlikely that any of the believers in IUT will change opinion if the editors decide to refuse. Having the work published would at least have the positive outcome of a final version and an end to the moving targets that Mochizuki has on his homepage (all the four IUT papers are updated this April and no changelog is provided).

75. **Peter Woit**
April 13, 2020

mahmoud,

Yes, Mochizuki has claimed Scholze-Stix misunderstand him and are wrong, but virtually no experts in the subject believe this to be the case, based on hearing both sides of the argument.

The point of stopping PRIMS from publishing an incorrect proof is not to convince the true believers that it's incorrect but to try and protect the integrity of the mathematics journal literature. If PRIMS does this, why shouldn't other journals? Is it really all right if the standard for publication of a proof of a major conjecture becomes not whether it is right but whether the author and his allies have the political muscle to get it done? We increasingly live in Orwell's world where truth no longer matters, but all need to resist being pushed farther down that path.

76. **anonymous**
April 13, 2020

I am not sure that a petition is a right thing to do. However, a semester at IAS (or similar institutions) devoted to checking IUT would settle the matter. Experts who care about the general state of maths could step forward.

77. **W**
April 13, 2020

@Taylor Dupuy

I'm just saying that you can reverse the argument to an extent. Given two curves X_1, X_2, with an isomorphism of their fundamental groups, if you check that the geometrical pi_1 of X_1 is sent to the geometric pi_1 of X_2 by this isomorphism, then it follows that this isomorphism arises by "base change" from an isomorphism of Galois groups of local fields. If this isomorphism of Galois groups of local fields arises from an isomorphism of fields, then the fact that X_1 is isomorphic to X_2 comes from Mochizuki's first p-adic Grothendieck conjecture theorem. If this isomorphism of Galois groups of local fields does not arise from an isomorphism of local fields, then we can get a conjecture if we know that base changes of strict Belyi type curves are never a curve. So Mochizuki's theorem that strict Belyi type curves are determined by their pi_1s, is basically equivalent, modulo these prior results (I think…), to a special case of your question

@abc

> I feel confused reading through the blog. If someone with established expert status in a nearby field "give his/her nod" or "shake his/her head" regarding a paper, is this enough to replace the traditional journal referee process?

No one is suggesting that we decide this based on our prior knowledge of Scholze, Stix's, and Mochizuki's level of expertise. Instead you're supposed to read Scholze-Stix's critique and Mochizuki's response and see – based on as much of the mathematics as you can understand, as well as the tone and such – who is more plausibly right.

One could also look at this comment thread. Specifically, note that everything Peter Scholze is saying is an elaboration of what's in the original note. He's not jumping to a new objection in every comment or anything strange like that. He's just calmly explaining the key points of the argument. (Though much more clearly than I could explain them!)

@mahmoud

Even before the Scholze-Stix manuscript (but not too long), Scholze and Conrad (and maybe others) had publicly highlighted Corollary 3.12 as the key step in the proof that did not seem to make sense. There is no comparison to a long computational argument where case after case is checked but one can't be completely sure there wasn't a small but crucial mistake in one of the cases – here there are hundreds of pages of trivialities, followed by a single step which multiple mathematicians carefully read and independently observed was not properly justified. Of course many papers contain a step whose justification as given in the paper is not complete, but when these are pointed out, the purpose of the refereeing process is to fix such things.

@mahmoud again

What Peter Woit is attempting to do is not just report on some kind of they said – he said. He's trying to look at what the two sides said and figure out if it is plausible or not. It's not very plausible that someone would be able to look at their own theory and a radical simplification of it and not be able to explain why they are different, it's also not very plausible that the explanations in Mochizuki's note are valid.

It just simply is the case that any diagram in a category where all objects are naturally isomorphic is equivalent to a diagram where all vertices are labeled by the same object and edges are labeled by automorphisms or endomorphisms of that object. It is the case that, if the arrows are isomorphisms, the complexity and mathematical value of the diagram is controlled by the automorphism group of the object, and Mochizuki, in earlier work, bounded the automorphism groups of the relevant pi_1(X) (and even if he hadn't, he isn't able to point to any new lower bounds on the automorphism group or new isomorphisms more generally constructed in this work). It is the case that any argument for proving an inequality between two real numbers by combining a series of inequalities in various objects in the category of one-dimensional affine spaces over the real numbers can be converted into an argument for proving an inequality between two real numbers by combining a series of inequalities between two real numbers.

It is also the case that adding an ad hominem attack about a point of total irrelevance to your argument does not make it more convincing, but rather quite the reverse, and …

It is true that no progress has been made if you ignore these points and various similar ones. But if you accept any of these arguments then enormous progress has been made.

78. **Sam Hopkins**
April 13, 2020

I think the sociological critiques of Mochizuki's work are almost as damning as the specific mathematical critiques by Scholze-Stix et al. Namely, as Peter Woit has pointed out, there is no community of mathematicians who claim that they can understand and communicate Mochizuki's work to the broader mathematical world; and furthermore the elaborate machinery developed by Mochizuki has so far apparently only been used to resolve exactly one famous conjecture in number theory, with no other applications. Consider by comparison the development of scheme theory. At the time they were developed (and still!) learning about schemes was considered very difficult; nevertheless, quickly several communities of experts across the world (in Paris, Boston, Moscow, etc.) emerged, and also almost immediately the theory was applied to many, many nontrivial problems. (I guess perfectoid spaces would be another similar example, although that might get too close to the personalities involved in the current dispute.)

79. **Peter Woit**
April 13, 2020

anonymous,
Many people seem to remain under the misconception that the problem here is that Mochizuki's proof is insufficiently well understood or checked. This was the problem a few years ago, but is not the problem now. The problem now is that a specific gap in the proof has been identified, but the author refuses to acknowledge this, while neither he nor anyone else can explain how to overcome the gap. Under these circumstances, no one competent is going to go spend a semester at the IAS discussing this (and, for his own reasons, Mochizuki himself is unlikely to do so either).

80. **Timothy Chow**
April 13, 2020

Peter, I largely agree with what you are saying, but I slightly disagree with this claim: "Assuring that the proofs of theorems given in a paper are correct is the main concern of the reviewing process at a math journal (secondary concerns are how interesting the theorems are and expository quality)." In our idealistic moments we might believe that this is the case, but I think that in most cases, the main concern of the refereeing process is to assess how interesting the theorems are. It is quite common for referees to *not* check every detail of the proofs for correctness, but to trust the author.

Having said that, I do agree that there are exceptions. If a paper claims to solve a well-known, difficult problem (as is the case here), then the referees are normally expected to scrutinize the correctness of the proof very carefully. Also, if a credible critic raises serious questions about the correctness of a proof (regardless of whether it's a famous open problem), then everyone would expect a respectable journal not to publish the paper until those questions are satisfactorily addressed. I agree that the current situation is unprecedented. Even in the case of Hsiang's proof of the Kepler conjecture, there was not this level of public criticism of the proof by other experts until *after* the paper had been published.

81. **Taylor Dupuy**
April 13, 2020

Will's comment has insprired me to write a little bit more since he seems to be paying close attention (thank you Will). I kind of felt like Peter W.'s comments were a call to close the dialogue.

It seems to me that Peter S. has two claims:

1) One involving the diagram in his manuscript with Jakob in section 2.2. That the setup here gives a contradiction is undisputed. The fact that the setup is valid is disputed (see C8 of Mochizuki's comments). It also seems very dubious to me that the contradiction would be so tautological and I can't find these claims in the manuscript.

2) That one can identify all fundamental groups at bad non-archimedean places using the identity and this will not change anything (maybe he wants to assert this for every structure in a "base hodge theater"?). This includes across the theta link and across log links. This is in say Footnote 8 of their manuscript.

Peter, how do you propose to show that (2) implies (1)? I also don't understand the level of your assertion. Do you want to conjecture (2)? Do you want to claim (2) as a theorem? Do you want to claim/conjecture that (2) is true and implies some contradiction?

There is something in footnote 12 of your manuscript that I spent a little time with and if it is supposed to claim this is the explanation of (2) implies (1) then it seems to be squeezing around 15 assertions into one footnote and omits the explicit claim that (2) implies (1). In particular I don't see how to recover the normalization that needs to be simultaneously in force in (1) to derive their contradiction.

Anyway, I still see Peter's arguments as still being in the realm of a meta argument.

Maybe it is obvious to him an everyone else how to apply the definitions in IUT3 and convert these into proofs but this is not obvious to me. Again, for me 3.11 is made up of about 15 different assertions and uses a large number of definitions that I don't have at my fingertips…

82. **mahmoud**
April 13, 2020

@w
I mostly agree with what you write, I only find it a sad sort of "progress" that it has become increasingly clear that Mochizuki can't explain why he thinks the alleged gap isn't really there. If one assumes that he is behaving honestly, he believes himself that he has a correct proof but is clearly failing completely to communicate his ideas to other mathematicians; and that issue has been apparent ever since he made his papers public.
My issue is mostly with the focus on publication in PRIMS; the "integrity of the mathematics journal literature" (to the extent there still is one) will survive I'm sure, even though the integrity of this particular journal might suffer. On the political side of this affair it's more worrying that some people apparently are trying to obtain money from the UK government for research into a theory that increasingly seems like a mathematical case of being not even wrong.

83. **Anon**
April 13, 2020

This thread is somewhere between depressing and necessary – thank you PW for hosting it. But I would be far more interested in a comment thread about Peter's Fontaine rings over Z. Wow. What is he about to do with them?

84. **Peter Scholze**
April 13, 2020

Let me take Taylor's comment as an opportunity to more clearly state several related but distinct criticisms that are explicit or implicit in my manuscript with Stix, and the previous discussion on this thread.

(1) The non-necessity of passing from X to $\pi_1(X)$
(2) The non-necessity to replace $\pi_1(X)$ with infinitely many distinct copies of it
(3) The inconsistency of the identification of various copies of ordered 1-dimensional real vector spaces

Off these, only (3) points to (what seems to us) an actual mistake. (1) is about the question whether anabelian techniques — which are supposed to be at the heart of the matter — are of relevance. (2) is about whether the huge diagrams that Mochizuki considers are actually relevant to the argument. Neither (1) nor (2) alone would really falsify anything; but if non-necessary, not much is left of these manuscripts.

As only (3) is about an actual mistake, we focused on this in our manuscript. (1) is Remark 9, and (2) is Footnote 8 in my manuscript with Stix. In my first comment here, I concentrated on (1), while point (2) was addresses in my second comment in response to the fourth point raised by Taylor. [I should apologize that while my current (2) corresponds to the (2) of Taylor's last comment, it is my (3) that corresponds to his (1).]

The reason I brought up (1) and (2) here is that if one only stresses (3), as we did in our manuscript with Stix, then it may seem plausible that we simply misunderstood something at this point of the argument, but some quite powerful machinery had been built and one could plausibly finish the argument differently. However, (1) and (2) mean that quite the opposite, all machinery that is in place seems to have no power.

To me, (1), (2) and (3) seem logically independent. For (3), we explained everything in Section 2.2 of the manuscript with Stix: What the various ordered 1-dimensional real vector spaces are, what identifications one wishes to do, and that these identifications lead to nontrivial monodromy, i.e. are inconsistent. The loop one has to take in order to get the monodromy is rather large (6 identifications). I have seen no convincing argument that this nontrivial monodromy does not lead to problems. Of course, one could just decide to cut the loop at any point, but then one has to make sure that the argument never uses that disallowed identification. In particular, one has to decide in advance where to cut — if you know where, please let me know. (That in various parts of the argument only small, locally consistent, parts of the diagram are relevant, does of course not help as the argument altogether must be consistent. So the only way to achieve a consistent argument is to decide not to use one of these identifications.) I agree that this contradiction is very tautological. It seems the more surprising to me that it can be altogether neglected. (Yes, Mochizuki can't possibly mean this. But regardless of what he means, this inconsistency is simply there!)

About (1), Mochizuki's anabelian theorem states that relevant X's are equivalent to relevant $\pi_1(X)$'s, which is as much as can be asked for regarding a proof.

About (2), it's hard for me to prove this (and it's not required for the main point, (3)), as Mochizuki of course asserts that this is false, and there are thousands of diagrams one might have the occasion to look at, and I can't look into Mochizuki's mind to find all of them. What I can say, and this is basically Footnote 12 in my manuscript with Stix, is that we checked that Theorem 3.11 holds up with (2) in place, and in fact is completely tautological, so if anything Footnote 12 is meant to "prove" (2) to the extent this seems possible. More generally, (2) seems extremely plausible to me, and with all diagrams I've looked at in Mochizuki's papers it was holding up; and if you doubt it, you can just answer to my challenge of pointing to a single diagram whose commutativity is rescued by allowing some indeterminate isomorphism.

I do not claim that (2) implies (3) or anyway leads to a contradiction, although my recollection is that Mochizuki said that (2) alone would contradict his papers — he agreed that it is impossible to think that his argument might work if all of these copies are simply the same. (Maybe the idea is that one of the identifications we use to get nontrivial monodromy in (3) is omitted by having distinct copies of $\pi_1(X)$'s. But that's not actually the case.)

As I said, it's very easy to convince me that (2) is wrong: Just point to one diagram whose commutativity is rescued by allowing this indeterminate isomorphism of $\pi_1(X)$'s.

85. **Peter Woit**
April 13, 2020

I very much do not want to close the remarkable and very valuable dialogue going on here about the mathematical issues with the Mochizuki proof. Taylor Dupuy however was correctly picking up on my wanting to help make sure the mathematical discussion stays focused on these issues. A broader discussion of the mathematics would quickly get beyond my already marginal abilities to moderate something like this.

Note that this particular comment thread is being moderated with an even heavier hand than usual: most submitted comments are getting deleted in an effort to keep the discussion focused and informative.

86. **David Roberts**
April 13, 2020

I'm sorry to keep banging on about it, but Peter S's (2) is an artefact of a weird approach to diagrams in categories that Mochizuki is using. Reading M's 2018 Report closely, he claims things like that you can't define manifolds if you build them out of colimits of diagrams where the objects are all the same 'copy' of R^n (this is LbEx5). Or that you incorrectly calculate the perfection of a ring if in the usual sequential colimit you don't create separate copies of the ring in advance (this is LbEx3). This is patently absurd, but makes sense if one assumes that diagrams *must* be injective functors, or rather, literal subcategories. Recall that M assumes that he is identifying isomorphic functors, so that the concept of a diagram qua functor is severely underdetermined. Working up to isomorphism like this, and replacing a diagram with one that produces an isomorphic (co)limit, one can safely assume that diagrams are subcategories—but it is super weird, and it took me ages to realise that was what he was thinking. This is why he talks about things like "forgetting histories", because he is thinking that you need to somehow create fresh, distinct copies of objects in order to not collapse the subcategory down, and thereby give a different diagram. So when someone versed in standard category-theoretic language says "let's identify these objects", he seems to hear it as "let's collapse this subcategory to something trivial". And when he says "I need distinct copies", it seems totally weird and unmotivated. So when I look at LbEx3 in the 2018 Report it looks like the sort of mistake a student would make, when learning category theory for the first time. The problem is his conceptions of basic notions seem to be so idiosyncratic that without a serious translation filter, what he is saying seems to be completely off the wall.

If one takes category theory seriously, and DL poked a bit of fun at me for this (we talked privately afterwards), then one can *at the level of foundations* forget the equality predicate on the objects of categories, so that the equality or otherwise of random objects of a category is not even something you can consider. Alternatively, one can pass to a skeleton of the category at hand, in which case you just don't have distinct copies at hand, but *nothing breaks*. So there can be zero mathematical effect of the whole issue of distinct copies or otherwise, it is merely a psychological crutch. Once one realises this, the actual mathematics can then be discussed, for instance something like creating a formal colimit of a diagram all of whose objects are pi_1(X) (or whatever), with appropriate gluing maps. But this is not what I wanted to address, and is out of my sphere of expertise.

(on a separate note: thanks to Peter W for his patience and willingness to host this public discussion)

87. **UF**
April 13, 2020

@Peter Scholze: Thank you very much for addressing these comments of Mochizuki relevant to your (2). Let us consider the simplest situation where we just consider two neighboring columns of log-links and disregard for the moment the theta-link (I think we agree compatibility with theta link at most creates more trouble).

Then even in this simple situation (omitting theta-, but keeping log-links) Mochizuki seems to claim (C7) in Cmt2018-05 that if one rigidifies the $\pi_1(X)$'s in the columns (by identifying them using identity maps, making the logarithms Galois-equivariant), there is no "switching-symmetry" permuting the two columns.

As you say, this seems quite bizarre, since one has two columns of isomorphic data, so why should one not be allowed to switch?

I think a way out may be the following:
It seems quite likely Mochizucki uses "switching-symmetry" in a technical sense, synonymous with "multiradiality" of some algorithm reconstructing the data (here a rigidified column of log-links) at hand from some choric data, as he often does, compare e.g. [Alien, p.51].

His statement would then mean that if we rigidify the vertical columns, then there is (unlike in the non-rigidfied case) no multiradial algorithm to recover this column from certain choric data. This does not sound so absurd anymore (to me).

Now which multiradial algorithm does he mean here?
I would suggest it may be the multiradial algorithm in [IUT III, Cor 2.3], more specifically, the first part of 2.3 (ii) which concerns its compatibility with log-links.
Note that close by, [IUT III, Rem 2.1.1 (ii)] the issue we are talking about "why π_1 only upto indeterminate iso?" is discussed. For further discussion see also in [IUT II, Rem 3.6.4 (i)].

In any case, I agree this is an important issue to track down.

88. **W**
April 14, 2020

@David Roberts

Please keep banging on about it! I think your interpretation of Mochizuki's argument in the response was an important insight and underappreciated.

Let me ask you what I think is an important follow-up question. Suppose you take the same argument and present it in two different languages – one, the standard categorical language, and two, Mochizuki's language where distinct copies of an isomorphic object are relevant for colimits and other categorical constructions. Assuming no other knowledge of what the argument actually is or how it is written, which language is more likely to conceal a subtle error in calculations or other mistake, and which language is more likely to make such mistakes easier to see?

I think this question is within your sphere of expertise, and the sphere of expertise of many other mathematicians – far more than have read carefully a portion of the document.

I also think its relevance to the broader topic of discussion is clear.

89. **Peter Scholze**
April 14, 2020

David Roberts: Thanks for your thoughts on this!

Actually, something related happened in our Kyoto discussions: We realized that we could not get on common grounds regarding the issue of whether one needs separate copies of a ring to form its perfection, so we decided that we simply have different psychological crutches (as you call it) on this, and that we better focus on some actual mathematical statement where related issues undisputably become important. However, no such focal point ever appeared, despite us going through the essence of the IUT manuscripts. So it seems to us that to the common mathematician, his whole big log-Theta-lattice essentially comes down to one Hodge theater — which is really just the elliptic curve you started with (the category of Hodge theaters is equivalent to the category of elliptic curves isomorphic to your given one) — together with the p-adic logarithm map ("the log-link") and some isomorphism ("the Theta-link") of two copies of a local Galois group acting (trivially) on a monoid isomorphic to $\mathbb{N}$ (I'm obviously simplifying, but not too much — I'm basically considering only one bad place, while you have to consider all places, but I'm already telling you about the most interesting place). The generator of this monoid $\mathbb{N}$ is one time regarded as the value of the Tate parameter q, one times as the value of the Theta-function (a collection of such values, really, but never mind). But of course this isomorphism of abstract monoids is totally incompatible with these "interpretations". Initially, one might think that Mochizuki claims that there is some isomorphism of the pair of (local Galois group acting on local units) that takes the q-value to the Theta-value — this would obviously have great consequences, and would probably require the use of exotic isomorphisms of local Galois groups — but this is just not the case, one can easily give counterexamples; and it can't even be true locally "up to blurring", only a global statement, averaging over all places, can be true. The isomorphism is just on the level of (local Galois group acting trivially on monoid isomorphic to $\mathbb{N}$) and the relation of this monoid isomorphic to $\mathbb{N}$ to the local units is completely external.

So for all we can see we simply followed the procedure you suggested, and reinterpreted his distinct copies in the way usual mathematicians think. We recorded the outcome of this in our manuscript: You can read there the details of what everything is, in particular that his log-Theta-lattice really boils down to essentially the simple data above. How could one possibly go from here to any nontrivial result? Of course, as also W suggests, all of this is much harder to see through in his language.

@UF: The remarks from IUT that you cite make heavy reference to his paper on etale theta-functions, which seems to play a key role in the IUT papers. This paper gives some neat algorithm to start from the fundamental group of a once-punctured elliptic curve with bad semistable reduction, and recover its Tate parameter q and some Theta function; I forget the details. While this is all good and well, I don't see the relevance: Mochizuki's more general anabelian theorems, discussed previously on this thread, tell you that from the fundamental group you can simply recover the whole curve. In these comments of Mochizuki that you reference, Mochizuki is discussing some nitty-gritty details of this algorithm, but this seems completely besides the point if you just remember that relevant $\pi_1(X)$'s are equivalent to relevant X's, so of course you can recover all invariants of X, and you can do so functorially in $\pi_1(X)$.

Generally, a point seems to be made that Mochizuki's algorithms have some magic power and that really the content of the algorithms is critical, so in the context of the previous paragraph, it would matter in some way how I invert the functor $X\mapsto \pi_1(X)$ using some explicit construction (or that I don't actually invert it but only read off Theta-values using some other roundabout algorithm). This seems very surprising to me.

Regarding Mochizuki's algorithms, let me add that I was surprised that the following procedure counts as an algorithm for Mochizuki.

In IUT-3, Theorem 3.11 (i), an algorithm is discussed, that does the following. The input is data concerning only p-adic fields; it is basically a profinite group isomorphic to the absolute Galois group of your given p-adic field. The output is something like the Theta-value of the elliptic curve you chose at the beginning of the IUT papers (cf. part (b) of that data).

How is this possible? The input data doesn't even know anything about the elliptic curve! This is completely magic!

The resolution is that the elliptic curve has indeed been fixed once and for all in these papers, and so of course you can produce that Theta-value — simply look at the elliptic curve you have fixed, and take its Theta-value.

Of course, there is some packaging done around this, but this is the essence of this "algorithm"; Mochizuki confirmed this.

90. **Taylor Dupuy**
April 14, 2020

I think we are mostly on the same page now. No worries about the indexing. I'm going to use your indexing in what follows.

–Regarding (3): The "cut" is supposed to occur at identification of the theta side of the theta link; in that global realified frobenioid we don't normalize that Picard group according what you would want the degree of the theta pilot object to be. For the interested reader, details are in my manuscript with Anton after we introduce theta pilot divisors. I think Mochizuki includes this in one of his responses too.

–Regarding (1) and (2) not implying a contradiction (directly): we agree. I would consider (1) and (2) open as well. We agree on that too. Also, as I'm sure everyone will agree, statements need to be pinned down a bit more and directly tied to what Mochizuki has written. So I think even *exact* statements of (1) and (2) are also open. I will say a little more about (1) below.

For reasers who want to look at this, the obvious thing to do is to take isolate single claim in IUT and just start running with it, then build out from there.

–Regarding not using automorphisms of fundamental groups: we should observe that without indeterminacies, there are no indeterminacies. This is tautological, yes, but indeterminacies appear in the statement of Cor 3.12 and without them we are really talking about something else entirely.

Also, this all goes back to how the indeterminacies allegedly afford us the ability to compare the "volume" of the hull of the multiradial representation of the theta pilot region with the degree of the q-pilot divisor (definitions can be found in my paper with Anton)—this is the infamous "Mochizuki switcharoo".

I could talk more about this more but right now but I will be stating a bunch of (useful) isolated facts that readers would need to assemble for themselves (if it is even possible to do so). I think I might be burned at the stake for this as well as run the risk of making mistakes in public!

–Regarding (2): I think we need more language about "infinitely many copies" but basically I'm of the same mindset as David on this. I think everyone agrees we shouldn't think about "different copies" so much in the same way that you don't need two copies of $\mathbb{R}$ to talk about $\mathbb{R}^2$. I'm not sure this is what you or Mochizuki means though Peter. On the other hand there certainly are cases where you need multiple monoids.

–Regarding (1): we basically agree here. I think groups may be much more convenient and I think the representations are definitely important. The statements Mochizuki makes involve etale theta and the reconstruction of evaluation points and the representation of $\operatorname{Aut}(\pi_1^{\operatorname{temp}}(X" _{\underline{v}}))$ on these interpretations (last time I tried a double underline it didn't work out so I'm using double prime this time, here we need to take an analytification or formal scheme with log structure). Technically speaking, I suppose $\operatorname{Aut}((X")_{\underline{v}})$ acts on the same objects but maybe it isn't as easy for me to see these actions.

–Getting your hands dirty in the definitions like UF has begun doing is the way to proceed in these investigation. I can give some basic definitions of "switching" but I believe they are not adequately developed for discussing IUT3.3.11. Maybe we should take that offline? Whatever you guys want. Mochizuki discusses the formalization of multiradiality in a remark following IUT3.3.11 but that remark mostly says "you can do it" without any details as I recall.

–As a side remark, and I know Mochizuki would hate me saying this, it does feel like mind reading at times. I strongly agree with this sentiment. He tries though. I believe attributions of malintent are misplaced. But still, lots of mind reading. 😛

–I am intentionally omitting a discussion on "power". If people want me to step into this world of speculation I can do it. I'm getting more of a "show me the money" vibe though.

91. **Taylor Dupuy**
April 14, 2020

Peter: I think we posted at the same time… I'm going to read your comment now.

92. **Taylor Dupuy**
April 14, 2020

Quick comments:

–Peter, I think the $\mathbb{N}$'s should be regarded as embedded inside a monoid with enough roots of unity and nth roots to do Kummer theory.

–You definitely need more than one part of the "Frobenius-like" objects of the Hodge Theater — the abstract monoids. I also think you should think about overloading free variables; this thing is some sort of F'd up quotient of a free construction. This of course isn't precise.

–The term "algorithm" is trash. I think it is a big part of the problem. Also, we should note that has been going on in anabelian geometry for a very long time and it isn't a "Mochizuki thing". For the most part I have found that
algorithms = interpretations in infinitary first order model theory
And I very very emphatically agree with you that it does *not* suffice to treat "functorial algorithms" as functors alone, you need more. This is certainly omitted in Mochizuki's exposition.

Also, this interpretations stuff also goes off the rails a little bit…
1) you need to be able to consider structures up to automorphism as well.
2) There is also a backwards version of this where he considers "lifts" of structures that interpret lower structures.
I talk about this a little in my first manuscript with Anton.

–Regarding 3.11.ii this is an independence results. He is saying it doesn't matter which lift of all these things that interpret the absolute galois groups "at the bottom" you take. This thing you construct independent of the lift (by the way this points to the automorphisms of fundamental groups you were looking for).

Here is a funny observation: there exists a "shitty multiradial representation" where you can take the union of all images of the theta pilot region in measure spaces cooked up from absolute galois groups of p-adic fields at $\underline{v} \in \underline{V}$. This is ALSO independent of the lift. Proving that it is "multiradial" is tautological.

Yet, this one doesn't use log-links and it isn't claimed that this "shitty multiradial representation" can be related back to the minimal discriminant.

93. **Peter Scholze**
April 14, 2020

Dear Taylor,

first, thanks for explaining where to do the cut. In your comment, I don't actually understand where you want to cut, so I'll have to look at your note with Hilado. (In my manuscript with Stix, which direction does the isomorphism go? Horizontal/slanted? In the lower or bottom half? In the left or right half?)

About (2) not leading to a contradiction, you actually made me realize that probably it does: I don't see why part of Mochizuki's indeterminacies, I believe for example (Ind2), is necessary, but omitting it leads to a form of ABC that is provably too strong. I agree it would be hard to "prove" a strong enough form of (2), but I think the burden of proof is on Mochizuki here, to show where the argument needs indeterminacies like (Ind2) — which is basically the issue (2) we're discussing.

Reading your first comment above, I actually don't really see where we disagree.

Regarding your second comment, the relevant $\mathbb{N}$'s are manifestly not part of monoids in which you can do Kummer theory! Yes, Mochizuki includes some extra factor, but that's just along for the ride.

About the last bit, to be sure we're on the same page: I was talking about part (i), not (ii), of Theorem 3.11.

94. **Peter Scholze**
April 14, 2020

OK, I quickly looked at your manuscript. If I understand it right, that's the upper left slanted arrow? In our terms, that's the difference between the "abstract" Theta-pilot — a generator of an abstract monoid $\mathbb{N}$ — and the "concrete" Theta-pilot — the actual Theta-values of your elliptic curve. (Mochizuki seemed to conflate the two originally, or so it seemed to us.) If you cut there, then the Theta-link no longer links anything to actual Theta-values! This of course removes any inconsistencies, but it also removes what's supposed to be the key, namely the identification of q-values with Theta-values, in some form.

On the other hand, I read say on page 140 of IUT-3 that Mochizuki considers the Theta-intertwining, which I believe simply means this identification of abstract Theta-pilots with concrete Theta-pilots. He wants to be very careful with using this etc., but I do believe he wants to (and has to) use it somewhere. So I don't think you can simply cut there. I think the closed loop that Mochizuki discusses on page 143 of IUT-3 is also relevant here. See also on page 144 the simultaneous Theta-intertwining and q-intertwining he wants to have (up to indeterminacies etc…).

95. **Taylor Dupuy**
April 14, 2020

Yep, the theta pilot doesn't map to the actual theta values *on the theta side*. On the q-side it does.

I will check your manuscript again in a bit. Dinner then bedtime (I am barbecuing).

I want to check again to make sure I didn't miss something.

96. **Taylor Dupuy**
April 14, 2020

I realize I have my phone… so yeah, you don't normalize the degree on the left hand side of your diagram. It is like we are all saying you can't something be equal to two different things at the same time…

Also there is only *one* copy of the real numbers.

97. **David Roberts**
April 15, 2020

@W

gosh, thanks!

> Suppose you take the same argument and present it in two different languages – one, the standard categorical language, and two, Mochizuki's language where distinct copies of an isomorphic object are relevant for colimits and other categorical constructions. Assuming no other knowledge of what the argument actually is or how it is written, which language is more likely to conceal a subtle error in calculations or other mistake, and which language is more likely to make such mistakes easier to see?

This is tricky: it depends who's reading it. Who are you envisaging seeing mistakes? I can't imagine (ignoring the fact this is IUT and tremendously baroque) that someone who's had a decade of practice with their own idiosyncratic style of working would make mistakes more frequently that someone using the language of the majority, all things being equal, apart from the fact the latter person has more potential external checks and balances. This latter point I think can't be overemphasised. Andrew Wiles was still speaking the language of his community by the time he emerged with his (first attempt at a) proof of FLT, and even engaged the help of someone else to try to check the subtle parts of the argument before that. This hasn't happened here…

A bigger problem is the rigid commitment to definitions/structures that are explicitly admitted as being far more general than necessary (*cough* Frobenioids *cough*). This increases the friction for potential eyes on the IUT papers, if you'll permit me a worrying metaphor mix.

98. **Taylor Dupuy**
April 15, 2020

Peter: Below is a more detailed response.

To recap, you made three posts. One in response to David and UF, and then two smaller ones. I'm going to address the newer ones first and then go back and address those older comments.

****
Responses to Newer Comments
****

Regarding the "cuts": I think I addressed this. Let me know if you want to talk about it more. I think if you are not taking two log-linked strips of Hodge Theaters and only have one theta monoid it is going to get rough. He wants all the computations in on particular Hodge Theater in the log-linked strip on the q-side to be the "usual normalization" (sorry for referencing such large objects, I know this is super abusive… I'm sure there is a better way to talk about this than to make blanket references to Hodge Theaters — really the relevant "official constructions" here use the $\prec$ prime strips (I think) in the Hodge Theater… that is not a fun reference chase.)

Regarding (2) [infinitely many fundamental groups]: So I think we need to clarify this what you mean by (2). I'm not sure which indeterminaciees you want to get rid of. At some points I see that you are thinking about using "one fundamental group" and at some points you are saying "use one Hodge theater". I think these have different consequences — one is about representations on monoids and one is about the groups solo. Are you wanting to get rid of ind3 and this log-kummer correspondence? What do you want to kill exactly.

I agree with you that tracing the proof for simplifications which removes or modifies inequalities to the point where they are false is a good strat for finding flaws.

Aside: I will always agree with you that the burden of proof is on the writer to explain things. In modern arithmetic geometry there is too much flexing on the reader. IUT is a bit of a weird flex in some ways.

Regarding $\mathbb{N}$'s and Kummer Theory in the $\Vdash \blacktriangleleft \times \mu$ prime strips:
As a recap: You stated that they are isolated, I said the have a Kummer theory. I want to clarify: technically you are correct the monoids in a components at a bad place of $\Vdash \blacktriangle\times \mu$ prime strip are just $\mathbb{N}$'s. BUT… they are interpreted structures. So they come from other structures where it does make sense. Note also that in isolation, there is no action of the $\mathbb{N}'s$ on the corresponding copies of $\mathcal{O}_{\underline{v}}^{\times \mu} \otimes \QQ$. (Just as a reading note: Mochizuki sometimes calls this his "holomorphic structure". I think he also uses the words "embedding" or "link between unit group and value group portions"). I can speculate a little about what is going on on either side of the theta link if you want.

*Subremark. This is sort of an ongoing theme I want to highlight: Given a structures A and B there may exist two ways of interpreting B in A (called them $\mathbf{B}_1$ and $\mathbf{B}_2$) which are not equivalent. This for example could for example be distinguished by the representations $\operatorname{Aut}(A) \to \operatorname{Aut}(\mathbf{B}_i(A))$ (I'm not saying this is the case here, I'm just trying to give a concrete example).

*Subremark. Sometimes I find it useful to think about there being a single $\Vdash \blacktriangleleft \times \mu$ strip that lives in different "charts" (after applying the correct automorphisms). I am not sure how helpful this is, but it is kind of fun to think about.

Regarding My Remarks on 3.11:
A quick summary: You had stated how ridiculous it is to construct anything involving Tate parameters from absolute galois groups of p-adic fields. I said some words about lifting G's to an interpretation so we view G as $\mathbf{G}(\Pi)$ for some fundamental group Π and said these constructions are uniform in Π (let me say this is a cartoon picture right now, we actually need a lot more structure on this. In particular what I had in mind was a lift of the structures "at the bottom" of 3.11.i to log-linked collections of prime strips — I made need to modify the structures in this statement to make it exactly correct). I had made some remarks about 3.11.ii being an independence result. Let me clarify, I was talking about $U_{\Theta} \subset \mathbb{L}^{\vdash,et}$ (the "(coarse) multiradial representation of the theta pilot region" inside the so-called "mono-analytic etale version of the log shells" all put together) being independent of the lift. Let me think about 3.11.i. I need to refamiliarize myself with this $\mathfrak{R}^{LGP}$ bullshit. If we are really going there right now then I think we need to introduce "abc-modules" (the primary data discussed 3.11.i and 3.11.ii). These are sort of pre U_{Θ} structures (used to construct U_{Θ}). I need to think about 3.11.i and get back to you. Also, we are in territory where I am pretty shaky. So… no promises…

Regarding "Theta Interwining":
Can you give me a reference with respect to a Theorem/Remark/Environment of some kind? I think we are reading different versions of the manuscript. (Let me just make one side remark— there needs to be a stable version of these documents somewhere in print; it has obviously become an important historical document. I'm not saying where and how, it just need to be immutable.)

****
Response to Response to David Roberts and UF
****
Let me just say, I don't think your simplifications were an unreasonable guess (and I want to clarify to the readers that this is actually not what Mochizuki meant in his setup. I'm just saying the whole thing is so crazy you need to start somewhere.) I think we all agree though if you take one Hodge theater it won't work as per your manuscript with Jakob.

Regarding Magic Powers:
I really like this comment. It is a very interesting thought regarding looking at the "conjugate constructions" from the perspective of curves. It does look funny. What is in this fundamental group sauce?! Here are some possible explanations:
1) There is more to what is going on than just fundamental group vs curves; Mochizuki uses the monoids and cyclotomes extensively. In particular he applies many "orthogonality" results.
2) Fundamental groups are first order structure: they are a topological space with a binary operation. The formalism of interpretations applies here (maybe by slightly increasing the signature), but you get to put everything in this nice box where represenations become automatic and you get to see how everything varies with respect to automorphisms. (Full disclosure, Mochizuki objects to the language of model theory for this stuff, he thinks it is unnecessarily complicating things. This is a matter of taste maybe.)

I think we need to unpack the comment ""The resolution is that the elliptic curve has indeed been fixed once and for all in these papers, and so of course you can produce that Theta-value — simply look at the elliptic curve you have fixed, and take its Theta-value."" What Mochizuki means is 'fixed in initial theta data' usually. I also want to repeat that I object to the usage of a single Hodge Theater. If HTbar is a log-linked collection of Hodge Theaters (which we view as a single massive infinitely sorted structure) the definable set we need is in like HTbar^2 (I said "like")

Regarding the comment: "it can't even be true locally "up to blurring", only a global statement, averaging over all places, can be true.…"
This is correct. His claim is a purely global statement. But… it is even WORSE than this! You need to take the hull and then take the volume and only then does he claim you see the comparison.

In this comment you also reminded me of some things concerning the shape of the inequality. I'm not going to do it now, but I'm going to make a note to try to talk about:
*Ind2 and moving around $q^{j^2/2l}$ — why you need Ind3
*Analytic number theory, what happens at large discriminants, and toy phenomenology for the inequality.

IOU: 3.11.i discussion.

======
Oh dear, all my triangles are off. The pointy bit should be to the right…

99. **UF**
April 15, 2020

I now think a good reason to for not identifying π_1's along log-links is as follows:
(It is very similar to [IUT-2, Rem 1.11.2 (ii)] for the theta-link; I am less precise here, taking the relevance of some reconstructions on faith, but it is a intuitive story, and precision can come later)

First, let us step back and look at the log-theta-lattice: It consists of Hodge-theaters and the log/theta-links as maps/functors between them. Now a formulation of (2) is:
Why do we, say for the log-links, not just take the "identity" isomorphism between the relevant π_1's instead of the full poly-isomorphisms between them?
Surly it is also a completely valid map between the theaters?

Yes, but: let us recall what we want to do with this log theta-lattice: we want at "suitable times(?)" glue the Hodge theaters along these links and then apply certain multiradial algorithms.

I think that if we would glue with the "identity" on the π_1's (and all the other prescriptions of the log-link), then this gluing will be inconsistent/not well defined (when combined with some multiradial algorithms), in some vaguely similar sense as if you try to define a complex structure on a manifold by charts, but in some region the procedure leads to two different, incompatible complex structures, i.e. the transition map is not holomorphic.

Indeed, in one Hodge theater, the π_1 is not independent of the rest of the data; it acts via the quotient to the Galois group on the monoids. Thus π_1 is "related" to the monoids, and it is not apriori clear we are allowed to glue two Hodge theaters by gluing π_1 and the monoids separately in whatever way we wish (and then follow certain multiradial algorithms).
In the above analogy, a certain region of the Hodge theater is supposed to be "determined" jointly by the π_1 and the monoids.
The multiradial algorithm we consider is roughly as follows: The action of π_1 determines on the (from the Galois group reconstructed) local monoids (with 0) in addition a ring structure (a "holomorphic" structure).

The output is roughly some etale version of some of the data originally present in the Hodge theater, and the reconstruction algorithm yields a canonical isomorphism between the original data and the reconstructed one (see e.g. [Alien, §2.12] for essentially such constructions).

If one now glues two Hodge theaters along a log-link (with in addition "identity"-gluing for π_1's), then this yields no consistent holomorphic/ring structure compatible with the above algorithm on some region:
Namely, consider the region of the ring (local units), which is glued via log (the actual log part of the log-link) to other Hodge theater; this yields one definition of "holomorphic" for this region. On the other hand, we can embed this region in the reconstructed monoids and use for the "holomorphic" structure on the reconstructed monoids the one induced by π_1 on both Hodge theaters and glue by the "identity".

The above roughly describes two incompatible holomorpic/ring structures on some part of the glued Hodge theater; they are incompatible, "because the transition map, essentially the log, is not a ring map". Such a situation is presumably avoided by taking the full polyisomorphism between π_1's, where the log map on the units alone defines the holomorphic structure on the relevant region.

100. **Peter Scholze**
April 15, 2020

Dear UF,

thanks for your answer. (Taylor, I will answer in a separate comment later.)

Removing all language from your message, I end up with the following message: The logarithm map is not a map of rings. This is why you have to consider source and target up to some indeterminacy.

The only way I see to make this into a valid thing is if the indeterminacy somehow allows you to map the logarithm map into a map of rings — after all, this is what you critized in the first place. But any automorphism of π_1's will only ever replace source and target by isomorphic rings. So the logarithm will still not be a map of rings. Note that I'm simply repeating what I already said in my second comment in this thread.

101. **Peter Scholze**
April 15, 2020

Dear Taylor,

addressing your last comment.

First half: I was refering to the current version on his webpage. I realize that this is dangerous, but it's the only thing that at least currently makes it possible for everyone to follow. In any case, to me it sounds like you are saying that the Theta-pilot has nothing to do with Theta-values. Well, strictly speaking (modulo minor issues) what Mochizuki does is the following: He takes the Theta-value (some nonzero p-adic number, not a root of unity), and takes the (multiplicative) submonoid M of the p-adic numbers generated by it, and then considers M as an abstract monoid. As an abstract monoid, it is then of course isomorphic to $\mathbb N$, necessarily canonically so; its generator is referred to as a Theta-pilot. Does the abstract monoid M know anything about the Theta-value? Of course not! But that is all that ever seems to enter the story of the Theta-link. At some point you do need to remember the interpretation of the Theta-pilot in terms of Theta-values — this is what Mochizuki calls the Theta-intertwining, and it plays a key role as I tried to reference. So I don't think that Mochizuki simply cuts our diagram there.

Now David Roberts previously mentioned that Mochizuki seems to have a nonstandard point of view on what a mathematical object is, requiring separate copies when they are not actually needed; he often refers to some "history" of these objects. Now maybe one could try to argue that because M was built out of Theta-values, it (the abstract monoid) still knows something about them, that can be even transported via an isomorphism of abstract monoids. (You made some similar remarks in your paragraph on $\mathbb N$ and Kummer theory, refering to "interpreted structures".) But that's evidently not the case. (That the abstract monoid M knows something about Theta-values might be debatable if for you an abstract monoid is really encoded — as it is in ZFC — in terms of its actual set of elements. But even then, this structure ("the interpretation") is clearly not transported by an isomorphism of abstract monoids.)

About the indeterminacies: I'm focusing on (Ind2); (especially) the part concerning automorphisms of local Galois groups (acting on local units if necessary). I don't see any diagram that doesn't commute when you take the identity isomorphisms, but does commute when you conjugate by an automorphism of a local Galois group (acting on local units). Why do you need that, expect because "you need to forget the history of your objects in order to apply reconstruction algorithms" or some magic like that? (There was actually a point where Mochizuki was surprised that by "forgetting the history of a group" one still has more than a group up to isomorphism: Namely, a group. That the datum of a group is strictly more than the datum of a group up to isomorphism seemed new to Mochizuki. I believe this is the (psychological) main reason he considers these full poly-isomorphisms. But really, forgetting "the history of the groups" you still have groups and they may still have natural commuting isomorphisms between them. Of course, for groups up to isomorphism you can't ask for natural commuting isomorphisms between them, then you only have "full poly-isomorphisms".)

Regarding the rest of your post, I don't see how you're really objecting to anything I said.

Finally a short answer to David Roberts' last message: I highly doubt your sentiment that the possibility of doing mistakes is not correlated with how well your language is adapted to the mathematics at hand.

102. **UF**
April 15, 2020

@Peter Schoze: I agree that the above should be surrounded by big caveats about the nature of the effects of passing to full poly-isomorphisms and I may interprete those incorrectly.

What my post above attempts to show, is: if passing to poly-isomorphism has the effect of doing no gluing/no identification of ring structures (arising from π_1, just the gluing from the actual log map), then the only gluing left is the actual log map, which gives one global chart, and no transition functions needed, essentially(?) since just one chart . I before never really seriously considered that full poly-isomorphism could have the effect of "no gluing arising from this part" (instead of "choose your favourite gluing"), but a similar thing is (I think) asserted for the case of the theta-link in [IUT II, 1.11.2(ii)], where the message is: full polyiso on π_1 means no sharing of ring structure arising from this.

Clearly this does not show by itself it really works like this, but it seems to reduce an argument for the log-link to some degree to an anologous one for the theta-link.

103. **Peter Scholze**
April 15, 2020

Dear UF (and Taylor and everyone),

I won't comment any further here on statements of the form "well, maybe Mochizuki actually meant (vague statement)".

A few comments up I summarized the situation with claims (1), (2) and (3). I have seen no valid objection to (1) and (2), and (2) alone would lead to a contradiction (as one gets too strong a form of ABC). To (3), Taylor indicated where to cut the diagram, but I really don't think this is what happens, as this would isolate Theta-pilots from Theta-values and effectively remove the actual Theta-values from the proof; while Mochizuki does consider this "Theta-intertwining" which is the association of the Theta-pilot with the Theta-values.

I will only comment further here if either a valid objection to (1) or (2) is mentioned, or further clarification is given regarding (3). Any further technical discussions are probably best done via e-mail.

Best,
Peter

104. **David Roberts**
April 15, 2020

@Peter S

sorry, that's not what I meant: from a purely mathematical point of view, my understanding of what M means by 'copies' is, divorced from all this context, mathematically consistent, if weird. I think things like working with functors up to isomorphism is a much bigger problem, especially when, eg, apparently more-rigid-than-usual "reconstruction functors" are at play. W asked about a very specific issue removed from the bigger context, which is the kind of counterfactual that is hard to answer sensibly. I agree than any language, mathematical or otherwise, that obfuscates what's happening is going to increase the risk of error!

105. **W**
April 15, 2020

@David Roberts I'm happy to take responsibility for my understanding, which I think was caused by me formulating the question poorly.

My intent was to focus on what kinds of inferences you (or anyone) might be able to make about Mochizuki's work, based on your knowledge of the response and your general knowledge of category theory, not based on reading through hundreds of pages of his papers as Peter Scholze did. I didn't intend to single out one particular difference in notation that happened to be among the least concerning ones, but I guess I did.

Anyways the point of this is that if Mathematician A writes a paper and Mathematician B says a particular formula is off by a factor j^2 then, all else being equal, there is a good possibility that either side might be correct. If they go back and forth discussing it the probabilities change somewhat, but at every point, all else equal, both probabilities are pretty high.

But if we find that Mathematician A is using language that increases the risk of errors, and Mathematician B claims to have found the error by removing that language, and Mathematician A refuses to change this language, and Mathematician A claims that they are using this language to reduce the risk of errors, then we have found a bunch of pieces of evidence that A is the one who has made the error and not B, even if we don't read the paper enough to follow either mathematician's reasoning line-by-line.

106. **David Roberts**
April 15, 2020

@W no worries 🙂

>Mathematician A refuses to change this language

this is the worrying part. And, IMHO, one of the biggest problems with the whole affair. The papers could have been rewritten in the past eight years to remove all the extraneous fluff, and using more standard terminology, based on feedback from the community. Forget about terminology and risk of error, it could have just simplified the papers.

>Mathematician A claims that they are using this language to reduce the risk of errors

I don't know about this bit.

But all this is very meta-reasoning, and not mathematics, like a lot in this whole affair.

BTW, "language" here is perhaps not the best word to use, given that it has three potential meanings: just the general idiom, full of metaphors and not-incredibly-helpful "motivation; the mathematical language (what I prefer to call 'terminology'); and the fact there are English- and Japanese-language documents on IUT (and unjustified questions about facility with one or the other out there).

107. **W**
April 15, 2020

@David Roberts

Sure, "terminology" is a better term. I don't think anything to do with the English or Japanese languages is particularly relevant, and the general idiom is clearly relevant but only incidentally to the main issue.

By "Mathematician A claims they are using this terminology to reduce the risk of errors" I mean passages like these, from Mochizuki's response:

> Omitting the labels leads to confusion concerning which copy
of the unity element $1 \in A$ is to be regarded as the unity element
for "Af ". Such confusion may, of course, be misinterpreted as
an "internal contradiction" in the theory of localizations of
commutative rings with unity. In fact, however, there is no "internal contradiction" in the theory of such localizations; the
apparent "internal contradiction" is nothing more than a superficial consequence of the erroneous operation of omitting the
labels

> relying, in mathematical discussions, on declarations of "remembering"
that are not accompanied by precise, explicit documentation of the labeling apparatuses that are employed incurs the risk that different people
will "remember" different labeling apparatuses, which result in structurally non-equivalent mathematical structures.

I can think of a different way to interpret them, though (that Mochizuki is only justifying some of his terminological choices here, and this justification depends on other terminological choices, and is valid once you accept those choices) so maybe this gloss is not completely fair.

108. **UF**
April 15, 2020

@Peter Scholze: Thank you for your comments.
Just to restate my view, in case I was unclear: I believe that the reasoning above for not including any specific identifications of the π_1's (i.e. just full poly-isomorphisms) in the definition of the log-link is entirely parallel to Mochizukis reasoning in [IUT II, 1.11.2(ii)] for not including any specific identifications of the π_1's in the definition of the theta-link.

109. **David Roberts**
April 15, 2020

@W

yes, I agree with your points. I just mentioned the other aspects to 'language', as there are readers here from a wide background, who might misconstrue what we are saying (there have been, I gather, accusations of racism thrown about that I want to head off here).

Those two quotes you have selected are indeed particularly weird, and reflect the psychological crutch I mentioned earlier. I even quoted the second one in my notes on Mochizuki's report. If this is truly M's thinking, then we are in "If a lion could speak" territory. This is not mathematics in the slightest.

110. **Rob W**
April 16, 2020

I understand that it might not be the best use of everyone's time but I have really enjoyed reading this. Seeing a well-mannered, real time discussion play out has been great (particularly in these times of lockdown). So while it might not be the most efficient way of trying to solve the problem / address the issues it is having some positive externalities (at least for me) .

111. **Taylor Dupuy**
April 17, 2020

Hi Everyone,

I'm just going to make one last post to close out some loose ends for interested readers. I also want to point out some things that we haven't covered that I think are important. I've omitted the discussions of asymptotics of Mochizuki's formula but other than that, I think I covered my IOUs. If there are any analytic number theorists who were really looking forward to that please email me.

Sorry for the length.

****
Regarding (3): Is Mochizuki's Proof Falsified?
****
There is no *proof* that Mochizuki's method doesn't work.

The following is what the Scholze-Stix manuscript proves:

Theorem. Assuming that one may identify Hodge Theaters in Mochizuki's theory and simultaneously impose "concrete normalizations" of q-pilot and theta-pilot degrees then there is a contradiction.

Remarks.
1) The hypothesis of "simultaneously imposing concrete normalizations" is equivalent to $l(l+1)/12=1$ for a fixed prime l. In the manuscript no machinery from Mochizuki's theory is used in this derivation. A protest to this identification is made in C12 of Mochizuki's response. Despite this, Peter S. insists this is what Mochizuki means. See his comments above, or the quoted comments below.
2) The hypothesis that one can identify Hodge Theaters is also protested by Mochizuki and runs counter to his stated objective. It is prudent to observe that the thesis of the Gaussian integrals survey is that sometimes in Mathematics one can introduce "alien copies" of objects to prove something about your original object. This runs counter to the assumption of identifying Hodge Theaters in the above theorem.

I am not taking the position that Mochizuki's proof is correct or will turn out to be correct but that, as it stands, the Stix-Scholze manuscript should not be held up as a reason to reject Mochizuki's proof. On the contrary, I am just saying that a falsification of the proof requires a fluency in the definitions which seems hard or impossible to achieve. Many of the definitions use nonstandard terminology and come off as ambiguous to many readers (I'm not sure if I want to get into a definition of ambiguous). Case in point: questions about the "embeddedness" (or in Mochizuki's terms "holomorphic structures") of the monoids involved in the $\Vdash \blacktriangleright \times \mu$ prime strips; these came up in Peter's previous post. Moreover, because of certain ambiguities in these definitions, readers are forced to search a large space of possible meanings. While these difficulties do not falsify the possibility of a proof, they make it so that what Mochizuki has written is not a proof in traditional terms. To speak plainly, flexing on the reader by omitting details is not something new in Arithmetic Geometry and IUT is a weird flex.

Finally, it is not outside the realm of reality that there could be 5 top notch international referees who have understood the proof as complete and correct. PRIMS has traditionally been a journal of very high quality and members of the editorial board have shown integrity in the past (look at how senior mathematicians are responding when asked by journalists to comment). Let's see what the print version looks like (hopefully it has a table of contents and remove bolding and italics).

What can we do?: I think we should all think carefully about the damage omissions have next time we are tempted to do it. Additionally, we should praise the writers whose writing we find "easy" and useful. Because of these difficulties I personally hold Mochizuki's document as a program for proving ABC and consider Mochizuki's formula a conjecture (until I can see this with my own eyes). Then again, there are a lot of Theorems I know about and use but can't prove. Also, be nice to everyone, we are all just people.

****
Regarding (1)
****
I see nothing wrong with (1). By this I understand replacing all constructions in IUT involving the fundamental group of an SBT curve with the corresponding construction in an actual curve. I think this is possible, but we would need to check that this doesn't break somewhere. If the claim is that all fundamental groups in the theory need to be eliminated, I would be more reluctant. There are a lot of weird curves. I think I need to see what a more precise statement looks like in practice to say for sure.

****
Regarding (2)
****

Regarding (2), to be clear, we should repeat that this is not what Mochizuki does (only using one fundamental group). Also, the statement as Peter has stated is a moral one not to be taken literally — there are many more groups appearing in the construction that are not isomorphic to $\pi_1(X)$ (profinite etale) so, like, it doesn't literally parse but I think I know what he means. Regarding its validity, I have reservations related to conjugacy synchronization and construction of "the diagonal" (points in Mochizuki's theory are replaced by conjugacy classes of decomposition group and evaluation of functions is replaced by restriction of cohomology classes to decomposition groups — since we want to evaluate at many points simultaneously one needs them to be determined up to conjugation simultaneously — we need a diagonal action of a conjugation not an action by a product of conjugations. This process involves multiple fundamental groups.) — BUT if we are going to dispose of these things entirely as in (1) you can probably scrap a lot from section 2 of IUT2. I need to think about how this construction works in order to say something precise. I personally would ask Emmanuel Lepage or Jakob Stix about this.

A more middle ground statement is that one can replace all "base Hodge theaters" by a single "base Hodge theater"—which have more than just $\pi_1(X)$ and a bunch of maps between them. Yet another variant of this would involve contracting even more fundamental groups in the base Hodge Theater (and this is where I think you might run into conjugacy synchronization and diagonal problems).

Also, there are a lot of monoids built into the theory which are excluded from the statement and I don't know if these are implicitly assumed to be identified as well. I think not.

Finally, to derive a contradiction, I think some things need to be said about *how* one proposes to reduce Mochizuki's construction to "a single fundamental group".

All in all to build this into an actual counter-example, as Peter claims, one needs to make the statement more precise.

Remark. In a post I read someone emphasized that Peter S. read "hundred of pages", or that he met with Mochizuki "for a week". Similarly, Fesenko has emphasized the number of hours people have studied the theory. These are personal reasons not to undertake something and not acceptable substitutes for proofs.

Now more comments…

****
Intertwining
****
>On the other hand, I read say on page 140 of IUT-3 that Mochizuki considers the Theta-intertwining, which I believe simply means this identification of abstract Theta-pilots with concrete Theta-pilots. He wants to be very careful with using this etc., but I do believe he wants to (and has to) use it somewhere. So I don't think you can simply cut there. I think the closed loop that Mochizuki discusses on page 143 of IUT-3 is also relevant here. See also on page 144 the simultaneous Theta-intertwining and q-intertwining he wants to have (up to indeterminacies etc…).

There is more of this on page 188 too (April 16, 2020 copy)

In the quoted statement above the "up to indeterminacies" is the point.

Mochizuki asserts the existence of TWO theta monoids you need to be thinking about relating. One that identified with q-monoid and the other which has been interpreted alongside q in the same Hodge theater. In Mochizuki's language one is in a "alien holomorphic structure" and the other is in interpreted from the same structure. Mochizuki's game is then relate the auxillary theta pilot using anabelian techniques (amphoricity in the language of Joshi's manuscript) in order to derive a relation between the two. This relation is a uniformity statement. All the thetas of the world can be blurred.

At one point I was confused about what is going on with the interpretations in absolute galois groups of p-adic fields. It is helpful to know that the measure spaces constructed from absolute galois groups of p-adic fields have measures which are well defined—in the initial construction in AAG3 (section 5?), the measures take values in an ordered one dimensional real vector space obtained by the process of 'perfection' ($\operatorname{colim} M$, nodes = $\mathbb{N}$, morphisms=$(a \mapsto ab)$ realized as multiplication by b) and completion. It turns out that because of initial theta data, the we know how to normalize the measures to give real numbers.

My point: the constructions of these measure spaces may look weird, but from the perspective of either interpreting structure these things give real numbers, and the values of these measures don't lie in some abstract ordered one dimensional real vector space. Also, there exists a region $U \subset \mathbb{L}^{\vdash,et}$ (this is my notation for the monoanalytic etale like big log-shell) that is invariant under automorphisms of log-linked collections of Hodge Theaters. In Mochizuki's terminology, "this region can be seen from both sides of the theta link".

>In any case, to me it sounds like you are saying that the Theta-pilot has nothing to do with Theta-values.

On the contrary, all theta pilots are defined *in* structures which includes an evaluation map like (theta monoid)$\times$(evaluation points)$\to$(constant monoids). Look at the diagram in IUT Remark 3.10.2 and read it clockwise starting from gau and ending at etale $\mathfrak{lgp}$. Each of these $\Vdash \blacktriangleright \times \mu$ strips are parts of a larger structure where multiplication of the "value group portions" may act on the "unit group portions". Eventually these "Kummer maps" lead to the construction of the region U_{Θ} described previously.

> Well, strictly speaking (modulo minor issues) what Mochizuki does is the following: He takes the Theta-value (some nonzero p-adic number, not a root of unity), and takes the (multiplicative) submonoid M of the p-adic numbers generated by it, and then considers M as an abstract monoid. As an abstract monoid, it is then of course isomorphic to N, necessarily canonically so; its generator is referred to as a Theta-pilot. Does the abstract monoid M know anything about the Theta-value? Of course not! But that is all that ever seems to enter the story of the Theta-link.

This goes back to my comments about his objects not having good black boxes (without some sort of language like the of interpretations). This also points to my point about his confusing writing style in the beginning. It is typically not sufficient to perform his constructions without knowing about the interpretation.

>At some point you do need to remember the interpretation of the Theta-pilot in terms of Theta-values — this is what Mochizuki calls the Theta-intertwining, and it plays a key role as I tried to reference. So I don't think that Mochizuki simply cuts our diagram there.

Again, from the horses mouth, read C12 of his responses. He says he does not do this. Also, please look at the displayed diagram below. I think this may clarify something for you. Also, in this "interwining", this is where the theorem about the amphoric/characteristic nature of the interpretation of the Jacobi theta function is supposed to be applied. I made some remarks before on this and refer to those.

>Now David Roberts previously mentioned that Mochizuki seems to have a nonstandard point of view on what a mathematical object is, requiring separate copies when they are not actually needed; he often refers to some "history" of these objects. Now maybe one could try to argue that because M was built out of Theta-values, it (the abstract monoid) still knows something about them, that can be even transported via an isomorphism of abstract monoids. (You made some similar remarks in your paragraph on N and Kummer theory, refering to "interpreted structures".) But that's evidently not the case. (That the abstract monoid M knows something about Theta-values might be debatable if for you an abstract monoid is really encoded — as it is in ZFC — in terms of its actual set of elements. But even then, this structure ("the

interpretation") is clearly not transported by an isomorphism of abstract monoids.)

I think this quoted text reinforces my points about "depth searches" and the ambiguities (percieved or not) in Mochizuki's writing. Peter I am going to use the words "My understanding" so you may want to skip this response.

Regarding ZFC, while this is true, we don't go this deep. That is not what is going on here. (for the uninitiated see https://stacks.math.columbia.edu/tag/0009)

My understanding of the "history of objects" is different, and I don't think this saves the day. "Forgetting history" is Mochizuki-speak for forgetting about the interpretation as you have suggested. Automorphisms of objects are no longer coming from the interpreting structure and this structure is no longer "going along for the ride".

In Mochizuki's language or the language of naked categories Mochizuki's theory does not have many good black boxes. This makes parsing the examples even harder because you need to carry around these large definitions in our small human brains (or use a large amount of paper). If you pick up a Hodges a "a Shorter Model Theory" or Olivia Caramello's book, or MacLane's Sheaves in Logic book, you will find perfectly fine definitions of interpretations that allow you to package all of that sloppy anabelian geometry/ "reconstruction algorithms" into nice little formulas.

Here are some of David Marker's notes:
http://homepages.math.uic.edu/~marker/math512-F13/inf.pdf

Exercise: Look at the first page of Marker's notes then show that the torsion of an abelian group is definable using infinitary formulas.

Exercise: People often complain about the non first orderizability of topological spaces. Read this post from stack exchange on how to define topological spaces:
https://math.stackexchange.com/questions/46656/why-is-topology-nonfirstorderizable

>About the indeterminacies: I'm focusing on (Ind2); (especially) the part concerning automorphisms of local Galois groups (acting on local units if necessary). I don't see any diagram that doesn't commute when you take the identity isomorphisms, but does commute when you conjugate by an automorphism of a local Galois group (acting on local units). Why do you need that, except because "you need to forget the history of your objects in order to apply reconstruction algorithms" or some magic like that?

I'm not sure what "that" is. I'm going to assume you mean ind2. I need to break this down in order to give you a coherent response. For me, ind2 is a representations of automorphisms absolute galois group of a p-adic field $G \cong G_K$ on a $\mathbb{Q}_p$-vector space $\mathcal{O}^{\times \mu}(G)\otimes \mathbb{Q} \cong (K,+)$ induced functorially. There are interpretations given from local class field theory (I'm going to release a table of these soon in my manuscript with Anton, alternatively you can find these in some papers of Hoshi). These preserve the $\mathbb{Z}_p$-lattice $\mathcal{O}^{\times \mu}(G)$ inside this vector space.

I'm not sure what sort of diagrams you want but here is one:
Let K be a finite extension of $\mathbb{Q}_p$ with uniformizer π where $\log(1+\pi) = \pi$ and $\log(1+\pi^2)=\pi^2$.
Let $\lbrace x\rbrace$ be a one point set.
Let $f,g: \lbrace x\rbrace \to K$ be given by $f(x) = \pi$ and $g(x) = \pi^2$.

$$\begin{CD}
@>>> \lbrace x \rbrace \\
@AAA @VVgV \\
\lbrace x \rbrace @>>f> K
\end{CD}$$
(I don't know how to make the diagonal arrow)
Considering K up to ind2 makes the diagram commute. Something tells me this is not what you had in mind. Ind2 has the property of "mixing valuations".

In terms of automorphisms of G these give you the freedom to move around the higher ramification groups. The reference for this is Joshi's manuscript.

Here is the standard warning: this will not save the day and you will NEED ind3 to make the formulas work as this sort of doesn't mix very much. The $\mathbb{Z}_p$-submodules $p^j \log(\mathcal{O}_K)$ will always be preserved under ind2, so $K = \coprod_{j \in \mathbb{Z}} p^j \log(\mathcal{O}_K) \setminus p^{j+1} \log(\mathcal{O}_K)$ and each annulus is preserves setwise under ind2.
This is saying, in some sense, that ind2 (and ind1) do not do too much. Moral: in order for Mochizuki's inequality to be true, you *do* need ind3.

The purpose of ind2 (and the other indeterminacies) is to perform a construction that is independent of the structure that it was constructed from.

>(There was actually a point where Mochizuki was surprised that by "forgetting the history of a group" one still has more than a group up to isomorphism: Namely, a group. That the datum of a group is strictly more than the datum of a group up to isomorphism seemed new to Mochizuki. I believe this is the (psychological) main reason he considers these full poly-isomorphisms.

Classic Mochizuki.

>But really, forgetting "the history of the groups" you still have groups and they may still have natural commuting isomorphisms between them. Of course, for groups up to isomorphism you can't ask for natural commuting isomorphisms between them, then you only have "full poly-isomorphisms".)

To be honest, I'm not sure what you mean by "history of groups" and it actually hurts my head to think about this or to think about you thinking about this. If you want to email me a reference I might be able to say what is going on here but I would need to see it. I'm also don't want to defend the usage of "history" in these documents.

>A few comments up I summarized the situation with claims (1), (2) and (3). I have seen no valid objection to (1) and (2), and (2) alone would lead to a contradiction (as one gets too strong a form of ABC).

I addressed this in the introduction.

>To (3), Taylor indicated where to cut the diagram, but I really don't think this is what happens, as this would isolate Theta-pilots from Theta-values and effectively remove the actual Theta-values from the proof; while Mochizuki does consider this "Theta-intertwining" which is the association of the Theta-pilot with the Theta-values.

I addressed how Mochizuki proposes to bring theta values back into the proof; using the anabelian geometry. How this actually works is unclear to me. Also, I think Mochizuki would object to your characterization "theta intertwining" here. He would say something about the "strong anabelian properties of the etale theta function" which might be equally imprecise. He would also point to a number of other constructions which would include MOD vs $\frak{mod}$ constructions, and the theory of cyclotomic synchronizations. How the q and Θ pilot objects are tied is the mystery and has been the subject of my conversations with everyone for the last several years (which is embarassing to admit outloud).

What is missing to me is the comparison between the U_{Θ} and q. Mochizuki and Hoshi have very patiently been trying to explain this to me for a long time now. Maybe you want to call this a gap. Maybe I'm
dense. Mochizuki will undoubtedly call this a "fundamental misunderstanding" and point to some aspect of his manuscript. Me (and Emmanuel Lepage and others) have

been talking about this since 2017 and are stumped.

****
Some "Refereeing" of the log-links discussions between Peter and UF
****

@UF April 11, 2020 at 9:02 pm
–C7 of the 05 comments actually says that you *can* switch.
–I don't think this rigidifying/derigidifying should be emphasized and will just confuse people. Calling a pair $(\Pi, \overline{M}) \in [\pi_1^{temp}(Z^+),\mathcal{O}^{\vartriangleright}_K]$ a "rigidified fundamental group" is weird.

@Peter Scholze, April 12, 2020 at 4:58 pm
In this Peter chooses to address the log-links as an example of indeterminate copies doing nothing. Here he claims these can be replaced by logs.

My understanding of the situation for log-links is different. I'm going to give an abstract setup and I claim something like this occurs in IUT. Fix $\overline{M} \cong \mathcal{O}^{\vartriangleright}_{\overline{K}}$. This can be decomposed as $\overline{M} \cong \pi^{\mathbb{Q}_{\geq 0}} \cdot \overline{M}_{tors} \cdot F$ where $\overline{M}_{tors}$ is the torsion subgroup and F is the free part (at finite level these are free $\mathbb{Z}_p$ modules). Furthermore for the subgroup of units we have $\overline{M}^{\times}\cong \overline{M}_{tors} \cdot F$. Suppose now that one only knows $\overline{M}$ up to automorphisms of $\overline{M}_{tors}$. In order to get a well-defined object, one thing that we can do is mod out by torsion $\overline{M}^{\times} \to \overline{M}^{\times \mu} = \overline{M}^{\times}/\overline{M}_{tors}$ this is now well defined.

Mochizuki would say the converse. That we want to manipulate $M^{\times\mu}$ (via ind1 and ind2) and this manipulation needs to be independent (lifted to?) from the $\overline{M}_{tors}$, which plays a role in the exterior cyclotome of the frobenius-like mono-theta environment, which is used for passing structures "down to the bottom" in IUT3 3.11.

@UF, April 13, 2020 at 10:16 pm
It seems that you are both talking past each other. Log links are about relationships between monoids *not* fundamental groups.

>It seems quite likely Mochizucki uses "switching-symmetry" in a technical sense, synonymous with "multiradiality" of some algorithm reconstructing the data (here a rigidified column of log-links) at hand from some choric data, as he often does, compare e.g. [Alien, p.51].

There is a technical sense. Given a morphism of connected groupoids $F:\mathsf{A} \to \mathsf{B}$ one can form the category $\mathsf{A}\times_{\mathsf{B}}\mathsf{A}$ whose objects are (A_1,A_2,f) where $f: F(A_1) \to F(A_2)$. When F is full and essentially surjective the switching functor is $(A_1,A_2,f)\mapsto (A_2,A_2,f^{-1})$. In practice, as I have said before, this seems to be note enough for applications as objects in categories seem to be more. Also, I think there is a problem because we literally want a map of sets at the end of the day. I haven't worked out how to use this formalism effectively.

>His statement would then mean that if we rigidify the vertical columns, then there is (unlike in the non-rigidfied case) no multiradial algorithm to recover this column from certain choric data. This does not sound so absurd anymore (to me).

Minor typo: "choric" should be "coric"

>Now which multiradial algorithm does he mean here? I would suggest it may be the multiradial algorithm in [IUT III, Cor 2.3], more specifically, the first part of 2.3 (ii) which concerns its compatibility with log-links. Note that close by, [IUT III, Rem 2.1.1 (ii)] the issue we are talking about "why π_1 only upto indeterminate iso?" is discussed. For further discussion see also in [IUT II, Rem 3.6.4 (i)]. In any case, I agree this is an important issue to track down.

This is addressed in the comments at the very very bottom.

@Peter Scholze, April 14, 2020 at 5:17 pm

>The remarks from IUT that you cite make heavy reference to his paper on etale theta-functions, which seems to play a key role in the IUT papers. This paper gives some neat algorithm to start from the fundamental group of a once-punctured elliptic curve with bad semistable reduction, and recover its Tate parameter q and some Theta function; I forget the details. While this is all good and well, I don't see the relevance: Mochizuki's more general anabelian theorems, discussed previously on this thread, tell you that from the fundamental group you can simply recover the whole curve. In these comments of Mochizuki that you reference, Mochizuki is discussing some nitty-gritty details of this algorithm, but this seems completely besides the point if you just remember that relevant pi1X's are equivalent to relevant X's, so of course you can recover all invariants of X, and you can do so functorially in pi1X.

If we are collection complaints about exposition I have another: As Peter has mentioned this and many other pieces of text in theorem environments punt you WAAAY back to topics in other papers. As Peter is mentioning this goes back to Etale Theta which I think is at least 5 papers back (IUT3>IUT2>IUT1>AAG3>AAG2>AAG1>EtTh) to be fair one could argue that AAGX and EtTh are independent. Either way, this is a big dependence, and we haven't even touched the dependencies of the AAGX papers.

I responded to the second part of this remark already. You asked about 3.11.i. Also, this $\mathfrak{R}^{LGP}$ is actually not so complicated. The one in Cor 2.3 $\mathfrak{R}$ that is the bad one (no pun intended). I'm going to postpone this dicussion until the end.

@UF April 15, 2020 at 9:04 am
>I now think a good reason to for not identifying π_1's along log-links is as follows:
(It is very similar to [IUT-2, Rem 1.11.2 (ii)] for the theta-link; I am less precise here, taking the relevance of some reconstructions on faith, but it is a intuitive story, and precision can come later)
>First, let us step back and look at the log-theta-lattice: It consists of Hodge-theaters and the log/theta-links as maps/functors between them. Now a formulation of (2) is: Why do we, say for the log-links, not just take the "identity" isomorphism between the relevant π_1's instead of the full poly-isomorphisms between them? Surely it is also a completely valid map between the theaters?
>Yes, but: let us recall what we want to do with this log theta-lattice: we want at "suitable times(?)" glue the Hodge theaters along these links and then apply certain multiradial algorithms.
>I think that if we would glue with the "identity" on the $\pi_1's$ (and all the other prescriptions of the log-link), then this gluing will be inconsistent/not well defined (when combined with some multiradial algorithms), in some vaguely similar sense as if you try to define a complex structure on a manifold by charts, but in some region the procedure leads to two different, incompatible complex structures, i.e. the transition map is not holomorphic.
>Indeed, in one Hodge theater, the π_1's not independent of the rest of the data; it acts via the quotient to the Galois group on the monoids. Thus π_1's "related" to the monoids, and it is not apriori clear we are allowed to glue two Hodge theaters by gluing π_1 and the monoids separately in whatever way we wish (and then follow certain multiradial algorithms).

I'm going to refer you to my forthcoming manuscript with anton (the prequel to the one with the IUT4 style computaions). There is some stuff on my vlog that is a (poor) template for this stuff if you don't want to wait.

>In the above analogy, a certain region of the Hodge theater is supposed to be "determined" jointly by the π_1 and the monoids.
The multiradial algorithm we consider is roughly as follows: The action of π_1 determines on the (from the Galois group reconstructed) local monoids (with 0) in addition a ring structure (a "holomorphic" structure).
>The output is roughly some etale version of some of the data originally present in the Hodge theater, and the reconstruction algorithm yields a canonical isomorphism between the original data and the reconstructed one (see e.g. [Alien, §2.12] for essentially such constructions).

This *is* a thing.

>If one now glues two Hodge theaters along a log-link (with in addition "identity"-gluing for π_1's, then this yields no consistent holomorphic/ring structure compatible with the above algorithm on some region:
>Namely, consider the region of the ring (local units), which is glued via log (the actual log part of the log-link) to other Hodge theater; this yields one definition of "holomorphic" for this region.

I can't parse this sentence.

>On the other hand, we can embed this region in the reconstructed monoids and use for the "holomorphic" structure on the reconstructed monoids the one induced by π_1 on both Hodge theaters and glue by the "identity".

This is true. You definitely have one structure from the base and one structure from pulled back from log. The diagrams commute though.

>The above roughly describes two incompatible holomorpic/ring structures on some part of the glued Hodge theater; they are incompatible, "because the transition map, essentially the log, is not a ring map". Such a situation is presumably avoided by taking the full polyisomorphism between π_1 where the log map on the units alone defines the holomorphic structure on the relevant region.

I'm not sure I parse this completely. I will say there is a way to get the a commutative diagrams of fields in the log-kummer correspondence. It depends on what maps you take. Any "log" has a backwards map which is an isomorphism of fields. I will refer to the forthcoming paper with Anton for details.

@Peter Scholze April 15, 2020 at 2:05 pm
****
>Removing all language from your message, I end up with the following message: The logarithm map is not a map of rings. This is why you have to consider source and target up to some indeterminacy.

The log-link is about the monoids and not the base (you use really only use the fundamental group to use Mochizuki's interpretation of a field in order to pullback this structure so you can take the logarithm).

I don't know if this helps but there is a "post-logarithm" that IS an isomorphism of rings and this IS used the definition of the log link. I think it is nice to factor the actual logarithm as $\log^{post}\circ \log^{pre}=\log$ where $\log^{pre}$ is the map in IUT. One can then use the map $\log^{post}:\mathcal{O}^{\times\mu}\otimes \mathbb{Q} \to K$ and pull back the field structure to get a new field $K_{\log}$ which is $\mathcal{O}^{\times \mu} \otimes \mathbb{Q}$ as a set but with this new field structure.

****
@UF April 15, 2020 at 4:57 pm
****

>What my post above attempts to show, is: if passing to poly-isomorphism has the effect of doing no gluing/no identification of ring structures (arising from π_1 just the gluing from the actual log map), then the only gluing left is the actual log map, which gives one global chart, and no transition functions needed, essentially(?) since just one chart.

Yes, but I think the point is what I was saying about killing indeterminacies. Doing log-links isn't "for sport" as Mochizuki would say.

>I before never really seriously considered that full poly-isomorphism could have the effect of "no gluing arising from this part" (instead of "choose your favourite gluing")

I don't think I understand how you are thinking about this.

****
Remarks on IUT3 2.3.ii
****
We are looking to see if this statement says something non-trivial about the bases of log-linked hodge theaters and multiradiality (I actually think this is barking up the wrong tree since, as I've said before, the bases in log-linked hodge theaters do nothing except impart ring structures to the monoids). Indeed this is the case because of assertion (2) below. Let me just remark though for Peter, that the maps between the $\times \mu$ prime strips are what are going to encode everything in Galois groups and what eventually gets the theta back to the other side.

Anyway, at the beginning of the proposition there is a certain amount of setup. BUT, notice in the setup, most of the structures are interpreted! This means that their morphisms are just functorially induced by the interpreting structures, in this case there is a prime strip of the $\times \mu$ variety, and a base hodge theater (actually, it is even simpler than this… see the note below). Looking at my notes… this looks tautological.

Also, just as a tip from as a person who has wasted his life doing this, the thing to look out for are maps that are NOT full polyisomorphisms.

In this item there are a total of three assertions.
1) log-links induce a full polyisomorphism of the $\mathfrak{R}$'s;
2) Theta links on log-links pairs of hodge theaters have $\mathfrak{D}_{\Delta}^{\vdash}$'s interpreted in $\mathfrak{D}_{\Delta}^{\vdash}$ which are isomorphic.
3) Using (1) and (2) the $\mathfrak{R}$ across is generically isomorphic across log-links; the $\mathfrak{D}^{\vdash}_{\Delta}$ data is generically isomorphic across Theta links.

Proof of 1: This only could be a problem because of the nature of the way the monoids are linked and the dependence of $\mathfrak{R}$'s on these monoids. In the data for $\mathfrak{R}$ there is exactly one place where the monoids interact. This is in the $\times \mu$ prime strips. Everything else is functorially induced. For example, in the definition he takes the monotheta environment interpreted from the base (this actually has well-definedness issues of its own!).

Proof idea of 2: As described somewhere in this note ind2 is isomorphisms of $\mathcal{O}^{\times\mu}(G)$'s induced by isomorphisms of G's. If you look up the definition of $\mathfrak{D}^{\vdash}_{\Delta}$ you will see that it is just a bunch of G's. This means the generic isomorphism of from the G's induce an ind2 on the $\times \mu$ monoids they interpret; the $\times \mu$ monoid isomorphisms in the theta link are the same thing.

Expositional Note: This is an example of a proposition where too much structure was invoked for my taste. In the fine print you notice that the interpreters are $\mathfrak{D}_{>}$ and $\mathfrak{D}_{\Delta}^{\vdash}$ (=fundamental groups at each place and absolute galois groups at each place respectively). In the statement he references the full base hodge theater. That's baggage. Also, you will notice that this could have been broken into many much simpler assertions each which can be individually checked.

****
Remarks on IUT3 3.11.i
****
Peter had asked (essentially) how can galois groups interpret theta values? How can they do anything?!

Well, I claim that Theorem 3.11.i and 3.11.ii are not the difficult parts of Theorem 3.11; Theorem 3.11.iii is the weird part. There are some subtle differences between the (abc)-module structure in both of these statements. In the first, the actors (b) and (c) are defined as subset of the $\mathbb{L}^{\vdash,et}$ (at the appropriate places) in part i. In part ii there is a clear module structure.

In the situation of (i) you lift to an richer stronger and more powerful structure that allows you to define (b) and (c) then then you stick them inside the log shell. What the proposition is saying is that this is well-defined up to ind1,2 — so everything that was stuck inside these log shells now is considered up to a jumbling of the type described in a previous response. I will refer readers to my manuscripts with Anton Hilado for these formulas.

A subtle difference that I want to point out to everyone here which they may not have noticed is the difference between the usage of the MOD, LGP constructions and the $\frak{mod}$, $\frak{lgp}$ constructions in the later.

****
Sorry if I made any errors anywhere. I didn't mean to and tried to proofread this. Hopefully we learn as part of the corrections.

Best,
Taylor

112. **Peter Scholze**
April 17, 2020

Dear Taylor,

thanks for these final comments! I think I should answer to this. Let me first say that I agree with much of what you write, and for the sake of keeping this short, I only jump at the few places where I disagree.

> Regarding (3): Is Mochizuki's Proof Falsified? […]

> Finally, it is not outside the realm of reality that there could be 5 top notch international referees who have understood the proof as complete and correct.

Really? I would have hoped that in that case at least one of them — not in their role as a referee, but simply as a mathematician who wants to share insight — would have come around and explain the key ideas in a way that is understandable.

> Because of these difficulties I personally hold Mochizuki's document as a program for proving ABC and consider Mochizuki's formula a conjecture (until I can see this with my own eyes). Then again, there are a lot of Theorems I know about and use but can't prove.

I very strongly object to the implicit (I believe) assertion that Mochizuki's result should now be considered just another of these really difficult theorems whose proof we never understood.

> *****************
> Regarding (2)
> *****************

> Also, there are a lot of monoids built into the theory which are excluded from the statement and I don't know if these are implicitly assumed to be identified as well. I think not.

Well, I think I would want to identify some, too. By mode of thought is that starting from your elliptic curve, you can easily cook up all the data that forms a Hodge theater, including those monoids. Simply take that collection, and always the same one. Later, when you study log-links, try to understand what they do, which diagrams do not commute, and if necessary enlarge your diagram (of course you get a non-commutative diagram if you want that the logarithm equals the identity). My issue lies with possible non-identity isomorphisms of Hodge theaters being relevant at any point; they are not for all I can see, as all possible non-commutativity can't be restored in terms of internal isomorphisms of Hodge theaters.

> Finally, to derive a contradiction, I think some things need to be said about *how* one proposes to reduce Mochizuki's construction to "a single fundamental group".

As the final step in Mochizuki (proof of Cor 3.12) is so unclear, it also seems impossible to fully justify where and how it breaks.

****
Intertwining
****

> Again, from the horses mouth, read C12 of his responses.

OK, I reread this. He talks about the q- and the Theta-holomorphic structure. This indeed sounds like there must be two distinct Hodge theaters around — Hodge theater is, I believe, the technical version of "ambient holomorphic structure". But there are not! All of them are isomorphic. And if I identify them (using whatever isomorphism) I can see plainly that this does not make any sense.

> He says he does not do this. Also, please look at the displayed diagram below. I think this may clarify something for you.

Details seem to be off in the example, but in any case I totally see that some non-commutative diagrams become commutative up to these indeterminacies — otherwise they would not be indeterminacies. But I'm asking about a relevant one.

> Also, in this "interwining", this is where the theorem about the amphoric/characteristic nature of the interpretation of the Jacobi theta function is supposed to be applied.

The "amphoric" nature here is just that you can recover X from $\pi_1(X)$, so in particular the theta function (and all else). I'm still failing to see the importance of etale theta functions in all of this.

> Exercise: Look at the first page of Marker's notes then show that the torsion of an abelian group is definable using infinitary formulas.

> Exercise: People often complain about the non first orderizability of topological spaces. Read this post from stack exchange on how to define topological spaces: https://math.stackexchange.com/questions/46656/why-is-topology-nonfirstorderizable

I'm totally lost about where you're trying to go here.

>About the indeterminacies: I'm focusing on (Ind2); (especially) the part concerning automorphisms of local Galois groups (acting on local units if necessary). I don't see any diagram that doesn't commute when you take the identity isomorphisms, but does commute when you conjugate by an automorphism of a local Galois group (acting on local units). Why do you need that, except because "you need to forget the history of your objects in order to apply reconstruction algorithms" or some magic like that?

Thanks again for the example in reply to this, but I'm asking about a relevant diagram in the relevant abstract setting.

> The purpose of ind2 (and the other indeterminacies) is to perform a construction that is independent of the structure that it was constructed from.

This slogan I understand, but where does Ind2 help with anything? Why do you need to introduce it?

> I addressed how Mochizuki proposes to bring theta values back into the proof; using the anabelian geometry. How this actually works is unclear to me. Also, I think Mochizuki would object to your characterization "theta intertwining" here. He would say something about the "strong anabelian properties of the etale theta function" which might be equally imprecise. He would also point to a number of other constructions which would include MOD vs
constructions, and the theory of cyclotomic synchronizations. How the q and Θ are tied is the mystery and has been the subject of my conversations with everyone for the last several years (which is embarassing to admit outloud).

> What is missing to me is the comparison between the U_{Θ} and q. Mochizuki and Hoshi have very patiently been trying to explain this to me for a long time now. Maybe you want to call this a gap. Maybe I'm
dense. Mochizuki will undoubtedly call this a "fundamental misunderstanding" and point to some aspect of his manuscript. Me (and Emmanuel Lepage and others) have been talking about this since 2017 and are stumped.

Well, I guess you are just pointing your finger to the same problem that I'm trying to point at. It is completely unclear how you get the actual Theta-values back in the game. You started this paragraph with "using the anabelian geometry", but as I argued long before, it is completely unclear how anabelian geometry helps with anything in his setup (by (1)).

> *******************
> @Peter Scholze April 15, 2020 at 2:05 pm
> *******************
> >Removing all language from your message, I end up with the following message: The logarithm map is not a map of rings. This is why you have to consider source and target up to some indeterminacy.

> I don't know if this helps but there is a "post-logarithm" that IS an isomorphism of rings and this IS used the definition of the log link. […]

My main question in the discussion with UF has always been the question of full poly-isomorphisms vs. identities between $\pi_1(X)$'s, i.e. issue (2). All you are writing is completely tangential to this. I think you actually agree that the log-link has so little to do with $\pi_1(X)$'s that it can't possibly be the reason to consider $\pi_1(X)$ up to full poly-isomorphism. Yet Mochizuki was trying to make that exact point when we were discussing.

> *******************
> Remarks on IUT3 2.3.ii
> *******************

Why are you discussing this? I'm lost. Is it saying more than Theta-values being the same in all Hodge theaters?

> *******************
> Remarks on IUT3 3.11.i
> *******************
> Peter had asked (essentially) how can galois groups interpret theta values? How can they do anything?!

You are simply ignoring my point!

Best wishes!
Peter

113. **Peter Scholze**
April 17, 2020

PS: I just realized that maybe the following information is worth sharing. Namely, as an outsider one may wonder that the questions being discussed at length in these comments (e.g., the issue of distinct copies etc.) are very far from the extremely intricate definitions in Mochizuki's manuscripts (his notation is famously forbidding, some of it surfaced in Taylor's comments), and feel almost philosophical, so one might wonder that one is not looking at the heart of the matter.

However, the discussions in Kyoto went along extremely similar lines, and these discussions were actually very much led, certainly initially, by Mochizuki. He first wanted to carefully explain the need for distinct copies, by way of perfections of rings, and then of the log-link, leading to discussions rather close to the one I was having with UF here. He agreed that one first has to understand these basic points before it makes sense to introduce all further layers of complexity. (I should add that we did also go through the substance of the papers, but kept getting back at how this reflects on the basic points, as we all agreed that this is the key of the matter.)

114. **UF**
April 17, 2020

@Taylor Dupuy: Thanks for your comments.
The context for comment (C7) is Mochizukis interpretation of footnote 5 in [Scholze-Stix]. Mochizuki gives this interpretation in the first display of (C7): the rigidification mentioned there is (I think) not (some kind of) rigidification of π_1 in one Hodge theater (which you seem to mention, by considering pairs (π_1, monoid)), but the rigidification among the different π_1's in one vertical column by choosing a specific isomorphism ("identity") instead of full poly-isomorphism

between the different π_1's in one column.

Mochizuki then says that one can consistently identify the π_1's as above, if one forgets about both log- and theta-links. (Mochizuki does not say so explicitly right here, but I think in this situation there would be a switching-symmetry. He says so in a closely related situation after the second display, which in my understanding amounts to the same situation).

In the second display in (C7), he seems to say (my " " are not meant here as quotes): In contrast, if one keeps log-links (or maybe similarly theta-links), then the rigidification of the π_1's "depends" on the other data, say "0-column Frobenius-like data (at different vertical spots) with log-relations", which do not admit a switching-symmetry between two vertical columns.
Here in my understanding "depends" indicates that the log-identifications between the 0-column Frobenius data cannot be made completely independently from the identity-identifications of the π_1's in the 0-column, since at a fixed vertical position the π_1 and the monoids are "related/not independent" (via the action). Implicit here (and relevant for the context of this C7) seems to be the assertion that because the rigidification of the π_1's "depends" on the 0-column Frobenius data (which does not admit a switching-symmetry) , something has to go wrong with switching (when π_1's are rigidified in a column), "because" it goes wrong for the related/dependent 0-column Frobenius-like data. (If this is *not* implicit here, then what in Mochizukis response in C7 is the objection to the vertical rigidification of π_1's?)

After the second display he says: If one forgets about the 0-column Frobenius data (in particular the log-relationship between them at different vertical spots), then there is a switching-symmetry between two neighboring columns.

This is how I understand Mochizukis C7; I may certainly understand it wrong in parts, and I would be happy to understand it better. All the rest I wrote is an attempt make this (from my point of view) "implicit objection to rigidifying π_1's" in the second display more explicit; but if my understanding concerning this is incorrect, then this is largely meaningless.

115. **Taylor Dupuy**
April 18, 2020

Hi Everyone,

I'm going to take a break today to attend WAGON:
https://sites.math.washington.edu/~jarod/wagon.html

Check it out!

After that I'll take a look at the new comments and see if I have something to add.

Best,
Taylor

116. **n (long time blog lurker)**
April 19, 2020

Dr. Woit,

"I read Mochizuki's blog entry when it came out. To the extent I could make sense of it via Google Translate …"

maybe DeepL

https://www.deepl.com/translator

would be worth a try; it's got only few languages, but Japanese is one of them, and it gave me better results than Google Translate.

117. **W**
April 19, 2020

There has been some discussion about this comment thread that focused on the importance of the differentiating between fact and opinion. There has also been discussion that the long thread may obscure the points that Peter Scholze and Taylor Dupuy agree on by focusing on their areas of disagreement. I have written a (very long) comment to try to help with these issues.

The way this comment is intended to work is that the numbered paragraphs (1), (2), (3) give facts that are difficult or impossible to dispute and the paragraphs after them give opinions building on those facts.

(1) The first couple hundred pages of the IUT papers introduce a lot of difficult new terminology. Scholze and Stix demonstrated that none of this new terminology is necessary to prove any of the formal statements in these pages. Moreover, when the new terminology is ignored, the proofs all become simpler and easier to understand. They all follow quickly from Mochizuki's previous work on the p-adic Grothendieck conjecture.

As a reader, this should already make you skeptical of the accuracy of the paper. How can dressing up simple statements in confusing and difficult terminology for hundreds of pages represent progress in turning the solution of one problem (the p-adic Grothendieck conjecture) into a completely different problem (ABC)? There are mathematical arguments that begin by introducing a lot of terminology (e.g. work of Grothendieck) but nothing like this ratio of terminology to content has ever been successful before. However, you certainly shouldn't rule out Mochizuki's work based only on this evidence.

As an editor or referee, you should also be very skeptical at this point. Setting aside concerns about correctness, you have some duty to ensure papers published in your journal are clear and get to the point. Having hundreds of pages that can be compressed to much less by the removal of new ideas rather than their introduction is not normally consistent with good mathematical writing, but one could imagine that the remainder of the paper justifies this sufficiently.

(2) Many people have tried to read the papers, read and understood the first few hundred pages, and then were unable to verify a key point – Corollary 3.12. This point is either the first or the second statement in the paper which doesn't fit into the hundreds of pages mentioned in (1).

As a reader this should make you very worried! This is is not a pattern one typically sees when people try to understand a correct but difficult argument (regardless of how well or poorly it is written). Instead, different people almost always get stuck at different points. This is certainly true if the reason people are getting stuck is a lack of background in anabelian geometry, or a refusal to put enough work into it – both reasons suggested by defenders of IUT. You would then expect to see different confusions in different places from people with different levels of background, or from people who made careless errors at different points. Of course, what we see is exactly what you would expect to see if the proof of Corollary 3.12 is not a valid argument but the rest of the paper is valid.

As an editor or referee, this should be completely unacceptable. Even if the proof is technically correct in the sense that Mochizuki or someone else can give a clear and precise argument which the proof of Corollary 3.12 could be said to summarize, allowing the paper to continue in its present form would be a failure at their duty to ensure papers in their journal properly explain their arguments. A paper such that everyone who studies it seriously, except a small inner circle, gets stuck at the same point simply isn't a proper explanation.

Some defenders of IUT like to point out that Scholze and Stix didn't give their precise objection until 2018. But this phenomenon, given that it was noticed by most people who read the paper seriously, should have been turned up by the refereeing process before then. This is, I think, the starting point for ethical concerns about the refereeing process. (For instance, OP's comment suggests that the editors could have asked a series of referees, ignoring those who have negative commentary, until they found someone willing to say it is good.)

Is it possible that the final version makes substantial changes to this argument and answers this objection? Everything is possible, but it seems unlikely. It is common practice in mathematics to edit the online version of the paper to the final submitted version, or something close to it, without the journal's formatting. As far as I know the main reasons not to do this are because one doesn't post online versions or doesn't edit them often, neither of which apply to Mochizuki.

Even if the editors and Mochizuki want to avoid this for some reason (like they want to make people read the journal to see the complete proof, I guess…) they could easily post some comment online like "Corollary 3.12 has been replaced with a series of simpler statements, each with a detailed proof, culminating in the key inequality, totaling about 35 pages" and get much less criticism from mathematicians and mathematical physics bloggers. Does anyone like receiving criticism? Is there any reason not to do this?

(3) Two serious mathematicians have come up with a precise objection to the proof of Corollary 3.12. Despite the fact that it is not clear exactly what Mochizuki means, they have come up with a plausible interpretation, and shown that, in this interpretation, the inequality that Mochizuki proves is off from the inequality he states by a factor of j^2. This is important because the improvement of the stated inequality over a certain trivial inequality is exactly by a factor of j^2. They have come up with additional arguments, which are unsurprisingly not completely rigorous, that any plausible interpretation of what Mochizuki means will have the same problem.

(One could say that it is not plausible that Mochizuki made such a simple mistake, but I think it is plausible in light of the previously discussed information).

Neither Mochizuki nor his defenders have come up with a convincing rebuttal to this. Mochizuki's response focused on arguing that it is possible for an argument like his to work, and that Scholze and Stix misunderstood it, rather than making basic clarifications to the argument that would aid in understanding whether the objection is valid, and that would certainly be possible if the argument is correct. For instance it is *provably* possible that any valid argument proving a concrete inequality using facts about affine spaces over the real numbers can be replaced with one that proves the concrete inequality using other concrete inequalities (or identities). Doing this would allow a more focused discussion because Scholze could either dispute one of the building-block concrete inequalities or dispute the implications from them to the desired statement.

For me this objection, combined with the other stuff, is devastating. Of course it is not the case that one must stop the presses of a journal every time a mathematician objects to an argument, and keep them stopped until that mathematician is satisfied. But combined with the other very worrying facts about the proof, this is an objection that must be answered for the paper to be published ethically. As mentioned earlier, if a better answer than what is in the currently online version has been delivered by Mochizuki to the journal, I would expect it, or at least an advertisement for its existence, to be posted online.

Despite the long comment thread, Peter Scholze and others have not exhausted all the reasons that a mathematician examining Mochizuki's argument should be skeptical that it, or even any argument like it, could possibly work. I could list these additional reasons, but they are not so relevant when the objections outlined above already mean that it would be inappropriate to publish the article in its current form.

118. **Dale**
April 23, 2020

Kirti Joshi has now posted a revised manuscript "On Mochizuki's idea of Anabelomorphy and its applications" discussed earlier in this thread. https://arxiv.org/abs/2003.01890

119. **Fierce Inertia**
April 24, 2020

This paper of Joshi is remarkably unconvincing to me. If I may caricature it slightly, it seems to only contain the following types of results:

1. Statements of the form "(Thing X / Property Y) depends only on the absolute Galois group of a p-adic field."

None of these are surprising or difficult: they all follow from basic class field theory or from the Jannsen-Wingberg theorem (which IS a difficult result, cf. here for a nice overview: http://www.numdam.org/article/AST_1982__94__153_0.pdf)

2. Statements of the form "(Thing X / Property Y) does not depend only on the absolute Galois group of a p-adic field."

These are even less surprising, and they also follow from Jannsen-Wingberg, or from five seconds of thought.

3. Completely unmotivated results (e.g. Theorem 16.5, Theorem 22.6).

4. Vague suggestions that various things can be interpreted anabelomorphically.

What evidence is there here that this perspective of anabelomorphy is actually useful? What can you DO with it? The answer this paper seems to suggest is: nothing.

I am happy to be convinced otherwise.

120. **David Roberts**
April 29, 2020

For what it's worth, the first two (of three) papers by Taylor and Anton Hilado are now on the arXiv:

"The Statement of Mochizuki's Corollary 3.12, Initial Theta Data, and the First Two Indeterminacies" https://arxiv.org/abs/2004.13228

"Probabilistic Szpiro, Baby Szpiro, and Explicit Szpiro from Mochizuki's Corollary 3.12" https://arxiv.org/abs/2004.13108

121. **Martin**
April 29, 2020

From the abstract of the first paper:

"This paper does not give a proof of Mochizuki's Corollary 3.12. […] These manuscripts are designed to provide enough definitions and background to give readers the ability to apply Mochizuki's statements in their own investigations. […] It is our hope that doing so will enable creative readers to derive interesting and perhaps unforeseen consequences Mochizuki's inequality."

It is my interpretation that the statement of Corollary 3.12 is reformulated in these papers. In the second paper, some consequences of the reformulation are derived. But aren't these consequences of an unproven, highly debated corollary – which most likely "cannot work" (Scholze)? Which kind of "creative reader" should use these reformulation then?

Taylor was quite active here, maybe he can comment on how these papers fit into the story?

122. **Peter Woit**
April 29, 2020

Martin,
Scholze's argument is not that the inequality can't be right, but that Mochizuki's proof of the inequality can't work. It's a reasonable project to understand the implications of conjectured inequalities, better if they're clearly labeled as conjectures…

In addition, another way to show Mochizuki's proof doesn't work and pinpoint exactly where it goes wrong would be to find a point where he derives something too strong, something that can be shown to be true by other methods.

123. **Taylor Dupuy**
April 29, 2020

Hi Everyone (and Peter),

In what follows I can give four proofs/reasons why a certain statement in Peter's manuscript with Jakob about replacing Hodge Theaters with fundamental groups is false. I believe these to be correct. Please check for mistakes.

Best,
Taylor

====================================

I noticed the following claim embedded into the manuscript.

Claim.(Scholze-Stix manuscript page 6, paragraph 4)
There is an equivalence of categories between a connected groupoid of objects isomorphic to a big Hodge Theater and a connected groupoid of schemes isomorphic to a once punctured elliptic curve over a number field sitting in initial theta data. This allows us to replace Hodge Theaters by once punctured elliptic curves.

Here is the exact text:

"In other words, up to equivalence of categories, choosing a Hodge theater is equivalent to choosing a once-punctured elliptic curve abstractly isomorphic to X, and this equivalence of categories is constructive in the sense that one can give an explicit functor that takes a Hodge theater and produces a once-punctured elliptic curve. Of course, the category of elliptic curves abstractly isomorphic to X (and isomorphisms of curves) is equivalent to the category whose only object is X that we started with."

This is stated in the manuscript without proof; they cite a number of propositions from IUT1 Corollary 6.12 (i), Proposition 6.6 (iii), Corollary 5.6 (ii), Proposition 4.8 (ii), Definition 6.13 mirroring Mochizuki's style.

I just want to point out that this is a MUCH more extreme a claim than what I thought Peter was claiming previously. This is why I had softened it for him in my response warning readers not to take him literally. After looking at the manuscript again it appears that he *did* mean what he said, literally.

This, I can dispatch. It is actually False in four different ways. It is false the first time because of the equivalence of categories statement. It is then false the second time because of the assertion that "picking a once punctured elliptic curve is equivalent to choosing a Hodge theater" statement. It is false a third time because these two statements are themselves not equivalent. We then give another independent proof that this is false by means of interpretation of initial theta data (similar to Mochizuki's original counter-argument in his "Report").

Also, most importantly, this type of reduction used to simplify Mochizuki's definitions is far from admissible. The notion of equivalence of categories and "equivalent" in a colloquial sense should not be confused. Equivalence of categories is too coarse of a notion to be useful in simplifying the definitions in IUT. The correct notion (for objects which are not considered up to automorphism) is the notion of bi-interpretability. This is a special type equivalence of categories which considers the types of formulas you are allowed to use. A reference to this notion in Olivia Carmello's book at the bottom of this post and another to the wikipedia article.

Remark. In the Scholze-Stix manuscript, they never actually say *which* number field the elliptic curve is defined over. I'm going to assume it is F as defined in initial theta data in IUT. If you take it to be the field of moduli you can still find examples that give a contradiction.

****
Lemma. $\operatorname{Out}(\pi_1(X_F))$ has cardinality strictly greater than 2 when $\operatorname{Aut}(F/\mathbb{Q})$ is non-trivial (which is the case for F in initial theta data).
****

We will use Tamagawa's proof of the absolute Grothendieck conjecture for curves over fields finitely generated over $\mathbb{Q}$.

See Theorem 0.4 of Tamagawa's paper "The Grothendieck conjecture for
affine curves" (Compositio 1997),
https://doi.org/10.1023/A:1000114400142

Here is a text version:
https://www.cambridge.org/core/services/aop-cambridge-core/content/view/1992BA14A2D63FA076DB39A34EC45E83/S0010437X97000614a.pdf/grothendieck_conjecture_for_affine_curves.pdf

Tamagawa's Theorem:
If F is finitely generated over $\mathbb{Q}$, and Z/F is a hyperbolic curve and (geometrically connected over F) then $\operatorname{Out}(\pi_1(Z)) \cong \operatorname{Aut}(Z/\mathbb{Q})$.

Now for the application.

Let E be an elliptic curve over $\mathbb{Q}$ which does not have CM geometrically (to be concrete you can take Cremona's 11a1). Let $F = \mathbb{Q}(\sqrt{-1}, E[30])$ and let $X_F = E_F – o$ where o is the origin so we have $X_F = \operatorname{Spec}(F[x,y]/(y^2-x^3-ax-b))$ for some $a,b\in F$.

Since $\operatorname{Aut}(X/\mathbb{Q}) \cong \operatorname{Aut}(F[x,y]/(y^2-f(x)))$ we see that $\operatorname{Aut}(X_F/\mathbb{Q})$ contains $G(F/\mathbb{Q})$ and it contains $\operatorname{Aut}(X_F/F)= \lbrace [-1]\rbrace$. These commute. Also note that $[F:Q]>1$. This means $\vert \operatorname{Out}(\pi_1(X_F)) \vert > 2$.//

Remark. I think the subtle point here is that $\operatorname{Out}(\pi_1(X_F)) = \operatorname{Aut}(X_F/\mathbb{Q})$ and not $\operatorname{Out}(\pi_1(X_F))= \operatorname{Aut}(X_F/F)$. Right? Either way, it is not so relevant because this isn't the biggest point of contention.

****
Lemma. Let HT be a big Hodge Theater. $\operatorname{Aut}(HT)\cong C_2$
****
Summary:
The automorphisms of the $\pm$ side of the Hodge theater is $\lbrace \pm \rbrace$.
There are only trivial automorphisms on the $\divideontimes$ side of the Hodge Theater.
These act independently because the way the two sides interact is through a fullpolyiso (this is described below).
This concludes the proof.//

Details According to Mochizuki:

Rem 3.5.2: "The morphisms of data are obvious." (I can't defend this remark. This is an omission.)

Prop 4.8(ii); Cor 5.6(ii): Auts of multiplicative base Hodge theaters are unique; these lift to morphisms of Hodge theaters.

Prop 6.6(iii); Cor 6.12(i): Auts of additive base Hodge theaters are unique; these lift to morphisms of Hodge theaters.

Rem 6.12.2(i)(ii): We regard the Θ bridge as being interpreted in the $\Theta\pm$ bridge. It talks about the $\Theta^{\pm \operatorname{ell}}\operatorname{NF}$ Hodge theater as being the additive and multiplicative part full polyisomorphismed along the interpretation in the previous item.

Defn 6.13(i): This is what I said above but I guess this is where he gives it a name.

Remark. For people who have no experience with Hodge Theaters, Figure 6.5 in IUT1 really contains all the information you need (with the technical definition of the "bridges"). There are 4 bridges and an "additive" and a "multiplicative side". It turns out that the only "not full polyisomorphism" part of these bridges are the downward ones in that diagram which connect local and global information.

Remark. I would like to check this part again and give more the details, but I think this is all correct.

****
Mochizuki's Falsification
****
Something like this was in Mochizuki's original response. This is the most important thing to understand why these reductions are incorrect. I think it was overlooked because people find his writing hard to read. His argument was that "$\pi_1(X)$ doesn't know about initial theta data". This is true.

More concretely, the fundamental groups at (say) double underline covers can't exist without the "global multiplicative subspace" (part of the initial theta data). They are defined in terms of the single underline cover which is the dual isogeny of the quotient determined by the finite group scheme $M \leq E$ (this M is the "global multiplicative subspace"). This is not interpreted in $\pi_1(X)$ in Mochizuki's papers or the Scholze-Stix manuscript (and I don't see how to choose one in addition to the many with choices of $\underline{V} \subset V(K)$ in a definable way).

Reference: The global multiplicative subspace is explained in my "statement" manuscript with Hilado (https://arxiv.org/abs/2004.13228). See the initial theta data section. We spell out the required "compatibility" between $\underline{V}$ and M there.

****
Categorical Structure is Not What Matters
****
I will explain why (naked) equivalence of categories is not the appropriate notion to be using to reduce structure in Mochizuki's proof. The appropriate notion is bi-interpretability. The idea here is that one needs equivalence of *highly structured categories* and if this notion is not used we lose a lot of information. David Roberts actually makes this point as well in his Inference essay.

Example. Consider a non CM elliptic curve up to isomorphism (as a relative object). If we were just going to consider it by itself then the connected groupoid of curves determined by this object is equivalent to a category with a single object and two morphisms (because the automorphism group will be a group of order two)! A connected groupoid with two morphisms doesn't allow you to do much.

Example. The structure $\mathbb{Z}$ (with its ring structure) has $\operatorname{Aut}(\mathbb{Z}) = \lbrace \pm 1 \rbrace$. Yet $Th(\mathbb{Z})$ is undecidable. This is a highly non-trivial but with a trivial automorphism group. The theory of a two morphism category with one object is certainly decidable.

The previous example shows the weird sort of things you can do if you admit replacing objects using equivalence of categories. In this case the connected groupoid of things isomorphic to a big hodge theater HT is equivalent to a connected groupoid of things isomorphic to $\mathbb{Z}$ (as a ring). The sorts of things you can do with $\mathbb{Z}$ are quite different from the sorts of things you can do with HT.

For structures which don't involve objects up to automorphism the correct notion I claim is bi-interpretability (btw, objects up to isomorphism and not up to isomorphism is something that is conflated in the SS manuscript). Two structures A and B are bi-interpretable if and only if there exists an interpretation of A in B and an interpretation of B in A such that when these interpretations are viewed as functors they provide an equivalence of categories. The functorial formulation can be found in Caramello's book for example.

See
https://www.oliviacaramello.com/Unification/ToposTheoreticPreliminariesOliviaCaramello.pdf
Definition 6.12

See for a formulation in terms of sets:
https://en.wikipedia.org/wiki/Interpretation_(model_theory)

(As a warning, Mochizuki's bridges and Caramello's bridges have nothing to do with each other… as far as I know).

124. **Peter Scholze**
April 29, 2020

Dear Taylor,

thanks for your comment!

Unfortunately, I cannot follow what you are saying.

First, as is the case throughout IUT, the initial Θ-data are fixed. In particular, we have fixed a number field F etc. Our claim was:

Choosing a Hodge theater is equivalent to choosing a once-punctured elliptic curve over F, up to equivalence of categories.

Proof of Claim: As the relevant elliptic curve does not have CM, $\mathrm{Aut}(X/F)=C_2$ is the cyclic group with 2 elements. Similarly, as you write, automorphisms of Hodge theaters are C_2. Moreover, both categories have precisely one object up to isomorphism. The induced map $C_2\to C_2$ can be checked to be nonzero, hence an isomorphism.

So you say that you gave 4 disproofs.

The first is a statement about $\pi_1(X)$ that does not seem relevant to the discussion — the question is about Hodge theaters vs. elliptic curves over F. I apologize that we did not explicitly say "over F" in the text.

The second is a statement about Hodge theaters that is a part of our proof. So actually, the correct version of the first (namely, automorphisms of X over F are C_2) and the second *prove* our claim.

The third is some vague statement. Regarding whether something "knows", for example, the global multiplicative subspace: The initial Θ-data are fixed throughout. Given an elliptic curve isomorphic to X, I can fix such an isomorphism, and import all structures that have been fixed for X, like the global multiplicative subspace. This may feel like cheating, but it is exactly what Mochizuki does say in Theorem 3.11 (i) as discussed previously.

The fourth is some vague statement. I don't really understand what you mean by "bi-interpretability" or "highly structured category"; certainly the functors in both directions can be made explicit, which seems to go some way towards "bi-interpretability". Note that Mochizuki goes to great pains to define Hodge theaters, including (the highly non-obvious) morphisms, so I naturally expect their category to be of relevance. (If you want to define some theory of diophantine equations over $\mathbb Z$, you should not spend your time defining the category of rings isomorphic to $\mathbb Z$! By the way, the ring $\mathbb Z$ does not have -1 as automorphism…) Of course, category equivalences can have power. But Mochizuki's central claim is that he chooses *different* Hodge theaters and that something that looks like 5 is more like 13 in the other, except that they are also the same, up to some ambiguity… . So you have to choose Hodge theaters in his proof. But for this very step, the category equivalence does tell you that you might as well choose elliptic curves isomorphic to your given one (and take the corresponding Hodge theaters). I'm fine with going to the other side when I need to. But precisely because maps of Hodge theaters are a highly non-obvious notion, making it easy to get confused about all sorts of maps, I find it easier psychologically to first choose the elliptic curves and then pass to the other side.

Best wishes,
Peter

PS: You claim that objects and objects up to isomorphism are conflated in our manuscript. Where do we do this?

125. **Peter Scholze**
April 29, 2020

Sorry, I should have more carefully proofread. The claim is of course

Choosing a Hodge theater is equivalent to choosing a once-punctured elliptic curve over F isomorphic to the given X, up to equivalence of categories.

(I omitted "isomorphic to the given X".)

126. **Taylor Dupuy**
April 29, 2020

>By the way, the ring $\mathbb{Z}$ does not have $−1$ as automorphism.

https://images.app.goo.gl/zfRudP7opfTU8dVU8

That being said, you can just take some equally stupid thing like $\mathbb{Z}$ as an abelian group. You don't get undecidability… but whatever. The point is you have something "nontrivial" equivalent to a category with one object and two morphisms.

I might give a more detailed response about the other stuff later. Right now, I hope that other people will start commenting about the Mathematics and that it leads to a productive discussion.

127. **Peter Scholze**
April 30, 2020

Dear Taylor,

I certainly understood your point there — you might also take the ring $\mathbb Z[\sqrt{-1}]$.

There is of course a big difference between the ring $\mathbb Z$ and the "theory" it defines, i.e. roughly the class of all subsets of all finite powers $\mathbb Z^n$ that are definable by polynomial equations. The latter is indeed a highly nontrivial category (where morphisms are given by definable graphs); it is of course not equivalent to a category with one object and two morphisms. If a category like this is in place in Mochizuki's work, I'm happy to hear about it!

Reading the IUT papers, however, you are presented with some extremely difficult notion of a Hodge theater, together with a highly non-obvious notion of isomorphisms of such: Isomorphisms do not preserve nearly as much structure as you would expect them to, and this is by design as Mochizuki points out. So I find it very hard to "guess" what something like a surrounding "theory" might be. For all I can see, Hodge theaters fit neither into the framework of "structures" as used in the wikipedia entry https://en.wikipedia.org/wiki/Interpretation_(model_theory) you linked to, nor the topos-theoretic framework of Caramello. (Regarding the first one: A "structure" in the sense of model theory has first of all an underlying set. I find it hard to take a Hodge theater and produce some interesting set that is functorial in isomorphisms of Hodge theaters, the problem being the very lax notion of isomorphisms of Hodge theaters.)

However, these long discussions are all about interpretations. Regarding the mathematics proper: I stand by the claim made in our manuscript, and have indicated the proof above.

Best wishes!
Peter

128. **Taylor Dupuy**
April 30, 2020

Hi Peter,

I think this discussion kills (1). More comments are below.

(Sorry if there are any mistakes or typos)

Best,
Taylor

#################
#################

>The first is a statement about $\pi_1(X)$ that does not seem relevant to the discussion. The question is about Hodge theaters vs. elliptic curves over F. I apologize that we did not explicitly say "over F" in the text.

So maybe I am misinterpreting you (math joke) but I thought your point was that because of absolute Grothendieck, $\pi_1(X)$ and X are "the same" and that you could just replace one with the other willy-nilly in any statement. I think you are saying that any proof with fundamental groups could be replaced by a proof with X's (whenever absolute Grothendieck holds).

Look at your comments April 6, 2020 at 9:28 am.
Look at the text following your claims on April 13, 2020 at 4:25 pm (this is the (1),(2),(3) post).

This seems to contradict your position now that X_F should be viewed as relative. I have a feeling say you want X_F to be absolute in one case and relative in the other (which seems to violate your own heuristic).

Remark. Before getting into the equivalence of categories stuff below let me stress again that I think this is a red herring as it is not what we should be talking about.

In either case if you want to X_F as an absolute scheme, you get to apply absolute grothendieck but don't have the equivalence. In the case that you view X_F as a relative scheme you get the equivalence of categories. The equivalence of categories is a red herring since it isn't the appropriate notion to use for reduction. In the relative case I agree that the associated groupoids of isomorphic Hodge Theaters, Isomorphic F-schemes, and isomorphic rings are all equivalent to a category with one object and two morphisms. We both agree this is a ridiculous category that contain little information (if all we are allowed to talk about are objects and morphisms). We can interpret nothing from this category. There are no q-pilots, no theta-pilots, no bogus diagrams, nothing. Hence, this must not be what is going on.

####################
####################
>For all I can see, Hodge theaters fit neither into the framework of "structures" as used in the wikipedia entry

We want sets. (as you said)

You might notice that I made the caveat of bi-interpretability being correct for things in IUT not considered up to automorphism. The way I currently think about it is in two phases.

In phase one you have your structures (I replace all the Frobenioids with pairs $(\Pi, \overline{M})$, fundamental groups by Π's etc), in this phase we do all this interpreting.

In phase two whenever we add the polyisomorphisms, I exchange that for an automorphisms and let those act on whatever it is that was interpreted.

Remark. Mochizuki's Species/Mutation stuff in IUT4 is his way of explaining this (poorly). I have not made it though that stuff and at this point I don't think I need it. My point is, I think one can write this all down carefully, but I haven't done so and I don't think Mochizuki has done so. There is an intereting discussion on ncatlab that discusses this stuff. It seems that Skoda alluded to what I am talking about now back in 2012!
https://nforum.ncatlab.org/discussion/4260/abc-conjecture/ read posts 13, 16-20, 37.

Remark. Hodge Theaters seem to be used more of a catch-all for all the stuff he will ever need. Every individual construction I have encountered always requires much less than the full Hodge Theater. I certainly haven't worked out what the signature of a Hodge Theater is but I do think this should be worked out. You will also see from the big tables

First orderizability is explained in the stack exchange post I mentioned earlier. I think you were a little confused about the context of that post but hopefully this is clear now.

>The third is some vague statement. Regarding whether something "knows", for example, the global multiplicative subspace: The initial theta-data are fixed throughout. Given an elliptic curve isomorphic to X, I can fix such an isomorphism, and import all structures that have been fixed for X, like the global multiplicative subspace. This may feel like cheating, but it is exactly what Mochizuki does say in Theorem 3.11 (i) as discussed previously.

I claim this is can be made precise. I view his claims as statements about "functorial algorithms" (which I view as interpretations). For whatever definition of a "phase 1 Hodge Theater" you take as described above, there exists a prime strip as a reduct (I regard coming up with a minimal signature for a "working" Hodge Theater as an open problem). From this prime strip you get a group isomorphic to $\pi_1^{temp}(\underline{\underline{X}}_{\underline{v}})$ as a reduct: view the Frobenioids their as pairs $(\Pi,\overline{M})$ and then forget the monoid. In your formulation there is just no "functorial algorithm" so it is not comparing apples to apples. You are asking for something entirely different from what Mochizuki is doing.

I said this about 3.11.i before but I will repeat because I think you will be more receptive now that we are on the same page with this equivalence of categories vs bi-interpretability thing. What Mochizuki does in 3.11.i is a "lift/construct/push".
You lift to a structure to a structure with more interpretive power that interprets it, you perform the desired interpretation, then you push it into a set that interpreted in your original structure. This construction is equivariant with respect to automorphisms of the lifted structure. You take the orbit of these (or in the case of ind3, you do something like "consider all possible lifts") and consider the interpretation only as existing only up to this indeterminacy. The result is the type of crap you get in 3.11.i where the interpretation up to automorphism is independent of the choice of lift.

Remark. David Roberts recently pointed me to this 5 year old note of Kim where he picked up on the significance of the global multiplicative subspace:
http://people.maths.ox.ac.uk/kimm/papers/pre-iutt.pdf
I was impressed by how early he picked it up.

>You claim that objects and objects up to isomorphism are conflated in our manuscript. Where do we do this?

So I think by allowing yourself to replace polyisomorphisms by fixed isomorphisms and then at the same time cite Propositions from Mochizuki this could get you in trouble. I was worried about this at least.

129. **W**
April 30, 2020

(1) The issue is not whether switching between X and pi_1(X) could ever under any circumstances induce an error, but whether switching between X and pi_1(X) could ever be the deciding factor in whether Mochizuki's proof is valid. The idea that the discrepancy between the automorphism group of X as an absolute scheme and the automorphism group of X as a relative scheme could be responsible for confusion as to whether the proof is correct (either someone thinking it's correct when it's not, or thinking it's incorrect when it is) is absurd.

For one, there are many fields F with no automorphisms that one could run the argument over, and the discrepancy vanishes there. In any case, Mochizuki's argument is not an argument which is based on using the automorphisms of a field F to some kind of strategic effect.

(2) It is not, I think, in dispute whether it is possible to define an object on a structure that has few automorphisms, then "push" to a structure with more automorphisms by taking the orbit under its automorphism group. If you have two constructions which are each naturally defined in a different level of structure, then doing this might be helpful to compare them. But the issue here is that everything in sight is most naturally defined on the same structure, that being the structure of a (punctured) elliptic curve.

So this raises the question of what could be the benefit of artificially forcing some natural object to be invariant under some random unrelated group of automorphisms. Of course it is possible to imagine benefits that might possibly occur in some conceivable argument, but one has to explain what the benefit actually is in Mochizuki's argument and where it occurs (e.g. commutativity of some diagram).

One fundamental issue is that invariance under a group action is very useful for proving identities, but not useful for proving inequalities, unless one proves an inequality by first deriving an identity and using a separate argument to convert that identity into an inequality. But there don't seem to be any useful identities that can be proved using the invariance under automorphisms of the Galois group, because automorphisms of the Galois group never show up in an essential way at any other point in the argument.

130. **Taylor Dupuy**
April 30, 2020

Will, I completely 100% totally agree with (1). I think (2) is a misunderstanding of what I am talking about. We are not killing automorphisms but considering completely different structures. Also, I don't think you understand the definition of a structure. It isn't a hand-wavy thing. It is a collection of functions, relations, constants, and sorts. I need to think about your last two paragraphs before I can comment more.

131. **LMR**
April 30, 2020

Here are some relevant nLab entries that define the model-theoretic terms that Taylor has used in his recent comments. I hope this can clear up some confusion.

Structure: https://ncatlab.org/nlab/show/structure+in+model+theory

Interpretation: https://ncatlab.org/nlab/show/interpretation

132. **Peter Scholze**
May 1, 2020

Dear Taylor,

thanks for your further comments. I think W said it all.

Let me just make the following clarification regarding (1). You claim that you disproved some claim that I made in my manuscript with Stix, or some claim that I made in the current thread. This is wrong. In this thread, I looked at certain curves X (of strictly Belyi type and defined over a p-adic field) and claimed

The abstract curve X is equivalent to the topological group up to inner automorphism $\pi_1(X)$.

In the manuscript with Stix, this claim is also made, along with a different claim. Namely, for some other curve X defined over a number field F (appearing in the initial Θ-data of Mochizuki)

The relative curve X/F is equivalent to a Hodge theater.

In both cases, "equivalent" is meant in the sense of equivalences of categories of the relevant objects. (To be precise: a) The category of schemes that are hyperbolic curves of strictly Belyi type over a p-adic field, with morphisms being isomorphisms of abstract schemes, is equivalent to the category of topological groups that are isomorphic to $\pi_1(X)$ for some such X, and morphisms being outer isomorphisms of topological groups. b) The category of curves over F isomorphic to the given X, with morphisms isomorphisms of curves over F, is equivalent to the category of Hodge theaters as defined by Mochizuki, with morphisms the ones defined by Mochizuki.) We agree that both claims are true; in fact, both are theorems of Mochizuki.

You seem to argue that there is some tension between these claims, as one talks about absolute vs. the other about relative curves. Well, also the right side is different, so no wonder the left side is!

Actually, in the context of the current thread, it would have been a good question whether, given that a Hodge theater is a collection of certain topological groups isomorphic to $\pi_1(X)$'s for certain different X's, plus other data, with lots of relations, can you actually interpret all those things as some convenient structure on the side of schemes again? This is not a priori clear, and Mochizuki's central claim is that by passing to $\pi_1(X)$'s, he can do interesting new things. So he cooks up a Hodge theater. And … you can beautifully interpret it in good old schemes, it "is" just a curve over your original number field F.

The same happens for everything else I've seen in IUT or your comments.

I'm happy to continue any further discussions by e-mail.

Best wishes!
Peter

Lucien Szpiro 1941-2020

April 18, 2020
Categories: Obituaries

I'm very sorry to hear (via Michael Harris) of the death this morning in Paris of Lucien Szpiro, of heart failure. Szpiro was a faculty member here at Columbia for a few years, livening up the place at a time when the department was smaller and quieter than it is now. He then went on to a position at the CUNY Graduate Center and was often at the department here for number theory related talks. The Graduate Center has a short bio of him here, and on his website you can find more about his work, including some very nice short and lucid lecture notes on arithmetic geometry (see here and here). Some pictures of him and other mathematicians at his 70th birthday conference in 2012 can be found here.

What Szpiro is probably most famous for is the "Szpiro Conjecture" about elliptic curves which he first formulated in 1981. This is essentially equivalent to the later abc conjecture that has been the topic of recent controversy, so we really should have been all this time arguing about Szpiro, not abc. In a 2007 blog post I put out the news that Szpiro had announced a proof of abc at a talk he gave at Columbia (at Dorian Goldfeld's 60th birthday conference). Alas, a flaw in that proof was quickly found.

Update: Something about Szpiro from Christian Peskine:

> Lucien Szpiro est décédé d'une crise cardiaque samedi 18 avril. Ceux qui l'ont bien connu souhaitent d'abord saluer un homme d'exception. Lucien était tout à la fois un solitaire, un collaborateur passionné et un patron aimé et respecté. Un homme solitaire, intransigeant sur sa liberté, sur ses choix et sur la considération qu'il attendait. Un collaborateur passionnément ouvert au partage des idées et des projets. Un leader entrainant ses amis dans des aventures scientifiques nouvelles et enrichissantes.
>
> Recruté au CNRS après un cours passage comme assistant à la faculté des sciences de Paris, il y est resté jusqu'à son départ à City University (New York) au début du siècle. Le séminaire qu'il a animé pendant de nombreuses années a été pour beaucoup de collègues de tous ages un lieu d'étude et de formation. Son influence et ses recherches ont fait honneur au CNRS. Ses nombreux élèves en témoigneront de leur coté. Il était heureux à New York ou il avait trouvé une forme de sérénité.
>
> Ayant collaboré intensément avec Lucien durant de nombreuses années, je comprends que je perds un ami avec qui j'ai partagé des moments d'une intensité et d'une beauté rares. Il aimait la vie, il aimait la science et il aimait la recherche mathématique.

   April 18, 2020

   English translation, according to Google Translate:

   Lucien Szpiro died of a heart attack on Saturday April 18. Those who have known him well would first like to greet an exceptional man. Lucien was at the same time a loner, a passionate collaborator and a loved and respected boss. A lonely man, uncompromising on his freedom, his choices and the consideration he expected. A collaborator passionately open to sharing ideas and projects. A leader taking his friends on new and enriching scientific adventures.

   Recruited at the CNRS after a short course as an assistant at the Faculty of Science in Paris, he remained there until his departure from City University (New York) at the beginning of the century. For many colleagues of all ages, the seminar which he has led for many years has been a place of study and training. His influence and research have brought honor to the CNRS. Its many students will testify on their side. He was happy in New York where he had found a form of serenity.

   Having collaborated intensely with Lucien for many years, I understand that I am losing a friend with whom I have shared moments of rare intensity and beauty. He loved life, he loved science and he loved mathematical research.

   April 19, 2020

   He was a great mentor for me and without his course at TIFR where I took notes, and all the time we discussed mathematics, I doubt I would have become a mathematician. I attended his 60th birthday in Paris and he was kind enough to attend mine in Kozhikode. Thank you for all the things you did for me and all the wonderful memories.

   April 20, 2020

   That is sad news.

   This paper of Peskine and Szpiro is very beautiful (http://www.numdam.org/article/PMIHES_1973__42__47_0.pdf). I would argue that this work was the first to really demonstrate the Frobenius morphism as a tool of serious power and depth in commutative algebra, with relevance even to questions in characteristic zero. There is a direct line from this paper to the (ongoing) perfectoid revolution and its many amazing applications to pure commutative algebra, etc.

   I'm sorry to hear that. I attended Spziro's seminars and class many years ago at Columbia. I really learned a lot from him. I still remember his advice on how to understand the Grothendieck dualizing complex: "It doesn't matter what it is, what matters is how it moves", or in other words, how it transforms.

   As a friend of Lucien, I must say that no account of him is complete that does not include a reference to his love for cinema, for fine dining and for music and the opera. I accompanied him to these things often and I can attest to his love of ideas and the arts.
   He was a man of boundless integrity with a love of precision and an eye for the telling detail. I attended his seminars on Arakelov theory in the eighties at Columbia and on Number theory in NY (it was a joint CUNY Columbia NYU thing) when I was able to attend it. His taste was as impeccable as the precision of his grasp. He was totally dedicated to the life of the mind.
   I also wish to covey my consolations to his many students and colleagues and above all to his partner of his last years, Beth Pessum.

Why the Szpiro Conjecture is Still a Conjecture

April 18, 2020
Categories: abc Conjecture

There has been a remarkable discussion going on for the past couple weeks in the comment section of this blog posting, which gives a very clear picture of the problems with Mochizuki's claimed proof of the Szpiro conjecture. These problems were first explained in the 2018 Scholze-Stix document Why *abc* is still a conjecture.

In order to make this discussion more legible, and provide a form for it that can be consulted and distributed outside my blog software, I've put together an edited version of the discussion. I'll update this document if the discussion continues, but it seemed to me to now be winding down.

Depending on one's background, one will be able to get less or more out of trying to follow this discussion, but it seems to me that it makes an overwhelmingly convincing case that Mochizuki's articles do not contain a proof of the conjecture and should not be published by PRIMS. No one involved in the discussion claims that there is an understandable and convincing proof in the articles. The discussion is rather about Scholze's argument that there is no way that the kind of thing Mochizuki is doing can possibly work. While Scholze may not have a fully rigorous, loophole-free argument (and given the ambiguous nature of many of Mochizuki's claims, this may not be possible) the burden is not on him to do this.

To justify the PRIMS decision to publish the proof, one needs to assume that the referees have some understood and convincing counterargument to that of Scholze, one that nobody has made publicly anywhere. If this really is the case, the editors of PRIMS need to make public these counterarguments, and those mathematicians who find them convincing need to be able to explain them.

A note on comments: if someone has further technical comments on the mathematical issues being discussed at the earlier posting, they should be submitted there. For discussion of issues surrounding publication of the claimed Mochizuki proof, this would be the right place (and I've moved a couple recent ones to here). For comments about Szpiro and his conjecture, the posting about him would be an appropriate one.

Update: I hear that the editors of PRIMS are aware of the recent discussion of the problems with the Mochizuki proof, but have decided to go ahead with the publication of the proof anyway. They do not seem to intend to release any information about their editorial process, in particular what counter-arguments to Scholze's they considered. In effect, they are taking the stand that they have convincing evidence that Scholze is wrong about the mathematics here, but cannot make it public for confidentiality reasons.

Note that the discussion in the comment thread itself has some later entries after the ones gathered in the pdf document I created.

   This is not in response to any particular comments but to the overall discussion.

   It seems to me that there is a psychological issue at play here which might have not been made explicit. This is that for anyone who has devoted enough time to understand the basic setup and language of Mochizuki's papers, it is very hard to accept that in the end there is no proof and one has wasted a huge amount of time. I myself devoted most of three months way back in 2013 to going through the papers and it was a shock, on reaching Corollary 3.12, to realise that nothing is really proved. (One might say that this shows my lack of understanding, but the point is that Mochizuki himself says that this is the key part of his proof and if you see how the proof is written it is clear that there is something seriously wrong here.)

   Given the time that has passed since Mochizuki's manuscripts appeared and the objections that have been raised by many experts, the obvious interpretation of the lack of any serious revision by Mochizuki (going by Occam's Razor) is that there is actually nothing that readers have missed, it's simply that there is no proof. However, because of Mochizuki's past achievements, this is hard to accept (it was for me), perhaps especially for those who know him personally. This seems to have led to some people assuming that it is because of their lack of understanding of what Mochizuki "really means" and so devoting a lot more time to IUTT. Once one has invested too much time, I think it becomes psychologically almost impossible to give up hope, and the lack of precision in the papers sadly ensures that there is no simple statement in them which can be shown to be wrong and make it impossible to maintain faith.

   April 18, 2020

   Now that Scholze has explained what is going on with Mochizuki's manuscripts, it's time for other arithmetic geometry experts to revisit the papers and weigh in. Those of us in the field know that almost all the experts definitively side with Scholze-Stix, so it's frustrating that the popular articles (which most people base their opinion on!) depict the situation as if it were much more ambiguous, because experts are afraid of taking a stand. And when mathematicians do get themselves quoted, it's with painfully noncommittal lines like "I will withhold my judgement on the publication of this work until it actually happens, as new information might emerge" and "In spite of all the difficulties over the years, I still think it would be great if Mochizuki's ideas turned out to be correct". The purpose of granting tenure was so that academics could speak honestly, rather than hide behind these sorts of vague equivocations. With increasing resources being allocated to IUT, it's clear that the situation will only become more and more damaging to mathematics at large.

3. **NS**
   April 18, 2020

   One reason for the situation in the press that Ibj is frustrated with is simply that the publication hasn't publicly appeared. Experts are rightly hesitant to say something definitive about a paper that they haven't seen. If it turns out that PRIMS publishes a paper that, as is widely expected, just leaves the existing gap in the proof of Cor 3.12 essentially unchanged, then we'd see some more forceful statements from experts. Of course, by then the popular press will have moved on.

   Of course this means holding a public press conference without releasing the manuscript is pretty shocking and irresponsible in this context. The article I'd like to read is what on earth explains the willingness of these other great mathematicians at RIMS to go along with this charade.

4. **OP**
   April 18, 2020

   The comment of @naf hits the nail on the head. But I would go a step further: when confronted with a truly massive edifice of highly technical mathematics, nearly all experts need some kind of motivation to persevere beyond the final goal at the end of the tunnel. For example, a powerful heuristic to give confidence in the strategy, or some kind of intuitive guide to grab onto along the way to have a feeling of making progress (or at least interesting achievements along the way in the absence of a global guide). But here there is nothing of the sort, not even a compelling mathematical reason to believe at the outset that investing a huge amount of time is going to reap satisfying mathematical understanding. There is only patience to keep oneself going, and it can be very hard to rely on that alone after a lot of time.

This practical (albeit psychological) concern came to mind almost immediately after I was asked early on to be on the referee team for the IUT papers. I have great respect for Mochizuki's mathematical talent, and no doubt in the sincerity of his belief that he has a proof of the main result. But I could see that the referees would not only have to check the details of an extremely long work written in a very obscure style (which didn't provide insightful reasons for confidence in the approach being used). They would also have to engage in a herculean effort to get the writing substantially changed. It was too much, so I declined and communicated my concerns to the editorial board. (I recommended immediate rejection with a demand that the work be completely rewritten before it could be reconsidered.)

I am very sorry to see all these years later that neither the referees who were eventually obtained nor the editorial board obtained any real improvement on the clarity of the way the material is presented, not even at least an Introduction presenting key new insights in some conventional manner (to compensate for the way the technical material is presented). I hope the editors of PRIMS and the senior faculty at RIMS will reflect on their responsibility to the field of mathematics, and reconsider what they are doing.

Professor Woit: minor typo – 2108 should be 2018

"These problems were first explained in the 2108 Scholze-Stix document Why abc is still a conjecture. "

6. **Peter Woit**
April 18, 2020

derek,
Thanks! Fixed.

7. **David Roberts**
April 18, 2020

Thanks, OP. I wish the other referees would be so forthcoming, if it were indeed possible. Or if not, the journal could release their reports.

I note that Nick Katz was public about his refereeing of Wiles' first FLT paper, and his finding of the mistake, and it's public knowledge Gábor Fejes Tóth was one of the referees for Hales' Kepler conjecture paper that appeared in the Annals with a disclaimer. This is an extraordinary case, and warrants extraordinary actions, IHMO.

8. **David Roberts**
April 18, 2020

@Peter W – I notice you link, in your pdf, to my Inference essay, but not the technical note I pointed you to. I'd prefer the technical note is used, not the essay, which was written for the general public and much below the level of the comments here. In any case, I should have given you this link: https://doi.org/10.25909/5c5ce1fda4b7c instead of the one I originally sent.

9. **Peter Woit**
April 18, 2020

David Roberts,
Thanks for pointing this out! Fixed.

10. **OP**
April 18, 2020

@David Roberts:

Just to clarify: I wasn't a referee on the IUT papers, but rather was invited to serve as one, and I declined (giving the editorial board my recommendation for how I thought would be best to proceed). As for Katz' work as a referee on the initial FLT paper, my impression is that this only became public knowledge sometime after the fix was found and the corrected version had gone through the review process (e.g., maybe via the BBC video that was made about it).

11. **David Roberts**
April 18, 2020

@OP sure. By 'other referees' I mean the ones that accepted the job.

12. **KS**
April 20, 2020

For more sociological understanding , please let me put about some curious social situation around this issue in Japan.
On the official announcement of acceptance of the papers in Kyoto, two mathematicians Tamagawa and Kashiwara attended there, and Tamagawa is actually well-known expert in the anabelian geometry.But It seems likely that he can not explain about the mathematical matter of IUT in public so far.
In addition , Rigid geometer Fumiharu Kato already published the book "in 2019" about IUT "treated as correct theory" for general audience amazingly, but actually it wouldn't be sufficient to offer any insight for professional mathematicians.Furthermore , as Tamagawa is , he also has never wrote any rigorous mathematical papers about IUT as far as I know at present.
These facts seems to be indeed mysterious that is , " whoever did understand and can defense the theory sufficiently?" .

Anyway needless to say , since IUTT use too many and overlevel terminology ,so that if it cannot be expressed with crucial idea for proof , other mathematicians wouldn't accept it at all.

13. **Jeff Berkowitz**
April 20, 2020

Peter, I wonder if you could provide a little historical context for the non-mathematician. Are situations like this one common in the modern history of mathematics? Occasional? Rare? Unprecedented? Is there another situation you can compare this to?

14. **anon**
April 21, 2020

About the situation in Japan: do Japanese mathematicians in general accept the "proof" as it is? Or is it just (at least most) mathematicians at RIMS?

15. **Peter Woit**
April 21, 2020

Jeff Berkowitz,
This is unprecedented. I know of no other example in the history of the field of a reputable journal publishing a proof of a major result over the objections of experts in the field who have publicly argued that the proof is flawed, even that it cannot possibly work.

Very few Japanese experts in this field have expressed publicly an opinion that the proof is correct. I hear (second hand) that many of them privately say they are embarrassed by this situation. It would be helpful if they would say this publicly.

16. **Jay Watt**
April 21, 2020

I have been following this drama for quite a while now and there're a couple of things I just don't get:
