So we have a bunch of competing approaches staking out different "countries" in momentum space, each saying their country is better, & threatening to invade each other's territory in the future. But history has taught us that these "threats" tend to be hollow, & people tend to ignore the diminishing returns from their own approaches. & each ignores the fact their own predictability problems prevent them from extending into the other territories, whether due to renormalons, twist, or compactification.

41. **Attila**
November 9, 2015

Warren:

While I fundamentally agree, it seems I am more optimistic in general,
and not only in the case of my own area. 🙂

For example, in my own field (finite temperature field theory) there are actual examples where the applicability region of resummed perturbation theory and the lattice simulations overlap. In QCD (and even more in pure gauge theories) there are several observables, where high temperature lattice calculations can be compared to perturbative calculations, with good agreement. This includes the equation of state and fluctuations and correlations of conserved charges, for example.

I do not think one approach needs to “rule them all”, it is not a realistic hope. A more realistic one would be to make contact, and find an overlap in the applicability of approaches.

I know almost nothing about quantum gravity, but as an outsider, it does not seem completely hopeless to me that even if the UV completion is some kind of string theory, other approaches such as the asymptotic safety program with the functional renormalization group or CDT can be used as a low energy approximation of that. I could easilty be completely wrong on this one, but I don’t think I am wrong on QCD.

Sorry for the off topic posts, I will stop now.

Various News

November 8, 2015
Categories: Uncategorized

Later tonight will be the 2016 Breakthrough Prize ceremony, broadcast live on the National Geographic channel. While mathematicians and physicists are getting their popcorn ready, waiting to find out which of their colleagues will be $3 million richer, they might want to check out Mathematics Without Apologies, where Michael Harris is writing about his experience on the red carpet at last year's ceremony. In other news:

- A few miles down the road from the event tonight at the NASA Ames Center, the Stanford Institute for Theoretical Physics has a new website. They have various videos you can watch, as well as this account of the history of the SITP:

  > The gauge hierarchy problem was first addressed in the earliest days of SITP by Susskind and Dimopoulos, whose ideas eventually led to the introduction of supersymmetry into particle physics. The gauge hierarchy problem and the discovery experimental discovery of supersymmetry were principle reasons for the building of the Large Hadron Collider, but the puzzle remains. To this day Dimopoulos and his band of young postdocs and students have offered the most exciting proposals for discovering new physics in this area.

  Personally, I thought the Higgs was the principal reason for the LHC, but perhaps I was misinformed.

- Several people wrote to tell me about a USA Today article reporting Study may have found evidence of alternate, parallel universes, noting that this needed a new installment of This Week's Hype. I'm very pleased to see that the excellent science journalist Jennifer Ouellette has been on the case, debunking this much better than I ever could. The blame for this kind of thing is jointly shared by physicists and journalists, glad to see that at least some journalists are taking action to deal with the problem.
- There have also been several suggestions that I write about Leo Kadanoff, the great theoretical physicist who passed away a little while ago at the age of 78. Unfortunately I never met him, and only had a general acquaintance with his work. A very good obituary by Kenneth Chang did appear in the New York Times.
- I've also heard from lots of people with more stories about the Khrzhanovsky film about Landau described here. It seems that I'm the only one who didn't know about this. In other performing arts/physics news, Lee Smolin discusses here a project he has been involved in.
- The LHC has finished its 2015 run colliding protons at 13 TeV, will now turn to heavy ion physics. Integrated luminosity recorded by ATLAS and CMS is about 4 inverse femtobarns. Results of the analysis of this data may start to be available publicly around the time of Moriond in March. Consulting Jester to see what to expect, it looks like better limits on or evidence for stops, Z-primes and gluinos should be available. In particular, we'll finally see a conclusive test of string theory (Gordon Kane argues that string theory predicts a 1.5 TeV gluino, see here).
- In other news from the LHC, it seems that humanity narrowly missed a major problem back in August, when Simon Parkes, a Labour town councillor for Whitby in North Yorkshire, foiled a sinister plot by the Illuminati to "use the LHC to open an evil portal that would allow them to become more powerful."

Update: Awards ceremony hasn't started, but names are out: Ian Agol for mathematics, 5 teams of 1300 people for neutrino oscillations (with 7 specifically identified, including the 2 winners of this year's physics Nobel).

Junior recipients in math are Larry Guth and Andre Neves, in physics Bogdan Bernevig, Liang Fu, Xiao-Liang Qi, Raphael Flauger, Leonardo Senatore, and Yuji Tachikawa.

Update: The big news, via Michael Harris, is that Peter Scholze (to my mind a better mathematician than any of those who got prizes) turned down a $100,000 prize. Good for him.

Comments

1. **John**
   November 8, 2015

   That Illuminati link is a bit scary. I would suggest a global meditation session to defeat them ASAP. Just hope they don't turn it on at 3am again like last time, or we're screwed.

2. **Bill**
   November 8, 2015

   Whoever guesses Breakthrough Prize laureates before 10/9c gets a gift certificate from Peter worth 10 off-topic comments.

3. **Peter Woit**
   November 8, 2015

   Bill,
   Sorry, no such offer. If you are not guessing but do know the winners, if you let us know early, maybe I'll go for one off-topic comment (unless I get legal advice that that's problematic as a valuable bribe…).

4. **Bill**
   November 8, 2015

   It is possible that I've met some of the winners in real life but I don't know who the winners are at this moment, so would have to guess: Yitang Zhang for math, and Maxim Kontsevich for life sciences.

   It seems like Michael Harris knows something. From his blog: "And something tells me (just this morning) that this year's ceremony will be more interesting than I had anticipated."

5. **MSZ**
   November 8, 2015

   https://breakthroughprize.org/News/29

   No need to guess …

   The 2016 Breakthrough Prize in Mathematics to be Awarded to Ian Agol; The 2016 Breakthrough Prize in Life Sciences to be Awarded to Five Individual Recipients: Edward S. Boyden, Karl Deisseroth, John Hardy, Helen Hobbs, and Svante Pääbo; The 2016 Breakthrough Prize in Fundamental Physics to be Awarded to Seven Leaders and 1370 Members of Five Experiments Investigating Neutrino Oscillation: Daya Bay (China); KamLAND (Japan); K2K / T2K (Japan); Sudbury Neutrino Observatory (Canada); and Super-Kamiokande (Japan)

6. **gg**
November 8, 2015

Peter: I'm not a particle physicist and was a young graduate student at the time SSC was cancelled and LHC moved forward. My (vague) recollection is that the attitude at the time was that the Higgs would still show up at the Tevatron, and that SSC/LHC would fry bigger fish.

7. **Peter Woit**
November 8, 2015

gg,
The Tevatron never had much of a chance at the Higgs. Depending on mass, it had a chance at barely seeing evidence for it, not much more. From the beginning, the Higgs was the main aim of the SSC and LHC. The text I quoted gives some insight into how some theorists at Stanford see the world.

8. **Danny Calegari**
November 8, 2015

Your comment that Peter Scholze is "a better mathematician than any of those who got prizes" seems churlish, whatever your views on the value of the Breakthrough Prizes. Mathematicians have many different styles. For example, some are theory builders, others are problem-solvers. Ian Agol, as well as being a close personal friend, is one of the most gifted problem-solvers I've ever met. I'm delighted to see his wonderful contributions to mathematics made more visible to the wider public as a result of this award.

9. **Peter Woit**
November 8, 2015

Danny,
Yes, there are many different kinds of mathematicians with many different styles, and no linear ordering makes any sense. No criticism of Agol or the other winners was intended. I know none of their work very well, they all seem to be quite good at what they do. It's also true though that I suspect one could have identified a hundred other mathematicians just as talented and accomplished as those three and I don't see why the math community should take these prizes seriously.

I've edited what I wrote slightly to make it clear that I was expressing my own opinion and personal idiosyncratic judgement. Before this, based on what I understood of Scholze's work I had a high opinion of him as a mathematician. With his decision to turn down the money and, I hear, basically make no public comment, ignore these people and go about his work, I now have a very high opinion of him as a human being. Instead of the usual congratulations and singing of the virtues of the prize winners and their new-found wealth, I think the math community tonight would do well to instead congratulate Peter Scholze for embodying its best qualities.

10. **Mateo**
November 8, 2015

60 minutes had a piece tonight (new I think) on the LHC. Sounded to me like the potential for extra dimension and dark matter findings were being oversold in terms of the LHC but what do I know. Thought I'd provide the link in case Peter would like to comment:

http://www.cbsnews.com/news/extra-dimensions-dark-matter-a-more-powerful-collider-hunts-for-clues/

11. **John Baldwin**
November 8, 2015

I haven't yet decided how I feel about these awards, but I'd be interested to hear Scholze talk about his decision to refuse the award rather than to, say, use it to support struggling mathematicians in need of funding, or help a public library on the verge of closing, or donate it to a charity whose mission is to help relieve actual human suffering. I'd like a glimpse into Scholze's moral calculus.

12. **math_lambda**
November 9, 2015

@ John Baldwin : on paper what you say might make sense, but on the other hand the celebrity circus is such an insane thing, coming there would be condoning it, and apparently Scholze didn't want to. He's a tenured professor at Bonn when he could have a very high salary in the US, and you could make the same "moral calculus" remark for that. Never met him, but my guess is money and fame are the least of his worries, a respectable choice indeed.

13. **mh**
November 9, 2015

@John Baldwin.
Scholze is a mathematician. He has no moral obligation to become a philanthropist and he has no moral obligation to justify his refusal. He is doing science a great service by just ignoring this circus.

14. **Bill**
November 9, 2015

First of all, I think it will be difficult to identify 100 or even 10 mathematicians whose work was at the level of Ian Agol in the last 10 years. No matter what one thinks about these awards, he is not a bad choice.

As for Peter Scholze, would he have rejected the main prize? I feel (as he might have felt) that his work is worth more than junior prize, so he did the right thing. I am sure he will accept the Fields medal in 3 years.

15. **iv**
November 9, 2015

There appears to be a clear political agenda behind the Breakthrough Prize in Physics this year. Nima, Witten and Gross etc. want to push the Great Collider project in China led by Wang Yifan — the leader of the Daya Bay neutrino experiment. But Wang needs the appropriate status to convince the Chinese government to invest in this extremely expensive project. The rule for the Breakthrough Prize is to have the past winners to nominate the future ones, so Nima et al. can get this strange combination of neutrino experiments to share this prize so that Wang can get the international recognition that he needs. ~1000 people to cover this political move, wow!

16. **Peter Woit**

November 9, 2015

Bill,
I’m not saying at all that Agol was a bad choice, just that there would be very many equally good choices, for both prizes.

I doubt that Scholze’s reason for turning down the prize was that it wasn’t good enough. Michael Harris on his blog points out that by doing this Scholze removes himself from likely consideration for the \$3 million, which he otherwise would be a very strong candidate for. So, in effect, he’s turning down \$3.1 million.

I just watched some of the taped awards show, and it’s very clear why one might feel it was worth at least $100K to not participate. The Fields Medal is something rather different.

17. **Bill**
November 9, 2015

Peter,

On second thought I agree with you about Peter Scholze. The format of these awards treats scientists as expensive escorts to a costume party so, whatever his thought process was, he deserves a lot of respect. I wonder if previous winners have regrets now that the prize lost “some of its luster and legitimacy” (in the words of Michael Harris).

18. **David Ben-Zvi**
November 9, 2015

Independently of the hoopla, it seems clear Agol’s work deserves all the recognition it’s getting — I recommend Danny’s blog
for a discussion of one of the most spectacular breakthroughs.

19. **rc123**
November 9, 2015

Even though you seem to understand that no classificatory move is possible, it seem (at least to me) very rude to dismiss brilliant mathematicians who have gone on to do remarkable work as somewhat “worse than Scholze”. As you have said so, you don’t comprehend Agol’s work in topology or Nevé’s work in differential geometry, so why bother making such remark knowing it can be offensive (I’m not saying that was your intent)?

20. **Christopher Herzog**
November 9, 2015

My objection to these prizes is that the biggest winners are the U.S. and other federal governments. The prize winners, assuming they don’t turn around and donate their winnings to charity, will all have to pay a sizable chunk of their winnings to the IRS (or its equivalent in other countries). Why not take the same money and do what for example Simons or Howard Hughes do? Set up a foundation. Involve some scientists to do peer review. Issue grants that will fund your favorite kind of research, research you presumably already think that the government is not doing enough to support?

21. **Peter Woit**
November 9, 2015

rc123,
On the whole I think that “this mathematician or physicist is better (or worse) than that one” is a judgment best avoided, for the obvious reasons that different talents, accomplishments, and different areas of mathematics are not really easily comparable this way, and that of course, anyone’s knowledge is limited, so humility is in order. I think if you look at the thousands of pages I’ve written on this blog, you will find that such judgments are expressed extremely rarely (although I’m not unwilling to write something because some may find it offensive).

In this case though, I thought it important to point out that, of the four people awarded prizes, Scholze was not a random one, but widely considered by those who know him and his work to be the most talented young mathematician to come around in quite a while. His refusal of the money seems to have gotten zero attention in the press, partly probably because they know nothing about who he is.

I don’t know Agol personally, but I’d be surprised if he was particularly upset and offended that Peter Woit thought Peter Scholze was more talented than him. And if he does feel that way, he has $3 million to make himself feel better…

22. **Shantanu**
November 9, 2015

Peter and others,
Yours truly is one of the 1300 winners (although they have spelled my first name wrong) on the website. let’s see though how much share of the prize I get 🙂

23. **Peter Woit**
November 9, 2015

Shantanu,

Congratulations!

24. **Rompety Rabbit**
November 9, 2015

Interesting that this “hoopla” will be on the National Geographic channel, even while
a news item from today is about the impending destruction of that once great organization:
http://reverbpress.com/business/rupert-murdoch-national-geographic-layoffs/
(cited on http://www.truthdig.com)

Surely the new National Geographic will want to reach this demographic:
https://www.youtube.com/watch?v=mKKKgua7wQk

Christopher Hertzog makes a comment which must be far too sensible in the age of Trump:
“Why not take the same money and do what for example Simons or Howard Hughes do? Set up a foundation. Involve some scientists to do peer review. Issue grants that

will fund your favorite kind of research, research you presumably already think that the government is not doing enough to support?"

Why not? Maybe because that would take actual intelligence and wisdom?

25. **Peter Woit**
November 9, 2015

Please direct further comments about the Breakthrough Prize to the next posting
http://www.math.columbia.edu/~woit/wordpress/?p=8088

I've moved the latest comment there.

26. **gadfly**
November 10, 2015

I feel like Scholze should have accepted the prize and given it to charity or something…

27. **Avattoir**
November 10, 2015

Or, Gadfly, at least to the next posting.

There's much to admire about Professor Woit, including his periodic posting of drafts of his text-in-progress. There's an unexpected, for me, example from this thread. When several commenters attacked him for, as one called it, appearing (I think worse than that was implied, at least by some others.) "churlish". Yet Woit didn't react with anything remotely like the peevishness that usually accompanies churlishness, instead showing restraint, indulgence & patience in making his points again & in various ways. Soon at least a few of those who'd attacked him indicated they'd turned & had come to agree with him. One doesn't see that in many blogger-monitored websites. However, since this comment is "off topic", admonishment should follow, correct? It's like a test.

28. **Peter Woit**
November 10, 2015

Avattoir,
Thanks, I'm not completely immune to flattery, so, no admonishment.

The questions at issue about the mathematics prize I think are quite interesting, and I hope I can have some effect in getting people to think about them. Danny Calegari's comment I didn't take as an "attack", he was expressing a reasonable view which I can understand and I'm sure is widely shared. Whenever prizes like this are announced, in private people may express "so and so is better" judgments, but there are good reasons not to do this in public, since such judgments often are, well, "churlish" is a good word.

And yes, this discussion should be in the next posting, but I don't want to encourage more of it in either location.

2016 Breakthrough Prizes

November 9, 2015
Categories: Uncategorized

The 2016 Breakthrough Prizes were announced last night, discussed a bit in the last posting. Today there are programs going on at Berkeley, livestreams available here.

One thing that strikes me about these things is that the situation with the physics prize has changed dramatically since the first three years, when they went mostly to string theorists. Having a heavily promoted much larger cash prize than the Nobel, given largely to theorists for ideas many of which haven't worked out, raised obvious questions about the wisdom of the whole thing. The last two years have seen a 180 degree turn, with the prizes going to experimentalists for successful experimental results. Even better, there has been an unusual emphasis on making an award to entire experimental collaborations, not just a small number of "great men" identified as collaboration leaders or spokespersons. I don't know of any other major prizes that do this. The lack of an experimental Nobel for the Higgs discovery is one reflection of that problem, it's great that the Breakthrough Prize people are doing something about it.

This is now just the second year of the math prize, which has never been as problematic as the early physics prize. However, the institution of cash prizes of this size, promoted in a Hollywood style, is something I don't think anyone in the math community ever asked for, and it's not at all clear it's a good thing, or in keeping with some of the best values of the math research community. This year I think Peter Scholze set a remarkable example by turning down a prize, a move which unfortunately has gotten little attention in the media. I hope his action causes people to take a closer look at this gift horse. Instead of just celebrating the shower of cash and attention, research mathematicians may want to consider whether, just as they changed direction with the physics prize, Milner and Zuckerberg perhaps should be encouraged to listen to Scholze and move in a different direction.

Update: I just watched some of the talks at the afternoon symposia. Arkani-Hamed made the case for a Great Collider, mostly quite sensibly in terms of the desirability of better understanding the Higgs: is it pointlike? how does it self-interact? The argument is that addressing these questions goes beyond what the LHC can do, can be done by a large new collider.

On the math side, David Nadler gave a beautiful talk about Langlands/geometric Langlands, ending with a prediction for the future that a central role will be played by Peter Scholze's work, including recent ideas on what Nadler calls "Arithmetic conformal field theory". He suggested that 50 years from now, Hartshorne and other graduate textbooks on algebraic geometry will be replaced with new ones based on Scholze's perfectoid spaces. Maybe if they hadn't offered Scholze money they could have gotten him to talk about this stuff…

Update: The New York Times Science section has an article today about the goal of the Breakthrough prizes, to turn scientists into celebrities. Yuri Milner is quoted:

> "We are at the very beginning of this journey," he said, noting that if you were to look at a list of the top 100 celebrities in American society, there would not be a single scientist on the list.
>
> "The question is why?" he added.

The question this raises, which may have something to do with Peter Scholze's refusal to participate, is "what if good scientists don't want to be celebrities?" The impulse to do science and mathematics at the highest level and the impulse to be a celebrity may just be two very different, incompatible things.

The New York Times article doesn't mention the Scholze story, but it does discuss the young student, Ryan Chester, who was given a $400,000 award for making a film about special relativity. It turns out that doing a great job of making such a film has a lot more to do with interest in being a filmmaker than interest in being a scientist:

> Mr. Chester, however, said in an interview that he was not planning to study science in college, but instead will probably study film, hopefully at a school like the University of Southern California or New York University.

Update: Videos from the symposia and panel discussions at Berkeley are available here.

Update: In other large-check news of the day, the IAS has announced a $20 million donation from Robert Rubenstein, CEO of the Carlyle Group, a top private equity firm. This completes a $212 million capital fundraising campaign.

Comments

1. **Jeffrey M**
   November 9, 2015

   Peter,

   Agree about Sholze, but worth noting that he is following in the footsteps of Perelman, who turned down $1 million from Clay after he proved the Poincare Conjecture.

2. **Anonyrat**
   November 9, 2015

   We are witnessing the attempted transformation of mathematics and physics research into a "winners-take-all" culture. Instead of making life a bit easier for the many graduate students, post-docs and people struggling in tenure-track positions, money is being given to the stars. So it is becoming like professional sports, acting, etc., where the top becomes extremely wealthy; the next-to-the-top just make a living, and everyone else is waiting tables while trying to make a mark in the field.

3. **Bill**
   November 9, 2015

   Maybe, we shouldn't put words in Peter Scholze's mouth… Maybe, Quanta magazine can interview him.

   Is it just a coincidence that all mathematics prizes were in geometry?

4. **KJ**
   November 9, 2015

   "Milner and Zuckerberg perhaps should be encouraged to listen to Scholze and move in a different direction."

   In what direction is Scholze suggesting they move?

5. **Peter Woit**
November 9, 2015

KJ,
That may be a bit badly worded. I have no reason to believe Scholze has any particular suggestions for them, and no idea what his thinking about any of this is.

My point was rather that if arguably the best young mathematical researcher around turns down your effort to encourage mathematics research by giving him a 100K check, effectively saying he wants no part of what you are doing, you might want to reexamine whether what you are doing really is the best way to encourage math research. I sincerely doubt that if Milner and Zuckerberg went around to the best mathematicians in the world and asked them "what can we do to encourage mathematics research?", they would hear back "set up a Hollywood-style award ceremony and hand out $3 million checks".

6. **Baixiao**
November 10, 2015

Maybe this is a bit off topic here, but I find striking that Milner's prize has been awarded to just a few condensed matter Physicists so far. It is embarrassing to see all those Silicon Valley millionaires giving away their money to mainly high energy and cosmology Scholars. I am sure they are all perfectly aware that their fortunes largely come from technologies that heavily rely on the work of many (unfortunately, rather quiet) condensed matter Physicists.

I know this may not be the forum to air this kind of frustration. However, I find this neglect particularly painful these days after the recent loss of Leo Kadanoff, whose contributions, which were instrumental for Ken Wilson's Nobel winning work, were largely unrecognized by various "big prize" committees.

7. **Andrew**
November 10, 2015

Can you elaborate on why a winner turned down his cash prize? Misgivings about the way the math competition is organised? He thought other mathematicians were more worthy? He lives an ascetic or solitary life and didn't want such a change or attention?

8. **M**
November 10, 2015

Some recognition should also go to people, like John Bahcall (now deceased), who computed the flux of solar neutrinos claiming an anomaly with respect to measured rates. After all, the SNO neutral current measurement confirmed that they were right. And neutrino oscillation discoveries started from this anomaly.

9. **math_lambda**
November 10, 2015

Looks like a long joint paper by Cariaini and Scholze was posted to the arxiv precisely on sunday : http://arxiv.org/abs/1511.02418 Now that's funny!

10. **Peter Woit**
November 10, 2015

Andrew,
I don't know what Scholze's thinking was about this. I hope he'll comment publicly at some point. He's not someone like Perelman who leads an unusual solitary and ascetic life, so I don't think that has anything to do with it.

11. **Bernhard**
November 10, 2015

The case for a new collider to study Higgs properties is actually a sound one. Even with the Super LHC we won't know the Higgs width accuratly enough. Around 10% of the total branching ratio would stil be open for it to decay to exotic stuff.

12. **Thomas Larsson**
November 10, 2015

Baixiao, I may misremember, but I think Wilson has publicly stated that he thought his Nobel should have been shared with Kadanoff and Mike Fisher.

The status of the Nobel prize does not only come from the fact that it is big and old (although I know of no other prize that beats Nobel on both size and age), but also from the fact that the Nobel committees (in the sciences) have never made any serious blunders. This is bound to make the Nobel committees very conservative institutions, that are unlikely the change their practice anytime soon.

13. **Bernhard**
November 10, 2015

"from the fact that the Nobel committees (in the sciences) have never made any serious blunders."

Serious blunder maybe not, but the Nobel prize has a rather regular history of "forgetting" several people and in some cases, in an inexcusable way, like the fact that S. Nath Bose didn't get the prize.

The argument that they keep committing these mistakes and will keep making them out of tradition simply doesn't stick. They have the power to change the status quo and they should. Acknowledging for example that big science is done by large teams should not in any sense interfere with the rigorousness of the process.

14. **LK2**
November 10, 2015

Nobel prizes on Peace has few blunders. I would not say so for the other ones.
Milner prizes are a disgrace for sciences and now I really wonder why Scholze turned it down.

15. **Peter Woit**
November 10, 2015

All, please, enough with off-topic discussion of Nobel mistakes, real or imagined. That has nothing to do with the topic of this posting.

16. **rc123**
November 10, 2015

OK, my comment will be off topic, but it won't be about de Nobel: considering I'm a layman in mathematics, you all think of Scholze as a "problem solver" or a "theory builder", if you even can categorize him in such a binary mode?

17. **Peter Woit**
November 10, 2015

rc123,
He's definitely on the "theory builder" end of things.

18. **ronab**
November 10, 2015

Peter:
"… Even better, there has been an unusual emphasis on making an award to entire experimental collaborations…"

On the contrary, it seems to me that this approach makes the entire breakthrough prize utterly pointless. Why on earth does anyone care whether the Facebook founder's friend decides that some actress should say nice things about one particular 1000 person physics collaboration over another, and to give it a check that amounts to a few hours or days of its ongoing budget? If they give Witten a check for $3 million, at least it makes some difference to Witten, but relatively tiny awards by non-scientists to vast collaborations make absolutely zero difference to anybody.

19. **Peter Woit**
November 10, 2015

ronab,
I agree there's a real question "Why on earth does anyone care whether the Facebook founder's friend decides that some actress should say nice things " about any particular scientist, mathematician, or group of such. But, given that some people seem to care about these things (prizes, awards), giving yet another one to people who already have a long list of them on their CV already, and generally no need for the money, seems a way to make no difference. As far as I know, there are no other prizes given to such groups, so this means 1300 people now have an impressive sounding prize to put on their CV, which could be quite significant to them. If they're getting an evenly distributed cut of the money, that would be over $2000 each, and for many of them such a check might have more impact on their well-being than the multi-million dollar checks going to the well-off.

20. **ronab**
November 10, 2015

Peter,
"… an impressive sounding prize to put on their CV, which could be quite significant to them."

That's a very alarming thought. The physics hiring process is random enough as it is. Is it now to be further corrupted by random low-level researchers strutting around with Nobel-prize-lite's on their resumes simply because they happened to join the right large collaboration at the right time, ie shortly before the subject caught the fleeting fancy of a passing website entrepreneur? I'd been assuming that anyone with hiring influence would be smart enough to ignore such specious claims to fame. But if you're right and it might actually be significant to them, do you really think this would be a good thing?

21. **Peter Woit**
November 10, 2015

ronab,
The point of the prize is to reward people who have done work the funder thinks is admirable. If 1300 people have one, I don't think having this on one's CV is going to be a major factor in any hiring, but it allows people to point out "I worked on a successful, important experiment". Milner's goal of getting more recognition for scientists I think is fine, and this seems a good example of how to do it right (as opposed to trying to turn a particular scientist into a celebrity by giving him a large check and getting him to dress up and walk a red carpet).

22. **Jim Akerlund**
November 11, 2015

Watching the videos on the Breakthrough Prize Math Horizons II. At the 31 minute mark is a fire alarm that interrupts Ian's talk. The talk resumes at the 54 minute mark. I mention this for the potential viewers. I was viewer # 371. The video being on Youtube means that you can skip the offending section without too much trouble. The fire alarm did effect the talks in that the question and answers at the end of the talks were cancelled, and it seems some of the talks were shortened.

23. **Tom DeLillo**
November 11, 2015

As chair of a department at a midsize state university with budget shortages and students in debt, I have trouble taking much interest in all of these prizes. I can rarely hire new assistant professors to replace retirees. Even a funded three-year postdoc would be nice to give some young person a chance to stay in the profession.

24. **Bernd**
November 11, 2015

Peter,
I agree with you that when asking the best mathematicians how to encourage people to do research, they probably won't come up with large cash prizes, but why would you want to ask them in the first place? I'm not so sure that they are the most authoritative source on why young people decide to pursue one interest or another.

On the other hand, if one judges the effectiveness of the prizes by the coverage they have received in media geared at young audiences (Buzzfeed, Vice, reddit), then one has to say that these awards have been an utter failure so far.

25. **Peter Woit**
November 11, 2015

Tom DeLillo,
Thanks, I think you identify a crucial issue here. For many years middle-class academic jobs have been disappearing in the US, replaced by poorly paid adjunct positions, and a small number of well-paid positions for "stars". Prizes like the Milner-Zuckerberg one seem intent on making this worse, their idea is that what the field needs is more money and attention for the "stars".

26. **Math.Phys**
November 11, 2015

Why Scholze turned down the breakthrough prize? Probably because he's young and still remembers the reason why he decided to be a research mathematician and thinks that these people are doing damage to the subject.

27. **Peter Woit**
November 11, 2015

Bernd,
I think good mathematicians are the best source of advice about how to encourage good mathematics research, and that there is likely a strong consensus amongst them that turning mathematicians into wealthy celebrities isn't the way to do it (and that there's even a serious danger that will negatively impact the research community).

Considering the number of jobs available doing mathematics research, there are more than enough young people interested. Young people are exposed to mathematics on a daily basis in their schools and either the subject itself or an inspiring teacher convince many that they love the subject and want to learn more about it. If one sees a problem there, a much better way to spend money would be on getting better math teachers by paying them better. That would have a lot more positive impact than pictures of Maxim Kontsevich getting a big check and a glitzy orb from a starlet.

28. **Cynicism**
November 11, 2015

I think a comment in Michael Harris' blog is pertinent. Scholze used to play in a rock band himself. Now he is a professional mathematician. Robert Schneider of Apples in Stereo became famous as the frontman for a rock group. Now he is a graduate student under Ken Ono. If you look at mathematical conference photos, you will often see at least a few people dressed in a way that wouldn't be out of place at a metal concert. I can't speculate on the experiences of these two or anyone else, but I also played casually in a rock group and personally found the profession wanting.

I distinctly remember an instance where I worked extremely hard to sell a middling amount of tickets to a show and although I didn't get paid, the friends I brought along enjoyed it. Later on that week I ran a tutoring session and although it wasn't terribly fascinating stuff that I was teaching, I felt a whole lot better about seeing the "Oh, I get it now" look in someone's eyes and doing something that could actually make someone's life better than killing myself to play for free to an auditorium full of half-interested people. Plus I got paid for the tutoring! I think I played one or two more shows after that, and each time I couldn't help feeling that music was the sucker's bet and I was just wasting my time there. Perhaps this was a function of the times and the music industry collapsing, but I would certainly be sad to see mathematics become as susceptible to market forces.

29. **Curious Wavefunction**
November 11, 2015

"Milner and Zuckerberg perhaps should be encouraged to listen to Scholze and move in a different direction."

Just curious: What kind of direction would you think about here?

30. **Peter Woit**
November 11, 2015

Curious Wavefunction,

As indicated in my previous comments, I think it would be better to not spend money on those already doing very well, but on positions important to the profession that are not paid well. Two examples are
1. High school math teachers. If anyone deserves more recognition and support, it's them.
2. Permanent university teaching positions with a livable salary and with low enough teaching load to allow for a healthy research program. Such positions are disappearing in many universities in the US (see the comment from Tom DeLillo above). Endowing a bunch of these each year would have an impact, encouraging more people to think of math research as a viable career, not just something that only "stars" have a shot at.

If one wants to directly support math research, along the lines traditionally done by the NSF, I think the Simons Foundation does a good job of this, others could follow their lead.

31. **Jeff M**
November 11, 2015

Amen Peter to all the points. One thing in math, we have always prided ourselves (most of us anyway) on not having a Nobel or any sort of star system really. We basically all had the choice after grad school to go work on wall street for a ton of money. When I got my doctorate, the year the academic market in math collapsed, no one I know had a job offer until May. None of us had given up to go make a ton of money, we were all trying desperately to get academic jobs which honestly paid almost nothing, my first job, in 1992, paid $32,600. I worked at that salary for 3 years due to a contract dispute. If I had just gone to Wall Street I could have easily started at 5 times as much, with a big bonus. I would be retired now 🙂

32. **Yes, please.**
November 11, 2015

Did anyone else find the talk after Nadler's – the one by George Lakoff – strange? A lot of the things he describes as original finds of cognitive science, such as looking at multiplication as rotation, are just standard fare that one finds in the explanatory passages of college textbooks. I was so surprised by the triviality of the whole talk that I can't even mention it non-anonymously (nonymously?) for fear of being accused of being stupid or worse, mean-spirited. What am I missing?

33. **Chris W.**
November 11, 2015

I was wondering why Lakoff was even giving a talk at such an event. I guess the work and writings summarized in this section of Wikipedia's profile partly explain the invitation.

34. **Low Math, Meekly Interacting**
November 12, 2015

Lakoff appears to be arguing with people like Max Tegmark about the "reality" of maths. I assume whether or not one considers this a worthwhile discussion to have in the first place will determine their opinion about the appropriateness of Lakoff's lecture for the occasion.

Put me squarely in the "not" column.

35. **Jim Baggott**
November 12, 2015

There’s a long history of wealthy businesspeople distributing largesse for the benefit of science and scientists, all the way from Nobel, Rockefeller, the Carlsberg Foundation (which funded Niels Bohr’s institute and research programmes in Copenhagen), the Bambergers (who founded the Institute for Advanced Study in Princeton, bringing Einstein, von Neumann, Oppenheimer, Godel and Weyl to the faculty) to more recent examples including John Simons, John Templeton, Fred Kavli, and now Yuri Milner and Mark Zuckerberg.

Much of this is good, old-fashioned philanthropy. There are nearly always agendas at work beneath the funding, and in some cases these may be more visible. But good philanthropy is not PR – yes, the odd institute or professorial chair is named for the benefactor but often little else. In some cases, the names of the benefactors are not widely known or advertised.

I can’t help but wonder if the Hollywood, Oscar-style Breakthrough Prizes are saying
more about the benefactors in this case than the individuals who are being rewarded for their efforts.

36. **Chris W.**
November 12, 2015

Jim Baggott,
I assume you mean James (Jim) Simons.

37. **Bill**
November 12, 2015

Another problem is that universities will do anything to raise and keep their rankings high, and rankings usually put high weight on faculty with important awards. Quite often there are quite a few good candidates for any given award but only one gets it, often based on random factors. If later you compare the salaries of award winners and other equally good researchers, the difference can be quite dramatic.

38. **Truth**
November 13, 2015

Actually I think Neil deGrass Tyson would be among the top 100 most famous celebrities in the US. Maybe even Bill Nye too.

39. **Peter Woit**
November 13, 2015

Truth,
Depending on how you measure celebrity fame, I think there might be several scientists in the top 100. The problem is that the way you acquire celebrity fame is by getting on TV, and the people you mention are famous for their TV shows, not for their scientific accomplishments. I don’t think the Breakthrough prizes have created any celebrities, and as long as they reward scientific accomplishment and not talent as a TV personality, they likely won’t. I liked Michael Harris’s point in his latest blog entry:

“whatever the Silicon Valley celebrities may think, the deep motivations that make someone want to be a mathematician are hopelessly, comically, incompatible with the deep motivations that make someone want to be a rock star.”

40. **Justin**
November 13, 2015

Woit,

Can you explain why it is important to have funding to do math research? So long as one is earning a livable wage, I don’t see what difference it makes. A full time professor at a community college I would think would be in just as good a position to do math research as a professor at Harvard. Of course their outputs aren’t expected to be the same, but that’s because the professor at the community college is presumably less talented than the Harvard professor.

41. **Peter Woit**
November 13, 2015

Justin,

Math research is much less dependent on research funding than experimental science fields, where funding is needed for equipment, etc. However, it still does play an important role. A lot of funding from the NSF and private foundations goes to paying the salaries of postdocs and stipends of graduate students. Without such funding, there would be many fewer young research mathematicians at work. This kind of funding also supports conferences, workshops and travel, making it possible for people to get together with others working on the same topic, which is very helpful for making progress. It also sometimes pays for people to take time off from teaching responsibilities and devote full-time to research, including traveling somewhere to work with others.

Research funding also does go to mathematicians with permanent jobs to supplement their salaries, and one could question that (but I don’t want to start that debate here). Universities often take a cut of this, and as a result may reduce the amount of teaching such a person needs to do, providing them with more time to work on their research.

It is quite common for mathematics faculty without grants, at places with little research funding, to do excellent research. A notable example would be Yitang Zhang and his very successful work. But there is a huge difference between teaching at a community college and teaching at Harvard. At a community college one likely will be teaching something like 5 different classes/semester, which is quite a lot of work, leaving the average person with little energy for other projects. At Harvard right now, it’s more like one class/semester, allowing one to spend most of one’s time on research (whether or not one has a grant or any sort of funding).

42. **Bill**
November 13, 2015

Speaking about Yitang Zhang, I am still very surprised he didn’t get the Breakthrough prize. He was an obvious candidate in the sense that he clearly deserved it and that the prize could be seen as a payback for all lost wages. I thought he would be the most apolitical choice, but clearly there was some politics involved.

43. **Bill**
November 15, 2015

I know it’s maybe not a good time for comments, but I thought this might cheer people up: a new breakthrough theorem by Peter Scholze.

44. **Chris W.**
November 16, 2015

It was mentioned above that Peter Scholze used to play in a rock band. Manjul Bhargava (in that photo talking with Scholze) is an accomplished tabla player, according to Wikipedia.

45. **pindaroi**
November 17, 2015

On the subject of Mathematics creeping into popular awareness:
Some of you may be familiar with the series Lewis from ITV in the UK, which is the successor to the Inspector Morse series.
The scene of the opening crime in the case presented by the latest episodes 5 and 6 of Series 9 is the Andrew Wiles building in Oxford's Math department. and the solution depends on the representation of the structure of a specific knot in knot theory.

46. **rc123**
November 17, 2015

Also, about mathematics going popular, in the TV show Elementary, I just realized three mathematicians (all in separate episodes!) have gone on to be murderers…

47. **been there**
November 20, 2015

Why is everyone assuming that Scholze turned down the prize because he does not like the money? Has it crossed anyone's mind that he may have simply not liked the bother to have to cross the Atlantic, dress up in a tuxedo, and in general act as you are told by the organizers and not as you please? Four days of your life for a $100,000 check (minus taxes). If you don't show up, no prize.

48. **Peter Woit**
November 20, 2015

been there,
Maybe I'm wrong, but as far as I know, winners are not required to dress up and perform to get the check (especially the junior ones who I don't think appeared on TV), he could have accepted and politely declined to attend the ceremony. I hope some day we'll hear from him about his thinking about this, I haven't heard anything about him feeling that his motivations have been mischaracterized.

49. **been there**
November 21, 2015

some years back you were required to. as I said – been there.

50. **Pierre**
November 29, 2015

https://www.math.univ-toulouse.fr/spip.php?article645&lang=fr

51. **Peter Woit**
November 29, 2015

Pierre,
Thanks. Sounds like he'll accept that one, and presumably also the Fields medal when he gets in it 2018…

This Week's Hype

November 17, 2015
Categories: This Week's Hype

This week's string theory hype comes to us from USC physicists Clifford Johnson and Nick Warner, courtesy of the USC press office (see here and here). It's garden variety hype of this kind, exactly the same claims about strings and extra dimensions that were being made thirty years ago. There's no acknowledgement these haven't gone anywhere, instead we're "closer than ever to an answer".

When the question of testability comes up, the multiverse is not invoked as an excuse. Instead, it seems that dark matter is going to provide the test:

> Observations show that dark matter and energy constitute more than 95 percent of the universe. Scientists have established that they are new forms of matter and energy, but so far their precise nature is unknown. They may hold the key to confirming the veracity of string theory, Johnson said.
>
> "It's really kind of amazing — and humbling. There are forms of matter that seem to show up naturally in string theory that could well be good candidates to be dark matter," he said. "People are hoping that this could be a key to making contact between theory and nature."

Hard to know what Johnson has in mind for his "show up naturally in string theory" claim. Presumably he's thinking of the ancient "we'll test string theory by finding superpartners" claim, somehow neglecting to mention that this hasn't worked out.

I'm especially impressed by the description of string theory's power to explain dark matter as "amazing – and humbling", deftly pairing outrageous over-the-top hype with an invocation of the selfless humility of the research scientist.

Comments

1. **David Nataf**
   November 18, 2015

   Peter,

   What are your preferred theoretical approach to the fundamental physics problems of dark matter and dark energy?

2. **vmarko**
   November 18, 2015

   "The coolest thing about string theory is it's the *only* theory out there that reconciles quantum mechanics and general relativity," said Warner

   What is not so cool is Warner's complete ignorance of all non-string theories out there, that are at least equally as successful in this reconciling.

   "There's always the possibility that the framework is incomplete, or just plain wrong," Johnson said. "We need a way of getting measurable predictions from the theory that we can go away and test — a key step in any scientific endeavor."

   At least Johnson can be ack-ed for not subscribing to ST-does-not-need-experimental-verification crowd. 🙂

   Best, 🙂
   Marko

3. **Peter Woit**
   November 18, 2015

   David Nataf,

   About dark energy, I have no idea.
   One thing I've never completely understood is the status of attempts to explain dark matter using right-handed neutrino fields. Such fields have no SM interactions, but there is a complicated story about neutrino masses, and it's not clear to me you can't get something massive that would explain the astrophysical observations, but would not show up in experiments designed to look for a very weak non-gravitational interaction. If anyone knows of a good source explaining this particular point, I'd like to hear about it. But I don't want to try and moderate a discussion board about these topics.

   vmarko,
   Johnson pays lip service to experimental verification, but my experience in discussions with him is that his attitude is de facto the same as claiming this doesn't matter at all. Back in the days of the string wars he wrote a long series of postings on his blog denouncing my book, and I tried then discussing with him the problems with "string phenomenology". After getting some odd responses I finally realized his position was that such things were of no interest and didn't matter (he also didn't see anything incompatible between denouncing my book and Lee Smolin's, and refusing to read them). From his latest, it seems to me his attitude hasn't changed, as he deals with the connection to reality problem by repeating very stale hype that no one knowledgeable about the subject would take seriously.

4. **Patrick Harris**
   November 18, 2015

   Dr. Woit,

   The article begins with the oft used (exhausted?) analogy of a wire (or straw) to describe how extra dimensions might be elusively small. While I can begin to wrap my head around extra dimensions from a mathematical perspective, I've never understood what physicists hope to "see" probing finer and finer distances. Would they actually observe these dimensions? Are they looking for violations of conservation laws? Or would they observe motion in 3 spatial dimensions that can only be explained by invoking more?

   I realize this question betrays my naivete and I don't want to contribute noise to your blog, but any pointers would be appreciated :).

   Thanks,
   Patrick

5. **PeterH**
November 18, 2015

With reference to the Dark matter test of String theory:
They may hold the key to confirming the veracity of string theory, Johnson said
How is this claim justified without definite predictions from String theory?

6. **Will Nelson**
November 18, 2015

I am generally far from your viewpoint but when I see someone describe some success as "humbling" the way Johnson does, that really irks me…and all the more so when it's not even a success yet. What he should really find humbling is the number of typos in his book on D-branes.

7. **Peter Woit**
November 18, 2015

Patrick Harris,
What you expect to see depends on the details of what physics is governing your extra dimensions and how this interacts with conventional physics. A simplest example would be one extra dimension, a circle of some size with its geometry fixed. If you Fourier analyze, you expect momentum components in that direction to be discretized in units proportional to the inverse size. So, for very small circles, you expect to not see anything, until you get to energy levels that excite modes with those large momentum components. Then you will have a different energy-momentum relation, one involving those components.

But, there's an infinite array of many other possible things you can do with extra dimensions to make them so far invisible, with new physics if you could see them. Many popular string theory books should have some more about this in the string theory context.

This is kind of off topic, note that even Johnson doesn't think it's plausible to claim we'll see such things.

PeterH,
There are no string theory predictions about dark matter. One might think that Johnson was well aware of this, and thus being intentionally misleading. From my experience trying to discuss such things with him, I think it's also plausible he just knows nothing about this beyond very old claims that string theory implies susy, and susy theories can have a dark matter candidate, hasn't paid attention to the fact these haven't worked out (or thinks that's irrelevant and one is free to keep telling the public that some day they might).

8. **Peter Woit**
November 18, 2015

To be clear. I've no idea what specifically Johnson is referring to as string theory "good candidates" for dark matter. Maybe he's thinking of axions. I've never heard any other string theorist making this claim, though, so the whole thing is rather odd.

9. **Syksy Räsänen**
November 18, 2015

Peter:

For sterile neutrino dark matter, see http://arxiv.org/abs/1204.5379 . I find nuMSSM particularly appealing, as you can also do baryogenesis with the right-handed neutrinos, all without introducing a new higher energy scale.

10. **Peter Woit**
November 18, 2015

Thanks Syksy!

11. **G.S.**
November 18, 2015

Patrick Harris,

When I was touring graduate schools in the early 2000s I remember researchers at University of Washington working on a (more or less) tabletop experiment to test the 1/r^2 law of gravity at short distances. One of the motivators was that if there were extra dimensions and if they were large (much bigger than the Planck scale, but still much much smaller than the distances being tested) then there should be some deviation from 1/r^2. I never followed up, but I'm guessing they never found a significant deviation.

12. **RandomPaddy**
November 18, 2015

> There's no acknowledgement these haven't gone anywhere, instead we're "closer than ever to an answer".

I don't think Theoretical Physics is going to be able to get out of this Tailspin. Particle physics anyway. There's no acknowledgement that the field isn't even going anywhere, having been stuck in more or less a hamster wheel theoretically for, is it three or four decades now? The generation of people now *retiring* can hardly remember a time when the field wasn't all about wild speculation and unsubstantiated results. I don't think this is a situation a community or disipline can just "snap out of".

The lack of progress is also pretty stark when you compare it to other fields in science and technology, which have in an understandable way made massive advances over the same period. At some point, especially if the LHC doesn't make further discoveries, or a successor accellerator never gets built, I think this contrast may become too big to ignore and particle physics funding will dry up. Large colliders may go the way of the Apollo program, but unlike NASA will theoretical physics have enough wider support (or credibility) to be able to "keep the lights on" for a few lean decades. A lot of knowledge and expierience could be lost because the public got tired of hearing too much "fairytale physics". Maybe this kind of "die-off" is actually what needs to happen to break the cycle.

Sorry for being so negative.

13. **Peter Woit**
November 18, 2015

RandomPaddy,

This kind of public relations effort from the USC string theorists does seem to be a response to the problem of people getting a clue that theoretical speculation (and especially string theory) has not been going anywhere for a long time. Unfortunately the idea seems to be to just have friendly media put out stories claiming all is well. This is of limited value in dealing with the NSF and other physicists, who may recognize empty hype for what it is. Perhaps the hope is that the public in general, and philanthropic billionaires in particular are not so savvy…

The experimental HEP situation seems to me quite different, with the LHC and the Higgs discovery definite recent progress. There the difficulty of getting to higher energy and the lack of new discoveries besides the Higgs are a looming problem, but a different one than that of having spent 30 years training students to work on unsuccessful speculative ideas.

14. **phil fogle**
November 18, 2015

Although it's decades since I was an active physicist (optics) I am amazed and delighted be the progess in experimental physics, particularly HEP.

I understand the frustration than has come from the stagnation over the past generation in the apparent lack of productive theoretical physics. However, it's a false premise to try to keep it alive by hyping failed theories…

15. **TS**
November 19, 2015

RandomPaddy,

I would add that also theoretical particle physics has been progressing in large strides, even if we ignore neutrinos, dark matter and other non-accelerator-related topics: calculational techniques have progressed hugely in the past few years: multi-loop calculations, many-body final states, model-independent approaches, automated calculations at NLO to name a few topics. The reality check the LHC provided has drawn brain capacity back from model-building (or model-concocting) to the tough work of doing actual calculations, and it's showing.

Now you can claim that unlike a successful calculation in solid-state physics there are no applications, but then you are back to the question of why one should do fundamental research at all.

16. **Thomas Larsson**
November 19, 2015

RandomPaddy,
There are some ways to rephrase your observations in more quantitative ways:
1. There has been no Nobel prize to any discovery in theoretical HEP made after 1973.
2. When Frank Wilczek becomes 65 in 2018, there will be no active (below normal retirement age) "fundamental" theorist with a Nobel prize, for the first time since H.A. Lorentz won the prize in 1902.
It is of course possible that HEP theorists or even string theorists win a Nobel prize for contributions outside HEP; BPZ are my favorite candidates for their contributions to statistical physics. But with the possible exception of Zamolodchikov, they are also beyond retirement age.

17. **Paul D.**
November 19, 2015

G.S.,

See the most recent publications from the Eöt-Wash group. No detections of new physics.

http://www.npl.washington.edu/eotwash/

18. **Douglas Crumfield**
November 19, 2015

I wish Clifford Johnson (or his supporters) would defend his views here. As a layman, it's hard to know whether I should believe Clifford or Dr. Woit.

19. **Peter Woit**
November 19, 2015

Douglas Crumfield,
For whatever reason, there have been no submitted comments here arguing that there's a case for Johnson's claims. He has his own blog, and way back when put out a long series of postings about criticism of string theory (which he characterizes as a Storm in a Teacup), see
http://asymptotia.com/more-scenes-from-the-storm-in-a-teacup/
Many of those postings have long and substantive arguments in the comments section.

Unless I've missed something though, I've never before heard this claim from him or anyone else about an "amazing" explanation of dark matter from string theory. It seems to be something he never used as an argument back then when other physicists were involved, but does think it's a good argument for a popular promotional article.

20. **piscator**
November 20, 2015

Having just looked at this briefly, your description seems pretty unfair. It seems there is a write-up by a journalist of an interview? a chat? some kind of talk with Clifford Johnson in a cafe. It is a good thing that scientists tell other people what they are doing, but there is commonly some loss of transmission when filtered through a journalist with possibly no science background.

`Hype' is putting out misleading press releases, not making genuine efforts to explain to a journalist aspects of a difficult and technical subject that are far removed from everyday life, and then finding that the non-expert journalist doesn't quite get everything right.

21. **Peter Woit**
November 20, 2015

piscator,
This is basically a press release. The author is a "Public Communications Manager" working at USC. I think characterizing it as hype is quite fair, with the dark matter business especially egregious. It doesn't even bother to try and explain what the USC faculty (Johnson and Warner) are currently doing.

I see no evidence that the writer is misunderstanding anything or getting anything wrong, rather that he is accurately transcribing the hype he was fed. For this kind of PR effort by a university, generally the faculty involved would be asked to look over the article before publication and make sure it is accurate.

Langlands Items

November 20, 2015
Categories: Langlands

There's an interesting development in the math-physics overlap, with a significant number of physicists getting interested in the theory of automorphic forms, often motivated by the problem of computing string scattering amplitudes. This has led to a group of them writing up a very long and quite good expository treatment of Eisenstein series and automorphic representations, which recently appeared on the arXiv. The emphasis is not on the physics applications (which an introduction explains come about when one is dealing with systems with discrete symmetries like the modular group or higher dimensional generalizations), but on the calculational details of the mathematics. There are quite a few expositions of this material in the mathematics literature but many (mathematicians included), may find the detailed treatment here very helpful.

Another aspect of this area is some overlap with the interesting of mathematicians studying Eisenstein series in the context of Kac-Moody groups. There's a conference this week bringing together mathematicians and physicists around this topic.

Turning to recent developments in the Langlands correspondence itself, which relates automorphic forms to Galois representations, when I discussed David Nadler's talk at the Breakthrough Prize symposium (the video is available here), I forgot to mention one thing he talked about that was new to me, the Fargues-Fontaine curve. Nadler explained that Fargues has recently conjectured that the local Langlands correspondence can be understood in terms of ideas from the geometric Langlands correspondence, using the Fargues-Fontaine curve. For more about this from Fargues himself, see materials at his website, which include lecture notes, links to videos of talks at the IAS and MSRI, and this recent survey article. Also informative is some explanation from David Ben-Zvi at MathOverflow.

In April there will be a workshop in Oberwolfach on geometric Langlands that will include this topic, for details of the planned discussions, see here.

Fargues was here today at Columbia, and gave a talk on "p-adic twistors". Nothing much about Langlands, this was about the question of what the analog is for the Fargues-Fontaine curve when you take the real numbers as your field (the use of "twistors" is that of Simpson's, see here, not the common use in physics, which is quite different).

I won't display my extremely limited understanding of this subject by trying to provide my own explanations here. A big problem is that this is mainly about the p-adic Langlands correspondence, something I've never been able to understand much about. After making a renewed attempt the last few days, I at least started to get some idea of what are the biggest problematic holes in my knowledge of the math background. Interestingly, it seems many if not most of them have Tate's name attached (Hodge-Tate, Lubin-Tate, etc, etc…). One pleasant discovery I made is that there are now some excellent expository pieces on this material available, often courtesy of some talented graduate students. One wonderful source I ran into is Alex Youcis's blog Hard Arithmetic, which has given me some hope that with his help I might soon make a little progress on learning more about this kind of mathematics. I don't know what's in the water at Berkeley, but something there keeps producing high-quality blogging by mathematics students, another example is here.

   November 23, 2015

   I can tell you that the bottom of the reservoir does not taste good right now.

4. **Marty**
   November 24, 2015

   Can I ask a naive question here, though in the spirit of the blog? As a mathematician working on and around the Langlands program for over a decade now, I'm sometimes asked about applications to physics. I can mumble "conformal field theory" and "partition function" and "BPS state". I even talked to a physicist asking about automorphic forms on exceptional groups a few times. But I don't really know enough to know where this fits in physics.

   So really… what's the shortest path from an honest *theorem/conjecture* in the Langlands program (geometric Langlands is fine) to an honest *physical observation/experiment*? Analogies don't count. Also… just because "conformal field theory" is full of physics words/motivations… mentioning it doesn't count on its own.

   Is the motivation of physicists to understand the Langlands program limited to the string theorists?

5. **Peter Woit**
   November 24, 2015

   Marty,

   No, the motivation to understand the Langlands program is not limited to string theorists (I'm at least one counterexample…)

   Maybe one should first differentiate between what mathematicians often mean when they say the "Langlands program" (relating arithmetic questions about Galois groups to automorphic representations) and just one side of that (the automorphic side). One example of quantum field theory that relates both sides is the Witten et al. stuff dealing with the geometric Langlands case, in terms of a mirror symmetry, with its origin in the modular invariance of a twisted N=4 supersymmetric 4d qft (with that explained in terms of a superconformally invariant 6d qft).

   As far as I know, the connections to string theory are just on the automorphic side, with one source the modular invariance of string theory amplitudes, explaining why you expect to get automorphic forms.

My own interest (and I think this has also motivated a lot of other work) is in the analogy between automorphic representations and conformal field theory on a Riemann surface, which Witten first pointed out back in 1988 (in "Quantum field theory, Grassmanians, and algebraic curves"). As I've learned more and more about the function field and arithmetic cases, the way automorphic representations appear there seems to me to indicate a profound unification between those subjects and those parts of QFT which we are able to understand purely in terms of representation theory. I think there's a lot more to discover there, but, maybe that's just me…

Besides the later connection to 4d SSYM, the geometric Langlands stuff from the beginning involved a crucial use of conformal field theory (see for example Frenkel's 1994 "Affine algebras, Langlands duality and the Bethe ansatz"). As far as I know, the connection between this appearance of QFT in geometric Langlands and the later 4d stuff remains poorly understood.

I keep seeing all sorts of interesting suggested ideas and analogies in this area, the above doesn't do justice to the range of such ideas. Conformal field theory plays a central role and I would describe that as 2d qft, not string theory (which to me means you try to integrate over the moduli of curves), but that's an argument over words that is best discouraged (I'll delete any efforts to carry it on here).

6. **David Ben-Zvi**
   November 27, 2015

   Marty – from my point of view it seems like the flow of information is predominantly in the other direction, from physics to the Langlands program, though perhaps the great breakthrough was the realization that [geometric] Langlands duality and electric-magnetic duality are both part of the same big picture. The geometric Langlands program is amazingly well explained from the perspective of physics — it fits perfectly into the structure of four dimensional gauge theory and even better into that of six dimensional conformal field theory (the relations with 2d CFT are AFAIK subsumed inside these bigger structures). This picture is subtle enough that it appears to know all of the bells and whistles and complications people have discovered in geometric Langlands — at least if you ask it the right questions. Further it suggests a richer structure behind geometric Langlands than one would have imagined before.
   From the point of view of physics geometric Langlands allows one to probe electric-magnetic duality on various kinds of defects in certain highly supersymmetric quantum field theories. Some of the structures in the math remain somewhat esoteric from a physics perspective, but others don't — for example, the appearance of W-algebras in the work of Feigin-Frenkel and Beilinson-Drinfeld (the link to CFT that Peter mentions) is directly tied to one of the hottest topics in gauge theory in recent years, the AGT conjecture. W-algebras themselves are an aspect of the theory of Whittaker vectors, a fundamental theme throughout the Langlands program, which in physicists' hands becomes something very geometric about "cigars" (making 2 of your 6 dimensions look like a cylinder capped off with a disc at one end). The relation of geometric Langlands with this 6d CFT more broadly puts in right at the heart of many questions in supersymmetric gauge theories, since maybe half of the so-called N=2 SUSY gauge theories (the subject of Seiberg-Witten theory etc) come from compactifications of this one theory, so that one finds the same structures scattered throughout the subject.

   By far the clearest introduction to the FF-curve is the guest blog post that Jared Weinstein gave on Persiflage blog—link below

   https://galoisrepresentations.wordpress.com/2013/07/23/the-fundamental-curve-of-p-adic-hodge-theory-or-how-to-un-tilt-a-tilted-field/

8. **Peter Woit**
   November 29, 2015

   Thanks David and sdf,

   I had forgotten to include a link to that Jared Weinstein blog entry, which is a great example of an expository blog article. There's a second part to it at
   https://galoisrepresentations.wordpress.com/2013/08/12/the-fundamental-curve-of-p-adic-hodge-theory-part-ii/

This Week's Non-Hype

November 23, 2015
Categories: Uncategorized

Since I often post here complaints about articles produced by the press offices of various institutions that hype in a misleading way physicist's theoretical work, I thought it a good idea to make up for this by noting a positive example of how it should be done. The SLAC press office this week has a Q and A with Lance Dixon, with the title [SLAC Theorist Lance Dixon Explains Quantum Gravity]() which is quite good.

Dixon gives an informative explanation at a basic level of what the quantum gravity problem is. He includes an even-handed description of the string theory approach to the problem, and explains a little bit about the alternative that he and collaborators have been pursuing, one that has gotten much less attention than it deserves. This is a very technical subject, so there's a limit to how much he can explain, but he gives the general idea, and includes a [link to his most recent work]() in this area.

Many promotional efforts for string theory begin by making claims that quantum field theory cannot be used to understand quantum gravity, due to the divergences in the perturbation series. This has been repeated so often, for so many years, that it is an argument most people believe. The situation however is quite a bit more complicated than this, with one interesting aspect of the story the discovery in relatively recent times that long-held assumptions about divergences in perturbative quantum gravity calculations were just wrong. Such calculations turn out to have extra unexpected structure, and thus unexpected cancellations, making naive arguments about divergences incorrect. Continuing progress has come about as Dixon and others have developed new techniques for actually computing amplitudes, uncovering unexpected new symmetries and cancellations.

For a good summary of the current situation, see this [talk by Zvi Bern](), especially page 7, where Bern details how, going back to 1982, "So far, every prediction of divergences in pure supergravity has either been wrong or missed crucial details". For N=8 supergravity, current arguments say that a divergence should show up if you could calculate 7 loop amplitudes, but Bern warns against betting on this. In that talk he also explains the recent work with Dixon and others that gets mentioned in the SLAC piece, about the surprising nature of the divergence in pure gravity at two-loops, making its physical significance and whether it really ruins the theory not so clear.

I was interested to read Dixon's account of his thinking back in the mid-80s:

> I began to be concerned that there may be actually too many options for string theory to ever be predictive, when I studied the subject as a graduate student at Princeton in the mid-1980s. About 10 years ago, the number of possible solutions was already on the order of 10^{500}. For comparison, there are less than 10^{10} people on Earth and less than 10^{12} stars in the Milky Way. So how will we ever find the theory that accurately describes our universe?

Although this never made it into media stories, I think that by a couple years after the initial enthusiasm for string unification in 1984, many theorists had already started to notice that the idea likely had fundamental problems, with a serious danger that it would turn out to be an empty idea. This now has become clear, but the idea lives on, with "QFT must have divergences" the main argument for continuing to take it seriously. Now that argument isn't looking so solid…

Update: A good [explanation of the situation from 4 gravitons]() who, thankfully, is not overly worried that he might be giving succor to the Woits of the world…

Comments

1. **Christopher Herzog**
   November 23, 2015

   I think it's interesting that one of the main tools that Dixon et al. use to compute scattering amplitudes in gravity is a relation between gravity and gauge theory amplitudes that in my opinion is simplest to understand from a string theory perspective — the Kawai-Lewellyn-Tye relations (Nuclear Physics B, 269 (1986) p 1-23).

2. **Peter Woit**
   November 23, 2015

   Christopher Herzog,
   Sure, that's one of several techniques they use. But if you look at Bern's slides string theory doesn't seem to be the source of the new phenomena that they've been discovering in recent years. It looks a lot more like they are uncovering new basic structures in perturbatively quantized gravity quantum field theories, and I don't see evidence that string theory is the way to understand them.

3. **Umesh**
   November 23, 2015

   Perturbative divergences aren't the only problem plaguing QFT-like treatments of gravity – this is a very retro, 80's way of stating it, and it's no fault of string theorists that it keeps getting reported/ repeated this way. The much more profound aspects of non-QFT like behaviour of gravity involve the area like scaling of entropy, for which there seems no sensible explanation from a local QFT point of view. The only known way is AdS/ CFT, which is string theory again (of course other examples of explicit calculations are Strominger/ Vafa etc, which involves string theory in a crucial way.). This isn't to downplay any of the the above work on perturbative supergravity amplitudes, but to make use of the above to attack string theory by cherry picking one aspect of perturbative quantum gravity is wrong.

4. **Peter Woit**
   November 23, 2015

   Umesh,
   This isn't an "attack on string theory", just reporting the fact that one of the standard arguments used to claim qft cannot describe quantum gravity shows signs of being in the process of being shown to be wrong.

   As for entropy scaling with the area not being possible in qft, recall that Hawking radiation is a semi-classical qft calculation.

   Going on about how poorly understood relations to AdS/CFT are the only way to understand quantum gravity in 4d dS is just pure hype, and trying to claim that such arguments show qft can't be used in this context is absurd.

5. **Umesh**
   November 23, 2015

   Hawking's calculation is indeed an 'semi-classical QFT computation', but the entropy in question is of the black hole background – which needs a quantum theory of gravity to be understood. QFT, with it's local degrees of freedom, can never produce an area extensive scaling. Of course effective QFT in a black hole background is sufficient to highlight this point, but the conclusion is about gravity (semi-classical in this case), not about QFT. To repeat, Hawking's calculation doesn't say anything about the QFT. Also, nowhere in my comment have I claimed that AdS/ CFT can be directly (or in any obvious way) used to understand dS quantum gravity. I have used it to highlight the conceptual issues about quantum gravity, the area scaling of entropy being one of them.

6. **Peter Woit**
   November 23, 2015

   Umesh,
   The posting was about conventional claims that you could never get quantum gravity out of qft because of its perturbative short-distance behavior now looking like they may be wrong. I don't think your claims about qft and area law behavior are any more solid. The history of qft contains a long list of claims that qft couldn't reproduce X (see the history of the Higgs mechanism and QCD) which turned out to be nonsense. Often this was because of the subtleties of gauge invariance and gauge degrees of freedom. The subtleties of geometrical degrees of freedom and diffeomorphism invariance are even greater.

7. **Umesh**
   November 23, 2015

   It is true that QFT has overcome many issues claimed to be beyond its reach in surprising ways in the past. The claim that QFT cannot reproduce the area extensive entropy are much more solid and quantitative – references are numerous – contrary to what you claim. Of course one cannot predict anything about the future, but perturbative finiteness doesn't mean non-perturbative consistency (which is where the trouble with quantum gravity lies, and the area extensive scaling is a hallmark of a non-perturbative effect in quantum gravity – leads to issues like loss of unitarity and so on). Barring some miracle (with local theories like QFT), it is in no way clear as to how to get an area law for something as universal as the entropy, at least in any obvious way. I'm also quite sure that nobody claimed 'you could never get quantum gravity out of qft because of its perturbative short-distance behavior' – it surely was one problem with making a conventional QFT of gravity for starters. If one thinks he/she has an answer to that, there's a huge list of issues waiting to be answered – area extensive entropy is next on that list.

8. **Peter Woit**
   November 23, 2015

   Umesh,
   Sure, there are problems with any theory of quantum gravity that go beyond the heavily advertised perturbative short-distance problems. I'm just pointing out there's a problem with the central heavily advertised claim here (do you deny this?).

   I personally don't see any point to entering into ideological arguments of the "my non-existent supposedly consistent but inherently untestable non-perturbative theory of quantum gravity sucks less than your non-existent supposedly consistent but inherently untestable non-perturbative theory of quantum gravity" sort. It seems clear to me that the bottom line is we don't yet know what the right fundamental degrees of freedom are to describe space-time geometry, or what the right way to go about quantization of these is. In such a situation, vague arguments about "entropy" and "locality" are no serious reason not to pursue any particular line of research.

9. **Noboru Nakanishi**
   November 24, 2015

   Two decades ago, I showed that the perturbative approach to quantum gravity is nonsense, because it is based on the wrong assumption that the zeroth-order approximation of the gravitational field is a c-number (see N. Nakanishi, Gen. Rel Grav. 27 (1995) 65). Quantum Einstein gravity can be formulated quite satisfactory and beautifully without using perturbation theory (see N. Nakanishi and I. Ojima, Covariant Operator Formalism of Gauge Theory and Quantum Gravity (World Scientific, 1990)). The method for solving qft in the Heisenberg picture is reviewed in N. Nakanishi, Prog. Theor. Phys. 111(2004), 301.

10. **Ralph**
    November 24, 2015

    I'm confused about the emphasis on the very-large-number of discrete string theory vacua.

    With atoms, we tend to make continuous approximations for collections of millions or just thousands of atoms. Why are solutions to string theories different?

    With 1e500 string theory vacuosities, why should one count discrete solutions, rather than making continuous approximations to the set of solutions, and using less precise but more informative notions such as dimension and measure?

    E.g. 1e500 solutions would be no big deal if they were all spread along a single "line" characterized by a single parameter. One could treat the parameter as a continuous variable until/if we ever managed to constrain the parameter sufficiently to reduce to a smallish number of physically realistic solutions, and then when justified, switch to the more precise discrete picture?

11. **vmarko**
    November 24, 2015

    Ralph,

    You should be careful to make a distinction between 10^500 solutions of a single theory and 10^500 different theories. The latter is the landscape problem in ST. It is the problem of 10^500 inequivalent ways to define one particular theory, before ever looking for any of its solutions.

    And no, you cannot parametrize those 10^500 theories with a single parameter (or any reasonable number of parameters), since there is no unique order relation between them (you cannot tell which vacuum would come "before" and which "later" as you increase the parameter). If such a technique were possible, people would be already using it. 🙂

12. **Umesh**
    November 24, 2015

    '..there's a problem with the central heavily advertised claim here (do you deny this?).'
    This particular claim is more complicated according to me to be responded to in simple confirm/ deny (or agree/ disagree) terms (also my denial is of no value in these intensely technical matters). As far as specialists are concerned, I think it is true that highly supersymmetric theories of gravity (as in {\cal N} = 8 SUGRA in 4d) might be perturbatively finite to high orders. That said, to claim that the whole issue of short distance divergence of gravity (the 'heavily advertised claim', as you put it) has started to seem wrong is false. In my limited view of the subject, it is still reasonably accurate to say that most garden variety field theory versions of gravity (even with less SUSY) are divergent in the normal sense. I don't know the full status of the field, but think it fair to claim that even experts would agree that the perturbative divergence issue in gravity as a field theory is far from settled. Again, let me emphasize the SUGRA community has done an amazing job with these intensely difficult calculations (not that my emphasis matters).

    "my non-existent supposedly consistent but inherently untestable non-perturbative theory of quantum gravity sucks less than your non-existent supposedly consistent but

inherently untestable non-perturbative theory of quantum gravity"
I cannot speak for you precisely, but I presume the aspect of the 'ideological debate' you refer to (in this case) is the case for gravity as a field theory (and its perturbative finiteness) vs. string theory as a quantum theory of gravity. As an aside, I should mention that there is a post somewhere on this blog that has a similar discussion, there the case has been about the 'asymptotic safety' scenarios for gravity (also to with gravity as a field theory) vs. string theory, and the same issues remain. Fundamental degrees of freedom describing spacetime geometry are well known in certain special geometries – again I've to refer you to many thousands of papers about the AdS/ CFT correspondence. Therefore, that we 'don't know the fundamental degrees of freedom of spacetime geometry' is a blanket statement that is wrong. Further, you say, and I quote '..vague arguments about "entropy" and "locality"..' . I must emphasize that the basic notions of 'entropy' and 'locality' in QFT and QFTs as applied to gravity are far from 'vague'. Right from Hawking's seminal paper full of quantitative calculations of entropy to other attempts at getting the area law and thousands of follow up papers (to Strominger/ Vafa's calculation) are very much counter to your claim.

13. **Peter Woit**
November 24, 2015

Umesh,
This discussion shows exactly why I generally make it a policy to avoid debates about quantum gravity. It's an extremely complex subject, with debates like this immediately degenerating into empty ideologically-driven sloganeering, with endless irrelevancies ("asymptotic safety"???) and dubious claims thrown in to make sure that no substantive question gets accurately addressed. This is just a complete waste of time.

Dixon is doing the opposite, addressing a very specific, well-defined technical issue with the theory and making progress at better understanding it. Given his success at this and his background doing important work in string theory, his opinion that looking at alternatives to string theory as a theory of quantum gravity I think is well worth listening to.

14. **Umesh**
November 24, 2015

I don't quite understand what sloganeering and dubious claims you're referring to. I mentioned that there was a blog post here relating to the asymptotic safety scenarios for gravity as a field theory, and as similar discussion ensued. I'm sure Lance Dixon is a great physicist and has much important to say about string theory (surely more than me), but on the other hand, I could invoke equally competent authority to claim that 'alternatives to string theory as quantum gravity' are quite futile. That wouldn't suit you, or help the discussion, would it? Just to repeat again, to make sure there is sufficient accuracy, here's where I stand:

The claim that gravity is finite in perturbation theory in no way makes the 'non-renormalizability of gravity' claims completely go away. It is true that highly SUSic theories of gravity are perturbatively finite. This by itself in no way dilutes the claim for string theory as correctly addressing the issues which remain once perturbation theory is accounted for.

Also, said blog post relating to asymptotic safety:

http://www.math.columbia.edu/~woit/wordpress/?p=2199

15. **Peter Woit**
November 24, 2015

Umesh,
Following that link to my old blog posting, the only content there relevant to this discussion is a sentence from a commenter pointing to a long rant by Lubos Motl, and I see Lubos has a new equally long one today. I find it hard to think of any bigger waste of time than trying to engage with those.

16. **Umesh**
November 24, 2015

Sure, you're free to decide whether or not to spend time on Lubos Motl's blog. There's more relevance than just the commenter's pointing to Lubos Motl's blog. Whether or not his post is driven by ideology is subjective and surely irrelevant. The only important thing is about the reference to black hole thermodynamics (surely independent of any ideology), which is discussed in the comment thread. I'm just pointing out the similarity to the discussion above. Let me copy-paste your reply to V_NO:

V_NO,

What Weinberg is talking about is the standard claim for string theory that it is needed to deal with the perturbative renormalizability problems of quantum gravity. That may not be true, either because of asymptotic safety, or also because of possible perturbative finiteness of some supergravity theories.

Non-perturbatively, you don't really even know what string theory is, I don't see how one can claim it's the only possible way to deal with non-perturbative problems in quantum gravity. The problem is more complicated than just invoking black hole thermodynamics, which was originally discovered as a semi-classical phenomenon in QFT.

If I understand your above reply correctly, you seem to be ambiguous regarding string theory being the only way to resolve non-perturbative issues of quantum gravity, one manifestation of which is black hole thermodynamics (please note similarity to above discussion, which is literally the same thing). If the problem is 'more complicated than just invoking black hole thermodynamics', then it stands to reason that one must solve that issue immediately if one thinks that he/ she has overcome the 'renormalizability problem of gravity' one way or other, before proceeding to 'more complicated' aspects you seem to refer to. If the same remains your stance pertaining to the above discussion, I've nothing more to say.

17. **Peter Woit**
November 24, 2015

Umesh,
If characterizing Motl as "driven by ideology" is "subjective", so is everything… Sorry, I've wasted enough time on this.

18. **Umesh**
November 24, 2015

It just means that Lubos Motl's blog posting is irrelevant to this this discussion. What is surely not ideology is black hole thermodynamics, and that's the bulk of my last comment. The question of whether or not when one solves 'perturbative issues in quantum gravity' one can indeed solve issues related to black hole thermodynamics is a sharp physical question, independent of Lubos Motl's (or yours, or mine or anyone else's, for that matter) ideology. If you can concentrate on this aspect, we can make progress about the issue at hand.

19. **chris**
November 24, 2015

Umesh,

why is pointing out progress in a direction that progress has been thought to be impossible 10 years ago so offensive to you?

Dixon&Bern have really done great work in the last decade. They picked up a task that 't Hooft gave up and made progress. Whether or not you like it, that does change the perspective on perturbative gravity for some of us.

And about that area-entropy relation: all you have to do is cut a QFT at the stretched horizon. Or use Ashtekar variables. Yes, holography is an interesting feature – but how that motivates string theory is beyond me. and even how that relates to the topic discussed here other than a distraction from it is even less clear to me.

20. **Umesh**
    November 24, 2015

    As I've made clear in my comments, the work of Dixon-Bern is far from 'offensive' to me, as you claim. I've even made it clear that Dixon is a great physicist (and achieved string theorist as well). Therefore, I don't understand why you feel the achievement of above physicists (which also I characterize as great, not that it matters) is 'offensive' to me. I should possibly be very clear that high order perturbation theory calculations in SUGRA are great. I have nothing against it, and am surely not advocating abandoning it or some such idiocy. Apart from that, because of my ignorance, I can't quite comprehend your statements about black hole entropy, maybe some paper/ reference would help. I don't think I've mentioned anything anywhere in my comments that imply 'holography motivates string theory'. If you are saying that there're other ways to get black hole entropy apart from strings, great, I don't know of them. What I don't quite follow is how impressive work on the finiteness of perturbative SUGRA (or asymptotic safety in gravity) would possibly imply that it is non-perturbatively consistent – without evidence coming from black hole thermodynamics and so on. Apart from that, lemme say again, tour de force work.

21. **vmarko**
    November 24, 2015

    Umesh,

    I agree with you that advances in perturbative QG are not going to teach us much about nonperturbative problems such as the BH entropy.

    But I am quite perplexed by your statement "If you are saying that there're other ways to get black hole entropy apart from strings, great, I don't know of them.". Wow, is it really possible that you haven't heard of, say, loop quantum gravity? The calculation of BH entropy in LQG doesn't involve AdS/CFT, doesn't involve SUSY, doesn't require 10 or 11 dimensions, doesn't require string-anything, but certainly does get the entropy calculation right. And the calculation works for an ordinary Schwarzschild black hole, as opposed to the extreme Kerr black holes that are doable in ST. And you haven't even heard about any of this?! Wow!

    If you honestly really didn't know that there exists a LQG calculation of BH entropy, start for example here,

    https://en.wikipedia.org/wiki/Black_hole_thermodynamics

    and look up the LQG-related references cited in there.

    Best, 🙂
    Marko

22. **Peter Woit**
    November 24, 2015

    Sorry folks, I'll delete any more attempts to carry on this argument about black hole entropy calculations. It really has nothing to do with the Dixon article, and anyone who wants to read an LQG vs. string theory argument about these calculations can find it a hundred other places.

23. **Chris W.**
    November 24, 2015

    In reading the SLAC Q & A, which is obviously intended for non-specialists and the general public, it is apparent that Dixon avoids discussion of the dynamics of spacetime itself. That is, the focus is on how far one can get a conventional QFT for a field that has the characteristics expected of the gravitational interaction in flat spacetime with a fixed metric.

    The upshot is that one can get considerably farther than was initially thought after early attempts. This decouples two issues that seem normally to be conflated; (1) can perturbative finiteness of a quantum theory of the gravitational field be achieved, and (2) can gravity be understood as an interaction in flat spacetime, for which calculated effects normally thought of as indicative of spacetime curvature can be given an operational interpretation in flat 4-dimensional spacetime that works for most or all "practical" purposes.

    Notice that (2) assumes we can *do* calculations, i.e., that (1) has been answered in the affirmative. The question then becomes, what do we make of this? Does it fly in the face of the lessons we thought we had learned from general relativity? Does it make the program implied by (1) essentially pointless, even if it is successful on its own terms?

    One possible response—perhaps more or less what motivates workers in this area—is that the effort is far from pointless. It would give a well-defined quantum theory of gravity in which one can do sensible calculations with results that can be compared with observation. If those comparisons show disagreements (as one might expect), then the theory has problems, but they are empirical problems, not internal problems that render the theory inherently nonviable. One will have to consider where to go next, but an extremely important milestone will have been achieved, which contrasts sharply with the current predicament of string theory (and the putative M-theory).

November 24, 2015

While I admire the attempts of Dixon and others to push and see how far one can get with the idea of perturbative QG, and the quality of the SLAC Q&A being an exquisite example of non-hype (as Peter says), I have to say that I am somewhat skeptical regarding the whole program of QG as a spin-two field in flat Minkowski spacetime. Chris has put it in a form of a question:

"can gravity be understood as an interaction in flat spacetime […] Does it fly in the face of the lessons we thought we had learned from general relativity?"

My answers would be that gravity is (1) unlikely to be understood like that, and (2) it certainly does fly in the face of GR.

Treating gravity as a spin-two field in flat spacetime is just like treating planet trajectories using epicycles — it can certainly be done, provided that you introduce enough free parameters, but it is unlikely to give you any real geometrical insight into what is going on, and it is ugly beyond anybody's taste. One of the major points of GR was that spacetime itself is participating in physical events, as opposed to being a "box" in which physics happen. This is called "background independence", and the approach to gravity as a spin-two field in flat spacetime (infamously endorsed and advocated by Feynman) simply ignores this lesson of GR. Besides, the background geometry is unobservable, so insisting on it is like insisting on aether in electrodynamics. You can have it, but to what purpose?

Even if one accepts the background-dependent approach, the question is which background is better, Minkowski or de Sitter? Given that we observe a positive cosmological constant, one can argue that de Sitter background would be more "correct" than the Minkowski background, rendering void most of perturbative QG in flat spacetime.

So while Dixon's research is valiant in its technical ingenuity, skill and very nontrivial analysis, I somehow doubt that it can have any fundamental impact on the problem of quantum gravity.

[attempt to discuss black hole entropy with oneloop edited out]

Best, 🙂
Marko

26. **Peter Woit**
November 24, 2015

Marko,
Perturbation theory isn't analogous to epicycles in celestial mechanics, it's analogous to, well, perturbation theory in celestial mechanics (where it has a very long history).

It's not unreasonable to expect that, for a weakly coupled theory, a perturbation expansion about flat spacetime based on gravitons might give an extremely good approximation, given that we live in a very nearly flat spacetime. If your perturbation expansion runs into trouble, you can argue that there's a conceptual problem with the whole idea. One advantage the string theory quantum gravity program always had was that they had an argument that they didn't run into this problem, but qft would (that argument now seems to have a hole).

What I think is interesting about the Dixon et al. stuff is that they are unearthing new structure in these supergravity theories. Once this is better understood, it could be either not very interesting (a complicated mathematical artifact of the specific calculation), or very interesting (a deep new symmetry, one saying something about both fermionic and bosonic degrees of freedom).

Dismissing what they are doing as useless because it's not "background independent" or doesn't reproduce an argument about black hole entropy, or isn't holographic, or whatever seems to me foolish. Quantum gravity research programs that just study pure gravity, with whatever features you find attractive, are clearly missing a huge part of the fundamental structure of the world. Personally I'm extremely dubious that you can understand quantum gravity purely independently of matter degrees of freedom, and if you do, you'll never know whether you're right since you can't test pure quantum gravity theories.

And, please, endless arguments about "background independence" are even more stale and tedious than the black hole entropy ones. Just stop.

27. **vmarko**
November 24, 2015

Peter,

"a perturbation expansion about flat spacetime based on gravitons might give an extremely good approximation, given that we live in a very nearly flat spacetime"

As an approximation yes, I agree, but promoting perturbation expansion into a fundamental theory is a different ballgame. And we already know that there are high-curvature regions of spacetime (say, inside black holes) where the perturbative expansion around flat background just isn't a reasonable thing to do. Promoting this approach to a fundamental theory of QG seems ill-conceived IMO.

"a deep new symmetry, one saying something about both fermionic and bosonic degrees of freedom"

I am not trying to dismiss Dixon's work, and people should certainly be encouraged to keep studying it. But extraordinary claims require extraordinary evidence. If it really turns out that such a deep new symmetry is found and understood, I'll probably become a believer. But until that happens, I'm simply very skeptical about the benefits of the whole perturbative approach.

And regarding matter fields, I completely agree that studying only pure gravity won't cut it. But the matter sector is also in a very poorly understood state. The Standard Model is complicated, reasons for particle families and symmetries unknown, and vast sectors not explored enough (dark matter, neutrinos…). It is questionable whether such a complicated structure can actually help in figuring out the properties of QG itself. IMO, QG should be studied together with matter fields, but only in a generic framework where the number and type of matter fields are not fixed in any way. Who knows what might come up next in LHC, or what dark matter is made of? One cannot really rely on any details of the matter sector when discussing QG — just generic properties and the type of coupling (equivalence principle, alternatives, etc…).

Best, 🙂
Marko

28. **Peter Woit**
November 24, 2015

Marko,
No one is claiming that a perturbative expansion is a fundamental theory. However, one might optimistically hope that if it succeeds, it will give evidence that one has identified a good set of fundamental fields and their symmetries. If one understands path integrals well enough (a big if..), one might then even be able to write down a fundamental theory.

"the matter sector is also in a very poorly understood state"
As opposed to the quantized geometry sector??? Here I disagree completely. The lesson of the last few decades in HEP is that we understand the matter + gauge fields sector depressingly well. And if your theory says nothing at all about this, and only deals with likely unobservable effects, you'll have no way to convince others you have the right one, other than endlessly trying to claim yours is prettier than other people's.

29. **Noboru Nakanishi**
November 24, 2015

Peter,
As I stated above, the perturbative approach to quantum gravity has a conceptual difficulty. In order to set up the interaction picture, one has to choose not only a particular space-time structure such as flat but also a particular coordinate system such as Minkowski metric by hand (Indeed, if one adopts polar coordinate system, perturbation theory will become completely different from the conventional one.). This procedure explicitly violates general-coodinate invariance (more precisely speaking, BRS invariance) at the operator level, that is, pertubation theory explicitly violates BRS invariance in each order.
The introduction of a particular c-number metric as the zeroth-order approximation of the quantum gravitational field is indeed wrong. The zeroth-order quantum gravitational field is a q-number; its explicit form was already given in terms of a complete set of Wightman functions.

30. **Peter Woit**
November 24, 2015

Noboru Nakanishi,
I certainly don't claim that I know how to set up such a perturbation expansion in a sensible way that properly handles local space-time symmetry via BRS. This is a question for Dixon et al. They have some calculational method which I believe they claim gives consistent, sensible results, and a lot of calculations of specific amplitudes to back this up. You'll have to ask them how they handle the problem you identify.

31. **Dave Miller in Sacramento**
November 25, 2015

Noboru,

You said:
>As I stated above, the perturbative approach to quantum gravity has a conceptual difficulty. In order to set up the interaction picture, one has to choose not only a particular space-time structure such as flat but also a particular coordinate system such as Minkowski metric by hand.

You're right, of course.

However, when I was a doctoral student at SLAC back in the early '80s, I did a bit of work on lattice theories: when I first heard about lattice theories, I objected that they violated Lorentz invariance in a *huge* way, and therefore could not be right.

I trust that everyone here will agree that my initial impression was missing the point: i.e.,. working on lattice theories can be useful, and lattice theories can (sometimes) indeed recover Lorentz invariance in the limit that the lattice spacing goes to zero.

Around the same time (circa 1980), I went to a seminar (I think it may have been by Dan Freedman, though I'm not sure — it has been a long time!) discussing early attempts at perturbative quantum gravity, and I made the same sort of objections that have been made here: the inability to deal with non-perturbative effects such as black holes, the breaking of general covariance, etc. The speaker tried to be polite, but clearly thought that I was an ignorant grad student who did not understand that you had to walk before you could run.

Perhaps the speaker was right: I continue to be intrigued by the issues I tried to raise way back when, but, after all, neither I nor anyone else has solved those issues. Perhaps it is best to try to do something where one can actually calculate?

Dave

P.S. Peter, I think discussion like this can help many of your readers think through these issues even if the discussion itself does not reach closure. After all, someday, some bright young physicist who is mulling over such conundrums may actually come up with something that will create a major breakthrough.

32. **vmarko**
November 25, 2015

Peter,

"No one is claiming that a perturbative expansion is a fundamental theory."

Wait, are you saying that Dixon is not trying to construct a fundamental theory of QG? So he is talking about the prospects of quantization and renormalization of GR that will in the end be an approximate theory of some other fundamental QG model? Given that quantization is a nonunique process, why would you even expect that two different quantization schemes (the perturbative one and the "fundamental" one) would be compatible in any way at all? If Dixon is **not** trying to construct a fundamental QG model, then in what way is his work relevant for QG at all?

Again, if he discovers some unexpected structure that can be used to construct a fundamental QG model, that's great, and I'll gladly change my opinion. Otherwise, I just don't see what is the benefit of his approach, aside from developing mathematical techniques to perform complicated multi-loop calculations.

""the matter sector is also in a very poorly understood state"
As opposed to the quantized geometry sector??? Here I disagree completely."

I said that the matter sector is **also** in a very poorly understood state. Namely, not as opposed to QG, but rather just like QG.

"The lesson of the last few decades in HEP is that we understand the matter + gauge fields sector depressingly well."

Really? Why do we have three families of particles? Are neutrinos of Dirac or Majorana type? What principle fixes the choice of SU(3)xSU(2)xU(1) gauge group? Can you be certain that in the future LHC will not find the fifth interaction, extending the gauge group by an additional SU(4) term, for example? What is dark matter made of? What is the cause of matter/antimatter symmetry violation? I'd say that our understanding of these things is not depressingly good, but depressingly bad.

The existence of the dark matter is a proof that the SM must be incomplete. So if we already know that, we have to expect that various properties of the SM are likely to change in the future (just look at what happened to the neutrino sector). It is a transitory theory, one that will keep being improved/substituted with various BSM models, as we learn new facts about matter fields from experiments.

So when discussing properties of QG, one cannot rely on the details of the SM, simply because they are likely to be modified as we collect more data about matter in the UV and IR regimes.

Best, 🙂
Marko

33. **Peter Woit**
November 25, 2015

Marko,
One could hope that the relation between perturbative QG and fundamental QG might be much the same as for other QFTs one understands (e.g. QCD). Arguing that it's not worth investigating the perturbative version is kind of like telling Feynman and Schwinger back in the late 40s "why are you wasting your time on those approximate calculations? Everyone knows the full QED theory is completely different, has a Landau pole, and that's the real problem that needs to be solved".

I don't know what to say about the claim that the state of QG is just like the state of the SM. Maybe there really are alternate universes and we're in different ones…

34. **vmarko**
November 25, 2015

Peter,

"Arguing that it's not worth investigating the perturbative version is kind of like telling Feynman and Schwinger back in the late 40s "why are you wasting your time on those approximate calculations? Everyone knows the full QED theory is completely different, has a Landau pole, and that's the real problem that needs to be solved"."

Well, the difference is that in QED we have access to experimental data that is described by the approximations that Feynman and Schwinger were developing, so they were obviously useful. But conceptually, this hypothetical criticism of Feynman and Schwinger is actually entirely valid — both QED and SM are **effective** field theories (i.e. approximations at a given scale), while the fundamental theory cannot be a QFT, precisely because of things like the Landau pole and such.

In case of QED, perturbative calculations make sense because we can perform experiments, and compare the "true" experimental result to the approximate theory. When we see agreement, we use it as a confirmation that the approximation scheme is good enough, whatever the fundamental theory may be.

In the case of gravity, however, we have no experiments, and there is no way to test if perturbative QG is anywhere near being a valid approximation to reality. So it's a bit of an academic exercise. Putting one's faith into it, then, is ideologically as biased as believing in the "truth" of string theory, LQG, or {insert your favorite QG model}.

Again, I am not saying that perturbative approach is worthless or a waste of time. But if people are to take it seriously, its proponents must make a strong convincing case why they think that nonperturbative effects can be ignored in the quantization procedure. In QED you have strong agreement with experiment to make that case. In QG you don't.

Best, 🙂
Marko

Quick Items

November 25, 2015
Categories: Uncategorized

A few quick items before the holiday:

- I hear that Luis Alvarez-Gaumé will be the next Director of the Simons Center, starting next Fall, taking over from John Morgan, the founding Director. My understanding is that the hope was to have the directorship alternate between mathematicians and physicists, and with the hire of Alvarez-Gaumé, they've managed to achieve this. His early work on supersymmetric path integrals and the index theorem (see here) was characteristically lucid and this remains one of the great points of intersection between modern mathematics and the quantum theory. One of the best relatively short introductions to QFT is this one (with a shorter arXiv version here). I think he's an excellent choice.
- In physics blogger news, Tommaso Dorigo reports that he has found a publisher for the book he has been writing: Anomaly! – Scientific Discoveries and the Quest for the Unknown, and it should appear next year. I'm very much looking forward to seeing a copy. His insightful but irreverent take on experimental HEP I'm sure will make this a fascinating read for anyone interested in the subject.
- Matt Strassler's blog has been dormant for a while, but he has now been heard from. After a couple year visiting position at Harvard, he says he's now "employed outside of science", but working on a book about particle physics for non-experts.
- Jim Holt has a review in the latest New York Review of Books of my colleague Michael Harris's Mathematics Without Apologies.
- By some accounting, today is the 100th anniversary of Einstein's GR field equations, which he presented November 25, 1915 at a lecture in ~~Gottingen~~ Berlin. This anniversary has been celebrated in many places, in many ways this year, so there's not any need for me to chime in. Among many excellent treatments of the topic, there's also an unfortunate tendency of some to use Einstein to grind their particular axes. Sean Carroll I suspect has Einstein spinning in his grave, using the PBS NewsHour to enlist Einstein as a multiverse fan:

  > The ability for seemingly constant things to evolve and change is an important aspect of Einstein's legacy. If space and time can change, little else is sacred. Modern cosmologists like to contemplate an extreme version of this idea: a multiverse in which the very laws of physics themselves can change from place to place and time to time. Such changes, if they do in fact exist, wouldn't be arbitrary; like spacetime in general relativity, they would obey very specific equations.

  Perhaps Carroll could enlighten the public by writing down these "very specific equations" he's advertising, for comparison to the Einstein field equations.

  If I were to grind my own ax here, it would be to note that Einstein's great breakthrough came about through close collaboration with some of the best pure mathematicians around, adopting difficult but deep ideas about geometry. Without the mathematicians, I'd guess that the theory of general relativity would have taken many more decades to come to fruition. Maybe there's a lesson there…

Comments

   November 25, 2015

   `Perhaps Carroll could enlighten the public by writing down these "very specific equations" he's advertising, for comparison to the Einstein field equations.'

   As if the public (as in "PBS") were enlightened even by Einstein's equations.

2. **Peter Woit**
   November 25, 2015

   Warren,
   It seems I was being too indirect. The point is that there are no "very specific equations" for the landscape, so Carroll is moving beyond axe-grinding into being intentionally misleading here. At this point no one knows what the space of configurations of a full string landscape theory might be, or what dynamical equations on this space might be the right ones. What exists are just some conjectured approximations in some very specific Rube Goldberg-esque constructions (eg KKLT), and even those are very complicated.

3. **Low Math, Meekly Interacting**
   November 25, 2015

   I think even the unsophisticated can get the basic gist out of the simplified expressions of Einstein's field equations one typically sees in popular treatments (or on tee-shirts). I'll never know the full power of the tensor maths embedded therein, but the "matter tells space how to curve, space tells matter how to move" aspect, and the impact of the modern inclusion (as well as Einstein's mistaken one) of lambda has, is appreciable on a superficial level. Not sure if I would be able to form sound judgments if one stuck the universe of Einstein next to a multiverse, expressed in equations. I am wise enough to know how useless the latter is to science unless it makes some testable predictions, which it hasn't, and very likely won't, ever. Juxtapose that fact with the successes of GR, and I should hope the depressing reality multiverse mania would be obvious to any interested layperson. What's sad is the lack of interest many in the media show in being hard-nosed about the facts, which are simply GR is a spectacularly successful theory, and the anthropic multiverse is utterly bereft of value until it makes even one testable prediction that isn't utterly trivial or tautological. Which it hasn't. And likely never will.

   `If I were to grind my own ax here, it would be to note that Einstein's great breakthrough came about through close collaboration with some of the best pure mathematicians around, adopting difficult but deep ideas about geometry. Without the mathematicians, I'd guess that the theory of general relativity would have taken many more decades to come to fruition. Maybe there's a lesson there…'

   Funny how it is that some of the best pure mathematicians around HAVE BEEN and ARE collaborating with physicists about deep and difficult ideas about geometry, topology, etc. They work on mathematics related to string theory (Kontsevich, Yau, Morrison, Donagi, Morgan, Freed, Donaldson,…).

The deepest ideas in mathematics and the deepest ideas in theoretical physics have been intertwined for centuries (Newtonian dynamics/calculus, Maxwell theory/fiber bundles, Einstein gravity/Riemannian geometry,…).

String theory has been the source of some rather deep results in mathematics over recent decades (monstrous moonshine, elliptic genera, homological mirror symmetry, Seiberg-Witten theory, …). The flow of ideas in both directions has been stimulating for both fields.

The cognitive dissonance of your love of mathematics and your antipathy toward string theory is simply breathtaking … and telling. Maybe there's a lesson there…

6. **zzz**
November 25, 2015

Nature has a story this week about his collaborations

7. **Shantanu**
November 25, 2015

Peter, I thought Matt is a tenured prof at Rutgers.
shantanu

8. **Peter Woit**
November 25, 2015

Emil,
My criticisms of string theory have never been about its effects on mathematics. That's an extremely interesting subject, but one of great complexity, beginning with the fact that "string theory" is now a pretty ill-defined term. Eliminating actual content and complexity by claiming all sorts of very different things as "related to string theory" is just a tedious ideological debating point.

If you're interested in what I think, and not in a dumb string theory rules/sucks argument, you could start by noticing that my complaints have always been about the effect of "string theory" on physics, not on mathematics. You write about collaboration between mathematicians and physicists on "deep and difficult ideas about geometry, topology, etc.", which is quite accurate. What you don't mention is such collaboration on deep and difficult ideas about physics. The string theory unification picture of the world has degenerated into a hideous pseudo-scientific story about the "Landscape" (do you think there is deep new mathematics there?) and wishful thinking that the LHC will see some evidence for SUSY (any collaboration with great mathematicians on making LHC predictions about properties of superpartners?).

There's a wide array of wonderful deep mathematical ideas behind fundamental physics and lots of very good mathematicians that would like to think about them. If physicists would admit that string theory unification has been a failure and abandon empty, dead ideas, there would be even more opportunities for new interesting overlaps of the two subjects.

9. **Peter Woit**
November 25, 2015

Shantanu,
Strassler resigned his position at Rutgers a couple years back.

10. **Jeffrey M**
November 25, 2015

Peter,

Did Strassler explain why he resigned? I would think Rutgers was a very good position, low teaching load, don't know how good the department is in physics (it's very good in math) but you are certainly near plenty of great people in Princeton and the city. Was he just sick of physics? Not if he took a visiting job at Harvard, I wouldn't think. Did he think a few years at Harvard would get him a better gig?

11. **Peter Woit**
November 25, 2015

Jeffrey M,
I have no idea why Strassler left Rutgers (which has a very good physics department), you'd have to ask him. He has continued to be active in physics research, no evidence this was because he'd lost interest in that.

12. **martibal**
November 25, 2015

Emil, there are also great mathematicians working at the interplay between geometry and physics, and not interested that much in string theory, e.g. Connes. There might also be a lesson here.

13. **Peter Woit**
November 25, 2015

martibal,
On the topic of Connes and string theory, it may not be 100 years, but 10 years ago I posted this
http://www.math.columbia.edu/~woit/wordpress/?p=313
The story about string theory and Chicago is rather funny, perhaps Emil knows who it refers to.

All, actually there was nothing at all about string theory in this posting. I'd like to encourage discussion of any other topic than that.

14. **ronab**
November 25, 2015

Peter,
In providing context for his failed grant applications, Strassler says: "U.S. government cuts to theoretical high-energy physics groups have been 25% to 50% in the last

couple of years”. Is this correct? I had no idea.

15. **Chris W.**
November 25, 2015

Einstein sought guidance from good mathematicians on how to mathematically formulate his ideas about how to solve certain problems in physics. Again, the initial ideas were *about physics*, and they were his ideas, with some inspiration from people like Ernst Mach.

S. S. Chern saw this clearly, and discussed it in a an edited collection of symposium talks published following the Einstein centennial year of 1979. (See pages 271-287.)

As of now we lack physical ideas of comparable fruitfulness in confronting the current problems in fundamental physics. We have no lack of mathematical ideas, but we don’t know how to select which ones we need, or clearly identify the kind of new mathematics that might be required. (I’m inclined to believe that the problem is primarily one of selection and reformulation; the array of available mathematical ideas is already vast.)

16. **Justin**
November 25, 2015

Woit,

Could you elaborate on Einstein working with great mathematicians? I’m not an historian on the subject, but I believe Einstein worked a little bit with Marcel Grossmann to understand some Riemannian geometry, but that except for this collaboration, he developed his theory quite independently.

17. **Chris W.**
November 25, 2015

PS: Chern’s essay (originally a talk) may have been republished elsewhere as well, perhaps in a volume of his collected papers.

18. **Peter Woit**
November 25, 2015

ronab,
That’s somewhat of an exaggeration. The DOE HEP theory budget numbers recently are
FY2013 66.3 million
FY2014 64.3 million
FY 2015 59.2 million
FY 2016 60.3 million (proposed)
Given inflation, and some of this an increase in Lattice QCD, there definitely has been a decision to decrease the amounts going to theory groups. Because of the details of how these grants work, some of the decreases have been large. For some discussion of the subject see
http://www.math.columbia.edu/~woit/wordpress/?p=6701
and this
http://www.usparticlephysics.org/sites/default/files/webform/p5/calamity.pdf

Justin,
Grossman was crucial in introducing him to modern geometry and the techniques he needed to formulate the theory. Around the time he announced the field equations, Hilbert found the variational form of GR, and other very well-known mathematicians (for example Noether and Weyl) made contributions to the understanding of the theory.

19. **D R Lunsford**
November 26, 2015

It seems a little inaccurate to mention Weyl as an afterthought or to put him alongside Noether, who I am not dissing here – it’s just that Weyl was one of three people who really got it right off the bat – with Eddington and Einstein. Noether’s theorem did not play a role in early geometrical ideas about gravitation and was not published until 1918. It was Weyl who first understood the physical problem of the GR action and conservation laws stemming from it, which work also came in 1918. I am pretty sure that Noether and Weyl did not meet until Weyl was at Goettingen, about 10 years later. So her work likely had no influence on Weyl when he was working on his generalization of Riemannian geometry. (Weyl of course had found special cases of Noether’s theorem. Nevertheless his intent was physical and he wondered if conservation laws could be found at all. I could be wrong. See “The Dawning of Gauge Theory” by O’Raifeartaigh. And certainly, he was greatly influenced by her in his later work on electron theory.)

-drl

20. **nicola**
November 26, 2015

Do these “very specific equations” also change from point to point by some yet another set of “very very specific equations”? . Maybe there is even more general set of “very very very specific equations” that govern the “very very specific equations”? Maybe there is an infinite sequence of equations like that? And then there may be equations that govern the whole infinite sequence.

That somebody takes ideas like that seriously is beyond me.

21. **chris**
November 27, 2015

Einstein did his greatest work when he had solid experimental (or observational) evidence and followed it to the end. Yes, GR is a triumph in its mathematical sophistication, but he had the Perihelion precession of Mercury as a guidance.

In later years Einstein followed beautiful mathematical ideas and deep connections – you all know what the outcome was.

22. **geoff**
November 27, 2015

I would hope that those who know the particulars of this history will chime in and correct or expand as needed, but I think part of the physical argument arose in the context of whether or not the energy momentum tensor was a true tensor versus pseudo tensor. Also, I believe Einstein spoke of the equations for gravitational waves as being nonlinear several years before formulating the field equations themselves, and it was the task of separating gauge degrees of freedom from physical ones that led Hilbert to enlist Noether’s help. (“With Einstein’s theory, one of the many paradoxical consequences of this failure of energy conservation was that an object could speed up as it lost energy by emitting gravity waves, whereas clearly it should slow down.)

http://arstechnica.com/science/2015/05/the-female-mathematician-who-changed-the-course-of-physics-but-couldnt-get-a-job/

I've never been sure as to whether or not Mach's principle is a philosophical argument, a physical argument, or an attempt to impose boundary conditions that was never really fulfilled. Also, I'll second the motion that Weyl is grossly under appreciated by physicists today.

23. **Dimitrelis**
November 27, 2015

@Chris:
Exactly, and just to add that before GR, the anomalous perihelion of Mercury was attributed to … unseen matter- the planet Vulcan.
But I guess unseen (or dark) matter was always a very convenient solution…

@Peter:
I think Einstein has no grave 🙂

24. **David Brown**
November 27, 2015

"… Einstein spinning in his grave …" Einstein does not have a grave. His body was cremated and his brain was removed at autopsy and preserved in formalin.

25. **Emil Martinec**
November 27, 2015

Peter,

I wouldn't say that string theory (removing the scare quotes) is an ill-defined term; rather that it is a somewhat inapt designation for a circle of ideas about fundamental physics, given that the primacy of strings is now understood as an artifact of perturbation theory. And the fact that all sorts of very different things (from finite simple groups to K-theory, to name but two examples) are related to string theory is not so much a 'tedious ideological debating point' as it is an indication that this circle of ideas has the depth and richness that one would hope for in a fundamental theory.

If your notion of deep and difficult ideas about physics is restricted to a narrow set of issues in particle physics, then no, mathematicians are not who one should run to for help. But fundamental physics is so much more than that. Einstein taught us the deep interconnection between geometry and gravitation, a notion which has been extended by the central role of gauge theory in the other fundamental forces. A useful role for mathematicians in this enterprise has been and remains to help develop the geometrical/topological/algebraic ideas that might be of use in constructing a physical theory. Sometimes those ideas are already at hand when the time is ripe for an advance on the physics side (e.g. Riemannian geometry was available to Einstein), sometimes mathematics is the beneficiary of developments in physics (e.g. quantum mechanics leading to developments in algebra and representation theory). String theory has been both beneficiary and benefactor of mathematics, for example K-theory was available to help understand brane dynamics, while properties of string worldsheet dynamics have led to developments in algebraic geometry such as mirror symmetry and quantum cohomology.

As for the so-called landscape, I regard the whole discussion as premature. A certain segment of the community is piling speculation upon speculation, and not really getting anywhere. It is useful to recognize that there is always going to be an issue with quantum cosmology — that the universe we inhabit had substantial quantum fluctuations early on, and we are now in one decohered branch of the wavefunction; and so what to make of all the other branches out there, and the question of how many are there. To make progress on a problem, one needs the tools to do so. Most of the analysis of the landscape is based on an analysis of effective field theory and the seeming existence of a plethora of solutions to the effective field equations. People spun their wheels for twenty years trying to solve the Hawking paradox using the same methods, without success.

We now understand that black holes are consistent with quantum mechanics in specific examples in string theory, yet we cannot point to the dynamical process which supersedes Hawking's analysis of horizon dynamics in effective field theory. I suspect that making progress on cosmology (i.e. global dynamics) will have to await a better understanding of such local dynamical questions. One of the least understood aspects of string theory is dynamics.

As for your desire for physicists to "admit that string theory unification has been a failure and abandon empty, dead ideas", good luck with that. People actually working in the field will pursue the directions they deem most promising, regardless of your little diatribes here.

November 27, 2015

Peter: thanks to the link to your previous posting. The quote of Connes is still pretty accurate ! Regarding the french CNRS that offers stable job at young people, there would be things to say (in my opinion, it has turned now into a "there is only a short interval of time after the PhD in which one has a chance to get a stable job, at PhD+ 5 one is already out", which has many perverse effects), but that is another story 🙂

27. **Peter Woit**
November 27, 2015

Emil,
One thing that strikes me is that you decided to comment here in response to an item I wrote, completely ignoring what that item was about. I'm curious: do you really think it's all right for physicists to go on PBS and tell the public that the multiverse is "Einstein's legacy" and that there are "very specific equations" describing it? If it isn't, who should be saying something about this? If not me and my "little diatribes" (that's what this one was about, not string theory), who is or should be taking on this job?

The argument for string theory that, while we don't know what it is (other than a "circle of ideas") various different kinds of mathematics have turned out to be useful to analyze some of the complicated structures that have turned up, isn't a very convincing one. Yes, this circle of ideas that grew out of string theory has led people to wander around in some mathematically rich areas, raising questions and finding interesting things that would not otherwise have turned up. That's great, and a perfectly good argument for pursuing this circle of ideas if you can't think of anything else to do. It's not an argument though for the 10d superstring (or related circle of ideas) as having anything to do with fundamental physics.

Back in 1985, at the beginning of your (and my, we were educated in exactly the same era) career, the idea that something like the heterotic string could unify physics was a reasonable one to try, but it's now thirty years later. The idea that you could predict something, anything, this way has collapsed, giving us multiverse pseudo-science. The idea that higher energy colliders would find SUSY, giving experimental clues pointing towards this scenario, has also pretty much collapsed, with the final part of that story to happen over the next year or two. Given this, I think there's a very strong argument that you and others need to face facts as scientists, admit failure, and move on.

You can dismiss this as a “little diatribe”, dismiss any evaluation of the current state of string unification efforts as “premature” (with the right time to consider admitting failure only when you’re no longer around) and try and prop up a failed idea by hyped connections to mathematics, but I don’t think you’re doing the subject any favors this way.

28. **Anonymous**
November 27, 2015

Ronab, Peter,

While the total DOE high-energy physics budget hasn’t gone down by much percentage-wise, the cuts haven’t been distributed equally. Some large collaborations at certain universities received much larger percentage cuts than this average (I don’t know of any place that received anywhere near a 50% cut, but possibly Strassler does.)

29. **Emil Martinec**
November 27, 2015

I was reacting to the last paragraph of your original post (which I quoted in my initial response). So my response was a comment about the interaction of mathematics and physics, and that some of the most fruitful interactions of this sort in recent times have arisen in the context of string theory. I don’t think that wholly inappropriate, given the general content of this blog.

You propose that “general relativity would have taken many more decades to come to fruition” if the appropriate mathematics weren’t already developed. Yet you seem remarkably impatient with string theory not being in final form thirty years on from its inception as a candidate for a fundamental theory, given that there is no ready-made theory of quantum geometry for us to read up on. (BTW, I would rather have said we are forty years on from the work of Scherk-Schwarz/Yoneya showing that string theory is a quantum theory of gravity.)

As for contact with experiment, indeed that may be hard to come by given the large disparity between the electroweak scale and the Planck scale. If the scale of extra dimensions and the string tension scale are close to the Planck scale, then string theory looks remarkably like a 4d theory of quantum gravity coupled to matter — ordinary particle physics up to near the Planck scale, a handful of odd resonances that we’ll never see, and then a spectrum of black hole states. But absence of evidence is not evidence of absence. String theory could easily be correct and not testable by humans — in fact that could well be true of any theory of quantum gravity given the remoteness of the Planck scale.

In such a situation, internal consistency is one of the few routes to progress. Einstein was initially motivated to resolve the apparent inconsistency between Newtonian gravity and special relativity. Today, we have the apparent inconsistency between locality, causality, and quantum unitarity manifested in the black hole information paradox. String theory has made undeniable progress in this direction, but not a complete resolution.

As for particle physics unification, while it would be nice for there to be some rigid structure and a limited possibility to arrive at anything other than the Standard Model at low energies, it has so far not emerged, and looks increasingly unlikely. And the number of clues we are likely to get from experiment seems increasingly limited. The situation is unfortunate, but again nothing here says string theory is wrong (rather than simply not useful in this particular context).

Which brings us back to the issue of multiverse speculation. It seems to me a legitimate scientific question whether the structure and parameters of the standard model of particle physics and cosmology are (1) predetermined, or (2) properties of the part of the state we have access to, and therefore environmental. I suppose (1) splits into subcases of being (a) calculable in principle, or (b) fixed metadata. Maybe we will know enough someday to say definitively one way or the other. What questions are worth pursuing differ depending on the answer. Again, this is an issue for any theory of quantum gravity, not just string theory.

At the moment, I think we are in no position to answer, and trumpeting one particular possibility in the media is not particularly helpful, and tarnishes the subject with a patina of unseriousness. We simply don’t know enough to say one way or the other. I cringe when I hear statements to the effect that a multiverse is a “prediction” of string theory. At best, it’s a possibility.

Such speculations are putting the cart way before the horse. Let’s get a quantum theory of gravity first, and learn how to calculate with it; only then might we hope to address such questions. I suppose it’s human nature to want to jump to the final answer, and fill in the details later. But what if the nature of the final answer depends crucially on the details?

I suppose you’ll dismiss this as some dodge that it’s premature to judge string theory (again the scare quotes). Your mind was made up long ago and I’m sure I won’t change it. I will simply conclude by stating that I still think the subject is making interesting progress on important questions; they’re just not the questions we were initially asking 30 (or 40) years ago about unification of particles and forces, and instead have more to do with the nature of quantum gravity.

30. **Peter Woit**
November 27, 2015

Emil,
So, it seems that your position is that string theory is unlikely to ever be testable by humans, but that showing it is an internally consistent untestable theory is the future of the subject. Since you don’t have an actual theory (what is M-theory again? everyone seems to have given up on even trying to answer that), what you’re actually talking about is just showing that a “circle of ideas” is consistent, while being completely empty of content. This is really nothing but a set of excuses for giving up on doing science. It’s not surprising that people doing this don’t clearly explain to the public the state of their subject, but instead produce such huge amounts of promotional hype.

31. **Emil Martinec**
November 28, 2015

My how you love to twist people’s words! I said that for ANY theory of quantum gravity that, because of the remoteness of the Planck scale, experimental or observational tests will be hard to come by, and it is a distinct possibility that such tests will be beyond our reach. Does that mean we should give up trying to reconcile the fundamental incompatibility of quantum theory and general relativity, two theories that we have abundant evidence for? Some (you, apparently) might say yes, others (me, for sure) continue to be intrigued. Having at least one example of a consistent theory that combines the two is still a useful exercise IMO. At the moment we don’t have any.

I wouldn’t say that people have given up on the question of what M-theory is, rather the focus has moved beyond the aspects of that question easiest to answer using existing tools such as perturbation theory around simple backgrounds, and effective field theory.

One outstanding issue is what becomes of the equivalence principle in a quantum theory of gravity. Accelerated frames are related to thermal effects in the quantum theory, and related notions of density matrices and quantum entanglement; so these are likely to be some of the ingredients, and they also tie into the information paradox. A conceptual framework that ties all these notions together is currently lacking, but is certainly a major topic of current research. I could give other examples.

The first-principles exact calculation of black hole entropy, absorption/emission amplitudes, and so on, in particular controlled examples in string/M theory, was a tour de force of theoretical physics. The “circle of ideas” (oh those scare quotes again) in which those calculations took place is hardly devoid of content, or unscientific.

32. **Peter Woit**
November 28, 2015

Emil,
I don't think I'm twisting your words to say that you have given up on explaining anything about observable physics, by giving up on unification and any of the open questions of the standard model. Worse than that, string theorists have constructed a scenario with no evidence for it, designed to avoid admitting failure, and are aggressively selling this in the media, to students and colleagues, ensuring that future generations won't try and attack these problems, since it is "well-known" that they can't be solved.

It is possible to pursue a question purely by the criterion of internal consistency, with no checks from the real world. Mathematicians do it all the time. But if you're going to do this, the lesson mathematicians all know is that you need to be quite precise about what you are doing, very clear in your arguments, and very honest with yourself when something doesn't work. As far as I can tell, the way quantum gravity is being pursued by "string theorists" (I think the scare quotes are important, at this point, any actual theory involving strings seems to have little to do with this) involves none of this discipline at all. It's pretty clear where this kind of activity ends up, and its not with any reliable understanding of anything.

33. **random reader**
November 28, 2015

The current Martinec/Woit discussion is one of the most incisive I have seen on this blog, and is getting to some core issues that previous string theorist commenters have denied or ignored (or evaded). Thanks to Prof Martinec for the candid and to-the-point remarks; I hope he continues the conversation rather than exiting at the crucial point as Distler, Motl, Polchinski et al have done in the past.

34. **Neil**
November 28, 2015

Yes, this exchange between Peter and Emil was tremendous, and I would love to read more.

But at the end of the day, I can't help thinking it can be reduced to Peter saying "Show me the money" and Emil arguing about what is meant by "show" and "money".

35. **Emil Martinec**
November 29, 2015

@random reader,
I'm not sure what you mean by "the crucial point"; the major points have largely been made above. If I discontinue, it's because at this juncture there is not much more to say without repeating myself.

@Peter,
As I have said, I am not a fan of the landscape/anthropics, precisely because it implies that much if not all of the structure/parameters of particle physics/cosmology are environmental and not fundamentally determined and so the calculational power of the most fundamental level of physics would be rather limited.

But just because I don't like it doesn't mean it's not a legitimate scientific issue. IF the theory of quantum gravity plus gauge theory and matter has a sufficiently complicated structure of metastable states and IF transitions among them are allowed and IF one can understand enough about how early universe cosmology works, then the part of the universe we inhabit is the outcome of a variety of quantum processes, and the post-big bang universe we experience is but one of many discrete possibilities. If a quantum theory of gravity and matter can be constructed which has these properties, it is worth taking seriously and trying to understand better.

However, not all the string theory community agrees with all the premises. For a rather thoughtful technical critique of the assumptions (which I largely agree with), see section 4 of Tom Banks' 2010 TASI lectures (arXiv:1007.4001). The landscape is not currently a settled consequence of string theory.

As for all the "media hype" (my scare quotes this time), at the risk of repeating myself, I think it's unfortunate, but I don't think there's much to be done. It is not my job (or any of my colleagues) to police the field. There's plenty of bad popularization of science. Maybe journalists should do a better job of researching their stories. Like any science idea, either it will have power and find support when we understand quantum gravity better or it will not.

Every problem has a time when it is ripe to be solved, and often premature attempts to solve it don't help. It's always a judgment call where to invest one's precious time for research; even unsuccessful attempts often bring up new ideas or move the field forward incrementally. But at some point people keep rehashing the same old ideas, and at that point it is prudent to wait until new tools arrive. I think the black hole evaporation problem is a quintessential example. There were suggestions that black hole radiance violates quantum mechanics; that the information is stored in microscopic remnants; that it disappears into a baby universe; and on and on. The problem wasn't ready to be solved until gauge/gravity duality came along, we understood much better what quantum gravity is about, and we could see that all of these suggestions were on the wrong track (at least in the examples where quantum gravity has a presentation as an ordinary quantum field theory).

36. **Curious Wavefunction**
November 29, 2015

I look forward to Dorigo's book. What do you think of Randall's book which was favorably reviewed in the NYT today?

37. **vmarko**
November 29, 2015

Emil,

"IF the theory of quantum gravity plus gauge theory and matter has a sufficiently complicated structure of metastable states and IF transitions among them are allowed and IF one can understand enough about how early universe cosmology works, then the part of the universe we inhabit is the outcome of a variety of quantum processes, and the post-big bang universe we experience is but one of many discrete possibilities."

All three IF-s that you name are theory-dependent, and experimentally very hard (if not impossible even in principle) to verify. It is one thing to study a theory which has all three properties, but it is quite another to teach students that there is no alternative.

It would only be fair to acknowledge the opposite point as well: IF the theory of quantum gravity plus gauge theory and matter has a sufficiently simple structure of metastable states, or IF transitions among them are not allowed, or IF one can understand early universe cosmology without inflaton fields, then the physics describing our local patch of the universe also describes the totality of it, and the post-big bang universe we experience is pretty much unique. The values of fundamental coupling constants then ask for an explanation, and it is quite legitimate to try to improve the theory by trying to calculate some of them from some first principles, as opposed to claiming that those values are an environmental accident.

And of course, yes, there are theories out there that satisfy either of those IF-s, and even those that actually attempt to reduce the number of fundamental coupling constants (say, the NCSM by Connes, Chamseddine et al. at least tries to improve/reduce the number of SM free parameters).

The actual problem is that landscape/anthropics is an ideology, and the fact that it is represented to younger scientists as the only possibility, with students in most major universities being actively discouraged from thinking about alternatives (no PhD advisors, no funding, etc). I've heard the sentence "string theory is the only way to quantize gravity" way too many times, on serious conferences, from leading scientists in the field. Even if we accept landscape/anthropics as a scientific possibility (for the sake of the argument), it is by no means the only one, or even the most plausible one. People involved need to be more honest and more humble about what is speculative and what is done-and-dusted, when communicating science to students and outsiders. This lack of this honesty is where the problem is.

Best, 🙂
Marko

38. **Peter Woit**
November 29, 2015

Curious Wavefunction,
I took a quick look at it in the bookstore, which convinced me that its content is pretty much orthogonal to my own knowledge and interests. I've never learned much about dinosaurs, the Oort cloud, relevant astrophysics of our galaxy, and for whatever reason, they're just not high on my list of things I'd like to spend time learning more about. So, for an informed take on that book, you'll have to look elsewhere.

39. **Peter Woit**
November 29, 2015

random reader,
I agree with Emil that such discussions as this tend to end when people feel they have nothing new to say. I'm approaching that point and I'm sure he is too. I doubt either of us will convince the other of much, but the usefulness of this is likely to be that of giving a clear expression of differing points of view on these topics, I hope more informative than the usual caricaturizations. I think the point of view he is explaining is a rather mainstream one among sensible string theorists, many thanks to him for providing it.

40. **Peter Woit**
November 29, 2015

Emil,

The common reference to "not liking" the landscape scenario I think completely misses the point. If string theory implied that string vacua almost always came with a low energy SU(3)xSU(2)xU(1) gauge symmetry and three generations of matter particles, but the Yukawas were all different in some exponentially large set of different vacua, then I'd say that it's a scientific theory that has to be taken very seriously even though I didn't like the implications. The problem though is that there is zero significant evidence for such a scenario. What's dangerous here is not that people are pushing an idea that goes against traditional optimism about what we can hope to explain, but that they are pushing as science an idea with no scientific evidence behind it (and with a rather obvious non-scientific motivation of wanting to avoid admitting failure of a cherished idea).

I don't think media hype for this or other dubious ideas can be blamed on journalists. In my experience they of course miss subtleties and complexities, but they do a pretty good job of giving an account of the story they're hearing from well-credentialed physicists. Quite a few prominent and distinguished theorists have decided it's a good idea to publicly promote the anthropic landscape (sometimes claiming they "don't like" the idea). That very few of their colleagues are willing to publicly disagree with this is a big part of the problem.

Time will tell whether the latest gauge/gravity inspired approaches to the black hole information paradox lead anywhere. I don't think any evidence for string/M-theory is going to show up this way, but it's not implausible such work will lead to more promising ideas about quantum gravity (as a fan of representation theory, the appearance of an interesting group in what Strominger and other have been up to looks to me intriguing), or maybe have significant spinoffs in other very different fields (condensed matter, quantum information). But still, I see a two-fold problem, the usual faddish concentration on one particular idea, together with really bad arguments that others are unlikely to lead anywhere. Way back when, I think the point of view of mainstream theorists on the quantum gravity research community was often that such research wasn't going anywhere, since it was divorced from the parts of fundamental physics that we had evidence for (with the argument for string theory that it captured both the SM and quantum gravity). It might be a good idea for present day string theorists to recall their previous point of view.

41. **random reader**
November 30, 2015

The "crucial" new elements of this discussion compared to others seem to me to include the following contributions from Prof. Martinec.

1. The clear statement that "At the moment we don't have any [example of a consistent theory that combines quantum theory and general relativity]." This is very different from the usual idea that the formal consistency checks on string theory are overwhelming and have essentially decided the issue, and of course also different from the idea that any consistent unification has to closely resemble string/M theory or be essentially equivalent to it.

2. The comment that "If the scale of extra dimensions and the string tension scale are close to the Planck scale, then string theory looks remarkably like a 4d theory of quantum gravity coupled to matter — ordinary particle physics up to near the Planck scale, a handful of odd resonances that we'll never see, and then a spectrum of black hole states. ". This is more specific than the usual "Planck scale remote implies quantum gravity hard to observe" and raises a couple of interesting possibilities. One, that there will not be a lot more interaction between string theory and 4d quantum gravity questions beyond the picture of stringy microstates for (some) black holes. Another, that there may be a more general and robust class of theories, perhaps falling short of a full theory of quantum gravity, that generate the Standard Model + "handful of odd resonances" + "spectrum of black hole states". In that case the stringy calculations are a particular and somewhat elaborate realization of a more general pattern that one might as well find and study on its own.

42. **Emil Martinec**
December 1, 2015

random reader,
Let me clarify on your point (1), as you seem to be eager to extract a takeaway message somewhat at odds with the point of view I was intending to convey. IMO the formal consistency checks on string theory ARE overwhelming evidence that there is a theory combining quantum mechanics and gravity, whose solutions include the ones we have found through string perturbation theory and effective field theory — at least the ones where additional structure such as supersymmetry guarantees the existence of such vacua. Which is not to say that non-supersymmetric vacua do not exist; we can simply say less about them, because our calculational tools are more limited.

Nevertheless, being convinced of the existence of such a theory and having it in hand are two different things. We are in a rather unprecedented situation that the part of the theory we know consists of a set of methods to construct a collection of examples of solutions, around which we can describe perturbation theory in terms of strings and branes. The perturbative limits, together with a set of duality conjectures for which there is strong evidence, piece together a complete picture of the solution space (again in examples with enough supersymmetry) which is conjectural but in the best sense — having myriad checks, eg involving elaborate mathematical identities that one conjectures based on the duality hypothesis and then verifies by independent means. But we don't have in hand the organizing principle, an underlying idea such as the equivalence principle from which all these results flow as consequences, and which would enable us to formulate the theory beyond these various limits and especially in non-supersymmetric and time-dependent backgrounds.

As to whether this edifice is unique and inevitable, I am an optimist that time will tell, and that the answer is yes. For now let me mention the example of N=8 supergravity in 3+1 dimensions, whose perturbation theory was the subject of a recent discussion thread. There is no limit of string theory that decouples all the "extra stuff" of string theory — the branes and extra dimensions — and leaves only the 3+1 dimensional quantum field theory of N=8 supergravity. So that's great, you might say, maybe there's a theory without all this extra baggage, that doesn't involve strings and is perfectly consistent on its own. Here is where one needs to think carefully about the spectrum. N=8 supergravity has 28 gauge fields. There are black hole solutions in supergravity carrying electric and/or magnetic charges sourcing these gauge fields. The extremal limits of these solutions are in fact the objects we tried to throw away — the strings, branes, and Kaluza-Klein modes — moving within or wrapped around the extra dimensions; or bound states thereof. We discover this by considering the spectrum as a function of the 70 moduli of N=8 supergravity; in asymptotic limits of that moduli space, the black holes become perturbative objects in string theory. So if there is a consistent theory with only N=8 supergravity in 3+1d without all the extra structure of string theory, it has to come with a reason why ALL the charged black hole solutions, which seem perfectly benign and not all that different from the uncharged black hole solutions, in fact are excluded from the spectrum of the theory. If they are not, then we are led back to the full structure of string theory compactified on a torus. One could go further and think about why these objects indeed cannot be excluded, because they will be pair created in external fields with some small but finite probability, etc, but anyway perhaps enough said.

As for your point (2), indeed the stringy structure in the sort of situation I described naively seems confined to understanding the black hole spectrum, but that is by no means assured. It's the regime that's hardest to analyze, because there are no small dimensionless parameters in which to do perturbation theory. Because black holes teach us that local field theory breaks down at some level, there may be subtle nonlocal effects that influence low-energy physics in ways we do not currently understand and should be on the lookout for (but that's a hope, not an expectation).

I share the sentiment that current string technology is a bit of a Rube Goldberg device when it comes to explaining black hole structure, each example having different particulars but always yielding the same Bekenstein-Hawking area law in the end. This is precisely why people are searching for a more universal explanation. That doesn't mean strings and branes and extra dimensions will disappear from the final formulation, see the discussion of N=8 supergravity above. They will still be present in the spectrum of excitations in solutions that do have sufficiently large extra dimensions, or weak string coupling, etc. Peter is often complaining that people seem to have stopped doing string theory. I don't think it's true, rather I would say people are trying to absorb and abstract the lessons that string theory has taught us in the known examples, into some basic organizing principles from which the rest follows.

43. **Peter Woit**
December 1, 2015

"Peter is often complaining that people seem to have stopped doing string theory. "

I often note that string theorists have stopped doing string theory, but that's an observation not a complaint (I'm glad to see that they're doing something more promising). To the extent there's a complaint, it's that such people are often still insisting on centrality of the original speculation about strings that they started with, long after it has become clear that didn't work out well, with other ideas now the center of attention. Explicitly or not, there's often an argument being made that "string theory is the source of all good ideas", discouraging work on ideas that don't fit into the line of thinking that led from string theory to currently fashionable topics.

44. **random reader**
December 7, 2015

Thanks again to Prof Martinec for the long replies, which are clarifying and refreshingly detailed compared to most previous online discussions of these matters.

Regarding (1), the strength of consistency checks (versus actual construction of the nonperturbative theory) as evidence for a well-defined theory: the evidence actually looks, from this outsider (mathematician's) perspective, to be mixed, both in its strength and in where that evidence is pointing.

It is already the experience of the past 3 decades that stringy subjects that are mathematized, or have strong overlap with things that can be constructed as mathematics — things like mirror symmetry, geometric Langlands, CFT/TQFT, loop groups, integrable systems, matrix models, Kac-Moody algebras, deformation quantization (etc) — do have a lot of interrelations, and may well be moving toward a unification. Maybe a topological M-theory, or a "mathematicians' fragment of string theory". But this seems very far from string theory as physics relatable, in principle, to observation. Rather, there may be a unification all the mathematical discoveries and coincidences from string theory, but it is likely to be in a generic framework that does not have unique relation to weird critical dimensions like 10 or 26, or big supersymmetry algebras.

Quantization is an example that looks stringy perturbatively (deformation quantization a la Kontsevich) but does not show stringy characteristics non-perturbatively, as far as anyone knows. Mirror symmetry looked amazing, and continues to lead to amazing things, but the physicists' curve counts were wrong starting around genus 10.

None of these situations where the mathematical framework can be constructed, shows any sign of the very special features of the 10, 26 or 11 dimensional string/M (or SUSY) theories. It looks like the critical string theories are a non-generic singular point in "theory space" where several submanifolds intersect, with the multiple overconstrained descriptions leading to the extra relations (dualities). In such a picture, the fact that (at least perturbatively) there is an intersection at all is miraculous and needs to be explained, but it may also be that a generic part of the picture is enough for describing nature, and strings are too special, but we cannot see this until enough math is developed.

The appearance of string- or brane-like structures in N=8 SUGRA or other theories does not seem all that surprising. The scarcity of accessible methods (by the standards of earlier unifications) to unify GR and QFT suggests that the new ingredients in different theories that even come close to success are going to be strongly related to each other, otherwise there would have been more freedom to find the new stuff in the first place. This is true of strings and noncommutative geometry, and I have read claims that loop/Ashtekar quantum gravity models (of which I know nothing) also embed into string theory. At any rate, string theory seems to be the most universal known model, so it is expected that all the present contenders will look as though large parts of them can be built from strings, contain stringy structures, or both. But it can also be that once an idea comes along that explains how to get a mathematically rigorous unification (or whatever unification-like thing is the ultimate output), strings will appear as only a universal solution of a specific constraint not tied to what is needed for unification — a special/sporadic/symmetric point in a much larger universe of consistent usable theories that do not all reduce to strings. Sure, if structures such as extremal black holes have a stringy description then whatever else describes them will also have a strong overlap with the string description. But if the "only game in town" argument is really only the "currently most universal object in the category of unification candidate-theories" argument, then finding a principle describing what the theory is about may also be exactly the thing that eventually renders the theory superfluous.

Of course, strings can be unique and consistent because of some universality phenomenon where some large class of underlying models looks like strings as some parameters or number of degrees of freedom get large. But in that case one could model quantum gravity by those underlying degrees of freedom, too.

In all, the quasi-mathematical "consistency checks and coincidences are unbelievably compelling" seems very strong, but not so much as an argument for string theory. The same evidence can point just as compellingly in one or more other directions that are surely related, but are not necessarily an indication that string/M theory will be the lesson to emerge from the consistent mathematics as it is developed. It seems to me that the evidence for the lesson being something non-stringy is stronger, since strings are not fitting any known pattern of what consistent (mathematical) theories end up looking like, and strings' subtheories that are mathematical have not provided any indication that this historical pattern is wrong.

45. **Peter Woit**
December 7, 2015

random reader,
Many thanks for your very thoughtful and well-informed take on this subject. This is the sort of discussion I'd love to see a lot more of. Unfortunately this is an extremely complex subject, with most mathematicians involved not knowing much about the issues of how the objects under study connect (or don't) to a hoped-for unified theory, and most physicists involved not knowing how the objects connect (or don't) to the rest of mathematics.

One of my original main reasons for skepticism about the proposed 1984 string theory unification proposal was that the direction one needed to go to connect string theory to the real world was kind of orthogonal to the directions in which I could see beautiful and deep connections to the rest of mathematics. In more recent years, this has become a much more complex topic, with different sorts of connections to possible unified theories via connections to 4d qfts coming into play. Looking at this whole subject for clues as to what is fruitful and what isn't, without trying to fit things into the original speculative framework of 10 dimensions and strings, seems to me a very valuable thing to do, although few are equipped to do so at the moment.

Super and Great Colliders

November 30, 2015
Categories: Book Reviews, Experimental HEP News

I've recently finished reading two new books on huge collider projects, which make an interesting contrast.

The first is From the Great Wall to the Great Collider, by Steve Nadis and Shing-Tung Yau. It's a very well-informed and topical book, a bit of a political document, designed to make the case for a Chinese "Great Collider". This is a proposed machine of up to 100km in circumference, that would operate first as an electron-positron collider, designed to be a "Higgs factory", allowing precision study of the Higgs. In a second stage the same tunnel would be used for a proton-proton machine with collision energies up to 100 TeV. This would be designed to explore the energy range above a TeV, in much the same way as the LHC, but with seven times the energy, thus a much higher energy reach. This energy would also allow study of Higgs self-interactions.

The Nadis-Yau book is an unusual document in many ways. Yau is a great geometer, but a main concern of the book is something completely different, the question of how one might construct such a huge physics and engineering project. There is a great deal of information in the book about the history and current state of experimental HEP, but from an unusual angle, that of the many Chinese contributions to the subject. I've read many histories of HEP, but learned a lot of new things from this one, with its very different emphasis.

This is a short, rather than encyclopedic, book, with about 130 pages of text. It functions well in explaining the case for a large new collider to anyone interested, but has a distinct focus on arguments for the proposal to do this in China. The Chinese government and people in coming years will be deciding whether to go ahead with this, and this book is the perfect place for them to read a serious account of what this proposal is and why it deserves to be taken seriously.

The current state of affairs is that an initial conceptual design has been completed recently, which was reported here. This gave rise to some mistaken reports like this one that the Chinese government had given its approval to the project. There's still quite a ways to go before that happens, with a final conceptual design not due until next year, and even if there is a go-ahead, construction only starting in 2020-25.

For a detailed look at the physics to be done by such a collider, see this new review article. I was interested to see (page 32) that the previous description by one of the authors of the current situation as leading to only two possibilities ("natural" SUSY or some such, or the multiverse and the end of hope for explaining things) has been expanded to now include a more interesting third possibility: "correlation between the physics of the deep UV and IR".

Just after finishing the Nadis-Yau book, I got a copy of a new history of the SSC project, Tunnel Visions, by Riordan, Hoddeson and Kolb. This book has been in the works for a long time, with the authors starting to gather material back in the 80s, before the project was cancelled in 1993. I've been hearing about the book for quite a while, glad to see that it has finally appeared.

The cancellation of the SSC had a disastrous effect on the US experimental HEP program, moving the center of research conclusively to CERN and its LHC project. A central concern of any book of this kind has to be the "what went wrong?" question. The conclusions drawn are similar to ones I remember often hearing back then in the wake of the disaster: the SSC was a juicy target for a Congress intent on budget-cutting, easily portrayed as out of control (its budget kept increasing from $3 billion early on, to maybe $12 billion at the end), with little support from non-Texas representatives. In some sense the surprising part of the story is that the project got as far as it did before being terminated by an overwhelming Congressional vote.

One part of the story I had never understood was that as the SSC budget expanded it was coming into direct conflict with the plan to keep funding the other HEP labs (Fermilab, SLAC, Cornell, Brookhaven), and that was part of the story of the politics of this within the scientific community. I also hadn't appreciated the way the challenges of a project of this scale required bringing in companies and other parts of the US military-industrial complex, making it take on some of the aspects of a large defense spending project. A major topic of the book is that of the problematic interaction between this and the standard ways that physicists were used to doing business.

Unlike Nadis-Yau, *Tunnel Visions* is more of an academic book, with notes and references to a huge number of extensive interviews making up a large part of the text. It's not at all an inspirational story, nor is there all that much physics discussed. At the same time, it's the definitive work on a crucial part of the history of high energy physics in the US. One group of people who should definitely be reading it are those planning the Chinese project. Some of the difficulties they will face if they go ahead will be similar: the SSC was an 87km ring, of similar scale to the new proposal. That this almost got off the ground 20 years ago here in the US is a good argument that it is something that could be pulled off in China over the next 20 years if they want to do it.

Based on the fact that the SSC might have worked with more international support, the authors end with the conclusion

> Despite the added difficulty of organizing and managing them, pure-science projects at the multibillion-dollar scale should henceforth be attempted only as international enterprises involving interested nations from the outset as essentially equal partners. Nations that attempt to go it alone on such immense projects are probably doomed to failure like the Superconducting Super Collider.

The Chinese proposal is still in its infancy, but there's reason to expect it might be a "go it alone" project. Given the way the US budget operates, at this point no country is likely to look to the US as a reliable source of sizable funding. CERN has its own proposal for a 100 TeV collider, but it seems hard to believe that both projects will go ahead, although also hard to see the Europeans agree to give up energy frontier physics to China. Many of the lessons of the SSC funding debacle are rather specific to the US and the way budgets are done here. I have no idea what the considerations in China are for projects like this, I guess we'll start to find out in coming years.

   November 30, 2015

   The SSC was a classic "Plan B" approach, as described by Freeman Dyson, that overwhelmed the ecology of the field (e.g. destroying funding for the rest of the accelerator community). It is also one of the few instances I know of where the sunk cost fallacy was not allowed to operate in the public sector ("we've already spent X on it, we can't give up now [even though the budget keeps exploding and the completion horizon keeps receding]).

2. **Lamont**
   November 30, 2015

   As an incredibly naive first-order guess, doesn't it seem fairly likely that China could pull it off as a "go it alone" project? All they'd have to do is sell themselves the idea that it would be a point of national pride to do what America was not capable of doing…

   November 30, 2015

I'm glad to see that the Riordan et al. book is out. I'm very interested in the story of the SSC. I feel that the usual story that the SSC was killed by shortsighted politicians is greatly oversimplified. It was clearly a mistake to try a giant leap forward at an entirely new laboratory while there was a healthy program going at Fermilab (and SLAC).

It also not clear to me whether the SSC really would have worked as advertised (this is obviously impossible to know, and I am certainly not an expert). The LHC was a natural evolution of earlier machines, and had significant teething problems. Also, in accounts of the Higgs discovery it is always emphasized how important modern detector technology and computing was in making this possible. I'm not sure that the Higgs could have been discovered almost 20 years ago.

4. **TS**
December 1, 2015

In terms of scale, ITER is probably the project to compare to. It had its share of organisational trouble, many of which could be traced to a structure where ITER itself has (had?) no funds, but for all I can tell, it seems to be moving forward steadily, in spite of cost overruns, delays and all the usual troubles.

Yet, the comparison falls short in a very important way: ITER is applied science insofar as its aim is — to phrase it boldly — to replace a multi-billion dollar industry, namely that of electricity production. So the motivations for it and the case to be made for it are entirely different. There is also the question whether ITER really is the only game in town, like the chinese accelerator (or the FCC) would be. Wendelstein 7X is supposed to see plasma in 2015.

5. **Matt**
December 1, 2015

Anyone who followed the news or has seen the pictures of impenetrable smog in Beijing from the last few days probably realizes that China's least problem is the construction of a new multi-billion dollar particle collider. With an economy in severe trouble and an environment at the brink of collapse I strongly doubt if Chinese politics will ponder about paying for a new toy for particle physicists. Sometimes I feel like the HEP community is like the band aboard the Titanic, keep fiddling away while the ship is sinking. But hey, who knows?

6. **jd**
December 1, 2015

The most recent Science magazine (end of November) indicates that the timeline for ITER will slip 6 years with a resulting 2B increase in cost. Best not to compare any future accelerator project to fusion.

7. **iHEP**
December 1, 2015

Matt: A lot of Chinese strategy is based on looking good in front of the world and "catching up" with the US. China also has some fine scientists. Throw in a quasi-dictatorial milieu and I am not surprised at all that they would pick particle accelerators over environmental pollution mitigation.

8. **Dave Miller in Sacramento**
December 1, 2015

Peter,

I have a fondness for e+/e- colliders, having been involved in some of the early work on the PEP machine at SLAC (I wrote part of the software to model the drift chambers, before I went into theory): this seems to me the cleanest way to study details of the Higgs, and wringing out all the details of the Higgs seems to me the logical next step experimentally.

Do you agree? And, can you tell us the cost estimate for the first-stage (e+/e- collisions) of the "Big Collider"?

On the Riordan book: do they go into details about the physicists who managed the SSC project? I knew the two top guys, but was never clear whether they were part of the problem or just in the wrong place at the wrong time.

You wrote:
>One part of the story I had never understood was that as the SSC budget expanded it was coming into direct conflict with the plan to keep funding the other HEP labs (Fermilab, SLAC, Cornell, Brookhaven), and that was part of the story of the politics of this within the scientific community.

A friend of mine with ties in DC told me at the time that one of the top guys from SLAC was powwowing with Senate staffers around the time the SSC was cancelled: my friend, a former HEP experimentalist who had gone into defense work, was curious about a possible connection but had no inside details as to what was discussed. Does the book go into this? Were people from the four other labs out to get the SSC or was it just that their support was lukewarm or that they merely expressed concern for their own budgets?

Too bad that HEP has become a bit of a political circus, but it is interesting for those of us with a background in the field.

All the best,

Dave

9. **Peter Woit**
December 1, 2015

Dave,

I do think there's a good case that an e+/e- machine of sufficient energy to be a "Higgs factory" would be useful to study many aspects of the Higgs. It's not clear to me though whether you could go to high enough energies this way to study the Higgs self-interaction, which may be the most promising place for something new.

As far as I know, at this point no one is talking about cost estimates for these large colliders, whether in China, at CERN or elsewhere. For one thing, it depends a lot on how you count, but the numbers I would guess will be very large, $10 billion and up.

There's a lot in the book about the people running the project, including some indication of a feeling that it was a mistake that Maury Tigner, the head of the original design team for the SSC, was shunted aside in favor of Roy Schwitters, who became the director. There's some argument that the fact that Schwitters was not an accelerator physicist, and also not experienced dealing with a project of this scale, were both sources of problems.

I think the problem with the other labs was that they needed to fund their own futures. Doing this at the same time that the SSC spending was ramping up made the budget situation for non-HEP physics much tighter and didn't help with support in the wider physics community. Once discussions started about the cancellation, I'm sure the other labs were closely involved in figuring out how to protect themselves, as well as finding something to do with the large number of people who had moved to the SSC project, and all of a sudden were out of a job.

10. **dsatkas**
December 2, 2015

Correct me if i'm wrong but the reason the LHC uses baryons (protons, lead etc.) instead of leptons (electrons-positrons etc.) is that it's circular and there is much more radiation emitted with lighter particles (i think it's m^-4). So if that is correct how will the chinese use electrons-positrons in 100 km facility efficiently?

11. **Peter Woit**
December 2, 2015

dsatkas,
The point is that LEP (in the LHC ring), was just a bit too low in energy (209 GeV) to be able to study the Higgs. Now that we know what the mass is, it turns out you don't have to go that much higher in energy to do so. Even with a much bigger ring, the plan is to go just to 240-250 GeV, but that's enough.

12. **srp**
December 2, 2015

In more-hopeful news, there's this:

http://www.symmetrymagazine.org/article/shrinking-the-accelerator

Probably worth spending maybe $100 million over the next few years to tell if there is or is not a better way going forward.

13. **Curious Mayhem**
December 28, 2015

The biggest failure of the SSC was not getting international involvement earlier on. The Japanese were riding high at that point, toward the end of the "bubble economy," and certainly could have spared some money for it. (In 1991, they basically wrote a check to pay for a large part of the 1990 Persian Gulf war to eject Saddam from Iraq.) When the SSC was first proposed in the mid-80s, the project was sold at the political level with a 110%-Americanism — with allusions to Apollo and the Manhattan Project — that was overdone and imposed a cost a few years later, when it became clear that foreign money would be needed. Absurd claims were also made by some political figures; for example, the SSC would cure male pattern baldness (seriously!), which I'm sure made it more attractive to certain politicians.

The SSC was protected until 1993 by the alliance between Bush Sr., who was from Texas, and the Louisiana congressional delegation, which was rewarded with a piece of the LIGO experiment, I believe. But that same period was dominated by deficit politics and the 1990-91 recession. It led Bush Sr. to go back on his promise to not raise taxes and to Perot's 1992 presidential campaign, in which the interrelated federal and trade deficits were big issues. After Clinton became president in 1993, the SSC rapidly lost its political protection and became a target for budget cutting; it was canceled in the fall of 1993, if memory serves me. There were a couple earlier attempts to kill it, but the Bush Sr.-Texas-LA alliance saved it each time.

The cost overruns were also significant and dramatically stimulated strong reaction from other scientists in other fields against the SSC. No one may remember him now, but the late Rustum Roy of Penn State led the charge against the SSC for the condensed matter folks and was ecstatic when it was canceled; he believed that high-energy physics was too large of the US science budget and produced an oversupply of PhDs.

There's a 2013 Scientific American article about the SSC that's worth reading. I can't vouch for the accuracy of the quotes; e.g., I don't remember anyone proposing "Gippertron" as a name. But "Desertron" was certainly a contender.

I visited the SSC remains in 1998, and it was a sad sight (or site). Many of us no longer in high-energy physics know that the SSC cancellation was a big reason.

—–

The case against e+/e- is straightforward. For rings, the radiation goes inversely with the mass to the 4th power (see comment above), and that certainly makes hadron colliders more attractive, in the circular case, for energies higher than ~ 10 GeV. That's one reason why SLAC's collider for the Z0 (about 90 GeV) was a linear collider, with partial circular arcs at the end, and not circular. The LEP energy was limited to ~ 200 GeV for the same reason. This wasn't an issue for LEP I, at the Z0, but became a noticeable limitation for LEP II, just above the W+W- pair threshold.

The other problem with e+/e=, not mentioned above that I can see, has to do with incoming fluxes and cross-sections. With proper focusing, the current density from e+/e- is smaller than for hadrons. Then the cross sections kill your statistics: for point-like particles, they fall like 1/s, as opposed to hadronic cross sections that rise like s. This latter problem is an issue for either linear or circular colliders.

Not that I'm prejudiced against e+/e-. I did my doctoral thesis at such a collider and spent a couple years on an ILC (International Linear Collider) task force in the 1990s. The clean-ness of e+/e- was a compelling argument in favor. See various Web articles about the ILC, which has been floating around in proposal form for about 25 years.

Next Week’s Hype

December 2, 2015
Categories: Favorite Old Posts, This Week's Hype, Uncategorized

Next week there will be a workshop in Munich with the title Why Trust a Theory? Reconsidering Scientific Methodology in Light of Modern Physics. It’s organized by Richard Dawid, to discuss his ideas about “non-empirical theory confirmation”, developed to defend string theory research against accusations that its failure to make any testable predictions about anything make it a failure as a research program.

I guess the idea of such a workshop is to bring together string theory proponents and critics to sort things out, but looking at the program and talk abstracts, this doesn’t look promising, with the central issues to be evaded, and speakers likely to just talk past each other.

While the workshop title refers to “Modern Physics” in general, the talks are mostly focused on one very narrow part of the subject: quantum gravity. String theory is supposed to be something much more than a quantum gravity theory, explaining the Standard Model and low energy physics. This has been a complete failure, and the plan at the workshop seems to be to deal with this elephant in the room by ignoring it, or worse, claiming it isn’t there.

From the talk abstracts, about the only person discussing particle physics will be Gordon Kane (Quevedo may mention it, although his main interest is cosmology). Kane will be claiming that string theory makes testable predictions about particle physics, ones about to be tested. The problem is that he has been making the same claims for thirty years, arguing back in the 90s in the pages of Physics Today and a book that string theory would be tested at LEP and the Tevatron (by finding superpartners). As his predictions have been conclusively falsified, he just refuses to acknowledge this and starts advertising new ones. Perhaps the most outrageous case of this is his latest book (discussed here), which is a reissue of the old one, with falsified predictions simply deleted and replaced, without any acknowledgement of what happened. I don’t think this behavior raises any philosophical issues about theory confirmation, just the sociological issue of why the physics community tolerates this, or why he’s the one person invited to this workshop to address the largest problem of the subject.

Another central problem here is the hype problem. If you give up on testability, and allow theory confirmation based on claims that “my theory is just better” by some ill-defined metric, you open up the obvious problem of how to deal with people’s natural human inclination to praise the wonderful characteristics of their intellectual children. At the workshop, Joe Polchinski’s talk is entitled “String Theory to the Rescue”. I see nothing in the program about any planned examination of the significant string theory hype problem, or even any acknowledgement that it exists.

I’m actually in a way more sympathetic than most people to the idea that “non-empirical” evaluation of a theory is an important and worthwhile topic. Fundamental physics theory is facing a huge problem due to the overwhelming success of the Standard Model and the increasing difficulty of exploring higher energy scales. If it is to continue to make progress there is a real need to do a better job of evaluating theoretical ideas without help from experiment. There is a group of scientists who have a lot of experience with this problem, and have a well-developed culture designed to deal with it. They’re called “mathematicians”. Despite the fact that this workshop is hosted by the Munich Center for Mathematical Philosophy, the organizers don’t seem to have thought it worthwhile to invite any mathematicians or mathematical physicists to participate, missing out on a perspective that would be quite valuable.

Update: It’s now “this week”, not “next week”. Some tweeting from the conference going on, you can try the hashtag #WhyTrustATheory. Massimo Pigliucci comments from the Q and A session about a problem with this kind of thing: some people “very very much like the sound of their own damn voice”. I hear that David Gross claimed to have 20 possible observations that would invalidate string theory, but didn’t say what they were.

Update: Massimo Pigliucci is blogging a detailed account of the conference, see here (he’s also a speaker, slides here).

Update: I don’t think I’d noticed before that Lee Smolin has a very much to the point review of the Dawid book here.

   December 2, 2015

   > If it is to continue to make progress there is a real need to do a better job of evaluating theoretical ideas without help from experiment.

   I would go in the opposite direction. What about really scrutinising the theories we already have, against the data we already have. The LHC is producing and has produced presumably petabytes of data. I presume Fermilab’s results and many others are also on file. Who among theorists is looking at this data, testing it against newer theories? Has all value really been squeezed out of these? Given the plethora of untested theories, my guess is that theorists really aren’t in the habit of looking, and/or experimenters aren’t in the habit of showing.

   Could a lot of overly speculative theories be avoided if the speaker was required to say “I checked this against XYZ data sets and they didn’t immediately invalidate most of it”.

2. **Peter Woit**
   December 2, 2015

   RandomPaddy,

   As far as I can tell, phenomenological theorists and the experimentalists themselves are already trying the best they can to do what you suggest. Every HEP experimentalist I’ve talked to tells me its their fervent hope to discover something that disagrees with the Standard Model and that this is the main focus of their research.

   The problem with speculative theories is not that no one is trying to confront them with experiment, but that they’re too ill-defined to do so, or carefully constructed to evade the possibility of such a confrontation.

3. **Jim Baggott**
   December 2, 2015

   Peter,
   I don’t think it’s quite true to imply that Dawid has organised this conference on his own. I believe he’s also had inputs from George Ellis and Joe Silk, the authors of the short note in Nature last December which triggered the decision to hold this conference. That was a strongly-worded piece (aside from calling for a conference, they suggested that journal editors and publishers assign speculative work to research categories other than ‘physics’ and that ‘the domination of some physics departments and institutes by such activities should be rethought’).
   I think it’s highly likely that the protagonists in this debate will tend to talk past each other, but Ellis and Silk will be joined by Carlo Rovelli, Massimo Pigliucci, Helge Kragh and Sabine Hossenfelder, all of whom have been critical of the string theory enterprise, the community’s tendency to hype and distort its promise and the threat it

poses to the integrity of the scientific method and the public understanding of science.
I think there will be plenty of opportunity for argument, at least.
I don't have high expectations, but I'm hoping that the conference will help to foster a better understanding of the role that the philosophy of science can play in all this. This should be all about seeking to define an acceptable approach to theory development and selection in high-energy physics and cosmology, against the background of a relatively slow evolution of experimental and observational science (satellites take decades to plan, build and put into orbit; colliders take decades to plan, build and put into operation). I'm sure that much could indeed be learned from mathematicians, as you suggest, but it may be that the first step is get some kind of agreement that there is a problem here, before working out how we might try to resolve it.

4. **Foster Boondoggle**
December 2, 2015

"There is a group of scientists who have a lot of experience with this problem, and have a well-developed culture designed to deal with it. They're called "mathematicians"."

Haha! Nice try. Back when I was in grad school, the mathematicians were still trying to prove that interacting quantum field theory exists. W. Arveson, Berkeley math prof 17 years ago: "Here is a good problem for 21st century mathematicians: show that this program for quantizing nonlinear PDEs like [phi^4 theory] can be carried out in four spacetime dimensions. In other words, show that Quantum Field Theory exists in rigorous mathematical terms." (Have they succeeded yet? Does QED, by far the most accurately confirmed physical theory ever, exist?)

If we wait for the mathematicians to baptize physical theories as acceptable we'll be waiting a very long time. It took them 25 years to figure out how to formalize something as simple as the Dirac delta function.

Anyway, aren't there a bunch of mathematicians out there who absolutely adore string theory? As an ex-physicist, my difficulty with string theory was always that it seemed to be motivated mainly by the beauty of the math (and its offer of a way out of some of the more formal difficulties of field theory) – much closer stylistically to Einstein than to Feynman. (Think of Einstein's quote about how he would have reacted if the eclipse observations hadn't borne out his theory – "Then I would have felt sorry for the dear Lord. The theory is correct." vs. the Feynman quote about not being able to fool nature.) I don't mean that as a criticism of the field – it's more about my own limitations – but looking to mathematicians to bail fundamental physics out of its current difficulties seems a bit perverse.

5. **Bee**
December 2, 2015

I will do my best to be the voice of reason 😉

6. **Peter Woit**
December 2, 2015

Thanks Jim,
I do see that string theory critics will be represented, but they're mostly ones concerned about other issues than the ones I mentioned (with Rovelli somewhat of an exception, although not an HEP theorist, and Sabine well aware of the hype problem). The Ellis/Silk challenge to Dawid was mainly on the multiverse front, and there I'm interested to see that it's the multiverse proponents who don't seem to be well represented.

Foster Boondoggle,
My point was not about mathematical physics and whether it's the answer to any problems in physics, rather that mathematicians understand well the issues that arise when you try and make progress having only things like consistency as your guide.

Bee,
Good luck!

7. **Jon Forrest**
December 2, 2015

"If you give up on testability, and allow theory confirmation based on claims that "my theory is just better" by some ill-defined metric, you open up the obvious problem of how to deal with people's natural human inclination to praise the wonderful characteristics of their intellectual children."

It's been a long time, and I'm not sure what's happened since, but in the early 1970s the issue you mention was a problem in the field of Linguistics, specifically with the theories of generative syntax and generative semantics.

8. **Douglas Natelson**
December 2, 2015

After 16 years as a professor I still bristle at the implication that the only "real" modern physics out there is high energy physics.

9. **Low Math, Meekly Interacting**
December 2, 2015

What am I missing about Dr. Kane? I can think of no equivalent in another scientific discipline. He'd maybe have to be a paleoanthropologist who not only helped convince the majority of the field that Sasquatch exists, but also convinced them that the only plausible explanation for not bagging a Sasquatch by now is that the beast has evolved, through a complex process of phyletic dwarfism, into a nanobacterium-sized extremophilic autotroph that lives in old lava tubes 5km below the Cascade Range. Until core samples reveal no such creature, in which case the estimate is revised to 5.5 km below the Cascades.

I'm not really trying to be insulting, I'm genuinely mystified by this character.

10. **Peter Woit**
December 2, 2015

LMMI,
I don't think he's convincing anyone of this, with very few people in the field now taking his claims seriously. The real question is why he's given a public forum to make them. I think that's clearly because he's making a case for string theory. There are different standards for claims about string theory than for claims about other ideas…

11. **Low Math, Meekly Interacting**
December 2, 2015

It's a pretty darn weird thing to observe, whatever the standards.

I should add I'm using "Sasquatch" as an analogy for the kind of SUSY that "naturally" solves the hierarchy problem and gives us dark matter, etc., i.e. the kind of beast only cryptozoologists take seriously these days.

12. **Martin S.**
December 2, 2015

@Peter,
as a mathematician and having an experience of talks with other mathematicians about what directions of study are reasonable, the way according to common mathematicians would be: who is higher in hierarchy or generally in position of power.

PS Some mathematicians enjoy to pretend that their work has connections to empirical sciences, so that they can get more funding. It may explain why some mathematicians love the string theory…

@Jon Forrest,
decades ago I had seen a lot of ridiculing on linguistics. By now it seems that they solved a lot of issues by the big-data approach. If only particle physicists were able to do it alike.

13. **Shantanu**
December 2, 2015

Peter, I am also going to attend this meeting. If you have specific questions to specific speakers, email me.
shantanu

14. **Peter Woit**
December 2, 2015

Thanks Shantanu, I look forward to hearing what you think of the event. By the way, I don't have an e-mail address for you that works…

15. **vmarko**
December 3, 2015

Peter,

I'll be attending the conference as well (and my e-mail address should work, if you feel like compiling a list of questions… 🙂).

Regarding Kane's book, my feeling is that few of the actual experts in the field have actually bothered to read it, let alone both issues. So they are probably unaware of his "outrageous" behavior, or are reluctant to criticize him without investing some time to seriously read and compare what he said in the two issues of the book. For one, I am in that crowd, and I certainly have better things to do than read two almost-identical books on string theory hype.

Regarding mathematicians, I agree with you that they are underrepresented here, and it could be better. But on the other hand, my impression (based on working with and talking to mathematicians) is that they tend to shrug at any type of problem which cannot be formulated as a theorem. Or at least they are at a loss what to do with such a problem. Granted, I may have talked to wrong people or lousy mathematicians, but as far as I have seen, philosophers are much more adept to providing a clear formulation of a problem, especially when it is too vague to make rigorous sense.

Best, 🙂
Marko

16. **Jesper**
December 3, 2015

I agree very much with the notion that we can learn from mathematicians on how to evaluate ideas and structures, which are not directly empirically verifiable, and also that mathematicians should be involved in the development of such structures. Collaborations of this kind do exist. One example is Chamseddine & Connes and there are others 'out there'.

17. **andrew**
December 3, 2015

I didn't find Dawid's work particularly convincing. A question for the conference (or anyone interested): what's the relationship between non-empirical theory confirmation (NETC) and Bayesian confirmation theory (BCT)?

It struck me somewhat that many of the NETC arguments could be interpreted as reasons for having a high prior belief in a particular theory in BCT, e.g. few or no viable alternative theories. The "scientific" aspect of BCT – updating a prior with experimental data – is of course absent in non-empirical confirmation.

Also, NECT seems to invoke induction – we're told the fact that something qualitatively similar to a theory worked in the past helps to confirm that theory. How does this overcome Hume's problem of induction (w/o BCT)?

18. **Peter Woit**
December 3, 2015

vmarko,
I doubt experts paid attention to the books, but they've surely aware of his claims in papers and talks that he can use string theory to make predictions, as well as the fact that these predictions keep getting falsified, and he keeps making new ones.

I don't think mathematicians will only discuss rigorous theorems. It is true that their reaction to an attempt to discuss with them a topic in current quantum gravity research would likely be "I'm not understanding, could you more precisely explain your assumptions and what the question is you are trying to address?" Wouldn't hurt most physicists to try and engage in a discussion like this.

I hope to hear what you think of the conference, don't have a lot of questions for the speakers myself. For better or worse, I think I have a pretty good idea how most of them would respond.

19. **vmarko**
December 3, 2015

Peter,

Whenever I have tried to discuss quantum gravity with mathematicians, they always reacted in precisely the way you described.

But then if I try to engage them in a discussion, I end up realizing that they don't have a good grasp on QFT, in particular the renormalization procedure. Once I even gave a three-lecture course on renormalization, tailored to mathematicians who do not want to invest a lot of time into learning QFT in all gory detail (a writeup of the resulting lecture notes is here). I don't know if I did a good job or not, but I became painfully aware that even discussing QFT is way too remote from what mathematicians are used to, and we never reached the point where I could even formulate the problem of QG. And this experience was with the audience whose research is mostly related to TQFT, category theory and algebraic topology, which are arguably the areas of math closest to QG.

My point is that mathematicians live in a world of fully rigorous math (like TQFT), which is quite removed from what physicists deal with (QFT), already at the point of terminology, let alone any further common ground. They do tend to have good will and motivation to engage in QG, but when faced with a learning curve that involves a lot of things which are nowhere near as rigorous compared to the things they are used to, very few actually invest enough effort to swallow all that non-rigorous stuff in order to understand the basic concepts that QG deals with.

Note that I am not trying to criticize them, but only to point out that there is a huge divide in the background knowledge and a way of thinking of a mathematician versus a physicist. It's just a very big hurdle to cross, in both directions. So engaging them in any discussion related to QG usually stops at the point of that divide, unfortunately.

Best, 🙂
Marko

20. **Peter Woit**
December 3, 2015

vmarko,
What I was thinking of more was some of the discussion of new ideas of quantum gravity, where statements are being made like "ER=EPR". Maybe my mind has been deformed from too long in math departments, but my reaction to a lot of current discussion about quantum gravity is that I can't follow it not because there is some technical thing I don't know, but because it's very hard to figure out what the precise claim being made is. There's some web of conjectures being invoked, but it's often hard to understand what's being assumed about what.

21. **vmarko**
December 3, 2015

Peter,

Oh, now I understand what you mean, and I completely agree. Mathematicians are experts on stating explicitly all the assumptions of a certain claim or conjecture, and can provide nontrivial input into what is consistent with what, and how various conjectures do or do not fit together. That would certainly bring a lot more clarity into QG physics, and would certainly be a very good thing.

Best, 🙂
Marko

22. **Low Math, Meekly Interacting**
December 3, 2015

The histories I've read seem to indicate that mathematicians were helpful to Einstein because he was asking precisely the right kinds of questions. The equivalence principle he relied upon made the problem to be solved very clear. I look at current debates about, say, the firewall paradox, and there appears to be a distinct lack of clarity, namely because there is a lack of consensus that a "paradox" follows from what is understood about black hole physics. It could either the most important insight of the day, or an irrelevance built on faulty premises. It's just an example, but the field of quantum gravity apparently has a disturbingly large number of arguments about basic premises, even among adherents of the same theoretical framework. Is it reasonable to expect mathematicians could help if QG physicists aren't asking the right questions?

23. **Peter Woit**
December 3, 2015

LMMI,
The point I'm trying to make (this is much like my comment to Foster Boondoggle) is that the culture of mathematicians might be helpful here, as opposed to the subject itself (which may or may not contain helpful knowledge). I think you're right that a big problem is "distinct lack of clarity", and mathematicians are trained to recognize that problem and treat it as one of central importance. Physics has a different culture, with doing an explicit calculation more at the center of things, and an inclination that it doesn't matter much if the logic of the calculation is murky, since that's something that can be cleaned up later if the result of the calculation is interesting and reproduces the real world. If your calculations can't be checked against the real world, and all you have to go by is consistency, my argument is that you might have some things to learn from the way mathematicians operate.

24. **jim**
December 4, 2015

Non-empirical physics really sounds like an oxymoron. Why bother? I was under the impression that the purpose of physical science was to explain the reality that we can see and examine. Perhaps if theoretical physics can come up with an system which specifically predicts the Standard Model and gravity and within which there is a proof that no other such theory can exist we could be happy without empirical evidence. This doesn't seem likely. My concern is that the exuberance of theoretical imagination unchecked by any empirical examination over the last 35 years is exactly what has left us with the impasse of string theory/KKLT/landscape stuff where we now stand. Why should the application of more mathematical rigour and surety of internal consistency to any fervent ideas that may be forthcoming really take us any closer to understanding reality? This doesn't seem to have happened yet.

25. **sm**
December 4, 2015

vmarko:
In the early 90s I was involved in a similar effort with our maths department. A mathematician (a collaborator of Shelah – if I had known of the latter then I should have been warned!) in 10 lectures derived Weiner measure because we all knew the common lore of its equivalence to Feynman's path integral. In return I in 5 lectures was able to derive (using this term flippantly) in the usual physics manner not only Feynman's PI for the non relativistic case, but also the PI for the Dirac equation (the locally susy version with its grassman variables etc) to bout. All this revealed to me the chasm between physics and the 'equivalent maths'. For the first time I was exposed to a mass of new (to me then and probably even to most field theorists today – unless they are genning up to become financial engineers!) ideas such as sigma algebras,

measure theory, filtered probability spaces, martingales, large deviation theory … the list goes on, all needed just to define and compute Feynman's PI (more accurately its imaginary time version as I think I remember reading that the naive Feynman's real time version is known not to exist mathematically, even for non relativistic quantum mechanics – a sobering thought). If all this infrastructure is required just to properly formulate plain old non-relativistic QM, what hope do we have that mathematicians will help with QFT in the near term, let alone with 'string theory'? A highlight (if that is the correct word!) of my lectures was to justify why all my paths were differentiable (so the action could be computed for each path) when previously the mathematician had shown with complete rigour that with probability unity all paths contributing were continuous but nowhere differentiable! At that point I mumbled something about the renormalisation group!

26. **Urs Schreiber**
December 4, 2015

sm, for that reason one eventually needs a formalization of physics that captures the core mathematical structures of relevance "synthetically", i.e. without breaking them up into a heap of constituents, but capturing the intended properties right away. There was a talk about such an system at IHES last week. A video recording is linked to here.

27. **Interested Layperson-Not a Player**
December 4, 2015

The January 2016 issue of Astronomy Magazine has a one-page article that is very pro-multiverse. You are mentioned in the article, entitled "Not science fiction" and subtitled "Three cheers for multiverses!". The author, Jeff Hester, writes that if you have read his previous columns you know falsifiability is a big deal for him (I have not read all of his previous columns). In his current column he asks first if we can observe multiverses. He goes on to say that that is the wrong question. He says

"the right question is whether theories that rely on multiverses are more or less successful than theories that do not. Putting it differently, the statement 'multiverse theories will make more interesting and correct predictions than theories without multiverses' is itself a testable prediction."

He mentions David Deutsch's work on quantum information and that Deutsch himself says his work depends on Hugh Everitt's "many-worlds interpretation" of quantum mechanics.

If I have violated any copyright issues by quoting the author then just delete my post, but if you can check out his article and offer any comment here please do. On to the other hand you may feel it's just not worth the time responding to every popup supporting multiverses.

28. **Chris W.**
December 4, 2015

LMMI: *Exactly*. That is very much the point of Chern's talk for an Einstein Centennial conference (1981) that I mentioned in a comment on another recent post of Peter's. I got the impression that mathematicians are, for the most part, not particularly interested in groping their way to a clear formulation of a problem, when there are already plenty of clearly stated problems waiting to be investigated (and which show promise of being non-trivial and mathematically fruitful). Einstein was motivated to do this because he felt *as a physicist* that it was important and necessary. Most mathematicians would be content to say: "Good luck with that. Let me know how it turns out, and if so, whether you would like to consult me about anything."

I think there is a lot of self-selection working against us here. If a mathematician had the cast of mind to take a serious interest in these problems at these difficult early stages then they probably wouldn't be in a math department, or they would have already done some serious research bearing on it, despite being professionally identified as a mathematician. Such people are pretty rare, or at least their ideas on physics haven't been seen as worthy of attention.

29. **Couvent**
December 4, 2015

I'm a bit suspicious about the way the relation between physics and mathematics is described here. I spent a brief moment in a Theoretical Physics department and some parts of had a close relationship with the mathematicians at the university. This was certainly true for the Statistical Physics group. Some mathematicians even came to that group to get their PHD (an went back to the Mathematics department, got tenure etc.)

Isn't the problem you are talking about here mainly typical for theoretical HEP, String Theory etc.? My pet theory is that renormalisation is the root cause of it. Mathematically dubious, but it worked – suggesting that a bit of sloppiness and mathematically ill-posed problems are, well, no problem. It worked! String Theory etc. doesn't seem to "work" in that way, but the attitude is still there.

30. **Peter Woit**
December 4, 2015

All,
Please, enough unfocused generic discussion of the uses of mathematics in physics. The issue I was trying to raise in this posting really is something different, the question of what mathematicians might contribute to the topic of this conference (how do you evaluate theories without contact with experiment?). This is about methodology, not the substance of either field. My impression is that most physicists understand so poorly how mathematicians conduct research that they can't see the issue here (which would explain why no one seems to have invited any to participate).

31. **Peter Woit**
December 4, 2015

Thanks Interested Layperson,

A bit of the article is at
http://www.astronomy.com/magazine/jeff-hester/2015/11/not-science-fiction
I haven't seen the whole thing, but I don't have a problem with the part quoted. That there are no interesting and correct predictions from the string landscape multiverse is the problem, and thus according to Hester, this sort of multiverse has already been falsified.

By the way, if people want a detailed defense of the string theory multiverse, together with a detailed documentation of priority claims that it was basically his idea, Andrei Linde has a preprint at
http://arxiv.org/abs/1512.01203
I'm somewhat curious why he or others with a similar point of view (Susskind, Vilenkin, Guth, etc. etc.) are not speaking at this conference next week.

32. **sm**
December 4, 2015

Peter: "My impression is that most physicists understand so poorly how mathematicians conduct research that they can't see the issue here".

That is the point of my (perhaps simplistic) example – even questioning the differentiability (let alone continuity, which is true only for a narrow class of continuous time processes – as has been learnt the hard way by those have sought in vain to generalise Black Scholes to the real world!) of Feynman paths did not come naturally to physicists! The mathematicians were invaluable here.

I think it is obvious that the mathematicians' specific deep understanding of relevant concepts to physics is what makes them special. If you just need a very good critical listener that does not let you get away with any 'sleight of hand' (no names mentioned!), and these are just as important in the general scheme of things, then a mathematician is not necessary – a physicist will do. Sydney Brenner in mock disgust commented that Francis Crick (a former physicist of course) 'did not let him get away with anything'!

33. **Chris W.**
December 4, 2015

Peter,
The issue (isn't it?) is how to evaluate *physical* theories without contact with experiment (at least provisionally). Do pure mathematicians ever have to worry about this? They evaluate their own theories without contact with experiment, but that's because those theories don't refer to the outer "observed" world, i.e., they aren't empirical to start with. Their initial assumptions don't even need to have a physical interpretation. The end game is proof that an assertion follows from certain assumptions. What happens when the empirical soundness—and not just the consistency—of the assumptions is a central issue, perhaps *the* central issue?

Applied mathematicians presumably operate differently, perhaps most of the time. Is that who you're talking about?

34. **sm**
December 5, 2015

Peter: (sorry for my verbosity on this topic!). I looked at your link above to Linde's recent (no doubt justified) 'Lindecentric' historical account of inflation/multiverse. Maybe my measure theory example above (differentiability of Feynman paths) where mathematicians helped enormously is not as simplistic as it seems.

Linde gives the usual (a la, Guth, Susskind, Page, …) argument for the multiverse 'measure problem showing by example how you can easily get yourself in a twist trying to define probabilities when your set ('sample space') is infinite. The problem with this oft used example is that its 'measure' (the Cesaro or counting density – note mathematicians don't call it a measure) is not a measure. It does not satisfy all the criteria to be one – hence one easily (or naively, as in the case of philosphers of the past) produces a contradiction. What bothers me is that the reader is not warned,or at least I missed it. Is this to shield the poor reader from the horrors of measure theory or something else? Relevant mathematicians surely have something to say, if only because for 200 years they too have had all the confusion of an ill defined 'theory' without a foundation – probability theory. Amusingly, access to abundant empirical data did not help, if anything it hindered. Instead an rich array of logical problems associated with 'thought experiments' played an important role leading to Kolmorgorov's final synthesis and satisfactory definition of probability theory – one that now looks so obvious that one wonders wny it took 200 years to find. Depending on ones personal conviction, one may hope (and in much less than 200 years, but as they say, 'don't hold your breath') for a similar outcome with one or more of QFT, StringTheory, inflation theory … . Skim reading the abstracts of the Munich conference, I unfortunately don't see any obvious reference to this interesting, and to my mind, obviously relevant history (relevant even at the technical level) of mathematics, perhaps reflecting your point about the absence of relevant mathematicians. Note also that is well known that philosophers did not always have a positive role in creating a solid probability theory.

35. **Peter Woit**
December 5, 2015

Chris W.,
If your theory makes no contact with experiment, "empirical soundness" isn't really a meaningful criterion, For example, the people doing quantum gravity these days like to announce that they are showing how to get rid of space (and maybe time too). If their replacement for space makes no testable connection to reality, the only way to evaluate it is by whether it is well-defined, internally consistent, consistent with some other specified assumptions based on how one hopes to connect the idea to reality. Methodologically, this is the kind of thing mathematicians are trained to do (this has nothing to do with applied mathematics). By the way, mathematicians also have a huge amount of expertise about different ways to think of generalizations of the classical notion of space (i.e. a differentiable manifold), but that's another topic.

sm,
It does seem to me that mathematicians and philosophers of math would have something to contribute to a discussion of the supposed "measure problem" (my point of view though is that this isn't the problem, the problem is more fundamental, that you don't know the space your measure is supposed to be on). Again, I find it odd that there seems to be little discussion of the multiverse planned at this workshop. Perhaps this is because if proposed "non-empirical confirmation" is invoked as an ally by the multiverse maniacs, that would seriously discredit the whole idea in many people's view.

36. **vmarko**
December 5, 2015

Peter,

"I'm somewhat curious why he or others with a similar point of view (Susskind, Vilenkin, Guth, etc. etc.) are not speaking at this conference next week."

I'm curious about that too. All speakers have been invited by the organizers, and there is no option for contributed talks. So the list of speakers reflects solely the choices of the organizers.

Best, 🙂
Marko

37. **martibal**
December 6, 2015

A curiosity tangent to the topic: here is the text of the "Samy Maroun center for Space, Time and the Quantum" whose Rovelli (one of the speaker of the Munich conference) is president (see http://www.centresamymaroun.com): "[…] Institutional agencies supporting theoretical physics research focus on the development of mathematical tools, but research cannot confine itself to these tools, neglecting direct physical intuition. Physical intuition based on experimental results and the qualitative content of the successful physical has always represented, historically, the essential source of our understanding of the physical world. The main objective of the Samy Maroun Center is to promote fundamental research on Time, Space and Quanta, grounded in the first place on the capacity of intuition to imagine and describe the world."
I was quite surprised to read that mathematical physics is somehow over founded by institutional agencies !

38. **sm**
December 6, 2015

Peter,

"my point of view though is that this isn't the problem, the problem is more fundamental, that you don't know the space your measure is supposed to be on".

In the case of "probability theory" (as it was before Kolmogorov, or more accurately, before the early 1900s when the French mathematicians especially started to 'get a grip') the problem was even more fundamental than that – you didn't even know you had to use a measure in the first place. Despite this, the "theory" had great calculational success (hence the reason to find a proper foundation), rather like some, but not all, of the "theories" we have now.

As I am sure you know, the history of the development of probability theory over 200 years is very rich and with the benefit of hindsight, counterintuitive, in places even comical, involving very colourful characters (to say the least!). The history our modern "theories" so far, to my mind, has great parallels with all this and we still have a lot to learn from Kolmogorov and ancestors (and maybe even his descendents – although at the moment it seems to be going other way as far as probability is concerned), possibly not only at the meta level.

39. **Peter**
December 7, 2015

Peter Woit: 'my point of view though is that this isn't the problem, the problem is more fundamental, that you don't know the space your measure is supposed to be on'

This is supposed to be one of the good things about measure theory: you don't need to know that. You just need to know a containing space, and that can be much bigger, then ask where the support of your measure is. Here is an example.

Suppose you are interested in (Lebesgue-) measurable functions from $[0,1]^2$ to $[0,1]$. You only care about these up to equivalence on sets of measure zero (meaning: you can do what you like to a function on a set of measure zero, and I will say you didn't change it). Think of such a function as $f(x,y)$, and suppose you are interested in what functions show up as $f(x_0,y)$ for a given f and any fixed x_0, called 'points' (I know this is a strange name! There is a reason for this construction, it is a combinatorial graph limit, but you don't need to care). Now in principle such functions could be any function at all from $[0,1]$ to $[0,1]$, not necessarily even measurable, because f is defined up to equivalence on a set of measure zero and the line (x_0,y) has measure zero. So you only care about `typical points', meaning that (in some sense which should be rigorous) you want to get rid of that kind of silly example.

To be more concrete, if you are given $f(x,y)$ is 0 if $x\le y$ and 1 otherwise, then the 'typical points' $f(x_0,y)$ are a one-parameter family, so you should get the structure of a line out of this.

Here is how you do it. You take any given f, and any measurable set X in $[0,1]$. Now you generate a measure on $L_1[(0,1)]$ by setting the measure of $\{f(x_0,y):x_0\in X\}$ equal to the measure of X. Next, you declare the 'typical points' of f to be the support of your measure.

The thing to note here is that $L_1([0,1])$ is a truly huge space, and you are looking for low-dimensional manifolds in it, but nevertheless the measure theory happily lets you do this. And because you had a measure to work with, you could do this construction rigorously.

40. **Shantanu**
December 7, 2015

Peter,
Sabine asked the question about the observations. He pointed out just one of them
saying if that there is evidence for a long range force, or a vectorial/tensorial force
or evidence for 5th force it would invalidate the string framework.

41. **Peter Woit**
December 7, 2015

Shantanu,
I wonder what Gross is thinking of. I don't see any reason you can't have another long range force like the electromagnetic force, coupling to a charge. Presumably he means coupling to mass. Often one hears the exact opposite claim, that observation of a fifth force would be evidence for string theory, see for example here
http://www.math.columbia.edu/~woit/wordpress/?p=6561
In string theory you have potential long range forces due to moduli fields, in some sense the big problem of the theory is why you don't see these (how do you stabilize moduli?). So, I'm guessing he meant non-scalar forces that violate the equivalence principle, coupling to mass, violating various principles of GR + QFT, not just string theory. It's easy to come up with things that don't fit fundamental principles of QM or QFT, and say those would falsify string theory. The real question though is whether you can falsify the characteristic properties of string theory that are different than QFT.

I would bet good money though that if experimentalists discover a fifth force, the headlines will be "string theorists claim evidence for string theory", and if it's not scalar, some "string vacuum" will be constructed to reproduce whatever is observed…

42. **emile**
December 7, 2015

Shantanu: will the slides be put online?

43. **Shantanu**
December 7, 2015

I am not on the organizing committee. But I will check tomorrow, although I will pretty sure they will be at some point. Also they are videotaping the whole thing, so the videos will also be put online. However as a physicist, I didn't really get much from the philosophy talks
and the main talks I paid attention to were by Gross, Rovelli and also Helge Kragh
who mentioned some very interesting things about Eddington's fundamental theory, which I didn't know.

44. **vmarko**
December 7, 2015

Gross didn't really explain why he thinks that a new long range force would invalidate ST, and I think that at that point the majority of people in the audience were very grateful for that. Some people just don't distinguish between asking a question and giving a lecture, and don't know how to give back the microphone…

In other news, the majority of the discussion centered around Dawid's three-rule non-empirical theory confirmation criterion, and there was a big fuss about whether it's a misnomer, because it's more about theory assesement than confirmation (the latter being too loaded with different meanings).

Other talks were also interesting, but not controversial in any way. Overall it was nice today, we'll see how tomorrow goes.

Best, 🙂

Marko

45. **Alessio**
December 8, 2015

Douglas: I totally agree with you…in fact there is no paradigma shift, nor any crisis whatsoever in science, but, maybe, in some fields.

46. **Jeffrey M**
December 8, 2015

It's fascinating, there really is some sort of deep misunderstanding of mathematics, among both physicists and philosophers. From Pigliucci's blog – "Theorists may give up, or they may play with extrapolation, or toy models (i.e., thought experiments). They could also adopt strategies from other fields, like mathematics, where beauty is a criterion for success. [Uhm, that's pretty dangerous territory…]" But beauty is neither a necessary nor a sufficient condition for success in math. The primary criterion for success is of course proof, unless you can prove something correct it will not succeed. If you can prove something, there are various reasons why it might be a success. One is certainly beauty, mathematicians love beautiful results. Another is usefulness, mathematicians love plenty of not beautiful things because they are very useful. Physicists of course don't have proof really, even experiment isn't quite "proof," and this makes the use of the other secondary criteria a serious problem.

47. **Shantanu**
December 8, 2015

emile. The slides will be put online.
Today's highlights was the fireworks between Gross/others and Kane, when Kane mentioned that M-theory predicted Higgs boson mass of 126 GeV. Probably Marko or Sabine can/will add more either here or on Sabine's blog.

48. **Chris W.**
December 8, 2015

Massimo Pigliucci's post for today ("Why Trust a Theory? — part I") described another tense exchange (brief) on a less substantive matter.

49. **vmarko**
December 8, 2015

Ok, day two. 🙂 Arguably, the only thing more fun than a duel between a ST proponent and a LQG proponent is a duel between two disagreeing ST proponents… When Gordon Kane explicitly put on his slides "in 2011 M-theory predicted the Higgs mass at 126 GeV" (and he even gave the error bars of that prediction), David Gross had to intervene, and the fight was on! 😉 After some philosophers protested at the interruption and demanded that Kane continues on with the talk, Gross said (I'm paraphrasing from memory) "oh, we physicists have these discussions in the middle of a lecture all the time — you know, it's called the 'scientific method'…"

Eventually other talks went on, with some interesting but less controversial topics.

But the main party was in the afternoon, stolen by Slava Mukhanov. The incredibly funny yet lucid lecture spanned topics from inflation to dangers of falsifiability in the former USSR, including the equation which will probably become a classic:

inflation – theology = exp (-aH),

with a comment "even Lemaitre knew this"… You had to be there.

The party continued during the discussion session where Mukhanov played the role of "voice of reason", telling everybody that if a theory cannot be tested it is not physics, and redefining falsifiability away isn't going to change that. I'll just paraphrase an exchange regarding eternal inflation and the multiverse:

Gross: Multiverse is an important problem where philosophers can help, and it's a good topic to collaborate on.
Mukhanov: Maybe we should also invite theologists?

Really, you just had to be there… 🙂 I can only guess about tomorrow, when the multiverse will become the main topic.

Best, 🙂
Marko

50. **Tammie Lee Haynes**
December 8, 2015

Dear Dr Marko

I'm glad you were amused by Dr Mukhanov's comment on the Multiverse:
"Maybe we should also invite theologists?"

But as a Creationist, I ask this: Why would theolgists attend?
Christian Theology is based on the accounts of witnesses to the Miracles of Jesus.
Accounts of witnesses are "empirical data."
And as you note, the Multiverse Proponents like Dr Gross cant offer any to the theologists.

very truly
Tammie Lee Haynes

51. **Shantanu**
December 9, 2015

Something else to add about Slava's talk. Apparently he mentioned that he knew
the bicep-2 results were wrong, the day they came out. After talking to him, he mentioned that he said the same to Alan and Andrei, but they wouldn't listen to him.

Today's Sabine's talk was also awesome. She asked David(representing Polchinski)
if he was referering to Peter Woit's blog, when he mentioned "blogs attacking string theory" and David said no.
shantanu

Today’s Hype

December 9, 2015
Categories: Multiverse Mania, This Week's Hype

Joe Polchinski’s contribution to the ongoing Munich meeting has now appeared on the arXiv, with the title [String Theory to the Rescue](). Evidently he’s not actually to be at the meeting, I’m not sure how his paper will be presented.

It’s pretty much the usual hype about the string theory and the multiverse, with untestable ideas about quantum gravity the only topic. The one innovation is that it contains a calculation: the probability of a multiverse is 94%:

> To conclude this section, I will make a quasi-Bayesian estimate of the likelihood that there is a multiverse. To establish a prior, I note that a multiverse is easy to make: it requires quantum mechanics and general relativity, and it requires that the building blocks of spacetime can exist in many metastable states. We do not know if this last is true. It is true for the building blocks of ordinary matter, and it seems to be a natural corollary to getting physics from geometry. So I will start with a prior of 50%. I will first update this with the fact that the observed cosmological constant is small. Now, if I consider only known theories, this pushes the odds of a multiverse close to 100%. But I have to allow for the possibility that the correct theory is still undiscovered, so I will be conservative and reduce the no-multiverse probability by a factor of two, to 25%. The second update is that the vacuum energy is nonzero. By the same (conservative) logic, I reduce the no-multiverse probability to 12%. The final update is the fact that our outstanding candidate for a theory of quantum gravity, string theory, most likely predicts a multiverse. But again I will be conservative and take only a factor of two. So this is my estimate for the likelihood that the multiverse exists: 94%.
> This is not to say that the multiverse is on the same footing as the Higgs, or the Big Bang. Probability 94% is two sigma; two sigma effects do go away (though I factored in the look-elsewhere effect, else I would get a number much closer to 1). The standard for the Higgs discovery was five sigma, 99.9999%.

My problem with a lot of the West Coast theorists is that I don’t seem to have the same sense of humor, so often I have trouble telling when they’re joking (does anyone know when Andrei Linde is joking?). Here though it seems quite clear that Polchinski is pulling the leg of the philosophers gathered to hear him speak. My calculations show that the chance the above text could be a serious contribution to a philosophy of science conference cannot be above .1%.

The other evidence that something comical is going on here comes from some of the over-the-top claims about the virtues of string theory. In particular, we’re told

> A remarkable feature of string theory is that the dynamics, the equation of motion, is completely fixed by general principle. This is consistent with the overall direction of fundamental theory, describing the vast range of phenomena that we see in terms of fewer and fewer underlying principles. Uniqueness would seem to be the natural endpoint to this process, but such theories are truly rare…
> Indeed, when I assert that the equations of string theory are fully determined by general principle, I must admit that we do not yet know the full form of the equations, or the ultimate principle.

Polchinski is quite right that it is “remarkable” to know that you have a unique theory, with unique equations, fixed by a general, ultimate principle, but you don’t know what the theory is, what the equations are, or what the principle is. I’m curious to hear from people at the conference what gets the bigger laughs: this or Kane’s argument that the unknown theory predicts a 1.5 TeV gluino (unless it’s not found, in which case it doesn’t).

Update: See [here]() for the latest coverage of the meeting from Massimo Pigliucci, who comments at one point:

Update: For more on Polchinski’s paper there’s Sean Carroll on Twitter, [here]() and [here](), who tells us

> So strange how the public perception of string theory has been warped by a few contrarian voices. Good topic for some future PhD thesis.

and that Polchinski’s new paper

> lays out the case for string theory, and how unexpectedly successful it’s been.

I’m assuming by “contrarian voices” he’s referring to Polchinski. That string theory has been “unexpectedly successful” and the multiverse is a 94% sure thing is a highly contrarian point of view among physicists.

Update: More coverage of the workshop is available from [Sabine Hossenfelder]() and [Massimo Pigliucc]()i.

   December 9, 2015

   We are told Joe’s paper will be presented by David Gross instead.

2. **Shantanu**
   December 9, 2015

   Peter, David is presenting his talk. But he said he will disagree with Polchinski.

3. **Massimo**
   December 9, 2015

   Peter,

   the above comments are correct, David Gross will present Polchinski’s intervention (apparently, he is sick). This may turn out to be an unfortunate choice, for two reasons: i) Gross has had (far) more than his fair share of commentary already at the conference (he rarely actually asks questions of other speakers, he just gives his extended opinion on whatever they said); ii) it is going to be difficult for us to tell how much Gross will present Polchinski’s actual paper and how much editorializing he will do. I’ll report on today’s session at my platofootnote.org blog tomorrow, while my report on yesterday’s session will come out in about three hours. Cheers.

4. **Chris Oakley**
   December 9, 2015

   For some reason Polchinski’s words remind me of Cumrun Vafa’s argument (footnote 2 here: [http://arxiv.org/pdf/physics/0308078v4.pdf]()) that the reason we do not see hyper-advanced aliens around is that they will have migrated to a more happening part of the multiverse. This in a supposedly-serious scientific paper. I wonder whether the whole String Theory phenomenon is just a huge wind-up. I suppose that I have always assumed that it was, but still …

5. **M**
   December 9, 2015

   Polchinski emphasises the string understanding of black hole issues. At the conference Dvali presented his ideas about black hole issues, which are sensible and make any UV understanding (such as strings) irrelevant. What was the reaction by string theorists?

6. **AH**
   December 9, 2015

   Polchinski gave a talk which looks very similar to that arXiv post last week at the Einstein Centennial Conference in Berlin. He made the same comment about have unique equations following from a unique principle. He meant it seriously, although he also told us we were "allowed to laugh." Ashtekar pressed him on what it might mean, and the response was essentially that this was a property of certain approximate results which he expected to persist in the full theory (whatever that might be).

   We were told later in the conference that Polchinski was taken to the hospital with what sounded like rather serious symptoms. I don't know any details, but this would explain why he's not giving his talk in Munich.

   I've deleted some later comments about Polchinski's health. I hope that his health problems are not serious.

7. **vmarko**
   December 9, 2015

   Gross presented Polchinski's talk, basically read it from the paper, with very few comments of his own. No questions were asked since Joe is not here to answer (and because we were overtime). The 94% estimate for the multiverse produced a good laugh in the audience. 🙂

   Best, 🙂
   Marko

8. **andrew**
   December 9, 2015

   Peter,

   In your last post on this conference, I suggested Bayesian confirmation theory ought to be discussed, especially its relation to post-empirical confirmation (PEC), as I suspect PEC amounts to arguments for high prior probability in a particular theory.

   How sad I am read Polchinki's utterly fatous "calculation" in Bayesian probability.

9. **Bee**
   December 9, 2015

   David did a pretty good job. (Except for running badly over time.) I'll have a summary of the workshop at Starts With a Bang, but not sure how quickly Ethan will be able to get it out, today or tomorrow.

10. **Nobody**
    December 9, 2015

    Lies, damned lies and Bayesian statistics.

11. **Peter Woit**
    December 9, 2015

    Sounds like there was also some comedy from David Gross, who today was reading Polchinski's paper about the 94% probability of the multiverse, and string theory's ultimate unknown unique principle, but then explained that
    "The public is confused because there are a host of ppl who write blogs or books who attack string theory"
    https://twitter.com/skdh/status/674560758701801472

12. **Jim Baggott**
    December 9, 2015

    Peter,
    Under further probing by Sabine at the beginning of her presentation on cognitive and social bias in theory assessment (which was excellent btw) Gross said he wasn't referring to you. Heaven knows who he was referring to then…

13. **Staffan**
    December 9, 2015

    Polchinski's parody of Bayesian argumentation is interesting not least because Dawid's main argument for the "no alternatives argument" is Bayesian. One wonders if the parody is aimed at Dawid himself, which would be curious coming from someone like Polchinski.

14. **Chris W.**
    December 9, 2015

    Staffan,
    I'd guess that the intent of Polchinski's parody is to say, in effect, "we don't need no stinkin' Bayesian argumentation".

    The spurious Bayesian argumentation aside, Polchinski seems to be reiterating what has been the standard line for at least a decade. Remember when Susskind was declaring that the grumbling was to no avail, and it was time to stop worrying and love the Landscape?

    Indeed, Polchinski is arguing (yet again) that based on very general considerations about the prevalence of metastable states in more familiar physical contexts (accessible to experiment) we should have expected to end up here. That sounds to me rather like asserting in 1890 that the existence of an aether is inevitable, given everything we know about classical mechanics and electromagnetism, but it will sound convincing to many until a shift in perspective makes it seem otherwise, regardless of the problems of aether theory.

15. **Calvin Marshall**
December 9, 2015

Dr. Woit – Sean Carroll seems to be on the offensive with String Theory today. Check out his Facebook page: https://www.facebook.com/seanmcarroll?fref=nf

"So strange how the public perception of string theory has been warped by a few contrarian voices. Good topic for some future PhD thesis."

Earlier in the day he posted: "Joe Polchinski lays out the case for string theory, and how unexpectedly successful it's been." http://arxiv.org/abs/1512.02477

Wondering if he caught wind of your recent post about Einstein spinning in his grave after the PBS NewsHour interview?

16. **Peter Woit**
December 9, 2015

Calvin,
I saw those on twitter, added a mention as an update to the posting.

The Polchinski piece itself is clearly part of a PR offensive for string theory, and Carroll seems to feel the need to join in on the side of his tribe. I get the impression string theorists are feeling somewhat embattled these days, as the LHC no-SUSY results shut off the last hope for vindication from experiment, and the public perception that the theory has not been successful hardens. Not sure that going on twitter and saying it's all the fault of some blogger who has "warped" public perceptions is really going to do anything other than convince people that you're a sore loser.

It's funny to think of the situation 10 years ago when the argument was that string theory critics such as Lee Smolin and myself were just losers in the marketplace of ideas. Now that things haven't been going so well for them in this marketplace, they start complaining about market distortions…

17. **vmarko**
December 9, 2015

Maybe they feel embattled in part because of this conference. Despite the dominant presence of ST-related people, and the supportive opinions on ST by some philosophers, the unanimous conclusion of the participants today was that multiverse is nonsense. And yes, I mean unanimous, unless somebody silently lied when Gross initiated an opinion vote/poll.

The day started with an excellent lecture by George Ellis, who did a thorough analysis and the rebuttal of virtually all versions of the multiverse (save for the many-worlds interpretation of QM which is a different ballgame and was never really even mentioned seriously). There was no bashing or anything — Ellis presented in turn each multiverse idea as a legitimate scientific hypothesis, tried his best to take it seriously and interpret it charitably, and then mounted a fatal counterargument, rendering it either false or irrational. A textbook example of serious and proper scientific argument.

After Gross read/presented Polchinski's paper (and IMO did a fairly good job at that), there were several very nice lectures both on philosophy and physics. The panel discussion was "regular", basically what you would expect of any normal panel discussion, with a nice Q&A session at the end. All in all, a very nice conclusion to the event, if somewhat less vigorous than previous days. No serious controversies, only a couple of friction sparks here and there that are maybe better left unmentioned.

In the end, everybody I asked had a very positive overall opinion of the whole three-day event, myself included. Despite a few lectures that included some ST hype (the Polchinski lecture being by far the worst in that regard), most of the people expressed a very reasonable overall opinion both on ST itself and on the related philosophical issues. The conference was actually educational in the positive sense, IMO.

Best, 🙂
Marko

18. **Peter Woit**
December 9, 2015

Thanks Marko,
Too bad Polchinski wasn't there to be the lone voice for the multiverse. It really is an odd situation now, especially in the US. Here some of the most prominent theorists (either not invited to Munich or not willing to travel there), and many of the ones who most often appear in the media, act as if the multiverse is a done (or 94% done) deal. On the other hand, from your account of the conference, and my impressions from people I talk to, an overwhelming proportion of professional physicists don't think it's science (or, not successful science).

19. **Scott Church**
December 9, 2015

Peter,

I agree that the situation in the U.S. is particularly odd. If an overwhelming proportion of professional physicists don't think ST/multiverse passes for legitimate science, then the fact that some prominent theorists in America would go so far as to consider it a "done deal" demands explanation. It's one thing to see a wide range of opinions regarding some theory or idea. It's another thing altogether to see opinions sharply divided between strongly convinced, and strongly unconvinced… especially if one of these camps is a clear minority. It seems to me that in cases like this something other than science is driving things. If ST/multiverse really is a "done deal" why aren't there more than just a few American theorists who think so, no matter how prominent they are? I think it's fair to ask whether personal beliefs, agendas, or anything else having nothing to do with science might be contributing to the certainty these folks have. Thoughts?

20. **John**
December 9, 2015

Scott, I think all the multiverse love comes from a desire to think that the ultimate theory had been discovered in their lifetime. We all want to know the answer to life, the universe, and everything – we just don't want the answer to be found after we are dead.

21. **Peter Woit**
December 9, 2015

Scott,
First of all, I think it's too bad there wasn't a wider range of view represented at this conference, the deck was kind of stacked in favor of string theory and against the

multiverse, reflecting the point of view of the organizers. So, even if Marko is right and the consensus there was that the multiverse is nonsense, that doesn't necessarily reflect what is going on in theory groups, especially in the US.

My view is certainly that the side that sees the multiverse as not science has by far the better scientific case, so no need to invoke other reasons. As for what is driving multiverse mania among some theorists, I think it's a combination of factors:
1. If your interest is in having a high media profile, communicating to the public an inspiring tale of current scientific progress, then the multiverse works well: it's easy to explain, it sounds impressive, and it explains away uncomfortable questions about why the ideas you were promoting a few years back didn't work out. This is going to work much better on TV than "we're kind of stuck, haven't been making much progress…".
2. The string theory unification really has conclusively failed, and this puts people who have invested a lot of their lives in the subject in an uncomfortable position. Most of them (except for a few outliers like Kane) have given up on explaining anything about particle physics via string theory, and are concentrating on quantum gravity or connections to condensed matter, or quantum information theory, or anything else. Adopting the multiverse as an excuse in this situation is tempting: it gives you an argument for why the problem was insoluble. People then struggle with this temptation vs. knowing that this is an abandonment of science.
3. I think John has a point. Those who convince themselves of the multiverse can feel that, while they may not see a final theory, the framework they have devoted their life to working in is close to one.

22. **Bee**
December 10, 2015

(Rumor about Polchinski's health removed).

David said he wasn't referring to you, but not who he had in mind. Either way, as one of the few bloggers who write about quantum gravity I felt offended enough to defend the integrity of science bloggers. It is debatable who is to blame for much of the hype in the media, whether it's the scientists themselves, institutional press offices, or science writers. But the problem clearly doesn't have its origin in the bloggers, who most of the time just try to sort out fact from fiction. (I suspect David doesn't actually read blogs.)

23. **Jim Baggott**
December 10, 2015

I came away thinking that the conference had been a helpful meeting of minds, a chance for philosophers to set the record straight on the use of falsifiability criteria and help get past the slogans. But it was also a missed opportunity. Ellis and Silk made points in their Nature article last year that were simply not addressed. Instead, the conference was broadly configured as a way to defend string theory against the charge that it is untestable and so unscientific. Despite Kane's attempt to shoot the counsel for the defence in the foot with his absurd claims, I suspect the string theorists will be broadly satisfied with the outcome. Shifting attention to the multiverse was a clever ploy, as even astrology would look vaguely scientific in comparison (and it was indeed a great pity that Polchinski couldn't attend).

This was just an opening skirmish, I think. The success of a series of best-selling popular science books, a continuing stream of popular science articles and television documentaries, and the award of prestigious "breakthrough" prizes valued at $3 million have all helped to create the impression in the public consciousness that string theory is a valid or even "true" description of nature. This is surely not a good thing.

I was really struck by the consensus in the room that string theory is NOT confirmed or validated. In his opening presentation Gross explained that it's actually not even a theory, of the kind that can be put into a single equation and printed on a t-shirt. It is rather a "framework", a set of ideas, concepts and mathematical relationships. To become a theory it has to be set up in the right way. Gross admitted that we can test theories but it's really hard to test a framework. The trouble is that string theorists don't yet know how to set up the string framework in precisely the right way.

Setting aside the question of whether they will ever be able to figure this out, it seems to me that it would be really refreshing to see one or two leading string theorists make an honest appraisal of the status of the theory in a couple of popular science vehicles, much as Gross did at this conference. I think this would really help to set the record straight. People have all sorts of different reasons for wanting to invest belief in stuff like this, but making the position on string theory clear would in my view restore some sense of integrity.

24. **Shantanu**
December 10, 2015

For those who attended the meeting, does anyone know the name of the gentleman
who in the opening talk by David Gross mentioned that "my theory can be written on a t-shirt" after Gross said that you cannot write down the equations of string theory on a T-shirt. one thing no one brought up in the meeting is the disproportionate amount of funding given to string theorists and those who work on landscape and its very hard for people who don't work on this or LQG to earn a living. I was too tired by the panel debate,
but would have raised this issue, if I was there.
shantanu

25. **AcademicLurker**
December 10, 2015

After reading the last 2 comments, I'm wondering whether agencies that fund HEP theory should change their application process. "Send us a T-shirt with your proposed theory written on it…"

26. **Paul D.**
December 10, 2015

Report of the meeting from Sabine Hossenfelder (in SWaB):

http://www.forbes.com/sites/startswithabang/2015/12/10/why-trust-a-theory-physicists-and-philosophers-debate-the-scientific-method/

Near the end:

'But Gross has his worries: "The public is confused because there are a host of people who write blogs or books who attack string theory." As one of the few bloggers who regularity writes about quantum gravity, this remark offends me. The reality is that the biggest task of science bloggers – like Peter Woit, Ethan Siegel and myself – has become to clean up after sloppy science journalism. Hype is a real problem. But it's not the bloggers who are to blame for this.'

27. **Urs Schreiber**
December 10, 2015

In case some of the commenters above really don't know: the reason that there is not an equation defining perturbative string theory is that it is an S-matrix theory, so it isn't defined by an equation that constrains states, but by a prescription for how to compute the S-matrix elements: the string perturbation series.

28. **Joseph Conlon**
December 10, 2015

Jim: Regarding your last paragraph, I feel obliged to point out I have just written a book Why String Theory? on precisely this topic, with 250 pages on what string theory is today in 2015, what it means in 2015, and what are the various reasons people actually spend time working on it 😉 And indeed, it was published all of 2 weeks ago.

29. **Peter Woit**
December 10, 2015

Urs,
You might want to explain that point about not needing equations because it's S-matrix theory to David Gross. He was a student of Chew's doing S-matrix theory in the mid-60s. For his account of his 1966 realization that this "was less of a theory than a tautology", see here
http://link.springer.com/content/pdf/10.1007/978-1-4613-1147-8_7.pdf
I suspect he'd say the same about your claim to explain non-perturbative string theory this way.

Upon re-reading Urs's comment I realized I misread it as about non-perturbative string theory. As he wrote it, I really don't understand at all what he means. You can write down equations for perturbative string theory as a sum over worldsheets, and this isn't an S-matrix theory (or, you can compute the S-matrix, but not just the S-matrix).

30. **Peter Woit**
December 10, 2015

Joseph Conlon,

Looking forward to seeing your book. If it addresses the criticisms of string theory that for some reason got very little attention at the Munich workshop, and gives an honest appraisal of what the state of the subject is (not just hype a la Polchinski), that would be really great.

31. **Jim Baggott**
December 10, 2015

Joseph Conlon,

You'll be pleased to know your book was mentioned several times (by Fernando Quevedo during his presentation and personally to me by Graham Farmelo), and it's on my Christmas wish list. However, I'd still like to see some of the leading figures in the string theory community – Gross himself, perhaps, or Brian Greene or Lenny Susskind – make more effort to provide an honest appraisal of the current status of the theory, in much the way that Gross did at this conference.

32. **Kartik Prabhu**
December 16, 2015

@PeterWoit Some coverage of the Munich Conference: https://www.quantamagazine.org/20151216-physicists-and-philosophers-debate-the-boundaries-of-science/ You seem to have gotten some press too!

34. **John**
December 23, 2015

Is there a good Bayesian estimate of the probability that Bayesian inference is an adequate replacement for the empirical verification of scientific theories?

35. **Jim Akerlund**
December 31, 2015

David H. Bailey & Jonathon M. Borwein weigh in on the Munich meeting in this Huffington Post article, http://www.huffingtonpost.com/david-h-bailey/data-vs-theory-the-mathem_b_8886292.html. Most of the article is a rehash of what has been said here, and the article quotes you, Peter. It is the last paragraph that stands out. *"This does not mean that all research in string theory and the multiverse must stop. But the practitioners of these fields should recognize that the chips are down: they cannot exist much longer as science if they cannot at least establish some crisp, testable connections with the real world of scientific data and analysis. They should not be given a free pass for all time."*

White Smoke Over Oxford?

December 10, 2015
Categories: abc Conjecture

I've stolen the title of this posting from Michael Harris, see his posting for a discussion of the same topic.

A big topic of discussion among mathematicians this week is the ongoing workshop at Oxford devoted to Mochizuki's claimed proof of the abc conjecture. For some background, see here. I first wrote about this when news arrived more than three years ago, with a comment that has turned out to be more accurate than I expected "it may take a very long time to see if this is really a proof."

While waiting for news from Oxford, I thought it might be a good idea to explain a bit how this looks to mathematicians, since I think few people outside the field really understand what goes on when a new breakthrough happens in mathematics. It should be made clear from the beginning that I am extremely far from expert in any of this mathematics. These are very general comments, informed a bit by some conversations with those much more expert.

What I'm very sure is not going to happen this week is "white smoke" in the sense of the gathered experts there announcing that Mochizuki's proof is correct. Before this can happen a laborious process of experts going through the proof looking for subtle problems in the details needs to take place, and that won't be quick.

The problem so far has been that experts in this area haven't been able to get off the ground, taking the first step needed. Given a paper claiming a proof of some well-known conjecture that no one has been able to prove, an expert is not going to carefully read from the beginning, checking each step, but instead will skim the paper looking for something new. If no new idea is visible, the tentative conclusion is likely to be that the proof is unlikely to work (in which case, depending on circumstances, spending more time on the paper may or may not be worthwhile). If there is a new idea, the next step is to try and understand its implications, how it fits in with everything else known about the subject, and how it may change our best understanding of the subject. After going through this process it generally becomes clear whether a proof will likely be possible or not, and how to approach the laborious process of checking a proof (i.e. which parts will be routine, which parts much harder).

Mochizuki's papers have presented a very unusual challenge. They take up a large number of pages, and develop an argument using very different techniques than people are used to. Experts who try and skim them end up quickly unable to see their way through a huge forest of unrecognizable features. There definitely are new ideas there, but the problem is connecting them to known mathematics to see if they say something new about that. The worry is that what Mochizuki has done is create a new formalism with all sorts of new internal features, but no connection to the rest of mathematics deep enough and powerful enough to tell us something new about that.

Part of the problem has been Mochizuki's own choices about how to explain his work to the outside world. He feels that he has created a new and different way of looking at the subject, and that those who want to understand it need to start from the beginning and work their way through the details. But experts who try this have generally given up, frustrated at not being able to identify a new idea powerful enough in its implications for what they know about to make the effort worthwhile. Mochizuki hasn't made things easier, with his decision not to travel to talk to other experts, and with most of the activity of others talking to him and trying to understand his work taking place locally in Japan in Japanese, with little coming out of this in a form accessible to others.

It's hard to emphasize how incredibly complex, abstract and difficult this subject is. The number of experts is very small and most mathematicians have no hope of doing anything useful here. What's happening in Oxford now is that a significant number of experts are devoting the week to their best effort to jointly see if they can understand Mochizuki's work well enough to identify a new idea, and together start to explore its implications. The thing to look for when this is over is not a consensus that there's a proof, but a consensus that there's a new idea that people have now understood, one potentially powerful enough to solve the problem.

About this, I'm hearing mixed reports, but I can say that some of what I'm hearing is unexpectedly positive. It now seems quite possible that what will emerge will be some significant understanding among experts of a new idea. And that will be the moment of a real breakthrough in the subject.

Update: Turns out the "unexpectedly positive" was a reaction to day 3, which covered pre-IUT material. Today, when things turned to the IUT stuff, it did not go well at all. See the link in the comments from lieven le bruyn to a report from Felipe Voloch. Unfortunately it now looks quite possible that the end result of this workshop will be a consensus that the IUT part of this story is just hopelessly impenetrable.

Update: Brian Conrad has posted here a long and extremely valuable discussion of the Oxford workshop and the state of attempts to understand Mochizuki's work. He makes clear where the fundamental problem has been with communication to other mathematicians, and why this problem still remains even after the workshop. The challenge going forward is to find a way to address it.

Comments

1. **Eric Weinstein**
   December 10, 2015

   Hi Peter,

   Thanks for this post. I think what is so confusing about this situation actually comes from how many mathematicians portray the field (at least to the outside world). In this fantasy description, mathematics is a uniquely objective subject and the only thing that matters is the proof. To my mind, Mochizuki is taking this portrayal quiet literally. In so he is revealing to the wider world what many Mathematicians are reluctant to admit to the public if not themselves.

   In fact, the mathematical literature is very human in that it is filled with ambiguous statements, logical gaps, wrong proofs, attribution errors. With that said, there is *something* objective about it. In general, when well regarded(1) people from well known research institutions(2) with little history of making big false claims(3) are willing to write up something explicit(4) which is not too long(5) in roughly familiar terminology(6) in English/French/Russian or other major languages(7) and talk about their work to experts in seminars(8), they trigger a process that produces a level of scrutiny which is usually equal to the task of validating the claim in a matter of days to months. There is also the perverse requirement that the author not develop too much deeply original thinking(0) on her or his way to a proof if this process is to complete quickly.

   Now, the problem here is that Mochizuki is pushing enough on various parts of 0-8 that it exposes what mathematicians know but are not always happy to admit: that the field, if it is objective, is not objective in the simple way conveyed to the world. Rather there is an economics of mathematics, a politics of math, and numerous failure modes of math which dominate the short run. In fact many senior mathematicians are of two minds where they know that the field is somehow completely objective and non-objective.

   As a former insider turned outsider, I personally think this situation is terrific. In one simple stroke, Mochizuki has showed us that the field is driven by incentives, culture, and human failing. I hope that this proof is correct so that in the second act, he can show us that after the politics, recriminations, and resistance, the field usually ends up with something pretty close to objective truth. Over the long run things are much better, at least as far as the proofs are concerned (if not always the narrative and attribution.)

   Something opposite – Math Quartet Joins Forces on Unified Theory at Quanta: https://www.quantamagazine.org/20151208-four-mathematicians/

4. **Jeffrey M**
   December 10, 2015

   My two cents, as a mathematician, Peter has the process for this kind of thing exactly right. I watched it happen with Perelman's proof of Thurston's geometrization conjecture. I was at a conference maybe a week after it was released, and various experts in the field were there (my field is pretty close) – they had already been working on it feverishly the whole time. And they already were saying it looked likely to hold up. Of course that was a very different set up, since Perelman was doing work which followed in the footsteps of Hamilton (who teaches with Peter at Columbia), and basically what he did was to figure out a way to get through the wall which Hamilton hit. This seems way different, unprecedented more or less. I'm trying to think of a case where there was a completely new way of approaching something, and no one could understand, and I can't. Plenty of times someone comes up with a really new way to look at things, but it's always the case that people catch on pretty quickly, at least the examples I can think of.Usually, if a bunch of very good mathematicians look at something, and tell you it doesn't make any sense, it actually doesn't make any sense.

5. **Rubbernecker**
   December 11, 2015

   Given that

   1) Its basically in an entirely new sub field and its incredibly rare for someone to move from one area to another
   2) At least four people already understand a relatively young theory
   3) No mathematician understands the vast majority of extant proofs

   Is it maybe not that big a deal if experts working in other areas never understand this proof?

6. **Peter Woit**
   December 11, 2015

   Rubbernecker,
   This is supposed to be part of arithmetic algebraic geometry, and say new things about that subject. Many of the people at the workshop are among the best arithmetic algebraic geometers in the world.

   What went wrong yesterday is that two of the four people (Mok, Hoshi) who supposedly understand IUT were unable to explain it to anyone else. A third (Yamashita) will try today, but his talks were supposed to assume material from the other two.

   Yes, few people understand the details of many complicated proofs. As I was trying to explain here, that's not what's going on. What the experts are trying to find is a new idea that says something about arithmetic algebraic geometry.

   The danger here is that IUT is a subject disconnected from the rest of mathematics. If you spend more time studying it, you will learn lots of new definitions, be able to prove lots of theorems relating them, but learn nothing new about other mathematics.

7. **Chris W.**
   December 11, 2015

   z,
   Opposite indeed. That's an inspiring story—another great article from *Quanta*.

8. **RandomPaddy**
   December 11, 2015

   The Scottish legal system has a verdict which may be applicable in this case: Not Proven.

   The stark contrast between this conjecture and the recent, say, Polymath projects is glaring.

9. **Michael Hutchings**
   December 11, 2015

   Eric Weinstein: Your comment seems to imply that there is resistance to Mochizuki's work due to non-objective factors. There are of course various heuristics (usually with good reasons) which mathematicians use in deciding whether it is worthwhile for them to invest large amounts of time trying to understand something new. In Mochizuki's case, we have a conference of leading experts, including more than one fields medalist, getting together for a week to do their best to understand his work. One can't really say that his work isn't getting a fair hearing.

10. **Eric Weinstein**
    December 11, 2015

    Hi Michael,

    Thanks for this. I do not mean to imply that Mochizuki is running into something untoward. I mean to imply that we do a disservice to mathematics when we confuse the objective nature of the underlying subject matter with the way in which humans attempt to do mathematics. I don't mind the heuristics if they are recognized not to be fundamental truths.

    Of course there is a resistance here. He is (to the best of my understanding) not bending over backward to decrease the burden on the proof checkers. I would find that annoying were I an expert in this field. But I would never pretend that math is uniquely objective as a profession. Proofs may be objective, but proof checking is not.

    Let me make an analogy. In computer software, there is a difference between a code review done by a subjective human doing their best and a code review done by the compiler. What I find at turns amusing and annoying is when mathematicians pretend to be compilers. The compiler doesn't care about commenting code properly. It doesn't see whether a style guide has been adhered to or whether readability mattered to the developer. It just compiles or it fails.

Mochizuki seems not to care particularly for decreasing the burden on his proof checkers. For the subset of those proof checkers who are open about how prone to error and delay this process is, I believe he is acting sub-optimally and should be pushed to be more helpful. But, for those mathematicians who pretend that the profession is blind to all but the objective truth….I think this is a splendid reveal. No compiler takes this long.

Warmly,

Eric

11. **Peter Woit**
December 11, 2015

Eric,
What I was trying to get at in my posting is that "proof checking" isn't really what this is about (at some later date "proof checking" comes into play, but other things have to happen first: you can't sensibly check a proof you don't understand). What mathematicians actually do is something much less mechanical, trying to individually embody understanding of mathematical ideas, and share this understanding as a community. The problem here is that Mochizuki is not successfully communicating mathematical ideas to the rest of the community. "What we've got here is failure to communicate…" Why this is happening is a fascinating question, involving both the standard ways the community operates, as well as some very unusual special features of this case. I don't actually know of any other comparable example, and also it's not at all clear where this is going to end up.

12. **sdf**
December 11, 2015

Mochizuki has made minimal effort to engage with the community at large. In that case, workshops of this sort set a dangerous precedent. Simply the fact that he has already demonstrated that he is a first rate mathematician means that we should take this thing seriously without a real and proper involvement is silly. Until he begins making more of an effort it should be ignored. And the description given by Veloch of Kuehne's talk on day 2 shows, I think, that this thing is an embarrassment to the organisers and to Oxford by proxy.

13. **jsm**
December 12, 2015

There appears to be a black hole: if someone understands Mochizuki, then *he* can't be understood by anyone else.

14. **Gavrilov**
December 12, 2015

"The danger here is that IUT is a subject disconnected from the rest of mathematics."

This is not unprecedented. In 1968, P. S. Novikov and Adian published a
(negative) solution of the famous Burnside problem. The proof was more then 300 pages long, which is impressive but not unheard of even in 1960s. Its peculiarity is that it does not use any standard methods; the authors pretty much developed a whole new theory from scratch.

Not being an expert, I can't say to what degree this theory (extremely hard to master)
is detached from the rest of mathematics. But it looks like this far it has only been used in a very narrow area of research, more or less close to the original problem.

Admittedly, the "Bernside theory" is built on a rather elementary basis, while Mochizuki started from the height of arithmetic geometry, but I would not call it a radical difference.

If the analogy, and the proof itself, is correct, then eventually we will see half a dozen of experts in this theory who understand it, while the rest of mathematicians, even from close fields, won't bother. Not terribly promising, but we do not always have what we dream of, in life or in mathematics.

15. **Chris Austin**
December 12, 2015

Under an earlier post, a commenter said that Mochizuki is a family name associated with the samurai class.

A Scientific American article, "Japanese Temple Geometry," by Tony Rothman, with assistance from Hidetoshi Fukagawa, May 1, 1998, says that during Japan's period of national seclusion, (1639 – 1854), there was a tradition in which samurai and others would prove mathematical theorems, usually about Euclidean geometry, and inscribe them on delicately colored wooden tablets called sangaku, and hang them under the roofs of temples, as an offering to the ancestors. Perhaps Mochizuki views his work in this spirit.

16. **Timothy Gowers**
December 12, 2015

I am a complete outsider to this area, but it seems to me that a very important thing that is lacking is some kind of story that explains why Mochizuki's machinery might be appropriate for proving the ABC conjecture. If I contrast it with another area I don't understand — Grothendieck-style algebraic geometry — the latter comes out far more favourably (in this one respect — I'm not talking about the fact that it has obviously been checked by thousands of mathematicians), because there are all sorts of accounts of how the more abstract way of looking at varieties is a fruitful thing to do. I know that if I did want to learn it, I wouldn't be told that I had to become comfortable with a vast array of complicated definitions before any benefits fed back into what I already know about.

The case with Perelman was again very different: I don't understand his proof at all, but I did understand accounts for the non-expert that explained about Ricci flow and what it was supposed to achieve.

What I would want to see from Mochizuki and his followers is a baby result that can be proved by his methods, that points the way towards more complicated ones.

17. **math_lambda**
December 12, 2015

On this Mathoverflow page Minhyong Kim, who is one of the organizers, has just written the following :

Update (12 December, 2015): I've written a brief summary of the Oxford workshop on IUTT rather rapidly, so as to save people the trouble of circulating rumours. This seemed to be a reasonable place to put it. All errors in it are my own: http://people.maths.ox.ac.uk/kimm/papers/iutt=clay.pdf

18. **vmarko**
December 12, 2015

That link seems to be broken (also on the mathoverflow page)?

Best, 🙂
Marko

19. **Peter Shor**
December 12, 2015

The link is probably only temporarily broken … Kim explains it in MathOverflow; he took it down while getting permission to quote Mochizuki.

20. **Gavrilov**
December 12, 2015

Gowers,

There are cases when it is impossible. The Novikov-Adian theory I mentioned
is an example of a huge machinery designed specifically for an extremely
difficult but very narrow target, which is difficult to use for anything else.
No baby results there.

As I know nothing about IUT I can't say if it is the case, but it may be
a possibility.

21. **Timothy Gowers**
December 13, 2015

Gavrilov, that's very interesting, but it raises an obvious question. If the only way to hit a narrow target is via a huge, elaborate, and seemingly irrelevant theoretical apparatus that has no other applications, then how does anybody discover that apparatus in the first place? There must be some story. The least Mochizuki could do is tell us that story. What is the story in the Novikov-Adian case? It cannot be that, just for fun, they developed an incredibly complicated theory and then observed to their great surprise that it solved precisely one interesting problem. Sometimes the story is that a theory is developed for another purpose but turns out to be useful for the given problem, but you imply that that is not the case for the the Novikov-Adian theory.

I realize that your point is that there aren't baby results along the way. Maybe I should generalize my requirement and say that there should be a path from not understanding the theory at all to understanding it completely that does not require huge leaps of faith that there is some point to what one is learning.

22. **Klas M.**
December 13, 2015

I'm far from an expert on the Burnside problem but describing the proof as isolated and without baby results does not seem correct to me. As I have understood it Novikov and Aidan set out to understand and classify periodic words and cancellation in groups and as a result of that work could prove that there are infinite Burnside groups. So before they got to their famous result they also had relevant "smaller" results.

23. **Gavrilov**
December 13, 2015

Gowers, you ask questions I would like to know the answers myself.

Apparently, the idea of a solution first came to Novikov in 1950s, but
I do not know how far it was from the final theory, and what was the *story*.
Much less what is the path "from not understanding the theory at all to
understanding it completely" in this case.

These are interesting questions, but probably they could only be answered by an expert.

24. **Gavrilov**
December 13, 2015

For those who are interested, I have found a nice piece about the solution
of the general Burnside problem on Mathoverflow, by Mark Sapir.
http://mathoverflow.net/questions/48184/a-synopsis-of-adyan-s-solution-to-the-general-burnside-problem
In particular, it is said that there is no "short description" of Novikov-Adian work.

25. **Yatima**
December 14, 2015

Thank you Chris Austin for the sangaku reference. That was an interesting read:

"Many of the problems are elementary and can be solved in a few lines; they are not the kind of work a professional mathematician would publish. Fukagawa has found a tablet from Mie Prefecture inscribed with the name of a merchant. Others have names of women and children—12 to 14 years of age. Most, according to Fukagawa, were created by the members of the highly educated samurai class. A few were probably done by farmers; Fukagawa recalls how about 10 years ago he visited the former cottage of mathematician Sen Sakuma (1819–1896), who taught wasan (native Japanese mathematics) to the farmers in nearby villages in Fukushima Prefecture. Sakuma had about 2,000 students….

The best answer, then, to the question of who created temple geometry seems to be: everybody. On learning of the sangaku, Fukagawa came to understand that, in those days, many of the Japanese loved and enjoyed math, as well as poetry and other art forms."

Sorry Peter for the off-topic posting. Please remove if inappropriate.

26. **Gavrilov**
December 14, 2015

Gowers, using your terminology from “Two cultures”,
the work of Novikov and Adian is much closer in spirit to problem solving then
to theory building. This is why there is, apparently, no way to describe it in two words.
There are other examples of this sort, although less extreme, such as the Feit-Thompson theorem.
(But probably there are reasons to call this work a new theory, albeit an odd one,
and not a huge collection of tricks. It may be systematic in its own way.)

My point is that when you are focused on a single extremely difficult problem,
then no matter where you started, you have an (unfortunate) chance of producing something as incomprehencible as the Novikov-Adian proof.

27. **David Roberts**
December 14, 2015

@Tim Gowers

I think Mochizuki *has* been telling the story of how he came to think of his ideas, and how one should think of his work as approaching the solution: by analogy with other theorems and so on. The problem is that this other, existing, body of work requires something that doesn’t exist in the arithmo-geometric world, and this is what his theory is designed to give, at the expense of catapulting out of the usual techniques and objects.

The problem is, there’s too much analogy (“alien arithmetic structures” and so on) and less middle-ground explanation before one gets to pages and pages of definitions. I think Lieven le Bruyn did a great job of working through what a Frobenioid is, in a simple and known case. Such unpacking is something Mochizuki didn’t do; clearly somebody or some collection of somebodies needs to go back to the precursor papers and fill in all the worked examples that are absent. This is for me the clearest way forward, and how to approach the massive wall of definitions with something like a climbing strategy.

28. **Rh L**
December 14, 2015

@Tim Gowers

I think Mochizuki has attempted to tell the story of how he came to develop his ideas in the slightly more expository piece, A Panoramic Overview of Inter-universal Teichmuller Theory, available on his website:

http://www.kurims.kyoto-u.ac.jp/~motizuki/Panoramic%20Overview%20of%20Inter-universal%20Teichmuller%20Theory.pdf

As far as I can tell, and this is with the caveat that I could be very wrong in such a brief space, this grew from Mochizuki’s proof of a conjecture of Grothendieck in anabelian geometry. One of the first things he seemed to have done, after proving Grothendieck’s conjecture, was to build an analogue of Hodge theory for Arakelov geometry, which he called Hodge-Arakelov theory and wrote about in papers in 1999 and 2002.

In the introduction to Panorama, he characterised the current theory as the result of trying to overcome the difficulties of applying scheme-theoretic Hodge-Arakelov theory to diophantine geometry. The resulting theory appears to be (in part) a theory of non-scheme-theoretic deformations, i.e. a theory that presumably involves geometric structures that go beyond schemes.

29. **random reader**
December 14, 2015

(Rh L) “[he built] an analogue of Hodge theory for Arakelov geometry, which he called Hodge-Arakelov theory and wrote about in papers in 1999 and 2002. ”

That’s strange, because it would have been more important than proving ABC if he had succeeded. Building a working machinery that unifies Hodge theory with its number theoretic analogue (etale cohomology and site, l-adic Galois representations) has been a central goal in algebraic geometry for the past 50 years. It would have been the news of the millenium had somebody done this.

The more limited goal of building a more adelic Arakelov geometry, has been around since the late 1970’s, and also considered very important. It is a fearsomely technical subject in ways that run in a different and much less algebraic direction than anything Mochizuki is known to have published or studied. If he had surmounted the difficulties (1) at all, and even better, (2) using his methods that don’t rely on heavy doses of modern differential geometry and analysis, that would be considered a titanic achievement. It would have been noticed and recognized in the past 15 years.

That comes to one of the weird points about the Mochizuki ABC papers: where in those documents is there any of the hardcore analysis that one would expect, relating the very general algebra to the analytic number theory problem that is ABC? One would expect at least a page or two (or fifty) of grungy estimates and hard analysis at least for getting a weak form of ABC that might be boosted to full ABC by more algebraic arguments. Mochizuki does seem to use the latter, but there isn’t much sign of hard analysis in his papers, and one should be able to find it just by skimming if it’s there. This is a question that must have come up in various forms at the Oxford conference — where is the hard work being done? — and it would be a big confidence builder if the believers would just point to the locations in Mochizuki’s papers where the analytic-number-theory part of the action takes place. The idea that it can be black-boxed into a few lines of analysis and 500 pages of algebra doesn’t sound right.

Having said that, I think the sociological concerns about not leaving Japan to explain the proof, the papers not having been refereed, etc, have been overplayed. The papers contain plenty of motivation and exposition that is illuminating apart from the stated goal of proving ABC. They are quite discursive compared to anything else in the field of arithmetic geometry, which has more than its share of long dense papers, and are not in the impenetrable dense theorem-proof style.

(can’t get the formatting to work when posting with firefox, sorry about that.)

30. **lieven le bruyn**
December 14, 2015

@David Roberts, thanks for the nice words. I only “checked” one paper as a non-specialist, got stuck and then discovered the wealth hidden in the Arakelov bit. Just the same, if a student would hand in Fobenioids1 as a paper, she’d have to rewrite it seriously.

Sad to see that some refer to my blog as criticising Mochizuki (or even calling his work ‘nonsense’), most recently at “Todeszone der Mathematik”. I’m just getting tired of his lack of interest in reaching out.

Also sad to see that Minhyong Kim did not (yet) put his report on last week’s Mochizuki-Fest in Oxford back online. I learned a lot from it. Anyway, luckily there’s always the mysterious @math_jin Twitter account to repost images of ‘lost’ files.

As my own ‘lost’ blog is getting more hits recently I’ve put a little story online about the Log Lady and the Frobenioid of Z. It’s about the Arakelov bit, but probably only digestible if you did see Twin Peaks, the log lady, and Norma at the Double R Diner, way back then…

31. **Brian Conrad**
December 14, 2015

@random reader: The “hard analysis” you’re looking for is contained entirely in the known equivalence (from several decades back) between Szpiro’s Conjecture for elliptic curves and the ABC Conjecture when each is formulated over general number fields (proof going via consideration of Frey curves associated to an ABC triple and a robust variation of the ground field).

Everything Mochizuki is doing is focused on proving Szpiro’s Conjecture for all elliptic curves over all number fields. Moreover, it is in the nature of the method that his main work is in the case of elliptic curves satisfying certain auxiliary local and global properties that necessitate working over a somewhat large number field (and the general case is then deduced by a very short argument); in particular, his method does not work directly over Q in the main parts.

For the same reason, one cannot get some insight into Mochizuki’s methods by trying to unravel what they are saying in the context of some of the other known concrete consequences, since his entire proof takes place in the setting of Szpiro’s Conjecture (whose link to the known consequences via ABC goes through long-known arguments which treat Szpiro’s Conjecture as a black box).

It is somewhat akin to the fact that Wiles’ proof of Fermat’s Last Theorem works not with the Fermat equation, nor even with elliptic curves over Q (for which general modularity in the semistable case was sufficient to apply to hypothetical Frey curves), but rather with Galois representations and modular forms, which in turn admit powerful operations having no interpretation in terms of elliptic curves (let alone the Fermat equation).

That is, one cannot get insight into Wiles’ method by thinking solely about the more concrete framework of elliptic curves (because spaces of weight-2 modular forms with a given level generally have Hecke eigenvalues that are not rational, so not all eigenforms in the space are related to elliptic curves).

32. **random reader**
December 14, 2015

Brian Conrad,

thanks very much for the comment. Good to see the big guns weighing in here.

I don’t see how Szpiro and ABC differ here, or how the lack of visible hard analysis is comparable to Wiles’ proof of Fermat’s Last Theorem.

In Wiles’ work on FLT, the analytic objects he was showing to exist were known to have a rigid algebraic description with rich properties, and conjectured to satisfy a relatively precise (Langlands) equivalence between the algebraic and analytic sides of the coin. Wiles made a breakthough on the Galois (algebraic) side and consequences on the automorphic (analytic) one flowed, but this transfer of results was not itself the novelty of his work. The relations to analysis and the automorphic side of Langlands philosophy were, if vague memory serves, encapsulated in the use of some results from Tunnell’s work on icosahedral(?) representations. Correct me if that’s wrong, it is surely in your line of expertise and not mine. But the point is that a sufficiently precise translation to the non-analytic setting was already known and Wiles used it, maybe with some new twists, but the main action was in the algebraic theory, deformation of Galois representations, the commutative algebra of Hecke rings, and the patching argument with auxiliary primes.

It is a reasonable and important question to understand what Wiles’ proof does at the level of concrete objects such as coefficients of modular forms, since he is ultimately proving an existence theorem for concrete objects and it is a bit outre if there is no way to describe in principle how the machinery unpacks to some sort of complicated manipulation of those objects. Asking the equivalent about Mochizuki’s work does not strike me as a form of confusion or category error, but a basic conceptual point that (if answered) would clarify what is happening in his papers.

Returning to Mochizuki’s proof and the absence of visible hard analysis there:

Both the Szpiro conjecture and ABC are analytic conjectures, one about numerical invariants of elliptic curves and the other about invariants of pairs of integers (or infinite families of either type of object, and the extension to number fields). In both cases one would expect a proof to include some sort of nontrivial estimation process involving inequalities, real/complex/harmonic analysis, L-functions, differential equations, etc to take place in order to obtain conclusions. Mochizuki works with some version of theta functions, which (maybe in a different setting) were known for a long time to have a more algebraic description, so to an extent there is an algebraization of the things to be proved, but I am not aware of any purely algebraic statement that is known to imply ABC or Szpiro or Vojta conjectures. His papers do involve some estimates, but rather short ones that make up very very little of the content of the papers. This is not the distribution of labor one (or this one commenter) would expect in a paper that purports to accomplish an amazing feat in what is ultimately analytic number theory.

In brief, even taking Szpiro/ABC equivalence as a black box, which might or might not contain a lot of hard analysis, it’s hard to see how the Szpiro part can then be proved without lots of additional hard analysis. Perhaps Mochizuki shows that there is so much uniformity in the way the elliptic curve invariants vary, that easy estimates will do. But even this would require some strong results interconnecting the algebra and the analysis and at some point estimates seem likely to intervene.

33. **Brian Conrad**
December 14, 2015

@random reader:

Perhaps I was unclear in the analogy I was trying to make. The aspect of the proof of FLT I was alluding to was just that even though the statement of most primary interest is about showing that a specific equation has no Q-solution or that a specific q-series with Q-coefficients is in fact a modular form, the actual context for the argument must take place (as you are aware) with Hecke operators acting on spaces with eigenvalues outside of Q and with Galois deformation rings, neither of which can be “interpreted” entirely in terms of an initial more concrete structure of interest (such as a Diophantine equation or a specific q-series or a specific elliptic curve over Q).

That is, it was just meant as an illustration of the well-known fact that to prove a theorem of interest about a concrete thing we may need to enlarge the scope of the problem and then could lose the ability to “interpret” the core ideas of the proof in terms of operations involving just the original concrete thing. An expert in analytic number theory asked me recently how to unravel Mochizuki’s arguments in the context of some other concrete consequences, and I had given a related explanation for why that couldn’t be done and that this isn’t a danger sign at all, and so I tried to import the same explanation for my original reading of your question: I had mistakenly thought you were specifically asking about trying to see where in his arguments he is getting his hands dirty with estimates involving ABC-triples. You won’t find it in that form because he never works with ABC-triples.

In the context of Szpiro’s conjecture, he also doesn’t apply IUT to any old elliptic curve, but has to assume several local and global properties which are always attained after a finite extension of the ground field with controlled degree. So it is an essential feature of his technique that he is permitting rather general ground fields, and in fact the conditions he needs can’t ever be fulfilled over Q.

In the end he is going to aim to prove Szpiro (for a given epsilon, with elliptic curves satisfying some specific local and global properties) with a constant depending on the ground field only through its Q-degree, so it is kosher for him to making extensions of controlled degree in the middle of the argument. There is a separate “short” argument using Belyi maps that reduces the general case of Szpiro to the ones he actually handles in the IUT machinery, but this latter argument is a clever proof by contradiction that makes things ineffective roughly as in Roth’s theorem.

To tell you where the “analysis” yielding an inequality should be found, I need to say something about what is going on in his method (for which I only have an impressionistic awareness based on some lectures at the Oxford workshop last week). He uses serious algebro-geometric constructions with p-adic theta functions to make cohomological constructions that encode some local numerical invariants arising in Szpiro’s conjecture (for an E satisfying the local and global hypotheses alluded to above) in terms of a special kind of fibered category (arising from E – {0}) called a Frobenioid. This encoding involves a controlled ambiguity after accounting for variation of choices made in the construction (i.e., what is intrinsic is not a specific cohomology class, but rather a certain coset by a controlled subgroup of an ambient cohomology group on a certain fundamental group). The full force of Mochizuki’s work on the anabelian properties of hyperbolic curves is used to show that everything which just happened can be expressed in terms entirely intrinsic to a Frobenioid without any reference to the original elliptic curve.

The purpose of encoding number-theoretic data (with controlled error) in terms of Frobenioids appears to be that Frobeniods admit additional intrinsic operations (such as a weak version of “Frobenius maps”) which one can’t express in terms of the original geometric objects (such as punctured elliptic curves). By analyzing how the cohomological constructions interact with those operations (this involves introducing yet more abstract notions, such as “Hodge theaters”) eventually after a lot of work he arrives at two bounded domains in an R-vector space, one domain inside the other, and comparing their volumes (which have to be computed!) gives the desired logarithmic form of the inequality with an “error term” (arising from various ambiguities in the constructions) that is the desired uniform constant if one can exert sufficiently precise control on it uniformly in the original elliptic curve. So it is in this final step of computing volumes with an “error term” that your sought-after “hard analysis” should be found.

But the constant obtained in that way isn’t the one for Szpiro’s Conjecture (for a given epsilon) for all elliptic curves over number fields of controlled degree! It is only suitable for elliptic curves satisfying a specific list of local and global properties. To bootstrap this back to general elliptic curves over an original number field of interest, one needs to go through a proof by contradiction as mentioned above, so in the end the final constant is ineffective (but depends on just epsilon and the Q-degree of the original ground field). So one recovers Mordell but not effective Mordell.

34. **Rh L**
December 15, 2015

Wow, I didn’t expect my comment to have sparked off such an excellent discussion.

@Brian Conrad: Thank you for the illuminating comments and for the excellent notes on the Oxford IUT Workshop you’ve posted here (via the “mysterious” @math_jin):

http://mathbabe.org/2015/12/15/notes-on-the-oxford-iut-workshop-by-brian-conrad/

@Lieven le Bruyn: I’ve also very much appreciated your expository work on Frobenioids. Thank you for pointing out the @math_jin account, it would seem to be very useful at this stage.

@random reader: I was going to chime in on your comment to my remark on Hodge-Arakelov theory, but I think Brian Conrad has addressed that in his notes, i.e. that what was produced in the earlier papers would not have lived up to your expectation of what a “Hodge-Arakelov theory” would be. I think Mochizuki had said as much in the introduction that I was paraphrasing.

35. **Peter Woit**
December 15, 2015

For those following comments here, but not updates, you should be reading Brian Conrad’s report on the workshop here
http://mathbabe.org/2015/12/15/notes-on-the-oxford-iut-workshop-by-brian-conrad/

36. **David Roberts**
February 9, 2016

Commenting because I can, and because it’s not true that people don’t read old comment threads[1]: they are an important source of a) historical information b) inside information. The number of times I’ve searched for things mathematical and found blog discussions on it that I found excellent…

I also wanted to comment on the mathbabe thread after it was closed, to prove up-to-date links for people trawling the interwebs for the history of this interesting episode.

[1] Sure it was a generalisation: I had assumed though that old comment threads were closed to prevent spam. The suggestion of starting a new blog to continue the discussion baffles me.

37. **Peter Woit**
February 9, 2016

David Roberts,
The main reason is because of spam, but more specifically because after a certain period the ratio of non-spam/spam comments becomes quite small, and the great majority of traffic to the postings is spambots trying to break in.

LHC Run 2 First Results

December 14, 2015
Categories: Experimental HEP News

First results using the full data from Run 2 at 13 TeV will be presented tomorrow at CERN at 15:00 Geneva time, with a live webcast available here. For some relevant commentary, see Tommaso Dorigo and Matt Strassler.

Among relatively reliable rumor sources, Jester is tweeting about a supposed excess at 750 GeV in the diphoton spectrum. We'll see tomorrow, but the problem with this is that it would be hard to understand why such a thing didn't show up in Run 1 at 8 TeV. Tommaso explains why it is only at higher masses that one expects the Run 2 data to be competitive with that from Run 1, and suggests that what to look for is a 2 TeV excess in the dijet spectrum, since there were already hints of such a thing in the Run 1 data.

Matt describes 13 TeV results recently published by the ATLAS and CMS groups looking for exotic behavior at very high mass (predicted for instance by various theories of extra dimensions). Nothing there.

One other thing to look for is whether Gordon Kane will get his Nobel Prize. He's predicting a 1.5 TeV gluino, with current limits around 1.4 TeV, and this year's Run 2 data perhaps enough to push those up a bit. It may though be that such analyses will be among those that take longer, not appearing until the Moriond conference in March.

Update: CMS went first, results now publicly available here. Tommaso was pulling our leg, the 2 GeV Run 1 excesses have gone away. There is a diphoton excess at 766 GeV, but an unimpressive one (2.6 sigma locally, 1.2 sigma with look elsewhere effect).

Gluino mass limits have moved up, some as high as 1.7 TeV. Presumably Kane is now at work on new string theory predictions.

Bottom line: nothing beyond the SM so far.

Update: ATLAS next. No gluinos up to 1.8 TeV. 2.2 sigma for the 2 TeV excess that CMS doesn't see.

They also see an excess in diphotons around 750 GeV, 3.6 sigma local significance, 1.9 sigma with look-elsewhere. So, starts to look interesting if combined with CMS, the rumor was right. They also reanalyzed the Run 1 data, nothing there at 750 GeV, no combination of Run 1 and Run 2.

Results available here.

Bottom line: only thing interesting is the possible 750 GeV diphoton excess. One can predict a flood of theory papers with models predicting such a thing. Will have to wait until at least next summer though to see if this gets confirmed or goes away.

Commentary from Matt Strassler here.

Update: As expected, best explanation and discussion of the implications of the diphoton excess is from Jester, see here.

Reasons to be excited: naively combining CMS and ATLAS gives something of 4 sigma significance, people are making the analogy with the early Higgs signal. Reasons to be less excited: in the case of the early Higgs signal, the tentative signal was what was expected from the Higgs, and we had very good reasons to believe there was a Higgs roughly in that mass range. Here I know of no well-motivated models that predict this: extraordinary claims require extraordinary evidence, and this is not that.

Comments

1. **Tom Weidig**
   December 15, 2015

   Lubos is offering bets. May be you should take it if you believe in a non-discovery.

   http://motls.blogspot.lu/2015/12/a-new-750-gev-boson-is-very-likely-there.html?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed:+LuboMotlsReferenceFrame+(Lubos+Motl%27s+reference+frame)

2. **Peter Woit**
   December 15, 2015

   Tom Weidig,
   Not interested in betting against this (especially not at 10-to-1 odds). I do think the likelihood is now stronger that this will go away than that it will survive, but it would be fantastic if this were true: the non-standard model physics we've been waiting to see for 40 years, at an energy where the LHC can start to study it.

3. **vmarko**
   December 15, 2015

   If the 750 GeV event eventually turns out to be really a new particle, I am sure that Gordon Kane will easily modify his ST model such that it… hmm… will have had predicted… precisely that particle, several years ago. 🙂

   And if you ask him how is that even possible, he'll give the (by now famous) answer: "go and read my paper, it's all written there."

   Best, 🙂
   Marko

4. **NeapTide**
   December 15, 2015

   Nice, hope it is really true.

   LUX (the dark matter experiment) also published a nice paper this week. They seem to have calibrated way better than ever before, and aren't seeing the low-mass WIMPs that were claimed.

5. **Peter Woit**

December 15, 2015

Marko,
I don't think Kane has shown interest in "predicting" unexpected things like this. So far his claims have been about string theory "predicting" the Higgs, and "predicting" that the Higgs will behave like the standard model says, as well as a long history of "predictions" of superpartner masses.

A couple interesting things to watch for over the next year:
1. Once Kane moves his "prediction" of the gluino mass up again in coming months, who will invite him to give a talk explaining why string theory "predicts" a 2 TeV gluino, and not mentioning any of the earlier string theory "predictions" of the gluino mass that marched up from a few 100 GeV years ago to 1.5 TeV in Munich recently? Will the organizers of the Munich conference publish in their proceedings the news of the falsification of string theory? Will Physics Today publish an update on the "supertestability" of string theory?

2. Any reasonable hope for vindication of SUSY at the LHC is rapidly disappearing, at what point will all those besides Kane who advertised SUSY at the LHC as a "test of string theory" admit failure and face up to the implications of this failure?

6. **Ralph Dratman**
December 15, 2015

"One can predict a flood of theory papers with models predicting such a thing."

Does your theory of theory paper flooding give any quantitative predictions? There might be some surprisingly energetic papers in flight right now, from a University far, far away.

7. **Cosmonut**
December 15, 2015

"Gluino mass limits have moved up, some as high as 1.7 TeV. Presumably Kane is now at work on new string theory predictions."

In an universe where string theorists are not continually revising their predictions, they do not exist because nobody was willing to sponsor a program of research which promised a theory of everything and delivered nothing after 40 years.

This is a demonstration of how useful the Anthropic Principle is for explaining properties of the universe that we observe. 🙂 🙂

8. **RandomPaddy**
December 15, 2015

How many times has a maybe-maybe-not bump like this appeared before? Are there examples where it did and didn't result in a new particle being ultimately confirmed?

9. **Peter Woit**
December 15, 2015

Random Paddy,
Jester refers in his posting to early hints of a Higgs that disappeared
"It is a very large effect, but we have already seen this large fluctuations at the LHC that vanished into thin air (remember 145 GeV Higgs?)."
I think one can probably come up with quite a few such examples, there's a reason that people in this field have adopted the "5 sigma" standard. In this case it's tricky how to take into account the two different experiments (they haven't combined their data), as well as the fact that you're looking at lots of different channels, so increasing the probability of seeing a fluctuation in one of them. I doubt that at this point the statistical significance of this is near 5 sigma. In addition, the fact that this doesn't correspond to anything theoretically well motivated argues for added caution (and also, added excitement if it works out).

Run 2 and SUSY

December 15, 2015
Categories: This Week's Hype, Uncategorized

What surprised me most about today's Run 2 results (see here) was that CMS and ATLAS were able to already significantly push up limits on superpartner masses, especially the gluino mass. Limits on the gluino mass went from 1.3-1.4 TeV in Run 1 to something like 1.6-1.8 TeV in the new Run 2 data (this depends on exactly what channels one is looking at). This not only kills off Gordon Kane's string theory prediction of a 1.5 TeV gluino, but it also removes a large chunk of the remaining possible mass region that the LHC will be able to access. And it wasn't just the gluino: ATLAS quoted limits on sbottom masses moving up from 650 GeV in Run 1 to 850 GeV today. Whatever you thought the remaining probability was for SUSY after the negative Run 1 results, it's significantly smaller today.

Almost all the news has been about the possible diphoton excess, ignoring the quite significant story about SUSY. Davide Castelvecchi at Nature though today talked to Michael Peskin, who has been one of the more consistent proponents of SUSY over the years, and this was part of his story:

> Meanwhile, searches for particles predicted by supersymmetry, physicists' favourite extension of the standard model, continue to come up empty-handed. To theoretical physicist Michael Peskin of the SLAC National Accelerator Laboratory in Menlo Park, California, the most relevant part of the talks concerned the failure to find a supersymmetric particle called the gluino in the range of possible masses up to 1,600 GeV (much farther than the 1,300-GeV limit of Run 1). This pushes supersymmetry closer to the point where many physicists might give up on it, Peskin says.

I had thought that the "physicists give up on SUSY" story wouldn't get going until next year, but maybe it's already started.

Update: In just a few hours after the announcement already 10 papers on hep-ph devoted to explaining the diphoton resonance. SUSY explanations not among the popular ones.

Update: Another eight or so papers explaining the diphotons. And the press has the obvious explanation: string theory:

The idea seems to be that since people were looking for Randall-Sundrum gravitons (which somehow counts as string theory) then if they find something in the diphoton spectrum it could be a graviton. I'm no expert, but none of the dozens of hep-th papers seem to discuss this possibility, and the papers about searches for Randall-Sundrum gravitons (like this one) set limits way above a TeV. On the other hand, I don't doubt that some "string vacuum" can be found that will explain the diphotons, and that we'll hear more about it in the press.

Comments

1. **Noboru Nakanishi**
   December 15, 2015

   SUSY cannot be a (spontaneously broken) symmetry of the elmentary-particle physics. This proposition is a logical consequence of quantum Einstein gravity. It is quite surprising that there are still many people who do not want to give up SUSY!

2. **Brandon Enright**
   December 16, 2015

   Is there any chance at all that this 750 GeV bump could be the boson super partner to a SM fermion? I take it diphoton decay is not the expected SUSY signal?

3. **Peter Woit**
   December 16, 2015

   Brandon,
   I'm sure one could come up with some kind of SUSY model to explain this, but it's not what's expected in simpler such models.

4. **Bernhard**
   December 16, 2015

   Peter,

   But isn't electroweak SUSY production still not the last hope? I remember in these searches the gluino mass is assumed very high and "decouples" from the LHC phenomenology. The cross section for electroweak production is lower, so I would consider these scenarios to be still possible (not that I personally believe on them). I know ATLAS and CMS have produced limits there too, but should not be competitive with strong production.

5. **Peter Woit**
   December 16, 2015

   Bernhard,

   Sure, the easiest thing to see is strongly interacting superpartners, and it's only those that the LHC is now putting new bounds on. Maybe all the strongly interacting ones are very massive, but there are electroweak ones you can detect with enough luminosity. Very much worth looking for, especially because you might find something else interesting. But, I don't know of any serious motivation for the idea that strongly interacting superpartners are very massive and decouple, other than a desire to avoid conflict with what experiments are now telling us.

   I suppose I should look at materials from people promoting the ILC, I think that looking for such things is one of the arguments for that kind of machine.

6. **David**
   December 16, 2015

   I believe that the SUSYers can "explain" the diphoton excess in the next few days. 🙂

7. **Peter Woit**
   December 16, 2015

   David
   Already done, see

http://arxiv.org/abs/1512.05333

Also, it seems that string theory can explain this, see
http://arstechnica.co.uk/science/2015/12/first-high-energy-lhc-results-supersymmetry-still-dead-watch-for-gravitons/

8. **Luka**
December 17, 2015

Brandon Enright: *Is there any chance at all that this 750 GeV bump could be the boson super partner to a SM fermion?*

But wouldn't this violate the R-parity?

9. **Douglas Natelson**
December 17, 2015

I've heard grumbling (Strassler alludes to this) that ATLAS didn't combine with their Run 1 results (which would have lowered the significance considerably, since there seems to be no hump in Run 1 near 750 GeV). Any word on the reasoning here, since it's presumably not naive cherry-picking?

10. **Peter Woit**
December 17, 2015

Douglas Natelson,
I'm no expert, but I've heard two problems with such a combination are
1. Backgrounds are different at 8 and 13 TeV.
2. Even if there is a new 750 GeV state, you don't know what produced it, can imagine that production rates are quite different at 8 and 13 TeV. One way this could happen is if this new state is the result of a decay of something even heavier, heavy enough so that there's a big difference in production cross-section.

11. **AS**
December 18, 2015

The problem with RS gravitons is that they predict
sigma(pp->gamma gamma) = sigma(pp-> e+e- + mu+ mu-).
But no peak is observed in dileptons. See page 9 of
http://arxiv.org/pdf/1512.04933v1

12. **Peter Woit**
December 18, 2015

AS,
Thanks for explaining that, and thanks for the useful reference.

13. **mfb**
December 19, 2015

@Douglas Natelson: I'm surprised that CMS did some combination, and apparently just for the backup slide in the presentation – I have no idea how they did it and they didn't publish it. How to combine 8 and 13 TeV? The cross-section ratio depends on the production process, which is unknown.

14. **Howard Baer**
March 5, 2016

The question of when to give up on weak scale supersymmetry is addressed in a recent paper arXiv:1509.02929 (PRD93 (2016) 035016 entitled

Upper bounds on sparticle masses from naturalness or how to disprove weak scale supersymmetry

Gluino masses can range up to about 4 TeV before much fine-tuning sets in.
In this case, LHC has explored only a fraction of the allowed SUSY parameter space.
The Higgsinos have the most direct connection to naturalness, but these particles are exceedingly difficult to see at LHC. They are better searched for at an e+e- collider such as the proposed ILC.

15. **Peter Woit**
March 5, 2016

Howard Baer,

I find it hard to reconcile your present claims with the many colloquia about SUSY I've sat through during the past 20 years (Peskin and Arkani-Hamed are among the examples that come to mind), in which an explicit claim was made that if SUSY was the mechanism to explain fine-tuning, it would definitely be seen at the LHC. For another example of this, there's your such 2009 talk

http://arxiv.org/abs/0908.2785

where you state
"On the theory side, quadratic divergences associated with the scalar sector require new physics at or around the electroweak scale. Also, we have no guidance as to the origin of the generations, the quark and lepton masses and mixings or the origin of the gauge symmetries. We also need a consistent merging of the SM with a quantum mechanical theory of gravity.
On the positive side, data from existing experiments are already pointing the way to a new, more elegant paradigm for the laws of physics as we know them. In addition, data from experiments soon to operate, especially from the CERN LHC, should clinch the deal."
and
"These data, matched against SUSY theory, seem to point to the Minimal Supersymmetric Standard Model (MSSM) (or MSSM plus gauge singlets) as being the correct effective theory of nature between the weak and GUT scales. The truth will be revealed by experiment as the LHC era gets under way, since weak scale supersymmetry predicts a host of new matter states, many of which should be accessible to LHC searches."

Given this history, I don't see why one should take seriously claims that this idea isn't dead because the LHC was never going to be able to resolve the issue.

Updates

December 16, 2015
Categories: Multiverse Mania

Some new items mostly updating older ones:

- Natalie Wolchover has a very good article at Quanta, entitled A Fight for the Soul of Science, reporting on the recent Munich conference discussed here. David Gross sounds a little bit like John Horgan, emphasizing the problem of HEP physics getting too difficult, with an "End of Science" danger. I think he has the problem right:

  > "The issue in confronting the next step," said Gross, "is not one of ideology but strategy: What is the most useful way of doing science?"

  I hadn't realized quite how radical Dawid is. He seems to have moved on from discussing theory "assessment" to theory "confirmation". Even the most devoted string theorists like Gross may be unwilling to sign on to this, comfortable with the idea that string theory deserves a positive assessment, as a promising idea still worth working on, much less so with claims from Dawid that one can sensibly discuss string theory as a "confirmed" theory, one that belongs in our school textbooks.

  There was much discussion evidently of Bayesian confirmation theory, and Gross was enthusiastic about this

  > Gross concurred, saying that, upon learning about Bayesian confirmation theory from Dawid's book, he felt "somewhat like the Molière character who said, 'Oh my God, I've been talking prose all my life!'"

  He may have become a bit less enthusiastic later when faced with Joe Polchinski's Bayesian calculation showing a 94% probability confirming the multiverse.

  Sabine Hossenfelder and Carlo Rovelli both explained well the danger of such claims of non-empirical Bayesian confirmation of one's ideas:

  > The German physicist Sabine Hossenfelder, in her talk, argued that progress in fundamental physics very often comes from abandoning cherished prejudices (such as, perhaps, the assumption that the forces of nature must be unified). Echoing this point, Rovelli said "Dawid's idea of non-empirical confirmation an obstacle to this possibility of progress, because it bases our credence on our own previous credences." It "takes away one of the tools — maybe the soul itself — of scientific thinking," he continued, "which is 'do not trust your own thinking.'"

- For more on the "non-empirical science" front, see Alan Lightman's long piece in Harper's on "Quantum Cosmologists" Sean Carroll, Alexander Vilenkin, James Hartle and Don Page. Lightman waxes poetic on the importance of "The need to ask the really big questions", but unless I missed it, there's nothing there about the need to provide any evidence for the answers that one comes up with. At least one of the four quantum cosmologists, Don Page, seems to see no particular distinction between theology and science.
- On the Mochizuki front, there's this report in Nature about the Oxford conference. On the question of what went wrong with the later talks

  > But Conrad and many other participants say they found the later lectures indigestible. Kim counters that part of the difficulty lay in cultural differences: Japanese mathematicians have a more formal style of lecturing than do those in the West and they are not as used to being questioned by a testy audience, he says.

  I don't think the "Japanese culture" explanation of the problem holds water. Of the three problematic speakers, one (Mok) is not Japanese at all (from Hong Kong), and the other two certainly understand that explaining mathematics to someone is about more than reading a lecture to an audience. It's not plausible that the reason they didn't have satisfactory answers to questions from the audience is their Japanese cultural background. For the case of Mochizuki himself, he grew up here in New York, went to prep school, undergraduate and graduate school in the US. The question of why following him is so difficult is a fascinating one, but I don't think the answer to it has anything to do with his choice to move to Japan.

  A must-read detailed report on the situation is Brian Conrad's, available here.

Update: For some other commentary on the Munich workshop and relevant issues, see Sabine Hossenfelder and my Columbia colleague Andrew Gelman (who I think, unlike anyone in the theoretical physics community, actually knows something about Bayesian methods).

Update: Fesenko has a comment at the Nature article, where he makes the claim: "There are no questions about the theory which are left unanswered." I agree with my Columbia colleague David Hansen's response to this, that this seems to be an absurd statement.

Update: There's a very good report on the abc conjecture workshop from Kevin Hartnett at Quanta. His take on what happened agrees with others:

> Kedlaya's exposition of Frobenioids had provided the assembled mathematicians with their first real sense of how Mochizuki's techniques might circle back to the original formulation of Szpiro's conjecture. The next step was the essential one — to show how the reformulation in terms of Frobenioids made it possible to bring genuinely new and powerful techniques to bear on a potential proof. These techniques appear in Mochizuki's four IUT theory papers, which were the subject of the last two days of the conference. The job of explaining those papers fell to Chung Pang Mok of Purdue University and Yuichiro Hoshi and Go Yamashita, both colleagues of Mochizuki's at the Research Institute for Mathematical Sciences at Kyoto University. The three are among a small handful of people who have devoted intense effort to understanding Mochizuki's IUT theory. By all accounts, their talks were impossible to follow.

There's also a report now from Fesenko, available here. His take on this is that the problem wasn't the talks, it was the audience:

> Labor omnia vincit. Progress in understanding the talks correlated with preparation efforts for the workshop. There were participants who came unprepared but were active in asking questions, many of which were already answered in recommended surveys and some of which were rather puerile.

Unclear what the point of such remarks is, unless the goal is to make sure that many of the experts who attended the workshop won't come to any more of them.

Update: The paragraph from Fesenko's report on the workshop quoted about has been removed, replaced by

> Без труда не выловишь и рыбку из пруда. Progress in understanding the talks correlated with preparation efforts for the workshop. Lack of reading of non-classical papers of the theory often correlated with the depth of asked questions.

Update: Nature covers the Munich conference as Feuding physicists turn to philosophy for help.

Update: The Fesenko report has been further edited, with the paragraph mentioned above now reading

> Без труда не выловишь и рыбку из пруда. According to the feedback, progress in understanding the talks and quality of questions often correlated with preparation efforts for the workshop and reading of non-classical papers of the theory.

Update: Michael Harris's take on the press coverage of the Oxford conference is here.

Comments

1. **Low Math, Meekly Interacting**
   December 16, 2015

   Well…I was recently in a video conference with some potential Japanese collaborators, and it was impossible to get answers to all but the most straightforward and anodyne questions. Incredibly awkward. The translator sometimes would just sit there, fidgeting slightly, apparently so abashed by what we were saying she couldn't speak it aloud in Japanese. You could tell how well the men (all men) around the table could understand English, though, by how red their faces were getting with whatever mix of mortification and rage they were attempting to conceal beneath stone-faced stoicism. I've worked with loads of Japanese researchers who've done a lot of post-graduate or post-doctoral work in the West and were fairly acclimated. Never had a problem. But perhaps without some amount of pre-exposure, there can be substantial cultural barriers to useful dialog, and a lot still gets "lost in translation". Or not translated at all!

2. **Staffan Angere**
   December 16, 2015

   Bayesian confirmation theory is very, very popular in philosophy right now, especially in epistemology. My guess is that this is mainly because (i) it is simple and often lots of fun to play around with, (ii) it is mathematical and therefore rigorous in at least one way, and (iii) you can use it to prove more or less anything.

   Dawid's treatment of the no-alternatives argument (published in a paper in the British Journal for the Philosophy of Science this year, written together with Hartmann and Sprenger) is a good example of (iii). Given the model (or "framing") they use, and their assumptions about the priors, the argument is certainly valid. But the model is just one possibility out of countless, and while most of their assumptions sound prima facie reasonable in that specific model, other models would give quite different recommendations.

3. **Scott Church**
   December 16, 2015

   Peter,

   Regarding Lightman's piece, I got the same impression you did–he seems to think that when asking "the really big questions" one needn't bother with meaningful searches for evidence for the answers that one comes up with. But that said, I don't think Don Page is blurring science and theology. As a Christian, he believes the hand of God is manifested in the workings of nature and that fills him with wonder. But rest assured he is quite clear that this is a *metaphysical* stance well outside the realm of his science. It certainly hasn't kept him from contributing to quantum cosmology research–he's a leader in the field.

   I believe his comments are in response to Sean Carroll and Lawrence Krauss (also mentioned in the essay), both of whom are outspoken atheists who actually *have* made a point of publicly blurring the distinction between science and theology (or "a-theology" if you will), and on many occasions. Page is simply setting the record straight by pointing out that his faith coexists quite nicely with his quantum cosmology research–that science and theology are separate but complementary realms that are neither incompatible, nor mutually exclusive, and they shouldn't be encroaching on each other's turf. If anything, it is *he* who is who is clear about this rather than the others.

4. **Peter Woit**
   December 16, 2015

   Scott Church,
   I don't think Page always so cleanly separates his science from his theology, see for instance
   http://arxiv.org/abs/1412.7544
   I see that Carroll has just finished writing a book: "ON THE ORIGINS OF LIFE, MEANING, AND THE UNIVERSE ITSELF", which starts out with the fundamental nature of reality and ends up with a code of ethics. This strikes me as designed to compete with the great religious texts, although presumably in the parts not quantum cosmology he is often invoking well-grounded scientific facts.

5. **Scott Church**
   December 16, 2015

   Thanks Peter! I hadn't seen that paper of Page's, but I plan on reading it more closely soon as I get a chance. At first blush it looks as though he's attempting to argue via inference to the best explanation in both scientific and philosophical areas, invoking (among other things) well-grounded facts wherever they seem relevant. I haven't seen Carroll's book yet, but based on what you said I get the impression he's trying to do the same.

   Part of the problem with this sort of thing is that fields like quantum cosmology unavoidably take us into realms where the line between physics and metaphysics is easily blurred and it becomes increasingly difficult keep the two separate, and all the more important that we do so. This is a problem because (in my experience at least) not many physicists are well-trained in philosophy–particularly philosophy of science and religion which is what's really needed for that. Some folks do cross the line from time to time, but I don't think that necessarily means they aren't doing their best to appropriately honor it. More than one physicist of late has suggested that perhaps it's time for more dialog between physicists and philosophers, and I for one, agree. Speaking of which… I find it telling that Krauss–who runs rough-shod over that line every chance he gets–is openly contemptuous of philosophy, including the philosophy of science, and has been called out for it by many commentators including Carroll himself.

6. **vmarko**
   December 16, 2015

   Peter,

   Dawid's usage of the term "confirmation" was a matter of vigorous analysis and debate during the conference.

   As Dawid explained during the Q&A session, he uses the term confirmation as synonymous to "increasing the Bayesian probability that for the viability of the given theory", or something to that effect (there was also a big discussion what "viability" means in this context, but that's another story). Here the word "confirmation" is being used as a highly specialized technical term, defined in the context of Bayesian analysis. Dawid's point was that, according to latest understanding in philosophy of epistemology, the term "confirmation" can actually have no other meaning except the above Bayesian one.

   Despite the fact that he is probably right about latest results in epistemology, he was still heavily criticized for using the word confirmation, from two sides. First, if you ask a random person on the street what does it mean that a theory is confirmed, they are not going to start talking about Bayesian epistemology etc. Common meaning of the word "confirmation" in everyday usage is waaay different than the specialized technical meaning that Dawid uses. Of course, the common meaning is ill-defined, does not stand up to epistemological scrutiny, and eventually boils down to the technical Bayesian meaning when one thinks about it really hard. But despite this, ordinary people still understand the word in that common everyday sense ("being confirmed means that it's true"), just like a whole bunch of other ill-defined terms (like truth, proof, reality, etc…). So this is bound to introduce confusion.

Second, George Ellis mounted a very strong criticism of Bayesian analysis itself, distinguishing between adjusting the prior in light of new data, versus adjusting the prior in light of new theories. The former is useful and good, the latter does not really make sense. In short, Bayesian analysis is legitimately applied to information. However, theory is not information, and Bayesian analysis cannot be applied to theories.

My impression is that Dawid acknowledged these criticisms. The biggest part of the problem (although not the only one) turned out to be just the poor choice of terminology.

Also, another thing that became overwhelmingly obvious was the misinterpretation due to ignoring the proper context. When you hear the main single-sentence claim by a philosopher, it can sound scandalous or overstated. But when you listen to their lecture which explains the claim in more detail, you become aware of all the footnotes, side-remarks and technical definitions that reinterpret the scandalous main claim into something much more reasonable, well-measured and uncontroversial. It's like in journalism — the title of the newspaper article produces a "Wow!!! Seriously?!" reaction, but when you read the whole article, your reaction reduces to "Oh, of course, it's obvious and trivial, nothing to see here really (yawn)…".

So Dawid's statement is much less controversial when one understands the appropriate context and technical definitions of the terminology being used. The only criticism beyond that is basically the one given by George Ellis.

Best, 🙂
Marko

If the new scalar at 750 GeV really exists and if it will turn out to be there for no natural reason, it would make a direct contradiction with anthropic selection arguments

10. **Ali**
December 17, 2015

As the pragmatist (and radical empiricist) C.S. Peirce already argued convincingly over a century ago, Bayesian inference has no place in valid scientific inference (or in inference of any sort, for that matter, e.g. in business decision making). That Bayesian inference now plays an increasingly prominent role in particle physics, astrophysics/cosmology, and now biology is unfortunate and personally very depressing (I have watched this develop over my time working in these three different communities). This is what happens when scientists hand over the keys to statisticians and philosophers of science (don't expect the philosophers to come to the rescue either…I strongly dispute Dawid's claim that Bayesian inference is the only solution to the problem of confirmation, as reported above by Marko). It would probably help if there were more dialogue among these communities. What would be useful for many would be to simply revisit Peirce's writings on scientific inference, which were way ahead of his time (and still ahead of our own time apparently…he would have been sorely disappointed with the Munich conference). The enormous amount of nonsense written in the intervening century (in both statistics and in the philosophy of science, and in their intersection, e.g. Popper) may still prevent most from appreciating how fundamental and relevant his writings remain.
****

"The relative probability of this or that arrangement of Nature is something which we should have a right to talk about if universes were as plenty as blackberries, if we could put a quantity of them in a bag, shake them well up, draw out a sample, and examine them to see what proportion of them had one arrangement and what proportion another. But, even in that case, a higher universe would contain us, in regard to whose arrangements the conception of probability could have no applicability." (Peirce 2.684, i.e., volume 2, section 684 of his collected papers)

****
"Every argument or inference professes to conform to a general method or type of reasoning, which method, it is held, has one kind of virtue or another in producing truth. In order to be valid the argument or inference must really pursue the method it professes to pursue, and furthermore, that method must have the kind of truth-producing virtue which it is supposed to have. For example, an induction may conform to the formula of induction; but it may be conceived, and often is conceived, that induction lends a probability to its conclusion. Now that is not the way in which induction leads to the truth. It lends no definite probability to its conclusion. It is nonsense to talk of the probability of a law, as if we could pick universes out of a grab-bag and find in what proportion of them the law held good. Therefore, such an induction is not valid; for it does not do what it professes to do, namely, to make its conclusion probable. But yet if it had only professed to do what induction does (namely, to commence a proceeding which must in the long run approximate to the truth), which is infinitely more to the purpose than what it professes, it would have been valid." (Peirce 2.780)
****

For those curious about the further details of this history, you can refer to my book draft. In this draft, I also present a novel and optimal approach to general statistical inference, one that is strictly frequentist in nature and in complete accord with Peirce's guidelines, providing a concrete example of just how relevant his ideas continue to be:
http://arxiv.org/abs/1301.5186

(Apologies to Peter for the self-promotion, but this history and perspective is unfortunately not presented anywhere else in the literature.)

11. **Chris W.**
December 17, 2015

Ali,
In the excerpt from your comment below, are you indicating that Popper was the source of some of that nonsense? (I should note that he was a great admirer of Peirce's contributions.)

The enormous amount of nonsense written in the intervening century (in both statistics and in the philosophy of science, and in their intersection, e.g. **Popper**) may still prevent most from appreciating how fundamental and relevant his writings remain.

12. **Chris W.**

Andrew Gelman's post (the pingback above) is highly relevant.

13. **Peter Woit**
December 17, 2015

Bee,
Thanks, I did see that, strongly recommend that those interested in this read your article, so added another link to it (and to the Gelman posting).

14. **Ali**
December 17, 2015

Chris,

Peirce of course considered falsification an important aspect of inference, but he also recognized the narrowness of this purely "negative" view of inference (which Popper never properly conceded). What is missing in Popper is the "positive" basis of the process of scientific inference on Occam's razor. Peirce recognized the importance of Occam's razor, but even he didn't go as far as I would in stressing its essential nature. There are really just two aspects to scientific inference (and epistemology, period), the statistical frequentist notion of goodness-of-fit or what I more generally refer to as "concordance" (and which Peirce alludes to in the above quotes) and Occam's simplicity. Without Occam, we are lost in a sea of possible theories; we need simple theories to make the fastest growth in our knowledge of the universe (see Peirce's discussion of the game of twenty questions, which I also write about in my book draft). Without goodness-of-fit applied to real-world observations (e.g., most famously through Pearson's chi-squared test, but even more fundamentally through the statistical approach that I develop in my book draft), we are slaves to arbitrary conventions (Bayesian "flat priors"). But the latter is a deeper argument, the details of which you will find in my book draft.

I have long thought that Peter's view of string theory as "not simple" is indeed the most important criticism of the entire endeavor. That it is "not even wrong", i.e. not testable (easily), is also of course important, but its lack of simplicity is more critical. These two critiques embody well the dual competing aspects of scientific inference, simplicity and concordance.

15. **Ali**
December 17, 2015

For more details on Popper's views, I recommend Deborah Mayo's book "Error and the Growth of Experimental Knowledge". While she also admires Peirce, she is an avowed Neyman-Pearsonian ("confidence intervals" are unfortunately merely a "confidence trick" as Arthur L. Bowley noted long ago and Edwin B. Wilson, Gibbs's sole student, did his best to inform us of). While I disagree strongly with her on her defense of Neyman-Pearson (see my book draft for further details), her presentation of Popper's views is very interesting.

I need not point out that it's of course better to be a Karl-Pearsonian or Fisherian or Neyman-Pearsonian or Popperian frequentist than to be a Bayesian.

But even better is to be a Peircean frequentist.

16. **srp**
December 17, 2015

Dogmatic frequentists and Bayesian comments read to the outsider much more like religious than scientific claims. Both are inveterate proselytizers of the unchurched.

17. **Cormac O'Raifeartaigh**
December 17, 2015

That's a very nice summary of the Munich meeting from Bee in Forbes magazine, Bee.
However, there is one aspect of the debate that still puzzles me: one lesson from the history of theoretical physics is that many 'sleeping beauty' theories showed little sign of connecting with experiment at first, but did eventually throw up predictions that could be tested. It seems to me that we should not assume that the difficulties in connecting string theory to the real world may one day be overcome…the real question is, how long along the road does one travel before losing heart?

18. **Cormac O'Raifeartaigh**
December 17, 2015

P.S. Indeed, one can draw a useful link between the Munich conference and the recent conference on the history of GR in Berlin as follows:
After the initial excitement following Eddington's observations of the bending of light in 1919, GR went through something of a 'low watermark' period. It was not until the observation of evidence for exotic phenomena such as quasars, pulsars and black holes in the 1960s that GR became a topic of major interest to the community. So it took 50 years for a theory of gravity to connect with the macroscopic world – how long should we allow for a theory concerning the sub-atomic world to mature such that it can make predictions about that world? Who can know that such predictions will not be rendered possible through some unimaginable mathematical breakthroughs down the road?

19. **Jeffrey M**
December 17, 2015

Cormac

I think trying to compare string theory and GR is pushing it. After Eddington GR was essentially universally acknowledged to be the theory of gravity. It wasn't necessarily such a big deal for a long time because no one thought there was much to do with it. I mean Newton works just fine for almost anything anyway, and there weren't any big problems out there that anyone thought GR would apply to. And there were very good people working on it, coming up with all sorts of solutions of the field equations. And it was THE theory. String theory is almost the opposite, there are plenty of big question out there people hoped it would apply to, but of course there has not ever been any way to test any of it. Beyond what is going on at the LHC now, where SUSY is NOT showing up, which as best I understand it would be a real problem for ST.

20. **Scott Church**
December 17, 2015

Cormac,

It is true that "sleeping beauty" theories sometimes surprise us by turning out to be more testable than we thought. There certainly are times when deciding how far to travel a road before giving up isn't easy. But that said, there are at least two differences between string theory and your GR analogy.

First, Eddington's observation of gravitational light bending *was* in fact an unambiguous test of GR. For that matter, so was the perihelion precession of Mercury. In both cases GR made specific predictions that could be accurately measured, and they were verified. These two observations alone were reason enough to embrace GR no matter how long a low-watermark period ensued. Despite 40+ years of effort no such thing has occurred with string theory.

Second, as already noted, GR makes clear predictions–the kind that can be tested and falsified if they're wrong. String theory doesn't. The problem isn't just that testing it is likely to be out of reach for the foreseeable future–the larger problem is that it's fluid enough to predict literally *anything* we might observe. Hence, the title of Peter's book and this blog: *Not Even Wrong*. GR *could* have been wrong… and it wasn't. As it stands today string theory can't be, and that situation isn't likely to change anytime soon.

IMHO, these problems are more than enough reason to justify turning down a different road.

21. **Peter Woit**
December 17, 2015

I'd rather if Cormac's comment not be the excuse for rehashing rather old arguments about string theory, and GR isn't a great analogy, for many reasons.

I don't know how much it got discussed at the Munich workshop, but the "when do you give up and try something else" question is obviously a central one for string theory, as well as for the philosophy of science in general. I've noticed in recent years a change in how string theorists respond to the "when can it be tested" question, from "by finding SUSY at the LHC, by observing cosmic strings, by Planck CMB results, etc." to "maybe something unexpected will appear". While unexpected progress can't be ruled out, and is a good argument that some people who think they see a way forward should keep trying, the shift to this argument is an indication of a problem. How do you keep this argument from being used to justify sticking with a failed research program, since, no matter how bad things look, it's always the case that maybe a miracle will happen?

22. **Chris W.**
December 17, 2015

Scott Church's reply to Cormac is exactly what I was thinking of saying. The "something unexpected" that is needed is a large reduction in the flexibility of string theory to which he refers. That does not refer to relevant observations or the lack thereof. It refers to how the theory *responds* to observations.

Ali,
In my mind this flexibility is what the lack of simplicity of string theory is really about. Simplicity is essential to making a theory *meaningfully* testable, and not merely capable of cranking out quantitative assertions that one might try to compare with observation. If GR's predictions of gravitational light bending and the perihelion precession of Mercury had been conditioned on hidden structure that could be freely adjusted to achieve agreement with observation, then GR would have been viewed in a different light—maybe a signpost on the road to a good theory, but not satisfactory as it stood. And that inadequacy would have nothing to do with an inability to produce numbers that could be compared with experiment, either in theory or in practice.

PS: Another way to put this is to say that ability to generate assertions about observable objects or events is a prerequisite for testability of a theory, but by itself falls well short of testability in the usual sense.

23. **G.S.**
December 17, 2015

This is probably just semantics, but is the perihelion precession of Mercury considered a "prediction" of GR? It adequately explains the deviation from Newtonian gravitation but the effect had been known for quite a while. I would think that any new theory of gravitation which failed to explain the precession would have failed to gain attention. In that sense, it's more of a "post-diction". The deflection of light and gravitational redshifting of light strike me as the true "predictions".

24. **vmarko**
December 17, 2015

Peter,

"I don't know how much it got discussed at the Munich workshop, but the "when do you give up and try something else" question is obviously a central one for string theory, as well as for the philosophy of science in general."

It did get discussed, that was one of the main topics actually. David Gross kept repeating the word "strategy" all too often, there was a big debate what does it mean to say that a theory is "viable", etc. If Gross and Rovelli agreed on anything at all, it was the operational definition of "viability". A theory is considered viable "if I want to keep working on it", Gross said, and Carlo shouted "Yes! Yes! That's it!". 🙂

And in the absence of experiments, what criteria do we have to estimate the viability of the theory? The whole motivation for the conference was Dawid's proposed answer to that question, condensed in his three criteria: No Alternatives Argument (NAA), Meta-Inductive Hypothesis (MEH) and Unexpected Explanations Argument (UEA). The big debate was whether NAA, MEH and UEA taken together can be considered a good or useful criterion for viability of a given scientific approach (they obviously don't work when taken separately one by one, but together they are more robust).

I did not see any sort of consensus being reached on the issue during the conference. And the issue is certainly important, not just for string theory, but for all other approaches to quantum gravity as well — some due to practical problems, some due to conceptual problems, but none of the QG theories can actually be tested. So the issue is wider than just ST.

If anything, the Munich conference raised awareness among people (philosophers and physicists alike) that this is an important question to answer.

Best, 🙂
Marko

25. **Ali**
December 18, 2015

srp,

There are three modern (and major) viewpoints in statistics as far as I can tell: (1) Frequentism is the "only game in town" (e.g. Deborah Mayo), (2) Bayesian approaches are the "only game in town" (there are many that claim this), (3) Frequentism and Bayesianism have been reconciled. You will find that all three views have their dogmatic defenders. Which camp do you fall into? I suppose category #3, in order to acknowledge the "worth" of camps #1 and #2 (they did work on their ideas for such a long time…it would be a shame if this were all for nothing)? But this is an equally untenable dogmatism. As statistics now increasingly impacts how science is done (how it is reported and even planned…see biology), this is an important fight. You can either participate in it or you can watch from the sidelines. I actually fall into a subcategory of camp #1, as I dispute the worth of Neyman-Pearson confidence intervals (as did many frequentists before me before, until dogmatism and simple inertia allowed confidence intervals to supplant other approaches and the search for better ideas…now Bayesianism is doing the same…sound familiar?).

The main reason I don't acknowledge Bayesian approaches is that they are based on an obvious logical fallacy, that we can construct a "flat" prior (in one coordinate system) and use it to construct a meaningful posterior probability distribution on which we can be confident actually applies to our universe. But this "flat" prior will be "flat" in only one coordinate system. As physicists, it is obvious that a simple coordinate change will completely alter what is meant by "flat" and therefore what one then gets as a "posterior" distribution. The whole deep desire to construct probability distributions on data is the really the problem (equally a problem with frequentist "confidence intervals"). As Edwin B. Wilson tried to tell us, all we really have is the p-value for certain statistics (e.g. Pearson's chi-squared/p-test, which is the physicists' favorite tool, for good reason). This is the only thing we can all agree on. It should be noted that Wilson is often reported as the discoverer of "confidence intervals" (by Neyman himself), a false characterization of his work that he disputed his entire life. So essentially, Neyman was lumping Wilson in with Neyman-Pearson. I guess you could say Wilson was being "dogmatic" about this. I think it's the lack of people willing to be "dogmatic" that has led to the current complete disarray and confusion within the field of statistics and certainly to outsiders (no one criticizes any more, at least not like they did in the past). So here's to dogmatism (especially when it's in the defense of science)!

Chris,

I was a bit glib in the above discussion of "not even wrong" and "not simple" criticisms of string theory. These claims cannot be so easily separated, as simplicity is what ultimately allows for testability.

Chris and G.S.,

The prediction of light bending vs. the postdiction of Mercury's perihelion represent an important focal point in the field of the philosophy of science (it comes up everywhere). Basically, the prediction of light bending was not really seen as convincing as the postdiction of the perihelion. An interesting mental exercise: Imagine if there were no historically/currently testable predictions from G.R., only the postdiction of the perihelion of Mercury. G.R. would still be heralded as a fantastic triumph, as it is simple and gives exactly the right postdicted result for the perihelion. If all string theory did was postdict the mass spectrum with either zero or even only a handful of free parameters (less than the number of masses, but not 10^100), then it would also be celebrated (and not just by those working on it!). It would need to make no new predictions. That's also, by the way, why Popper's views are restricted. They don't acknowledge the importance of the simplicity of certain theories that postdict successfully.

26. **Manfred Requardt**
December 18, 2015

The ongoing discussion about the theory of confirmation of scientific theories is certainly very important. However, concerning the work of Don Page I would like to remark, that he wrote quite a few fundamental papers which I carefully studied and I never had the slightest impression that he was mixing up theological with scientific reeasoning whatever his own beliefs are.

27. **Natalie Wolchover**
December 18, 2015

Peter, many thanks for linking to my article and facilitating a great discussion.

Following up on vmarko's last comment, I wanted to clarify that "viability" as "something worth working on" was not the definition used in Munich, at least not by the philosophers in the room. Dawid said repeatedly that what he means by the "viability" of a theory is its ability to account for observations at the scales it intends to describe. Newton's theory is "viable" as a theory of gravity at low energies and speeds, for example. "Viable" is basically a substitute for "true," since a viable theory will ultimately turn out to be encompassed by a larger theory and is not therefore true in a universal sense.

So, when Dawid argues that the NAA, MEA, and UEA arguments increase the Bayesian confirmation that string theory is viable, he's not merely saying that they increase the probability that you should work on string theory, he's saying that these arguments increase the Bayesian confirmation that string theory correctly describes nature at the Planck scale. It's a stronger claim.

The reasoning is that these three non-empirical arguments impose limits on underdetermination; they decrease the likelihood that there are other theories out there that are also able to describe nature at the Planck scale, which in turn increases the likelihood that string theory is viable. Dawid doesn't claim that these arguments can ever completely kill underdetermination or (in other words) drive the confirmation of string theory's viability up to 100 percent, but he argues that they can get us pretty far — far enough to account for the trust/confidence in string theory exhibited by many of its proponents.
Thanks again!
-Natalie

28. **Low Math, Meekly Interacting**
December 18, 2015

In my field, we have to contend with greedy sociopaths trying to circumvent scientific scrutiny by suppressing the evidence. From a philosophical point of view, that threat pales in comparison to an open-ended proposition to eschew testable hypotheses so long as something strikes enough people as beautiful and/or unique. Liars get caught, eventually, if the evidence exists. In science, it always should, from the greatest physicist to the lowliest stamp collector. How can it possibly be otherwise? I've been reading about this conference for days, and it just seems like…madness! Bayesian epistemology in place of evidence, built around a "framework" of theory generation of nearly infinite malleability? For decades? With no end in sight? How is that not unthinkable? A days-long dialogue between some of the brightest minds in the world devoted to…this! I'm grateful for all the wonderful coverage, but I still can't quite believe it.

29. **Peter Woit**
December 18, 2015

LMMI,
A lot of this doesn't make much sense until you realize that Dawid, Gross and others are taking as starting proposition a well-entrenched ideology about string theory, then working backwards to find a philosophical framework to justify it as science. I believe Dawid is sometimes even quite explicit about this: he's just writing down the arguments string theorists use to justify what they do in the face of conventional failure as science.

30. **NeapTide**
December 18, 2015

There are `sleeping experiments' too… superconductivity was discovered in 1911 but wasn't well described by theory until 1957. CP violation was discovered in 1964 but didn't have a good theory until 1973.

You don't always need a theory to make experimental progress. Maybe, if we finally get the mass scale of the neutrinos established, we'll see a pattern that still isn't evident. Ditto with the CP violating phase in neutrinos.

Dark Matter is a long, long sleeping experimental discovery, one that has had lots of phenomenological impact but still doesn't have a good theory.

Maybe science is a process, and maybe theories aren't things defined by falsifiability or degree of Bayesian probability. Maybe theory is just a repository for the discussion in a sort of standardized format. And maybe the highest calling is to evade the problem of the most charismatic or insistent human defining right from wrong, but be guided by something bigger than a human (at least ideally) like experiments, observations, and some sort of durable beauty in the theory.

31. **Laurence Lurio**
December 18, 2015

I'm a little surprised that in this discussion no one has taken issue with Wolchover's analogy that no one has observed an atom e.g. " modern scientific theories typically make claims far beyond what can be directly observed — no one has ever seen an atom — and so today's theories often resist a falsified-unfalsified dichotomy".. Individual atoms have been pretty clearly observed. The most dramatic example being STM images of Silicon, but x-ray diffraction, observation of fluorescence from a single atom in an atomic trap, even radioactive decay of a single nucleus in a Geiger counter, all observe single atoms pretty clearly. The observability of atoms seems a remarkably poor example of how theories can't be falsified.

32. **vmarko**
December 18, 2015

Laurence,

"I'm a little surprised that in this discussion no one has taken issue with Wolchover's analogy that no one has observed an atom […] Individual atoms have been pretty clearly observed."

I guess what Natalie meant was that atoms have not been *directly* observed back at the beginning of 20th century, when the modern atomic theory was first introduced. There were things like Brownian motion and such, but these were all *indirect* observations of (various effects of) atoms, and I guess back then nobody was even contemplating any possibility of direct observation of individual atoms. Direct observations (via X-diffraction etc.) came quite some time later.

Best, 🙂
Marko

33. **Magnema**
December 19, 2015

@LMMI: I think "Bayesian epistemology in place of evidence" is misphrasing the point. Rather, it would be "Bayesian epistemology as a generalization of hypothetico-deductive evidence." After all, evidence is taken into account in the updating rule… the question is what to do with evidence which is not set up from an experiment.

I'd like to note that "flat priors" – while usually used (as the principle of indifference) for naive guesses – are generally not taken as acceptable, for the reasons Ali mentions (flat priors are no less special than any other set for a different problem). I think a lot of the issues that physicists run into occur when they try and apply really naive methods (such as the principle of indifference) and try and get results… it would be akin to saying "well, we don't know what our error is, so we'll say 5%… and then look, this result is statistically significant!" You make one statistically irresponsible decision and get nonsense results. This isn't necessarily a problem with a Bayesian interpretation itself, but rather with trying to apply Bayesian methods with a fast-and-loose approach.

Accordingly, the retrospective alterations that Peter and LMMI refer to, I would guess (although I don't know the community well enough to say for certain anything about the particular of the individuals), come from the way they choose their priors and their probabilities to fit their conclusion rather than their choice of BCT as a theory of philosophy of science in its entirely. I.e., classical overconfidence in their probability determinations rather than reconstructing their entire philosophy of science.

As another error physicists make: as noted in the "Gathering of philosophers and physicists…" article above: Bayesian methods are designed for when one can explore the complete parameter space. When one only has access to a selection of parameters in consideration, there's no guarantee you'll get accurate results, and physicists are (generally) trying to apply those fast-and-loose results to what is already a limited parameter space.

34. **Ali**
December 19, 2015

Magnema,

To construct the posterior probability distribution, you need to assume a prior probability distribution (which can be updated with whatever data are at hand). The posterior is however completely set by the prior (which is not unique). There is no way around this in Bayesian statistics. This is the definition. The only argument from Bayesians that I have ever seen against this is that we should not take the posterior distribution so seriously, but then what's the point?

The desire to construct the posterior probability distribution is of course strong (not only in Bayesian statistics, but also in traditional frequentist approaches), but it's not logically sound, as Peirce points out above. Bayesians have largely won over a sizable chunk of the scientific community because they give scientists what scientists they think they want (you can even find many Bayesians who admit this). But scientists are also no experts at understanding the subtleties of the probabilistic assessment of data. Again, as both Peirce and Wilson pointed out, the only thing we really have is the p-value for particular statistics based on the cumulative distribution (which is invariant to changes in the underlying coordinate system). In my manuscript I develop an entire framework for optimal statistical inference based on this idea and using a particular and remarkable statistic that I call the "fidelity" (a specific interpretation of the Gibbs entropy). I show that it is superior to maximum likelihood (the previous "gold standard") for parameter estimation and superior to the chi-squared/p-test (the previous "gold standard") for goodness-of-fit assessment. I also generalize Student's t-test to completely arbitrary distributions, with now an automatic means for goodness-of-fit assessment. Additionally, I straightforwardly extend the notion of the "fidelity" to non-parameteric testing, developing a test that is superior to the KS test (also considered the "gold standard" for such testing). That all of this is possible in a way that is coordinate-system invariant is remarkable. Again, the entire system is based on the p-value of the fidelity, a statistic constructed from the coordinate-independent cumulative distribution. My approach avoids the thorny problems that characterize both Bayesian and traditional frequentist approaches. For example, my approach is the only solution that I'm aware of to Neyman's paradox, which led Neyman to believe that there is no fundamental approach to statistical inference and that we should only use good judgement or "good behavior" in assessing data in order to not be misled. But Neyman's paradox (a bit of mathematical sleight-of-hand by Neyman) is simply resolved by sticking to the cumulative distribution and respecting the topological ordering of the coordinate system.

I only give the above details to show that there are other possible ways of performing statistical inference. But, if you are a Bayesian, you are done. You already have a complete system for doing any kind of inference (one that is of course fatally flawed). The only work to be done is to find better applied math techniques and algorithms to more efficiently perform the necessary computations (which was the real barrier to applying Bayesian approaches in the past…now we have cheap and much more powerful computers).

35. **Peter Woit**

December 19, 2015

Please, stop the repetitive rants about Bayesian inference. I'm deleting them and any more on the topic. This has little to do with the topic of the posting and drives away people with relevant comments.

36. **Visitor**
December 19, 2015

" I believe Dawid is sometimes even quite explicit about this: he's just writing down the arguments string theorists use to justify what they do in the face of conventional failure as science."

Does Dawid anywhere explain the reasons underlying his apparently naive and uncritical acceptance of such arguments? That's a question potentially more interesting than the theoretical apparatus he's constructed. I would hope that his reasons amount to more than a simple appeal to authority.

37. **vmarko**
December 19, 2015

Visitor,

"Does Dawid anywhere explain the reasons underlying his apparently naive and uncritical acceptance of such arguments?"

I think it's naive to call his arguments naive and uncritical. Despite the fact that I disagree with everything he said in his lecture, I have to admit that the arguments and reasoning presented in his lecture (and I guess his book as well) is very thought-through, and anything but naive and uncritical.

What he did was to look at what string theorists were actually doing, provide an abstract description of it in terms of the NAA, MIH and UEA, and then promote this description into a normative statement ("this" is what they are actually doing, and it is also what they should be doing). And he was very up-front with all that, while including a great deal of analysis of the interactions between NAA, MIH and UEA, assumptions, pitfalls, caveats, characterizations, etc…

You are welcome to disagree with his proposals (as many people do, myself included), but it is just plain wrong to call them naive, uncritical or appealing to authority.

Best, 🙂
Marko

38. **Peter Woit**
December 19, 2015

Marko,
I think what "Visitor" means by "simple appeal to authority" is much the same as what you describe as "promote this description into a normative statement". As far as I can tell, what Dawid is doing simply ignores the main question: isn't all this just an attempt to prop up a degenerating research program? The tactic seems to be to forgo that obvious interpretation of the situation in conventional terms, in favor of a point of view taking string theorists as authorities, with the job just to justify their arguments.

39. **Natalie Wolchover**
December 19, 2015

Visitor, vmarko, Peter,
Dawid says there is one way in which his arguments are normative, or at least, following conventional policies of how science should work. Any of his three criteria, he argues, could disconfirm a hypothesis, just as easily as it might confirm it. This makes each one a sort of test.

Also, to the question of what I meant by "no one has ever seen an atom," the STM images are extremely impressive, but aren't we still interpreting data? Fantastic interpretation, I agree – hence the near-100 percent confirmation of atomic theory. In the late 20th century, physicists worried they would never manage to rule out all possible alternative interpretations of the indirect evidence they possessed in favor of the existence of atoms. Atomic theory was "undetermined." But eventually, everyone decided that the indirect effects of atoms (like the way dust flits through the air) should count as empirical data. Almost everyone, that is — Ernst Mach refused to believe in "the reality of atoms" to his dying day, in 1916.

-Natalie

40. **Peter Woit**
December 19, 2015

Natalie and Marko,
Looking again at Dawid's three criteria, I think that they might more accurately be characterized as a typology of arguments for a degenerating research program:

1. No Alternatives: no matter how bad things look for our ideas, they're better than anyone else's.
2. Meta-inductive: we had a good reason to start looking at these ideas, since this kind of thing had worked before. That reason is still good, no matter had bad things turned out and look now.
3. Unexpected explanatory coherence: the more we study our ideas, the more devoted to them we get, so there must be something to them.

41. **couvent**
December 19, 2015

I'm not an active physicist anymore, but these three criteria seem to be unconvincing.

"No alternatives" might have a sociological explanation. "Unexpected explanatory coherence" depends on what it is that you explain – black hole entropy etc. seems, to me at least, fairly unconvincing. But the weakest criterium is "meta-inductive". What do people mean when they say this kind of thing worked before? What is "this kind of thing"? The graveyard of physics is littered with things that didn't work. I bet most physicists have had more ideas that don't work than ideas that do work. If you only look at the published ideas that did work, you're suffering from a serious case of confirmation bias.

42. **vmarko**
December 19, 2015

Peter,

"I think what "Visitor" means by "simple appeal to authority" is much the same as what you describe as "promote this description into a normative statement"."

When listening to Dawid's lecture, I didn't get that kind of impression (despite the fact that I was expecting to hear precisely something like that). Dawid doesn't promote descriptive to normative because string theory physicists are very smart, but because he believes that his three arguments are the only sensible way one can assess a theory absent any observational evidence. So he's not appealing to authority, but rather saying there's nothing else we can do.

Of course, I disagree with him on that, and yes his arguments do indeed support a degenerating research program. But his arguments were not designed so that they would support string theory, that is somehow a side-effect. The arguments were designed to capture what we can say about the quality of a theory when we have no access to experiment. And of course, I believe they are very very wrong, but I failed to see any appeal to authority there.

This is funny, btw. I heavily disagree with Dawid's points, but somehow I keep sounding like I'm defending his ideas here. That's certainly not my intention.

Natalie,

"Also, to the question of what I meant by "no one has ever seen an atom," the STM images are extremely impressive, but aren't we still interpreting data?"

If you put it that way, then no one has ever seen a chair either — all we see is light coming to our eyes, and then we're interpreting that data. Interpreting the data from X-ray experiments is really no worse in any way (neither qualitatively nor quantitatively) than interpreting the data when we look at bacteria, red blood cells, chairs and tables, or other galaxies.

Best, 🙂
Marko

43. **atoms are real**
December 19, 2015

You can see an individual trapped barium ion glowing with the naked eye.

44. **RandomPaddy**
December 20, 2015

They should do more of these conferences for unresolved problems/speculative theories in physics. Everything from Multiverse to dark matter all the way down to quantum foundations. I suspect if you allowed physicists to talk about things in such a setting you'd get to hear more dissatisfaction that you would suspect.

That said, from the coverage of this conference things might just boil over altogether into a furious series of shouting matches. Shamefully, I must confess this prospect would make me even more likely to buy a ticket.

45. **Radioactive**
December 20, 2015

When you win a Nobel prize you earn the right to fly to nice cities and have conferences about the meaning of simple English words like "test", "verify" and "true". I am sure the coffee break pastries were fantastic, but I really don't think there was anything there to inspire so much hand-wringing debate. The outcomes were completely banal.

In stark contrast to the abc conference which is scientifically and sociologically fascinating on many levels.

46. **Manfred Requardt**
December 20, 2015

Today I read the Consilience section in the recent Sci.Am. (Dec. 2015) and I think there are some useful remarks in it concerning the ongoing debate about scientific verification. Shermer mentions the 19-th century philosopher William Whewell and his notion of "consilience by induction´´. He argues that for a theory to be accepted it must be based on more than one induction or a single generalization drawn from a specific fact. It must have multiple induction that converge on one another , independently but in conjunction (Book: The Philosophy of inductive Science).

47. **Low Math, Meekly Interacting**
December 20, 2015

Magnema: I tend to think of "evidence" used to update priors in science as something other than a human judgment about, say, the beautiful unifying properties of a theoretical framework. Rather "evidence" is the result of an objective measurement of a natural phenomenon. Of course, when one has a functionally infinite landscape of possibilities to choose from, I suppose one can exclude some of those from the newly-inferred probability distribution (say, when a particular model predicts sparticles of a certain mass that are not observed). But that process seems to have made little dent in the posterior assessment. "Evidence" in this new paradigm seems to mean something quite different than what is healthy. The ability to calculate probabilities using Bayes' shouldn't obscure this. If, functionally, this epistemic paradigm allows so many lines of "evidence" but cannot assign to them a proper weight, perhaps it is suspect.

48. **George Ellis**
December 20, 2015

You comment "…Andrew Gelman (who I think, unlike anyone in the theoretical physics community, actually knows something about Bayesian methods)." If you and Golman bothered to read the article, you'd see this was indeed debated at the meeting by both physicists and philosophers. This kind of snide remark undermines your attempt to provide useful comments on what is going on.

49. **Peter Woit**
December 20, 2015

George Ellis,
Apologies for the snideness. I wasn't there so don't know all that was discussed. Note that my remark was directed at theoretical physicists, not philosophers or others. From reading Wolchover's report and others, my impression was that the main invocation of Bayesian confirmation from theorists was coming from Gross and Polchinski, using it in ways that I think are extremely hard to take seriously. While I've often seen a sophisticated use of ideas about probability, including Bayesian ones, in several areas of physics in the analysis of experimental data, I haven't seen this at all in theorist's work divorced from experiment. Quite possibly there are cosmologists or those who study quantum measurement theory who are capable of this, I don't think the same is true of string theorists.

50. **Peter Woit**
December 20, 2015

Marko,
You say that Dawid claims “his three arguments are the only sensible way one can assess a theory absent any observational evidence… there’s nothing else we can do.”

I didn’t hear the talk, but I did read his book, and I don’t recall seeing a “no alternatives” to “no alternatives + two others” argument anywhere there. Rather it seemed to me that he was taking as his starting point a reading of arguments made by string theorists, trying to come up with a classification of those arguments. It seems to me that he was starting from the conclusion he wanted. If you instead started from the general question “what are good, justifiable ways of evaluating theoretical progress”, I think you’d end up with a different list.

An obvious alternative to Dawid’s three that immediately comes to mind would be the criterion for progress “are these ideas moving away or towards successful contact with experiment as they develop”. This seems to me the most common way of evaluating theoretical ideas, which mostly start life unable to make contact with experiment, then either move towards being able to do so, or get abandoned as failures. In the case of string theory unification, the ideas started life with a program for contact with experiment, claims that they were nearly there. The history of the last thirty years has been one of moving in the wrong direction, headed towards zero possibility of any contact with experiment.

Did this sort of thing come up at the workshop? I’d argue that there’s a reason this kind of criterion for confirmation is not being put forward by Dawid: it makes string theory look bad…

51. **vmarko**
December 20, 2015

Peter,

I listened to the lecture, but didn’t read the book (and have no intention of doing so), so information that I have is kind of complementary to yours. 🙂

Basically I agree with everything you said above, and it’s a subset of the reasons I have for disagreeing with Dawid’s criteria. And no, during the conference nobody has discussed the criterion of moving towards or away from experiment or any similar idea (I like your proposal, provided that you can give some operational way of estimating the notions “moving towards” and “moving away”).

I also agree that Dawid was probably looking at what string theorists were doing when he was constructing his arguments. But Dawid’s position does *not* strike me as the one where he is deliberately cheering for ST. I agree that he was looking at a very skewed and biased sample of scientists, but I don’t think that he cherry-picked them intentionally. If anything, he didn’t take a good enough sample of HEP and QG theorists during his research, so one can blame him for constructing his criteria based on an unrepresentative sample of scientists. And I do think that is the case. But I also believe it was an error out of ignorance, not that he did it on purpose.

Of course, I might be wrong, but that was the impression I got after listening to his lecture and talking to him in person. Maybe I’d have a different impression if I had read his book, I don’t know.

Best, 🙂
Marko

52. **Armin**
December 20, 2015

Peter,

Just a quick observation: your apology makes it sound like you consider George Ellis a “philosopher or other”. Also, I think that referring to theoretical physicists in your remark without qualification is far too strong a claim.

53. **Peter Woit**
December 20, 2015

Armin,
I think you’re misreading my comment here. My intent was purely to acknowledge that a snide remark wasn’t a great idea and to instead try to make clearer the thought behind it (which has nothing at all to do with Ellis).

54. **Laarbi**
December 21, 2015

Can anybody provide us with a link to the video of the Munich conference?

Thank you!

55. **Peter Woit**
December 21, 2015

Laarbi,
My understanding is that the talks were recorded, at some point (not yet) will be made available here
http://www.whytrustatheory2015.philosophie.uni-muenchen.de/media/index.html

56. **Kartik Prabhu**
December 21, 2015

@PeterWoit
A more optimistic article about the abc conference: https://www.quantamagazine.org/20151221-hope-rekindled-for-abc-proof/

57. **Peter Woit**
December 21, 2015

Kartik Prabhu,
Thanks! That article is quite good, but I don’t think the bottom line is any different than other reports from the conference:

“The next step was the essential one — to show how the reformulation in terms of Frobenioids made it possible to bring genuinely new and powerful techniques to bear on a potential proof.These techniques appear in Mochizuki’s four IUT theory papers, which were the subject of the last two days of the conference. The job of explaining those papers fell to Chung Pang Mok of Purdue University and Yuichiro Hoshi and Go Yamashita, both colleagues of Mochizuki’s at the Research Institute for

Mathematical Sciences at Kyoto University. The three are among a small handful of people who have devoted intense effort to understanding Mochizuki's IUT theory. By all accounts, their talks were impossible to follow."

I'll add a link to this to the posting. There is also a report on the conference from Fesenko,

https://www.maths.nottingham.ac.uk/personal/ibf/files/iut-i-rep.html

which blames the audience for what happened:

"Labor omnia vincit. Progress in understanding the talks correlated with preparation efforts for the workshop. There were participants who came unprepared but were active in asking questions, many of which were already answered in recommended surveys and some of which were rather puerile."

I'm not sure what the point of such a comment from Fesenko is, unless he's trying to ensure that most of the experts who showed up at this workshop won't attend future ones.

58. **Daniel**
December 21, 2015

I wonder why people like Weinberg, t'Hooft and Wilczek were not invited…

59. **lun**
December 22, 2015

George Ellis – the deluge of hep-ph papers about the "750 GeV bump" shows the snarkiness is justified by quite a few sigmas since the hypothesis of knowledge by theoretical physicists of Bayesian probability has quite a low p-value. 🙂

60. **vmarko**
December 22, 2015

Daniel,

"I wonder why people like Weinberg, t'Hooft and Wilczek were not invited"

Actually, this question was asked during the conference (not for those three names in particular, but for someone else, I can't remember now for who), and the response from the organizers (Dawid in particular) was that actually they were invited, but were unable or unwilling to appear. Again, I don't know about Weinberg, t' Hooft and Wilczek in particular — but apparently many more renowned scientists and philosophers were invited, but for one reason or another, didn't show up. Unfortunately (but understandably) no names were spelled out, so…

Best, 🙂
Marko

61. **Daniel**
December 22, 2015

vmarko,

Thanks for the info!

62. **DrDave**
December 23, 2015

" This "no-alternatives" argument, colloquially known as "string theory is the only game in town," boosts theorists' confidence that few or no other possible unifications of the four fundamental forces exist, making it more likely that string theory is the right approach."

So, the only way to disprove string theory would be to come up with a a fake alternative which could not be tested and makes no predictions. How strange is that?

63. **William M Briggs**
December 23, 2015

Bayes's theorem doesn't work to say a theory has this-and-such probability is true. Giving any theory a probability only makes sense comparatively. Why? Well, here's a longer argument:

http://wmbriggs.com/post/17544/

64. **Rh L**
December 28, 2015

Peter,

I think you'd love the newest edition of Fesenko's comment (ca. December 27, 2015):

"Без труда не выловишь и рыбку из пруда. Occasionally, a baby-like attitude to attend the workshop without reading any surveys or non-classical papers of the theory affected the quality of asked questions and progress in understanding the talks."

65. **Peter Woit**
December 28, 2015

Rh L,
It seems that Fesenko has been editing that text every day or so. I no longer see the paragraph you quote, but he has added this complaint:

" These papers contain a large variety of new ideas and concepts (listed in the letter to participants) and it is a rather naive question to ask to single out the most important idea/concept."

I think that's a misunderstanding of the attitude of many of the experts there, who were trying to find a new, powerful, idea in Mochizuki's formalism they could understand, because that is what would give them the insight needed to make some progress on understanding the proof. It’s not that there was an expectation that there is a single important new idea here, quite likely several are needed, but one has to start by finding and understanding a first one.

66. **David Hansen**
December 30, 2015

@Peter: And now that comment is gone in turn. What a joke.

67. **Paul D.**
January 9, 2016

Tom Hartsfield comes down against attempts to abandon empiricism for the sake of string theory:

http://www.realclearscience.com/blog/2016/01/string_theory_has_failed_as_a_scientific_theory.html

Why String Theory?

December 25, 2015
Categories: Book Reviews

I recently got a copy of Joseph Conlon's new book Why String Theory? and was pleasantly surprised to find that it's quite good. Conlon is a lively, entertaining writer, generally sensible about the scientific issues involved, and I think does a great job of explaining the point of view of typical physicists now working on string theory. He also very ably explains the "sociology" of the field, the different kinds of people who work in this area and their varying sorts of goals and motivations.

The book is explicitly motivated by the desire to answer a lot of the criticism of string theory that has become rather widespread in recent years (wasn't always so…). For a typical example from the last few days, see Why String Theory is Not a Scientific Theory at Starts With a Bang. I have mixed feelings about this sort of thing. It gets the main point quite right, that string theory unification is untestable, having failed to make any predictions, and by the conventional understanding of the scientific method, it's past the time at which most theorists should have abandoned it and moved on. On the other hand, I don't see at all the point to arguing about the term "scientific theory". Sure, it's a scientific theory, a failed one. I've personally never noticed any consistent usage by physicists of terms like "theory", "model" and "hypothesis" in ways that accurately indicate degree of experimental support, don't see why some writers insist that there is one. I also very strongly object to the article's standard move of trying to make a failed theory a "mathematical theory". Mathematics is about well-defined ideas, and there is currently no such mathematical construct as "string theory". The problems with string theory have nothing do with mathematics, rather have to do with a physical idea that didn't work out.

To a large extent the problems Conlon is struggling with are ones that the community of string theorists has inflicted on itself. The great majority of writing for the public by string theorists is characterized by large amounts of outrageous hype. For a very recent example, see Daniel Harlow here, who seems to think string theory is a huge success at explaining the standard model

> although it hasn't quite managed to reproduce the complete standard model of particle physics, it comes very close and the obstructions seem more or less technical.
> I want to emphasize that postdictions are just as good formally as predictions for testing a theory; the distinction is purely sociological.

and that it is also much more (did you know that string theory is what explains the existence of black holes?)

> the main reason to work on (or be inspired by) string theory from a scientific point of view is that it may provide explanations of phenomenon that have ALREADY been observed: the existence of black holes, the small positive cosmological constant, and the evidence for an inflationary phase of the early universe.

As for the problem with the multiverse making no predictions, that's just wrong. We just don't know what the theory is, when we figure it out, surely it will make predictions:

> the issue is not that it doesn't make predictions. The issue is instead that we do not yet understand it well enough theoretically to know what the predictions are!

I've always found reading this kind of thing quite puzzling. My impression of most string theorists is that they're smart and rather sensible, well aware of the difference between ridiculous hype and an actual scientific argument. Unfortunately such sensible string theorists also have seen no point in trying to write for the public until now, and I'm glad that Conlon's book finally changes that.

If you followed the reports from the recent Munich conference, you likely heard that the assembled philosophers and physicists nearly unanimously found the anthropic multiverse point of view Harlow advertises to not be legitimate science. Conlon expresses his opinion in this way, and I think it's the majority one among string theorists, whatever you might have heard:

> The most serious problem with the anthropic landscape is that it provides a cheap and lazy explanation that does not come from hard calculation and also has no clear experimental test. It sounds exciting, but does not offer lasting sustenance, and may even act as a deterrent against necessary hard work developing new calculational tools.
> Of course, this does no mean that the anthropic approach is necessarily wrong. However the triumph of science has been not because it contains ideas that are not necessarily wrong, but because it contains ideas that are, in some important sense, known to be true: ideas which have either passed experimental test or are glued together by calculation. The anthropic landscape is neither of these. It represents incontinence of speculation joined to constipation of experiment.

Instead of Harlow's claims that string theory makes lots of postdictions, coming very close to reproducing the complete standard model, modulo some technical issues, Conlon deals with the situation in a much more honest and straightforward fashion. Of the fourteen chapters of the book, chapter 7 is entitled "Direct Experimental Evidence for String Theory." Here's the entire content of chapter 7:

> There is no direct experimental evidence for string theory.

Conlon's point of view is different than that of the majority of string theorists in one way, which he explains in detail.

> My interest in string theory is in what it can offer to physics that can be probed by experiment.
> This view is far from universal. It may seem odd, but most of those who work on string theory are essentially uninterested in any connections with experiment, any public claims that they may make to the contrary notwithstanding.

He backs this up by the observation that less than 10% of talks at recents Strings 20XX conferences have any connection to observable physics.

Here, I'm again in the majority, with his colleagues, who I think have made an accurate evaluation that connecting current string theory to experiment is a failed and hopeless project (I differ with them on prospects for this changing). Conlon has a research program to investigate potentially observable effects of moduli fields, something his colleagues are skeptical about. While I'm also skeptical about this, it does seem like a reasonable thing to investigate, especially since such things may be generic to all theories with extra dimensions, not just string theory. The chapter of the book describing this research is one with material you won't find in other popular books.

Many of his colleagues have adopted the attitude that, while connecting string theory to experiment is hopeless, it deserves investigation purely as an idea about quantum gravity. While Conlon devotes a fair amount of space to the arguments about quantum gravity and string theory claims about them (including some criticism of loop quantum gravity) he avoids much of the usual hype, and also makes it clear that he himself isn't interested in pursuing this because of the lack of any hope of ever testing one's ideas. In some sense I think he and I agree here: it is only if one's idea for quantizing space-time degree of freedom connects up somehow to our successful theories of other quantized degrees of freedom that one will have any hope of ever knowing whether one has the right theory of quantum gravity. Absent a connection of this kind, one is doomed to become just another cog in an endless fruitless ideological argument about whose quantum theory of gravity is better (or at least, whose sucks less).

Conlon claims that at this point, most string theorists are interested in string theory not as a theory of quantum gravity, but because of applications of ideas that have emerged from string theory to other fields (e.g. AdS/CFT). Here he gives a reasonable account of attempts to use AdS/CFT to say something about condensed matter physics. One place in the book where he, unusually, descends to conventional incantations of hype is his account of applications of AdS/CFT to heavy-ion physics, where he says nothing about the fact that this doesn't work very well, just repeating some rather stale hype.

There's a lot else to like in the book, for instance a chapter of highly perceptive descriptions of the different kinds of theorists and the different ways they work, including some rather amusing and mostly friendly caricatures of common behavior. For an example of the kind of thing you'll read here but not in any other popular string theory book, he notes that certain persons have recently received multi-million dollar prizes based upon model-building ideas that didn't work out.

There's a lot more in the book than I have time to discuss, some of which I agree with, some of which I don't. Obviously I have a different point of view than Conlon's, but his at least I find to be one with serious arguments behind it, unlike all too much of the popular string theory literature. One thing I found rather discouraging after my book came out ten years or so ago was what seemed to me a lack any serious response from sensible string theorists. Quite a few years later, it's great to see that Conlon has written such a thing, and I recommend it highly to anyone who cares about these issues.

And, Happy Holidays!

Update: Sabine Hossenfelder has a posting with a similar take on the Siegel piece. I also like her description of the Munich workshop:

> There was, however, not much feud at the workshop, because it was mainly populated by string theory proponents and multiverse opponents, who nodded to each other's talks. The main feud, as always, will be carried out in the blogosphere…

I haven't seen the full piece, but New Scientist now seems to be covering the multiverse as theology, which is about right.

Update: Over on Facebook Dan Harlow explains the "technological problems not relevant for questions of principle" needed to get string theory predictions

> the idea is that in order to view string theory as a theory of nature, we need to view it as providing a unique probability measure on the space of low energy theories. This would be computed by understanding both the structure of the landscape and the dynamics of eternal inflation. We can then compare our observations to the predictions of this measure, and if they are atypical the theory is ruled out. We are far from doing this though, except for the imprecise cartoon that seems to more or less work for the cosmological constant. This seems just as scientific to me as quantum mechanics, except that we don't yet know how to compute the probabilities.

I see a bunch of problems of principle here, starting with not knowing the underlying non-perturbative theory and going on from there. Some commenters over there think "It's hard to even begin to imagine how one can even take Woit seriously.", but it looks like they take seriously Harlow's claims that this "seems just as scientific to me as quantum mechanics", with the minor difference that you can't calculate anything.

Comments

1. **Bee**
   December 26, 2015

   I preordered the book, but it hasn't yet been shipped. Looking forward to reading it.

   As to experimental evidence. This isn't an issue specific to string theory. Actually I think that string theorists are more interested in phenomenology than those working on other approaches to quantum gravity, where (aside from lip confessions) the interest is a grand total of zero.

   My point of view has always been that quantum gravity isn't science as long as one doesn't at least try to find experimental evidence. The only other thing worth doing is to prove that one particular theory is the only possible one given certain assumptions, and there doesn't seem to be much effort devoted to this either. (And why would they? We'd end up in a situation where we would argue about which assumptions are the right ones.)

   Why are there so few people working on finding experimental evidence for quantum gravity? I can tell you it's not for lack of interest, at least not among the young people, it's for lack of funding. I get a lot of requests from students and postdocs who want to work with me, but I have to turn then away because I have no funding. I barely managed to get funding for my own research (kudos to FQXi). And lest you think it's because I am just a mediocre scientist, let me add the following twist.

   At some point I concluded that quantum gravity phenomenology is a bad, bad field to work on because it flops through peer review, which is almost certainly conducted by people who in the majority think that funding should go into further mathematical speculations. Seeing that my colleagues who work on AdS/CFT have funds thrown after them, I applied for funding in that field too. Nevermind that I have basically zero prior experience and the field is entirely overpopulated already. I got on first try funding for two postdocs positions (or actually for my own position, a complication that I still have to sort out).

   Then I have to listen to certain Nobelprize winners who insist that the reason scientists work preferably in one field and not another has nothing to do with funding, which eventually is allocated by peer opinion, leading to a rich-get-richer trend. No, scientists are totally unaffected by this and only follow their personal interests, in a completely objective and unbiased manner. So now I work on AdS/CFT (or rather, my postdocs do). Completely unbiased by funding opportunities.

   The problem is that the people at top institutions, the ones with the big names and the many awards and the big prizes, are the ones who we read about in the press. And they have by and large pretty much no contact to the reality of research life.

   Why don't journalists for a change call up some dozen string theory postdocs and ask them how they came to work on what they work on and why they work on what they work on? I have asked this question to a lot of postdocs over the years and I can tell you what the replies would most likely be. "I read Brian Greene's book," is a reply I got to hear a lot. But besides this it is mostly "I wanted to work on quantum gravity and string theory was the only option." And most young students don't realize that they are very likely to get stuck on the topic of their PhD thesis, unless they switch fields very quickly afterwards. And so it happens. These are the stories the public does not get to hear about.

   Sorry for the rant, I find it all very frustrating, seeing that so little has changed in the last ten years. And happy holidays to you too 🙂

2. **Giotis**
   December 26, 2015

   I don't see a contradiction or a distinction here.

   By now it is more than clear, even to its critics I believe, that String theory and the generic Stringy framework with all of its tools is more than relevant for Nature; it has been proven again and again that it can be used to help us answer some (if not all) of the deepest questions about the fundamental nature of reality and in the process it raises new ones which is equally important.

   The theory is at the center of a web of deep ideas binding them together; but the picture is far from being complete or clear; in that respect people have no choice but to follow the theory and see where it leads. To do so they must explore all of its streets and highways and this is what people do I guess; phenomenology is one aspect of this endeavor.

3. **Warren**
   December 26, 2015

One thing even string people seem to forget is the reason string theory got started in the first place was the experimental fact that both the spectrum and small-angle scattering of hadrons follows linear Regge trajectories that are predicted only by string theory. The facts that the known string theories predicted the wrong intercepts and spacetime dimension turned phenomenologists off to this approach.

4. **Jesper**
December 26, 2015

@ Bee, I would suggest that one reason why Quantum Gravity phenomenology is not very popular to work on might be the obvious one that we don't yet have a credible theory of quantum gravity that produces predictions – and without that we don't know what experimental evidence to look for. Am I wrong?

In all this debate about quantum gravity, experimental evidence and whether we should change the notion of science I would say that a credible test of a 'final theory' is that it should essentially postdict the entire standard model – or at least most of its essential structure such as number of generations, gauge groups etc. Nothing less. And until we have that – and the wait might be infinite – then the question of a final theory should simply be left as 'undecided'.

Also, I can report that the "No, scientists are totally unaffected by this and only follow their personal interests,…" is not correct. I think that we all have a responsibility and obligation not to give in to the funding pressure and insist on following our own interest – essentially at all cost. Because if we don't we become corrupt, we become part of the problem.

Of course the system sucks – but systems often do! And nothing can prevent someone from just doing whatever he/she wants if he/she insists – there are other ways to fund research than through research grants and university positions.

5. **Peter Woit**
December 26, 2015

Bee,
Thanks for the comments. The AdS/CFT phenomenon is quite remarkable and deserving of its own book. I see that the Maldacena paper is up above 10,000 citations, way off scale anything that has ever happened in the history of physics. What I've heard time and again from young theorists is that they go into AdS/CFT because it's something that seems to be not understood, seems to be both a new deep idea about quantum gravity, and to have other applications, and, of course, it's where most of the jobs are. The coverage of AdS/CFT in Conlon's book reflects this, with hype level a bit less than the usual, still somewhat uncritical to my taste. An accurate take on this story awaits another book, one by someone who has mastered some fraction of those 10,000 papers and is able to cut through the hype and seriously evaluate what is known, what isn't, what works and what doesn't. Unfortunately I don't think we'll see this soon.

6. **Peter Woit**
December 26, 2015

Warren,
Some things about the Conlon book I didn't mention is that he's rather skeptical about how successful AdS/CFT has been as a technique to study QCD. He writes somewhat wittily:
"This research, aiming to reproduce the properties of the actual strong force, has now been carried on for over a decade, with more or less degree of rigour and less or more degree of success."

One place where I strongly disagree with him is that he argues essentially that it's not worth working on strongly-coupled QCD, that this is no longer an important frontier problem in physics, so does not deserve to be funded.

7. **Conrad**
December 26, 2015

Bee, Peter,

quantum gravity is a tough field to work in for two reasons. First of all, people honestly are looking for observable effects. This prevents them from going to far into fantasyland. Secondly, many models predict the lack of such observable effects.

Even the simple prediction of an observable effect would make a researcher famous. But no prediction has ever been formulated that stood up to the test of the community.

My personal impression, following the field in the past decade, is that no observable quantum gravity effect exist (except the cosmological constant, of course). Of course, this conclusion is tough to swallow. But if the impression is correct, it is a wise move to change field!

We can also ask the opposite question: Bee, why are you convinced that other observable quantum gravity effects should exist in nature? There must be some reason(s) for your gut feeling and for your – admirable! – tenacity. Can you try to formulate it?

8. **Shantanu**
December 26, 2015

Peter: Is Conlon a physicist? What does he critic about LQG? Does he say anything about asymptotic safety or CDT?

Bee, Peter : Yes unfortunately there is a lot of hype about certain trendy fields (ADS/CFT been one). Another one been is calculating the GW signal from black hole/neutron star binary where gravity division of NSF has thrown in lots of money.
OTOH no funds for QG phenomenology and also various other interesting topics
in GR and alternate GR theories. However weren't institutes like Perimeter institute
and other such places set up to give freedom to people to work on non-mainstream ideas? It looks like they are also following fad trends.

9. **Bee**
December 26, 2015

@Jesper,

The whole point of phenomenological models is that you work them out to test for "new physics" even if you don't know the complete underlying theory. In quantum gravity, the most common examples are space-time fluctuations (eg decoherence caused by), defects in the structure of space-time (deviations from GR), violations or deformations of Lorentz-symmetry, consequences of the Planck length setting a limit to the resolution of shortest distances, and so on. All these are possible consequences of quantum gravity that can be searched for by help of phenomenological models.

In particle physics there is a whole industry behind producing phenomenological models that quantify "beyond the standard model physics" so that data can be analyzed for traces of it. We've spent the last 3 decades hunting for particles that aren't there. I think it's more than time to look for something more promising.

Incidentally, you are wrong in saying that it "isn't popular". It is in fact very popular, which has its own downsides. Every time someone writes a paper that supposedly tests something quantum gravity, it is all over the news. Unfortunately, much of this research is rather shallow and low quality, an issue that would be remedied by better funding.

And your remark "of course the system sucks" is one of the most common excuses I hear. So common you will find it mentioned on the slides of a recent talk that I gave as the main cause of the problem. There isn't any "system" other than us.

10. **Bee**
December 26, 2015

@Conrad,

My main point is really the following: If you don't think that quantum gravity has observable consequences, then it isn't science and no science funding should go into it. If you invest into quantum gravity as research in a scientific discipline, you also must invest into studying its potentially observable effects. Where are the dozens of research groups dedicated to quantum gravity phenomenology?

As to my "conviction". In brief I'd like to quote the "principle of finite imagination," that says just because you can't imagine something doesn't mean it's impossible. Over the history of science, it has happened over and over again that something once deemed impossible became possible. I haven't come across one single convincing argument that no quantum gravitational effects can be detected. Why are you so convinced that it isn't possible? And just to be clear, I don't necessarily mean direct effects.

To speak of my personal opinion, presently the most promising areas seem to me CMB entanglement and massive quantum oscillators. Both of these only test the perturbative end, but at least that would move quantum gravity into the realm of being an actual science. Imagine how awesome this would be. You'd think that hundreds of people work on this. Instead it's maybe 10 and I'm being generous on that count.

The non-perturbative end is of course much more difficult. You would want to look at relics from the early universe, and to solve the inverse problem one would almost certainly have to combine different observables.

Another possibility are naked singularities. It has been claimed some years ago that naked singularities (contrary to expectation) might actually be created in gravitational collapse without requiring very special initial conditions. This would mean that we potentially could have uncensored view of strong curvature regions. Remains the question how would you tell a naked singularity from a black hole and what could we learn from this?

You might not agree that these are interesting experiments. But getting an answer for which experimental avenue is the most promising is exactly why this field needs funding.

11. **Jesper**
December 26, 2015

@ Bee

perhaps we have misunderstood each other slightly. I read your first comment as a complaint about the system, which eventually lead you to apply for funding in a field, which you are not interested in, namely AdS/CFT – and that you are now working there (or your postdocs). My reaction is that I find this a wrong choice of action. I do not like "bread-and-butter" type research, where people do research in order to survive and progress in the system as it is now. There is way too much of that. I think that funding should not play a role when choosing a research subject.

And I completely agree with you when you write that there is no system except us – and I would love to see more people try to rebel against it.

To change a system takes sacrifice, it is always easier to work with it. In my own case I have now worked for more than four years without research funding – essentially because I refuse(d) to work on subjects, which might have secured me a career. I don't see any law of Nature that dictates that you can only do research on university funding.

As to phenomenology I am certainly no expert. There is of course a difference between BSM physics and quantum gravity phenomenology – and my take on the latter is very much aligned with what Conrad wrote in the above. I suspect that the only observable effect of quantum gravity might be the standard model itself.

12. **Lee Smolin**
December 26, 2015

Dear Bee,

I agree with your main points but would disagree when you assert that "those working on other approaches to quantum gravity, where (aside from lip confessions) the interest (in phenomenology) is a grand total of zero." Here is a list of potential quantum gravity phenomena which have been proposed and studied over the years by different people.

-Lorentz symmetry breaking.
-Deformation of Poincare invariance.
-Dispersion by Planck scale discreteness of quantum geometry.
-CPT violation
-parity violation connected to lorentz symmetry breaking.
-parity violation in gravitational wave production by inflation leading to detectable effects in tensor modes.
-Corrections to Hawking radiation, coming from planck scale geometry, observable in patterns of lines superimposed on thermal Hawking spectrum, potentially observable in bursts coming from evaporating primordial black holes.
-Planck star models of black holes as sources of fast radio bursts.
-Effects at low l modifying the CMB spectrum coming from a bounce replacing the initial singularity.
-Diffusion in momenta of quanta propagating on causal sets.
-Dimensional reduction, ie modifications in the spectral dimensions of quanta propagating on quantum geometries.
-Gravitationally induced non-linearities in quantum evolution (Penrose, D'iosi etc).

Apart from pure quantum gravity phenomenologists, these proposals have come from people studying LQG, spin foam models, causal sets. asymptotic safety, causal dynamical triangulations, emergent gravity. As you know well, because you are an organizer of it, there are enough people working on quantum gravity phenomenology to populate a 80-100 person meeting every year or two.

I agree that so far no novel phenomena have been observed, but we do have impressive limits on some of these, some of these above the Planck scale.

Thanks,

Lee

13. **Gregor**
December 26, 2015

@Peter:

10000 citations is really a lot. But the statement that this is "way off scale anything that has ever happened in the history of physics" is exaggerated. It is well known that the largest fraction of physicists work in the field of condensed matter physics. In this context electronic structure methods are the theoretical workhorse. Therefore it is natural that a search for the most highly cited articles in APS journals mainly reveals articles related to electronic structure theory. These articles are more often cited than Maldacena's paper. Here is a (very incomplete) list:

Physical Review 136 (3B) B864; Physical Review 140 (4A), A1133; Physical review letters 77 (18), 3865; Physical Review B 45 (23), 13244; Physical Review B 23 (10), 5048; Physical Review B 46 (11), 6671; Physical Review B 41 (11), 7892; Physical Review B 59 (3), 1758; Physical Review B 13 (12) 5188; Physical Review B 54 (16) 11169

Of course, this only tells us that there are more people working in this other subfield of physics or, perhaps, that the citation manners are different in these two areas. If Maldacena's paper is a basis for the usage of certain mathematical structures in different areas of physics then an explanation for the high citation numbers might be that it is interesting for a much larger crowd of physicists than only the string theory community.

14. **4gravitons**
December 26, 2015

Interpreting Harlow's post as arguing that the standard model is a postdiction of string theory seems fairly disingenuous, as the clarifications that he added to the post should show. String theory does get quite close to reproducing the standard model, and the obstructions there do indeed appear to be technical. That doesn't mean it uniquely reproduces the standard model as the only possible stable state, or even that the standard model is the most likely such state, just that the standard model appears to be one possible configuration. Meanwhile, as Harlow clarifies, the "postdictions" he's referring to are things like the existence of gravity, not the standard model.

15. **Neil**
December 26, 2015

"It represents incontinence of speculation joined to constipation of experiment."

Very quotable.

16. **Peter Woit**
December 26, 2015

Shantanu,
Conlon is a well-known young string theorist. His criticism of LQG is fairly long and I can't reproduce it here (and am not interested in engaging in that particular argument). I don't recall anything about asymptotic safety or CDT, and as I noted I don't think Conlon is fundamentally that interested in the quantum gravity issues, for reasons he explains.

4gravitons,
What Harlow is referring to by "it comes very close [to completely reproducing the standard model] and the obstructions seem more or less technical." are arguments that you can get essentially any low energy physics out of "string vacua". I think he's found the most misleading way possible of saying that string theory is a completely empty idea as far as particle physics goes. Any one who wants to can read what Harlow wrote, read what I wrote, and decide who it is who is being disingenuous here. The added material you mention is mainly his response to Scott Aaronson's pointing out to him that his claim of no real distinction between postdictions and predictions is nonsense.

I did go take another look at the Facebook posting, noticed that after writing that long piece of hype, Harlow's attitude is that he's now too busy doing serious science to respond to any criticism of it. I would like to see him respond to Conlon, who explains clearly what the problem with Harlow's claims about the multiverse are.

I also see that writing a posting mainly saying nice things about a book defending string theory and wishing everyone happy holidays draws comments from string theory ideologues about what an embittered person I am….

17. **Peter Woit**
December 27, 2015

All,
Please, if it's not about the Conlon book or the Siegel or Harlow pieces, please resist the temptation to submit comments, especially those about how you feel about quantum gravity…

18. **Bee**
December 27, 2015

@Jesper,

Yes, I think you misunderstood this, sorry. I am still working on qg pheno. But I am feeling rather stupid about it to be honest. Not because I think it's not a good research area, but because I am willingly sabotaging my future prospects of continuing to work in academia at all. (Actually, I wanted to leave, but then the money came through. So now I have two years to figure out what to do next.)

Your idea that scientists 'should not' be affected by funding opportunities is just totally past reality. People go where money goes. Show me any reason why I should believe this isn't so in science.

The people who 'rebel' against the system are the ones who are forced to leave. That's reality. Consequently the ones who stay are the ones who are, by and large, fine with what's happening because they themselves benefit from it.

19. **Bee**
December 27, 2015

Dear Lee,

There are enough people to populate an 80-100 person meeting, yes. The next one of which, incidentally, is due next year and doesn't have any funding whatsoever. As I said above, it's not that there is no interest in the topic. This isn't the problem, especially not among the young people. The problem is that there's no funding and no positions.

The vast majority of people working on these topics do it as an occasional on-the-side paper because it's not research that one can actually live from.

How many people can you list who have a position that pays full time for qg pheno? I could come up with maybe ten. How many positions have there been in the last decade searching for candidates in qg pheno? I know of maybe three. How many research groups on qg pheno are there in the world? Two? How many positions have there been for LQG and string theory in comparison? How many departments have string theory or LQG groups, or the occasional other theoretical (mathematical?) approach to quantum gravity. Right. Do you really believe that this is a good balance between theory development and phenomenology?

Best,

B.

20. **Low Math, Meekly Interacting**
December 27, 2015

I didn't think Siegel's piece was so bad. A bit extremist perhaps, but maybe more people need to stick their necks out a little and advocate for staunchly conservative point of view, even if it's a bit mythical. I'll take that over "post-empirical science" any day. I've said more-or-less the same thing before, but in just about every other branch field of physics (or any other branch of science, for that matter), there's no need for these philosophical debates. Contact with experiment is taken for granted, and difficulties that are generally down to instrument sensitivity or funding. If quantum gravity and unification research could be sufficiently compartmentalized, I doubt anyone but a few esoterists would care about the debate, such as it is. But it can't be compartmentalized. Many scientists from all disciplines and millions of non-scientists alike idolize people like Einstein and Hawking. It's human nature to be fascinated, even spiritually moved, by the search for an "ultimate theory". So when the very people who are perceived as holding this knowledge go around re-defining science to fit a "post-empirical" paradigm, the effect is disproportionately influential on public perception, and, in my opinion, highly damaging. Maybe Siegel missed some nuances. There's so much nuance in the discussion already veritable geniuses can't agree on the most basic level about what "science" is anymore. I'll take Siegel's perspective over that alternative any day.

21. **Jesper**
December 27, 2015

@ Bee

"Your idea that scientists 'should not' be affected by funding opportunities is just totally past reality. People go where money goes. Show me any reason why I should believe this isn't so in science.

The people who 'rebel' against the system are the ones who are forced to leave. That's reality. Consequently the ones who stay are the ones who are, by and large, fine with what's happening because they themselves benefit from it."

I actually agree with you – but I don't think it has to be that way and I don't agree that people, who are forced to leave, have to stop doing research. Why is it a black and white picture, where either you are 'in' and doing research or you are 'out' and not doing it?

Imagine if you applied the same logic to artists – do artists stop producing art when they have no money? No, of course not, they eat porridge for a while, live on the dole, find a patron, whatever. I think that science and art are related in this respect, its a question of passion, idealism –

– the only example I can give you (but I'm sure there are others) is myself. I was forced to leave some years ago – my research is way off mainstream, but I publish in top journals – and I have continued my work and have manage to get funding elsewhere.

I see very little reason to stop doing what I love just because the flow of cash stops – I just have to adjust and push on, and I'll do that as long as I believe in what I do. This is the type of rebellion I would wish to see more of. If the funding system sucks, well, then find your money elsewhere! If you really believe in what you do, then you'll find a way – I don't agree that being a scientist is a profession – to me its a lifestyle, a passion, a vocation.

22. **Shantanu**
December 27, 2015

Jesper : if you don't mind, could you list the sources from where you get funding, since I am sure that would be of interest to many people. FWIW, I know another person, who had a hard time getting a job (or invitations for conferences/seminars) for about 8 years, but still published papers in top quality journals by working in evenings and weekends and taking a day job in biophysics to pay bills. eventually he did get a job in a teaching university with time available for research. But I agree with Bee that probably such cases are almost non-existent. Maybe you and him are the only current examples.

Lee : once upon a time PI had an option where anyone could propose to organize conferences as long as the LOC/SOC involved one PI resident faculty and it would provide logistic support. Is such a service no longer available? At any rate I do hope that PI would organize the next incarnation of the QG phenomenology conference to keep the tradition.

23. **Jesper**
December 27, 2015

@ Shantanu,

I know that there are very few examples of people who work without research funding. My point is that I don't see why it need to be that way. An example: Schwarzschild did his important work while fighting in WWI. History is full of people who didn't stop just because conditions were a little (or very) challenging. But it appears that today people just stop when they don't get paid to do research. This I don't really understand. I think that the analogy with artists is relevant.

As to your question: I don't want to expose my private finances here, I can just say that at the moment I finance my research out of my own pocket.

Perhaps one can turn the question around: isn't it conceivable that one can get better research conditions outside the universities, where so much time is now taken up with things that has nothing to do with research?

24. **Peter Woit**
December 27, 2015

Jesper/Shantanu,
This has gotten completely off-topic. Whatever the prospects are for financing one's research oneself (easy for some people, impossible for many others), efforts like Sabine's to hold the current system to account are extremely important. Conlon's book discusses funding issues extensively, and his efforts, like those of Harlow, have a

lot to do with fighting to preserve funding for string theory in the face of bad PR like Siegel's article. None of them are planning on giving up this fight in favor of doing string theory in their spare time.

25. **4gravitons**
December 27, 2015

@Woit,

I do appreciate your perspective on Conlon's book, but I wasn't intending to gloat about it. 😉

(More seriously, I suspect you'll see more pieces like that as time goes on. Science communication seems to work by establishing tropes and building on them, and the sort of tropes Conlon is working with are a newer invention, the result of a younger string theory community finding its voice.)

I just think you're being more than a little unfair to Harlow. Yes, he's using older tropes…but in the context of a (non-Sean-Carroll) facebook post. Most of his expected audience understands what he's referring to, or at least are people like Scott Aaronson who are likely to ask for clarification. I doubt Harlow expected his post to go viral.

26. **Peter Woit**
December 27, 2015

4gravitons,

I don't see Harlow as using older tropes, but actually newer ones, albeit highly extremist ones. Does anyone not trained at Stanford believe claims like his that the reason we don't currently have testable statistical string landscape predictions is "a purely practical problem, not one of principle"? I don't think there's any way to construe that statement as anything other than a piece of outrageous hype. Sure, if you wanted to, you could find some way of construing some of his other statements so that they weren't obvious nonsense (e.g. by making his "postdictions" claim not apply to the SM, although he makes it in that context and doesn't explicitly say it doesn't apply there). I think he honestly believes what he's saying, but I also think most physicists recognize it as not science, and if voices like his dominate those like Conlon's, you're going to see a lot more, accurate, "String theory is not science" articles in the future.

One amusing thing about his post. According to his definition, everything I teach and think about all day is "string theory". I hadn't realized that….

27. **Gil Kalai**
December 28, 2015

I liked Harlow's piece. It is clear and short and it makes quite a few interesting points some of which are new for me. I liked especially the following points:

"3) Just because string theory reproduces known physics, that of course doesn't mean that we should declare victory for it. But it does mean that we should take it seriously. In particular one should note that none of its "competitors" have done this.

4) Except for one: the effective field theory of the standard model coupled perturbatively to general relativity (EFT for short). This theory also accounts for almost everything we have observed (except dark matter, neutrino masses, perhaps inflation). EFT is the real nemesis of string theory: what would convince us to prefer string theory to it?

5) I would say that there are two basic reasons by which we can prefer one physical theory to another. One is of course if one theory correctly accounts for observed phenomenon that the other doesn't. The other is if one theory explains the same observations using fewer parameters.

6) As far as we can tell, string theory may eventually beat EFT on both of these criteria…"

So Daniel's point is that (at present) the main scientific alternative ("nemesis") of string theory is not the even more speculative and much more partial suggestions for quantum gravity (the "competitors" as Daniel referred to them), but a rather straightforward coupling (EFT) of the standard model with general relativity. (I suppose that like string theory also EFT should not be thought as a single possibility but is quite board. Perhaps not quite as board as ST itself.)

Daniel expects (or hopes) that eventually some variants of ST will beat all variants of EFT (which is a perfectly fine), and, taking for granted the ST framework (which is also perfectly fine), he even regards some major remaining difficulties as of "technological" nature irrelevant to "matters of principle."

There were other interesting points (like the value of postdictions, the distinction between practical matters and "matters of principle" and a few more) in this piece, so I was quite happy to read it.

Regarding the issue of "science". Since I regard mathematics as science the debate regarding this term is little moot for me (interesting questions arising from philosophy of science notwithstanding.)

28. **Peter Woit**
December 28, 2015

Gil Kalai,

Saying "string theory reproduces known physics" is extremely misleading, when what you mean is that it can reproduce not just known physics, but basically anything. As for the idea that string theory reproduces the standard model with less parameters, that's simply untrue. If he wants to hope that string theory will beat EFT on these criteria, he's welcome to do so, but, after 30 years, there's zero evidence of this working. There's a fundamental problem with the way he and other string ideologs argue, which is basically: "First, assume everything we would like to be true is true, then…" As for the claim that the problems are just "technological", not "matters of principle", I think that is not just hype, but absurd hype.

29. **vmarko**
December 28, 2015

Regarding the "technological problems" of ST, it would be really good if people would remember the extremely sarcastic way in which Pauli was mocking some of Heisenberg's similar statements, a century ago. Namely, he took an empty canvas, put it in a frame, and said "This proves that I am as good a painter as Titian. Only some technical details are missing."

Also, I often hear the off-the-cuff statement that general relativity can be combined with the Standard Model in an EFT. This isn't really true — one can only combine them classically, i.e. take the classical limit of the SM and plug it into Einstein's equations. There is no such thing as an "effective quantum theory of gravity", be it GR+SM or otherwise. Looking at low-energy behavior (i.e. putting a cutoff at some scale) isn't enough — one needs to define the path-integral measure for the effective gravitational degrees of freedom (if one is to have a quantum theory at all), and this is an unsolved problem even in the context of EFT.

This is in contrast to the SM in flat spacetime, which certainly can be regarded as a low-energy EFT of some more fundamental theory. The measure is there, the dof's are known, everything is well-defined. But for gravity none of this works, because we don't know what are the dof's, and because of measure issues — and this *despite* the presence of a cutoff.

So I'd say that neither ST nor EFT can describe all observed experiments. ST has trouble with the matter sector, EFT has trouble with the gravitational sector. Lose-lose.

Best, 🙂
Marko

30. **Anonyrat**
December 28, 2015

Marko,
What is the experimental result or observation that EFT has trouble with?
Thanks in advance!

31. **vmarko**
December 28, 2015

Anonyrat,

The trouble with EFT is not experimental, but theoretical: there is no theory! Nobody is able to write down the equations for an effective low-energy quantum theory of gravity. The measure of the gravitational path integral is not well-defined, so the theory does not exist, let alone experimental predictions. This was known back in the '60s and '70s, when DeWitt was studying the measure for the gravitational path integral. Already then it was obvious (to the well-informed) that any discussion of QG requires one to formulate a UV completion, precisely because an effective field theory doesn't exist. If a QG EFT were possible, by now people would have long forgot about strings, LQG and other Planck-scale theories, and be content with an effective low-energy theory.

Best, 🙂
Marko

32. **Peter Woit**
December 29, 2015

Sorry, but I have to keep pointing out that this is not a quantum gravity discussion board. If people want to discuss Marko's comment with him, please contact him directly.

33. **amused**
December 29, 2015

Since Conlon apparently discusses sociological aspects, did he explain why, in competition for jobs in particle theory, N single-author publications in Phys.Rev.Lett. by a non-string researcher (N being any number between 1 and infinity) count for flat zero when weighed against just one article in, say, PRD by a string researcher where he/she was one of eight authors on the paper with the others all being more senior people?

34. **Peter Woit**
December 29, 2015

amused,
No mention of that…
More generally, I didn't notice much awareness of the problem of faddishness, of pressure to work on certain designated "hot" topics if one wants a career in the business.

35. **srp**
December 29, 2015

I just read Maguejio's 2003 book on VSL (found it used). Minus his profanity and ageism, the same points about U.S. theorists all working on the same trendy stuff and getting funded only for doing it is in there. It would be nice to see some systematic evidence about this funding issue.

36. **Peter Woit**
December 29, 2015

srp,
Quantifying the grant issue in the US would be a bit tricky, for one thing many grants are to groups. As many US HEP theorists will tell you, grant amounts have been going down, as far as I know, independently of area people work in. It would be interesting though if anyone has any data.

One somewhat more promising way to quantify faddishness and which fields are hot would be to look at the postdoc hiring data here
https://sites.google.com/site/postdocrumor/
You'd have to figure out how to categorize people's research fields, which would not be so easy.

In Conlon's book, one thing he emphasizes is that he has had to convince committees of non-string theorists to give him a grant (and has been successful). He emphasizes quite a lot that connection to experimental testability is an important part of his work, and seems well aware that that argument is now an important one to be able to make if you're a string theorist and want a positive evaluation from other physicists. That may not actually be a good thing, if you believe that the current state of string theory cannot successfully make contact with experiment, that the best hope for the future is more formal work that would uncover something new about the underlying theory, something with a better chance at connecting to experiment.

37. **Scott Church**
December 29, 2015

Peter or Anyone,

Regarding grant requests and/or postdoc hiring for string theory research emphasizing "[connections] to experimental testability," how many of these proposals are based on postdictions rather than predictions? Can such proposals be taken as a sign that things are trending away from [Texas sharpshooting](), or what might be called the Kane Effect? If so, how many of these proposals seem to show real promise?

38. **Peter Woit**
December 29, 2015

Scott Church,
I think most people hoping to get a "test of string theory" are looking for predictions, would be happy though to get a postdiction, and this hasn't changed. As I've documented extensively on this blog, the story of "tests" of string theory is that they're never tests that can falsify string theory. They refer to some possible observable effect in some model, a model supposed to have something to do with string theory (sometimes just "string-inspired"). The problem is that if such an effect is not observed, that just means you change to a different model. Kane's "predictions" are of this kind, and Conlon's work on observable effects of moduli is also of this kind (Kane is different in the way he markets such "predictions", in the much stronger claims for them he makes). I don't think any of these show significant promise, since the models being invoked don't actually plausibly explain anything we know about.

Conlon I think does explain this fairly clearly. The motivation of his search for models with observable effects of moduli is not that string theory implies such specific models are likely. It's more that string theory provides the inspiration for looking at such classes of models, which give new ideas for unexpected things to look for. While such things are unlikely to show up, if one did see them, they would indicate dramatic new physics of some kind.

39. **life of brian**
December 30, 2015

[Low Math Meekly "Interacting] I didn't think Siegel's piece was so bad…[]…maybe more people need to stick their necks out a little and advocate for staunchly conservative point of view"

It's certainly one possibility…that Siegel has taken a courageous stance for deeply held principle. Another possibility is the severe to terminal String Theory critique in media has lately begun to fizz.
Finger in the wind or principled and potentially self-sacrificial harsh criticism? In the end you'd have to decide what else you'd expect to see given one, or the other respectively.
Evidence of serious long term consideration perhaps. One way to get an indication on that might be to ask what are the hackneyed positions out there. If the space is starting to fizz, then chances are the ill thought through, pointless or point-missing, components of criticism are the ones becoming commonplace so hackneyed, so the ones showing up disproportionately right now. How's he doing so far?

40. **Peter Woit**
December 30, 2015

life of brian,
More or less identical arguments over string theory have now been going on for a decade or so, without a lot of change. The only thing that I see having changed in the last couple years is that the LHC results are shutting off the last hope for some observable new physics relevant to string theory (pre-LHC a common argument argument from string theorists was that connection to experiment would be made through the discovery of SUSY at LHC energies).

The naive "it predicts nothing observable so it's not science" critique of string theory is now more powerful than it used to be, as more and more string theorists adopt the attitude that nothing observable is not a problem for the theory, attracting a reaction like that of Ellis/Silk. My impression is that Siegel is well-aware of some of the subtleties of the arguments over string theory, also aware of the fact that the naive critique has gained force from recent developments, so he thought it was worth making now (popular science articles in Forbes aren't a place you can really do subtlety).

41. **Greg**
January 1, 2016

Peter,

is string theory probable at all? I ask for the following (humorous) reason. A supersymmetric theory has about 105 free parameters. Each parameter can have at least 10 million possible values (a rough guess). That makes 10^735 possible parameter combinations. But the landscape/multiverse has only 10^500 options. I would deduce that there is only a probability of 10^-235 that standard model plus gravity is part of the landscape.

What is wrong with the reasoning? 🙂 Happy holidays to you too!

42. **Ignatz Ratzkywatzky**
January 3, 2016

Going through John Baez's Crackpot Index, I note that the last and highest scoring item is #37:

"50 points for claiming you have a revolutionary theory but giving no concrete testable predictions."

Hmmm.

End of Year Links

December 30, 2015
Categories: Uncategorized

A collection of links to round out the year:

- The Seminaire Bourbaki talks this January look unusually interesting. Luckily I'll be in Paris at that time.
- For an end of year present, Jacob Lurie has posted a version of his unfinished next book, Spectral Algebraic Geometry. It's advertised as much more user-friendly than previous versions of the same material and that's quite true after reading the first chapter.
- If 850 pages or so of this sort of thing isn't enough to keep you busy during the break between terms, try Lurie's Harvard colleague Dennis Gaitsgory's A study in derived algebraic geometry, a book project with Rozenblyum, also in a preliminary version (around 1100 pages), with more to come. I'm hoping for the more user-friendly version of this one…
- Also from Harvard, videos of last month's Current Developments in Mathematics talks are now available here. At least the first of Peter Scholze's talks is rather user-friendly.
- Very, very user-friendly (especially if you read Japanese) are the Japanese television versions of Edward Frenkel's talks earlier this year at MSRI, available here.
- If you just can't get enough of the new 750 GeV particle, you probably should read Tommaso Dorigo's take on it.
- Back when I was writing about the AMS's role as a mouthpiece for the NSA in its attempts to mislead people about their role in backdooring an NIST crypto standard (see here and here), one thought I kept in mind was that since this standard supposedly was never used in anything important, maybe one shouldn't get so upset. Recent news (see Matthew Green for an explanation) is that this bad crypto actually was used in something quite important: widely used firewall/VPN hardware from Juniper Networks. Quite likely this was used by the NSA to get access to much of the traffic on a wide variety of networks.

  The story is actually much more complicated than one can believe, with a still unclear sequence of changes in the software indicating that others, possibly a foreign government, took advantage of the NSA backdoor to compromise these systems. Green points out that this makes very clear the problem with government-mandated backdoors: even if you trust the government, they make it much easier for others to take advantage of the security problems they have introduced:

  > One of the most serious concerns we raise during these meetings is the possibility that encryption backdoors could be subverted. Specifically, that a backdoor intended for law enforcement could somehow become a backdoor for people who we don't trust to read our messages. Normally when we talk about this, we're concerned about failures in storage of things like escrow keys. What this Juniper vulnerability illustrates is that the danger is much broader and more serious than that.
  >
  > The problem with cryptographic backdoors isn't that they're the only way that an attacker can break into our cryptographic systems. It's merely that they're one of the best. They take care of the hard work, the laying of plumbing and electrical wiring, so attackers can simply walk in and change the drapes.

- If you just can't get enough of my and other people's views on string theory, Ben Winterhalter has a piece on the Jstor blog, telling the story of his attempts to figure out what's going on with extra dimensions.
- Among the many great articles at Quanta, I can recommend this one, which features my Columbia colleague Wei Zhang.

Happy New Year!

Comments

   December 31, 2015

   Thanks! Have a nice change of year too!

2. **John Fredsted**
   December 31, 2015

   Thanks for all the nice blog posts this year, always interesting to read. I am looking forward to new ones in the year to come. Happy New Year!

3. **uair01**
   December 31, 2015

   Agree with the others: many thanks for the blog and have a good New Year.

4. **Tim May**
   December 31, 2015

   Many thanks for your blog over the years. I especially appreciate the links to mathematics work. It's through this blog that I first heard about the Langlands project. And it does appear that the most interesting "fallout" of the string theory effort has been in the AdS/CFT work.

   I arrived on your blog some years ago, maybe around 2004 or so, just before your book, but possibly just after Smolin's book. Not sure. I know I had read his "Three Roads" book.

   I'd been unpersuaded by a string theory popular book I read around 1987 or so, from before the later changes, and then still unpersuaded by the Brian Greene book. And so I was pretty skeptical of the hype.

   However, I think things have gotten a lot healthier in recent years. Some of the hype of the "we now know that everything is vibrating strings, a symphony of different chords" has settled down.

   I've seen several talks by Lenny Susskind and am much impressed. (Not a lot of talk about string theory, though.)

   Anyway, Dr. Woit, I have enjoyed your blog as a breath of fresh air. And I appreciate the many links to modern mathematics. (I am still amazed that even pure mathematicians like Gaitsgory refer to physics!)

   I hope to be reading your blog ten years from now.

5. **geometriclanglander**

December 31, 2015

Frenkel's MSRI lectures were meant to be aimed at undergraduates, but watching the first two, they actually seem to be more appropriate for middle schoolers.

Thanks for the CDM links in particular. Scholze's lectures are truly beautiful. Donaldson's review of Kahler-Einstein metrics for Fano manifolds is also a fantastic overview. The subtlety (and comedy timing) with which he trolls Gang Tian with the '4 different proofs now exist' at the beginning of his second lecture is quite amusing.

6. **Ramsey Glissadevil**
   December 31, 2015

   Happy New Year Peter!

7. **Neil**
   December 31, 2015

   Happy New Year! Looking forward to 2016 and news from LHC. May the 750 GeV bump be with us.

8. **paddy**
   December 31, 2015

   Like the rest above, I send wishes for a Happy New Year and a thanks for all the columns and links.

9. **MathPhys**
   January 1, 2016

   Best wishes for 2016!

10. **Happy New Year**
    January 1, 2016

    For me this is the greatest blog on physics and mathematics. It's serves students, researchers, and the general public.
    Happy New Year Peter and everyone who has posted a comment or simply read this blog.

11. **Peter Shor**
    January 1, 2016

    Happy New Year!

12. **srp**
    January 1, 2016

    Happy 2016!

13. **Dave Miller in Sacramento**
    January 2, 2016

    Peter,

    Thanks for your ongoing coverage of the NSA backdoor cryptography story. It is interesting to note that a news story that broke towards the end of the year is that NSA intercepted communications between Netanyahu and members of Congress and passed them on to the White House. Congress is not pleased… should be an interesting story as it unravels.

    Thanks for all your work on this blog, and Happy New Year.

    Dave Miller in Sacramento

14. **Mario**
    January 3, 2016

    I was searching for this info, but haven't found anything related serios: In 2016, LHC should provide ~10times the number of collisions compared to 2015, which means the 750GeV boson riddle will be resolved. But when will we get trustful information about it? I assume that there will be some high-energy conferences in 2016, where it is expected that ATLAS and CMS will provide updates. Can somebody point to dates and names of such conferences? Or will we find out in other ways (at this blog, like for the Higgs 3.5years ago 😉)? Thanks!

15. **Peter Woit**
    January 3, 2016

    Mario,
    The current schedule has a first period for physics data-taking April 25 – End May and if that goes well they should have more data than from the 2015 run, enough to see if the bumps persist. My impression is that two of the major summer conferences are June 13-18
    https://indico.cern.ch/event/442390/
    and August 3-10
    http://www.ichep2016.org/
    My totally uninformed guess is that June 13-18 is too early to have analyses ready (but I may be wrong, I was surprised how much was done by Mid-December this year, only 6 weeks after the run was over). So, August 3-10 might be the dates to keep in mind. Also, they seem to now like to announce important things at CERN instead of at regularly scheduled conferences, so the dates of the conferences may be irrelevant.

    Post-Higgs, I've to some extent retired from putting much effort into tracking down reliable rumors, but if I hear something interesting, it likely will be a topic here…

16. **Low Math, Meekly Interacting**
    January 5, 2016

    Despite your retirement from the rumor mill, here's hoping something shows up that's worth reentry.

Best wishes for 2016!

17. **Low Math, Meekly Interacting**
January 5, 2016

Nice layman's article on the use/abuse of Bayes' Theorem by John Horgan @ SciAm. Hopefully relevant and useful to your less statistically-savvy readers, given the recent meeting in Munich.

http://blogs.scientificamerican.com/cross-check/bayes-s-theorem-what-s-the-big-deal/

18. **Peter Woit**
January 5, 2016

All,
I second the recommendation about John Horgan's discussion of the Bayes business, but please discuss this over there on his blog. My earlier experience with discussions about this here convinced me that the world is full of people who want to argue about irrelevant aspects of this, and that Joe Polchinski's Munich contribution conclusively proved that the idea of evaluating string theory/multiverse research this way is laughable.

19. **Low Math, Meekly Interacting**
January 6, 2016

OK, sorry! Glad it was worthy of note in your latest post, at least.

Various and Sundry

January 6, 2016
Categories: Uncategorized

Some short items on a wide variety of topics:

- The Hawking/Perry/Strominger paper on a new idea about the black hole information paradox (see here for an early discussion) based on BMS supertranslation symmetries has now appeared on the arXiv. I'm no expert on the intricate arguments about this paradox, so have no idea what the implications of this paper for that really are. However, it does seem to be a very interesting approach to quantum gravity questions (although the paper mostly deals with simpler gauge theory calculations). The ideas are squarely in the mainstream of what has been the most successful way of making progress in fundamental theory: identifying new implications of symmetries that are at the center of our core theories (the standard model and GR). Such a new understanding looks like a far more promising way forward than much of what is currently popular in the subject.
- For an example of what is currently popular, the KITP is hosting a workshop this week of the the It from Qubit Simons Collaboration, on Quantum Error Correction and Tensor Networks. I gather this is supposed to somehow explain AdS/CFT, but I've never understood how this is supposed to come about. Evidently I'm not the only one wondering about this. John Presskill reports that, in his talk leading off a series of lectures on this, Patrick Hayden commented that

  > I'm unsure what we are trying to learn from these tensor network models of holography.

- Tonight PBS will be showing the film Particle Fever, which I wrote about here. It's a great film, highly recommended, despite the larding with comical nonsense about the multiverse (if you believe the theorists in the film, the multiverse is supposed to be tested by its prediction of a mass of 140 GeV for the Higgs). The capsule summary in the New York Times TV listing this morning for the film is "Scientists recreate conditions from the big-bang theory". While the LHC has nothing to do with the big-bang theory, maybe this summary refers to the comedy of the theorists and another well-known TV show, in which case viewers may be a bit disappointed.
- In other LHC related news, the AMVA4NewPhysics project now has a blog, latest posting explains the basics of b-tagging.
- I've never been able to really make sense of many of the arguments about "Bayes's Theorem", and the recent attempts to justify string theory using this just seemed bizarre. John Horgan has a great explanation of what is going on here, including this take on the Bayes/string theory/multiverse business:

  > In many cases, estimating the prior is just guesswork, allowing subjective factors to creep into your calculations. You might be guessing the probability of something that–unlike cancer—does not even exist, such as strings, multiverses, inflation or God. You might then cite dubious evidence to support your dubious belief. In this way, Bayes' theorem can promote pseudoscience and superstition as well as reason.
  >
  > Embedded in Bayes' theorem is a moral message: If you aren't scrupulous in seeking alternative explanations for your evidence, the evidence will just confirm what you already believe. Scientists often fail to heed this dictum, which helps explains why so many scientific claims turn out to be erroneous. Bayesians claim that their methods can help scientists overcome confirmation bias and produce more reliable results, but I have my doubts.
  >
  > And as I mentioned above, some string and multiverse enthusiasts are embracing Bayesian analysis. Why? Because the enthusiasts are tired of hearing that string and multiverse theories are unfalsifiable and hence unscientific, and Bayes' theorem allows them to present the theories in a more favorable light. In this case, Bayes' theorem, far from counteracting confirmation bias, enables it.

- The recent Munich conference trying to justify string theory by Bayesian methods wasn't the only example of European funding for philosophers to weigh in on the latest in fundamental physics. Another just announced European LHC-related project is a 2.5 million Euro research unit aiming to investigate the LHC "from an integrated philosophical, historical and sociological perspective."
- I just ran across a recent paper by Kristian Camilleri and Sophie Ritson on The role of heuristic appraisal in conflicting assessments of string theory. It is very good, unlike almost every other discussion of this topic, I think it gets right the central serious argument of the "string wars": how does one evaluate the prospects for the string unification idea? There is no simple answer to this, you need to understand what the state of efforts to connect a hoped for unified string theory to reality really are, how they have evolved, and try to make a sensible judgment about whether this is a failed idea or whether there is hope left. I highly recommend reading this for those who are not completely tired of this subject.
- In the same journal I noticed another quite good article, by Porter Williams on naturalness. He carefully explains the different incarnations of "naturalness" and I think comes to the right conclusion that it is best thought of as the idea that physical behavior at widely different distance scales should not be correlated. By the way, the name "naturalness" for this is a bit of marketing genius (how could "nature" not be "natural"?).
- In geometric representation theory news, the Simons Center is running a program on the topic this month, videos here. Here at Columbia Roman Bezrukavnikov will be the Spring 2016 Eilenberg lecturer, with his topic "Geometric categorification in representation theory". I believe talks will be Thursdays at 2:40, watch the Columbia math department website for more news.
- Personally, I'm about to head out tomorrow night on vacation, so expect minimal blogging and possibly even shutting off of comments. When I get back, I'll be teaching our spring semester graduate course on groups and representations, see here. Also trying to finish my book on quantum theory and representation theory. Current state (see here, comments always welcome) is that I've gone over and rewritten the first 34 chapters (except the introduction), planning on rewriting and adding material to the rest of the manuscript this semester. This better be done by this summer, partly because that's when it is supposed to be delivered to Springer, partly because I'm already quite tired of this project and want to work on other things…

Update: Any mention of Bayesianism seems to attract a large number of people who want to discuss it, especially aspects that have nothing to do with the string theory/multiverse business. Please discuss this topic with John Horgan at his blog.

Update: Sabine Hossenfelder has more on the Hawking/Perry/Strominger paper here.

Update: Scientific American has an interesting interview with Strominger, who explains some of the ideas behind Hawking/Perry/Strominger. Jacques Distler has come out of retirement at Musings to object that this work violates two central ideological tenets: one should not pay attention to gauge invariance, and the answer to all questions should be string theory or AdS/CFT.

Comments

1. **Jeffrey M**
   January 6, 2016

   Could someone please educate a mathematician about how physicists get to say this in a paper – "Recently such an a priori reason for doubt has emerged from new discoveries about the infrared structure of quantum gravity in asymptotically flat spacetimes." Infrared structure of quantum gravity? Quantum gravity? Did someone come up with a correct theory for quantum gravity while I was sleeping? Is the implication somehow that ANY theory of quantum gravity will have the exact same infrared structure in asymptotically flat spacetimes? Really?

2. **Peter Woit**

January 6, 2016

Jeffrey M,
The famous problems with quantum gravity are ultraviolet problems, so shouldn't be relevant for the infrared structure. And the infrared structure should be largely determined by the fact that you want GR in the classical limit.

All,
Those who want to argue about Bayesianism and Horgan's views should do it at his site.

3. **Kartik Prabhu**
January 6, 2016

@Jeffrey M
Any theory of quantum gravity should reproduce General Relativity in the far asymptotic region ("infrared"). The infrared structure you quote comes purely from studying the symmetries of asymptotically flat spacetimes in General Relativity.

So even if we don't have a full quantum theory of gravity, _any_ such theory better reproduce this structure to be physically viable.

(original post: https://kartikprabhu.com/notes/re-quantum-gravity-infrared-structure)

4. **Jeffrey M**
January 6, 2016

Thanks for the answers, that makes sense. Now I'm only confused about "new discoveries" since they can't mean new discoveries about GR, right? Or do they mean new implications about possible theories which have the right classical limit? Have there been limits found in that direction? Personally, I think Hawking was right in the first place about black hole information loss, and you just don't actually have unitarity, but what do I know.

5. **vmarko**
January 6, 2016

Peter,

Is there a draft or something of the Porter Williams paper that is not behind the SD paywall? I looked it up on the arXiv, and failed. Yet from your description it seems a very interesting article to read, so…

Best, 🙂
Marko

6. **Peter Woit**
January 6, 2016

Marko,
Try the philosophy of science version of the arXiv
http://philsci-archive.pitt.edu/11529/

7. **Kartik Prabhu**
January 6, 2016

@JeffreyM for some context:

The infrared structure here refers to the symmetries of asymptotic flat spacetimes given by the BMS group. This has been known for a long time in classical GR. Some recent work by Strominger relates these symmetries to the so-called "soft theorems" in scattering calculations (involving gravitons) in perturbative QFT. In essence, what it says is, since the BMS group is infinite-dimensional, there is an infinite-dimensional degeneracy in what one would like to call the "asymptotic ground state".

How this shakes out for the information "paradox" remains to be seen.

(original post: https://kartikprabhu.com/notes/re-quantum-gravity-infrared-structure2)

8. **Narad**
January 6, 2016

> I just ran across a recent paper by Kristian Camilleri and Sophie Ritson on The role of heuristic appraisal in conflicting assessments of string theory.

I haven't read it yet, but this is the first time that I've seen an editorial office include a boxed notice of this sort: "When citing this paper, please use the full journal title *Studies in History and Philosophy of Modern Physics*."

Neither CASSI nor Crossref has an entry, and "Stud. Hist. Philos. Mod. Phys." doesn't appear to have much competition on the abbreviations front.

9. **vmarko**
January 7, 2016

Peter,

Thanks for the link! 🙂

The Williams article is an excellent read, cutting straight through the naturalness ideology that has been dominating particle physics for too long, IMO. In a more general context, it is refreshing to see that QFT ideology is on the retreat — first a step back from fundamental QFT to EFT, then the serious criticism (even failure) of naturalness as a guiding principle. The next in line will be renormalization, once enough people gain enough awareness that gravity is nonrenormalizable (which puts a wrench into the gear of renormalizability as a guiding principle, so to say), and demote it to simply a useful technique of studying EFTs. Williams also hints in this direction in the article, but doesn't want to stray too much from his main topic…

The era of QFT dominance is fading. With the latest results from the LHC (mainly evidence of Higgs and no evidence of SUSY), serious cracks are beginning to show in the QFT paradigm. This is important, because people really need to get disenchanted of QFT as a set of ideas that are universally valid. Once that happens, the younger generation of string theorists will gain awareness and courage to step back and ask "wait, what are we really doing here when constructing ST?", and start thinking outside the box.

The Williams article is one of the first, but extremely important steps in this direction.

Best, 🙂
Marko

10. **Anonyrat**
January 8, 2016

…physical behavior at widely different distance scales should not be correlated…

If AdS/CFT relies on the asymptotic spacetime being AdS, but claims to describe string-scale physics, isn't that a correlation of physical behavior at widely different distance scales?

Thanks in advance!

11. **vmarko**
January 8, 2016

Anonyrat,

No, not really — AdS/CFT is a duality between two theories, rather than between two different scales of the same theory. For example, UV range of CFT maps into IR range of AdS, which by itself doesn't tell you anything about the IR range of CFT. And vice versa.

An example that actually does violate naturalness would be the UV/IR mixing in noncommutative geometry models.

Best, 🙂
Marko

12. **Anonyrat**
January 8, 2016

Thanks, Marko!
—
Porter Williams lists some work in progress:
http://porterdwilliams.com/research/
including ""The explanatory failures of the multiverse".

Looking forward to the results of that research!

13. **AdamT**
January 9, 2016

Peter, vmarko,

I am struggling to understand what a physical theory that is highly correlated at different scales would look like? Are we talking about a "fractal" theory here?

Any explanations that would inform intuitions on what these theories might look like from a big picture sense would be appreciated!

Adam

14. **Peter Woit**
January 9, 2016

Adam T,
Simple examples would be free field theories or conformally invariant theories. In some sense what's surprising is the "natural" behavior, that the behavior at long distances is so independent of how you define the theory at the cutoff scale.

15. **vmarko**
January 10, 2016

Adam,

In addition to what Peter said, it is interesting to imagine what nature would look like if Standard Model were not "natural" as much as it is. For example, imagine that all quark and lepton flavors/generations had substantially long lifetime. In such a scenario, despite the fact that the top quark is very heavy and contributes only on TeV scales, the low-energy behavior of the theory (say, chemistry) would be completely different (read: much richer) than it is.

So "naturalness" is a statement that for example chemistry has properties based on up/down quarks and the electron, regardless of what other particles may exist at higher energies. This behavior is, as Peter said, actually very surprising. In an "unnatural" SM chemistry would highly depend not only on these three particles, but on all possible particles that can exist in nature (and I mean *all*, up to Planck scale, not just the particles we have discovered so far). That's what "mixing of the scales" would mean.

IMO, the word "naturalness" is a complete misnomer for the phenomenon.

Best, 🙂
Marko

16. **Krzysztof**
January 10, 2016

Back in late 1940s no "naturalness" was expected – by "common" opinion the QED should die at 100 MeV, or so.

17. **Chris W.**
January 10, 2016

One could argue that "naturalness" (or whatever else one might call it) is extremely important for the development of science. Given "mixing of the scales," the progressive, staged development of physics and chemistry would be far more difficult, if not altogether impossible. (I'm reminded of the importance of "separation of concerns" in computer science and software engineering.)

18. **Thomas Larsson**
January 11, 2016

Naturalness and symmetry are in some sense opposites. In quantum theory we expect parameters to renormalize to generic values, even if the bare parameters vanish, unless:
1) some symmetry principle forbids it.
2) the bare parameters are finetuned.
Thus symmetry and finetuning result in the same experimental signature: non-generic values for parameters. That the Higgs mass seems to sit at the only a priori non-generic value – the boundary of the stability region – is rather striking from this pow.

19. **M**
January 12, 2016

Schellekens posted an interesting paper (Big Numbers in String Theory, http://arxiv.org/pdf/1601.02462.pdf) with a funny joke about landscape scanning:
«We were hit directly by the Big Number problem because the computer program experienced some mysterious segmentation faults each time it was starting to explore a very large hidden sector. We finally discovered that this was due to a message stating something like "remaining time …. years; aborting". The number of years, expressed as an unlimited size integer, was so large that it overflowed the text buffer allocated for it.»

20. **zzz**
January 12, 2016

lots of good bits in that paper

from the abstract:

"…I correct a huge but inconsequential error, …"

21. **Zathras**
January 13, 2016

So Peter have you heard anything more about the LIGO rumors which have been going like crazy over the last few days?

22. **Chris W.**
January 13, 2016

Another: "There are no negative results in science, just bad expectations." 🙂

23. **RM**
January 13, 2016

Hi,

Loved that statement about the moral message in Bayes theorem. As an ex-particle physicist on Wall Street, I would say to my former colleagues that you have no idea how good you have it! Abuse of Bayes theorem and statistics is rampant in the business world to the point that correct usage is almost a cause for suspicion.

Best,

RM

24. **Larry Lurio**
January 17, 2016

On the subject of statistical bias and LIGO there is a very nice book by Harry Collins called "Gravity's Shadow". He looks at statistical bias more from a philosophical point of view than a mathematical one. The book focuses on experimental bias in the search for gravity waves. One very interesting story that comes out of this is how the LIGO collaboration eventually rejected a test signal injected into the data to simulate a gravity wave.

25. **angry Jonny**
January 20, 2016

"Jacques Distler has come out of retirement at Musings to object that this work violates two central ideological tenets: one should not pay attention to gauge invariance, and the answer to all questions should be string theory or AdS/CFT."

You're kidding, right? Just in case there are actually some smart young people reading this blog who can't tell you're kidding, you should clarify that you were kidding, that Distler acknowledged that gauge degrees of freedom become dynamical at boundaries, only it wasn't clear why this is appropriate for horizons of decaying, non-eternal black holes. I mean, I get it- "don't read that, Distler is a knee jerk ideologue" is your code for "read Distler's blog, there's a discussion thread of 25 or so posts by people who've actually published in this topic." But not everyone's hip to your satire, the way you criticize the internet's rancorous politicization of physics by pretending to be so focused on the politics you've lost track of the physics- and I wouldn't want the kids to miss out on a cool discussion.

26. **Peter Woit**
January 20, 2016

angry Jonny,

When I wrote that, the substantive discussion thread over there hadn't really started, I'm glad to see it did. I was being somewhat humorous, but certainly didn't say "don't read that". If I want people to not read something I ignore it, don't advertise and discuss it here.

As far as the youngsters being misled, I think the misleading thing would be to point them in Distler's direction without warning them he's a knee jerk ideologue and what the ideology is.

Back at Work

January 21, 2016
Categories: Uncategorized

It's been a while since the last posting here, mostly because I've been away on vacation, but also because I haven't seen anything that newsworthy. But, since I'm back in the office and there have been complaints, here are a few items:

- For the first time in a very large number of years, a new volume has appeared in the series of Bourbaki treatises, dealing with algebraic topology (table of contents here). From the table of contents, it appears to be a rather modern treatment mostly of the fundamental group, but still in the Bourbaki style of exhaustive coverage and abstract point of view (I don't see any mention there of actually computing the fundamental group of anything…).
- While in Paris I attended some of the Seminaire Bourbaki talks. You too can watch via Youtube, or read the written versions.
- Far from mathematics and physics, one thing I did in Paris was stop by a store selling Breton products, and had a discussion with the owner about Kouign Amanns. He had a short hand-written list of a few places they could be had in the US. When I got back here, the next morning I went out to my local bakery (Silver Moon, at Broadway and 105th), and found that while I was away they had started selling them.
- On the Mochizuki front, there's a new paper by Vesselin Dimitrov, claiming that if Mochizuki's argument is correct, it implies something even stronger than Mochizuki claims, an effective version of the abc conjecture. The next workshop about this will be in Kyoto in July. One mathematician who has gotten interested in this and is listed as planning to attend is Edward Frenkel.
- If you can't get enough of the "Is HEP physics dead or what?" debate, see John Horgan on How Physics Lost its Fizz.
- Among the things going on here at Columbia this semester, there are Eilenberg Lectures on geometric representation theory (starting in a few minutes…) by Roman Bezrukavnikov, a course by Michael Harris on Lafforgue's recent work on the Langlands correspondence for function fields (also the topic of one of the Seminaire Bourbaki talks), and a conference celebrating Dusa McDuff's 70th birthday.

Better leave now to get a seat at the talk…

Comments

   January 21, 2016

   Kouign-amanns are fairly common now at San Francisco bakeries and coffee shops, and yes they are delicious.

2. **David Roberts**
   January 21, 2016

   Ronnie Brown would be happy that the van Kampen theorem is proved for fundamental groupoids and not just for groups, and has a thorough treatment of groupoids generally.

3. **Ramsey Glissadevil**
   January 22, 2016

   Bryan…Multiple layers of sweet resplendency.

4. **Chris Kennedy**
   January 22, 2016

   I see that Trader Joe's sells frozen pack of four that you have to proof before baking. Has anyone tried those?

5. **John**
   January 22, 2016

   What is your take on the big rumor that GW's were found at the advanced LIGO run?

6. **Peter Woit**
   January 22, 2016

   John,
   I know nothing about that rumor. That advanced LIGO sees something has always been the expectation, so a detection would in some sense not be surprising (although a great breakthrough in opening up a new kind of astronomy).

   As for whether putting out the rumor on Twitter was a good idea, my own prejudice is that one should only put out rumors that one has a very good reason to believe, at a point where there's no good argument for keeping information secret. I think the history of rumors about LHC results so far has been that they've been pretty accurate, something that those in other fields should try and emulate…

7. **Yatima**
   January 22, 2016

   "Kouign-amann is a speciality of the town Douarnenez in Finistère, Brittany, where it originated in around 1860. The strict recipe of Douarnenez requires a ratio of 40 percent dough, 30 percent butter and 30 percent sugar."

   Solid fare for the morning, indeed.

8. **Bernd**
   January 25, 2016

   John,

   it's known that LIGO people sometimes deliberately put in fake signals and only reveal it when the publication announcing the discovery is about to be submitted. It's called "blind injection", and they do this as a test of the detection procedures: http://www.ligo.org/news/blind-injection.php

Hitler doesn't get a postdoc in High Energy Theory

January 23, 2016
Categories: Uncategorized

I recognize that this is a genre that is a bit tired, and arguably in poor taste, but the commentary on the HEP theory postdoc job market in the video [Hitler doesn't get a postdoc in High Energy Theory] is insightful. As far as I can tell the HEP Theory postdoc/junior faculty market has been the same for the last 45 years or so: far more people than jobs, and if you want one you better be working on one of a small number of "hot" topics. One might speculate that this correlates with the lack of progress in the field during this time. I'm a bit better informed about the mathematics job market for fresh PhDs, which is much healthier, as is the intellectual state of the field.

A recent trend does seem to be fewer jobs in the US, more in Europe. Anyone with better information about what is going on is encouraged to comment here (and, condolences if this is because you're on the market).

Comments

1. **Jeffrey M**
   January 23, 2016

   Peter,

   You are certainly correct that the job market in math is much better than in HEP, but just so no one gets the wrong idea, the job market in math sucks. It's sucked for 24 years. I managed to get my Ph.D. the first year it collapsed, and while I got a job, and so did most people I know, they weren't what we were expecting, and it got worse. Got better for a bit with some new NSF postdocs, but now it's much worse again. It's no picnic, even with a good advisor and a good thesis. My thesis was published in Mathematische Annalen, and I was lucky to get a job with a 4 course teaching load.

2. **RhoPhi**
   January 24, 2016

   Does anybody have data on post-doc jobs offered, faculty jobs offered and drop-outs every year? can think of a couple of ways to measure these from rumor sites and arXiv.org but I was wondering if data exists.

3. **Manfred Requardt**
   January 24, 2016

   I have just seen the video Hitler doesn`t get a postdoc in HEP and I think, it is a brilliant piece of modern art.

4. **DR**
   January 24, 2016

   > My thesis was published in Mathematische Annalen, and I was lucky to get a job with a 4 course teaching load.

   Damn.

5. **John**
   January 24, 2016

   One can argue that the tight job market in the USA should be no problem for people, because they can just move to Europe, right? Or China for that matter. Well, the problem for people to move to another place is often a very personal one.

   For example, my wife and I live in Europe. I have a postdoc position, my wife has a good (non-academic) job and we have a young child. This means my academic career will soon end because I cannot just move with my family to pursue some other postdoc position somewhere. My wife would have to quit her job. She already did it once for me, but this cannot continue.

   Because scientists are supposed to do various postdoc positions at various places before entering a tenure-track position (with not having job security even then), my question is:
   Are there scientists out there who have a partner with some professional ambitions? If yes, how do you manage?

   I think it is very old-fashioned for one partner to work and the other to stay at home, but this seems to be the effect of the postdoc-system.

6. **Ramsey Glissadevil**
   January 24, 2016

   Enjoyed the Hitler video. Yet, I'm sadden so many bright and dedicated physicists leave the their fiancé for finance.

7. **Chris Oakley**
   January 24, 2016

   God knows how many sets of fake subtitles I have seen for that clip from *Der Untergang* … the original one was about Hitler being banned from Xbox Live, but there has also been his problems with installing printer drivers, problems with booking a skiing holiday and many others. What distinguishes this one, though, is the lack of spelling errors. So maybe that it the thing, out-of-work or soon-to-be-out-of-work particle theorists: if you cannot get a job compactifying fluxes in 11 dimensions maybe you should consider teaching English.

8. **anonymous**
   January 24, 2016

   @ John:

   That's a tough situation and I sympathize. My wife and I are both academics, so our situation is a little different (worse in some ways, better in others). We married right around the time we graduated and spent the next five years apart jumping through all the academic hoops. We eventually found dual positions, but it was challenging and we both sacrificed better positions to be together.

Someone remarked to me that it's easier to find a spouse than an academic job. Given the competitiveness of the job market, I think this is unfortunately true. Are aspiring academics supposed to remain single and unattached until they get a TT position? Or find a partner who is willing to relocate every couple years? Ugh. It's a nightmare.

The majority of academics I know have a spouse who fits the mold of "stay-at-home". The exceptions are older couples who were on the job market 10-15 years ago, or those with a spouse who travels a lot for work or can work from home.

I wish you well in your situation.

9. **Ignatz Ratzkywatzky**
January 24, 2016

I recall an apocryphal story my supervisor told me.

After a lot of applications, talks, and networking, a clever HEP theory postdoc at a national lab was offered an assistant prof position at a major university.

However, his wife had a well established career with a high paying job in the nearby large city. Her job was not very transportable.

After quite a bit of soul searching, the postdoc told his colleagues that he was going to turn down the offer.

They reacted,

"Are you nuts?
You may never get another such wonderful offer.
You can always get another wife."

10. **Tim May**
January 24, 2016

All, it's hard to post an optimistic personal account here that doesn't appear to be boastful. But I think sometimes the negative stories need to at least get some counter-response.

In 1970 I was accepted at MIT, Stanford, and Berkeley for college. I transferred my acceptance and Regents Scholarship from Berkeley to UC Santa Barbara. A lesser school compared to Berkeley, on overall grounds, but a more interesting fit to my interests. (College of Creative Studies, with many advantages.)

By around 1972 it was clear the Big Drought was unfolding. Tales of Ph.D.s driving taxi cabs, professors advising that the odds of the then-current Ph.D. candidates getting a real position were dwindling. (Besides the overall downsizing of HEP and other physics funding, there was a glut of physics professors who had been hired in the post-Sputnik boom era….and they were still 30 years or more from retirement.)

Fast forwarding, I decided to not apply to grad school and instead join a small semiconductor company. There, I worked on a bunch of "engineering physics" probems. Because we were the leaders in dynamic RAM memory, I had exposure to some intersting problems. One of them was the mysterious issue of bits sometimes being flipped, but not permanently. In fact, the bit flips were apparently random and occurred only once (or at least close to only once…).

My physics background served me well, as I knew about the physics of how the devices worked (more so than a lot of the EE folks, who thought in terms of circuits), and I knew some geology. I had a brain storm that maybe low levels of uranium or thorium or the like in our ceramic and glass packages were causing the problem. Some experiments confirmed this. And all of the physics calculations about charged particle tracks in silicon matched. A lot of stuff I don't have the space here to describe.

So my career was launched. Lots of papers on this "soft error" phenomenon. (Oh, and the cosmic ray corrollary was indeed obvious: but in 1978 when the first paper was presented, it was insignificant as a source as compared to alpha particles.)

Instead of spending until 1980-82 doing a Ph.D. and then 4-8 years or more as a post-doc, I had some fun and retired from Intel in 1986.

I've been pleasantly able to pursue whatever interested me ever since.

So, there are also some alternatives to going to a hedge fund (not an option in the 1970s, early 80s, of course). And some of these may even let you do some fun physics and make some good money.

I'm not saying the options are the same today. But it shows that the pure academic track is not the sinecure it was in the WW II to around 1920 period. The poor prospects for good employment are sort of a reversion to the earlier situation, I think.

I have no guesses on what some current options might be. But I'm pretty sure most HEP grad students and post-docs will be facing some tough choices.

–Tim May

11. **Richard Séguin**
January 25, 2016

Tim:

I remember that bleak 1972 period. Where I was at the time, mathematics grad students were urged to take some computer science or statistics courses as fall backs. It was very discouraging, especially if you were not particularly interested in those topics.

12. **Ross McKenzie**
January 25, 2016

RhoPhi asked about data on "attrition". I don't know it for math or physics. However, there is hard data for biology, summarised in a nice graphic.

http://www.ascb.org/where-will-a-biology-phd-take-you/

It is pretty depressing. In particular, less than 8 per cent of entering Ph.D students become tenure track faculty.

13. **Anonymous**
January 25, 2016

I don't know if postdoc employment situation is really better in Europe, but I can say that getting a permanent university position is definitely just as difficult here as it is in the US. Maybe you can get a postdoc position or two after your PhD, but that is just postponing the inevitable; in the end you have to think of something else because there are just not enough permanent positions in the academia for everyone. If you want to save yourself a couple of years of moving from country to country and a lot of stress, you might as well quit academia after PhD (ever even after masters).

I don't believe that this system even chooses the best people for the professorship positions. It merely chooses people who have the mental fortitude to withstand all this bullshit for a decade. Most people (no matter whether they are good physicists or not) see the bleakness of their future prospects already during their PhD or first postdoc and leave.

14. **Tim May**
January 25, 2016

Yes. Richard Séguin, 1972 (plus or minus a year or two) was a terrible awakening.

An awakening about how many graduating physicist would find no jobs.

I don't recall panicking, just realizing that any thought of being a university physicist was probably a fantasy.

By around 1973 I think I was ready to move into industry. For various reasons, my small group hosted Feynman. I was the designated grillmaster, so I ended up cooking a steak for Feynman. As he sat on a couch at our place, chewing on his probably-overcooked steak, we grilled him (ah hem) about the future of physics.

He opined then, in the spring of 1973, that he thought if he were then starting out, he'd go into computer science. (He did a lot of fundamental work in CS not long after.)

He influenced me a lot. About a year later I joined Intel. For about a year I thought I was not figuring out the fundamental laws of the universe, but then I came to like what I was doing and realized that only about a couple of people per 30 years really do much about figuring out the real basics.

I appreciate guys like Nima, whether he is right or wrong, but most of us will not be Nimas.

(Not a big fan of string theory, but I like Nima's talks.)

I sometimes think Physics–the industry–has gone too far in emphasizing the Hero, the Conquerer, the World-Changer.

–TM

15. **Bernd**
January 25, 2016

I don't work in HEP, I work on more condensed-mattery stuff, but I sometimes get applications from HEP people. My impression is that the postdoc situation is a bit easier in Europe because all the hotshot postdocs go to the US, so the competition in Europe is less harsh. For real jobs, it's a different matter because 1) there are way less permanent positions than postdocs and 2) many of the people who went to the US for a postdoc are trying to come back.

16. **John**
January 25, 2016

@Ignatz Ratzkywatzky
Your anecdote nicely illustrates how sick the community is.

Let us not forget what it means to be in science: you have a parttime teaching job with most of the rest of the time supervising students, writing grant proposals, dealing with institute evaluations, meetings etc. There is no such thing as independent research because you need have impact, so you are stuck with the hot topics. You are crazy to choose this over your family. The only reason some people still do it seems to be status. A lot of tenured staff are in it for the status, and do not really care about science.

But, if you want to do real independent research and do not care about status, then take, say, a parttime job as a webdesigner and spend your spare time on research.

@anonymous (January 24, 2016 at 4:14 pm)
Yes, it's a nightmare. And especially so for women. For a woman, if you wait until you have a tenured position before choosing a partner, then you lost maybe all of your childbearing years. Women tend to be attracted to someone she can look up to. So, choosing a jobless partner who stays at home all day may not be attractive. Governments ask why there are so few women in science. Well this is your answer, right there.

17. **chris**
January 25, 2016

At least in Germany we are flooded with postdoc money. It is difficult to get a decent postdoc because there are so many open positions. And it is especially difficult as you have to tell them that after 6 years there is close to 0 chance they will land a permanent job.

And yeah, basically all my tenured colleagues have spouses that gave up their career or are single.

18. **Confused**
January 25, 2016

Dear All,

I liked the video, but I am left confused. Could you please explain to me why in the video Hitler is angry for not having any academic job offer but He's saying "… you want me to spend another year teaching undergrads…" Is that not an academic job? Or am I not understanding the american academic system?

Thank you.

19. **Richard Séguin**
January 25, 2016

Tim:

"But, if you want to do real independent research and do not care about status, then take, say, a parttime job as a webdesigner and spend your spare time on research."

You realize, though, that dropping out of official research environments (academia, research institutes, and the less common structures in private industry) makes actively participating in the research community more difficult. It's not impossible, but you have far less day to day contact with others of like mind, it's generally harder to network, and unless you've previously established a reputation, you have the sniff of a crank unless proved otherwise.

20. **AcademicLurker**
January 25, 2016

Confused:

My understanding is that most postdocs don't teach undergraduate classes. Perhaps they made a special exception for Hitler.

There's such a thing as a "teaching postdoc" that combines research with undergraduate teaching, and I think is designed for people who plan to apply for jobs primarily at small liberal arts colleges.

21. **Peter Woit**
January 25, 2016

Confused,
You need to understand that much of the US system is now a two-tiered one, with poorly paid adjuncts doing much of the undergraduate teaching, full-time tenured faculty doing relatively little undergrad teaching, more grad teaching, research, supervision of graduate students. Postdocs generally don't teach (although in some cases may pick up extra funding by adjunct teaching). I took the reference you quote as being to the prospect of having to try and support oneself as an adjunct if no further postdoc position was to come through.

22. **Tim May**
January 25, 2016

Richard Séguin,

Just to be clear, I didn't write the paragraph about being a part-time Web designer and doing research on the side.

I've already said enough in this thread. But I agree with you that doing physics on the side, or as in independent, is tough. Math may be easier to do this way.

23. **Michael Hutchings**
January 25, 2016

With a couple of spectacular exceptions (Perelman, Zhang,…), being isolated from the community is generally fatal for serious mathematics research.

24. **Jeffrey M**
January 25, 2016

@Michael Hutchings,

Well, Perelman had positions at Courant, Stony Brook, and Berkeley, and then at Steklov. And Zhang, who was out of math for a number of years after grad school, did get a job as a lecturer at UNH. Neither of them were really isolated, though Zhang certainly didn't have the usual teaching load for a high level researcher. I would agree isolation is generally fatal, I can't offhand think of any real result coming from outside the academic community in recent years.

25. **Michael Hutchings**
January 25, 2016

Jeffrey M:

Yes, but my understanding is that Perelman proved the Poincare conjecture while hiding away for a long time in the woods in Russia. And I suspect that Zhang didn't have much contact with the number theory community while doing his famous work. I think that even for professional mathematicians with solid training and credentials, going into isolation is usually very bad. In this regard it will be very interesting to see what happens with the abc conjecture…

26. **a job market survivor**
January 25, 2016

@Confused, @Peter, most graduate students in HEP theory are supported on TAships in the US (as NSF, DOE funding has been cut so much that even rich institutions can't support theory students on RAs anymore). Hitler is saying he's not willing to postpone his graduation for another year in the hopes that he'll have better luck on the postdoc market next year.

@John, while the whole issue of childbearing, and more broadly speaking, the likelihood of facing long-distance relationships during the grueling postdoctoral phase of an academic career is a big structural problem that badly, badly needs addressing, I can assure you that the issue of underrepresentation of women in the sciences starts with the systematic discouragement of girls from pursuing science and math in grade school, and good old-fashioned bias, both implicit and explicit, is still a very real factor.

27. **Peter Woit**
January 25, 2016

Thanks a job market survivor,
I should have realized that, somehow was thinking of Hitler as a current postdoc, not a student…

28. **Peter Woit**
January 26, 2016

All,
Please resist the temptation to use an interesting comment about the effect of the postdoc system on women's careers as an excuse to start exactly the same argument about why women don't go into science that one can see a million other places. Surely you don't want to read those arguments again, so why do you think it is a good idea to start them?

29. **Anonyrat**
January 26, 2016

How is a healthy, sustainable particle physics community of active researchers possible in these circumstances? When the winnowing out of the field is this brutal, the formation of a monoculture becomes much more likely.

30. **Confused**
January 27, 2016

@AcademicLurker, @Peter, @a job market survivor,

Thank you very much for your answers.
So as I understand you, it is more difficult to find postdoc positions.
But are teaching undergrads easily found in the US after one's PhD is completed (like here in north africa)? I mean, can people who have not done any postdoc in HEP find a permanent undergraduate teaching position, so that one supports oneself while doing independent research without funding?

Thank you very much again.

31. **AcademicLurker**
January 27, 2016

@Confused,

Low paying adjunct positions teaching undergraduates are reasonably easy to find post PhD. These have no job stability and are renewed each semester.

Permanent teaching positions are much more difficult to get. Even bloodthirsty fascist dictators have trouble securing them.

32. **Anonymous**
January 27, 2016

"I recognize that this is a genre that is a bit tired…" Noooooooo! I will never tire of Hitler Downfall parodies.

Now if someone would figure out how to combine it with Rickrolling…

33. **twistor**
January 28, 2016

@ RhoPhi:

Rough computation: assume the number of jobs is constant. Assume each professor has about ~10 phds / academic lifetime on average. Then 10% of phds will get a permanent position…

Certainly in Europe the # of jobs in t-HEP is a constant, perhaps slowly declining if any.

34. **Alex K**
January 28, 2016

Did anyone else notice that they replaced "Stalin" by "Nima"

I don't think he's *that* bad 😛

35. **Low Math, Meekly Interacting**
January 28, 2016

@Anonymous

This particular Unterganger left me conflicted. The final comment about the pants was so poignant…the resulting wave of sympathy for the Führer was a tad unsettling.

36. **gadfly**
January 28, 2016

"How is a healthy, sustainable particle physics community of active researchers possible in these circumstances? When the winnowing out of the field is this brutal, the formation of a monoculture becomes much more likely."

Well, HEP stuff is not currently insightful to the rest of science, and evolved out of a hyper-reductionistic paradigm that is dead outside of physics. Moreover, it's pretty obvious that without actual data to play with, you can't learn more about how the world works. So why manufacture pointless, grandiose sounding philosophical questions when there are so many things that we don't understand that we can research instead?

The hiring situation is getting worse in CS/quantitative biology disciplines (biophysics, bioinformatics) where I moved after my physics B.S., but it's nowhere near as bad as HEP or pure math. Engineering and C.S. PhD's I meet get TT positions without even doing a post doc.

When the fact that your field is antiquated and anachronistic has become obvious to everyone else, why not simply move on and work on other perfectly interesting problems for which there is plenty of good data and a will in the lay public to fund it?

–Just a gadfly

37. **Shantanu**
January 30, 2016

Peter and others. OT to this, but the videos of the LMU workshop on why trust a theory are online
http://www.whytrustatheory2015.philosophie.uni-muenchen.de/program/index.html

38. **Peter Woit**
January 30, 2016

All,
Please, the HEP theory job market is on-topic, whether HEP theory is dead isn't.

More From Polchinski

January 28, 2016
Categories: Multiverse Mania

Joe Polchinski has a rather odd preprint on hep-th, more of a blog posting than a paper, summing up his views on string theory and the multiverse. This is a revised version, wisely dropping a really unfortunate section. The material previously here explaining the background to what was in that section has been moved elsewhere, and I've renamed the posting.

I've never personally met Polchinski, and from those who know him I've heard that he's a nice guy. I've also recently heard that he's ill, wish him the best.

Update: It seems that I misunderstood why Polchinski removed the section about me from his arXiv article. He's now claiming that it was just because, since he'd gotten trackbacks to my blog banned, it would be unfair that there would be no trackback to his article (true enough…). This whole situation is a level of bizarre beyond the heights reached way back when during the string wars.

For those reading the version of Polchinski's article on his website rather than the current one on the arXiv, to understand what this is about, please read the material here.

Some News

January 31, 2016
Categories: Uncategorized

Not much time for blogging at the moment, with one reason that I'll be giving a talk at Rutgers on Wednesday, and need to get that prepared. A few quick items:

- As some commenters have mentioned here, talks from the recent Munich conference (discussed here) are now available. From the little time I've found to look at them, I think Rovelli's is the talk that makes the point about all of this most worth making, with Massimo Pigliucci good at explaining the wider implications.
  While interesting comments on the talks are encouraged, for reasons that I can't explain publicly, discussion here of the Polchinski contribution is not welcome.
- Besides watching Gordon Kane in Munich on string theory predictions, he also has a paper about this out now.
- Congratulations to Bert Kostant on the award of the 2016 Wigner Medal. Kostant has been one of the major figures over the years in developing many deep ideas about the intersection of mathematics and physics, as well as a leading figure in the algebraic approach to Lie algebras and their representations.
- A lot of mathematicians and physicists want you to use TurboTax.
- Steven Weinberg's sensible opposition to guns in UT Austin classrooms has gotten a lot of media attention (for instance here). Of the many obvious reasons why this is a bad idea, he correctly points out that it may well make it difficult for UT to recruit faculty.

Update: A commenter points out that more videos from the Munich conference are available here.

Update: John Horgan has a wonderful interview with the remarkable and ubiquitous Sabine Hossenfelder. Highly recommended.

Update: For news from the LHC, see last week's Chamonix LHC performance Workshop. From the summary, the goal is about 30 inverse fb of pp collisions this year.

   This place contains more videos from the conference: https://videoonline.edu.lmu.de/en/wintersemester-2015-2016/7475

2. **nicola**
   January 31, 2016

   I went through Kane's talk.

   It is not the first time he mentions Newton's law or the Schroedinger equation and then claims that their predictions are analogous (in methodology) to string theory (slides 9 and 10). He says that in both cases (Newton or Schroedinger) you have to propose the force or the Hamiltonian and then see if they work with the experiment. In ST one provides the compactification scheme and then see if it works too – and so they are analogous in methodology.

   I think Kane is missing a very simple fact that disqualifies his analogy. The point is that for both Newton and Schroedinger theories we know what are the elementary constituents interacting and we know what is their interaction (whether it is electromagnetic, gravitational or any other know interaction). In principle we could write corresponding potentials for all the interacting constituents and so there is no guess work about the Hamiltonian to which Kane is referring. In Newton or Schroedinger equations there is in principle no room for proposing the potentials unless one is considering some effective potential due to complexity of the system considered. However exact potential are solutions of concrete equations (e.g. Maxwell) which have been tested experimentally many times.

   On the other hand in ST one starts with guesses about the compactification schemes and ends up in theories that has never been verified. There is no analogy here, I'm surprised he is bringing this up.

   Other thing that surprises me in his talk is slide 17 where he claims that "Gravity, YM theories, gauge fields,…. – all are prediction of and evidence for ST". He is certainly confusing a prediction with the postdiction – you cannot predict something that has been already discovered, but I hear many STheorists making this error.

3. **Narad**
   January 31, 2016

   > A lot of mathematicians and physicists want you to use TurboTax.

   I'm afraid that they've failed to adequately explore the parameter space – the free version last year started concealing the information that it won't do self-employment tax (without buying the premium version) until late in the exercise.

4. **David Roberts**
   January 31, 2016

   I would have appreciated Kane putting references for all the claims in his paper. If it was Wikipedia, there would have been a good many [citation needed] tags. Also, are any of the 'incorrect predictions' he refers to due to himself?

5. **Frank**
   January 31, 2016

   Kane did mention Lee Smolin and Peter at the 6 minute mark in the presentation. Sounded like he has some major disagreements with them.

6. **Peter Woit**
   January 31, 2016

   I was really surprised the organizers chose Kane as a speaker. His point of view doesn't really have anything to do with the "post-empirical" topic of the conference. His idea seems to be to do conventional empirical science, making distinctive falsifiable predictions. The innovation is to just ignore it when they get falsified. He just puts out a new paper or new edition of a book, replacing the falsified ones with new ones, repeating as necessary.

7. **andrew**
   February 1, 2016

Looking forward to reading your perspective on your book 10 years on (if slides are available). Will there be e.g. a second edition with a new preface?

I guess the book has aged reasonably well; whilst a lot of things have changed in the last decade, a lot of things have stayed the same.

8. **Peter Woit**
February 1, 2016

andrew,
I think the argument of the book has aged very well, with evidence for it now stronger than when it was written (most dramatically, no SUSY at the LHC). Main developments since then have been the discovery of the Higgs (expected, but I was hopeful that it might turn out to behave in an unexpected way), multiverse-mania, and, personally, I've learned a lot more about mathematics, which would change how I'd write some of the book if I were to do it again.

I'm trying to finish my textbook the next few months, and then want to pursue a bunch of ideas that have been on hold while I work on the textbook. Spending time on popular writing isn't something I want to do much of, but perhaps I should write some kind of piece about the "string wars", ten years later.

Slides from the Rutgers talk will be available.

9. **Balazs Vagvolgyi**
February 1, 2016

https://videoonline.edu.lmu.de/en/node/7494

In her talk Sabine Hossenfelder has a brilliant interpretation of how the Multiverse theories are born.
It starts at 8:22 in the video.

She basically argues that in any physical reality with any set of physical laws where intelligent beings get to think about their physical laws, there will always be unobservable/unmeasurable factors that will prevent them from coming up with a complete set of axioms to represent the theory of everything.
Then eventually their physicists, after long struggle, will always come up with a theory that will group all the unobservables/unmeasurables into a framework that will just be a version of the Multiverse.

10. **phil fogle**
February 1, 2016

OK, this isn't physics, so delete if necessary; but I applaud Weinberg's stance at UT; the mere thought of a disgruntled student in a classroom is very disturbing for the lecturer; would he be breaking the law if he refused to teach after an anonymous threat, for instance?

This has to be on the outer fringes of state insanity.

11. **Kevin S. Van Horn**
February 1, 2016

I'm not a physicist myself, but it seems to me that the No Alternative Argument would be more appropriately named Proof By Lack of Imagination.

12. **TS**
February 2, 2016

The idea of grading people who might want to discuss their grades while carrying a weapon is fairly scary. It shouldn't take a Nobel laureate to see that.

On a more delightful / depressing note: Kane writes that Witten discovered M-Theory in 1995. How amazing! I was only aware of him conjecturing the existence of an M-Theory in the same year, but I totally missed that he also made the next step! And in such timely fashion!

13. **John**
February 2, 2016

"The idea of grading people who might want to discuss their grades while carrying a weapon is fairly scary. It shouldn't take a Nobel laureate to see that."

So how do you know they don't carry an illegal gun now? To get a CCW permit you must go through training, background checks and other obstacles. Seems to me these students are more vetted then others which you know nothing about.

But then most people are scared of what they don't understand.

14. **Peter Woit**
February 2, 2016

Sorry, but I'll cut off further debate about the advisability of having armed students in one's classroom. Nothing anyone says here is likely to affect most people's opinion that this is obviously crazy. I am curious to know if it will have an effect on UTs ability to hire faculty.

15. **Miki**
February 2, 2016

Peter,
I read Kane's paper, but I am not an expert in ST and cann't follow his arguments and claims.
Supeficially, the paper looks "scientific" and sound – what is your opinions about it?

16. **Peter Woit**
February 3, 2016

Miki,
Kane makes a complicated argument, involving a lot of different assumptions. As explained above, he has a long history of doing this, making "predictions" which are falsified time and time again. I don't see any point to spending time understanding the details of the latest ones.

17. **SteveB**
February 3, 2016

Thanks for the LHC news links.

Can anyone explain the long technical stops that coincide with year's end?

Why would the world's most expensive machine be turned off and then have to go through 4 weeks of recommissioning every year? I realize some maintenance is required but it seems such a long time to be idle.
start silly comment
I am hoping that the answer is not that the people working there want long vacations, but if that is the case I wonder if the many people on this site that complain about finding HEP jobs, might be willing to replace those people at 80% of their salary and keep the machine up.
end silly comment

18. **zzz**
February 3, 2016

its really easy to accelerate particles from your keyboard, a lot harder from
an actual accelerator

19. **Nilay**
February 3, 2016

Off-topic, but perhaps of interest, is a New Yorker piece by Lawrence Krauss on the waste of money that is the Breakthrough prizes:

http://www.newyorker.com/tech/elements/do-the-new-big-money-science-prizes-work

20. **Anonyrat**
February 3, 2016

I hope that your Rutgers talk becomes available!

21. **30 inverse fb of pp collisions this year**
February 3, 2016

– is 30 inverse fb of pp collisions this year enough data to
1- decide on 750GEV diphoton excess
2-determine if natural SUSY exists or rule it out
3-incease bounds on gluino masses
4-determine if LSP neutralino dark matter exists ?

22. **Fred P**
February 3, 2016

@SteveB-

Here's a rundown of what they did for commissioning last year: http://lhc-commissioning.web.cern.ch/lhc-commissioning/2015/2015-comm-plan-schedule.htm

This doesn't look like an excuse for a vacation to me.

23. **downtime**
February 3, 2016

Part of the answer is electric utility rates, especially during peak holiday periods. A better answer is from Fred P. It's typically a mad scramble to get everything installed on schedule. The correct question to ask is "how do they get so much done with so little down time?" But the best answer is "ask someone at CERN (or SLAC, Fermilab, etc.) how do they manage to do as much as they do within the limited downtime available?"

24. **A.J.**
February 3, 2016

SteveB:

It's the world's most complicated machine. Four weeks a year of maintenance would be a miracle. However, the period you're talking about, the 'recommissioning period', isn't so much maintenance as 'the process of turning the LHC on'. The LHC doesn't run during the winter season because fuel costs are higher then and the budget is limited. During this time, the physicists and engineers do maintenance and upgrades. Then in the spring, they turn on and tune all the subsystems in their proper order so that they can have collisions in the summer and fall.

* I wonder if the many people on this site that complain about finding HEP jobs, might be willing to replace those people at 80% of their salary and keep the machine up.*

Those are theory jobs they were talking about. Putting theorists in charge of LHC maintenance would be a bit like giving a dentist a scalpel and asking him to perform brain surgery. Maybe you'll get a discount, but you probably won't get the desired effect.

25. **chris**
February 4, 2016

Steve B,

the LHC being the "world's most expensive machine" is off by at least an order of magnitude.

The total cost of the LHC is about $9 billion.

Just for reference: The total cost of the ISS is $150 billion. The cost of a single CVN-78 Class Aircraft Carrier is close to $10 billion. (And the R&D cost for the F35 plane was a staggering $320 billion).

Even looking at physics alone, the LHC is not the most expensive machine. The cost estimate for ITER is >$15 billion and the current projection for the Webb telescope is $8.8 billion.

26. **Peter Woit**
February 4, 2016

Nilay,
Thanks for pointing that out. I pretty much agree with Krauss, although I think the standard "instead support young people who are just entering the field" alternative he suggests is problematic. The problem I see (especially in theoretical physics) is not that good young people can't get postdocs, but that there are so few permanent jobs for them. It would be a great idea for the math/physics community to try and convince Milner and Zuckerberg to stop giving these large personal awards, and instead endow permanent positions in the name of the honoree.

30 inverse fb

1. yes
2. no (or, maybe, yes, since it is already ruled out).
3. yes
4. no (you can always push the mass up higher).

27. **Alex**
February 5, 2016

In case anyone is interested in some technical details, here is a fairly good short summary of the model Kane and his collaborators have been working on where you can read about some of the assumptions and how much connection to M-theory it actually has: https://ncatlab.org/nlab/show/G2-MSSM

28. **30 inverse fb of pp collisions this year**
February 8, 2016

2. no (or, maybe, yes, since it is already ruled out).

are you saying the result of first run @ 8 TEV is enough to rule out TEV-scale SUSY?

29. **Peter Woit**
February 8, 2016

30 inverse fb,
If susy is supposed to be "natural", it really is supposed to show up at the weak scale (100 GeV), and the current bounds on superpartners rule that out. You can claim if you want that there is just some fine-tuning, so the superpartners are at higher mass, even push them up above the point the LHC will see them in this run.

As for "TeV-scale susy", depends exactly what that means. There are different bounds on different superpartners, best bounds on the strongly interacting ones, which already have to be above a TeV, but if you think a few TeV is "TeV-scale", that's not yet ruled out.

30. **Anonyrat**
February 12, 2016

Clara Moskowitz, on page 14 of the February 2016 Scientific American, in an article on XENON1T tells us "WIMPs are a prediction of superstring theory". Little did I know!

31. **Peter Woit**
February 12, 2016

Anonyrat,

She just doesn't mention that no WIMPs are also a prediction of superstring theory…

Rutgers Talk

February 4, 2016
Categories: Uncategorized

Slides from my talk at Rutgers are now available here. The idea was just to advertise to physicists there the point of view that is all too familiar to regular readers here. The final speculative comments about relations to mathematics shouldn't be taken too seriously, these are things I hope to work on and write about much more in a few months once my current book project is completed.

Update: Interestingly, my Princeton advisor Curt Callan yesterday gave a talk at the KITP with a bit of a similar theme, starting off by arguing that the success of the standard model made future progress in HEP very difficult. His answer to the problem is quite different than mine (his involves trying to make contributions to biology). The first question at the end (from David Gross) is about the relation to new mathematics.

Comments

1. **Ian Agol**
   February 4, 2016

   If you use \documentclass[handout]{beamer}, it should shrink your pdf document from 125 to 32 pages (eliminating the strip-tease feature).

2. **Peter Woit**
   February 4, 2016

   Thanks Ian,
   That's a useful fact I didn't realize. Will change that in the morning.

3. **G.S.**
   February 4, 2016

   I like pacing through the talk bullet by bullet. It makes the material easier to digest.

4. **Bernd**
   February 5, 2016

   I'm not so sure that the current obstacles in experimental HEP mean an end of being able to conduct experiments at all. Rather, I have the impression that only the paradigm of the particle accelerator is coming to an end. Instead, we have to think about how to conduct new types of experiments that allow us to probe effect occurring far beyond the electroweak scale. For instance, some people are working on probing Planck-scale physics with optomechanical oscillators. This is actually not that crazy, at least far less crazy than expecting the Chinese to build yet another accelerator and hoping for a miracle to show up there.

5. **Peter Woit**
   February 5, 2016

   I've changed the pdf file to one with single-pages.
   G.S.,
   For you and anyone else who likes the pauses, that version is at
   http://www.math.columbia.edu/~woit/rutgers-withpauses.pdf

6. **Peter Woit**
   February 5, 2016

   Bernd,
   I wasn't intending to claim that there are no possibilities for non-accelerator based experimental progress (or, lower energy accelerator-based things like neutrino experiments). Such things should certainly be pursued, my point was just to provoke thought about what can be done in the absence of new data.

7. **lun**
   February 5, 2016

   Did you get any interesting questions?

8. **Peter Woit**
   February 5, 2016

   lun,
   Some good questions, mostly people who sensibly wanted to challenge my provocatively negative take on prospects for progress (for instance: what about cosmology? what about neutrino masses? what about previous fallow periods in the history of the subject?). No string theorists there who wanted to argue about that.

9. **LK2**
   February 5, 2016

   There are also possibilities for accelerator-based progress.
   Magnets technology is progressing fast. Superconducting cavities: same thing.
   A lot of progress in wakefield plasma accelerator with a lot of R&D at SLAC and CERN.
   Do not forget the possibility of ILC and a muon collider.
   Sure: very expensive projects but all this could push the end of collider physics decades in the future.
   Accelerators are needed anyway for all the precision physics measurements. Just to name a few: mu2e, g-2 , pi to 3e, B-factories…
   Anyway: Peter I liked your perspective in the talk.

10. **LK2**
    February 5, 2016

As for the neutrinos, there are powerful experimental efforts. The Fermilab's DUNE project will clear up a lot of things: hierarchy (non and inverted) and CP phase in the lepton sector. The Japanese are progressing towards Hyper-K with similar goals. This stuff will be also useful for cosmic neutrinos and proton decay.
I do not see a grey future for HEP right now. Maybe in >50 years.

11. **Jake**
February 5, 2016

Reading thru now, got to page 15 "There is one science that does not rely on empirical testing to make progress: mathematics." and aren't those fighting words at an institution that employs Doron Zeilberger?

12. **Gregor**
February 5, 2016

@Peter:

I also scrolled through the slides and found a very basic statement (not central to your talk) that is not so clear to me: On slide 24 you write "Observables correspond to self-adjoint linear operators on H". This depends a lot on your definition of observables. I think it does not cover the Berry phase which also gives you a measurable quantity of quantum mechanical systems. Is this not considered to be an observable?

13. **paddy**
February 5, 2016

Jake: (At the risk of being OT.) After refreshing myself on DZ's opinions, yes they are rather amusing in juxtaposition to PW's talk. Thank you.

14. **Peter Orland**
February 6, 2016

Gregor,

The Berry phase is a matrix element of an observable. The operator, not the matrix element is the observable. This is not in conflict with the idea that self-adjoint operators are observables.

15. **Yatima**
February 6, 2016

Doron Zeilberger

Never heard of him before. Damn! [I suppose he is using Coq now]

There is one science that does not rely on empirical testing to make progress: mathematics.

The judgment of whether something is "empirical" or "à priori" (I am at a loss to find the best contextually relevant antonym of "empirical") is really on a sliding scale. *"Do you judge this statement to be a theorem of this hopefully self-consistent system"* is a call performed by resource-constrained, imperfect judges that moreover have to rely on external memory like paper and state-tracking systems like blackboards. Such is life…

16. **Michael Gogins**
February 6, 2016

Many thanks for the slides of your talk. I'm not a scientist, but I found this a very helpful distillation of your blog and point of view that gives me more of a feeling that I am getting a glimpse of the issues. I also think I agree that going over the details of the mathematical physics with mathematical insight and rigor is likely to be very helpful, but what is the role of "physical intuition" (like Einstein's thought experiments e.g. about the equivalence principle) in this?

Hasn't mathematics itself gone through several episodes in just the past century of redefining what exactly is a proof (Russell's Paradox/incompleteness, computer proofs, categorification), and what kind of mathematical tools and objects can or should be used in proofs?

Even more, is there any danger that "mathematical proof" can become so difficult that progress slows or halts, by analogy with the increasing difficulty of high-energy physics experiments? Is there a "human intelligence limit" here somewhere? How much of the increasing difficulty, assuming it is real, is due to mere complexity, and how much is due to increasing abstraction/sophistication? Can computer-assisted proof help with this?

I'm a mathematical Platonist like Godel, but I'm not sure I'm a radical Platonist in your sense. How does a radical Platonist learn which mathematical entities give the most insight into physical reality without experimental decision?

17. **Peter Woit**
February 6, 2016

Gregor,
Peter Orland is right that this is still an operator on states. This kind of operator is very interesting though, not of the same sort as local fields, which have an interpretation in terms of a representation of a Heisenberg Lie algebra (in physics terms, canonical commutation relations). Things like Wilson loop and 't Hooft loop operators indicate that fields may naturally be quantized in a quite different way than matter fields.

18. **Peter Woit**
February 6, 2016

Michael Gogins,
I don't think the basic idea of what a proof is has changed in quite a long time. It's fundamentally just the idea that you need to make your assumptions and claimed logical implications completely explicit.

The remarkable thing about mathematics is that it continues to progress, despite the use of ever more difficult to absorb formalisms. I find this really striking and well worth thinking about it. Naively one would expect progress to have ground to a halt, as the whole thing became too difficult for humans to master, but this hasn't happened.

I don't think you can understand the deep connections between physics and math by just looking at one of the two subjects. As for whether you can find new relations between math and physics of the sort I expect, the point is that you already know a lot about the physics side (the SM), and the argument is that you should focus on that. All experiment has been telling us for many years is "pay better attention to the SM". Would be great if new experiments told us something more than that, but this may not happen.

19. **Douglas Natelson**
February 7, 2016

Very nice. I am going to have to try to go through your book at some point, though I worry that I'm not sufficiently math-literate, in the sense that I don't really know how enough of the vocabulary to think intelligently about phrases like "the tangent space at the identity of the group". I know separately what a tangent space, an identity, and a group are, but mathematicians have a way of speaking that I haven't learned. If you have any advice on a "how to read about modern math for non-mathematicians", I'd greatly appreciate it.

20. **Peter Woit**
February 7, 2016

The book I'm writing does try to convey exactly what you're asking about, at least the first half of it, which tries to explain basic examples of Lie algebras, groups, representations in a concrete way, while also taking somewhat of a mathematician's point of view and language. The second half of the book things aren't so simple, I'm trying to work out basic examples of QFT using some different mathematics than usual. This I suspect both mathematicians and physicists will have to struggle a bit to follow.

21. **David**
February 7, 2016

I'm working through your book notes (haven't gotten to QFT parts, yet) and am enjoying it, but I must say it's a struggle. Biologist here, with some physics background. If a reader hasn't prepared with a couple books on lie algebras, group theory, and the basic math of QM (linear algebra, hilbert space, operators) before trying your book, I'd think he/she would get lost quickly.

22. **Low Math, Meekly Interacting**
February 7, 2016

Is calling mathematics a "non-empirical science" also intentionally provocative? There are quite a few learned people who would consider maths a separate field and feel mathematicians have a different métier from that of scientists. Furthermore, they would say maths and the natural sciences are all the better for this differentiation, while acknowledging the former's "unreasonable effectiveness". I'm on the fence about this distinction myself, and just wonder why you favor looking at it as a "science" vs….well, something else.

23. **Peter Woit**
February 7, 2016

LMMI,
Yes, that's intentionally a bit provocative, I'm well aware that many if not most people have a different view of mathematics. But from the "radical Platonist" point of view, mathematics is not different than other sciences, it is the science of the study of certain kinds of objects and their relations, objects with a deep connection to the physical world. The only thing different is the role of empirical experiment (arguably there are also "experiments" in math, e.g. numerical calculations checking examples of a number theory conjecture, but these are "non-empirical" in the sense of not measuring something about the physical world).

Vaguely relevant is this comic, putting the sciences on a scale together…
https://xkcd.com/435/

24. **vmarko**
February 7, 2016

Peter,

You *are* aware of the popup text (when you hover the mouse over the comic) in that particular xkcd, right? 🙂

Best, 🙂
Marko

25. **Peter Woit**
February 7, 2016

vmarko,

Yes. Gell-Mann liked to say that. Until a mathematician explained to him about SU(3)…

26. **Eli Rabett**
February 7, 2016

Your take on mathematics continuing to progress w/o empirical data, of course raises the question of what is progress. Is it finding additional answers to ad hoc puzzles, or finding new understanding through the solution of puzzles?

27. **Peter Woit**
February 8, 2016

Eli Rabett,

Mathematics progresses by discovering new interesting mathematical objects, and better understanding the ones we know about. Solving specific problems (like the Poincare conjecture or Fermat's last theorem) are in some sense just evidence that one has better understood the relevant objects.

28. **Will**
February 8, 2016

I know you're not a fan of Tegmark's multiverse enthusiasm, but your "radical Platonism" sounds something like Tegmark's Level 4 multiverse (the mathematical multiverse). Am I misunderstanding one of you?

29. **Jeffrey M**

February 8, 2016

As a mathematician I would make the argument that math is NOT an empirical science. Even if one is a Platonist, since the Platonic objects are not accessible via anything but math. Now that I'm thinking about it perhaps mathematics is really the multiverse, if it is Platonic. In the Platonic universe of mathematical objects there would have to be contradictory ones, which were internally self consistent. Say, the universe where the continuum hypothesis is true and the one where it isn't. Two different universes, with different rules. Not a problem for us mathematicians, you just have to decide which one you want to live in. Kind of a big problem for physicists, who are supposed to describe the universe we do actually live in 🙂

30. **Peter Woit**
February 8, 2016

Will,
In one sense I'm on-board with Tegmark, identifying the physical world with a mathematical structure. In another sense, our visions are opposite. He sees a multiverse of different physical laws corresponding to the infinity of all possible mathematical constructs (which to me is an empty idea). I see ultimately one specific set of physical laws unifying physics (something not too far from the SM + GR) corresponding to the fact that mathematics is a highly structured subject, with a unifying fundamental set of ideas (which we don't yet completely understand).

31. **Curious Wavefunction**
February 8, 2016

Excellent set of slides. I think your lessons from math on slide 17 could well be applied to other disciplines where models are gradually claiming to replace hard experiments and simulation is becoming an impressive if misleading source of hype and funding.

32. **random reader**
February 9, 2016

[Peter Woit wrote:] "mathematics … continues to progress, despite the use of ever more difficult to absorb formalisms. … Naively one would expect progress to have ground to a halt, as the whole thing became too difficult for humans to master, but this hasn't happened."

I don't think the naive expectations are necessarily so different from what is happening. The training time to get to the frontier and make meaningful contributions is, as expected, getting longer and longer. More and more giant papers appear that very few people understand, and take years for the community to digest.

Total progress has accelerated as the number of PhD's has exploded, but progress per mathematician may be slowing down as higher complexity and diminishing returns set in. This is masked somewhat by the availability of ever more powerful technology and the new growth areas that creates within mathematics. The increases in productivity from LaTeX and email and Skype and github (or similar tools) are one-time jumps so that one expects a slowdown to set in at some point, unless funding is pumped in to increase the number of trained specialists. If there is a salvation through AI coming online that would also be a kind of validation of the Horgan thesis, and would probably only be temporary.

Voevodsky's program of proof formalization is based exactly on the "incomprehensible complexity" thesis and he gives some examples from his own research experience.

33. **random reader**
February 9, 2016

p.s. Peter, I had meant to write a long reply to Brian Conrad at the Mochizuki thread, but did not get there before you closed the comments? Is there any possibility of reopening it? The thread on ABC at Cathy O'Neil's blog is also closed, so no ability to continue there. I guess I can start a blog if necessary but was hoping to answer under the blogpost where Conrad's comments appeared.

34. **Peter Woit**
February 9, 2016

random reader,

It's true that the trend is for mathematics research to get more specialized, with new developments understood by smaller fractions of the community (the number of people who understand the proof of FLT is pretty small). And I'm somewhat mystified how students manage to get to the frontiers of the subject and make a contributions in a finite amount of time (then again, as I get older, the ability of some of the young to quickly absorb difficult ideas never ceases to amaze). But it's undeniable that significant progress keeps happening, of a sort that hep-th isn't seeing. We'll see if this continues, I'm not optimistic that more Ph.D. students or proof formalization are that helpful.

I've changed the parameter that sets the date for closing old comments, so you can still comment on that old posting. One problem with this is that typically no one looks at old comment threads, so an ongoing discussion there is not very likely. I would encourage you in the idea of setting up your own blog and thus having a place you can easily write more extensively. I promise to link to it!

February 9, 2016

Mathematical progress includes the development of ever-improving language for efficiently organizing the mathematics, so that conceptual complexity is reduced in some ways at the same time as overall difficulty and amount of knowledge increases. Scheme theory, derived geometry, homological/homotopical algebra, and perfectoid spaces all are complicated (and interrelated) formalisms with heavy upfront investment for learners, but they systematize and simplify what was done before, allowing the same human cognitive capacity to achieve more in finite time.

Other than that, however, the different impression of progress rates between math and physics (or math and any other field with well understood benchmarks of progress, such as nuclear fusion, AI, space travel, lifespan extension etc) is largely because of a cultural difference in standards of progress. In math one can always formulate and explore new problems that look solvable and define solutions of those as progress. Every once in a while an old and difficult benchmark problem falls to new tools but that's a rarity. Theoretical physics has this to a degree, but a much lesser one because there is a much smaller set of problems considered fundamental. "Have you unified GR and QM yet" (or predicted new particles, or understood dark matter, etc) is a very hard standard to meet.

In math there is also a tendency to accept weak notions of "solve", such as qualitative or nonconstructive existence proofs, or proofs of concept that don't necessarily blossom into a working tool after finding some in-principle solution to a problem. In
physics, particularly experimental physics, it is hard to accept something that claims to be predictive of some particle mass but does not actually lead to a precise number that can be checked against experiment. In math the equivalent is often considered a full solution.

36. **Radioactive**
February 9, 2016

You will be aware I'm sure that Lubos has gone through your slides point by point. Less the hysterics, some of what he says is valid. Have a look at any random day of hep-th and ignore the popular press. The field has moved on quite a bit from the pair of pants diagram and the Randall-Sundrum model.

You have also no doubt heard rumours of gravitational waves detected by LIGO. On the verge of this massive experimental discovery you're announcing that empirical confirmation of new physics models is impossible and we should instead turn to noodling around with group theory and see what happens with the massive web of conjectures comprising the geometric Langlands program. Certainly these things are interesting mathematics but does this honestly seem like a promising direction for physicists? What should physicists do about it? Most are far less mathematically inclined than you and care about predicting the results of real experiments – check any day on hep-ph. What kind of career do you propose for the workaday phenomenologist?

37. **Peter Woit**
February 9, 2016

Radioactive,
I think it should be obvious there's little point to me responding to Lubos's ranting, his agenda is just to misinterpret and misrepresent what I have to say. Obviously the few words that fit on a slide can't convey the actual arguments I'm trying to make (much fuller versions are available of course in many places, for instance my take on the hype problem is http://www.math.columbia.edu/~woit/wordpress/?cat=8, not just the two particular examples in the talk). As I pointed out at the beginning, the intent of the talk was to point to where the actual arguments were, and to be provocative, not make a bunch of carefully worded, fully hedged and defended claims.

There's no argument in my talk that experiment is dead. Obviously whatever experimental avenues are available should be explored, and I've no expertise to advise experimentalists about what they should be doing. The question I was raising was that of, if you're a theorist interested in certain questions, with no experimental help in sight, what can you do? The Munich conference I was referring to was based on the assumption that a significant part of theoretical activity is now "post-empirical". A perfectly defensible attitude towards this is that it's a mistake, that theorists should should stick to thinking about things with some reasonable connection to experiment. A lot of people read my book as making that argument, but that's not really what I think, and the talk was an attempt to explain why. I do think it is possible to make progress by trying to better understand the internal logic and mathematical structure of a theory, even without help from experiment telling one if one is on the right track. And if you try and do this, there's a lot you could learn from mathematicians about how to make progress.

38. **random reader**
February 9, 2016

"see what happens with the massive web of conjectures comprising the geometric Langlands program"

That is not quite accurate. Geometric Langlands is not like some neighboring subjects where there are vast pyramids of conjectures that go far beyond any proven theorems and with no hope for an imminent proof. There is a massive web of both conjectures and theorems, and the weight of the latter is considerable. Lots of the conjectural picture, although still developing, has been proved, and the time span between conjecture and proof has been far shorter for geometric Langlands than classical arithmetic Langlands (because the geometric theory is easier and more structured). The subject is in flux but in a very healthy way where more and more of the expected picture is falling into place, leading to new refinements of that picture, and further cycles of conjecture-proof-application.

39. **Radioactive**
February 10, 2016

Physics unlike mathematics has both logical and experimental tests to pass. Working on mathematical structure is what string theorists do and have done for years. You are advocating a more rigorous mode of working – axiom, conjecture, theorem, proof, consequences – instead of trying to leap over steps as physicists are wont to do. But it seems if people actually followed your approach then we would be more or less in the same place.

If everything was formulated nice and consistently what then? Streater and Wightman's axioms had very little effect on the important developments of the 20th century. Do you think that the mental labour involved in proving rigorous theorems about string theory would stop people from hyping it in the popular press?

40. **Peter Woit**
February 10, 2016

Radioactive,
I'm not advocating that physicists adopt mathematician's standards of rigorous proof, just that, especially when they can't make contact with experiment, they devote more attention to making clear what they understand and what they don't. Sure, leap over steps and see what happens (little known fact: mathematicians do this too), but be aware that you're doing it and make that clear to others. Would this not make any difference? Maybe. But my experience with string theory has been that the extreme difficulty in figuring out exactly where the subject is, what is understood and what isn't, has not only made the public hype problem worse, but makes it difficult to make progress (with the progress needed sometimes just achieving clarity on what doesn't work).

As for QFT, again, I'm not arguing for applying full rigor to what is well understood. An example of what I have in mind is the question of whether the electroweak theory (chiral gauge theory) has a well-defined formulation outside of perturbation theory. Can you even in principle consistently do non-perturbative calculations? This appears to be irrelevant to contact with experiment, and the general assumption is that this is an uninteresting technical issue, but maybe there's something to be learned there. For people to be motivated to work on it though, there has to be some perception that there is a problem there, and some idea of what would count as progress.

41. **Andre**
February 11, 2016

Peter,
Interesting you should mention chiral gauge theories – there is a recent article by D M Grabowska and D B Kaplan
http://arxiv.org/abs/1511.03649
which combines two nice ideas in lattice field theory in a proposal to non-perturbatively regulate chiral gauge theories.

February 14, 2016

“Streater and Wightman’s axioms had very little effect on the important developments of the 20th century.”

Is this attitude fair? Bisognano and Wichmann took those axioms as hypothesis and published their theorem a year before Unruh published his result. Also, the irony of this comment appearing on this blog in particular is, Streater and Wightman published their book more or less motivated by their disappointment with a talk by Geoff Chew.

As to what concerns workaday physicists, sure, e.g. Lawrence’s collider experiment paradigm is about studying effective field theories at different scales of contractable minkowski space. Ultra cold physics cares about field theories on stratified manifolds and non-abelian braid statistics. Many important insights there have genealogies traceable to VFR Jones and to Mandelstam’s (Kadanoff-Ceva inspired?) string localized excitations studied via DHR theory of superselection sectors in the Haag-Kastler axioms (Frohlich credits D.Friedan’s talks as inspiration for his paper on non-abelian statistics- I should mention, BTW, it takes a lot of chutzpah to walk into Greg Moore’s physics department and tell them they need to do more math). Shoot, over and above Jones’ huge influence via Witten, there’s a paper Jones presented at a conference where he asked for something like the Wegner’s self-dual lattice models but with Hopf Algebras from finite non-abelian groups. So along came this guy named Kitaev, and…

It sometimes feels like we say the phrase “contact with experiment” as if there’s some static, God given collection of experiments, faithfully streaming new phenomena at physicists who would then be surely remiss if they didn’t spend all their time, like Beatrice in the Paradisio, staring at this God given stream of Data. I think we say it this way because it’s an honest reflection of a workaday phenomenologist’s experience- new kinds of experiments can sometimes take an entire career to bare fruit. You must publish or perish, and attempts at rigorizing interacting field theories is, notoriously, a graveyard of ideas. Sure, you can listen to the siren song of mathematical physics but only after your men have tied you to the mast. True, an individual who dives off his boat in pursuit of their song will surely perish. But, also, someone eventually realized those were wales and made an industry out of fueling lamps with the stuff. If there were high priests of lay-internet discussion of sirens back then, maybe no one ever would have.

44. **Daniel**
February 17, 2016

Hi, maybe not unrelated to the content of your talk, Smolin in a recent paper (http://arxiv.org/pdf/1512.07551) commented on the role of Mathematics in HEP, and what lesson should we draw from Einstein’s General Relativity.

Stacks Project Party

February 7, 2016
Categories: Uncategorized

Last night I got to attend a major event of the Manhattan social season, a party celebrating the fact that [the Stacks Project]() has [reached the milestone of 5000 pages](). As far as anyone knows, no one has ever printed out the whole thing, but to give an idea of scale, the party featured a large stack of reams of paper totaling about 5000 pages.

I was going to include a party report, describing the various celebrities there, their outfits and conversations, but one of them (Mathematics Without Apologies) has its own blog, so I'll just refer you there.

For some background about this amazing project, from when it was a mere 4000 pages, see here.

Gravitational Wave Predictions

February 10, 2016
Categories: Uncategorized

I think I can confidently predict that tomorrow morning either one of two things will happen:

- The first observation of gravitational waves will be reported by the LIGO experiment.
- A large fraction of the scientific community will be really, really angry at members of the LIGO collaboration.

I'm betting on the first of these two alternatives, and like everyone else will be watching to see what happens tomorrow. If you want some informed commentary on what it all means though, this isn't the place (what I know about gravitational radiation is basically the little that I learned in a GR course about 40 years ago…), so for now I'll leave comments closed.

One place advertising a live feed is Nature. I'll be happy to list better possibilities here if people let me know about them.

Update: Another place to try for the webcast is here.

Update: Big event here at Columbia. Roone Arledge auditorium packed.

Update: Quite amazing, just as predicted, observation of two black holes coalescing, a historic discovery. That stuff I was taught 40 years ago really works. More details many places as the embargo is lifted, with some good examples Natalie Wolchover at Quanta, Dennis Overbye at the New York Times, and Davide Castelvecchi and Alexandra Witze at Nature. The paper has been refereed and is here at PRL.

Update: Better info about the waves is available elsewhere, but I can report here on something pretty amazing: my graduate school roommate's gravitational wave soup bowl.

This Week’s Hype

February 13, 2016
Categories: Multiverse Mania, This Week's Hype

This week’s dramatic announcement of the discovery of gravitational waves was a major milestone for the fields of physics and astrophysics. The LIGO observation validates a lot of previously untested aspects of our understanding of general relativity, and promises the imminent opening up of a new field of observational astronomy, as LIGO sees other astrophysical sources of gravitational waves. Watching the announcement, the lead up to it, and the press stories that came out, many immediately as the embargo was lifted, I was struck by the general high quality of the stories in the press (I linked to a few of them in the last posting, but there are many more). Congratulations to whoever organized this, and to all the science writers who have done a great job producing enthusiastic but generally hype-free coverage of the story.

Unfortunately, those physicists brought in by major news organizations to tell the public what the significance of this is often can’t resist the temptation to indulge in the usual hype. At the Wall Street Journal today, Michio Kaku’s commentary is labeled Riding Gravity Waves to the Big Bang and Beyond, and subtitled “Once again, Einstein’s theory of relativity is confirmed by scientists. Next stop: Creation.”

There’s nothing in his piece about what else LIGO might observe and what we might learn from it about the universe. Instead, it’s all about the big bang, Creation, and before the big bang, things which as far as I can tell, LIGO data is highly unlikely to tell us anything about:

> Now we are witnessing the third great revolution in telescopes, the use of gravity waves to open a new chapter in astronomy. For the first time, waves from the very instant of creation might be observed, giving us “baby pictures” of the universe as it was born. High-school textbooks may have to be rewritten to incorporate the new discoveries coming from this third generation of telescopes.
>
> This may also have philosophical implications. Right now the big-bang theory doesn’t tell us what banged, why it banged, and what caused it to bang. It only tells us that there was a bang. But if space-based gravity-wave detectors similar to LIGO’s detectors can measure the radiation emitted an instant after the big bang, then, using mathematics, one can run the equations backward to determine what set off the big bang in the first place, in effect answering the biggest question of all: What banged and why?
>
> When Einstein postulated gravity waves a century ago, he not only opened up an entirely new chapter in astronomy, he also opened the door to answering the most important philosophical questions of all time, including the creation of the universe.

Over at the New York Times, in the Sunday Review, Lawrence Krauss has a more sensible piece, entitled Finding Beauty in the Darkness. Multiverse mania seems though to be irresistible, as he ends up with this summary of the physics significance:

> Ultimately, by exploring processes near the event horizon, or by observing gravitational waves from the early universe, we may learn more about the beginning of the universe itself, or even the possible existence of other universes.

Comments

1. **Sesh Nadathur**
   February 13, 2016

   To be fair, he does mention “this third generation of telescopes”, which might refer to gravitational wave detectors in general, including those such as (e)LISA and others, which might possibly detect gravitational waves from the early universe. Though these are at best far in the future whereas LIGO is here and now.

   On the topic of good science reporting, I agree that the standard was generally very high, though an amusing failure appears in The Independent:
   http://www.independent.co.uk/news/science/gravitational-waves-discovery-could-let-scientists-build-a-time-machine-to-look-into-the-universe-s-a6867466.html

2. **Peter Woit**
   February 13, 2016

   Seth,
   Thanks, that mainly looks like a headline writer failure. On next generation experiments, the piece does have eLISA launching in 2020, whereas it seems it’s going to be much later than that. This 2014 presentation says 2034

   https://astro.uni-bonn.de/~sambaran/DS2014/Modest14_Talks/Benacquista.pdf

   and it looks like the idea that even this later generation of detectors is going to tell you something about before the big bang (“Creation”) or the multiverse is, well, just hype.

3. **Syksy Räsänen**
   February 13, 2016

   Sesh, referring to any detectors that look for signals from the early universe, or that just probe physics that is relevant for understanding the early universe, as time machines has (sadly) become standard. Both Planck and the LHC have been called time machines. In the former case, this was even done by ESA itself:
   http://www.esa.int/Our_Activities/Space_Science/Planck/ESA_s_time_machine

4. **Peter Shor**
   February 13, 2016

   One thing I haven’t seen any mention of is what this means for the supporters of MOND—Modified Newtonian Dynamics? Do they just give up and admit general relativity is correct, or do they continue supporting their theory?

   (Maybe this is off-topic, but there are certain similarities to one of the main topics of this blog.)

5. **anon**
   February 13, 2016

   eLISA is definitely not launching in 2020. As far as I know, eLISA hasn’t even been selected for launch yet. ESA has chosen gravitational waves as the science theme for the third large-class mission slot (L3), planned for 2034. But unless I’ve missed the news, the precise mission concept has not been decided, so the eventual gravitational wave telescope may not resemble eLISA plans.

6. **Shantanu**
February 13, 2016

Peter, MOND is not a relativistic theory But any relativistic version should behave same as GR in the strong field and should produce tensorial fluctuations like in GR. Right now the signal cannot rule out scalar-tensor theories.

7. **Peter Woit**
February 13, 2016

All,
As I feared with the last posting, there's a large number of people wanting to discuss the significance of this signal for GR and black hole physics. This doesn't work very well with my lack of willingness to moderate such a discussion, given that I know nothing much about the subject, and suspect that half of those wanting to make claims about it know as little as I do. So, unless someone has something more on topic, like an explanation of how LIGO is going to provide evidence for the multiverse, please try and find a better venue, hosted by someone who knows more about this. I'll be very happy to advertise that here.

8. **Tim May**
February 13, 2016

This discovery is refreshing in so many ways.

But the connection to this blog theme, I think, is that _experimental_ physics is again vindicated. Actually _seeing_ the waveforms, without elaborate processing and appeals to 1.5 sigma or 2.1 sigma probabilities, is refreshing. And this is far from the only case–the astronomical discoveries of dark energy (or whatever is causing an accelerating expansion of the universe) and of non-luminous or dark matter (the galaxies passing through each other), and all the results with the CMB….these need no hype by journalists or scientists themselves.

Maybe it's time to slow down on the theories that may be centuries (or more) from any hope of testing. (To be sure, the best mathematicians and theorists will continue to work in many areas–and may even have breakthroughs. But maybe it's time to not have most physics departments dominated by one particular area.)

This is an obvious theme, the costs and timelines for the MeV energy range, up through synchrotrons and linear colliders and rings past the GeV range and up to TeV and beyond. The pickings seem to be getting slimmer despite huge increases in cost. With no "surprises" to suggest new physics. A next generation collider may be the last one for a long, long time. When the next big jump in energy requires GNP-level spending, it just won't get funding.

Sometimes it may just be best to switch efforts to a more fruitful field. As I have been reading, the LIGO and Advanced LIGO cost well under a billion dollars. Money well spent!

And how can "multiverse" hype compete for enticing young minds–or spending by governments– with the now dead certain detection of black holes a billion light years away spiraling in and radiating away massive amounts of energy?

Personally, I think this puts a cork in the hype bottle for a long time.

9. **upstate_cyclist**
February 14, 2016

There was one bit of particle related news buried within the detection paper and one of the supplements. Using a simple Yukawa-correction, they put a bound 90% credible limit on the graviton mass at 1.2 x 10^-22 eV/c^2. This is the best dynamical bound to date but still not as "good" as the some of the others from galaxy clusters & weak lensing. But still, its another experimental bound necessary for a theory of quantum gravity, which I thought was what these folks were trying to sort out in the first place.

And at some point, with enough sources, one is able to do some cosmology with these standard sirens, but how to get there never seems to arrive on the page. Also, space-based detectors are sensitive to super-massive black hole and white dwarf binaries, not the primordial waves (if they even exist) from the Big Bang. It looks like both Krauss and Kaku are in some wishful thinking, i.e. "if only the BICEP2 signal hadn't been dust, then … MULTIVERSE".

They are perfectly welcome to do that on their own time and not muddle an article difficult subject to discuss with the public with their fatuous navel gazing.

10. **Mark Hannam**
February 14, 2016

The prime targets for Advanced LIGO are, as you say, astrophysical sources of gravitational waves, especially binary mergers — they are expected to produce the strongest signals.

LISA isn't due to be launched until after 2030, so there will hopefully be many impressive observations and discoveries long before we get anywhere near observing GWs from the big bang.

I think one of the coolest things about this observation was that it is the closest we have ever come to measuring a signal *from* a black hole.

I wrote about what we saw here,

http://fictionalaether.blogspot.com/2016/02/gravitational-waves.html

and a bit about the experience of the last few months and the final announcement here,

http://fictionalaether.blogspot.com/2016/02/what-it-feels-like-to-detect.html

11. **vmarko**
February 14, 2016

Folks, there seems to be some confusion about which kind of gw-detector would be able to look for CGB (the gravitational analogue of CMB), so just a short note: neither ground-based detectors (such as LIGO or the most advanced idea of ET), nor the space-based detectors (such as LISA or the most advanced idea of BBO) would be able to see anything even remotely in the range of CGB frequencies (and this despite the name of the BBO).

The way we *can* look for CGB signals is using the pulsar timing arrays (IPTA and SKA). Only those types of gw-detectors would be useful to "look at Creation" (pardon the language), or at least somewhat close to it. 🙂

A nice map of what kind of detector can see what can be found here:

http://rhcole.com/apps/GWplotter/

The map is interactive, so you can choose which sources, which detectors and which observable will be plotted. The CGB (aka the "stochastic background") goes from 10^(-7) Hz and downwards. So there is no chance for any Solar-system sized detector to catch this signal, aside from the nature-provided detection with the PTA.

GW community has so far been very good at steering clear from hype, so we should help them keep it clean in the future as well.

Best, 🙂
Marko

12. **HarrisTeter**
February 14, 2016

Hello all,

Starting around 37 minutes into the NSF video here: https://www.youtube.com/watch?v=aEPIwEJmZyE, Kip Thorne states that LIGO will see gravitational waves from cosmic strings–listen to the LIGO video and you will hear: "Giant Strings that reach across the universe. They're thought to have been created by the inflationary expansion of the fundamental strings that are the building blocks of all matter that expanded through inflation at the beginning of the universe."

This probably has a greater influence on the perception and direction of things than Kaku and Krauss.

Also, might anyone know when a second signal might be detected by LIGO? Thanks! 🙂

13. **Anonymous Mathematician**
February 14, 2016

@HarrisTeter:

The rumors are that a second signal has already been detected by LIGO (although nowhere near as strong as the first signal). The press conference said they expected at least a handful each year.

14. **Davide Castelvecchi**
February 15, 2016

Thibault Damour, one of the people who predicted gravitational waves from cosmic strings (in work with Vilenkin), told me that even if such signals are discovered by LIGO/Virgo, we wouldn't know if these strings were generated by the fundamental strings of string theory or some other mechanism.

15. **Peter Woit**
February 15, 2016

Davide,
Hype about this has been going on forever, and I've written several times about it on the blog. For an early example, see

http://www.math.columbia.edu/~woit/wordpress/?p=37

which was about a 2004 press release from UCSB claiming that LIGO would within two years "test" string theory and possibly confirm it, by seeing evidence of cosmic strings.

What's going on here is that there is a long story about one-dimensional configurations in the Higgs fields of certain GUT models, which you might expect to be created in some early universe models. At some point certain string theorists started pointing to some fundamental string theories that also had such solutions and started up a hype campaign about them. As always, the story about string theory "predictions" is that you can get any "prediction" you want out of string theory: no cosmic strings, cosmic GUT strings, fundamental strings that look like cosmic GUT strings, or whatever.

I've been glad to see that the press coverage of the LIGO discovery has generally ignored this nonsense.

16. **John**
February 15, 2016

As an interested "lay person" I was disappointed in many of the headlines and quotes. I read that this was the "Holy Grail of physics" and that the discovery "fundamentally changed our perception of the universe". Hype isn't limited to the multiverse it seems. It's a great achievement in experimentation but it verified not changed our perception of the universe.

I do have what I think is an interesting question. Right now we measure distance using the light from "standard candles". Light is subject to lensing effects but I read that the gravitational waves are not "hindered" in any way. They also based the distance to the 2 black holes strictly on the properties of the gravitational waves.

So do you think that gravitational waves can or will be used to verify distance to far off objects? Or at least be used to verify if the "standard candle" method is accurate?

17. **MM87**
February 15, 2016

On Scientific American we learn that "WIMPs are a prediction of superstring theory."

http://www.scientificamerican.com/article/last-call-will-wimps-show-their-faces-in-the-latest-dark-matter-experiment/?wt.mc=SA_Twitter-Share

18. **Chris W.**
February 15, 2016

John,
Gravitational waves should be subject to lensing effects. For example, see arXiv:1309.5731.

19. **upstate_cyclist**
February 16, 2016

@Peter — While there was a search for string cusps in the previous science run before the upgrade began (http://arxiv.org/abs/1310.2384), I expect that cluster resources are going to be allocated such that a repeat of this effort is very far down the priority list. So at least from the instrumental/search side of things, the best bet is continued silence.

Though if primordial B-modes truly recede into the background, one may see another flare-up of interest in this source as theorists grasp for old-new straws as aLIGO reaches design sensitivity and new machines come online.

20. **Davide Castelvecchi**
February 16, 2016

I'm guessing that anything that travels along geodesics should be subject to lensing effects. What's more surprising to me is that the positive cosmological constant might produce dispersion (with no need for gravitons to be massive) and thus chromatic aberrations in the gravitational waves — in other words different wavelengths refracting at different angles. This is apparently one consequence of the work by Ashtekar's team
http://arxiv.org/abs/1510.04990

21. **Ethan**
February 16, 2016

Peter,

Isn't the LIGO result at least some sort of refutation of the Munich symposium on the necessity of experimentation to validate scientific theories? String theory might not have been able to come up with falsifiable experiments of its own, but the detection of gravitational waves one hundred years after being predicted shows that what Richard Feynman said about what science is remains true: https://www.youtube.com/watch?v=EYPapE-3FRw , namely, it doesn't matter how beautiful a theory is or how smart is the guy who proposed it. Unless you can correctly predict outcomes in falsifiable experiments, your theory is not scientific.

22. **Navneeth**
February 16, 2016

For what it's work, Rainer Weiss though the NYT article was bad. 🙂
https://www.youtube.com/watch?v=8_brgtd-zY4
(Don't remember the exact moment he said that.)

23. **Daniele V**
February 16, 2016

Personally, what I find really upsetting is the sentence "High-school textbooks may have to be rewritten": new discoveries in science add chapters to textbooks, do not throw away anything (of well-established theories, of course). Classical mechanics has continued to be normally taught in schools and universities after Relativity and Quantum revolutions, nobody uses Einstein's Equations to make an airplane fly. It may seem just a fussy detail, but in this way people are driven to think that scientific knowledge is not trustworthy at all, because "today scientists assert something, next century the opposite" (heard from a friend of mine) as it were a matter of pure opinions.

P.S.: it's my first post here, I thank the blog master for his hospitality and his interesting blog.

24. **Peter Woit**
February 16, 2016

Ethan,
I don't think the gravitational wave result has much to do with the problems of string theory, or of that part of theoretical physics in general which suffers from not having any prospect of getting relevant data. It's a wonderful example of the canonical scientific method in action, but doesn't change the problems that have led people down roads divorced from experiment (and I need to keep pointing out that there's not anything necessarily wrong with that, the question is how you go about it).

Daniele V.,
Thanks! I think you're right that that's a problem. Possibly what people writing something like that have in mind is something more sensible (that the LIGO experiment will make in into the textbooks as a confirmation of GR, beginning of new kind of astronomy), can't quite help themselves from embracing the trope of a "revolution" overturning the old.

25. **Shantanu**
February 17, 2016

Peter Shor: Let me add something to your MOND question. Eight years ago we proposed that if the relativistic MOND theories are correct then the galactic Shapiro delay of GWs should be much smaller than that of photons/neutrinos (see arxiv:0804.3804). So one acid test
would be comparison of relative arrival time between GWs and photons/neutrinos.
If the Fermi GBM detection at 0.5 seconds is confirmed to be due to this GW signal, then such theories are dead.
Another way is to look for vector modes of GWs. This was suggested by Eva Sagi (See
arxiv:1001.1555) and references therein. As mentioned in the LIGO tests of GR paper, right now they cannot rule out extra polarization states. of course these are just one class of relativistic MOND theories. If MOND is due to modified inertia or something, then at its still an open question.

26. **Venp**
February 18, 2016

Most impressive discovery based on a single event since Omega-minus some 50 years ago.

27. **Shantanu**
February 20, 2016

Peter: something else about this result directly connected to particle physics.
if the Fermi GBM signal seen 0.4 second after the LIGO event is confirmed to be due to
this GW signal, then brane world models are ruled out (as they predict GWs arrive much earlier.) See Fig 1 of
http://arxiv.org/pdf/gr-qc/0105114.pdf

28. **Nathalie**
February 21, 2016

On LISA:

It is sad to see how LISA has been treated up to now, both by NASA and ESA. Much work was done on the project already in 1990s, see for example
http://pubman.mpdl.mpg.de/pubman/item/escidoc:52079/component/escidoc:52080/schutz_60668.pdf
and now I see that the plan is to launch it in 2034. I know that many scientists have devoted their scientific lives to it. Can someone tell me what has been going on?

29. **bnewsbd**

30. **Michael R. Sabino**
March 26, 2016

Yes, I think you're right that LIGO isn't the appropriate experiment to detect gravitatational relic radiation. There are several experiments looking at higher, more thermal frequencies for that. Some of them use tiny resonant masses, others like the holography detector at Fermilab use lasers.

Yet More About Grothendieck

February 16, 2016
Categories: Uncategorized

Since Grothendieck's death somewhat more than a year ago, quite a lot of new material about him and his mathematics has become available. Visit the Grothendieck Circle to find a lot of this, with just one example some new chapters of the English translation of the third volume of Scharlau's biography.

This month's AMS Notices has the first of two parts of a long article with contributions from many mathematicians discussing Grothendieck's work and their memories of him and his influence on their careers. Colin McLarty has an excellent expository article, maybe the best of attempts I've seen to explain some of the themes of Grothendieck's mathematics in a relatively accessible manner.

While you're there, this latest issue of the Notices has quite a bit else worth reading, from my colleague Ivan Corwin on KPZ universality to Beilinson on Gelfand's seminar, and an amusing attempt by Jeremy Gray to guess not the next Fields medalist, but who would have gotten one in 1866.

Various and Sundry

February 23, 2016
Categories: Uncategorized

- The online magazine Smashpipe has the first part of a two-part article written by Gerald Alper, who recently came up here to Columbia to talk to me about string theory/etc. It was an interesting conversation, so I'm curious to see what he makes of the more substantive part, which is in part two, planned for next week.
- If instead you'd like to read about a conversation with my colleague Brian Greene, there's a piece at Cosmos Magazine. Brian is taking his World Science Festival to Australia next month and will be on tour there.
- In other Columbia news, LHC experimentalist Emlyn Hughes has evidently baffled the students in Frontiers of Science again. Three years ago he undressed for the students, this year the performance somehow involved a student mistress (see here and here). No, I don't understand any of this either.
- As a last Columbia story, this semester in the physics department Bill Zajc is teaching a string theory course for undergraduates, Physics W4012, based on the Zwiebach book. While Zajc isn't a string theorist, he is a frequent commenter at Lubos Motl's blog.
- There's a new issue out of Inference, which has some interesting articles, including an essay by Pierre Schapira on category theory (French version here). Also there's Jean-Pierre Luminet on holography.

  Inference is a bit of a mystery, unclear who is editing it (some speculation here). Whoever it is though, it's quite worth paying attention to.

- The HEP Postdoc Project is collecting anonymously information aimed at helping potential postdocs (or even Ph.D students) find out more about what it's like to work with various senior HEP theorists. No, like Inference, I have no idea who is behind this.

Comments

1. **Harald**
   February 23, 2016

   Inference, oh my? Whoever Michael Fumento is, he does support my theory that no journalist ever will get the difference between watts and watt-hours right.

2. **jsm**
   February 23, 2016

   There are some interesting articles in Inference (but did they have the authors' permissions to publish?).

   However, a supposedly scientific article (Fumento, The Nuclear Reaction) that quotes the Cato Institute in its first paragraph arouses deep suspicions among those of us who regard the Cato Institute as a far-right propaganda mill.

3. **Scott Church**
   February 23, 2016

   Peter,

   Michael Fumento, who also contributed to this issue, is a long-time Far-Right PR hack. He's been a key player in the anti-global warming propaganda machine for nearly 20 years as well as other under-the-table antienvironmental lobbying. At one time or another he's been affiliated with the Cato Institute, the Hudson Institute, the Competitive Enterprise Institute, and a number of other industry-funded astroturf fronts. A quick overview of his background is available at ExxonSecrets, and Tim Lambert has been tracking his antics for some time now at Deltoid. I'm not advocating poisoning the well here, but from long experience I can tell you that any forum he's associated with isn't likely to be a good source of science.

4. **Peter Woit**
   February 23, 2016

   jsm/Scott Church,
   The question of who is editing Inference is still a mystery to me. I linked to Michael Harris's speculation about David Berlinski as the only serious guess I've seen, and I wouldn't be surprised if he and/or people connected to him had something to do with it. This doesn't change the fact that whoever is behind this has gotten some intelligent people to write some interesting things worth reading.

   For a very small number of publications, based on long experience I trust the editors completely and start reading the articles they edited assuming I'm reading something reliable. For most though, if I don't know about the author I don't start out assuming reliability. About 30 seconds of googling "Michael Fumento" gave some indication of where he's coming from, and it wouldn't occur to me to expect an even-handed treatment of his subject.

   My own main scientific interests (mathematics and theoretical physics) mercifully are topics that don't line up ideologically in any of the conventional left-right ways. So I find that I can get something out of articles on these topics written by people whose political and cultural views I strongly disagree with, while at the same time finding appalling some articles by people I'm otherwise on the same side with (e.g., the multiverse…).

   I appreciate the point people make about Fumento, but, all, it wasn't an article that seemed worth paying attention to. Please help me out by keeping the usual left-right fights out of this comment section. I'm generally a partisan of the left, but that doesn't mean that I have any interest in reading more of my side's take on the usual hot button issues, and I suspect I'm not the only one.

5. **srp**
   February 23, 2016

   Mr. Alper's first part seems a tad self-indulgent, but I'm hoping part 2 gets out of his head a bit more.

6. **crazy_horse**
   February 24, 2016

   I suspect Waddingtons are behind the HEP Post-doc Project – it's obviously a ruse to collect data for a new Top Trump cards game about famous physicists..

   I play Susskind, Degree of expertise in general physics 10

7. **adrian**
February 25, 2016

Dear Peter,
the las intention of this comment-post is to be aggressive or offensive. Please, read it with that in mind.

Periodically, you write an article "This week hype" where, in my opinion, you correctly criticise some online or newspaper article/TV show, etc. I believe it is a healthy exercise to alert people that an exaggeration, deformation of truth, misrepresentation of reality, etc, is being made.

I read the first part of the article by Mr. Alper in the website "Smashpipe". While I found charming the fascination he has with academia and its environment, you will probably agree with me that phrases like

–'all semblance of ordinariness falls away and you quickly realize you are in the presence of a remarkable mind'

–'he is putting the finishing touches on a major textbook'

— ' the famous theoretical physicist who had written the controversial, radical book, Not Even Wrong: The Failure of String Theory and the Search for Unity in Physical Law.'

–'only a little bit louder than the click heard around the world on February 11, 2016, signaling the detection and verification for the first time in history of of Einstein's prediction of gravitational waves'

[this last one, is just imprecision with poetic license]

–'Top flight mathematicians, I can see, think twice as fast as the ordinary person'

–'He seems to be concentrating fiercely, in a private self-space into which only he can slip at will and where no one is allowed. It's the place where lonely geniuses like Gary Kasparov […] '

[these last two, poetic ways of describing you]

Perhaps you will agree that these are also forms of 'hype'.
As I mentioned, I find the article 'endearing' (I am professional physicist and know the environment, Columbia, etc), but you can imagine the impact this may have on a young person.

So, may be you could also criticise that article for its 'hype' content. Also for being (this part one) contentless for a blog like yours—that characteristically contains interesting links and information. You wrote a line about that. I await for part II.

The article about Brian Greene's visit to Australia is also misrepresenting his place among his theoretical Physics peers. One may understand, these are journalist licenses. But let me insist, they can play badly on the young person, who could believe, is in presence of a *great* scientist.

thanks

8. **a l**
February 25, 2016

Inferences publishes high quality work and obviously there is money behind it. The Editors offer a mix of popular science with (right wing) political views and one understands why they prefer to remain anonymous. Just for fun one can check some authors and look what pops up, e.g.:
Henri Lepage, Mont Pelerin society
William Kininmonth, climat sceptic,
Michael Denton, anti-Darwinist

9. **Peter Woit**
February 25, 2016

adrian,

My concern about "hype" has always been about misrepresentation of scientific ideas, trying to convince the public that ideas that don't work are actually successful science. The world is full of other kinds of hype that are more harmless and that people themselves should be able to easily recognize, not needing my help to point out. Most profiles of people in magazines make them out to be more accomplished, more significant and more interesting than they really are, and I don't think I should need to explain that to people. The young will sooner or later figure this out for themselves…

10. **Jeffrey M**
February 25, 2016

I will point out, for those who aren't mathematicians, that in the math community there is quite a lot of argument about category theory. Interesting obviously, anything Grothendieck worked on is bound to be interesting, but there are issues. One of my professors in grad school, who was a student of Eilenberg's at Columbia when Eilenberg was busy developing category theory, used to call it "general abstract nonsense." And he liked it and used it all the time. I swear every proof for an entire year of topology was "the diagram commutes."

11. **Radioactive**
February 25, 2016

Peter, if you read back your last comment and don't see the slightest bit of irony I don't know what to do for you.

12. **Peter Woit**
February 25, 2016

Radioactive,
Well, no more irony in that comment than in most of mine, so I guess I'm beyond help. I do try my best to stick to criticizing (hype about) ideas rather than people, can't think of an example of my writing about an article and criticizing it along the lines of "this says X is so great, but he's not". That people, young or old, might believe incorrect claims about science made in usually reputable information sources seems to me to make challenging such claims worth the effort. Not so with claims about personalities…

13. **adrian**
February 25, 2016

Dear Peter,
your answer to my comment and that of the reader 'radioactive' is satisfactory in my opinion. Indeed, I do notice that when you entitle "This week's hype" you mostly discuss a mis-represented idea, experiment, or a misrepresentation of its consequences.

I agree with you, the hype is to be criticised. The public must be correctly informed. Many times, it is not the fault of the scientist, but of the journalist (or in most cases, the journalist's editor).

There is one point I wish to comment with you—not sharply related to the one we discussed above, but that is "around that".

The public should also know, or be explained, informed and appreciate the fact that technical issues about science are to be decided by the practising scientists, in the usual forum. Let me take an example, close to your heart: the validity of the theory of strings (or a subset of it) as a physical description of reality. This technical issue is NOT going to be decided in a blog. Neither yours, not Motl's nor anyone else's. It will certainly NOT be decided in a newspaper's hardcopy or online article, by some enthusiastic or critic journalist.
It will be decided in the arXiv, the regular seminars, the conferences.
I mention this, because in various popular presentations I gave recently, I noticed how people—specially young people–confuse 'science' with 'what they read in the blogs'.

This is (I think/hope it is clear!) not an accusation in any form. But a suggestions, that, from time to time, it would be good if you can prevent your readers, specially those who are not professional physicists, that some of the topics discussed are NOT "free debate" and that the people who work on those things are not idiots awaiting their illuminating comments. In this sense, I find Strassler's blog, the one that best delivers this idea (and others related).

I do appreciate the role of the blogs. The discussion is nice, sometimes it is interesting.
Some issues can be talked about and your blog, specially, is in some cases an important source of links and information.

But please, consider this comment. I started to feel, since some years ago, this influence of the blogs on lay people. Most worryingly, in young people. On the one hand, it is good as people are interested, on the other hand, it is making them confuse what the thing is actually about.

thanks

14. **Peter Woit**
February 25, 2016

adrian,
I just don't see the problem. Before there were blogs, non-scientists got their information about string theory from magazine articles and popular books, which generally were full of misleading, over-enthusiastic claims about string theory (often put forward not by journalists, but by scientists themselves). To do something about this I wrote a book, and some fraction of the entries on this blog. For people who know nothing about the subject, all this does is tell them that there is a disagreement about the issue. For those who know more about the subject, they can read both sides, think for themselves, follow links and learn more, and see if they can make their minds up about who has the better arguments.

I think what's really bothering you (and bothers Matt Strassler, and a lot of people who are not happy with my blogging), is that some of the arguments made on my blog discredit conventional sources of authority in the subject. My response is that unfortunately this is a very unusual situation in which certain such authorities are, because of human unwillingness to admit failure, making a serious mistake. Their behavior threatens to discredit their own subject, which is one I care about. The worst of this is the string theory multiverse, which is a way to avoid admitting failure, at the cost of abandoning conventional standards of what is science and what isn't. The whole point of this abandonment is to ensure that the issue of failure cannot be adjudicated in the usual ways, by careful argument in the scientific literature. There is no way to show that the string theory multiverse is "wrong" (it's "not even wrong"…).

For those unhappy about this situation, I think the proper thing to do is to take your complaints to the people who have led the subject into this mess, not complain that I'm pointing to the problem.

15. **Erik**
February 26, 2016

I looked around a bit on the HEP Postdoc Project website. I am not a high energy physicist, but I think it is an interesting project. Unfortunately, it struck me that there are already a few hateful/insensitive/harsh 'reviews' on there. How hard can it be to give an honest review of somebody's teaching/supervising skills without bashing them completely? Somehow I had hoped that physicists would prove to be better than the general audience, which also has a tendency to do this.

16. **Ned**
February 26, 2016

Dear Mr. Woit,

sorry for butting in – just in regard to your 7:44 pm comment to adrian I wanted to say as a grateful longtime reader of your blog that I've never yet read such a succint and concise statement about the point you're coming from.
If you ever should put up something like a FAQ or a "mission statement", these 2 paragraphs maybe would have a place there.

17. **Scott Church**
February 26, 2016

Peter, I second Ned's comment. Great summary of the service you're providing to the physics and lay communities here. 🙂

18. **Yatima**
March 5, 2016

[Attempt to carry on a tedious left/right argument deleted. Please don't do this. No sensible person wants to read such a thing.]

Anyway, I finally got around to reading Pierre Schapira's article on Category Theory, which references this nice Scientific American blogpost about computer-assisted theorem proving which I would like to point out:

[Voevodsky's Mathematical Revolution]

We red:

The same week as the Heidelberg Laureate Forum was a conference in Barcelona on univalent foundations, which Voevodsky skipped in order to be with us. A special issue of a journal (perhaps Automated Reasoning — Voevodsky couldn't quite remember) will come out of the conference, with papers written by the participants. Almost all of them will be submitted together with the formalized proof in Coq. That's most likely the first time such a thing has ever happened.

Some of those computer verifications rely on a library of verified proofs that Voevodsky himself has created, so Voevodsky decided to submit his library to ArXiv. He imagined a one-page description of what the library is, along with all of his Coq files. It turns out, however, that ArXiv isn't yet up to the task — while it can accept attached files, they can't have any directory structure. Voevodsky plans on pestering the folks who run ArXiv until they make it possible.

Said blogpost references a no-longer existent lecture video, which however can be found on YouTube:

Vladimir Voevodsky: Univalent Foundations: New Foundations of Mathematics

Beyond Experiment: Why the scientific method may be old hat

February 27, 2016
Categories: Multiverse Mania

This week's New Scientist has an article by Jim Baggott and Daniel Cossins entitled Beyond Experiment: Why the scientific method may be old hat, which deals with the recent controversy over attempts to excuse the failure of string theory by invoking the multiverse. The article (unfortunately behind a paywall) does a good job of describing the nature of the controversy: what do you do when it becomes clear your theory can't be tested? Do you follow the conventional scientific norms, give up on it and work on something else, or do you try and find some kind of excuse, even if it means abandoning those norms?

Much of the article deals with the issues raised at the recent Munich conference (discussed here). Two of those quoted (Dawid and Gross) are not multiverse partisans, instead argue that the motivations that got people interested in string unification more than 30 years ago are good enough to justify indefinitely pursuing the theory, no matter how bad things look for prospects of connection to experiment. On the other hand:

> Their enthusiasm is far from universal, and some physicists are downright alarmed. Woit warns that the need for empirical vindication could be pushed so far into the background as to be invisible. Carlo Rovelli, a theorist at the University of Aix-Marseille in France, believes that this scenario has already come to pass. Rovelli … argues that the last thing we need is a system that legitimises failed theories. "A theory is interesting when it teaches us something new about the real world," he says. "Not when it becomes a house of cards that delivers nothing but university positions."

On the question of the string theory multiverse as science, those gathered at the Munich conference were pretty uniformly hostile. As a proponent of this, the article quotes only one person, who wasn't there:

> Sean Carroll, a theorist at the Caltech Institute of Technology at Pasadena and a leading advocate of the multiverse, insists that if anyone is being unscientific, it is those physicists who seek to enforce outmoded philosophical principles and impossibly high standards. "People support these theories because they offer the best chance of providing a useful account of the data we actually do collect here in our universe."

I'm not sure how the string theory multiverse provides an account of data we have collected that is "useful", except in the sense of "useful to those who don't want to give up on string theory."

Carroll has explained his views in more detail here, arguing that falsifiability is an idea that needs to be retired, to be replaced by "empiricism". "Empiricism" seems to mean "ability to account for the data", with "the multiverse did it" an acceptable way to account for data, even if not falsifiable. He'll be giving a talk on this at the American Astronomical Society meeting in San Diego this summer, with abstract:

> A number of theories in contemporary physics and cosmology place an emphasis on features that are hard, and arguably impossible, to test. These include the cosmological multiverse as well as some approaches to quantum gravity. Worries have been raised that these models attempt to sidestep the purportedly crucial principle of falsifiability. Proponents of these theories sometimes suggest that we are seeing a new approach to science, while opponents fear that we are abandoning science altogether. I will argue that in fact these theories are straightforwardly scientific and can be evaluated in absolutely conventional ways, based on empiricism, abduction (inference to the best explanation), and Bayesian reasoning. The integrity of science remains intact.

Carroll's argument seems to be that the conventional understanding of how science works that we teach students and use to explain the power of science has always been wrong. Falsifiability by experiment isn't necessary, instead, what is the "absolutely conventional" way to do science is "empiricism, abduction (inference to the best explanation), and Bayesian reasoning". I'd never heard of abduction as a basis of science before. If you believe Wikipedia, this goes back to Charles Sanders Peirce, whose view in later years was:

> Abduction is guessing. It is "very little hampered" by rules of logic. Even a well-prepared mind's individual guesses are more frequently wrong than right. But the success of our guesses far exceeds that of random luck and seems born of attunement to nature by instinct (some speak of intuition in such contexts).

As for "Bayesian reasoning", I would have thought that Polchinski's Bayesian calculation of an "94% chance" of a multiverse would have conclusively shown the absurdity of that.

Comments

1. **Carl**
   February 27, 2016

   The fundamental problem with trying to apply Bayesian reasoning to the multiverse is that it requires you to presume a multiverse to begin with. If there's only actually one universe, it's meaningless to talk probabilistically about the properties of that universe.

2. **Jon Awbrey**
   February 27, 2016

   (sp) Peirce

3. **Jon Awbrey**
   February 27, 2016

   Peirce is simply describing the process by which we seize on an initial hypothesis or model. That will in practice be constrained by all sorts of previous experiences with the phenomenon in question but in principle our choice can be very wild indeed, revealed in a dream or stepping off a bus or whatever it may be. The only real test of the hypothesis or model comes by way of the deductive consequences that follow from it and the inductive confirmations or falsifications that follow those. The word *abduction* is a clumsy translation of Aristotle's *apagoge* from Prior Analytics 2.25.

4. **Felipe Pait**
   February 27, 2016

   What exactly would one be able to learn about the real world using a theory that cannot make predictions that are falsifiable?

5. **Peter Woit**
   February 27, 2016

   Jon Awbrey,

Thanks, fixed.

6. **Peter Woit**
February 27, 2016

Felipe Pait,

By Carroll's notion of science, I think he can claim to be learning about the real world, but I don't think he can answer the question "How will you know if you are wrong?" Empiricism, abduction, Bayesian reasoning, etc. will get you to a model that seems to you to describe the real world, but how will you know if you're mistaken? It is this ability of experiment to shoot down a model that you are fond of that seems to me to be the most distinctive part of science, and I don't see that anywhere in Carroll's conception.

7. **john lowery**
February 27, 2016

Because Darwin wasn't there when his Evolution occurred– he used abduction (inference to the best explanation) to formulate his theories.

8. **Jon Awbrey**
February 27, 2016

There has always been a lot of misunderstanding about the requirement of falsifiability. At root it is simply the idea that an empirical law is not a logical tautology. I don't see any reason to dispense with that just yet. In practice the principle affords us leverage only when we have two or more competing theories for the same domain.

9. **Harry Dale Huffman**
February 27, 2016

When you have to change the definition of "science" (decades into your research, especially), it means you are no longer a good, honest scientist. Period. (It's much the same as changing the data to fit the theory.) Throw those criminals out of science.

10. **Bayes_or_bust**
February 27, 2016

I don't think it's fair to judge Bayesianism by Polchinski's text, which was indeed absurd.

I think you're right, though, to be wary of scientists invoking Bayes as a get out of jail free card for their ideas. Bayesianism provides a strict framework for updating degrees of belief in light of data by a so-called Bayesian evidence. Polchinski did not use that framework – he just pulled numbers from thin air.

It seems that many wish to claim their arguments are Bayesian or that their theories are supported by Bayes, but actual calculations seem beneath them. If they don't make the calculations showing their theories to be more plausible than alternatives, they shouldn't be allowed any refuge under the cover of Bayes.

11. **Peter Morgan**
February 27, 2016

A tangential note that Carlo Rovelli has just become the editor of Foundations of Physics, http://www.springer.com/physics/journal/10701, replacing Gerard 't Hooft. It will be interesting to see how the journal changes.

12. **Jon Awbrey**
February 27, 2016

Another thing that needs to be understood is that Bayes reasoning or anything that involves probabilities has anything to do with the initial abduction, which takes us from a state of unquantifiable uncertainty to the first hypothesis of a model category or reference class. It is only after these choices are made that speaking of probabilities becomes possible.

13. **Jon Awbrey**
February 27, 2016

Correction: has nothing to do with

14. **Nick M.**
February 27, 2016

Peter,

I think you meant to quote "Polchinski's Bayesain calculation" as a "94% chance" of a multiverse; just makes it sound all the more absurd.

15. **Peter Woit**
February 27, 2016

Nick M.,
Thanks, fixed.

16. **Jon Awbrey**
February 28, 2016

I probably shouldn't judge a talk by its abstract, but the more I read Carroll's the more Wikipedisch it sounds. The phrase "inference to the best explanation" was coined by Gilbert Harman in his attempt to explain abductive inference but it conveys the wrong impression if anyone takes it as a substitute for the whole course of inquiry rather than just its starting point. Peirce himself was always very clear about this.

17. **M**
February 28, 2016

150 years ago the dominant theory was that particles are vortices in the aether. What a pity that the scientific method forced us to replace this empirically superior understanding with quantum mechanics and relativity.

18. **sm**
    February 28, 2016

    Carl:

    "The fundamental problem with trying to apply Bayesian reasoning to the multiverse is that it requires you to presume a multiverse to begin with"

    No. It only requires a non-zero 'probability' for a multiverse to begin the algorithm, and it can be as small as you like (e.g., 10^{-100} but make sure you are using double double precision in your computer program!). Here 'probability' is a number between 0 and 1 representing your subjective 'belief' in the multiverse (calling it a probability just because it takes values between 0 and 1 is a mistake because it muddles subjective belief with frequentist probability). Bayesian analysis tells us we can have confidence in the existence of a multiverse if the flow of all relevant information into the Bayes algorithm has driven this 'probability' sufficiently close to 1 that everybody agrees there is a multiverse (0.94 is clearly no where near close enough for readers of this blog!). If someone still rejects the multiverse they should state just how close to 1 they need for 'belief' and if the belief reaches that value at some point in the future then accept the multiverse. On the other hand if the belief is driven sufficiently close to 0 then the multiverse hypothesis can be rejected in the same spirit. Or they can reject the whole idea of Bayesian analysis (which by the way is at the root of a major part of modern technology nowadays).

19. **vmarko**
    February 28, 2016

    Sm,

    I would begin the algorithm with exactly zero initial probability for the multiverse, since it reflects my belief that there is no multiverse to begin with. So how do you continue the calculation from there? Is there any hard data regarding the multiverse that can move the zero prior even to 0.5, let alone 0.94? I don't think so.

    🙂
    Marko

20. **a l**
    February 28, 2016

    Falsificationism came to replace verificationism as it became obvious that general statements, e.g. "all electrons in the universe are identical", are not really verifiable. Thus the burden of proof is shifted: it is the opponents/deniers who have to provide evidence. And evidence can be disputed, e.g. do muons disprove the general statement or are they something else?

    The existence of a multiverse is obviously not a general statement but an existential one: its supporters are supposed to provide evidence and not just beliefs.

    We can see Science devolving: originally it was 'How the world is'; that became 'How do we know it' and next 'Why do we believe it'. The Bayesian argument ultimately reduces knowledge to the best one among of our beliefs – which is no more than to say 'Just now we are unable to imagine something better'.

21. **Bayes_or_bust**
    February 28, 2016

    a 1, that's right: Bayes tells you to believe the most plausable theory you can find and provides a recipe for evaluating the plausibility of a theory. What more do you want? Do you want Bayes' theorem to invent new hypotheses for you or prove no-go theorems that preclude viable hypotheses?

    I really think you're all barking up the wrong tree by criticising Bayes itself. I'd advise scrutinising the Bayesian multiverse arguments – do they actually calculate anything? Can you express their arguments as equations in terms of probabilities? – so far the arguments strike me as being rather specious and not calculations within the framework of BCT.

    In other words, accept the use of Bayes, and ask does Bayes actually give support to eg the multiverse? My feeling is that there are difficulties, to say the least. I'd like to see what eg Caroll has actually calculed when he says these things.

22. **sm**
    February 28, 2016

    vmarko:

    'I would begin the algorithm with exactly zero initial probability for the multiverse,'

    Not only an incorrect application of the algorithm, but also a pretty religious and dogmatic position you adopt, if I may say so!

    Wouldn't a more scientific approach be to take a small prior (not really necessary though) and watch the information flow in the fullness of time drive that prior to zero, thus confirming your initial belief, if in fact that happens? Also, I wonder what would have happened to a large fraction of the Atlas/CMS higgs analyses had they taken a zero prior for the existence of the Higgs!?

    Perhaps a more thoughtful criticism would be that the multiverse proponents have not (yet?) focused on a definite method for calculating the likelihoods. Unless I am mistaken, this is the point Peter is always making.

23. **Jon Awbrey**
    February 28, 2016

    I think that is correct. Bayes' theorem is a deductive identity that adds no information to the situation, nor is that its job. It does not add rows or columns to the contingency matrix or make the observations that populate its cells. Those are jobs for the independent capacities of abductive and inductive reasoning.

24. **Peter Shor**
    February 28, 2016

    If you have enough evidence for your hypothesis, Bayesian reasoning and ordinary statistics will give the same results.

    So applying logic, this means that the only time you need to use Bayesian reasoning is when you don't have enough evidence for your hypothesis. It seems to me that this statement also has quite a bit of empirical evidence supporting it.

25. **Anonyrat**
    February 28, 2016

The problem is not just with the tiny but non-zero subjective belief in the multiverse. Any feature of the world that occurs only in only some branches of the multiverse does not drive the subjective probability of the multiverse any higher, because of the very large number of branches of the multiverse. Features of the world (say, Lorentz invariance) that are true for almost all branches of the multiverse (e.g., in string theory) do increase the Bayesian subjective belief of a multiverse; but also make the multiverse scientifically unnecessary.

26. **vmarko**
February 28, 2016

Sm,

I choose the zero prior because the multiverse idea isn't testable experimentally, by definition. It's like with religion, an atheist chooses zero prior for the existence of God not because he wants to apply Bayesian analysis to God, but because Bayesian analysis isn't applicable (no new data can ever be provided for or against the existence of God, by definition).

In contrast, things like the Higgs hypothesis, the GW hypothesis and low-energy SUSY hypothesis are all highly testable, and the new data (respectively observed, observed, not observed) can change the prior using Bayesian analysis.

The point is that new *data* can change the prior, while new *beliefs* cannot. If we were to use beliefs as data-points, the existence of God would be very supported by Bayesian analysis. Ditto for the multiverse. So one needs to be careful to apply Bayes only to testable hypotheses.

🙂
Marko

27. **steven johnson**
February 28, 2016

Karl Popper knew something about falsificationism. And he knew that by its standards Darwin wasn't a scientist and natural selection etc. wasn't science. Somebody managed at last to cobble up some minor experiments, or maybe hypothetical experiments, so that he finally agreed to retract this rather embarrassing conclusion.

As an historical science, evolutionary biology isn't very big on the properly falsificationist experiments. It tends to be big news when someone actually conducts a controlled experiment in evolution. In historical sciences like evolutionary biology, geology and cosmology, experiments tend to make assumptions about how laboratory experiments demonstrate physical principles at work. Of course, this evades the problem of induction: How do we know that an experiment on the behavior of perovskite in a lab really provides a valid generalization? Here too falsificationism condemns the historical sciences as unscientific. (Popper wanted to condemn all history as unscientific because he disliked Marxism, being an extreme right winger, one of the founders of the notorious Mont Pelerin Society.)

On the other hand, it is routine to find perfectly good falsificationist experiments in the works of such scientists as J.B. Rhine and Michel Gauquelin. Their tradition lives on in whole fields, like parapsychology and evolutionary psychology.

So, I'm sorry but until it's possible to clarify some of the peculiarities in the notion of "falsification" as exemplified in its great champion, the assumption that it's enough to cry "Unfalsifiable!" isn't quite acceptable to everyone. It really does seem to me the shoe is on the other foot. After all, by falsificationist perspectives, how can the widespread use of models be justified? When is adjusting a parameter pursuing a failed theory?

As I understood it, abduction is probabilistic reasoning. Since it seems that learning how things really are (which is what science seems to be so far as I can tell,) instead of proving a logically necessary a priori by deduction, that doesn't seem to be a bad thing.

When I understand Bayesian reasoning (as opposed to Bayes' theorem,) I'll decide what I think about that.

28. **Ben**
February 28, 2016

sm, I think you must not have read Polchinski's argument (which is in arXiv:1512.02477). He calls it "quasi-Bayesian", but the actual argument is "I'll start with a 1/2 prior probability, and multiply it by 1/2 for each of these three reasons to believe in a multiverse".

If you actually wanted to use "Bayesian" techniques to figure out the odds of a multiverse, I suppose you'd start with

$P(M|E) : P(\neg M|E) = P(E|M)\, P(M) : P(E|\neg M)\, P(\neg M)$

where M is "there's a multiverse" and E is the evidence and : is a ratio representing relative odds. He takes $P(M) = P(\neg M) = 1/2$ as his prior. I guess his three reasons to believe in a multiverse with a 1/2 probability assigned to each means he wants $P(E|\neg M) = 1/8$. If you take $P(E|M) = 1$, the odds for a multiverse are 8:1 ≈ 89%. Other values of $P(E|M)$ give lower odds.

Setting aside that Polchinski did the math wrong and showed no sign of understanding what Bayesianism even is, the main problem is that $P(E|\neg M)$ is made up out of nowhere. It's similar to what happens with the Drake equation, where the argument boils down to "it's clearly true that $a/z = (a/b)(b/c)\ldots(x/y)(y/z)$, and we know some of those factors accurately, and others approximately, and the rest not at all so I'll make up some values, and plugging in all of that we get that a/z is high (or low depending on my preconceptions), and you can trust it because it came out of this self-evidently correct equation, and I totally didn't tweak my guesses until I got the answer I wanted".

There's obviously a well-defined sense in which the Bayes equation is correct. When people disagree with what you get out of it, they're disagreeing with what you put into it.

vmarko, a prior of 0 in Bayesian terms means you're impervious to any evidence whatsoever, even the end of the world happening exactly as prophesied in Revelation. sm is right to make fun of you for that.

29. **ID**
February 28, 2016

re: Sean Carroll, is there a reason to prefer multiverse to intelligent design? can Bayesian reasoning provide a probability for ID?

30. **Peter Woit**
February 28, 2016

steven johnson,
"the assumption that it's enough to cry "Unfalsifiable!" isn't quite acceptable to everyone"

This is a straw man argument. No one, Popper included, claims that falsifiability is all there is to this issue. I've written extensively about this, including a chapter in my book, and endless discussions here.

About bringing evolution into this, do you really want to go there? Carroll's argument that the string theory multiverse is "straightforwardly scientific and can be evaluated in absolutely conventional ways" is in danger of being interpreted as a claim that untestable multiverse theories are of the same nature as the testable theory of evolution (some other string theorists have explicitly made this argument). The ID people love this…

31. **srp**
February 28, 2016

Economists have grappled some with the applicability of formal probabilistic decision theory (especially Bayesian expected utility maximization) to different types of questions. A distinction often cited by anti-mathematization advocates is one Frank Knight made between "risk" (where probabilities can be reliably assigned to relevant events) and "uncertainty" (where they cannot). The usual Bayesian riposte is that a probability distribution of probabilities still yields a probability distribution.

More fundamentally, along the lines of what I think Jon Awbrey is getting at, Ken Binmore pointed out that even the leading developer of subjective expected utility theory, Leonard Savage, in 1951 made a distinction between "small world" questions where it made sense to assign probabilities to events and "large world" questions where it did not. The multiverse question seems to me to be the largest large-world question possible.

32. **Justin**
February 28, 2016

I think some people don't realize just how destructive the multiverse enterprise is. In my case, it literally turns me away from physics. I feel depressed that the greatest joy in my life has become a complete joke.

33. **Jon Awbrey**
February 28, 2016

I have no horse in this race (cat in this box?) as far as multiverses and polycosmoi go — I will limit myself to clearing up popular confusions about Peirce's concept of abductive reasoning. Analytic philosophy swayed many people into thinking that science could be reduced to purely deductive reasoning, eliminating induction and ignoring abduction, but Peirce was a practicing scientist who worked outside that warp. In his model of the inquiry process abduction is at root logically prior to any discussion of probabilities, however true it may be that all three modes of inference work in tandem to advance any moderately complex investigation. There's more information on the history and function of abductive inference in the following article:

• Functional Logic : Inquiry and Analogy

See especially:
• Section 1.2. Types of Reasoning in C.S. Peirce
• Section 1.4. Aristotle's "Apagogy" : Abductive Reasoning as Problem Reduction

34. **vmarko**
February 28, 2016

Ben,

I am fully aware what a zero prior means, I picked it up deliberately. But I guess the point I was trying to make didn't really get accross. I assign zero prior to the existence of multiverse, of unicorns, of the Loch Ness monster, and of UFO implants in people's necks. The reason why I do that is because none of these are any part of testable and falsifiable science, so whether one believes in those is a matter of personal choice, and only priors of 0 and 1 make sense. That is, one either believes in this (uncritically) or one does not (also uncritically). Either way, it is not a subject of Bayesian analysis.

Some people are trying to spin the multiverse idea as something scientific, or at least motivated by well-established science. This is misleading – what string theorists study is a conjecture on top of a generalization on top of a conjecture on top of an extrapolation on top of a generalization of existing established well-tested theories of physics. And when this whole edifice of theoretical construction falls short of their initial expectations (i.e. the landscape problem), they invent yet another layer of extrapolation which provides a catch-all panacea-like answer to any remaining unanswered question: "multiverse did it". And when I refuse to assign a nonzero prior to that, people think that I don't know what a zero prior means…

🙂
Marko

35. **David Nataf**
February 29, 2016

Justin,

It's not sensible for the multiverse research to turn you away from physics. The vast majority of physics research out there has nothing to do with the multiverse.

36. **Peter Woit**
February 29, 2016

All,
I'm deleting further attempts to debate vmarko's point, which are going nowhere.

37. **Butters**
February 29, 2016

You are doing a disservice by convincing gullible people that confirmatory experiments are the only way to make progress in science.

38. **Peter Woit**
February 29, 2016

Butters,
Another straw man argument that I've never made.

39. **Ali**
February 29, 2016

Peirce is spinning in his grave regarding Carroll's conflation of Peirce's notion of abduction and Bayesian inference. Peirce spent much of his life fighting the "inverse probabilists". His collected writings still represent the most compelling, systematic, and sustained arguments against Bayesianism. His critiques (made over decades) also happen to be among the earliest criticisms of inverse probability (along with his contemporary Venn, but Peirce's views were even more systematic).

40. **Veríssimo**
February 29, 2016

How is abduction any different from belief bias ou confirmation bias?

41. **Scott Church**
February 29, 2016

I think the issue here is what constitutes "proof". The idea behind abduction, or "inference to the best explanation", is problematic only if we think of it in these terms rather than likelihoods. Given two or more inconclusive theories offered as explanations of some body of evidence, testable or not, we cannot claim to have *proven* any of them via abduction or Bayes reasoning. But we can use such reasoning to claim that one or more of them are more likely to be true given what we know of the world so far. And the more evidence we gather that favors one over the others, the more reason we have to be confident in it. If the body of evidence becomes so large that all but a handful of cranks would favor another alternative, then perhaps we could start calling it fact, but not before. In any event we shouldn't be calling it science until it's at least testable in principle.

The key is to treat abduction as a measure of *confidence* rather than proof, and Bayes reasoning formalizes this approach well. Problems only arise when we try to apply it numerically to situations where the background and probability spaces involved (particularly the probability of the evidence obtaining if the hypothesis isn't true) are ambiguous and difficult or impossible to quantify. But even if we can't meaningfully apply numbers, we might still be able to frame a general argument in Bayesian terms. For instance, I don't see how one could calculate the probability that NASA faked the moon landings on a sound stage at Norton Air Force Base in San Bernadino, but I doubt anyone would dispute that the likelihood of the evidence given the background alone is small enough to merit rejecting that theory.

In the case of the multiverse, the issue isn't Bayesian methods per se. It's the fact that in the absence of a rigorously understood mechanism for actually producing one it's all but impossible to pin down the sample space involved, or even to define a meaningful probabilistic measure when we can only observe our universe. The same is true with the string landscape. With Bayesian analysis everything depends on how one defines the *reference classes* and how they're discriminated from the background. The biggest problem with Carroll's "empiricist" approach is that within a Bayesian framework, he wants to treat theoretical "elegance", or "beauty" as *evidence* that infers to the best explanation. Stunningly gorgeous (in his opinion) would passes for proven fact. On this logic, "my wife is hotter than yours!" would pass for "science". Really…? Even if he were married to Miss July, and I to a roller derby queen who lost a head-butting contest with an East African rhino, how exactly does one formally demonstrate such a claim? History is strewn with the wreckage of heart-achingly beautiful theories that ran afoul of the real world, and as Edmund Burke once said, those who are ignorant of the past are doomed to repeat it.

42. **Jon Awbrey**
February 29, 2016

Let me just say again that abduction is not "inference to the best explanation" (ITBE). That gloss derives from a later attempt to rationalize Peirce's idea and it has led to a whole literature of misconception. Abduction is more like "inference to *any* explanation" (ITAE) — or maybe following Kant's phrase, "conceiving a concept that reduces the manifold to a unity". The most difficult part of its labor is delivering a term, very often new or unnoticed, that can serve as a middle term in grasping the structure of an object domain.

43. **Ignatz Ratzkywatzky**
February 29, 2016

Justin says:
February 28, 2016 at 9:47 pm

"I think some people don't realize just how destructive the multiverse enterprise is. In my case, it literally turns me away from physics. I feel depressed that the greatest joy in my life has become a complete joke."

How odd.

Aside from the tiny part of physics phase space that are the completely speculative parts of astrophysics and HEP, the rest of physics has never been healthier.

No lack of interesting questions to work on in condensed matter, optics, soft matter, biophysics, experimental astrophysics, etc. all of which still adhere to the only way to do science – the scientific method.

I'd leave theses "angels on a pin" arguments to others and find a more productive and rewarding way to spend my life.

44. **Scott Church**
February 29, 2016

Jon Awbrey,

Perhaps "inference to the best explanation" wasn't what Peirce had in mind, but for better or worse that seems to be how the term "abduction" is most commonly used today. The Wikipedia page on Abductive Reasoning even defines it as such. In any event, I'm not particularly attached to that label so if it isn't the best one feel free to toss it. 🙂 My only intent was to draw the distinction between *confidence* and *proof* in how we adjudicate between theories and what passes for science.

45. **David Levitt**
February 29, 2016

Justin: "I think some people don't realize just how destructive the multiverse enterprise is. In my case, it literally turns me away from physics. I feel depressed that the greatest joy in my life has become a complete joke."

For me, a 73 year old professional scientist that still remembers my fascination reading about physics and physicists in Scientific American 60 years ago, it is more of an "Emperor has no clothes" moment. I now realize that theoretical physicists are no smarter, honest or perceptive than many of the scientists in my own much more pedestrian field.

46. **Bernhard**

February 29, 2016

Sorry if this has been discussed already. Is Carroll still advocating Weinberg's "prediction" of the cosmological constant as a pro-argument to the multiverse? I forgot about this argument but now reading it again it's pretty clear to me I have no idea what this argument has to do with multiverse. I get the environmental argument, but that's it. Specifically:

"If the universe we see around us is the only one there is, the vacuum energy is a unique constant of nature, and we are faced with the problem of explaining it. If, on the other hand, we live in a multiverse, the vacuum energy could be completely different in different regions, and an explanation suggests itself immediately: in regions where the vacuum energy is much larger, conditions are inhospitable to the existence of life. There is therefore a selection effect, and we should predict a small value of the vacuum energy. Indeed, using this precise reasoning, Steven Weinberg did predict the value of the vacuum energy, long before the acceleration of the universe was discovered."

The argument that a small cosmological constant means necessarily a multiverse beats me…

47. **Unifier**
February 29, 2016

Bernard,

The reason can be found in this talk given by Nima Arkani-Hamed,
entitled "Why is There a Macroscopic Universe?"

https://www.youtube.com/watch?v=F2Fxt_yCrcc

Peter,

In that same talk, Arkani-Hamed said that people who are quick to
dismiss the multiverse as a possible solution to the CC problem have
never actually worked on the problem. What do you think about this?

48. **Peter Woit**
February 29, 2016

Unifier,
I don't dismiss the multiverse as a possible solution to the CC problem. Maybe that's the way the world is. The problem is that "the multiverse did it" is a scientifically empty argument. The worst part of what is going on here is that this kind of empty argument is being made in order to justify refusal to admit failure.

But, ignoring that, what I mean when I say it's empty is this: the string theory landscape does not allow you to calculate a real probability distribution of CCs, so what people do is choose a flat probability distribution over the anthropically allowed range, and then congratulate themselves that the observed CC is not probabilistically extremely unlikely (although how unlikely it is depends on all sorts of assumptions). I agree with Arkani-Hamed that there's no good idea about what sets the CC, so I propose the Peter Woit CC theory, which is "I have no frigging idea why the CC is one thing rather than the other". What are the observational predictions of the Peter Woit CC theory? Well, since there's no reason for the CC to be one thing or another, my observational prediction is that it will be in the anthropic range (this is a tautology), with a flat probability distribution. Funny, but this is exactly the same prediction that you get from the string theory landscape. Now do you see why I say "the multiverse did it" explanation of the CC is empty of conventional scientific content?

49. **Shantanu**
March 1, 2016

Peter , OT. But from a recent preprint by ellis, it seems Lev Okun is no more. RIP.

50. **Mike Sharples**
March 1, 2016

In the rarefied atmosphere of Theoretical Physics I suspect that the elite 2% sometime forget that when Bayesian statistics or arguments on the principle of falsification are invoked, then this is an area where many can meet them on completely equal terms.

There is no intellectual argument that is so esoteric that it can transcend the more prosaic principles that these simple concepts demand.

So when an argument looks circular to the "ordinary guy" there is a pretty good chance that it is. You have to be able to justify yourself in ordinary terms. If you cannot then it is certain that your arguments are too weak, not too complex.

51. **Jr**
March 2, 2016

"Carroll's argument seems to be that the conventional understanding of how science works that we teach students and use to explain the power of science has always been wrong. "

Well, I think that philosophers would argue that conventional descriptions of science taught to students in science courses vastly oversimplify how science works, or should work. A lot of science is not really about trying to falsify theories.

52. **Peter Woit**
March 2, 2016

Jr,
I don't recall as a student being taught any rigid notion of what was science and what wasn't, other than the importance of being able to find out if your were wrong by doing an experiment. This is what Carroll is now campaigning against, and the goal is to have multiverse pseudo-science written into the textbooks. Do you really think that teaching students about the multiverse and explaining to them that this is "absolutely conventional" science is a good idea?

53. **Jr**
March 3, 2016

No, I do not think teaching the multiverse theory seems like a good idea and it does strike me as seriously misguided. But independently of that, it may be a good idea to make the textbooks at little more nuanced on the topic of falsification. I do not want to go into to much discussion on the point since anything I could say has been said much better by philosophers already.

54. **Jon Awbrey**
March 4, 2016

Re: Scott Church

Names are not important of course, except for the purpose of communication. The important thing is for us to distinguish hypothesis formation from hypothesis evaluation. Now, there happens to be a long tradition of using the word *abduction* to distinguish that former, most incipient stage of inquiry and I think it serves communication to preserve that tradition.

Concepts, hypotheses, and theories have to be formed, logically speaking, before they can be evaluated. In complex inquiries extending over long periods of time, formation, evaluation, and re-formation will of course proceed in cascades of parallel and series operations, but the analytic distinction between elements and mixtures is still worth its salt.

The role of ab-, de-, in-duction in the cycle of inquiry is discussed a bit further in the following article:

☞ [InterSciWiki • Inquiry]

55. **Masood-ul-Alam**
March 7, 2016

Your mention of "Bayesian reasoning" in reference to Polchinski's Bayesian calculation of an "94% chance" is worrisome.
There are books on gravitational waves or astrostatistics that include discussions on the so-called Bayesian and frequentist "viewpoints." It is one thing to say which "mathematical formula" is applicable in which
situation. It is another thing to discuss philosophical issues which generate potential source of esoteric matter and confusion in physics teaching. It think it will be a great service to science and students of science if authorities sit together and set the meaning of the phrase "Bayesian" in gravitational physics and drop it if it is unnecessary.

56. **LM**
March 7, 2016

Would "testable prediction" be the same as "falsifiable"? I think next to everybody can agree that a theory with no testable predictions is pure speculation. Now, what would be the distance between testability and falsifiability?

57. **Peter Woit**
March 7, 2016

LM,
I don't think the issue of how you test a scientific idea can be summarized in any one word, whether its "testable" or "falsifiable". This is a complex question, and you have to look at exactly what is being claimed as a "test".

The relevance of falsifiability is that there's obviously something suspicious about a "test" that you can't fail. But also obviously, that can be meaningless. String theorists are known to claim string theory is falsifiable because it is based on quantum mechanics and quantum mechanics is falsifiable, but claiming "my theory is falsifiable, because it says that "absurd thing X won't happen" is obviously problematic. Any time spent thinking about this leads to the conclusion that this is a complicated issue, with bogus "tests" easy to come up with, meaningful ones not hard to recognize as such. My claim is just that string theory is not capable of giving a meaningful one, and to evaluate that claim you need to look at what supposed string theory "tests" are.

58. **LM**
March 7, 2016

I agree that the distinction doesn't answer all questions but the point is that no one would argue that to be science a theory must be tested. So it's a matter of test. There has to be a definite and defined test, it has to be reproduceable, and yield definite results. It has to be new – in the sense that a new theory cannot be based exclusively on previous tests (it wouldn't add any new knowledge – if I'm not mistaken, the Occam's razor). And as long as theory aims to describe real world the test has to be empirical i.e based on observable reality. So wouldn't these discussions better served defining testability – the notion that may indeed be evolved and extended with time?

59. **Peter Woit**
March 7, 2016

LM,
The problem is that of defining what a good "test" is. You've given some criteria, but they don't address the relevant problems that come up. For instance: some physicists like to claim that their multiverse theory is testable, because it is conceivable within their framework that certain distinctive patterns would appear in the CMB. So, there's a test: does this pattern appear or not in the CMB? If it did, that would definitely be evidence for their theory. The problem with non-falsifiable tests appears though: if the pattern doesn't appear, that isn't evidence against their theory. If you look into their theory, you see that it's so poorly defined that it says nothing at all about the likelihood of such patterns appearing. There's obviously a problem here with claiming "my theory is testable", when there is no possibility of failure. This is the main issue with "tests" of string theory or the multiverse.

60. **LM**
March 7, 2016

Peter, I understand your concerns but maybe we are living in a different world today? For example, the Net is full of stuff of all kinds from obvious garbage to brilliant ideas and insights. It's all there, nobody can possibly falsify it all because new stuff just comes out faster than any capacity for policing.
Where's the answer? How do we deal with it? With openness and collective memory (e.g. rating). As long as test is clearly declared, and it fits the clear and precise scientific criteria a theory must declare its results, openly for everybody to see and make their own judgement. A theory with a hundred unconfirmed tests (and these need to be new tests, specific to purported new knowledge) would still have a rating of zero, and no talks and speculation could change that for anybody with a capacity for rational judgement. Could it be enough – I don't know just thinking of some way forward. And for already mentioned reason, I wouldn't even call an idea, concept, hypothesis a "theory" until it comes up with a set of tests that fit the criteria of science.

61. **Scott Church**
March 7, 2016

Few people would dispute that science needs to be testable in the sense of accounting for observation. That's not the problem here. The real question is… *to what degree* do they do so? It's not enough to come up with a model that explains things (what Sean Carroll and others have dubbed the new "Empiricism"), nor is it enough for it to be "elegant" or "beautiful"… the "my wife is hotter than yours" approach. To be testable in any sense that matters scientifically a theory must account for observation *specifically,* and *uniquely*.

General relativity predicted the bending of starlight in the gravitational field of the sun, and the perihelion precession of Mercury. These predictions were scientific because they were specific enough to be tested practically to great accuracy, but more importantly, because they were consequences of GR alone. Newtonian physics did not predict either, and could only account for them with ad-hoc contrivances ripe for Occam's razor. It is true that for a while Mercury's perihelion precession could be explained by the gravitation of an unseen planet called "Vulcan", but once the solar system had been mapped thoroughly that explanation went away. There's also the fact that the solar system actually *could* be mapped accurately enough to rule out the Vulcan hypothesis.

String theory and the multiverse are only "testable" in the weak sense of being able to loosely (*very* loosely) account for observation… the way the Vulcan hypothesis once did. What makes them unscientific is that their "predictions" are neither specific enough, nor unique enough to render them potentially favorable over their competitors by any foreseeable test. The ability to hit a barn at 5 paces with a sawed-off shotgun does not make one a marksman, nor does it earn one a sharpshooter medal if a hundred other folks can do the same thing blindfolded.

Who’s Winning the String Wars and Why Should You Care?

March 1, 2016
Categories: Uncategorized

Part two of Gerald Alper’s piece at Smashpipe is now available there, with the title Who’s Winning the String Wars and Why Should You Care?, and some more substantive material than in part one. One of the great things about having a blog is that whenever anyone writes anything about you that you think might not be 100% correct, you can blog about it, and explain yourself ad nauseam. So, here are a few clarifications for readers of that article:

- About the “horrible sentence”

> The Hilbert space of the Wess-Zumino-Witten model is a representation not only of the Kac-Moody group, but the group of conformal ~~representations~~ as well.

I don’t think it’s a bad sentence, it succinctly conveys the main point about the close relationship of the WZW QFT to representation theory. Like a certain number of things in the book though, it’s not intended for everyone. There were certain things I wanted to explain, and the way I went about this was to try to as clearly write them down as possible, in a way accessible to as many people as possible, but well aware that not everyone would understand everything. Unlike writing “the WZW model is related to mathematics like X is to Y”, where X and Y are things most people would recognize, you’re not going to get fooled into believing you understand something you don’t by what I was writing. Those who do understand the sentence will understand a real idea.

- I AM VERY CONFIDENT that I AM RIGHT. No one has ever critiqued string theory with the level of detail that I have.

Not sure exactly how I said this, but I suspect the “no one has ever” wasn’t intended to convey that this was a good thing. I’ve clearly spent too much of my life thinking about this. I also should specify that what I’m confident about is that current “string vacua” models don’t correspond to reality. They’re complicated, ugly, and don’t explain anything. My suspicion is that even Witten might not completely disagree with this, acknowledging that at our current understanding of string theory, there is no convincing model. I think a more accurate way of characterizing where Witten and I disagree here is with how promising it is to pursue this particular vision of unification. I am not at all confident that Witten or someone else pursuing it might not come up with something really new and successful some day. I just think it’s a relatively unpromising route to keep heading down, although I acknowledge it’s possible it might lead to finding a more interesting path. Doubtless Witten feels the same way about things I find more promising.

Comments

1. **Bee**
   March 1, 2016

   I’ve summed up Witten’s thoughts here. 😉

2. **Peter Woit**
   March 1, 2016

   Thanks Bee,
   That’s really wonderful, hadn’t seen it.

   And congratulations on ten years of Backreaction, as well as its new sponsor!

3. **paddy**
   March 1, 2016

   Peter,
   There’s your problem. You lack Ms. Hossenfelders rhythm. And thank you for the link.

4. **paddy**
   March 1, 2016

   Peter,
   Sorry for two posts. After reading the Alber’s article it is my opinion you come off quite well. No need for caveats.

5. **Low Math, Meekly Interacting**
   March 1, 2016

   I hold you blameless, but I hated that “interview”. I learned ten times more about the interviewer than his subject, most of which was irritating. I learned precious little else about science or other scientists, beyond the obsequiousness their high IQs induce in Mr. Alper. Allegedly there were three-plus hours of fascinating conversation. I wish the fascinating parts had actually made it into print.

6. **MC**
   March 2, 2016

   Is there a part three? Because I see no interview in part two.

7. **jim**
   March 2, 2016

   Personally, I read your blog at least partly because you write clearly and honestly.

8. **Chris Oakley**
   March 2, 2016

   I second LMMI’s comment above.

   In regard to the “horrible sentence”, I think the point is just that Not Even Wrong (the book) is not really written for a general audience. It is more a book for people like me who already have a D.Phil. (or Ph.D.) in Elementary Particle Physics. I loved it, but admit that, not knowing anything about the WSW model, I cannot claim to have found the “horrible sentence” much more comprehensible than Alper or Holt did.

Which reminds me: you need to update the non-paywall link to the Robert Matthews review of your book to this: http://www.cgoakley.org/qft/RM%20Strings%20FT.html

9. **Low Math, Meekly Interacting**
March 2, 2016

I’m also mystified by the critiques of your writing (both your own and others’) in this piece. OK, not a lot of flowery prose, but I tend to like it when authors resist the urge to sacrifice clarity and directness to show off their facility with adjectives and metaphors. Better still if they apparently lack the urge altogether. The visual presentation of the blog very much reflects the content, and I think that’s great: uncluttered, efficient, clear. Nothing remotely wrong with that. Nothing “rough-hewn” about it, either. Not being showy or self-indulgent doesn’t make one unrefined, for heavens sakes. It’s just different, and far too rare in online content, IMO.

10. **Bernhard**
March 2, 2016

LMMI,

I second your last comment very much. Peter, many of us that come here like your clear argumentation and sober conscious between what you know and what you do not. Don’t ever change it! 🙂

There is also another thing that’s irritating in this interview which is a an obvious reverence to authority. The whole part on “Witten is the greatest string theorist who ever lived” makes that clear, just to give an example.

Very little content in this interview and too pompous to my own taste.

11. **KJ**
March 2, 2016

The interview and this discussion of it nicely illustrate the difference between a mathematician/scientist and a journalist. When the former communicates, the primary goal is the efficient transfer of meaningful information. To the latter, the story and how it is told take precedence. It is no surprise that most readers of this blog prefer the former.

12. **Chris W.**
March 2, 2016

I was going to say some things about Alper’s style, but others have already expressed my reactions well. I also heartily endorse LMMI’s comments and the follow-ups on them.

13. **Scott Church**
March 2, 2016

I’m currently reading Lee Smolin’s book *The Trouble With Physics* and enjoying it very much. Regarding references to authority (e.g. “Witten is the greatest string theorist who ever lived…”) he tells a story about a talk Alain Connes gave at a symposium in Chicago in 1996. A little ways into the talk a prominent unnamed string theorist got up and left. A couple years later Connes gave the talk again at the Rutherford Laboratory and the same guy was there, but this time he sat through the whole thing with rapt attention and praised it later in his own talk. Shortly thereafter Connes ended up sitting next to him on a bus. He asked him point-blank… “How can it be that you attended the same talk in Chicago and you left before the end, and now you really liked it?” The guy’s answer was… “Witten was seen reading your book in the library at Princeton…!”

According to Smolin, this sort of thing is not uncommon and he had many similar anecdotes. As an outsider I’m in no position to comment–certainly not as well as Peter and many others here. But if he’s right, the string theory community is on the verge of becoming a mega-church with Witten and one or two others as it’s high priests. To be fair, Smolin also said that this sort of thing is staring to change and he’s starting to see string theorists willing to admit that their field is “in crisis”. But even so, this strikes me as beyond troubling.

14. **Peter Woit**
March 2, 2016

Scott Church,
That story about Witten is well-known, but a couple comments

1. There are far worse reasons for getting interested in something than finding out that Witten was interested. Paying some attention to what the best people find interesting isn’t a bad idea at all.

2. Things have changed quite a lot, and it has been a long time since Witten’s enthusiasm for something has had much of an effect. The fact that Witten was working on geometric Langlands for quite a while didn’t seem to cause many physicists to get interested. Arguably these days physicists aren’t paying enough attention to his enthusiasms…

15. **Jeffrey M**
March 2, 2016

Scott and Peter,

Well, first, I think Peter is right, it’s a good idea to pay attention to what the best people in your field are interested in. That said, I’ve never had a satisfactory explanation of why physicists are so enthralled with Witten. He’s clearly a brilliant mathematician, there’s a reason he won the Fields. My orals in grad school were to present a paper of his which was published in JDG. I spent several weeks trying desperately to understand it, finally went to one of my committee members, who pointed me to a book by John Roe which was essentially the paper, explained in much more detail. Beautiful beautiful stuff. But I’ve never figured out what physics result, confirmed by experiment, is Witten’s. He can’t be loved so much just for string theory? I think he was a postdoc at Princeton when I was there in the late 70’s, what was he doing then? I remember people talking about him (I was in physics back then, ended up in math after I transferred to Hampshire).

16. **Scott Church**
March 2, 2016

Thanks Peter… that’s good news! Smolin did make a point of emphasizing what a great physicist Witten is and how much he’s brought to the field (as though anyone would question that). I guess what worried me was that this wasn’t the only such anecdote he told, and the overall picture he paints is one of the string community treating

Witten's interests not as a matter of expertise, but as authoritative… Witten is interested, so it must be *true*. If that's changed somewhat since the book came out (2007), wonderful! We're not going to get very far if we start treating scientists as authorities rather than experts. 🙂

17. **Peter Woit**
March 2, 2016

Jeffrey M,
Witten came to Princeton in 1980 (he had been a grad student there mid-70s). His reputation in physics isn't really built on string theory: he was by far the most respected figure in the field in 1984, before string theory hit (his decision to take it up was influential for that reason). My popular book has a chapter where I try to explain what he was doing pre-string theory, why it was important both as math and physics.

Witten really was just born too late. Basically there have been no Nobel prizes for theoretical developments post his grad student days, so you can't hold it against him that he doesn't have one.

18. **Jeff M**
March 2, 2016

Peter

I wasn't holding against him the lack of a Nobel prize. We math types disdain the Nobel 🙂 I just never had anyone talk about what he did in physics. Anyway, as I said, he's certainly a brilliant mathematician, or he was. Funny I thought he was at Princeton when I was there, maybe I remember people talking about him from when he was a grad student and how great he was. By 1980 I was at Hampshire…

19. **curious**
March 2, 2016

My suspicion is that even Witten might not completely disagree with this, acknowledging that at our current understanding of string theory, there is no convincing model. I think a more accurate way of characterizing where Witten and I disagree here is with how promising it is to pursue this particular vision of unification. I am not at all confident that Witten or someone else pursuing it might not come up with something really new and successful some day. I just think it's a relatively unpromising route to keep heading down, although I acknowledge it's possible it might lead to finding a more interesting path. Doubtless Witten feels the same way about things I find more promising.
^

So uh have you ever spoken to Ed Witten about this?

20. **Peter Woit**
March 2, 2016

curious,

No. But I think there's a reason he doesn't these days work on "string phenomenology" models. If he thought there was a convincing model, I think he would be working on that.

21. **Justin**
March 2, 2016

"Doubtless Witten feels the same way about things I find more promising."

By this you mean he "does" or "does not" feel that these other things are promising?

22. **Luca Signorelli**
March 3, 2016

Peter,
I'm no scientists, but a former professional journalist and editor of a major magazine in Italy. And this interview is dreadful. Unprofessional, badly written, confused and tedious. As others have noted, the author is so enamored of himself he forgets he was supposed to write about you. A hack job if I've ever seen one, which I've wouldn't ever allowed to print had I've been the editor. Sad (albeit hardly your fault)

23. **Thomas Larsson**
March 3, 2016

Actually, I think the sentence is a bit horrible, but for a different reason and because I have struggled a lot to formulate sentences like that myself. I would say that the Hilbert space carries a representation, or that the representation acts on the Hilbert space, or that the Hilbert space is a module for the Kac-Moody group, thinking of a representation as matrices and of a module as the vector space on which they act.

24. **Peter Woit**
March 3, 2016

Justin,
My guess is that he doesn't find promising things that I do, again, with the best evidence that he doesn't work on them.

25. **Urs Schreiber**
March 3, 2016

Or he thinks he has done the math-phys that was his job to do, setting up the right theory, and others are to work out the phenomenology.

In the recent words on Gordon Kane,

at 21:23 in https://videoonline.edu.lmu.de/en/node/7485 and referring to Acharya-Witten, Witten-Atiya and Witten's work on [M-theory on G2-manifolds](#):

> Witten sort of took the attitude: well, the whole thing is set up, we are done, this is the right answer. He went off and did mathematics after that. But this is where we began.

26. **Peter Woit**
March 3, 2016

Urs,
In the same talk Gross took the unusual step of intervening and pointing out that almost no one in the theory community believes Kane's claims about using this to make predictions. I strongly suspect Witten would agree with him.

Witten's Ph.D. thesis was on phenomenology and he's written many papers over the years on phenomenology, not mathematics. I see no reason to believe that he believes in the kinds of claims Kane is making, but just doesn't want to work on any of that himself, preferring to stick to things like Khovanov homology.

27. **John Baez**
March 7, 2016

"The Hilbert space of the Wess-Zumino-Witten model is a representation not only of the Kac-Moody group, but the group of conformal representations as well."

This sentence would be less horrible if it said "group of conformal transformations". That, at least, is a thing!

I see that in your book you indeed said "transformations", not "representations". Whew!

So where did the typo first creep in? I see it's in Alper's *description* of Holt's complaint.

28. **Peter Woit**
March 7, 2016

Thanks for pointing that out John!

I'm a bit disturbed that I read that and repeated it on the blog without noticing the problem…

Checking, it looks like the typo is Alper's. I realize that I wrote about it here
http://www.math.columbia.edu/~woit/wordpress/?p=464
and way back then the typo wasn't there.

29. **lucy m**
March 8, 2016

I read because I see a man with integrity and a cause I believe in. The fact he's stuck to it, all these years through good times and bad. It was never going to win friends or boost his career, much nearer the reverse than that. I just feel so damn rare in our time. Also he virtually never publishes my comments and Groucho Marx yes sir!

30. **Daniel Kagan**
March 23, 2016

Wow is this interview bad. Why does the author spend so much time talking about a review of Peter's book, rather than the book itself? This article illustrates the differences between bad journalism and good journalism, rather than the difference between scientists and journalists.

Michael Atiyah's Imaginative State of Mind

March 3, 2016
Categories: Uncategorized

Quanta magazine has an intriguing article by Siobhan Roberts out about Michael Atiyah, and what he's up to these days. It mentions some new ideas about twistor theory I hadn't heard about, that emerged from a conversation with Penrose, which Penrose wrote up as Palatial twistor theory and the twistor googly problem. Penrose explains the name:

> The majestic ambiance of the unusual location (Buckingham Palace) of a brief discussion with Atiyah, no doubt provided inspiration for the initial thought that non-commutative twistor algebra should be the key to those subsequent developments described in this paper.

The Quanta article explains:

> One day in the spring of 2013, for instance, as he sat in the Queen's Gallery at Buckingham Palace awaiting the annual Order of Merit luncheon with Elizabeth II, Sir Michael made a match for his lifelong friend and colleague, Sir Roger Penrose, the great mathematical physicist.
>
> Penrose had been trying to develop his "twistor" theory, a path toward quantum gravity that's been in the works for nearly 50 years. "I had a way of doing it which meant going out to infinity," Penrose said, "and trying to solve a problem out there, and then coming back again." He thought there must be a simpler way. And right then and there Atiyah put his finger on it, suggesting Penrose make use of a type of "noncommutative algebra."
>
> "I thought, 'Oh, my God,'" Penrose said. "Because I knew there was this noncommutative algebra which had been sitting there all this time in twistor theory. But I hadn't thought of using it in this particular way. Some people might have just said, 'That won't work.' But Michael could immediately see that there was a way in which you could make it work, and exactly the right thing to do." Given the venue where Atiyah made the suggestion, Penrose dubbed his improved idea "palatial twistor theory."

The article links to this recent talk about the role of beauty in mathematics, and describes some very speculative ideas he's been working on, which I guess correspond to for instance this paper.

About this kind of work he has this to say:

> If you try to direct science, you only get people going in the direction you told them to go. All of science comes from people noticing interesting side paths. You've got to have a very flexible approach to exploration and allow different people to try different things. Which is difficult, because unless you jump on the bandwagon, you don't get a job.
>
> Worrying about your future, you have to stay in line. That's the worst thing about modern science. Fortunately, when you get to my age, you don't need to bother about that. I can say what I like.

When asked if he's risking his reputation this way, he has this sensible response:

> My reputation is established as a mathematician. If I make a mess of it now, people will say, "All right, he was a good mathematician, but at the end of his life he lost his marbles."
>
> A friend of mine, John Polkinghorne, left physics just as I was going in; he went into the church and became a theologian. We had a discussion on my 80th birthday and he said to me, "You've got nothing to lose; you just go ahead and think what you think." And that's what I've been doing. I've got all the medals I need. What could I lose? So that's why I'm prepared to take a gamble that a young researcher wouldn't be prepared to take.

Update: For an alternate source of information about "palatial twistor theory", see slides here, video here.

Comments

1. **wam**
   March 4, 2016

   Whenever possible, could you link to non paywalled
   versions of articles. Some of your readers may not have
   an academic affiliation that allows them access.

2. **Peter Woit**
   March 4, 2016

   wam,
   I generally do try to do that. In this case, I don't know of any other source for Penrose's "palatial twistor" paper, if anyone else does, please let us know.

3. **Dom**
   March 4, 2016

   Is this it? Or a similar paper "Towards an Objective Physics of Bell Non-Locality: Palatial Twistor Theory"
   Downloads the PDF from http://www.ijqf.org

4. **Peter Woit**
   March 4, 2016

   Dom,
   Thanks. That's similar, not the same, refers for details to the other one.

5. **David Roberts**
   March 6, 2016

   There is no non-paywall version that I could find. Heck, my library, I found, only subscribes to the Proceedings of the RS via a two-year moving paywall, which means I will only be able to read this article in 2017!

6. **Peter Woit**
March 6, 2016

David Roberts (and others),

I've added a couple links, to a set of slides and a video of Penrose lecturing on this. The drawings in the slides may in any case be more helpful than the graphic-free paper.

7. **wam**
March 8, 2016

Thanks for links. 'In person' is invariably better than 'on paper'. In RP's case it makes a big difference – how else to understand his prelapsarian graphics. How he fits it all onto a transparency using magic markers is somewhat miraculous. For other, possibly more primitive examples look into the back issues of Twistor Newsletter.

8. **anon**
March 9, 2016

Can you actually make some critical comments about "twister theory" as you do "string theory", please? Just quoting Penrose on twistors is like blogging quotes from Witten on string theory.

I realise that the amount of existing hype for each is vastly different, so that it is justified to treat twistors as news, rather than hype, but what about the connections of the 2 spinors in twistors with the usual standard model spinors?

9. **Peter Woit**
March 9, 2016

anon,
"twistor theory" isn't a subject that has led to any specific well-defined physical theory, but I think it's very interesting in the way that it shows that one can study 4d geometry in a way that builds in spinors and conformal invariance from the beginning. It has always seemed to me that you need some new ideas before building qfts based on this kind of geometry. Arkani-Hamed several years back was claiming a new approach to qft based on these variables, but what has come out of that (theories based on amplitudes, defined in terms of volumes of geometrical objects) leads to interesting things, but nothing that seems to me to answer questions about the SM and its relation to gravity.

The reason for bringing this up in the blog post was the claim by Atiyah and Penrose that there's a new idea here. I've spent a little time looking at it, still don't understand well enough to see if it goes somewhere. The sort of quantization Penrose is trying to do always has confused me, because it seems to be purely quantum mechanical, whereas I'd like to see what this does for QFT. Thinking more deeply about this (and whether the "palatial twistors" help) seems worthwhile, I haven't had the time recently to do so.

10. **manyoso**
March 9, 2016

Peter,

Speaking of Arkani-Hamed and his Amplituhedron work, if I remember correctly that was tied rather explicitly to N=4 supersymmetric Yang-Mills theory. I gather that it also borrowed heavily from Penrose's twistor theory, but I wonder whether these new "palatial" ideas either implicitly or explicitly depend upon supersymmetric theories?

Also, given the rather disheartening news for SS theories now that the LHC has significantly constrained the parameter space, is Arkani-Hamed working on something else? All I can find from him lately seems to be "motivational" talks and papers on the way forward for particle theory and under consideration next generation colliders.

11. **Abbyyorker**
March 9, 2016

Very interesting article on M.Atiyah. He says he is going back reading Einstein and Dirac and finding stuff people missed. It would be great to see what he has found.

12. **Peter Woit**
March 9, 2016

Manyoso,
For something very recent from him, see
https://www.youtube.com/watch?v=1HRdqNcgOOo
Some motivational stuff about colliders, etc, but also a long section on the latest on amplitudes. There's the usual story about motivating work on amplitudes by hopes for finding a common origin of spacetime and QM, but I don't see any particular progress towards that.

Three may be one, but I don't know of any relation of the "palatial" stuff to SUSY.

13. **David Roberts**
March 9, 2016

If people want to skip to the 'new' material in Penrose's talk, for instance if they are familiar with twistors, then jump to 45 minutes in (yes, I had to watch all that to find the actual point). He then says that palatial twistor theory is not any sort of quantum gravity, but then proposes another deformation of the algebra to make more commutators nonzero—he explicitly calls it a 'crazy new proposal'—to maybe be able to do something. The comments Penrose makes in the question time are some of the best bits.

Multiverse Observed, South of Glasgow

March 4, 2016
Categories: Multiverse Mania

It turns out the multiverse does exist, just off the A76, 25 miles north of Dumfries in Scotland. It's called the Crawick Multiverse and is now open 10 am to 4 pm. Admission is 5 pounds, but parking is free.

For more details, see this story, which explains about the huge mounds, and that

> There's also a mound where mudstone slabs trace a spiral path up to the top that represents the multiverse. Along the way, some of the slabs are carved out to symbolise other potential universes where different physical laws apply.

The idea seems to be that

> the park is a modern take on Neolithic monuments such as Stonehenge, which paid tribute to the movements of the Solar System – but this time the focus is on the latest advances in physics, such as chaos theory and the idea of parallel universes.

so while Stonehenge was designed to last forever and show that a primitive people understood about the solar system, this is going to show our descendants that 21st century humans knew about the multiverse.

Since it is well known that the LHC is our best chance of figuring out if multiverses exist, it seems that the people at CERN have agreed to have the same person build something like this there. This should ensure that when any future generations excavate the LHC site, they will get some idea of its purpose, and marvel at how much progress the human race made after the Neolithic era.

Update: Another observation of a multiverse, this one in Trieste.

Comments

1. **Chris Oakley**
   March 4, 2016

   Stonehenge is obviously the remnants of a neolithic gas holder and has nothing to do with astronomy. The metal has long since rusted away, but one can see that the raised stone ring would have supported an enormous tank, supplying, I expect, most of the south of England (in this universe, at least: I cannot speak for other universes).

2. **Jon Awbrey**
   March 4, 2016

   No one expects the entanglish exposition.

3. **John**
   March 4, 2016

   PT Barnum had it right oh so many years ago.

4. **Bayes_or_bust**
   March 4, 2016

   I know you're mocking it, but I actually like the look of it! I like massive land art and sculpture parks. It goes without saying that a multiverse would profoundly affect the way we think about ourselves, and it's cool to explore that through art. This is one spin-off from the multiverse we can enjoy.

5. **Bernhard**
   March 5, 2016

   Bayes_or_bust,

   Maybe we should be even more radical and try to explore the multiverse exclusively through art.

6. **David Bailey**
   March 5, 2016

   I think that when science starts to ditch experimental proof, and rely on beauty, it merges with art and becomes understood more as a metaphor than a statement about reality.

   I hope this enterprise does well and even features on cosmology TV programs, because (probably unintentionally) it might force science to contemplate just where it is heading.

   I don't think the rot in science is confined to HEP.

7. **Staffan Angere**
   March 5, 2016

   Benhard,

   that is probably the most reasonable way to proceed. After all, the word "multiverse", with roughly its contemporary meaning, was coined by Michael Moorcock in his fantasy and science fiction stories (the word appears in William James, but with a very different meaning).

8. **vmarko**
   March 5, 2016

   Now we just need to propose the idea of a "nulliverse" – a situation where only zero universes exist, and we will have a complete offer for any metaphysical ideology:

nulli-, uni- and multi-verses. So far people who align with solipsism were underrepresented in modern cosmology, but nulliverse could change all that for the better.

Also, aside from the fact that it doesn't need any experimental evidence whatsoever (whatever the argument others offer, just claim it's all your imagination and the real world doesn't actually exist), it would be trivially cheap and easy to build a theme park for the nulliverse. Just so that future generations know that we didn't leave solipsists out in the cold in modern cosmology…

🙂
Marko

9. **Anon**
March 5, 2016

As reality goes
which one is most terse:
a nulli-, a uni-, or a multi-verse?

Or why not a poly-
If that be our curse
For a poly-multi-verse can't be much worse…

10. **Lucy M**
March 5, 2016

Hi Anon, I quite like the idea of the multiverse, megaverse, multi-level-multiverse bubbleverse, and so on, all as merely parochial regions of the perverse

11. **Yatima**
March 5, 2016

The satanic multiverses cannot be far off.

12. **Jon Awbrey**
March 5, 2016

I have done the calculations and compute that the probability of a universe with bagpipes is vanishingly small, so we are clearly living in an outlier.

13. **paddy**
March 6, 2016

So why, Jon Awbrey, are Glaswegians seen typically as aliens?

14. **MC**
March 7, 2016

Everybody knows that the real universe is the one with the City of Amber at its center. The others are just shadows…

15. **Jim Given**
March 8, 2016

"Believe me, if you've seen one multiverse, you've seen them all."

This and That

March 9, 2016
Categories: Uncategorized

A few short items:

- Nature has an editorial this week summarizing the situation with the 750 GeV possible diphoton bump. It mentions a new paper analyzing related data (the number of theory papers on this as a function of time). The paper is called A Theory of Ambulance Chasing, and claims that looking at a large collection of similar fads producing theory papers, the high-level behavior of the HEP theory community can be well summarized by a model that requires only two parameters to fit the data.
- If you're at Stanford tomorrow and a fan of multiverse mania, you can go hear Alexander Vilenkin talk about The Universes Beyond the Horizon. According to the Stanford PR for this

  > Despite the similarities between Vilenkin's theory and the Wikipedia summary of the film Interstellar, many scientists have hope for the multiverse theory.

  Stanford physics faculty members seem to have innovative ideas about the scientific method, with one of them quoted as claiming

  > Once a reasonable idea comes, you can never say it's wrong.

  which I guess could be taken as some sort of motto for research into string theory and the multiverse.

- CERN is running a series of articles about the Theory group there, first one is here.
- Norbert Bodendorfer has a nice new blog about loop quantum gravity and related topics.
- The Templeton Foundation has mercifully stopped giving huge financial prizes to people for dubious attempts to bring religion and science together. I hadn't even realized they had already given out this year's Templeton Prize, which went to a British Rabbi.

  Among the many things they fund is a recent $1.1 million grant for this project on the philosophical implications of quantum gravity. They will hold a summer school this year (with Amanda Peet and Carlo Rovelli, that should be fun), and there's a Youtube channel.

- Chris Quigg has an interesting overview of the future of HEP physics. I particularly like his emphasis on the questions

  > How are we prisoners of conventional thinking?

  and

  > Might we have misunderstood the hierarchy problem, and so need to reframe it? Perhaps it is time to ask whether the unreasonable effectiveness of the standard model (to borrow a turn of phrase from Eugene Wigner) is itself a deep clue to what lies beyond.

   March 10, 2016

   An initial burst of interest followed by a decline is typical real discoveries (like the Higgs and neutrino oscillations) as well as of anomalies that go away. So I don't see any real content in the chasing-ambulance paper, apart for the provocation. Its author would become famous if the 750 GeV anomaly will turn our to be real.

2. **CM**
   March 10, 2016

   The Nature editorial was worth reading. However, there was one sentence that is hyperbole at best
   "Still, people at CERN, the European particle-physics lab that hosts the LHC, have scarcely talked about anything else since. "
   Although I am not personally at CERN but work remotely on one of the two large experiments, all the people I converse with have been intently focused on getting ready for the start of data taking in a few weeks. Discussions about the 750 GeV diphoton bump might constitute a pleasant diversion during work breaks, but there are usually more important or interesting things to occupy even break time.

3. **Bayes_or_bust**
   March 10, 2016

   @M The goal of The Theory of Ambulance Chasing is modelling the behaviour of physicists (specifically the number of papers they make) after an anomaly is announced. I don't think there's any suggestion (in the paper or elsewhere) that one should attempt to infer whether an anomaly is genuine or a fluctuation from any such analysis of the dynamics of the number of papers written about it.

4. **Low Math, Meekly Interacting**
   March 11, 2016

   "Many of these universes collapsed and formed black holes, Vilenkin said. If the black holes are big enough, they may have inflating universes inside of them, and these expanding universes would be connected to the visible universe by wormholes."

   …and? I take another hit off the bong and get my mind blown, or we observe some consequence of this?

5. **my milkshake brings all the boys to the yard**
   March 14, 2016

   Hi Peter. well, it seems Neil Turok agrees with you about string theory: "Instead it's given us a huge collection of theories where, if you like, there's no overarching theory to tell which particular version of string theory is the one that describes the world. It's almost self-destructed…" etc. etc. (Though I disagree myself.)

   Turok also asserts (in the video at least) that the universe is simple. That is either an article of shear faith or ignorance of our current theories (e.g. QCD). He also asserts (in the text) "Our most secure knowledge about the world, about the natural world, is physics." That is hopelessly naive and flat out wrong: has he never experienced the greenness of green (i.e. qualia?) He doesn't give me much confidence that he knows what he's talking about at all.

   Then (in the text) he talks about the founding principles. Well, okay.

6. **Peter Woit**
   March 14, 2016

   Thanks MMBATBTTY, I hadn't seen that. It deserves a separate posting…

   At this point I don't think my point of view about string theory is an unusual one at all, not surprised to hear what Turok has to say. He obviously is not ignorant about QCD, which, yes, is from a fundamental point of view extremely simple (in the limit of massless quarks, no free parameters at all (except maybe the number of colors).

7. **James Mc**
   March 16, 2016

   Hi Peter you might be interested to know Andrew Wiles was awarded to the 2016 Abel Prize

The Ultimate Simplicity of Everything

March 14, 2016
Categories: Uncategorized

There's a wonderful interview with Perimeter Institute director Neil Turok here, entitled *The Ultimate Simplicity of Everything*, and done for a Canadian radio program.

Turok discusses his point of view on whether we're at "the end of physics", and I'm very much in agreement with what he has to say:

> I think what people are sort of expressing is that we haven't had a big revolution in physics. String theory was hoped for to be that revolution in the 1980s but it hasn't really panned out in the sense that it hasn't given a single prediction. Instead it's given us a huge collection of theories where, if you like, there's no overarching theory to tell which particular version of string theory is the one that describes the world. It's almost self-destructed, I would say because it turned out to be not just one theory but this vast collection of theories which could all give different descriptions of the world.
>
> So I think that sort of theoretical catastrophe, as I view it — meaning the logical pursuit of quantum mechanics and relativity over a hundred years was tremendously successful at some level but finding its own successor theory, it hasn't been successful. I think that is also laying the ground for some sort of revolutionary change in the sense that we basically will have to go back to the founding principles. It looks like the founding principles of modern physics — quantum theory and relativity — have played out and they have not given us the answers we need. And so we have to go back and question those founding principles and find whatever it is, whatever new principle will replace them. So matching these great puzzles posed by the observations are equally great puzzles in our fundamental theories. And so that is just a wonderful thing to contemplate in itself. I mean, partly people become very pessimistic and say, oh my god, I've devoted 50 years of my life to studying this incredibly technical and difficult theory and now I find it's blown up in my face, it's not giving any predictions at all… and so some people talk about the multiverse where the universe would be wild and chaotic on large scales and almost anything you could imagine would actually exist somewhere in the universe. I mean, this is literally a scenario which became very popular among a category of physicists, that there is a multiverse out there. Yet the evidence is exactly the opposite. That, as we look around us, things could not be simpler. There's no evidence for chaos on large scales in the universe. It's totally the opposite. It's pristine, elegance, minimalism is all we see. So, I think this is a very, very exciting time to be doing theory. The challenge is enormous. The clues are enormous. We're waiting and we're preparing and we're encouraging people to take radical leaps.

Comments

   March 15, 2016

   "The chance is high that the truth lies in the fashionable direction. But, on the off chance that it is in another direction – a direction obvious from an unfashionable view of field theory – who will find it? Only someone who has sacrificed himself by teaching himself quantum electrodynamics from a peculiar and unfashionable point of view; one that he may have to invent for himself." – Feynman's Nobel prize lecture, 11 December 1965.

2. **Giotis**
   March 15, 2016

   "It's almost self-destructed, I would say because it turned out to be not just one theory but this vast collection of theories which could all give different descriptions of the world."

   Obviously Turok as most of String theory denialists is mixing the notions of a theory and the solutions (or vacua if you like) of a theory.

   The theory is one and unique, the solutions are maybe many.

3. **vmarko**
   March 15, 2016

   Giotis,

   "Obviously Turok as most of String theory denialists is mixing the notions of a theory and the solutions (or vacua if you like) of a theory."

   So you would be comfortable putting David Gross and Gordon Kane in the ST-denialists category? Because they also say that ST is a framework, and only once you choose a particular vacuum you fix one particular theory. In that theory you can then fix various boundary conditions that specify one particular solution or another.

   The way I understood ST is that the choice of the vacuum is not a boundary condition within a theory, but the choice of the theory within a framework, just like you can choose the gauge group SU(3)xSU(2)xU(1) within the QFT framework to get one particular theory (the SM).

   Btw, this isn't my analogy. David Gross was very explicit about this during the Munich conference, and I've also heard a bunch of ST experts make similar statements for years now. I don't think Turok has anything mixed up here.

   🙂
   Marko

4. **Peter Morgan**
   March 15, 2016

   "There's no evidence for chaos on large scales in the universe." OK, but if Physics is only interested in scales where there is simplicity, the "large" ones, what's all this other stuff? Fortunately for those who are willing to get their hands dirty there is condensed matter physics, biophysics, etc. http://www.forbes.com/sites/chadorzel/2016/03/13/why-isnt-the-biggest-conference-in-physics-more-popular/#6d10d6f77594 makes a worthwhile case at least for the CM.

   Without detracting from the utility and intellectual interest of effective simple models, it's not necessarily that the world is simple, it can equally well be that we sift the world for simplicity; it might be inadvisable to be in denial about the dross.

5. **Andrew Thonad**
   March 15, 2016

   Giotis: "String theory denialists". You make people who disagree with string theory sound like the flat Earth society. People who disagree with string theory aren't denialists because it is not a proven theory. I'm afraid you're the one who comes across with a head-in-the-sand worldview.

Peter Morgan, yes, Neil Turok says we live in the "messy middle". So there's plenty of complexity yet to be understood in the middle scales. In fact, that's probably going to be more of a challenge in the long run.

6. **Cormac O'Raifeartaigh**
   March 15, 2016

   The statement "Yet the evidence is exactly the opposite. That, as we look around us, things could not be simpler. There's no evidence for chaos on large scales in the universe" doesn't feel quite right to me.
   My understanding is that the one point that hypotheses such as the multiverse bring to the table is to highlight what may be an unjustifed assumption – i.e., we cannot at this point be sure that what we measure locally is an accurate representation of what may exist on larger scales.
   I hope that ssomeone will one day prove that cosmic inflation happened to all of the universe, or none. But until that time, it seems it is logical to leave open the possibility of disconnected regions…however distasteful we find the idea …

7. **Chris W.**
   March 15, 2016

   Cormac,
   Frankly, I think it's about time we made some unjustified assumptions *that can be tested*. In science, hedging bets can be toxic.

   Why don't we try assuming that certain things are simpler than we think they have any right to be, and then—at worst—find out exactly how and why that turns out to be wrong? If the multiverse forces itself on our attention because of unexpected *observations* that would be a tremendous improvement over the current situation.

   Of course, for that to happen we will almost certainly need a much better formulation of the idea than we have now.

8. **vskrin**
   March 17, 2016

   Apropos the above discussion, and Turok's statement,

   "…and so some people talk about the multiverse where the universe would be wild and chaotic on large scales and almost anything you could imagine would actually exist somewhere in the universe. […] There's no evidence for chaos on large scales in the universe. It's totally the opposite. It's pristine, elegance, minimalism is all we see.",

   I believe that this part of a Feynman's lecture is very relevant: https://youtu.be/-Km7-6-J81k?t=18m20s .

   Feynman speaks about a slightly different issue, also related to anthropics, but the way I see it his argument is equivalent to Turok's argument against the multiverse.

   Cheers!

9. **Jim Akerlund**
   March 18, 2016

   vrskin,

   Thanks for the the link to the Youtube Feynman lecture videos. Wow.

10. **Low Math, Meekly Interacting**
    March 19, 2016

    We may get some new sense of how messy the middle really is by summer. Jester tells us the 750 GeV bump is…not dead yet. In fact…no, I don't want to get my hopes up!

Number Theory News

March 16, 2016
Categories: Uncategorized

- Andrew Wiles is the recipient of this year's Abel Prize. I have to confess that I found this surprising, since I assumed he'd already won this. His work in general and specifically the work that led to the proof of Fermat's Last Theorem is on any reasonable list of the top few achievements in mathematics in recent decades.

  If you haven't seen the documentary about the FLT proof, you really should, it was a BBC Horizon show in the UK, Nova here in the US, transcript here.

  I'd heard and Nature confirms that Wiles has for quite a while now been working quietly on the BSD Conjecture, maybe some day there will be another very dramatic moment in the subject, and another documentary.

- Erica Klarreich at Quanta has the story of a surprising new result about prime numbers from Kannan Soundararajan and Rober Lemke Oliver. They have found that, given a prime number with a certain last digit, there are different probability for the last digit of the next one (among the various possibilities). This violates usual assumptions that such things are in some sense "random", indicating just how subtle this "randomness" is.

  For more details, there's an excellent blog post from Terry Tao. This might be a good time to point out that people sometimes complain about the quality of coverage of scientific advances aimed at non-experts. From what I've seen in recent years, the coverage of mathematics advances has been of extremely high quality, with this story a good example.

- April 29 is the release date for The Man Who Knew Infinity, a film about the life of Ramanujan. It's based on a great biography and a fascinating story. I hope this turns out better than the similar situation with the film about Turing.

Update: It turns out that an astronomer, Chung-Ming Ko, had already a while ago done some calculations showing non-randomness in the last digits of primes, see here. The new paper has been updated to refer to that.

Reports about the Ramanujan film are that they took great pains to get the mathematics right, with Ken Ono and Manjul Bhargava working extensively on the film.

Comments

1. **Jeff M**
   March 16, 2016

   It should be noted that the result on primes is suggestive and not a proof. Essentially they noticed something numerically, and came up with heuristic arguments, which depend on a conjecture of Hardy and Littlewood, to explain the numerical results. So, might be true, might not be. I'm perfectly willing to believe Terrence Tao, who thinks it makes sense – he's a much better number theorist than I am 🙂

2. **Roger**
   March 16, 2016

   The Abel Prize only started in 2003, so it had a backlog of deserving recipients.

3. **Peter Woit**
   March 16, 2016

   Roger,
   Sure, he's only the 17th recipient ever of the prize. My surprise was just that I would have guessed he'd have been much higher on the list ordered from the beginning of people awarded the prize.

4. **anon**
   March 16, 2016

   I think he's the youngest person to receive the prize thus far. Maybe the committee has prioritized older people when they've started clearing the backlog. Many recipients were in their late 70s or 80s, so they wouldn't have necessarily had that many years left (though I think all but Nash are still alive).

5. **Peter Woit**
   March 16, 2016

   anon,
   I think that's right. I hadn't realized they were still so heavily concentrating on much older people and hadn't yet gotten down to those in their sixties.

6. **geometriclanglander**
   March 16, 2016

   I do feel it's a great shame that Israel Gelfand wasn't awarded the Abel Prize before he died.

7. **Jeffrey M**
   March 17, 2016

   In addition to the age issue, the Abel hasn't been for a single result, it's been for people who've made multiple high level contributions to math in diverse areas. It's not like the Nobel. Wiles was too old for a Fields, but he was given a special citation at the ICM the year he would have won the Fields.

8. **Daryl**
   March 17, 2016

   Hasn't Wiles already proven a special case of BSD conjecture?

9. **Davide Castelvecchi**
   March 18, 2016

I'd like to point to Evelyn Lamb's article as another example of excellent coverage 🙂
http://www.nature.com/news/peculiar-pattern-found-in-random-prime-numbers-1.19550

And I'm glad I'm not the only one who thought that Gelfand should have gotten the Abel.

10. **Mário da Silva**
March 18, 2016

Not only Gel'fand… They probably thought Arnol'd would have lived longer (he died too young for nowadays standards). He did not receive a Fields Medal for mysterious reasons. At least he was awarded the Wolf Prize.

Anyway, there is now that "Breakthrough Prize in Mathematics", but with such a dumb name I doubt it will catch the others in prestige.

11. **Michael Weiss**
March 18, 2016

It is wonderful when the Abel Prize goes to an extraordinary senior mathematician who in his or her younger years did not receive the Fields Medal. A joyous example was John Tate, whose generosity and deep insights were seldom accompanied by a drive to publish. Despite the legendary status of his PhD Thesis at Princeton, this work was not formally published for almost 20 years. Yet scores of landmark publications by others thanked Tate for sharing key insights and relied on methods that he pioneered and conveyed in meetings. Tate's methods also contributed as an essential foundation to Wile's proof of FLT. As an aside, generations of Harvard undergraduates found Tate to be inspiring and approachable, not only in formal courses but also in the dining halls of Adams House and later Dunster House — and even on the basketball court! The prestige of the Abel Prize was enhanced by John Tate's recognition.

12. **JSM**
March 19, 2016

Much as Wiles deserved the prize, this appears to confirm that they are not going to give it to Langlands. If they were going to, this should have been the year.

13. **Bob**
March 20, 2016

JSM, that's just a Langlands conjecture …

14. **Mario**
March 21, 2016

Peter – is there some reason that you did not cover the update of the 750GeV diphoton resonance? You were my source #1 for rumors on the Higgs in 2012. Can't you use some of your connections? 🙂

15. **Peter Woit**
March 21, 2016

Mario,
I just don't have any information or thoughts about that that aren't much better discussed elsewhere. I can only keep telling people to read Jester at Resonaances so often….

I don't think the recent update materially changes the situation. The evidence is marginal, and we should know for sure one way or another later this year (July if you're an optimist). If there really is a state at 750 GeV it will revolutionize the field, which will be quite exciting.

Maybe reliable rumors will appear here, but at the moment it seems others have better sources, and you should look to them for the latest on this.

16. **geometriclanglander**
March 22, 2016

The paper by Ko was published in Chaos, Solitons and Fractals… it's unfortunate really, given that journal's rather chequered reputation. One can't really be too surprised if it wasn't taken seriously.

17. **IM**
March 28, 2016

Peter,
Off-topic, but probably you should mention in a future posting that the second part
of Grothendieck's obituary has come out in the AMS Notices.

18. **Peter Woit**
March 28, 2016

IM,
Thanks for pointing that out. I noticed that the last page of the Grothendieck obituary material in the AMS Notices included a large recruitment ad for the NSA. May be some spinning in his grave going on…

Two Book Reviews

March 28, 2016
Categories: Book Reviews

Blogging has been light here, trying to finish a complete draft of the book I'm working on, this should be done very soon. Here are a couple all-too-short reviews of books with some relation to math or physics.

A Doubter's Almanac

The main character of Ethan Canin's new novel A Doubter's Almanac is a mathematician, one who solves a great problem early on in his career (as a graduate student in Berkeley, then a faculty member at Princeton). It's a beautifully written work, with a remarkably convincing portrayal of a talented young mathematician struggling with a difficult problem and making his way through life. I wouldn't have guessed that anyone who hadn't lived and worked in this kind of environment would be able to describe it so realistically.There are only a couple false notes in the many details of the part of the story set in academia. In particular, I don't think anyone would consider a "subchairmanship" to be much of an inducement, even at Princeton, and they don't give Abel Prizes to young geniuses. Besides getting the details right, the characters come up with some quite insightful remarks about mathematics, including some that deal with the way talent and immersion in a mathematical problem may alienate one from the rest of the humanity.

While I greatly enjoyed the first half of the book, I have to admit that the later part held less interest, turning away from academia to a long story of family relations and the ravages of alcoholism. Not at all an upbeat book, if that's what you're looking for, but I can't think of another novel as good that so deeply engages with some aspects of mathematics and the mathematical life.

Black Hole Blues

Janna Levin's Black Hole Blues has just been published, with excellent timing for anyone who wants to know more about the story of LIGO and its first observation of gravitational waves. The main strength of the book derives from her interviews with some of the people crucial to building LIGO (in particular Kip Thorne and Rainer Weiss). Together with research and other interviews she has put together a rich version of the history of the project and the roles of the three physicists (Drever, Thorne and Weiss) whose vision and dedication made it successful. LIGO has been a very long term project, with its beginnings going back 40 years. It's remarkable that it didn't get abandoned or defunded at some point, with the NSF playing a very important role in supporting the project over many years.

Drever, Thorne and Weiss will likely soon be the recipients of all sorts of well-deserved honors and prizes (I'd bet on this year's Breakthrough Prize and probably the Nobel too). I was sad to learn that this is coming too late for one of them, Ronald Drever, who is ill and suffering from dementia. The physics of LIGO has a bright future, it's great to have the story told of the people who made it happen.

Comments

1. **Richard Séguin**
   March 28, 2016

   Janna Levin was on Wisconsin Public Radio today for an hour. Podcast available here:

   http://www.wpr.org/shows/quest-hear-universe

   I have a copy of A Doubter's Almanac, but found that the smell of the ink or paper made me sneeze, so I'm not sure when I'll get to it. I've never had that problem before.

2. **Richard Gaylord**
   March 29, 2016

   just wanted to note that Levin's book was not published 'with excellent timing' by happenstance but rather because the publisher decided to rush the book into print now rather than at its previously announced Summer or Fall (i forget which) publication date after the detection of gravitational waves was announced. a very good (and an unexpectedly intelligent one, based on my dealings with publishers on four scientific programming books) move by the publisher. also, i recommend Levin's first book which is a nice little scientific memoir but i found her second book, a novel, dealing with Turing and Godel to be unreadable.

3. **tulpoeid**
   March 29, 2016

   Just for the record, have you read "Uncle Petros and Goldbach's Conjecture"? Not tremendously well written, but quite amazing in talking about "the way talent and immersion in a mathematical problem may alienate one from the rest of the humanity" and in engaging "with some aspects of mathematics and the mathematical life".

4. **Dragster**
   March 29, 2016

   I heard Ethan Canin at a book reading. It turns out he has no real background in math or mathematicians at all. After completing the original draft of the book he happened across a local topologist who gave him the math jargon and sociological insights, and he went back and wove these into his text. It then took multiple drafts to get it to sound authentic enough, but not so technically intimidating that the publisher would fear frightening away the general public.

5. **Scott Church**
   March 29, 2016

   The LIGO story has a personal connection for me. My thesis adviser left the University of Washington in 1988 to accept a position with LIGO at Caltech. The last thing he did before leaving was oversee my defense. After handshakes and well-wishes, he hopped in the car with his family and headed off to Pasadena. Today he is the director of LIGO Hanford and his name might appear in Levin's book. 🙂

6. **Sebastian Thaler**
   March 29, 2016

   Thanks for these reviews, Peter. I hope we can look forward to a review from you later this year of Roger Penrose's new book, "Fashion, Faith and Fantasy…", which offers a critique of string theory among other areas of science.

7. **Shantanu**
April 4, 2016

Peter, was sufficient credit also given to Russell Hulse and Joe Taylor in this book
for their discovery of H-T binary pulsar and subsequent observations? After all, its the decay of the orbit of PSR1913B+16 over more than a 20 year period which convinced skeptics that GWs carry away energy and also helped buttress the case for funding of LIGO. After the LIGO announcement, I was surprised to see not even a single interview of Joe Taylor or Russell Hulse.

8. **Peter Woit**
April 4, 2016

Shantanu,
There are a couple pages in the book about Hulse/Taylor and the binary pulsar story.

Short Items

March 30, 2016
Categories: Uncategorized

A few short items:

- Beams are back in the LHC. You can follow what is going on here real-time, or here for details of this year's beam commissioning. Physics runs scheduled to start last week of April.
- There's a wonderful interview with John Baez in two parts, here and here.
- For news of US HEP, take a look at the HEPAP presentations as they appear here. Reports from the LHC experiments are scheduled for April Fool's Day.
- In the last month the omnipresent Nima Arkani-Hamed was giving talks at the David Gross Fest (video here, nice comments about Gross at the beginning, presentation here), a series of lectures in Trieste (see here), and a colloquium talk at Fermilab.

  In the FNAL talk Arkani-Hamed advertises a "Modern S-matrix program", based on recent work on amplitudes. He's a reliable source for what the conventional wisdom is among the most influential people in the field, and he has this to say about the current situation (right at the end of the talk):

  > String theory killed QFT, then QFT killed string theory back, now QFT is king. We're in a situation where most people think QFT is king and string theory a derivative thing in some limits.

  His own opinion is that we need "something else", neither QFT nor string theory, but he doesn't know what it is.

- I seem to have missed this paper on String theory and general methodology (arxiv version here) when it came out quite a few years ago. At the time the authors felt that

  > the majority has not been convinced and they continue to believe that string theory is the right way to go.

  I'm not sure if the authors had any data to back that up, curious if anyone would still make this claim now. Arkani-Hamed seems to think the majority opinion has changed, with QFT killing string theory.

- For some interesting talks at one of the few conferences not featuring Arkani-Hamed, see the Nambu Memorial Symposium.
- I was sorry to hear recently that Rudolf Haag passed away back in January. For a short biography, see here. For an earlier posting linking to an autobiographical piece, see here. His book Local Quantum Physics is well worth reading. For a discussion of perhaps his most famous result, Haag's theorem, see here.
- Multiverse mania shows no signs of slowing down, with a long BBC article here. Despite the length of the article, the author doesn't seem to have been able to locate anyone who could add a note of skepticism amidst the usual thick layers of hype.

Update: A lot of data on recent DOE funding trends is available here and here. From FY 13 – FY 17, theory funding is down %20 at universities, 2% at labs. A bit over $20 million/year is now being spent by the DOE on HEP theory and computational research. For the most recent round of reviews, 23 groups were funded, and of these two were ones not previously funded, with two previously funded turned down.

   March 30, 2016

   I really appreciate these short item updates you provide.

2. **Anon**
   March 30, 2016

   It is really impressive the comment of Haag on String Theory: people like Witten can spend time on such stuff but is a pity if an entire young generation (generations?) do it.
   I always thought something like this but this is the first time I read it from a famous physicist. I see also now people whom was hired years ago for building string theory groups and now they do not really do any research of any impact. I think that the hiring departments made "unlucky" bets..

3. **anon**
   March 31, 2016

   These two consecutive sentences in an otherwise very interesting interview with John Baez (see Part 2) sound perhaps a bit ironic:

   "But I'm trying to travel less, because it's bad for the planet.

   You've gained some fame for your "crackpot index".

4. **John Fredsted**
   April 1, 2016

   To me, the two sentences

   1.) "So, I felt the need to alert people and try to dream up strategies to do something. That's why in 2010 I quit work on n-categories and started the Azimuth Project."

   and

   2.) "What I really like is getting out of the US and seeing the rest of the world."

   in Part 2 of the Baez-interview sounds like cognitive dissonance on the part of Baez, although "But I'm trying to travel less, because it's bad for the planet" softens it up a little bit.

   In my opinion, climate change is not a technological challenge, it is first and foremost a mental challenge: without a fundamental change in the very sentiments of our species, our civilisation is already doomed; we have to learn to abstain from opportunities. Although, a lot of words are uttered from people on behalf of the climate and the planet, the actual actions of those very seem people far too often speaks volumes to the opposite.

5. **John Fredsted**
   April 1, 2016

   seem -> same

6. **John Baez**
   April 1, 2016

   John Fredsted – I’m well aware of the cognitive dissonance there. I agree that if we don’t change our habits we’re in trouble. I also have incipient diabetes and still enjoy doughnuts.

7. **John Fredsted**
   April 1, 2016

   John Baez: Maybe I was being too harsh in my criticism; if so, please forgive me. In any case, perhaps it was unreasonable of me to criticise you in third-person. Luckily, though, you were aware of this thread.

8. **John Vastola**
   April 4, 2016

   Professor Arkani-Hamed’s comment is very interesting, but I’m not sure that I completely understand. I’ve heard that, in some sense, different versions of string theory are dual to quantum field theories; if this is true, then understanding string theory can in principle be reduced to understanding quantum field theory. Is this what he is talking about? Or is he simply saying that QFT has been a successful framework for actual (experimentally accessible) physics, whereas string theory has not? Or neither? Clarification from someone who actually knows what they are talking about would be greatly appreciated!

9. **Peter Woit**
   April 4, 2016

   John Vastola,
   I think he’s clearly referring to the duality business, to AdS/CFT. The big problem with string theory has always been “what is string theory, non-perturbatively?” AdS/CFT says that the answer is given by a QFT. So, one lesson would be that what’s fundamental is QFT, which can be defined perturbatively or non-perturbatively. In other words, QFT is more fundamental, because you can define it without reference to string theory (although in a strong coupling limit, string theory may be a good approximate calculational technique), whereas, outside of a perturbation expansion, string theory is defined in terms of a QFT.

Is String Theory Scientific?

April 1, 2016
Categories: Multiverse Mania, Uncategorized

Among the various April Fool's things on the web, the most subtle one I've found is by the people at James Madison University, who are advertising an April 1 event discussing the question of Is String Theory Scientific?

Part of the joke surely is Betteridge's Law or Hinchcliffe's Rule, which assure us that that answer to the question is "No".

Update: Among today's other April Fool's efforts, Kyle Cranmer updates an oldie but goodie, supersplit supersymmetry.

Update: Another April 1 effort, this one an essay on the multiverse by Robert Lawrence Kuhn. Kuhn claims that the majority of cosmologists disagree with George Ellis about the problems with the multiverse, and that Andrei Linde (with Steve Weinberg agreeing with him) represents the consensus viewpoint. Very funny.

Update: INTO THE MULTIVERSE: God's Voice in String Theory is labeled March 31, but surely it too is an April 1 effort.

Comments

1. **Davide Castelvecchi**
   April 1, 2016

   Hi Peter, did you know that supersplit supersymmetry was back?
   http://theoryandpractice.org/2016/04/Supersplit-750/#.Vv3wNGOgq5g

2. **Peter Woit**
   April 1, 2016

   Hi Davide,
   You seem to have missed my update…

3. **Narad**
   April 1, 2016

   JMU did miss an opportunity to site the event in "upstairs room 500" rather than a real meeting venue, although that would play better if there weren't an actual fifth floor (the ballroom).

4. **anon**
   April 2, 2016

   The whole YouTube channel that you linked to in your third update looks like an April 1 effort…

5. **Jim Akerlund**
   April 2, 2016

   It looks like the third update is a serious thing, not in the vane of April Fool's. There is a certain group that does lots of pingbacks to this blog that will be interested in this, if they don't already know about it. The video looks like a new morph of Intelligent Design into Intelligent String Theory. A quote from the video; "Evolution itself, I'm not down with…", occurs at the 23:09 point.

6. **John Baez**
   April 3, 2016

   I reported a new convex polyhedron with regular faces.

   I also reported a proof that there's a Turing machine that computes uncomputable functions. But this is actually *true*, once you insert the fine print (which I have not done here).

Local Debates

April 4, 2016
Categories: Multiverse Mania

I noticed that tomorrow (Tuesday, April 5) evening here in New York City there will be not one, but two debates involving theoretical physicists:

- At 7 pm the American Museum of Natural History will host the 2016 Asimov Debate, with this year the topic Is the Universe a Simulation?. You can watch a livestream at that site.

  I confess that if this were a few days earlier, I would be convinced it was definitely a joke. But, it seems not, that instead this “has become a serious line of theoretical and experimental investigation among physicists, astrophysicists, and philosophers” and that it’s a “provocative and revolutionary idea”. One thing this is not is new. Nearly nine years ago it got a lot of media attention, and I wrote about it here (and here, where quite possibly my Message to Our Overlords kept them from turning us off). Sadly, the “blink” feature of html no longer seems to be supported, so the red text there won’t blink. Maybe it annoyed the overlords and they had it turned off.

- Much further downtown, at the New York Academy of Sciences, at the same time there will be a panel discussion on a much more sensible and interesting topic What Does the Future Hold for Physics: Is There a Limit to Human Knowledge?. Also at 7 pm, livestream here.

  If I’d been asked (actually I was asked, and then unasked, a rather mystifying situation) for my views on this, I’d make the point that there’s no way to know what the limits will be to human understanding of physical laws. It has however become all too clear what the danger is of what will happen when we reach those limits. Instead of prominent theorists frankly admitting “we don’t know”, there will be an attempt to sell the story to the public that theorists have a wonderful, successful theory which describes everything, which sadly has the unfortunate feature of not making any falsifiable predictions. The string landscape/multiverse scenario now is being very aggressively sold as exactly this kind of endpoint to physics, to a large degree by people unwilling to admit the failure of string theory-based unification. There’s a very real danger that this will enter the textbooks, and that we will in our lifetimes see the end of fundamental physics as a human endeavor. The limit we will have hit will be due not to the nature of our minds, but instead the nature of our sociology.

  I suppose one other way of seeing if we’ve reached the end of physics would be if physicists started spending their time debating things like whether we live in a simulation. Oh, wait…

Update: At the NYAS evidently there was some discussion of the multiverse, with the audience told “The multiverse hypothesis is no more speculative than the universe hypothesis”.

Update: Clara Moskowitz at Scientific American has a report from the AMNH debate. At least there is one participant I agree with:

> And the statistical argument that most minds in the future will turn out to be artificial rather than biological is also not a given, said Lisa Randall, a theoretical physicist at Harvard University. “It’s just not based on well-defined probabilities. The argument says you’d have lots of things that want to simulate us. I actually have a problem with that. We mostly are interested in ourselves. I don’t know why this higher species would want to simulate us.” Randall admitted she did not quite understand why other scientists were even entertaining the notion that the universe is a simulation. “I actually am very interested in why so many people think it’s an interesting question.” She rated the chances that this idea turns out to be true “effectively zero.”

One thing I’ve noticed about these kinds of things: they often feature physicists going on about mathematics, but mathematicians are never invited…

Update: The Asimov debate is available here, the NYAS one here.

Comments

1. **Peter**
   April 4, 2016

   Asimov was a serious scientist. I don’t think he’d like it.

2. **phil fogle**
   April 4, 2016

   I can’t understand people who have a block about saying “I don’t know”. To me, it’s the very foundation of our civilization, and kudos to those who say it, and are prepared to go out and actually do something about it!

   Sadly, it’s humans, not the overlords, who are addicted to entertainment and fantasy.

3. **Bee**
   April 5, 2016

   John Barrow wrote a whole book about the 2nd question “Impossibility: The Limits of Science and the Science of Limits”. The summary is basically: there either is a limit or there isn’t. We’ll either reach it or we won’t. And that, I think is pretty much all that sanely can be said. (In case someone is interested, it’s a good book, I reviewed it here).

4. **John Fredsted**
   April 5, 2016

   The first topic, that on simulation, made me immediately think of the science fiction crime thriller ‘The Thirteenth Floor’. I must admit that it made quite an impression on me, unscientifically of course :-).

5. **adrian**
   April 5, 2016

   Dear Peter,

   You wrote:
   ”Instead of prominent theorists frankly admitting “we don’t know”, there will be an attempt to sell the story to the public that theorists have a wonderful, successful theory

which describes everything, which sadly has the unfortunate feature of not making any falsifiable predictions
”

Given that the debate/conversation between Balasubramanian, Silverstein and Weiner did not happen yet, I believe it would be good not to have a prediction of what will be discussed (that ”we do not know” will not be said, or to write that it will not be a useful debate).

The three mentioned above are very good physicists, with a very strong record of research papers. Certainly able to give their views on the topic ”what is the future of Physics”. Of course, nobody knows the answer and they will voice ”opinions” or ”feelings” for how they see the things. But the three of them have the authority to voice these opinions.

thanks

6. **Richard J. Gaylord**
April 5, 2016

“we will in our lifetimes see the end of fundamental physics as a human endeavor.” while i agree with your comments and dissatisfaction with the current state of theoretical physics, i disagree with your apparent view of what is fundamental (perhaps it should be called foundational). There are a great many (perhaps endless) still unexplained phenomena that physics has yet to solve. As Nobel prize winner P.W. Anderson has observed (see his article “More in Different”
http://robotics.cs.tamu.edu/dshell/cs689/papers/anderson72more_is_different.pdf
“The ability to reduce everything to simple fundamental laws does not imply the ability to start from those laws and reconstruct the universe. At each new level of complexity entirely new properties appear. The understanding of the new behaviors requires research which is as fundamental in its nature as any other. It requires entirely new laws, concepts and generalizations that necessitate inspiration and creativity to just as great a degree as in the less complex one.”

7. **oliver knill**
April 5, 2016

Wittgenstein once said it adequately: “Wovon man nicht sprechen kann, darueber muss man schweigen.” (“Whereof one can not speak about, thereof one better must be silent”).
While such debates could also stimulate the interest in science. A bit more than 200 years ago, 1812, Michael Faraday got tickets for public lectures of Humphry Davy and shortly after revolutionized physics. But what a difference it is: at the time of Faraday, public lectures for which tickets for the public were sold, actually featured live experiments about new findings. But maybe we compare wrong things: today, the arena for new findings is much larger and the entire world notices and follows great experiments in our time: instruments on Mars finding evidence for water, accelerators detecting the Higgs Boson or detectors finding gravitational waves or neutrino oscillations, telescopes seeing further and further back in time, the discovery of exciting new materials like graphene or nano technology advances etc. We actually live in a very successful and exciting time in physics. Such discussion events could help to wake interest in science. Maybe a young “Faraday” will attend and leave with an important insight: “mumbling about the end of human knowledge is not what science is about”.

8. **Peter Woit**
April 5, 2016

Adrian,
You misread what I wrote. I was discussing my own view of what the danger is of how the “end of physics” will happen, not predicting anything at all about what the panelists will have to say.

9. **anon.**
April 5, 2016

“Instead of prominent theorists frankly admitting “we don’t know”, there will be an attempt to sell the story to the public that theorists have a wonderful, successful theory which describes everything, which sadly has the unfortunate feature of not making any falsifiable predictions.”

Nature abhores a vacuum, as does politics: “Le roi est mort, vive le roi!” Any admission of ignorance is used by “critics” of modern physics as an excuse to ignore the whole subject as being incomplete. Please also avoid tying yourself to Popper, who ignores the very sensible idea of doing experiments *before* formulating a theory. Popper’s basic premise is that theories should be speculative but falsifiable. That’s not science. Really useful theories begin with empirical evidence and make some predictions that are wrong, that are labelled anomalies or issues, requiring further work. Most real world theories are modified or expanded, not falsified, after tests.

Superstring theory is supposed to be doing just that in three ways; 1. by achieving unification by incorporating spin-2 gravitons into a framework that might also include a standard model, 2. by making extrapolations of *empirical*running couplings meet at a common value near the Planck energy, and finally 3. by possibly allowing for the observed positive dark energy with the immense anthropic landscape of metastable vacua, and dark matter possibly with sparticles. I personally think that all of these pro-string arguments are simplistic and hype as you argue, but I don’t like the Popperian argument about “falsifiability” that you keep bringing into this blog! There is so much experimental data waiting for theoretical explanation that it’s a red-herring or strawman to ask for more experiments. The key problem is that superstring theory doesn’t really *quantitatively interrelate existing experimental data very well for the number of ad hoc assumptions and extra parameters it introduces,* not that we need falsifiability. We need theories that better correlate existing data. Before you are annoyed at this, please realise that it is not just your blog when it’s the leading opposition to string. If you use weak arguments, the blog caters to mainstream dogma.

10. **Dom**
April 5, 2016

anon.
I don’t recognise the person you describe as the views I read of Peter’s here. It would be interesting however to see a theory in the true sense of the word that meets your criteria but is not falsifiable.

11. **Peter Woit**
April 5, 2016

anon,
You’re arguing against things I’m not saying (where did I “ask for more experiments”?).

My argument is with the string landscape/multiverse “theory” which is now in the process of being institutionalized as canonical textbook science. The problem with this “theory” is that there is no plausible way to ever show that it is wrong. It’s pseudo-science with exactly the problem that “lack of falsifiability” conventionally refers to. If you have a better term that I can use in sentences where I refer to the problem I’m open to suggestions, but obviously I can’t everytime I mention this issue engage in a long disquisition on the subtleties of the demarcation problem.

12. **Apostolos Syropoulos**
April 5, 2016

A few years ago I attended a workshop somewhere in England. In a discussion, I dared (!) to say that I find stupid the idea that we actually live in a computer simulation and we are not real. A "prominent" English professor of Computer Science told me that I am solipsist…

13. **Confused**
April 5, 2016

Only if we do live in a multiverse will I be able to watch the two debates simultaneously, for then I just have to watch the 2016 Isaac Asimov debate while my other copie will be watching the live stream from the New York academy of sciences 🙂

14. **Chris W.**
April 5, 2016

Apostolos,
I would have loved to hear what that professor thought a solipsist was. What a ridiculous response…

15. **paddy**
April 5, 2016

I am a wee bit concerned by the NYAS discussion as its description invokes the "God of the gaps" and it is funded by (drum roll please)…

16. **Peter Woit**
April 5, 2016

paddy,
I suspect the NYAS panelists won't be that interested in discussing the limits of what we can know about physics in terms of "divine intervention", even if Templeton is helping fund this. Less sure what they think about "the multiverse did it", which is functionally similar.

Actually, I would have thought that funding the AMNH "Is the Universe a Simulation?" discussion would be more the thing to do if you want to bring religion into science. I don't see much of a difference between prominent physicists sitting around discussing "are we the creations of some superhuman beings, running a mysterious computer program that governs everything we do", or "are we the creations of some divine being(s), who control us and our universe by some unknown mechanism for some unknown purpose". Having the AMNH explicitly holding theology debates between physicists would at least have the virtue of novelty.

17. **Chris W.**
April 5, 2016

In these "Is the Universe a Simulation?" discussions, how often do people address the "it's turtles all the way down" infinite regress that such a notion implies? Given how problematic the idea is in other ways I would except to start there and ask why we should even bother with more extended consideration of the notion.

18. **anon.**
April 5, 2016

Sorry Peter, but did appear to effectively ask for more experiments, simply by your demand for falsifiability. How can a theory be falsified without more experiments?

"The problem with this "theory" is that there is no plausible way to ever show that it is wrong."

That's dangerous again! There are 10^500 versions of superstring to be falsified before we give up. You seem to be simply repeating Popper's argument, which was based mainly on the Michelson-Morley experiment which falsified one version of Maxwell's light-carrying aether. After that, Lorentz and FitzGerald modified the theory a bit so that moving objects are contracted in the direction they go. So if experience is anything to go by, the way this sorry saga will eventually end is that Witten or someone will eventually come up with some falsifiable prediction, which will be falsified by experiment, and then he'll just modify the theory a bit. Popper's falsification ignores examples of theories that were simply modified to agree with new results. The reason old theories disappear from textbooks is not because they are falsified, but because something better replaces them.

Can you think of one example of a mainstream theory that was debunked by experiment, without a new rival theory already being present to take over? (Don't say Michelson-Morley 1887 because in the gap until 1905 there was FitzGerald and Lorentz's ad hoc modification.) I don't know of any example of falsification really working. It's always been invoked only after another, better theory has taken over.

19. **Peter Woit**
April 5, 2016

anon,
I'm afraid you're completely ignoring the argument I actually make in favor of discussing different issues about how science works that you are concerned with. All I'm doing is repeating myself at this point, but, again, the simple point is that the problem with the string theory/multiverse "theory", "scenario", "framework", or whatever you want to call it is that there is no plausible way to ever show that it is wrong (or even that it needs to be modified). It's in the same category as empty ideas like, well, the theory that we're a "simulation".

Again, I think referring to this as a falsifiability problem seems to me an accurate use of language. What I seem to keep seeing is that there's some sort of political correctness language problem here, that anyone using the word "falsifiability" gets immediately accused of being a naive "Popperazi". If someone will tell me what the politically correct word is for referring to the problem, I'll consider using it instead.

20. **Another Anon**
April 5, 2016

If string theory is becoming canonical textbook material then it seems to me that that part of physics is become more like philosophy: thousands of papers, self-perpetuating, self-referential, but plenty of material there for a university course. And just as few people with philosophy degrees go on to become philosophers, I suspect most of the physicists will just take their excellent mathematics training from string theory and go into finance.

Physics then is not so much interested in explaining the universe. It's more interested in generating publications, and training for future careers elsewhere.

However, I think you're misjudging the situation. I see the tide has turned in a big way against string theory over the last five years. It's perceived as a theory which has not come up with the goods. If something else big comes along soon, I think there'll be mass desertion from string theory overnight.

21. **Peter Woit**
April 5, 2016

Another Anon,
It's been true for a long time that if a promising idea about unification comes along, string theory unification will become a lot less popular. The problem I see though is that young people potentially interested in the problem are being fed now from a young age a diet of conventional wisdom that there's no point in even trying. We're assured that a wonderful new discovery has been made, a new, better decentering of our place in the universe, showing that the answer to such questions is just "the multiverse did it". This is actually independent of string theory.

Unfortunately I see this point of view becoming more and more popular, with skepticism about it all too uncommon. Making progress on unification is an extremely hard problem, discouraging people from ever trying is really easy.

22. **Robert**
April 5, 2016

If the arc of physics has led most theorists into a wasteland in the last decades, it's mind boggling to think that a whole field can be so wrong! Further, it's scary to think how defensive people get to preserve such a state. How does one correct a whole field that has gone off track? How do you council young aspiring theorists to think independently? Professional peer pressure seems insurmountable.

Also, I have a very curious eight year old physics loving nephew who is in love with the idea of string theory. He's enamored with all the hype and feel I'll just confuse him by knocking it down. Any thoughts anyone? Thanks.

23. **anon.**
April 5, 2016

"… there is no plausible way to ever show that it is wrong (or even that it needs to be modified)."

I simply don't understand why you want a theory than can be shown to be wrong. The standard model is a minimalist theory based on three observed field theories, with very little speculation, and thus very little possibility for falsification. Suppose the Higgs boson had not been discovered, do you really believe the standard model would have been totally falsified? Surely it's better to look at positives in evaluating theories, instead of requiring a way to "prove them wrong". Superstring's "positives" all relate to things that have not really been observed. Nobody has seen a spin-2 graviton, a heavy sparticle, or a whether couplings are equal at the Planck scale. If these things had all been seen, then surely you'd accept superstring theory as a good working theory (akin to the standard model), regardless of whether it is possible to disprove it.

24. **Peter Woit**
April 5, 2016

Robert,
The strange thing is that I think most professional theorists are well aware of the emptiness of the multiverse/string landscape business. What's unfortunate is that the ones who like to be on TV and make good copy are the ones willing to promote an easy to understand, grandiose sounding, but scientifically worthless set of ideas. It's up to others who know better to speak up if they care about their field. There is no problem of professional peer pressure to go on about the multiverse, instead one reason for the evangelical behavior of multiverse proponents is that they're well aware of how skeptical their colleagues are.

The outrageous and damaging hype aimed at the public and the young I think already has had a couple decades effect of driving sensible young people away, and attracting those susceptible to impressive sounding but empty ideas. As for your nephew, I think confusing him would be a good idea…

25. **Peter Shor**
April 5, 2016

The *really nice* (???) aspect to the theory that the universe is a simulation is that you don't actually have to reconcile quantum mechanics and general relativity. You could just postulate that the code is buggy, and that the universe will crash when the first black hole evaporates 10^68 years from now.

26. **Peter Woit**
April 5, 2016

anon,
I complete disagree that the standard model cannot be shown to be wrong, and likely with some aspects of what appear to be your views on complex issues of what science is, but that's irrelevant. Again, you want to argue the subtleties of theory confirmation/falsification and I'm talking about something completely different, the problem of people promoting pseudo-scientific empty ideas.

27. **Another Anon**
April 5, 2016

Anon: "I simply don't understand why you want a theory than can be shown to be wrong. The standard model is a minimalist theory based on three observed field theories, with very little speculation, and thus very little possibility for falsification."

There's all the difference in the world between a theory with little possibility for falsification because the theory gets it right every time and complies with all experiments (the standard model) and a theory with little possibility for falsification because the theory suggests eleven dimensions of space time which we can never see or infinite parallel universes where we can never go. All the difference in the world.

28. **A.J.**
April 5, 2016

I don't think it's a good idea to burst an 8 year old's bubble. Let him be excited. But don't hesitate to point him towards less speculative reading materials. The history of astrophysics and particle physics is full of wonders.

29. **Low Math, Meekly Interacting**
April 5, 2016

Forgive this naive non-physicist, but isn't the "Standard Model" in some sense already "falsified", i.e. it's certainly incomplete, and neutrino masses already exist in tension with the theory without even considering dark matter and dark energy.

The "best" unifying candidate gives us a framework for tying up these loose ends, but a virtually infinite number of ways to do so, while the other favored "alternatives" don't incorporate matter, and may not even be compatible with special relativity at energies we already know it holds.

Sounds pretty awful overall to this outsider, and also like a huge opportunity for a young upshot to shake the foundations of physics, if enough young upshots are given the opportunity to do so. Ditching empiricism strikes me as too radical a remedy just yet, and that does appear to be the only means for the status quo to remain viable.

30. **Peter Woit**
April 5, 2016

All,
I don't want to turn this into a discussion of the Standard Model. No, the Standard Model is not like the string theory multiverse. At all. Questions about unsatisfactoriness of the SM, with respect to for instance neutrino masses or dark matter, are very interesting, but they're well-defined problems of conventional science, have nothing to do with the problems of multiverse theories. Trying to discuss these things together will shed light on neither.

31. **vmarko**
April 5, 2016

There are two kinds of people in the world — those who debate whether the Universe is a simulation or not, and those that have learned and understood quantum mechanics (especially the implications of Bell inequalities) well enough to know that even if the Universe were a simulation, it would be a very weird one, namely one that is not being executed by an algorithm (given that fundamental quantum randomness is uncomputable).

Also, there are two kinds of people in the world — those who debate whether there is a limit to human knowledge or not, and those who have learned and understood mathematical logic (especially the implications of Goedel's incompleteness theorems) well enough to know that the obtaining new knowledge is a process that does not converge, while being simultaneously aware that there will always exist an infinite amount of facts about the Universe that we fail to understand.

Finally,

"There's a very real danger that this will enter the textbooks, and that we will in our lifetimes see the end of fundamental physics as a human endeavor. The limit we will have hit will be due not to the nature of our minds, but instead the nature of our sociology."

Very well said. However, being an optimist, I believe that fundamental physics will not end, but will rather be reabsorbed into math. The drought of experimental data in quantum gravity is already pushing it from physics departments into math departments. Mathematicians are much more adept at developing theories with no contact to experiment, and I hope that fundamental physics will not die but be preserved within math departments, until technology catches up and enables us (or our descendants) to perform new experiments.

Best, 🙂
Marko

P.S. Robert, by all means do burst your nephew's bubble. Have him learn real physics, teach him to question everything, teach him not to trust any authority figure. Teach him the difference between enthusiasm and hype — not just in science, but in life in general.

32. **Dom**
April 6, 2016

Anon
"I simply don't understand why you want a theory than can be shown to be wrong. "

That is not really how I understand falsifiability, it is the concept that there is in principle a test that can be performed that would show it to be incorrect. The alternative is indistinguishable from magic.

33. **John**
April 6, 2016

So Tegmark said there was a 17 percent chance that we are in a simulation. I couldn't tell if he was serious or how he arrived at 17%. Chalmers said that you can't prove that we are not in one because any proof could be simulated.

Not sure how this got classified as a science debate. It was a philosophical debate pure and simple.

34. **Michael Weiss**
April 6, 2016

The discussion of whether we live in an actual universe or within a simulation reminds me of a wry solution to the Shakespeare mystery: these magnificent plays and sonnets of the Elizabethan era were not in fact written by William Shakespeare (wrong social class and educational background), but instead by another Londoner named William Shakespeare. We stand enlightened.

35. **Robert**
April 6, 2016

Peter (and Marko),

Thanks for the advice about my nephew. I can 'teach the controversy' but still want to
very be careful that I don't turn him off to physics by giving him a big disappointment.
Of course at only 8, the physics of ordinary cotton strings is more relevant anyway.

Peter, I am currently enjoying reading your book. The first parts bring back memories of my physics student days at University of Illinois in the mid to late 70's.

36. **Jeff M**
April 6, 2016

John

Just a guess, but maybe Tegmark did the Hampshire summer studies in math, and that's where the 17 comes from. Hampshire recently changed all the speed limit signs on campus to be 17mph in Kelly's honor.

YP17

37. **Tom Andersen**
April 6, 2016

I watched 80% of the NYAS discussion. The first thing I noted was that all three panelists were essentially cloned as far as their outlook on physics was concerned.

I submit the not very popular viewpoint that the internet for all the good it has done us has basically wiped out individual viewpoints in physics. Case in point: its not unusual or weird to discuss the multiverse or 11 dimensions as they are part of the current accepted legend, while truly new 'obviously wrong' ideas are not tolerated. 'Physics' (being the entire community) will not admit that it failed to predict dark matter, dark energy, high Tc superconductivity, etc. The list is embarrassing and getting longer every year. Meanwhile astronomers and condensed matter workers keep finding new data. Its ok to be wrong.

38. **A**
April 6, 2016

arXiv seems to be doing a survey – asked in the comments for trackbacks from this blog to be allowed again, other readers might want to do the same.

39. **Another Anon**
April 7, 2016

At the NYAS evidently there was some discussion of the multiverse, with the audience told "The multiverse hypothesis is no more speculative than the universe hypothesis".

Good grief. I've never heard of the "universe hypothesis" before – probably because it's not a hypothesis. The universe is defined as "all of time and space and it's contents"(thank you Wikipedia). The universe therefore exists. Does the multiverse exist? There is no evidence that it does. Therefore the multiverse hypothesis is more speculative than the "universe hypothesis".

I think what he means is that you can't prove that something doesn't exist. OK, but that still does not raise the multiverse hypothesis to the same level as the "universe hypothesis", for which we have unambiguous evidence. In fact, his suggestion seems to be that the multiverse is clearly separated from the "universe", in which case if the universe is defined as the set of all the things which exist, then the multiverse does not exist – by definition.

40. **A third Anon**
April 7, 2016

As someone who listened to the whole thing, I think the explanation for that comment was that both hypotheses refer to the region beyond the visible horizon. Presuming everything is the same even everywhere where we cannot see is as presumptuous as assuming the conditions are variable. Neither is visible, so both equally speculative. Anyway most of the dialogue was not about that.

41. **Another Anon**
April 7, 2016

Yeah, but the string theory multiverse proposes different laws of physics in different universes. That's a whole step beyond "presuming everything is the same everywhere".

42. **Peter Woit**
April 7, 2016

A third Anon,
Sure, there's some sense in which that comment is true. But it's also worded not so as to enlighten anyone but anything, but to instead score a propagandistic point. I'm curious whether anyone at the NYAS event made any attempt to explain the problems with the multiverse, as opposed to trying to justify and sell it.

43. **A third Anon**
April 7, 2016

Hi Peter. Most of it was not about that. If I have it right, this was just the extreme end of a more general discussion of how to deal with the distinction between complicated versus simple/symmetric explanations of things. One speaker pointed out that in dark matter, from the point of view of the dark sector our visible particle physics is more complicated than Occam's razor would justify. So these parts of physics we don't measure yet could either be complicated or simple as far as we know, and it's not clear how to judge that.
I guess the multiverse/universe thing is about that kind of question but beyond the horizon. I wouldn't know what of it was propaganda but it didn't seem like that, just some interesting musings on this topic.

44. **anon.**
April 7, 2016

Hi Peter. Of course tested theories like the SM have evidence. The problem you know is that certain superstring theorists have – since the 80s – argued that coupling unification and spin-2 gravitons are a kind of evidence. There are two differences. First, time ordering. In other words, the Pauli-Fierz 1939 spin-2 graviton idea predates the string theory framework that incorporates it. I don't understand why the historical order is so important here. Physicists in some other galaxy might have come up with a spin-2 superstring gravity framework before deducing that spin from universal attraction of similar charge sign in quantum gravity! Secondly, the number of such postdictions is far, far smaller in superstring, than it is in the SM. This is the real problem to me, not whether the model is contrived to fit empirical data, or is making way out predictions of hitherto unknown phenomena. A danger in your approach may be that, if some supersymmetric particles seem to turn up at the LHC, you'll be debunked, even though it won't be a proof that any particular existing supersymmetry model is right. The anthropic landscape is so big it will be claimed it covers whatever turns up…

45. **Peter Woit**
April 7, 2016

anon.,
You're still just ignoring everything I write and insisting on arguing about the complexities of a completely different topic and what my "approach" to that is, even though you have no idea what my views are on the topic you insist on discussing or what my approach to that topic is (if you really must know, short version: it's complicated.). Sorry, but this has become a complete waste of time.

46. **TCS**
April 7, 2016

In the age of steam, when engineering was developing increasingly precise machines, a prevailing view was of a beautifully precise mechanical Universe.

In the age of computing, when computers are simulating increasingly complex systems, an emerging view is of a beautifully complex simulated Universe.

Plus ca change?

47. **Sirius**

April 7, 2016

Will everyone just please stop simulating themselves. Some of us have work to do!

48. **Shantanu**
April 8, 2016

Can someone point me to links of videos of these talks if they are archived?
Thanks
shantanu

49. **Confused**
April 8, 2016

Shantanu,

Here is the archive for the NYAS video:
http://livestream.com/newyorkacademyofsciences/physics1

There is nothing archived yet for the 2016 Isaac Asimov debate.

PS: I managed to watch the two debates, not because we are living in a multiverse as I hoped, but thanks to the fact that we live in a computer simulation. I just had to go throw the program twice, once branching towards the AMNH and once towards NYAS. I am looking forward to read in this blog an expression like the "Computer Simulation Mania".

50. **Confused**
April 8, 2016

Sorry for the typos:
I meant "….to go through the program…" not "….to go throw the program…".
There must be a virus in my simulation, or else that it should be upgraded. 🙂

51. **Zoviyer**
April 8, 2016

Peter, related to the last sentence in the second update. Kontsevich in the 2015 breakthrough prize Math Panel (you can watch this around minute 19 of the video that is publicly available in YouTube) said he believes we're in a simulation but in this case because he doesn´t have a good explanation of why the mathematics of quantum mechanics work.

52. **Peter Woit**
April 8, 2016

Zoviyer,
Thanks. That may just be Kontsevich's sense of humor. At least I hope that's what it is…

53. **Jim**
April 8, 2016

It is kinda odd because saying we are living in a simulation is really identical to saying that God exists, but none of the participants wanted to go in that direction. It wasn't even brought up. I guess some physicists are more comfortable with master computer programmer than they are with a God.

54. **zzz**
April 8, 2016

yeah, really, really strange, its like they think "The Matrix" is a plausible historical documentary

55. **Fred P**
April 8, 2016

The main problem I have with Universe as a simulation conjectures is that the hardware requirements would be enormous (i.e. ludicrous).

Let us suppose 1 x 10^80 particles in the "simulated" universe. The memory requirements alone to track each particle would be at least the same number of particles in the "real" universe. Furthermore, these particles would have to be organized in a way that communication and processing can occur in finite times between many of these particles, and so that they are not dense enough to prevent organized motion. I guess I could do the math directly, but this is plainly infeasible; we are proposing creating a computer with more mass than the observable universe into a space far smaller than a galaxy. It would quickly collapse under its own gravity.

One could argue that one has an algorithm that reduces these memory requirements by, say, 10 billion or so (which is highly infeasible). We are still talking about trying to create memory for a computer that far exceeds a galaxy in size, and needs to be compressed into a relatively tiny space (compared to a galaxy) to function, without having gravitational collapse.

Even if the memory requirements were met by, say, having a constellations of close galaxies somehow communicating with each other, each having their own local processing of information, that just makes the problem even worse – since the cost of the Turing-like machine is then replicated in many different places, each of which requires significant mass, and additional communication problems.

I don't see this working without positing (for no reason other than to support this conjecture) wildly different physical laws, and deity-like powers on the simulators, in which case why would they be simulating our wildly different universe?

56. **Chris Oakley**
April 8, 2016

Re: "The Matrix" – how could the machines who created this simulated world for humans while simultaneously harvesting their body heat and brainwaves be sure that some other even more advanced race was not doing the same thing to them?

57. **Mitchell Porter**

April 8, 2016

Robert – you can tell him about testing a theory. Particles have masses and charges, and in string theory those properties come from the shape and size of the extra dimensions, etc. The crowning achievement of string theory would be to explain the specific mass, charge, etc. of the particles we actually see, but that hasn't happened yet.

58. **G.S.**
April 9, 2016

Fred P.,

From the 2012 paper by Beane, et. al (http://arxiv.org/pdf/1210.1847v2.pdf):

"... the discovery of the string landscape, and the current inability of string theory to provide a useful predictive framework which would post-dict the fundamental parameters of the Standard Model, provides the simulators (future string theorists?) with a purpose: to systematically explore the landscape of vacua through numerical simulation. If it is indeed the case that the fundamental equations of nature allow on the order of 10^500 solutions, then perhaps the most profound quest that can be undertaken by a sentient being is the exploration of the landscape through universe simulation."

So, evidence that we are inside a simulation would be evidence in favor of string theory. However, lack of evidence that we are inside a simulation has no repercussions for string theory.

59. **vmarko**
April 9, 2016

Now I'm getting confused — is the multiverse inside a computer simulation, or is the computer simulation part of the multiverse? Or is it somehow both at the same time? Oh string theorists, please help me understand this deep physics!

😀
Marko

60. **Low Math, Meekly Interacting**
April 9, 2016

That's what so mind-blowingly awesome about about it: you can have a simulated multiverse embedded in a real multiverse, or another simulated one! I think infinity x infinity makes anthropics a googolplex times more plausible, don't you?

I don't get all the hate for the simulation hypothesis, though. What if the simulators are advanced humans? They might be interested in us because they like to simulate alternate versions of their past. Maybe they can simulate a quantum mechanical universe and solve problems associated with the embedded lattice QCD or whatever because they've coupled the simulation to a "real" quantum mechanical experiment or quantum computer. Anyway, there are probably ways to deal with any of the sundry criticisms and perceived implausibilities. In my mind it puts the simulation hypothesis on firmer ground, scientifically. There must be a non-zero probability the simulators will eventually plaster "Oh, all right, you got us; yes, you're a simulated brain in a fancy jar" across the heavens before rebooting. There's zero probability we will observe other bubble universes beyond our causal horizon. Which is where they all must be, apparently.

Not that either is more useful for solving current problems with physics, nor more or less ridiculous to debate professionally.

61. **Peter Woit**
April 9, 2016

All,
I'm now deleting any more comments explaining why the simulation argument is stupid. Yes, it is. Comments about the panels are fine, what's intriguing here I think is why very smart people are involved in such a dumb argument, not the argument itself.

62. **anon-e-mouse**
April 10, 2016

Having programmed for most of my life the temptation to see the world through the eyes of coding is irresistible ("What the heck is the state machine for this flower?"). I get that, it makes sense, it is my suspicion that all immersive disciplines experience their own unique filters on the world. However, every programmer takes shortcuts, and bugs are only bugs if users find them. So consider the downside. The universe may not have been QA approved for shipping yet…it may not even be a fully functional alpha release…

63. **BittenByBits**
April 10, 2016

Seriously, I think the only reason for this "the universe is a simulation" nonsense is because people who spent too much time coding instead of doing real math or physics
(1) have experienced a self-induced delusion where they start thinking everything is really 0's and 1's
and/or:
(2) want to believe their time hasn't been wasted learning arbitrary rules, and that they are really onto something much more profound, thus wasting everyone else's time with "serious" speculations which are amusing only when turned into science fiction by a talented author, and which were always tongue-in-cheek in the first place, except possibly in the case of Philip K. Dick, who was not only an amazingly creative writer but battled very real paranoia and schizophrenia.

Exhibit A: Wolfram.

64. **Another Anon**
April 11, 2016

" why very smart people are involved in such a dumb argument"

Physics has always been influenced by the technological advances of the day. As an example, steam power influencing the development of thermodynamics.

65. **Tammie Lee Haynes**
April 11, 2016

Dear Dr Woit

In re “the Universe is a simulation”
Have you ever heard of anything more creationist, in the literal sense?

Starshot

April 12, 2016
Categories: Uncategorized

I don't know what this is about, but Stephen Hawking and Yuri Milner are here in New York today, with a press conference downtown scheduled at noon, supposedly to announce a mysterious new space exploration initiative, to be called Starshot. There's also evidently some sort of Columbia connection, with a reception scheduled up here. More later, when we find out what this is all about. Last year there was a Hawking/Milner announcement of Breakthrough Listen and Breakthrough Message, projects related to communication with alien civilizations.

Update: Livestream will be available here.

Update: According to this source (and Google translate…), this is a project to send a small space probe to Alpha Centauri.

Update: "Breakthrough Starshot" is a $100 million research program, hoping to develop (ultimate cost of order $10 billion) very small probes attached to light-sails, pushed towards Alpha Centauri by ground-based lasers (a "Silicon Valley approach to spaceflight"). The claim is that such things could travel at a significant fraction of the speed of light, get there in 20 years or so. One thing I'm not seeing is how you get a signal back to earth.

Update: They have a website here, there's a story at the New York Times here, at Scientific American here.

One thought about this is that if you really could accelerate probes this way with lasers, sending them out to solar system planets in days would seem to be a more interesting application.

Update: A more detailed story is here.

Comments

1. **S**
   April 12, 2016

   That is the genius part. The probes will be loaded up with literature about the multiverse. When the Alpha Centaurians find out about the scientific virtuosity of earthlings, they will come up with their own way to send a signal back to earth.

2. **Art**
   April 12, 2016

   Light sails accelerate slowly, but they accelerate constantly. A mission to a solar system planet might not be much faster than conventional rockets because it would take so long to get up to that 0.2c speed. Once it gets there though… zoom.

   I'm sure communication will be one of the significant engineering challenges. One of the things I'd investigate is if you could have the sail change its shape to modify the reflection of the driving laser and still see the reflection back on Earth.

3. **Peter Woit**
   April 12, 2016

   Art,
   The plan seems to be to accelerate very quickly (days?) with very high powered earth based lasers, using the fact these things are so light.

   Another problem I saw someone pointing out: can you decelerate at Alpha Centauri?

4. **Low Math, Meekly Interacting**
   April 12, 2016

   If the thing is small, then I would imagine there's no way at all to decelerate (short of a collision), unless the Centaurians have some powerful lasers of their own.

5. **NoGo**
   April 12, 2016

   Some details there:
   http://arstechnica.com/science/2016/04/breakthrough-starshot-announces-plans-to-send-ship-to-alpha-centauri/

   On acceleration, for example:
   "Propulsion will be outsourced to a facility on Earth. The small spacecraft will be equipped with a light sail, and a phased array of lasers in the 100GW range will provide the sail with enough push to get the craft moving at roughly 20 percent the speed of light in just a matter of minutes."

6. **anon**
   April 12, 2016

   What about all those poor birds and monarch butterflies flying into the 100 GW laser beam? Pretty soon they will need bird traffic controllers…

7. **cedric bardot**
   April 12, 2016

   The roadmap for interstellar laser driven spacecrafts has been thoroughly outlined by Philip Lubin in http://arxiv.org/abs/1604.01356

8. **Robert**
   April 12, 2016

   This concept is the engineering equivalent of String Theory. You end up with a lot of PR but nothing useful in the long run.

9. **NoGo**

April 12, 2016

List of challenges:
http://breakthroughinitiatives.org/Challenges/3

10. **Jakob**
April 12, 2016

The deceleration part seems like a big problem and I would be very interested in how this could be achieved safely (a very robus parachute maybe?). In the roadmap Cedric linked to the possibility to accelerate larger spaceships with the same method sounds like a really intriguing next step. Although I'm quite sceptical at the moment, I think it's awesome that such a bold, alternative idea gets funded.

11. **AcademicLurker**
April 12, 2016

Another problem I saw someone pointing out: can you decelerate at Alpha Centauri?

Important consideration. In case there's an advanced alien civilization in Alpha Centauri, it would be pretty rude to send even a small space craft slamming into them at 0.2c.

12. **Low Math, Meekly Interacting**
April 12, 2016

Per cedric's reference:

"Thus a 1 kg spacecraft going at 0.3 c will have an effective "yield" of 1 MT or roughly that of a large strategic thermonuclear weapon."

No way in Hell that thing is slowing down, even if it's a ship-on-a-chip.

Note the word "deceleration" doesn't even appear in the article.

13. **Dale C.**
April 12, 2016

There is no need for deceleration. At solar system scale, even at 0.2c there is plenty of time to snap a few pictures when you fly past. I am curious about communication back to earth. The communication appears to be laser-based, but how can that be detected at a huge distance to earth from a device weighing a few grams?

14. **Low Math, Meekly Interacting**
April 12, 2016

Assuming it's a wafer craft, what kind of detail could you resolve with optics that tiny (presumably on the order of what my iPhone can boast)? It would traverse the Earth-Moon system in roughly five seconds. How close does it have to get to something to improve on the space telescopes we'll have when that thing finally arrives? If you needed to be a few million kilometers away for a productive flyby of a planet, is it possible to aim that precisely over those distance and time scales without being able to adjust trajectory? I guess they must be thinking of these sorts of things, but tall order indeed.

15. **lzp**
April 12, 2016

Can a laser beam be focused to achieve such an incredibly small divergence at such distances? A related question: how large is the best focused laser dot on the Moon–I kind of recall ca. 1 km in diameter?

16. **Steve Huntsman**
April 12, 2016

Quoting from the Economist story on this: "At its destination it would beam back pictures of the star's planets with its on-board laser. No current observatory could possibly pick up such a signal—but the kilometre-wide launch array should be able to. The optical systems used to meld the output of the lasers could be used in reverse as a vast and sensitive telescope."

17. **JackLothian**
April 12, 2016

One of my favourite low-brain activities is reading science fiction. I will have to read it & see how it compares with Larry Niven novels.

18. **M**
April 13, 2016

A photo taken at $v \approx c$ would be an interesting demonstration of relativity, even without going to Alpha Centauri

19. **Hans**
April 13, 2016

Of coarse anybody is free to think/believe that there are 'aliens' out there and fantasy about technology to contact 'these things' – but actually doing so is not to decide to the likes as 'some nutty professors' and/or 'some wealthy Santa Clauses' – this is first and fore all a serious political issue that concerns us all and should be dealt with at the UN or so.

20. **Avattoir**
April 13, 2016

[What's with all these negative waves?]()

Sure, maybe there's no way to decelerate the little wafer ships, or retrieve and relay back here pictures or data of any kind, and maybe all that ends up happening is firing off the equivalent of an armada of thermonuclear devices that'll vaporize anything any of them strike. But why isn't anyone posting how beautiful this all is, something righteous and hopeful for a change?

21. **Daniele V**
April 13, 2016

At 0.2c even a very small dust particle could destroy the probe if they clash, this is also a big problem.

22. **bugannoyer**
April 13, 2016

I'm sure their engineers have thought of this, but since I didn't see it addressed in the articles, I'd wondered how they intended to deal with the likelihood of radiation damage from ambient particles impacting the electronics at ~.2C.

23. **Low Math, Meekly Interacting**
April 13, 2016

This multi-kilometer mirror array…it can theoretically receive a data stream from something like a laser pointer 4.4 light years distant. If you made two of these things half as big each and used it as an interferometer, what could you resolve at the same distance? I'm just not getting why one would spend that kind of money to send a downsized 2MP phone camera to the closest star system under the proposed conditions when much of the required technology would apparently yield an instrument with such sensitivity to light in the (I assume) visible spectrum. It's a ginormous laser cannon, but it's also the most amazing light collector anyone has dreamed of building. Avattoir has a very good point: we can strafe Alpha Centauri with a hail of kiloton kinetic energy ordnance, or, you know, maybe just look at it.

24. **Ben**
April 13, 2016

The likelihood of them getting destroyed is why they launch so many.

As far as the damage the probes themselves could do… even at 0.2c, a few grams is more in the kiloton range, and detonations that large (from meteorites) happen in our upper atmosphere reasonably often, sometimes without anybody on the ground noticing (without specialized instruments).

I think "phoning home" is really the biggest problem. It's not just a question of increasing sensitivity, because if the signal is that faint than other sources and noise will be present as well.

25. **Herr Weh**
April 13, 2016

At this point it seems more like a research project for interstellar travel in general rather than an already fixed proposal with predetermined details. What counts – and I think that is very interesting – is that somebody came up with real money to actually get it on. Definitely better use for his money than some of the other projects Milner has funded. For those interested in interstellar travel I recommend following Paul Gilster's excellent Centauri Dreams blog. Here's his take on the Starshot project: http://www.centauri-dreams.org/?p=35402

26. **Low Math, Meekly Interacting**
April 13, 2016

Looks like it'll be a 1 watt laser sending bursts of telemetry, so relatively much more powerful (during a burst) than a laser pointer at least should be. The array will reportedly receive 10-14 of the photons transmitted, assuming it can be aimed, because the beam would only be about 1000m wide, if the sail can focus it well enough.

This is all obviously way, way beyond me.

27. **paddy**
April 13, 2016

What makes me think that long before these cell phone probes arrive for their flyby, solar system based technology will have learned all about Alpha Centauri?

28. **vmarko**
April 13, 2016

I have a feeling that the Starshot project is similar in many aspects to the Mars One project. In short, it's a nice-sounding idea that attracts a lot of attention and wishful thinking, sounds plausible when looked at naively, but is ultimately burdened with some insurmountable engineering problems which eventually render it fail. The devil is in the details, as usual.

Hopefully they'll prove me wrong. 🙂

🙂
Marko

29. **Ken Wrona**
April 13, 2016

The probe can most certainly be decelerated. If aimed squarely at the host star it will decelerate from photon pressure. The question is whether it will be destroyed before it reaches a sufficiently slow speed. The Lubin roadmap isn't sanguine about this but it is discussed. There are a lot of variables.

Anyway, this is an interesting engineering project that should rightly be undertaken with private money. It's likely that a lot of interesting things would be learned.

30. **Jesper**
April 13, 2016

I think that the best solution to the "phone home" problem would be to kindly ask the Alpha Centaurians to make the call for us. I mean, if you live in the Alpha Centauri system you must have some super-cool powerful equipment and surely you won't mind making a collect call for a crazy flyby probe that hurtles through your system at near light speed

31. **SunJammer**
April 13, 2016

From Wikipedia article, "Sunjammer":

“Sunjammer” is a science fiction short story by Arthur C. Clarke, originally published in 1963,[1] and included in the March 1964 issue of Boys’ Life. The story has also been published under the title “The Wind from the Sun” in Clarke’s 1972 collection of short stories with this title. It depicts a yacht race between solar sail spacecraft.

Plot Summary:
John Merton, a spaceship designer, develops and promotes a lightweight spacecraft with a large area of solar sail, to be powered entirely by radiation pressure—the so-called wind from the sun. The sun-yachts start their journey in Earth’s orbit, and, pushed simply by sunlight, can achieve a speed of two thousand miles an hour within a day.

The concept leads to the development of the sport of sun-yacht racing, and after several years of refining his ideas, Merton competes in what will be his final race. His hopes for victory rest on the low mass of his craft which he has made possible through advances in automation enabling him to fly it solo.

Soon, all but two of the competitors have dropped out, mainly due to damaged craft, and it is a straight race between Merton’s craft and Lebedev, entered by a Russian crew from the University of Astrograd. Although the Lebedev is lagging Merton’s yacht, its senior pilot delivers a surprise blow by announcing that he plans to jettison his co-pilot in an escape capsule now that the earlier, navigationally intensive part of the race has finished.

Merton responds by recalculating his expected margin of victory and realises that the race is now going to be neck-and-neck at the finish line. At this point news arrives of a massive, and potentially deadly, solar flare. The race has to be abandoned, and there is no winner, though Merton abandons his craft with its sail still fully extended in order to ensure that it will be blown into interstellar space.

Planned 2014 solar sail mission

NASA planned to launch a solar sail technology demonstration mission titled ‘Sunjammer’. The title is a reference to the story.[3] The mission was cancelled in October 2014.[4]
…………
Comment: of course the nano-idea and use of lasers is a new twist on this idea.
Don’t know if Clarke was the first to think of it, but my memory was jogged by this
item and I remembered some great story by him, so thanks to Google, in one second I had found it!

32. **Ralph**
April 13, 2016

Re comms back to earth, another problem: receiving a very weak signal requires very fine tuning. But the tuning will have large uncertainties…

The signal from the probe will have a large doppler shift. In principal you just change the tuning of your receive to compensate but…. Any residual drag from radiation pressure etc will cause a drift in the doppler shift, destroying the tuning.
The latter tune drift is proportional to frequency, so using lasers not radios for communications makes this orders of magnitude worse.

Multi kilometer phased array operating at very-precise-but-constantly-changing optical frequencies coping with both 100GW and sub attowatt power levels?

Also, what will be the heat load from interplanetary / interstellar gas at 0.2c? Changing temperatures will cause further frequency drift on the source making the comms even more challenging.

33. **In Hell's Kitchen (NYC)**
April 13, 2016

Let’s hope the Centaurians don’t mistake Yuri’s armada for a relativistic weapon and retaliate: https://en.wikipedia.org/wiki/The_Killing_Star

34. **ZZZ**
April 13, 2016

A related idea is to use ground based lasers to heat propellants in a spaceship to achieve much higher specific thrust than possible with on-board chemical energy. Some national governments have been pursuing this for a while.

35. **MikeS**
April 14, 2016

Whatever the engineering merits of this project, it is clearly intended in the realm of space exploration rather than SETI.

If we really though there was intelligent life at Alpha Centauri then it would make more sense to just send the laser beams – with some suitably encoded data – and wait for the Centaurans to fire back.

36. **anon**
April 14, 2016

In principle you can actively decelerate a craft like this the same way you accelerated it – incorporate a detachable mirror that reflects the laser beam backwards onto the main craft, whose light sail is turned around once it has detached from the mirror – the mirror would of course be rapidly accelerated away from the main craft. In practice, this would need the ability to maintain a near-earth-based laser focused over interstellar distances. I have no idea if that is practicable.

37. **Paul D.**
April 26, 2016

This idea requires multiple engineering “miracles”, many of which would be very useful for other applications by themselves, even at lower levels of performance. So I’m not sure why he’s funding this instead of going after the pieces individually.

Example: he imagines reduces the cost of the continuous lasers from \$10/W to \$0.10/W. At that cost it becomes feasible to power aircraft via lasers in orbit (no CO2 emission, unlimited range, no fuel weight.)

As for sending spacecraft elsewhere in our solar system: the likely application there would be beamed power for plasma engines, like Hall thrusters or VASIMR, with an exhaust speed of perhaps 100 km/s. The power and energy requirements would be orders of magnitude lower than if one used light pressure for thrust.

Various and Sundry

Categories: Uncategorized

Some quick links:

- Via my Columbia colleague at Mathematics Without Apologies, a documentary about Perelman that I was unaware of.
- I learned something yesterday about another math department colleague, Mikhail Khovanov: he has games called Ringsanity and Ringiana available as apps.
- Took a quick look at a Stephon Alexander's new book The Jazz of Physics, which is now in bookstores. While I enjoyed reading some of his account of his career in theoretical physics, I'm afraid that his two main topics, jazz and models of the big bang, both are things that pretty much leave me cold. For those with more interest in either topic, you probably should take a closer look.
- I'm sorry to see that there's some sort of fight developing over Grothendieck's papers. A shame.
- Previous attempts to figure out what "ER=EPR" is supposed to mean have left me baffled. Trying to read Susskind's write up of his IAS lectures on the topic hasn't helped, I'm afraid.

Update: Mikhail Khovanov tells me that Ringiana for Android can be found here. It was developed jointly with Nikolay Gromov.

He also comments that "Thompson groups V and T act on the states of Ringiana and Ringsanity, correspondingly. These groups were the first two infinite, finitely-presented, simple groups discovered by mathematicians."

Comments

   April 14, 2016

   I am looking forward to see some content in English about the fight over Grothendieck's papers.

2. **Yatima**
   April 14, 2016

   Reste à savoir quelle est la valeur de ces archives. "Difficile à dire, tant que l'université refuse tout échange avec nous", poursuit l'avocate, "mais on peut imaginer que des grandes universités américaines avec beaucoup de moyens seraient prêtes à payer le prix fort."

   The relatives' lawyer says that the value of those documents (apparently hidden somewhere in Montpellier in a secret vault and being scanned to the tune of 45KEUR but with no intention of publishing them – indeed it seems Grothendieck did not want them published in the first place) is difficult to judge as the university refuses to engage but that big monied american universities would be willing to lay down large wads of cash.

   It sounds all pretty sordid.

   That article has a weird last paragraph saying that Einstein was a major factor of "The Bomb" (oh really?) and that no-one knows what might come out of Grothendieck's stash of unpublished notes. Huh.

3. **ptmalloy**
   April 14, 2016

   Are there Android versions of the two games? Just looked for Ringsanity, but could not find it in the Google Play store.

4. **Anonymous**
   April 14, 2016

   ptmalloy,
   "Ringiana is available for both iPhone and android, while Ringsanity you can get for iPhone, with android version in the works."
   http://ringsanity.blogspot.com/2016/03/mathematics-of-ringiana-and-ringsanity.html

   It can be downloaded from here:

5. **ptmalloy**
   April 15, 2016

   Anonymous,

   Thank you very much! I will look for it.

   ptm

6. **Bill**
   April 16, 2016

   I am curious what was Mikhail motivation to create those apps…

7. **Abel Molina**
   April 17, 2016

   Wow, Ringsanity looks really cool. Thanks for posting the links, gonna get it for sure!

8. **Davide Castelvecchi**
   April 20, 2016

What I find interesting about the documentary on Perelman is that there is no mention whatsoever of his Jewish heritage — or of the antisemitism he had to fight during his life as a student in St. Petersburg. Masha Gessen gives the full story in Perfect Rigor, her superb biography of the man.

The Man Who Knew Infinity

April 16, 2016
Categories: Film Reviews

Last night I went to see a showing at the Tribeca Film Festival of the new movie about Ramanujan, The Man Who Knew Infinity. It was extremely good, infinitely better than the most recent high profile film about a mathematician, the one about Turing (see here).

The story of Ramanujan is one of the great romantic stories of mathematics, with a large part played in it by the Cambridge mathematician G. H. Hardy. The filmmaker was inspired by Robert Kanigel's excellent 1991 biography of the same name (he says his mother gave it to him to read, she had it through her book club). The book is an excellent source for the story of Ramanujan's life, and Hardy's A Mathematician's Apology is something everyone should read (for one thing, it's short). For some more about the film from an expert on Ramanujan's work, the AMS Notices have this from George Andrews.

Some dramatic license was taken, for instance in having Jeremy Irons play Hardy as a much older man than he actually was when he met Ramanujan. After the film there was a panel discussion, with filmmaker and screenwriter Matt Brown explaining that it took 10 years to get the film made, largely because of the difficulty of financing it. He claimed that he could have gotten the financing much earlier if he had been willing to go along with certain plot changes the financiers wanted: in particular they wanted the story to revolve around a love affair of Ramanujan with a (white) nurse, to be played by a high-profile starlet.

Also at the panel discussion were two mathematicians: Princeton's Manjul Bhargava and my Columbia colleague Ina Petkova. One reason the film is so true to the real story of the mathematics and mathematicians involved in it is the involvement of Ken Ono and Bhargava. Ono was heavily involved in the filming (and he has a memoir from Springer, My Search for Ramanujan, about to appear). Bhargava was involved in the editing, in particular in helping choose among the many takes of the actors acting out a mathematical discussion those which seemed true to life.

The film is supposed to be released here in the US on April 29, I can't recommend it enough.

Update: Scott Aaronson has a far better review of the film than mine here.

Comments

1. **Hugh Osborn**
   April 16, 2016

   The film skates over that Ramanujan married his wife when she was 10 (arranged by
   his mother) and left here in India when she was 15, very different from the impression
   in the film.

2. **Peter Woit**
   April 16, 2016

   Hugh Osborn,
   Thanks. Unlike the mathematics, the part of the movie about his wife didn't ring true, but I had forgotten about the real story there (read the biography over 20 years ago). I guess what went into the movie was a half-way compromise between the true story and the steamy romance with the British nurse.

3. **Fernando**
   April 16, 2016

   The other concession to cinematic tastes is that the actor playing Ramanujan is quite thin. As the photos show, Ramanujan was a little chubby until he got sick.

4. **Peter Woit**
   April 16, 2016

   Fernando,
   Yes, and the film starts out with a shirtless hot-bodied Ramanujan. Not clear if mathematicians should strenuously object to this kind of taking of cinematic liberties.

5. **Dav**
   April 16, 2016

   If I had the time & means, I'd love to one day make a movie about the mathematician Évariste Galois.

6. **Tim May**
   April 18, 2016

   I finally caught the Turing movie. About like the Hawking movie. A lot of mawkishness, not much of the science. (I thought about 2 minutes of "A Beautiful Mind' captures some of the mathematics of Nash..the rest was garbage.)

   I hold out little hope for films about major mathematicians or physicists.

   It wasn't very different 50 years ago–I was there– and we survived it.

7. **Daniel**
   April 18, 2016

   I wonder why no one has ever made a serious biopic of Einstein.

8. **Visitor**
   April 18, 2016

   My guess is that Einstein because lived a fairly public life it would therefore be rather more difficult to present the tissue of lies, falsehoods, misrepresentations, and distortions necessary to make the kind of "dramatic" and "absorbing" movie that has any hope of being financed.

   (And there might be the secondary problem of Einstein's appearance being too familiar to people: any actor portraying Einstein would look unlike him, and suspension of belief become rather difficult: the movie's psychological mechanisms wouldn't work. As an extreme example of a different sort, portraying Hitler seems an almost hopeless task; the only good movie portrayal is by Ganz, and even then it seems to take viewers quite a while to accept him. Chaplin's portrayal is also good but required a fundamentally different sort of movie in which to work.)

9. **Robert Matthews**
   April 18, 2016

   Must admit I was somewhat put off going to see The Man Who Knew…by the trailer, which shows Ramanujan bearing the brunt of racism. As far as I can tell, my battered copy of Kanigel's bio contains no evidence, so have put the film in the "Reality Just Isn't Interesting Enough" category (along with the recent Turing and Hawking bios).

   Maybe I should reconsider ?

10. **Parth**
    April 18, 2016

    Thanks for this positive review. I'm wary of such films, but having Bhargava and Ono on board brings optimism. Now I'm looking forward to the screening here in Sydney Australia (proper release date here is 5th May but going for advanced screening).

11. **Peter Woit**
    April 18, 2016

    Robert Matthews,

    It's likely the film overplays the extent of overt racism encountered by Ramanujan. It's not a documentary, takes lots of liberties with the true story. But what I think is admirable is that it does a good job of getting the core of the story right, the mathematics and the relationship of Hardy and Ramanujan.

12. **Jim**
    April 18, 2016

    The worst cultural assault that poor Ramanujan suffered was the horrible food he was forced to consume in Britain, which most likely led to his early demise. World War I war-time Britain wasn't so accommodating to vegans.

13. **Edward Friedman**
    April 18, 2016

    Actually, there are several dramatizations of Einstein. Check on YouTube

14. **Avattoir**
    April 19, 2016

    Prof Woit, at first I misread your second comment in this thread as, effectively, 'this kind take on mathematicians'.

    Hardy's notorious fondness for cricket, including in setting matches into which he led teams of mathematicians against teams of other schools, and most especially the photo of him leading a team of English mathematicians "against [mathematicians from the rest of] the world", was dadsplained by my late father – who was in the business (of maths & physics, tho also an amateur thespian, cricketer, footballer and knew several of these characters, served to inspire [this bit of comedic art.]

15. **Tim May**
    April 19, 2016

    About Ramanujan dying from having only British food to eat, I am skeptical.

    I think I read this about 50 years ago, probably in Bell's "Men of Mathematics."

    Having eaten some British food, having lived on a variety of various fast foods, having cooked as a bachelor, I think R. must have had some other issues, or some disease, etc.

    I think the meme that R. died from eating British food is just too facile, too much part of some popular meme. I haven't seen the new film, but I hope it doesn't perpetuate this meme (unless it justifies it).

16. **Peter Woit**
    April 19, 2016

    Tim May,
    "The Brits killed Ramanujan with their food" is a suspiciously provocatively entertaining meme. I think though the film portrayal of this is quite plausible: he is shown trying to eat in the college, being unable to get vegetarian food not cooked in lard. He's also shown having a lot of trouble trying to do his own cooking in his room. It's all too plausible that he had grown up without learning to cook, and that this together with difficulty in getting foods that fit his dietary restrictions led to health problems. His death is often attributed to tuberculosis, but whatever it was, it wasn't just malnourishment, because his health deteriorated and he died after returning to India, where presumably he was getting an appropriate diet.

17. **Avattoir**
    April 19, 2016

    Tim May, this seems to capture the consensus from the mid-1990s:

    "hepatic amoebiasis … that can result in dysentery [if] not treated properly", supported generally by a lot of evidence of Ramanujan suffering from chronic poor health since childhood, and most particularly by "two bouts of dysentery before he left for England", resulting in vulnerability to "lifestyle changes" capable of aggravating the living amoebae to the point capable of killing the host.

    FWIW my two English grandparents lived to 85 and 101 respectively, and the only one of their children who remained in England lived to 87 – a decade beyond any who moved elsewhere, including here.

18. **dom**
    April 19, 2016

Jim
As a native of these islands, I can confirm that vegetables do indeed grow in the ground and fruit trees work too. Additionally in wartime a much greater effort was made in growing these. They may have been different fruits and vegetables to southern India I grant you.

19. **srp**
April 19, 2016

This legend is as good as the one about Descartes being killed by having to get up early in cold weather because of the whims of Danish royalty.

20. **Stephane**
April 20, 2016

Linked to this film, see: https://www.youtube.com/watch?v=yvHrn-41XMU

"Where does mathematical genius originate and what does it tell us about the human mind? Join us for "The Infinite Mind: Exploring Mathematical Genius," as we explore these and related themes with mathematicians Manjul Bhargava and Steven Strogatz, together with Matt Brown, director of The Man Who Knew Infinity, a new film about Ramanujan to be released in April, starring Jeremy Irons and Dev Patel."

21. **Neeti Sinha**
April 22, 2016

Appreciate the inside information, have been waiting for it.. and look forward to seeing it. Although from the trailer, I did think too that the racism part was overdone, as that tends to happen in such historical takes, and might not be the truest picture.

22. **J. Pooh**
April 27, 2016

Recommended: 'N is a Number', a biopic film about Paul Erdös.

Nearly impossible to buy (unavailable new?, used DVD overpriced), but easy to find online. YouTube downloader app is useful for keeping a copy.

23. **Peter Lund**
April 28, 2016

Re. Descartes: Swedish royalty. The reigning Queen, actually. (Who was incidentally officially called "King" in Swedish because she actually ruled.)

https://en.wikipedia.org/wiki/Christina,_Queen_of_Sweden#Visit_from_scholars.2C_musicians_and_Descartes

24. **srp**
May 1, 2016

Saw "The Man Who Knew Infinity." Enjoyed by both my spouse and I.

Jeremy Irons's Hardy, whether accurate or not, seems like a real person you could meet on the street–excellent performance. They really overdid the ethnic prejudice angle, I think, and they skated over the fact that Ramanujan had actually published a couple of things in Indian journals before sending his letter to Hardy. But by traditional Hollywood biopic standards (e.g. black-and-white studio classics like the Paul Ehrlich and Marie Curie films) this movie was true to the main lines of its subject's life and caught the spirit of mathematical discovery pretty well, as far as I can tell from reading some history of the field.

This Week's Hype

April 19, 2016
Categories: This Week's Hype

It occurred today that the past year or so there haven't been as many editions here of This Week's Hype, with in particular the previously common "Scientists finally find a way to test string theory!" stories now less common than they used to be. What is often replacing bogus claims about testability though is just unvarnished hype about string theory, minus any claims that it can ever be tested. Examples I've run into today include Cumrun Vafa's Fundamental Lessons From String Theory presentation at the April APS Meeting, which tells us that

> String theory is leading to a revolutionary revision of many fundamental and long held principles of physics

despite a lack of any connection to experiment, either now or in the future.

In the local bookstore I took a look at Christophe Galfard's The Universe in Your Hand, which builds up to a final chapter with some sort of rather incomprehensible voyage with a robot to the string theory multiverse. Nothing anywhere to be seen there about whether this might be science or fantasy. Jennifer Ouellette has a review in the New York Times here.

While mulling over these thoughts about the new prediction-free environment for string theory, I noticed that an article has just appeared that seemed to contradict such thoughts, Natalie Wolchover's Physicists Hunt for the Big Bang's Triangles, with a headline claiming that "evidence for string theory" could be found in the sky. It's by far the best popular piece I've seen about "string cosmology", giving an excellent idea of what people in that field are up to these days (which includes large amounts of hype, coming from the scientists, not the journalist).

In summary, here's what we learn about current string cosmology. One of the main targets is a "prediction" of the level of non-gaussianity in the CMB, something which all observations so far have shown to be unobservably small:

- Matthew Kleban and Eva Silverstein are described as "cosmological clocksmiths", working out the non-Gaussianity "predictions" of a large range of string cosmology models. It seems that you can get any number you want this way by an appropriately complicated model. Kleban likes unwinding inflation and we're told:

  > "I think it's pretty plausible that some version of this happens," he said.
  >
  > Though Kleban acknowledges that it's too soon to tell whether he or anyone else is on to something, plans are under way to find out.

  Silverstein has "many string inflationary models" of all sorts, so can get you one with any amount of non-gaussianity you might want. As far as she is concerned, having plenty of complicated models with zero evidence for any of them, such that, no matter what you see or don't see, there's always lots more and more "predictions", is a perfectly traditional kind of science. Her reaction to people pointing out the problems with this?

  > I find it surreal, because we are currently doing some traditional science with string theory.

- Her Stanford colleagues Andre Linde and Renate Kallosh are taking a different approach, promoting theories with no observable non-gaussianity, and, it seems, no observable effects at all:

  > Linde isn't bothered by this. In supporting the alpha-attractor models, he and Kallosh are staking a position in favor of simplicity and theoretical beauty, at the expense of ever knowing for sure whether their cosmological origin story is correct. An alpha-attractor universe, Linde said, is like one of the happy families in the famous opening line of Anna Karenina. As he paraphrased Tolstoy: "Any happy family, well, they look in a sense alike. But all unhappy families — they're unhappy for different reasons."

- On the East Coast, there's Arkani-Hamed and Maldacena, with a paper last year on Cosmological Collider Physics. It described observable signatures of new physics at the inflationary scale, but the only comment I could find about how you would actually observe such things was

  > In terms of measurability, if the couplings are Planck suppressed, then it seems impossible to measure this through the CMB or large scale structure. (See e.g. for a discussion of measuring these effects via large scale structure.) But it might be possible using the 21cm tomography .

  Arkani-Hamed explains to Wolchover that there's a "cosmic variance" problem making things inherently unobservable, but he removed most discussion of this from the paper, hoping to get around it by changing the laws of quantum mechanics:

  > In his paper with Maldacena, Arkani-Hamed initially included a discussion of this issue, but he removed most of it. He finds the possibility of a limit to knowledge "tremendously disturbing" and sees it as evidence that quantum mechanics must be extended. One possible way to do this is suggested by his work on the amplituhedron, which casts quantum mechanical probabilities (and with them, unitarity) as emergent consequences of an underlying geometry. He plans to discuss this possibility in a forthcoming paper that will relate an analogue of the amplituhedron to non-Gaussianities in the sky.

  There has been further work on this by Kamionkowski and collaborators, and we're told:

  > Observing the signals predicted by Arkani-Hamed, Maldacena and Kamionkowski would be like striking gold, but the gold is buried deep: Their strength is probably near the gravitational floor and will require at least 1,000 times the sensitivity of current equipment to detect.

  No word on prospects for more than 1,000 times more sensitive experiments.

For about as long as I can remember, string cosmologists have been promising that their ideas would be tested by the Planck experiment. Now that negative results are in from that, we're told to instead look forward to a new generation of experiments. The ones mentioned in the article are SPHEREx and the LSST, with results next decade. SPHEREx claims that they may be able to push down bounds on non-gaussianity by a factor of 10, which would be an impressive result. This would rule out lots of string cosmology models, but of course there would still be plenty more.

The next experiment all involved are talking about is looking for signals in the 21cm hydrogen line, see Sabine Hossenfelder here for more about that. No time estimates on that one. As far as I can tell, the plan for this starts off with "First, build a base on the other side of the moon…"

Comments

1. **Bee**
   April 20, 2016

Peter,

The radio telescope on the moon is a dream experiment that, if it comes into being at all, will take decades of planning and construction. But there are already experiments measuring the 21cm line – like LOFAR and MWA – which I mention in my article (which you can btw read without the ad clutter here). So there will probably be first data in a few years.

And on the issue of experimental tests, I am (again) organizing a conference on quantum gravity phenomenology. (Which hasn't been announced yet, we only just got the website up.)

2. **M**
April 20, 2016

String models tend to make one "prediction": field excursions have sub-Planckian size. Unfortunately this implies that it's difficult to get inflation: the Lyth bound demands super-Planckian field excursions if the tensor/scalar ratio is large enough to be detectable. That's why most research in "string inflation" is inventing ad-hoc models that avoid the "prediction" and can give unusual features. Anyhow, the works that aim at reconstructing more primordial fluctuations from large-scale structures are interesting.

3. **Bayes_or_bust**
April 20, 2016

Peter,

What are your thoughts about Kane's preprint

The lightest visible-sector supersymmetric particle is likely to be unstable

Bobby S. Acharya, Sebastian A. R. Ellis, Gordon L. Kane, Brent D. Nelson, Malcolm J. Perry
(Submitted on 18 Apr 2016)

http://arxiv.org/abs/1604.05320

a generic prediction of ST: DM will be uncharged under SM gauge groups. The reasoning is actually simple, and doesn't require any technical details of ST. I'm not sure why no one's emphasised this point before.

4. **Shantanu**
April 20, 2016

Sabine: congratulations. I am happy you were able to procure funding for this meeting.
Peter: Jerome Martin wrote ~ 400 page review paper doing a laundry list of ALL models of inflation. Almost every BSM /QG theory has some model of inflation associated with it. Even I have written a paper on model of inflation arxiv:1510.08834 🙂 So I wish journalists take such string theory inspired models of inflation with a grain of salt.

5. **Peter Woit**
April 20, 2016

Bayes_or_bust,

This looks like the usual Kane way of doing science: for many years X is advertised as a "generic prediction" of string theory, about to be tested, then when X is not found, the discovery is made that "not X" is a "generic prediction" of string theory. The latest effort fits into the theme of this posting, with the new "generic prediction" of string theory that there won't be observable effects of string theory.

6. **AcademicLurker**
April 20, 2016

Slightly OT, so feel free to delete, but as a break from string theory hype, Matthew Buckley over at the Boston Review is doing a series of articles trying to explain quantum field theory to a general audience: http://www.bostonreview.net/books-ideas/matthew-buckley-search-new-physics-cern-part-2.

I'd be interested to hear Peter Woit's take on it.

7. **Peter Woit**
April 20, 2016

AcademicLurker,

Thanks, I had seen that, seems I forgot to mention it here. It's an interesting multipart series, with the idea to end later this year at the point when we find out if the 750 GeV bump is real, with the significance having been explained by the article. I'm glad to see somewhat of a trend towards trying to get some quantum field theory into popular articles, which is no easy task…

8. **Fred**
April 23, 2016

A question about the cosmological triangles sought (mentioned in Wolchover's article): since any trio of galaxies forms a triangle, is it more precisely *equilateral* triangles that will give a clue about inflation if they are found in greater number than predicted by chance?

For Your Reading Pleasure

April 21, 2016
Categories: Multiverse Mania

Since I just spent some of the morning not doing what I should have been doing, but reading about other things, in case you also want to do this, here are some options:

- I'm very excited to see an article at Smithsonian Magazine with the title Can Physicists Ever Prove the Multiverse is Real? (remember, answers always no to headlines). Unlike just about every other effort of this kind, the author (Sarah Scoles) brings up the obvious problems, quoting Carlo Rovelli:

> Some theoretical physicists say their field needs more cold, hard evidence and worry about where the lack of proof leads. "It is easy to write theories," says Carlo Rovelli of the Center for Theoretical Physics in Luminy, France. Here, Rovelli is using the word colloquially, to talk about hypothetical explanations of how the universe, fundamentally, works. "It is hard to write theories that survive the proof of reality," he continues. "Few survive. By means of this filter, we have been able to develop modern science, a technological society, to cure illness, to feed billions. All this works thanks to a simple idea: Do not trust your fancies. Keep only the ideas that can be tested. If we stop doing so, we go back to the style of thinking of the Middle Ages."

- John Horgan has a wonderful, very long, interview with Scott Aaronson. Highly recommended as a way to avoid work and learn all sort of interesting things from and about Scott, whose blog you should be reading anyway. If you want to discuss this, you likely can do so with the man himself here.
- If you just can't get enough of the multiverse, there's something else quite long available, a podcast of Sam Harris in conversation with Max Tegmark.

Comments

1. **Jeffrey M**
April 21, 2016

So in the Scoles piece Polchinski and Linde seem to argue that since the probability that everything comes out exactly the way it did in the universe, which makes life possible, is so low, there must be an infinite number of universes out there. Do they really not understand basic probability theory? Probability doesn't apply to single instances. Not that way. Why exactly doesn't anyone call them on this? Suppose you saw a random number generator, and you knew it generated numbers from 1 to 1000000. You see a 1 on it, does that tell you anything? No. It certainly doesn't tell you that there must be millions of random number generators out there since you happen to live with the one which is showing a 1.

2. **Peter Woit**
April 21, 2016

Jeffrey M.,
This is by now an ancient argument, I don't see any possibility of anything new being said about it, so would like to discourage anyone who wants to carry it on. You need a larger framework than our current physics to make sense of any of these issues of what is likely and what isn't. Linde et al. have one and are promoting it, the problem is that it's an empty, untestable one. Rovelli is right that this is going back to pre-scientific styles of thinking.

3. **John Fredsted**
April 22, 2016

A tiny correction: I guess 'Every' in the link to the article at Smithsonian Magazine should read 'Ever'.

4. **L**
April 22, 2016

Now, if we could stop addressing the "Middle Ages" like an intellectual wasteland, that would be great.

5. **Peter Woit**
April 22, 2016

John Fredsted,
Thanks, fixed.

L,
Good point. Whatever the failings of medieval theologians, I suspect they would have recognized the problems with multiverse explanations.

6. **Phil Koop**
April 22, 2016

I don't think that multiverse speculation is "an intellectual wasteland" a consequently I don't agree that comparing the speculators to medieval thinkers implies that the pre-modern era was an intellectual wasteland. One needs only a nodding acquaintance with history to be aware that medieval thought was rich, varied, and intricate. Indeed, the usual complaint of the student is that it was all too intricate.

But the fact remains that there is a basic qualitative difference between scientific and non-scientific modes of thought, and that the multiverse falls on the non-scientific side of the line. This is not to say that pre-modern modes of thought have disappeared, nor that scientific thought has no medieval or indeed classical antecedents. But today we (ideally) prefer to make decisions with a mode of thought that was alien to our forbears.

I really like Ada Palmer's treatment of this intellectual history in her "Sketched of a History of Skepticism" series (first post here: http://www.exurbe.com/?p=2725.)

> Science has not replaced religion–they coexist happily, productively, even symbiotically within many arenas, places and individuals, even as they chafe and vie in others. But in the modern West, the Scientific Method has largely displaced older systems for guiding daily micro-decision-making which were more closely tied to religion. We now use science-based reasoning a hundred times a day when we are called upon to make decisions. Whether making a sandwich, buying a new teapot or evaluating an argument, we think about data from past experiences, bring in what facts and hypotheses we have accumulated from educated and informed living, consider the credibility of sources, ask ourselves questions about plausability, probability, evidence and counterargument, speculate about the range of possible errors and outcomes …
>
> For my purposes today, the most important part of what I just described is that the belief or disbelief we extend to the politician (or to our teapot) is provisional …

April 23, 2016

The fact is that, despite the common conception, there's more in the Middle Ages than theologians. Universities were born, with its basic curriculum centring on logic in the trivium and four mathematical disciplines on four in the quadrivium (arithmetic, astronomy, geometry and music, seen as applied proportions); people studied, even empirically, every area of "natural philosophy"; in physics we have medieval thinkers derive the basics of dynamics and kinematics, discovering results often attributed to Galileo and his peers, and inquire the possible motion of the Earth, in addition to refining astronomical models; and in general, these people laid the basis of the scientific method.

A good short introduction on the matter can be read here.

8. **Denis Boers**
April 25, 2016

Peter,

I am a long time reader of yours, both your blog and the book,
and I am delighted to see your insistence on intellectual responsibility
is gaining traction. See for instance : https://arxiv.org/pdf/1604.06773

Keep up the good work, for science's sake !

Denis

Group Theory in a Nutshell for Physicists

April 22, 2016
Categories: Book Reviews

There's a new book out in the Princeton "Nutshell" series, Tony Zee's Group Theory in a Nutshell for Physicists. I liked his Quantum Field Theory in a Nutshell quite a lot, it's packed with all sorts of insights into that subject. Both books are written in a very light, chatty and entertaining style, full of various sorts of worthwhile digressions. Long ago I tried to use the QFT book in a course I was teaching, and there found that it functions better as a supplement to a standard QFT book. Zee's treatment is just too short, covering too much, to provide the level of detail most students need to learn the subject for the first time. For people who already have gone through a standard book or course, Zee's QFT book is great as a follow-on, likely to explain a lot of things they found confusing the first time around.

The new book on group theory has a length much better matched to the amount of material (it's longer than the QFT book, and the material covered is much less complicated). The level of detail for most topics should be a good amount for students encountering the subject for the first time. The main topics covered are:

- Finite groups and their representations.
- Unitary and orthogonal groups, their representations, and applications to quantum mechanics.
- Classification of simple Lie algebras.
- The Lorentz and Poincare groups and their representations, with a discussion of the Dirac equation and Weyl and Majorana spinors.
- A grab-bag of some other topics, including a little bit about conformal symmetry and grand unified theories.

While for each of these topics there are other good textbooks out there, this is a great selection for an advanced undergraduate/graduate physics course. I expect this to justifiably become a popular choice for such courses.

While I liked a lot about the book, I have to confess that there were things about it that did put me off. Some of this likely has to do with the fact that I've been working for the last few years on a book (see here) that covers some of the same topics, so I'm hyper-aware of both the technicalities involved, and the issues that arise of how best to approach these subjects. In addition, much of these topics is standard core mathematics, but Zee seems to have consulted few if any mathematicians (at least I didn't recognize any in his acknowledgements). Unlike some others, this is a subject where mathematicians and physicists really can communicate and teach each other a lot.

Some of the choices Zee makes that I don't think are good ones are things that input from mathematicians probably would have helped with. Maybe the most egregious is his decision to use the same notation for a Lie group and its Lie algebra, on the grounds that physicists sometimes do this, and to notationally distinguish the two in the usual way (upper vs. lowercase letters) is "rather fussy looking". Using the same notation for two very different things is just asking for confusion, and I remember struggling with this as a student. Zee is well aware of the problem, on page 79 having his interlocutor "Confusio" say:

> When I first studied group theory I did not clearly distinguish between Lie group and Lie algebra. That they allow totally different operations did not sink in. I was multiplying the Js together and couldn't make sense of what I got.

Please, if you're using this book to teach students about this subject, discourage them from following Zee in this choice.

~~There are places in the text where Zee gets things wrong in a way that just about any mathematician could likely have saved him from. One minor example is a footnote saying "Mathematicians have listed all possible finite groups up to impressively large values of n" (actually, they're classified for ALL values of n)~~ *(my mistake, I misread and wasn't looking at the finite group chapters carefully enough. Zee does get this right).*

One place Zee gets things wrong is when he writes down the Heisenberg commutation relations, and says this is an "other type of algebra", off-topic "since this is a textbook on group theory, I talk mostly about Lie algebras". Actually those are the commutation relations of a Lie algebra, the Heisenberg Lie algebra, and there's a group too, the Heisenberg group.

This gets into my own prejudices about the subject, with the story of the Heisenberg group to me (and I think to most mathematicians), a central part of the story of quantum mechanics, something little appreciated by most physicists. Another place where I think Zee goes wrong due to current physics prejudices is in ignoring Hamiltonian mechanics in favor of Lagrangian mechanics. As a result, instead of being able to tell the beautiful story of the Lie algebra of functions on phase space and what it has to do with conservation laws, he just mentions that Noether's theorem leads to conservation laws and refers elsewhere for a discussion. The connection between symmetry and conservation laws is one of the central parts of the connection between Lie groups and physics, and deserves a lot more attention in the context of a course like this.

So, in summary, the book is highly recommended, with the caveats that you absolutely shouldn't use the same notation for Lie groups and Lie algebras, and you should supplement Zee's treatment with that of a certain more mathematically-minded blogger…

Comments

1. **edmeasure**
   April 22, 2016

   So when (and where) will we see Peter Woit's version in print?

2. **Peter Woit**
   April 22, 2016

   With a little bit of luck, late this year or early next year from Springer. The current version available online is mostly complete, except for ongoing work on a few of the last chapters.

3. **Fernando**
   April 22, 2016

   All finite groups? No, only all finite simple groups.

4. **Peter Woit**
   April 22, 2016

   Fernando,
   Thanks. My mistake, I didn't look carefully enough, he does get this right. Will fix.

5. **anon**

April 22, 2016

At least as of year 2008, the number of (non-isomorphic) groups of order 2048 was not precisely known (the number is known for all smaller orders): see http://www.math.auckland.ac.nz/~obrien/research/gnu.pdf

6. **Peter Woit**
April 22, 2016

anon,
Thanks. I was being quite unfair to Zee about this, my misreading, due to not looking all that carefully at the finite group chapters. This is a topic he covers in quite a bit of detail, in a manner closest to the way mathematicians teach the subject.

7. **ronab**
April 22, 2016

I actually found Zee's QFT book extremely hard to read: Repeatedly, I'd be sinking my teeth into some interesting physics, when I'd be suddenly distracted as I hit upon yet another of his pointless anecdotes about some physicist's personal habits, completely breaking my concentration. These are scattered everywhere so you really can't avoid them. If this had been an online version I'd have suggested that at least a "Show Bullshit / Hide Bullshit" button might have helped.

8. **Peter Woit**
April 22, 2016

ronab,
There's a fair amount of that in the new book also. You can however miss a lot of it by ignoring the footnotes…

9. **theoreticalminimum**
April 23, 2016

I saw that this is Zee's 3rd contribution to PUP's "Nutshell" series, his 2nd being a book on general relativity, wherein he even has a small intro to twistors. I think what's generally interesting about reading Zee's books is the beautiful subtle insights he provides on different topics that one has been exposed to via standard courses supported by standard textbooks in graduate school. All this to say that I am eagerly waiting for his group theory book to show up at my doorstep soon!

10. **Ryan**
April 23, 2016

Although there are already several very good books on group theory for physicists like Robinson's "Symmetry and the Standard Model" or Schwichtenberg's "Physics From Symmetry", I think, it's great that Zee took the time to write this book. However, as with his QFT book, I think, it is better suited as a complementary book. In my humble opinion, he covers too many advanced topics, which aren't essential for beginners. Especially many beginners may feel the need to understand all these advanced topics before reading on and thus give up before they read about the most important topics, such as spinors etc. .

That said, after reading a quicker introduction to the essentials, it's great to read Zee's special perspective and his enjoyable explanations of advanced topics. As you already noted, exactly as the other books mentioned above, it lacks mathematical rigor and that's why I'm eagerly waiting for your book Peter, to fill this gap!

11. **simplicio**
April 23, 2016

Anyone have thoughts on Zee's Relativity book? I used his QFT book in conjunction with my class text (Peskin and Schroder) for my QFT class and found that it made the going a lot easier. I was thinking I might try and go through his Relativity book this summer, since I never had a class on the topic and wanted to learn.

12. **David**
April 23, 2016

His relativity book is excellent. I've tackled several other intro books on the subject (Hartle, Carroll, Schutz), and I'm not a physicist, just an amateur. Zee takes a unique approach, building up the mathematics of curvature in conjunction with variational principles and just enough group theory. The sections in which he derives classical mechanics from variational principles and symmetry considerations helps consolidate your math skills before diving into curved spacetime. He gives an outstanding exposition of how the field equations follow from the Einstein-Hilbert action. Overall, this book added a lot to my level of understanding.

Some caveats: the modern trend is to develop GR using index-free forms; Zee's book is almost entirely based on index notation. That's both a strength and a weakness. The last quarter of the book is a less-than-rigorous survey of some frontier topics that I found to be pretty worthless. If you don't like the dialogues with Confusio, you will find minor annoyances scattered throughout (though they do serve the purpose of letting the author point out common misconceptions and their antidotes).

13. **David Metzler**
April 23, 2016

A bit OT: your readers might be interested to know that the LHC achieved its first stable beams of the year yesterday, albeit with a tiny intensity.

https://indico.cern.ch/event/506406/

It seems that they are more or less on schedule, if I'm reading things correctly. Peter, do you know if last year's problem with the CMS detector is still around and likely to seriously degrade its performance, or not?

14. **Peter Woit**
April 24, 2016

David Metzler,
As far as I know, CMS has successfully dealt with that problem, see a relatively recent report at http://science.energy.gov/~/media/hep/hepap/pdf/201603/Olsen_CMS_HEPAP_April_1.pdf

15. **Frank Wilhoit**
April 24, 2016

This review is a prime example of the kind of thing that reviews ought to do, but in my view the conclusioon that the book is "highly recommended" is in conflict with the bulk of the review.

Zee is a good writer — and good writers need to be *extra* careful to get things right, because what they say is more memorable and more persuasive.

In my experience, teaching at the undergraduate level in a different field, it is *not* at all straightforward for the classroom instructor to try to correct the book. Patently bad books make this easier. Books that are well written and well packaged gain, thereby, an increment of credibility and auctoritas. For all these reasons, this sounds like a book I would stay away from.

16. **John McAllison**
April 24, 2016

Personally, I love the way Tony Zee adds colour to his texts via his interesting and sometimes hilarious anecdotes which creates a link to what's being learned. This is from his General Relativity book concerning the teaching of tensors:

Long ago, an undergrad who later became a distinguished condensed matter physicist came to me after a class on group theory and asked me:

'What exactly is a tensor?'
I told him that a tensor is something that transforms like a tensor.

When I ran into him many years later, he regaled me with the following story. At his graduation, his father, perhaps still smarting from the hefty sum he had paid to the prestigious private university his son attended, asked him what was the most memorable piece of knowledge he acquired during his four years in college. He replied:

"A tensor is something that transforms like a tensor."

17. **Peter Woit**
April 24, 2016

John McAllison,
The same story is in the new book.
One of the things that does grate about the book to a mathematician's sensibilities is that Zee uses the tensor product symbol for just about every kind of product, except the tensor product. Given the kind of confusion indicated by the story he likes, I don't see why he (and other physicists), don't just define the tensor product.

18. **Ryan**
April 25, 2016

@Peter Do you have a reference where the correct usage of the tensor product $\otimes$ vs. the direct product $\times$ is explained for physicists? Or maybe some quick example, where Zee gets this wrong and should use another symbol instead?

19. **Peter Woit**
April 25, 2016

The tensor product is a product of vector spaces, the things Zee does that I was referring to are
1. use the tensor product symbol for a product of groups (SU(3) times SU(2) times U(1))
2. use the tensor product symbol for the cross product of vectors (angular momentum is x times p). This is an unusual usage.

This distinction between types of product can become pedantic. The more substantive question in my mind is that of why he avoids use of the tensor product. I can see why physicists don't want to use the abstract, coordinate invariant definition, but the definition in terms of a basis is straightforward.

20. **Johnny**
April 25, 2016

I think that the fact that mathematically minded readers disagree with the choices he makes would only please Zee. He writes for physicists and is proud of the way physicists deal with pedantic issues.

21. **Peter Woit**
April 25, 2016

Johnny,
I'm sympathetic with Zee on avoiding pedantry, but things like distinguishing a Lie group from a Lie algebra are not pedantic distinctions, and one really confuses students by acting like they are by using the same notation for both.

22. **Johnny**
April 25, 2016

I haven't seen the book so I can't really judge, but I would be very surprised if Zee doesn't explain clearly that they are separate things, adding that it should be clear from context which is which in every case he discusses.

23. **Peter Woit**
April 25, 2016

Johnny,
That's exactly what he says. Of course he's aware that they are different things. This doesn't change the fact that using the same notation to mean quite different things and expecting your reader to figure out for themselves which one you're talking about is a bad idea. Especially when you're dealing with students trying to learn the subject for the first time.

24. **Jeff M**
April 25, 2016

He really uses the same notation for the Lie algebra and the Lie group? Pedantic mathematician that I am, I am appalled…

25. **A.J.**
April 25, 2016

Et's leke useng the same symbol for 'i' and 'e' when spelleng Englesh words. Weth suffeceent effort, your readers can fegure out what you meant. But there's no benefet to doeng et, et makes errors more lekely, and et makes you sound leke an edeot…

26. **Conductor**
April 26, 2016

"Et's leke useng the same symbol for 'i' and 'e' when spelleng Englesh words. … et makes you sound leke an edeot…"

Only if you're reading aloud.

27. **Justin**
April 26, 2016

I'm a layman, with no physics. I understand algebra at the level of Fraleigh from my undergraduate days. I'm interested in learning the representation connection to quantum mechanics, and was wondering how I could go about studying the prerequisites to Zee's book.

28. **cthulhu**
April 27, 2016

Anybody have opinions on how Zee's books compare to Susskind's "Theoretical Minimum" books? As an engineer who agonized between majoring in physics vs aerospace engineering in college, I am still quite interested in physics, and have enjoyed the Susskind books (although I'm not all the way through the quantum mechanics book, and there's no GR book yet). So I'm always on the lookout for stuff that can be understood by an engineer who made through tensor calculus and calculus of variations, even if I'm a bit rusty 🙁

29. **Johnny**
April 27, 2016

A.J. I don't think your example is good (it's not even funny). A closer example (not perfect though) would be to use the same symbol "x" to multiply numbers and vectors. Truly appalling, ha?

30. **Peter Woit**
April 27, 2016

Justin,
Zee's book is aimed a people with a significant background in physics, only real math background needed is linear algebra (which he reviews at the beginning). I don't think it's that useful if you don't already have a course in quantum mechanics.

Cthulhu,

Zee's is quite a bit more advanced that Susskind's, with Susskind explicitly trying to write for people with minimal background, Zee's book developed out of a course for advanced undergrads and beginning graduate students, and is more at that level.

Various Items

April 29, 2016
Categories: Uncategorized

A few short items:

- Things had been going quite well at the LHC, they were ahead of schedule, starting to ramp up intensity for the new run. Then at 5:30 this morning a weasel decided to visit a 66kV transformer, which did not end well either for the weasel or for the LHC power grid. The machine and a lot of its cryogenics lost power, and recovery is going to take a week or so.
- For some commentary on the excitement about the new run building up (pre-weasel), see Tommaso Dorigo (at least I'm guessing he's the author) here. He points to the twitter #MoarCollisions hashtag.
- In various Breakthrough Prize related news, first there's an announcement from Terry Tao about the new IMU Graduate Breakout Fellowships, funded by him and some of the other math prize winners.

  On the physics front, Caltech has Glitz and Qubits, about Alexei Kitaev and John Schwarz's experience with the prize. Schwarz still hopes for vindication of his string theory prize by a discovery of SUSY at the LHC, assigning a much higher probability to this than I think most other people would these days:

  > I would say the probability is on the order of 50 percent or so that it will show up.

  As for the glitz:

  > At the 2014 award ceremony, Schwarz says, he and his wife, Patricia, were "both struck by the fact that the Hollywood types showed no interest in mingling with scientists." And the media coverage also seemed to focus on the movie stars rather than the award winners.

  Kitaev points out a major positive effect of the $3 million: more respect from one's family:

  > But for Kitaev, the biggest impact of awards like the Breakthrough Prize in Fundamental Physics is on his family. "They don't really understand what I'm working on," he says. But thanks to these awards, they at least realize his research is a pretty big deal. "It helps me do more work because they have more respect for it," he says. "My wife is really proud of me."

- In other big money news the Perimeter Institute and the Stavros Niarchos Foundation have announced a new professorship for Asimina Arvanitaki, funded by $8 million. More about her here.
- At Nautilus you can read an interview with IAS director, theoretical physicist Robbert Dijkgraaf.
- At Edge, there's a conversation with Frank Wilczek. I'm quite curious what the following is about, have no idea:

  > What I've been thinking about today specifically is something of a potential breakthrough in understanding our fundamental theories of physics. We have something called a standard model, but its foundations are kind of scandalous. We have not known how to define an important part of it mathematically rigorously, but I think I have figured out how to do that, and it's very pretty. I'm in the middle of calculations to check it out.

Update: Two more:

- Jim Baggott has a post on Status Anxiety, with more thoughts about the Munich conference and the use of the term "theory".
- Discover magazine has an article in the upcoming June issue on The Fall and Rise of String Theory. The story seems to be that String theory for some reason ran into a little trouble in 2006, but now it's back, because Strominger has done some "string-inspired" black hole calculations, and some people are claiming inspiration from AdS/CFT for an approximate calculational method in some condensed matter models. The idea now seems to be that, starting from this, string theory is on its way to again finding a theory of everything. No comment on its hype problem.

Update: A special 2016 physics Breakthrough Prize has been awarded to the LIGO people. \$1 million split by Drever, Thorne and Weiss, \$2 million for the rest of the collaboration.

Comments

1. **John Sirois**
   April 29, 2016

   From context below that quote, particularly:
   "Who does this falsify? It's a funny situation where the theory of electroweak or weak interactions has been successful when you calculate up to a certain approximation, but if you try to push it too far, it falls apart. Some people have thought that would require fundamental changes in the theory, and have tried to modify the theory so as to remove the apparent difficulty. What I've shown is that the difficulty is only a surface difficulty…."

   A guess would be a "solution" for Landau Poles.

2. **tommaso dorigo**
   April 29, 2016

   Hi Peter,

   yes, the post at the AMVA4NewPhysics site was mine – good guess! And thanks for the link.

   About the weasel: it will cause a few days of delay, but by now we've gotten accustomed to the fact that our big machine can be stopped by improbable causes such as saving on resistors, bombing it with baguettes, and now munching on wire cables. I think the cause of the next technical stop is hard to predict, but I am a betting person so I offer the following:

   – sewage water flooding of the ATLAS cavern, 10:1
   – growth of fungus on the inner walls of the beampipe, 20:1
   – hijacking of the LHC control room by Corsican independentists, 15:1

   Cheers,

T.

3. **Anonyrat**
April 29, 2016

Further context from below the Wilczek quote:

> "**This thing that I mentioned before about what I was thinking about and am excited about is making the foundations of the standard model more secure.** This problem that we're addressing has been a worm in the rose for decades that has been worrying people. Most people don't want to think about it; they think it's somehow going to resolve itself.
>
> It looks very technical, but it's been there and it's been annoying for those of us who care about logical consistency."

So I think John Sirois' guess is a very good one.

4. **Low Math, Meekly Interacting**
April 29, 2016

I read somewhere the baguette thing is apocryphal. I, of course, want desperately for the the story to be true. Is it?

On the subject of animal attacks, some early pioneer of electronic music, Allen Strange, had a band, The Electric Weasel Ensemble. Perhaps this hapless mustelid was a fan.

5. **Abbyyorker**
April 29, 2016

Landau pole is a u(1) thing as I recall. I would guess that that would not be a fundamental enough problem to motivate Wilczek, assuming he thinks it is possible that it is contained in a GUT. But maybe he doesn't.

6. **Anonyrat**
April 30, 2016

Well, it is the QFT problems with a fundamental scalar like a Higgs, whether you call it Landau poles or quantum triviality.

7. **Nick M.**
April 30, 2016

If Frank Wilczek's idea pans out, it might mean a sort of *"mini retreat"* for certain sectors of the multiverse camp as well:

> "Who does this falsify?…….It falsifies speculative theories that have been trying to cure a problem that doesn't exist. It's things like certain kinds of brane-world models, in which people set up parallel universes where that parallel universe's reason for being was to cancel off difficulties in our universe—we don't need it."

8. **Mitchell Porter**
May 1, 2016

I think Wilczek is talking about naturalness and Randall-Sundrum.

9. **Stephane**
May 1, 2016

There is also a good article by Wilczek about "Entanglement Made Simple" in Quanta Magazine : https://www.quantamagazine.org/20160428-entanglement-made-simple/

10. **Gaucho**
May 1, 2016

Nothing about what Wilczek says really points to Landau poles or the multiverse or naturalness. Rather, it sounds like he is referring to the lack of a nonperturbative regulator for chiral gauge theories in d=4. The regularization of theories with global chiral symmetries currently involves domain wall fermions ("parallel universes where that parallel universe's reason for being was to cancel off difficulties in our universe"), and Grabowska and Kaplan have recently made a proposal to extend these techniques to gauge theories using gradient flow. The lack of a nonperturbative regulator for chiral gauge theories is certainly a situation where it was "not known how to define an important part of it mathematically rigorously." I would guess that this has motivated Wilczek to revisit the problem. Curious to see what he comes up with.

11. **Peter Woit**
May 1, 2016

Gaucho,
Thanks, your guess sounds quite plausible. I've never understood why this problem gets so little attention.

12. **srp**
May 1, 2016

How many times do English-speaking physicists complain that their progress is being held up by weasels? Funny that this time it is literal.

13. **Low Math, Meekly Interacting**
May 2, 2016

My sick sense of humor notwithstanding, it looks as if things ended quite poorly indeed for the sleekit saboteur. There may not have been enough of it left to determine whether it was a weasel or a marten. Perhaps also of interest: apparently the Tevatron suffered a raccoon raid in 2006, which was bravely repelled by Fermilab operators. Casualties were reportedly low, and the machine was unscathed.

http://www.npr.org/sections/thetwo-way/2016/04/29/476154494/weasel-shuts-down-world-s-most-powerful-particle-collider

14. **Visitor**
May 2, 2016

Raccoons have a very high incidence of rabies and are the single largest vector for rabies in human beings:

"Wild animals accounted for 92% of reported cases of rabies in 2013. Raccoons continued to be the most frequently reported rabid wildlife species (32.3% of all animal cases during 2013), followed by bats (27.2%), skunks (24.6%), and foxes (5.9%)." (from http://www.cdc.gov/rabies/location/usa/surveillance/)

15. **Other**
    May 2, 2016

    The baguette story is indeed true. On a related note, two beer bottles were previously found in the LEP beam line.

    http://blogs.nature.com/news/2009/11/exclusive_interview_baguette_b.html
    http://blogs.nature.com/news/2009/11/_a_tale_of_two_beer_bottles_1.html

16. **phillipe**
    May 3, 2016

    Jim Baggott link doesn't work.

    Scientific American article is behind a paywall.

17. **Peter Woit**
    May 3, 2016

    phillipe,
    There seems to be some temporary problem with Jim Baggott's web site, presumably it will get fixed, so try later. The Discover magazine article is mostly behind a paywall. Columbia provides electronic access via our library to Discovery magazine content, unfortunately I don't know of other options.

18. **Shantanu**
    May 3, 2016

    Peter and others: Those of you who have electronic access to Discovery magazine, please write to the author of this article to point out about the hype. Else such non-sense articles will continue.
    PS: have you seen any article/press release/statement arguing that LIGO results are evidence for string theory?

19. **Peter Woit**
    May 3, 2016

    Shantanu,
    The Nadis article comes pretty close to making the LIGO string theory connection, here's some of it (fair use…)

    "Using similar techniques originally inspired by string theory, Strominger's group has computed the spectrum of gravitational waves emitted when compact objects like stars fall into giant black holes — predictions that could be verified by the future Evolved Laser Interferometer Space Antenna, planned to launch in two decades (or maybe sooner). Strominger also believes that evidence of conformal symmetry might emerge from the Laser Interferometer Gravitational-Wave Observatory, which spotted gravitational waves for the first time earlier this year. Soon, he says, astronomers may be drowning in data that they cannot fully interpret. "We'd like to use ideas from string theory to shed some light on corners of this."

    At this point, I guess any use of conformal symmetry from now on will be described as an "idea from string theory".

20. **Peter Woit**
    May 3, 2016

    Shantanu,
    After taking another look at the article, I decided it was worth it's own "This Week's Hype" post, see the next posting.

This Week’s Hype

May 3, 2016
Categories: This Week's Hype

The June issue of Discover magazine has an article entitled The Fall and Rise of String Theory (sorry it’s behind a paywall).

I had added this as an update to the last posting, but just looked at it more carefully and realized that it’s squarely in the “string theory predictions” tradition covered by editions of “This Week’s Hype”. In particular, the article claims:

> The upcoming Evolved Laser Interferometer Space Antenna could help verify string theory’s predictions of gravity waves. Three spacecraft will orbit around the sun and measure tiny ripples in space-time via sensitive lasers.

The article starts off by explaining the history of string theory this way:

> String theory was once the hottest thing in physics…
>
> Strominger knew, even in the euphoric ’80s, that such assertions were overblown. And, sure enough, skepticism has seeped in over the years. No one has yet conceived of an experiment that could definitively verify or refute string theory. The backlash may have peaked in 2006, when several high-profile books and articles attacked the theory. But while string theory has receded from the spotlight, it has not gone away. “The theory is still evolving and getting better — and better understood,” maintains Juan Maldacena of the Institute for Advanced Study at Princeton University….
>
> Emerging from this diverse work is a new consensus: String theory may not be the fabled theory of everything, Strominger says, “but it is definitely a theory of something.”

The article’s main selling point for string theory is that it led Strominger to think about something else, ideas about the conformal symmetry of black hole solutions.

> Strominger subsequently realized that the presence of this symmetry, which hadn’t been recognized before, could be used to support a range of predictions. For example, he and his collaborators are currently trying to calculate the intensity of electromagnetic radiation emanating from the vicinity of a black hole. In a few years, Strominger says, once the worldwide network known as the Event Horizon Telescope comes online, astronomers can test those radiation estimates through direct measurements.
>
> Using similar techniques originally inspired by string theory, Strominger’s group has computed the spectrum of gravitational waves emitted when compact objects like stars fall into giant black holes — predictions that could be verified by the future Evolved Laser Interferometer Space Antenna, planned to launch in two decades (or maybe sooner). Strominger also believes that evidence of conformal symmetry might emerge from the Laser Interferometer Gravitational-Wave Observatory, which spotted gravitational waves for the first time earlier this year. Soon, he says, astronomers may be drowning in data that they cannot fully interpret. “We’d like to use ideas from string theory to shed some light on corners of this.”

From now on, I guess use of conformal symmetry in physics now likely to be sold as a “prediction of string theory”.

The article goes on to a different area of string theory hype, that of AdS/CMT. According to Andrew Green of University College, London, string theory is “the new calculus”, and according to the piece’s author “Strominger agrees.” It’s hard to come up with appropriate words to characterize this level of hype.

   Good news! String theory thusly predicts another twenty years for this blog to have meaning and purpose!

The Big Picture

May 3, 2016
Categories: Book Reviews

I'm about to head out on vacation to commune with nature in the Pacific Northwest, so there's likely to be no more blogging here until after May 17th. That's just one reason I'll leave comments closed here, another is that I'm sure you can find other, better, places on the internet to discuss the issues raised in this posting.

A little while ago I bought a copy of Sean Carroll's new book The Big Picture, which is now reaching the bookstores. This posting is not really a review of the substance of the book, but more a reaction to its basic conception. The first point to make is that I mostly agree with what Carroll has to say, to the extent that one reason for not writing a more usual sort of review is that I didn't bother to do more than skim a lot of the chapters, since the theme seemed both so familiar and so unobjectionable. One exception would be a small number of pages about the multiverse, which he contrasts with religion, ending with (referring to religion)

> This is the problem with theories that are not well-defined.

He's got the problem right, but doesn't notice that it applies equally well to this particularly dubious bit of "science".

The largest part of the book (from my rather quick read) is a very conventional argument for science as opposed to religion, of a sort that has existed for centuries, been common since the 19th century, and very common in recent years as part of the "New Atheism". One reason I can't focus on this is that I just don't see any evidence that science needs this sort of defense against religion, it seems to me to be doing extremely well without it. Our culture valorizes science and scientists very highly these days (much more so than ministers or theologians), and I just don't see what some other people see as a need for books arguing the case for science.

The really striking thing about this particular book though is that Carroll has a much more unusual and ambitious goal than just arguing for science. He wants to promote what he calls "poetic naturalism", which as far as I can tell is a term of his own invention ("naturalism" by itself is now a conventional term for the "science, not religion" viewpoint). Beyond the "science instead of religion" idea though, "poetic naturalism" seems to me to simultaneously lack any real content, while claiming to address the deepest human questions of meaning and morality. Asked in this interview the question

Your book, The Big Picture, roams far beyond cosmology and physics, into consciousness, philosophy and the meaning of life. What do you hope to achieve?

he answers

Well, this is the book that should accompany the Gideons Bible in all hotel rooms in the world – that would be a nice achievement!

I'm not sure what Carroll might have had to do with this, but poetic naturalism is now listed on Facebook as a possible choice for one's religion.

Perhaps the strangest thing in the book is a chapter devoted to Carroll's replacement for the Ten Commandments, which he calls the "Ten Considerations", since they're not commandments. They are:

- Life Isn't Forever.
- Desire Is Built Into Life.
- What Matters Is What Matters To People.
- We Can Always Do Better.
- It Pays to Listen.
- There Is No Natural Way to Be.
- It Takes All Kinds.
- The Universe Is in Our Hands.
- We Can Do Better Than Happiness.
- Reality Guides Us.

It's hard to argue with such sentiments, but also hard to understand what they have to do with the author's expertise as a theoretical physicist.

The last chapter of the book begins with a description of Carroll's early experiences in the Episcopal church, which he was quite fond of. I also had such experiences (I was an altar boy for several years at an Episcopal church, the American Cathedral in Paris). Unlike Carroll, I was never a believer, but just figured this was one of quite a few mystifying things that adults got up to, and that it seemed I had to go along with it until I got older. Thinking back to those days, I was struck by the realization that I recognized the tone and a lot of the content of Carroll's writing. It very much sounds like a sermon, one evangelizing the good news not of Jesus, but of science, and is aiming for much the same effect: "I want to shiver with awe and wonder at the universe".

My own point of view on all of this is that I just don't think theoretical physicists have anything useful to tell the average person about meaning and morality, other than that it's a mistake to search for it in our discoveries about physics. I don't understand why we're increasingly seeing texts promoting physics as inspiration for how to live (for another recent example among many see here). I'm with Steven Weinberg, and his famous line

> The more the universe seems comprehensible, the more it also seems pointless.

Given that, the best advice to people who come to physicists looking for the meaning of life seems to me to politely tell them that they're looking in the wrong place and asking the wrong person.

While I deeply value and respect my many friends and colleagues among physicists and mathematicians, I can't imagine why anyone would think they have any unusual insight into the great questions of meaning and morality. I'm afraid that to some extent the opposite is true. My background, career and circumstances are quite similar to Carroll's, and when I think about them my main thought these days is that I lead an extremely lucky and privileged (and not just in the white/Anglo/male/hetero sense) life, well-isolated from many of the challenges that most people have to deal with. There are a lot of beautiful, wonderful, and useful things one can learn from physicists and mathematicians, but our expertise is in something very far-removed from the question of how to live a good life in the face of significant challenges.

It seems likely that one motivation for books with this defensive attitude about science is the current ugly environment of our politics and culture. This ugliness I believe is driven by the economic disaster that has been inflicted on a significant fraction of our citizenry over the last few decades by the privileged and well-educated, both Democrats and Republicans. While Carroll and I were enjoying our respective times at Harvard and similar places, and have ended up turning our upbringing and Ivy League experiences into a very pleasant and cosseted lifestyle in the wealthy enclaves along either coast, things have not been going so well for many others. They're now in bitter rebellion against what has happened to them, with an anger sadly turned against other racial groups, but even more so against self-satisfied elites. I don't think a book like this has much hope of speaking to such people, to their view of science or their experience of religion. Scientists who want more respect should stick to what they know, and avoid the temptation of "science-splaining" to the public. In particular they should avoid preaching about meaning, morality, and other issues that they know no more about than anyone else.

Update: Robert Crease has a review of the book in Nature. He also finds odd the "greeting-card-like homilies" that appear in the book.

May 18, 2016
Categories: This Week's Hype, Uncategorized

Now back after a satisfying vacation amidst very large trees. Here are some things of note from the past couple weeks:

- For those fascinated by the arguments over string theory, you might want to look at a document sent to me by Ilyas Khan, The People vs. String Theory. It's also available in a free Kindle version, here. Some claim characters in this are recognizable to those well-versed in the subject.
- One thing that has always annoyed me about popular accounts of string theory is that they often claim that known particles are just like vibrational modes of a physical string, bringing music into it, as an argument for the beauty of string theory. No one ever mentions that the analogs of physical string vibrational modes have nothing to do with observed particles. If they exist at all, they're some sort of Planck-scale states. Known particles are modeled typically by zero modes, with the classical analog not playing your guitar strings, but picking up the guitar and carrying it around, a much less musical activity.

  I don't remember ever bothering to make that argument publicly, because it seemed likely to lead nowhere but to silly arguments from string theorists. I'm now glad to see that 4gravitons has taken up the issue with a blog entry Particles Aren't Vibrations. And, yes, check the comments for the expected response.

- Kudos to John Horgan for his talk at a recent Science and Skepticism conference here in New York. I've never quite understood why conferences like this seem devoted to a defense of ideas about science that are pretty much mainstream, especially in a place like New York, while ignoring pseudo-science when it comes from people considered members of the pro-science tribe. Horgan has some discussion of reaction to the talk here.
- Maybe this should have its own entry for This Week's Hype, but I'll just mention here that the June Scientific American has The Collider That Could Save Physics. It seems that SUSY is needed to "save physics". Way back when it was LEP that was going to "save physics" by finding SUSY, then it was to be the LHC. This year's LHC run should put the final nails in that coffin (data is now starting to be collected, see for instance here). Unfortunately the reaction of many SUSY partisans is not to follow the usual norms for how science is supposed to work and give up on the idea, but instead to claim that the LHC results aren't conclusive, and a new machine is needed. In the SciAm article the ILC is advertised for this task. This electron-positron machine would have a much lower center of mass energy than the LHC, but one can find obscure SUSY models specially designed to have states that would be hard to see at the LHC, but could be seen at the ILC. I hope this isn't the best argument for the $10 billion ILC…
- The L-functions and Modular Form Database is up and running now, providing a wealth of data about a central part of modern mathematics. Persiflage has an expert's take on the significance of the project, including some criticism of the hype surrounding its launch (non-zero, but quite small on any scale used to measure theoretical physics hype). Other experts weigh in in the comment section, so don't miss that.

Update: One more I forgot to add. Some people at Rutgers have decided to show what can go wrong when you have the Templeton Foundation funding "philosophy of physics". They've scheduled a two-day Rutgers Mini-Conference on Multiverse, Theodicy, and Fine-Tuning, during which the speakers will consider the following two topics:

- **Everettian Quantum Mechanics and Evil**

  > The problem of evil has been around for a long time: How can an all-powerful and all-good God allow evil of the sorts we see in the world? If the Everettian interpretation of quantum mechanics is correct, though, then there is a lot more evil in the world than what we see. This suggest a second problem of evil: If Everettianism is true, how can an all-powerful and all-good God allow evil of the sort we don't see?

- **A Probability Problem in the Fine-Tuning Argument**

  > According to the fine-tuning argument: (i) the probability of a life-permitting universe, conditional on the non-existence of God, is low; and (ii) the probability of a life-permitting universe, conditional on the existence of God, is high. I demonstrate that these two claims cannot be simultaneously justified.

Update: One more, from CERN-TH, Is theoretical physics in crisis?. Nothing really new, but don't miss the photo of John Ellis's office…

10. **Low Math, Meekly Interacting**
May 19, 2016

I pretty much agree with everything John Horgan said. But I don’t agree that defense and promotion of skepticism and science literacy isn’t vitally important, even in New York. I see every reason to be concerned about a surge of pre-enlightenment thinking, and an increasing willingness in society to view the failures of individual scientists as a failure of science and secularism in general. Horgan is entirely right about what he criticizes, and everyone can use a good ombudsman. But if they can cease contributing to the problem, there’s a great deal of good a more self-aware movement of skeptics can do. The battle against willful ignorance is far from won, IMHO.

11. **Ptiede**
May 19, 2016

I would have to disagree with what Horgan said. Often what he complained about was already material the skeptical societies have written extensively about. His complaints seemed to be .ore with mainstream media than with skeptical society itself. For example his discussion about cancer rates and mammograms is completely off base. Lots skeptics have had the discussion about this. They didn’t need Horgan telling them about it. The same goes for the multimeter and string theory.

12. **Peter Woit**
May 19, 2016

LMMI/Ptiede,
I don’t want to get involved in discussions over what Skeptic organizations are up to, largely because I’m mostly ignorant about this. I would also assume that, like any large diverse group, you can easily find among their many activities some evidence for whatever argument you feel like making.

I should say though, that the reason I’m mostly ignorant about such organizations is that from the little I’ve seen they seem to engage a lot in a kind of self-righteous preaching to the converted that I’m allergic to. The one aspect of their activities I’ve followed a bit has been the way they deal with bad mainstream theoretical physics (e.g. multiverse/string theory), and there they seem more often willing to embrace it than to challenge it (a point that Horgan was making).

13. **Low Math, Meekly Interacting**
May 19, 2016

The echo chamber of self-righteousness (as well as the incivility) is precisely what turns me off to the capital-S-Skeptics as well. I’d rather my daughter go to church camp than Camp Quest. I’m too old-fashioned to get my head around kids singing campfire songs about Charles Darwin, regardless of my complete atheism. And Horgan is 100% right on about quasi-religious nature of the anthropic multiverse. As suggested, it may be no accident that some of the loudest proponents of Capital-S-Skepticism are prone to cooking up their own untestable hypotheses (memes, bubble universes). There is an uncomfortable similarity between the pot and the kettle.

That said, I do still believe very strongly that secularism and empiricism are in need of an organized defense. Too much of the third world is falling completely under the thrall of medieval religious fundamentalists, and American politics is flirting ever more dangerously with a newly-invigorated strain Eurocentric racialism and neo-fascism. It’s not enough for the John Horgans of the world to sneer, I’m afraid.

All right, I’ve said all I will say about that. Promise.

14. **Igor Khavkine**
May 19, 2016

A small note about skeptical organizations. Peter, I would agree that they are “more often willing to embrace it than to challenge” bad theoretical physics. But that is one failing among many positive things that they do: opposing the push of creationism/intelligent design into US public schools; publicly supporting the scientific consensus on climate change, vaccines and GMOs; informing the public about shams like astrologers, psychics, faith healers and the dangers of quack medical treatments; rationally opposing conspiracy theories; informing consumers about predatory businesses that base their products on scams or pseudo-science; generally getting people informed and excited about science. The list goes on. I would ascribe the above failing regarding bad physics to the fact that their priorities are simply oriented toward other battles, arguably more relevant to a large number of people. Of course, this is just all the more reason for people who are better informed and more narrowly motivated to keep pointing out the problems with bad physics.

Lastly, I think it’s no surprise that no movement, including the skeptical movement, is immune to the pull of preaching to gatherings of like-minded people. However, besides being their own reward, skeptical conferences also aim at giving their attendees some tools and arguments that they could use to stem the tide of pseudo-science in their own way, and that might as well be done through a bit of preaching. 🙂

15. **John Smith**
May 19, 2016

Wonderful and much-needed talk by Horgan, all his points are spot on. There is a large base among skeptics who support (or are quiet on) war mongering, which turns out to have a large impetus on the rise of fundamentalism in other societies. Thus not only do they lack proper focus, their efforts are in large part self-defeating as well.

16. **Peter Woit**
May 19, 2016

Igor Khavkine,
I'm sympathetic to the goals you mention, and hope these organizations are having a positive effect. It's quite difficult to tell from here in New York, where what they are advocating for is what is already the mainstream, consensus viewpoint. I hope they're also taking this message to parts of the country where it isn't, and figuring out how to change minds there.

17. **diphton**
May 19, 2016

If LHC finds 5 sigma evidence of a new 750 gev particle, SUSY along with technicolor and extra dimensions are all possible explanations, with SUSY and KK gravitons being evidence of string theory

regards
750 diphoton excess

18. **Peter Woit**
May 20, 2016

diphton,
Yes, since string theory can predict anything, anything is "evidence of string theory".

More on topic, it's interesting to consider the effect of seeing a 750 GeV state on the ILC project. I assume the current 500 GeV proposal would be dead. Depending on what this is, perhaps a new lepton collider proposal would emerge.

19. **Dave Miller**
May 20, 2016

Peter,

You wrote:
>I should say though, that the reason I'm mostly ignorant about such [skeptical, secularist] organizations is that from the little I've seen they seem to engage a lot in a kind of self-righteous preaching to the converted that I'm allergic to.

Peter, having followed some of these groups for some years (and occasionally considered getting involved with them), I would say it is worse than that. They seem repeatedly to get into strange internal sectarian squabbles resembling "political correctness" (although untangling who is "politically correct" can even be confusing). It reminds me of some political groupings I have observed (and occasionally been involved in).

There are actual scholars, such as NT scholar Bart Ehrman, who write books, give lectures, etc. about subjects they really are experts on: I think that is a good thing.

Otherwise… well, let's just say that some people need to be part of a "movement," and I wish them well.

Dave Miller in Sacramento

20. **Cormac O'Raifeartaigh**
May 20, 2016

That's an interesting article by John Horgan and I think his concept of 'hard targets' vs soft targets' is quite useful. However, it seems to me that Horgan misses an essential difference between the two :
One may question whether 'hard targets' like string theory or the multiverse are real science, whether they are merely over-hyped speculation, and wonder at those who suggest we move the goalposts of testability.
But such theories do not deny well-established science. Unlike 'soft targets' like astrology or AGW skepticism, the 'hard targets do not blithely ignore well-established facts and assert that the moon is made of blue cheese.
That 'soft target' is a very different sort of madness (and btw there is nothing 'soft' about trying to deal with climate skepticism in the media).
I think it's quite dangerous to draw a rough equation between these two phenomena.

21. **Narad**
May 20, 2016

> and btw there is nothing 'soft' about trying to deal with climate skepticism in the media

Or attempts by activists to undermine public health by sowing mistrust in vaccinations, not to mention the plethora of predatory cancer quacks. I could go on.

22. **astringtheorist**
May 21, 2016

hi peter,
as someone from the community, who often defends your views, I am surprised to find that you are genuinely confused about some of the basics of the subject that you have spent a lot of time analyzing.

1) first of all, the usual massless particles that we see are not just zero modes. If you look at the state-operator map, you will notice that the gauge boson, for example, (see Polchinski 2.28) is given by acting with a creation operator on the vacuum of the open string; similarly, the graviton, involves a for example, is given by a left *and* a right creation operator on the closed string. So the massless particles that we see do correspond to vibrational modes.
The zero-modes you are talking about are tachyonic states, which are projected out in the superstring.

2) second, the excited states are not at Planck scale; they are at string scale. In fact, perturbative string theory only works because it cuts off the running of the gravitational coupling constant at a string scale, which is far below the Planck scale. The ratio of these two is controlled by the string coupling constant. So, it would be good to be careful about this terminology.

23. **Peter Woit**

May 21, 2016

astringtheorist,

No, I'm not confused about these issues. Thinking back on it, I remembered that the main reason I never wrote about this earlier is exactly to avoid a long tedious discussion of your issue 1. The problem here is that the description of the ground state of a superstring with the SM as a low energy limit is a very complicated story, with no real relation to the classical string and its vibrational modes (and this is where the public is being misled). If you really want to make a non-misleading analogy between this system, with its zero-energy ground state and higher-energy tower of states, I think 4 graviton's point, which I agree with, is that the zero energy state corresponds to the classical non-vibrating string. Given the complexity of the ground state, you can if you want make other analogies, but if you don't want to mislead people, you should explain the issue raised here (and this is never done).

As for 2., of course I'm aware that the string scale can be anything you want (which is part of the problem of the theory's lack of predictivity). My reference was just to the general picture of the class of compactification models most often advertised to the public.

24. **David hurn**
May 21, 2016

Is it me or do the words following the

Everettian Quantum Mechanics and Evil

Mean absolutely nothing.

25. **Dave Miller**
May 22, 2016

Peter,

You wrote:
>The problem here is that the description of the ground state of a superstring with the SM as a low energy limit is a very complicated story, with no real relation to the classical string and its vibrational modes (and this is where the public is being misled).

Can you (or anyone else) suggest a reference that goes into detail on the supposed physics of this?

I have no rhetorical ax to grind on this — I am genuinely curious as to what is going on in the math/physics and have come to realize that the vague ideas I had are probably mistaken.

Thanks.

Dave

26. **4gravitons**
May 22, 2016

Peter,

I'm actually not making the point that the zero energy state of the superstring corresponds to the the classical non-vibrating string. There's a double meaning in the title: the particles (that "you" are thinking of) aren't the vibrations (that "you" are thinking of). They're still vibrations (at least, to the extent that the metaphor works at all with tachyons in the mix, which admittedly is fuzzy).

The misunderstanding I'm trying to clear up is a much more basic one. I've run into plenty of people who've seen a trailer for the Elegant Universe or the like, and think that there's some sort of one-to-one map between higher and higher states of the free string and more and more massive SM particles. (Someone in the comments on Lubos's post proposes a pretty clean example, of someone who thinks that muons and taus are just higher excitations of electrons.) The particles that they are thinking of are certainly not the vibrations that they are thinking of.

I don't think this misunderstanding is Brian Greene's fault, since he covers the important details later. Any work of science popularization is going to be misunderstood (mine being an instructive example!), especially by people who only get a partial story. It's the duty of the rest of us as science writers to clear up those misunderstandings when we find them. That's why I'm in favor of more people writing about string theory, not fewer.

I think both you and Lubos (but yes especially Lubos) occasionally need to take a breath and realize that not everything written on string theory is a salvo in the string wars. Some people just genuinely want to explain something.

27. **Peter Woit**
May 22, 2016

Dave Miller,
This is just about the standard story of the quantized relativistic superstring, which is described in standard textbooks (Green-Schwarz-Witten, Polchinski). It is a quite complicated story: even before introducing fermionic variables, you're trying to quantize a theory that not only has the complexities of relativistic quantum field theory (infinite number of degrees of theorem, indefinite Minkowski metric), but also has an infinite-dimensional group of reparametrization symmetries that you need to deal with in order to get a unitary state space. Popular books about string theory avoid discussing any of this, often leaving a misleading impression that there is a close connection of this kind of theory to vibrating physical strings.

28. **Peter Woit**
May 22, 2016

4gravitons,
I did understand exactly the point you were trying to make, and it is part of what I had thought of writing about in the past, but hadn't. I don't think Brian or most other string theory popularizers intend to mislead anyone about this, but that people will be misled in this way by the kind of thing they choose to write is unavoidable. There's an unfortunate lack of interest among string theory popularizers in dealing with this sort of problem. I was glad to see that you were doing this and thought it worth pointing to, sorry if you think that's a "salvo in the string wars".

I've had the misfortune of acquiring a huge amount of experience with the kind of reaction you've gotten to trying to say something sensible. One of my least favorite aspects of this are the invariable accusations that one doesn't know what one is talking about whenever one tries to say anything about a complex issue. This is a good example: there is a huge disjunction between talk of "vibrations" and the construction of the states of the superstring that are supposed to correspond to physical particles.

This leads on the one hand to popularizations seriously misleading people, on the other hand to people accusing one of not knowing what one is talking about if one tries in a blog entry to address what is misleading.

29. **Dave Miller**
May 22, 2016

Peter replied to me:

>It is a quite complicated story: even before introducing fermionic variables, you're trying to quantize a theory that not only has the complexities of relativistic quantum field theory (infinite number of degrees of theorem, indefinite Minkowski metric), but also has an infinite-dimensional group of reparametrization symmetries that you need to deal with in order to get a unitary state space.

Hmmm, yeah, I have both GSW and Polchinski: I think both sets of authors would claim that what they are doing is a natural generalization of, say, Gputa-Bleuler. I'll admit it gets so convoluted that I am very unsure that I am left with any real grasp of the physics, but I am never sure if that is just my own shortcomings or if they are pushing the formalism way beyond any reasonable limits.

I take it, though, that the first-order (maybe zeroth order!) approximation to the SM does lie in the basic stuff in GSW rather than in arcane details of, say, Calabi-Yau compactification? I know that something like Calabi-Yau would be needed (and there is the KKLT flux stuff, and so on) to actually get a real model, but if I actually understand the GSW stuff in their first few chapters, will I know what is relevant to this debate?

What bothers me is, quite aside from any actual ties to experiment, does string theory actually make sense in its own terms? Again, I honestly do not know, so I am not taking a position, just curious as to what I need to grasp to be able to judge.

Of course, maybe this is the fundamental point at issue between proponents and critics of string theory.

Dave

30. **Peter Woit**
May 22, 2016

Dave Miller,

Yes the levels of complexity I was referring to are just the beginning, then you have compactification and moduli stabilization to deal with. I don't think those though are relevant to the points that either I or 4gravitons were making, and this isn't the place for yet another discussion of them.

31. **Anosel**
May 22, 2016

The draft Anonyrat linked sums up the argument thus:

> An omnipotent God would get to choose the laws of nature, and hence the standard measure on initial configurations of the universe. Therefore, if the standard measure says that the chances of life are practically nil, then a theist who believes contemporary physics should think that the chances of life are practically nil, as a result of the laws that God chose. But then the theist and the atheist are in exactly the same epistemic situation: both are puzzled by the fact that we exist.

The whole thing seems to hinge on the measure over possible constants being a matter of physics rather than of metaphysics.

But I doubt that fine-tuning advocates really cast their argument that way so it seems like a strawman.

32. **Low Math, Meekly Interacting**
May 23, 2016

It's not clear to me what conclusions, if any, one can draw from the photo of Ellis' office. Looks to me like the blackboard etc. may be littered with nothing more than satirical graffiti that hasn't been removed because of its humor value. Gallows humor? Poking fun at the "critics"?

Killer Asteroids

May 24, 2016
Categories: Uncategorized

During my recent vacation I visited my old friend Nathan Myhrvold, and got a tour of his company's lab near Bellevue. At that time he told me about what he had been working on recently, which has now appeared on the arXiv here, and is the subject of news stories today at the New York Times and Science magazine.

I confess I've never worried much about killer asteroids, but am glad that someone is doing this. Nathan has always pursued a wide range of different interests, and killer asteroids has evidently been one of them. I first heard from him a year or two ago about how he had gotten interested in the question of how to model the observability of such objects. Such modeling affects choices to be made about how to optimally search for these things (space-based or earth-based telescopes? what kind?). He wrote a paper last year about this, which was published in March.

What Nathan told me when I saw him was that he had found significant problems with the modeling done by the NEOWISE/WISE group at NASA, and you can now judge for yourself by reading his paper. I'm very far from being able to understand the details of this story well enough to judge who's right here. I do know Nathan well enough to know that his work on this deserves to be taken very seriously, and would bet that he has identified real problems. As noted in the comments there, the reaction from one of the ~~NASA~~ WISE people quoted at the end of the Science article wasn't exactly confidence inspiring.

Update: There's a press release about this out from NASA today, pretty much devoted to attacking Nathan's work.

Update: For some specific criticisms of Nathan's work, see the comment thread here. For a response to some of this from Nathan, see here.

Update: Scientific American has an article about this here.

Update: As pointed out by Wayt Gibbs in a comment, those interested in some discussion of the main point at issue might want to read the exchange here.

Comments

1. **Ethan Vishniac**
   May 24, 2016

   Ned Wright is a professor at UCLA, not a NASA person. I urge anyone interested to read the papers rather than judge by your opinion of Ned Wright or Nathan Myhrvold. For those without the patience to do so, I note that Ned has been usually acerbic, and usually correct, throughout a long career in science.

2. **Peter Woit**
   May 24, 2016

   Ethan Vishniac,
   Thanks, fixed the affiliation, I think.

   I know nothing about Wright, but I do have a lot of experience with what happens when you tell smart scientists they're wrong about something. If you're the one who is wrong, you quickly learn immediately why. If it's them, you get this kind of thing (for which "juvenile" is more accurate than "acerbic").

3. **Henry Lichtenstein**
   May 24, 2016

   If triple "l" "Killler" is not merely a typo, please explain what you mean by it. Thanx.

4. **edmeasure**
   May 24, 2016

   It's entirely possible that some significant threats among the smaller asteroids could be missed, whether for these reasons or others, including ones that could flatten a city or a small country. The big ones, extinction level event size, not likely. That's not the case for comets. Giants could be out there coming and we wouldn't see them until it was entirely too late.

5. **Peter Woit**
   May 24, 2016

   Henry Lichtenstein,
   I do think the triple "l" looks quite good there, but I fear it is a typo that I'll fix.

6. **Henry Lichtenstein**
   May 24, 2016

   Whew! Glad it wasn't meant to imply another Chicxulub impactor was heading our way.

   🙂

7. **Dwayne Day**
   May 24, 2016

   "I do have a lot of experience with what happens when you tell smart scientists they're wrong about something."
   .
   I note that while you complain about the reaction of one of the WISE scientists, you neglect to address a very serious issue here: Myhrvold did NOT bring up these issues in a peer-reviewed paper, but by posting it to a blog and then having his public relations people notify various science journalists and bloggers about it. That's bypassing normal (and proper) scientific procedures. It's not really telling "smart scientists they're wrong about something,"–the way you do that is by publishing with peer review. This is unprofessional behavior.
   .
   In addition, Myhrvold also interjected himself into an ongoing NASA mission selection competition in an obvious effort to influence that selection. That too is unprofessional. He's not a knight in shining armor, he's a spoiler.

8. **Peter Woit**
May 24, 2016

Dwayne Day,
Nathan did not "post the paper to a blog". He posted it on the arxiv and submitted it (if you believe the NYT) to the journal Icarus. Among the fields I'm familiar with, posting a preprint to the arXiv at the same time as submitting it to a journal is the standard behavior.

I have no idea whether he would like to influence the NASA selection, but don't see why, if he's convinced there's a problem with the NEOWISE numbers, it is "unprofessional" for him to raise the issue. Put differently, if you knew there was a problem with the numbers being used in such a selection process, it seems to me that you would have some duty to raise the issue. He's an unusual case of someone who has deeply immersed himself in the relevant technical issues, while not being affiliated with any of the groups seeking funding (even more unusual in that not only is he not seeking funding, others have been seeking it from him).

9. **Henry Lichtenstein**
May 24, 2016

@ Dwayne Day

"… –the way you do that is by publishing with peer review."
.
That is certainly one way, especially if one is at leisure to do so. But it is not the only way. I've been to a few conferences in my day, and I can vouch for there being many other ways of telling people they are wrong.

10. **Henry Lichtenstein**
May 24, 2016

"… , while not being affiliated with any of the groups seeking funding"
.
A laudable way to be, indeed. Beware of geeks seeking funding, like some folks at East Anglia University.

11. **Jeffrey M**
May 24, 2016

Peter,

While posting to arxiv while you submit is totally standard, in math at least that's not what you would do if you thought you found an error in someone's paper. In my experience, the person who thinks they found the error would email the author, and let them know so they can fix it. This literally just happened to me, someone had emailed a while ago about a paper I wrote 15 years ago, and my co-author and I finally had the time to look at what they said. I spent all day emailing back and forth with her today, and we came to the conclusion that we were right in the first place, so we're emailing the person who thought we had an error to see what they say. If we had decided instead they were right, we would have posted a correction to arxiv, and to the original journal, acknowledging who found the error. Seems like a much nicer way to do things.

12. **Dwayne Day**
May 24, 2016

"Submitted" is not the same as "published." He's made his paper available online–prior to any peer review–and then had his flacks publicize it (see the comments over at NASAWatch).

And he not only raised the issue of NEOWISE data, but injected himself into the Discovery selection process re NEOCam. He's playing spoiler.

The scientists quoted in the article have pointed out that he should go through peer review instead of engaging in a public relations campaign bypassing the scientific process and going straight to the press. If his analysis is correct it will survive peer review.

13. **AdamT**
May 25, 2016

Jeffery M,

What makes you believe that Myrhvold didn't contact them in private beforehand? My reading of the article indicates they were talking before he published.

14. **Jeffrey M**
May 25, 2016

AdamT

Where do you see that? They clearly talked, but from what I read it looked like it was after his paper was on ArXiv, when errors in Myrhvold's paper were pointed out to him. I see nothing to indicate he wanted to give anyone time to fix anything, he pretty clearly wanted to make a splash himself.

15. **Peter Woit**
May 25, 2016

Jeffrey M,
As far as I know, there was discussion of this between the parties before the preprint appeared. Would of course have been better if that led to agreement on what was right and what was wrong. Resolving such an issue tends to be more straightforward in math than in other fields.

16. **G. S.**
May 25, 2016

There are a few things which bother me about this story:

– Normally, when a single author writes a 111 page article criticizing a large scientific collaboration's data analysis, I am a bit suspect. It doesn't mean that the person is wrong, but I assign a high prior belief to the author being in error. Regardless of the author's institutional affiliation, I am unlikely to give much credence to the claims until after they have survived peer review.

– According to the Science article, it sounds like there was quite a bit of back and forth between Myrhvold and NEOWISE. NEOWISE disagreed with his analysis and suggested that he submit the paper to peer review. That seems like the proper course of action to settle a scientific disagreement. I am troubled by the additional media blitz (initiated by Myrhvold?) where the author claims the scientific establishment is staying the course because they are worried about their NEOCam proposal. This is similar to the argument constantly used by climate change deniers for why climate scientists repeatedly publish papers confirming global warming. It's possible that Myrhvold is correct, but these tactics are moving my belief even further out of his favor.

– The media seem to love these stories of "lone non-expert proves scientific establishment wrong". It seems there is a new one that gets promoted every week. Almost all of them eventually get debunked (e.g., the Canadian teenager who found a lost Mayan city … that turned out to be an old cornfield). Unfortunately, the public never reads the debunking article and they are left with the mistaken belief that the scientific community is constantly being proven wrong by non-experts. This makes it extremely difficult for the scientific community to convince the public that its findings are a solid foundation for public policy.

17. **Peter Woit**
May 25, 2016

G.S.,
I think this is a rather unusual situation and cast of characters, so I don't think trying to figure out who is right by analogies of the kinds you are making is sensible. In addition, trying to paint Nathan as analogous to a climate change denier is pretty offensive.

And no, as usual, I'm not going to allow comments here from people who want to argue about climate change.

18. **G. S.**
May 25, 2016

I certainly did not intend to cause offence. I merely intended to point out which aspects of this story bias me a particular way and why. In my experience, my line of reasoning has biased me toward the eventual correct conclusion much more often than not. However I realize that my line of reasoning is not proof, which is why I fully encourage peer review from (hopefully) initially unbiased experts in the field.

19. **Henry L.**
May 25, 2016

@ G. S.
"…, I am a bit suspect."
—
Did you really mean to say that you are not to be trusted?

20. **G. S.**
May 25, 2016

@Henry L.

Ha ha, no. I always thought that "suspect" could be used in this way but the dictionary claims otherwise. I learn something every day.

Interestingly, if I did say that I was not to be trusted, would you believe me?

21. **Henry L.**
May 25, 2016

G. S.,
—
Thank you for taking my remark in the spirit that I intended it to be taken.
—
I would believe you but I wouldn't entirely trust you. 🙂

22. **Scott Church**
May 25, 2016

Peter, I'm not familiar with this issue, but it seems to me that your friend is entirely within legitimate bounds. Dwayne Day says,

"'Submitted' is not the same as 'published.' He's made his paper available online–prior to any peer review–and then had his flacks publicize it (see the comments over at NASAWatch)…"

I'll grant that submitted doesn't equate to published, but the Arxiv is well-known as a *preprint* forum where researchers routinely post work while it's in review. In addition to the journal/s it's been submitted to, this gets it in front of a larger audience where it can receive whatever expansion and/or correction it may need that much faster. Everyone does this… we're all the better off for it, and we don't accuse anyone of duplicity for doing so.

The press routinely trolls the Arxiv for anything that might fuel PM-Edition potboiler stories and regardless of what anyone says or publishes, "Killer Asteroids Threaten Humanity!" is bound to be like tossing a 10 lb bloody pot roast into a shark tank. It's little wonder they were all over it, and whether Myrhvold spoke to them first or not, you can bet they would've sought him and others out for comment soon enough anyway. If he, or anyone else chose to respond that hardly makes them "flacks" or "spoilers." I don't recall anyone labeling Stephen Hawking as either when he publicly bet Gordon Kane that the LHC wouldn't find the Higgs, only to turn around and proclaim that it could destroy the universe at any moment when it was.

As for NASAWatch, I've seen countless such *****Watch sites over the years. In my experience all were agenda-driven forums run by "activists" who invariably saw ***** as a cabal of nefarious evil doers against whom they had been anointed to be "whistle blowers" delivering "the truth" to the masses. Not surprisingly, NASAWatch is owned by SpaceRef–a self-described "new media company focused on the space sector" that among other things, has an "Intelligence Unit." According to the NASAWatch website header, "This is not a NASA Website. You might learn something. It's YOUR space agency. Get involved. Take it back. Make it work – for YOU." [sic]. The only references I was able to turn up to their content were at conspiracy websites. The words *objective* and *trustworthy* don't exactly leap to mind here.

23. **Henry L.**
May 25, 2016

@ Scott Church
—
I agree that Hawking's bets and proclamations do not make him a spoiler, but I fail to see how the outcome of his bet with Kane has anything to do with his proclamation about the Higgs possibly destroying the universe. The discovery of the Higgs at the LHC did not create the possibility that it could destroy the universe.

—
Perhaps I am misreading your comment?

24. **Scott Church**
May 25, 2016

Henry L.,

It didn't… I cited the two stories together only because both involved the Higgs, and both struck me as examples of situations similar to that involving Peter's friend that didn't lead to anyone being accused of being a flack or a spoiler. Other than that, you're correct–there is no similarity between the bet and the doomsday comment. Best.

25. **JeanTate**
May 26, 2016

I'm a bit surprised no one has yet commented on the actual content of the Myhrvold paper (arxiv preprint version anyway). There are sites where this is discussed, and which include posts by actual astronomers, professional and amateur, e.g. Challenge to Asteriod Size Estimates, at Yahoo Groups.

It seems that, among other things, Myhrvold did not do a good job of checking for consistency, both internal (e.g. radius vs diameter), and external (e.g. independent estimates of the sizes of asteroids, from studies independent of WISE, occultations, etc; there are quite a few such independent datasets, available publicly, for free)."

As far as I know, these sorts of simple, if sometimes rather tedious – astronomers tend to use rather a lot of different systems, and conventions, not all immediately obvious (surprisingly, radius vs diameter is one!) – consistency checks peer reviewers expect authors to do, before submitting to arXiv. Sure, if you're an outsider, you'll likely miss some, but I find it strange that a trained physicist would trip up over radius vs diameter, no matter how deeply you'd have to dig to get complete certainty ("size" clearly doesn't cut it).

26. **Anonyrat**
May 26, 2016

"Amy Mainzer, principal investigator for NEOWISE, pointed out that many of her projects' measurements have in fact been reproduced and confirmed. Japan recently operated an infrared telescope called Akari that was similar to WISE, and it measured many of the same asteroids."

28. **Anonyrat**
May 26, 2016

From the WaPo link:

He {Myhrvold} added that he tried to get WISE scientists to comment on his work for months, but that they'd refused to respond until he made his work public. Mainzer disputes this, saying she has offered corrections to the paper that Myhrvold has ignored, including an issue that he sees as a possible sign of fraud.

"In more than 100 cases, the reported asteroid sizes they listed were an exact match to prior papers, that's within the meter. That's just not possible to have happen accidentally," he said.
…
""We've tried to explain this many times," Mainzer said. Those measurements, she continued, are intentionally pulled from other sources — they're used to calibrate the measurements made using the spacecraft with previously observed data. It's not the case of a mistake or fraud, but a standard procedure."

"She also takes issue with the underlying thesis of the critique, which is that the NEOWISE calculations ignore Kirchhoff's law of thermal radiation."

""Of course this model doesn't perfectly conserve energy, and no one has ever said it does," Mainzer said. The model, she explains, sweeps away some of the complexities of an asteroid's heat distribution to make up for the fact that asteroids have incredibly complex surfaces. Scientists using these models don't have every data point they would need to do a perfect calculation, and that's the whole point of using the model in the first place.

"The paper is basically useless in the sense that he's complaining about a model which it has always been clear does not satisfy physical laws," Ned Wright told The Post. "So then the question is, does it work, is it a good approximation anyway, and the answer to that seems to be generally yes.""

29. **Anonyrat**
May 26, 2016

On a yahoo egroup, Joseph Masiero, Ph.D. Scientist, NASA JPL/Caltech, points out a NASA-JPL response (provides no link to that response)

https://groups.yahoo.com/neo/groups/mpml/conversations/messages/32026

Quote:

A sampling of the errors include:

— Equation 3 (page 7), equation 26 (page 20) and equation 33 (page 21) are all wrong by a factor of 4. This is because of a fundamental error confusing diameter and radius. It hasn't been possible to review the actual code used by the author(s) in implementing the thermal model, but if it follows these equations it will consistently get incorrect results for diameters, albedos and predicted fluxes. One example of this can be seen in Figure 21 (page 68), which shows a diameter for asteroid 295 of about 660 kilometers. Such a size would make this object bigger than asteroid Vesta, the second largest object in the asteroid belt. The actual diameter of asteroid 295 is estimated at about 30 kilometers from the Infrared Astronomical Satellite (IRAS), Japan's AKARI satellite, and WISE data.

— The paper mischaracterizes the use of the radar/occultation/flyby diameters. In Mainzer et al. 2011 ApJ 736, 100, the NEOWISE team uses these diameters to compute model brightnesses and compare them to the measured brightnesses for the objects. They are in excellent agreement. The radar/occultation/flyby sources are cited in this paper; later papers reference this calibration paper.

— The paper erroneously states that the NEOWISE data are not reproducible. On the contrary, in Usui et al. 2014 the authors find that IRAS, AKARI, and WISE are all in agreement to within +/-10% 1-sigma for the ~2000 asteroid diameters measured by all three observatories. This point is given in the abstract (See: http://arxiv.org/abs/1403.7854). These measurements were independently taken over a 30-year span beginning with the joint UK-US-Dutch IRAS mission and Japan's AKARI mission, as has been documented in peer reviewed papers. While Usui et al. 2014 is mentioned in the new report (on page 2), the central point of its finding was omitted.

–The paper has changed the standard asteroid thermal model (Harris 1998) that is widely used and has been extensively peer reviewed, but the paper doesn't show that the proposed model works better than the standard model at replicating the radar diameters.

— The paper mischaracterizes the NEOWISE use of visible brightness H; it is an observational constraint and not a free parameter (page 48.)

— In equation 32 (page 21), the brightness of the Sun is computed as being of order 10E-11 Jy. This is off by more than 20 orders of magnitude as currently written.

Data from the mission is publicly available. A quick guide to the NEOWISE data release, data access instructions and supporting documentation is available at http://wise2.ipac.caltech.edu/docs/release/neowise/. Access to the NEOWISE data products is available via the on-line and API services of the NASA/IPAC Infrared Science Archive."

30. **Anonyrat**

31. **Anonyrat**
May 26, 2016

Dave Herald of IOTA –
https://groups.yahoo.com/neo/groups/mpml/conversations/messages/32032
Quote:

There is a world-wide group of (mainly) amateurs who regularly observe occultations of stars by asteroids The main groups are located in Nth America, Australia/New Zealand, Europe, & Japan. These groups collectively observe over 200 actual occultations per year (and have high hopes for this number to increase significantly as Gaia data becomes available over the next few years). Their observations and results are annually archived at NASA's Planetary data System, Small Bodies node, Asteroid/Dust Archive – at http://sbn.psi.edu/pds/resource/occ.html.

The observed length of a single occultation chord routinely has a precision of about 1 km for a main belt asteroid. That is, we are measuring the outline of an asteroid at a 1km precision, at which level surface irregularities (let alone gross shape) are evident. To obtain a reasonable estimate of the asteroid size, you generally need at least 3 occultation chords spread across the asteroid. On occasions we have many 10's of chords located across the asteroid – with the shape and irregularities of the asteroid profile being blindingly obvious. We generally fit an ellipse to the observations – as asteroids are rarely spherical. And this raises the issue of the rotational orientation of the asteroid – as the profile is continually changing as the asteroid rotates. A consequence is that we do not get (or expect) a 'single' diameter measurement for an asteroid. On the other hand the observations can (and are) linked to light-curve inversion models to provide a scale (as well as validation) for those models. It seems to me that any study of the accuracy of asteroid diameter determinations from missions like NEOWISE is entirely academic unless it taps into this publically available data. The failure of Myhrvold to undertake this in the course of his criticism of the work of others is (IMHO) bordering on the inexcusable.

Turning now to a specific critique of Myhrvold's paper (which I find extremely tedious reading…) Fig 23 (on page 72!) is (from my perusal) the first (only?) point at which he presents diameters derived by his approach. It lists just three asteroids, and interestingly we have a single reasonably-well-determined occultation diameter for each of them. Importantly, for these three asteroids we have a measured diameter two compare against the two 'inferred' diameters, with the obvious ability to assess which inferred diameter is best in each case, and whether there is any consistency across different asteroids. To summarise the various results:

Asteroid # 208 306 757
NEOWISE 45.0km 51.6km 36.7km
Fig 23 146.5km 83.8km 6.6km
Occultations 48 x 42km 61 x 44 km 39 x 34km

Clearly the occultation results align extremely well with NEOWISE. In contrast there is major disagreement with the results of the author's 'bootstrap' solution – with the strong implication that his bootstrap methodology is seriously flawed. IMHO the consequence of this on the paper as a whole doesn't need to be stated…

A final comment. We (in the occultation community) have not undertaken a formal comparison of our occultation results with those from NEOWISE/IRAS etc. However I believe it is a fair comment to assert that the NEOWISE/IRAS diameters are 'about right' – and certainly more than reliable enough for our current prediction purposes. Furthermore I cannot think of any instance where the diameter determined from a well-observed asteroidal occultation was greatly different from a NEOWISE.IRAS diameter – especially when a shape model is available such that we can assess the effects of the shape model on the expected diameters.

May 26, 2016

NASA Response to Recent Paper on NEOWISE Asteroid Size Results
.
Press Release From: NASA HQ
Posted: Wednesday, May 25, 2016
.
A paper posted Sunday by Nathan Myhrvold to ArXiv.org and described in an article by reporter Ken Chang in the May 23 New York Times discusses interpretations of data on asteroids from NASA's NEOWISE mission. The paper was posted before undergoing the essential scientific peer-review process to catch and remove significant errors.
.
Examination of the paper by members of the science community studying near-Earth objects has found several fundamental errors in Myhrvold's approach and analysis—mistakes that an independent peer review process is designed to catch. The errors in the paper lead to results that are easily refuted, such as sizes for well-known asteroids that are significantly larger or smaller than their already-verified sizes. While critique and re-examination of published results are essential to the scientific process, it is important that any paper undergo peer review by an independent journal before it can be seriously considered. This completes a necessary step to ensure science results are independently validated, reproducible, and of value to the science community.
.

All of the published NEOWISE team papers providing their results have endured the peer-review process. NASA is confident that the processes and analyses performed by the NEOWISE team are valid and verified and stands by its data and scientific findings.
.
Data from the NEOWISE mission is available on a website for the public and scientific community to use. A guide to the NEOWISE data release, data access instructions and supporting documentation is available at http://wise2.ipac.caltech.edu/docs/release/neowise/. Access to the NEOWISE data products is available via the on-line and API services of the NASA/IPAC Infrared Science Archive. A list of peer-reviewed papers using the NEOWISE data is available at http://neowise.ipac.caltech.edu/publications.html

// end //

33. **south**
May 26, 2016

Having read the comments here and some testimonies online, Myhrvold comes across as an individual more interested in seeing his name and ideas talked about in the media than contributing to science. Similar to some of the individuals and their over-reaching ideas in the string theory that receive some criticism on this blog.

—

Also, all I see in the NASA statement is a dispassionate assertion that (1) the peer-review process is the proper hurdle to overcome, and that (2) experts have identified several errors in Myhrvold's work. I don't consider it an "attack" to state that someone's calculations are wrong — in fact, this is what Myhrvold himself has done to NASA. But he did so publicly and these exchanges should carried out professionally through a peer-review process. Since Myhrvold eschewed this process and was first to blast to the media about NASA's errors, I think it's necessary and responsible for NASA to defend their reputation by publicly stating their disagreement.

34. **Dwayne Day**
May 26, 2016

From the Washington Post article:
.
"Some of the things I've heard from third parties are, 'wow, we'll see if it makes it through peer review,' which makes me think they'll ambush it in peer review," Myhrvold said.
.
So he had his people contact the NY Times, Science, and apparently other websites pushing his claims before peer review.
.
https://www.washingtonpost.com/news/speaking-of-science/wp/2016/05/25/that-study-critiquing-nasas-bad-science-on-asteroids-is-pretty-bad-science/

35. **Anonyrat**
May 26, 2016

Myhrvold has evidently put in a lot of work, and it would be tragic if none of it is of value. What I don't get is that, from all accounts, he has resources at his command that I can only dream of, and he certainly could have hired a couple of smart students or even professionals to vet his work before publishing it. It is not as though someone was going to scoop him. If this turns out to be a fiasco, anything important that he has to say in the future will get little attention.

36. **Jeffrey M**
May 26, 2016

I think this makes clear that arXiv is now treated in a way it really shouldn't be. arXiv is for preprints. The odds that there are errors in things posted on arxiv are noticeably higher than for things published in reputable journals. I think a lot of people have forgotten that, they treat arXiv like a journal, which it's not. If Myhrvold tried to get the authors to fix mistakes he thought they made, and they didn't (either because they couldn't, or because they didn't feel they were mistakes), he could have gone to the journal editors where it was published. If even after that he got nowhere, he could put something on arXiv, and send it to a journal, but to make a big deal out of it is really out of bounds, no one has checked his work carefully, and someone did check the original work. The original referee might have screwed up, but Myhrvold hasn't been refereed yet. This shouldn't be happening in public. Myhrvold and NASA should just be waiting on the referee report on his paper, and if the referee says junk then no story, if the referee thinks Myhrvold is right, then it's a story.

37. **JeanTate**
May 26, 2016

I would be interested to hear how mathematics arXiv submissions are different from astronomy/astrophysics ones.

In the latter field, most authors clearly indicate whether the document has been submitted to a peer-reviewed journal, when/whether it has been accepted for publication, etc. How timely, or accurate, this info is is left up to the reader to decide. Some post the published version (modulo formatting etc), but I think that's rare. There are, almost always, significant differences between the "submitted to", and the "accepted for publication in" versions; sometimes these can be quite major. There are also quite a few arXiv documents that have, apparently, never been submitted to a journal, and some which apparently were submitted many years ago, but are still not published (in a peer-reviewed) journal.

In almost any published paper, you'll find "errors". Mostly these are trivial – a misplaced comma, say – but occasionally you'll find some howlers. A figure's axes that are mislabeled, say, or an equation that omits a key term. I've asked astronomers about some of these, and most seem quite unconcerned; the mistakes are "minor" enough that a fellow professional, working in the same sub-sub-field can work out what was intended; indeed, I've had responses where mislabeled axes, say, we're not even noticed!

So, how bad are the – many – "errors" in the Myrhvold preprint? Of the ones already noted, and copied here, some would require just minor tweaks, and the main conclusions would be unaffected. Others, not so clear (the misunderstanding/misrepresentation of H, for example). The basic physics, and statistical analyses seem OK, but their application seems flawed, in several places. Also, one of the central themes – picked up by the popsci articles, i.e. the "unphysical" modeling – is misplaced (as Mainzer notes).

38. **Ignatz Ratzkywatzky**
May 26, 2016

"Anonyrat says:"

Thank you for posting the only comments worth reading about this controversy.
The ones with astronomical content.

As for the rest

“What dire Offence from astro’mous Causes springs,
What mighty Contests rise from trivial Things,”

with apologies to Pope.

39. **Jeffrey M**
May 26, 2016

JeanTate

In math, from my experience, many postings on arXiv are done before something is submitted somewhere, but not long before. People are often trying to work out where to send something once they’re confident it’s right, so they’ll put in on arXiv while they’re trying to figure that out. People usually repost published versions, and corrected versions before publication. There are things on arXiv that have never been published, there are various reasons for that. I have a paper on arXiv which never appeared anywhere, I am sure it is correct, but it’s in a field not mine, and my co-author and I could never get our language to where the referees in that area would deal with the paper, so we just gave up. As you note, plenty of published papers have errors, referees miss things all the time. Usually not a big deal, but not always. There’s a famous example in my area, a paper of McKean where he claimed to prove that 1/4 is the bottom of the Laplace spectrum on surfaces. This was a big big deal, which unfortunately isn’t true.

40. **Anonyrat**
May 26, 2016

NASA pointed out that Myhrvold estimates the diameter of asteroid 295 to be 660 kilometers – this would be larger than the asteroid Vesta which is supposedly the second largest object in the asteroid belt. The diameter estimated by WISE, etc., is around 30 kilometers.

41. **Anonymous**
May 26, 2016

I would hardly characterize the NASA response as an attack. It simply states that peer review is appropriate for such claims. That’s pretty mild compared with what they could have said.

I’m frankly startled, given your critiques of the meddling of billionaires in the physics and math worlds, and of the rockstar culture in physics, that you are embracing Myhrvold’s science-by-public relations efforts.

42. **Peter Woit**
May 26, 2016

I’ve added as an update a link to something from Nathan explaining his point of view on this controversy.

While I have no expertise or ability to figure out who is right and who is wrong on the technical issues being raised on both sides here, I do have some expertise on the question of Nathan’s motivations, based on observations conducted over the long-term and over the shorter term of the last couple years. Some commenters seem to think this is a usual story of a wealthy person who wants to see his name in the papers, throw his money around and “meddle”in the world of science. They should note that devoting a huge amount of time and energy to rather tedious and complex issues of data analysis in a highly-obscure subject, and writing 60 page (successfully peer-reviewed) and new 110 page (out for peer-review) papers about this data analysis, are a funny way to go about this. Nathan has gotten a lot of media attention for various of his activities, and to whatever extent he might want more, he has lots of much easier ways to go about this. Among all the scientists I’ve met over the years, he’s one with an extremely unusual degree of enthusiasm and love for learning as much as possible about the technical details of a wide variety of scientific subjects, coupled with a brilliant mind and an insane amount of energy. Those criticizing his motivations seem to me to be missing the obvious: the guy loves real science with a passion and engages with it very seriously.

43. **Narad**
May 26, 2016

> The errors in the paper lead to results that are easily refuted, such as sizes for well-known asteroids that are significantly larger or smaller than their already-verified sizes. While critique and re-examination of published results are essential to the scientific process, it is important that any paper undergo peer review by an independent journal before it can be seriously considered.

This seems to be a very priggish approach coming from NASA. I know that the context is different (and I also worked on the make-the-final-product side of the AAS journals for over a decade a while ago and prevented more than a few errata), but virologist Vincent Racaniello recently was the subject of similar complaints.

Is there some sort of crucial difference between postpublication peer review and the prepublication version? I see no particular reason to delay the “more eyeballs” part until after solemnization.

44. **No Math, Meekly Interacting**
May 26, 2016

“But the most egregious problems with the NEOWISE project are dead simple to explain; indeed, this might be a good project for a middle-school science class.”

Ooooh-kay then! No mistaking the size of Dr. Myhrvold’s stones!

45. **Henry L.**
May 26, 2016

“No mistaking the size of Dr. Myhrvold’s stones!”

Would that be based on using the thermal model?

46. **Anonymous**
May 27, 2016

While I still think Myhrvold’s pre-publication publicity efforts are inappropriate, and still loath him as a billionaire patent troll, I’ve now looked at the paper and withdraw my comment about meddling. His argument (about the copied data, I can’t evaluate the thermal modeling) is pretty damning. The NEOWISE people have some explaining to do.

I do have some sympathy for their disinclination to engage with him, whatever the truth of the matter. Myhrvold hurts his case by his tone, which comes across as too similar to that of the many cranks that everyone at NASA or funded by NASA has to deal with on a daily basis.

47. **Anonyrat**
May 27, 2016

http://arxiv.org/pdf/1604.03444v1.pdf
MODELING THE PERFORMANCE OF THE LSST IN SURVEYING THE NEAR-EARTH OBJECT POPULATION

cites Myhrvold, if only to disagree with him. But they weren't ignoring him.

"The limiting magnitudes and solar elongation coverage presented here are at odds with Myhrvold (2016); his Figure 7 shows much fainter limiting magnitudes than presented here. While Myhrvold (2016) cites the possibility and capability of LSST observing at much smaller solar elongations, this is inconsistent with the published cadences provided by the LSST project and would potentially interfere with
its other science goals. Additionally, Myhrvold (2016) incorrectly assumes that an object need only be detected once for it to be counted as discovered, cataloged, and tracked"

48. **Anonyrat**
May 27, 2016

In https://arxiv.org/ftp/arxiv/papers/1605/1605.06490.pdf, Myhrvold writes about the NEOWISE claims of high accuracy, and that all the caveats are not included.

"This implies that the correspondence between NEATM model estimates and those from radar or other means has been calculated yielding a quantified numerical answer ≤±10%. In the passage above there is a caveat that the error estimate applies only with certain pre-conditions, but those caveats are frequently dropped from other references (as in the quote from (Masiero et al., 2011) in section 1 above.)"

A look at Masiero et al. 2011 is NEATM applied to main belt asteroids, not near-earth asteroids. NEATM is "Near Earth Asteroid Thermal Model". It was developed in 1998. This abstract (doi:10.1006/icar.1997.5865) essentially says that the thermal models for large main-belt asteroids were wrongly being applied to Near Earth Asteroids, that have very different properties, and that is the motivation for the NEATM model.

But it seems after that, NEATM was found to be much more widely applicable, giving good results with main-belt asteroids. Therefore, when Myhrvold complains that Masiero et. al. write "Using a NEATM thermal model fitting routine we compute diameters for over 100,000 Main Belt asteroids from their IR thermal flux, with errors better than 10%." (this is in the abstract) it is possible that NEATM model accuracies for main-belt asteroids can indeed by 10% while not being that accurate for actual NEOs. It is not clear to me.

Most of the Mainz, Masiero, etc. papers that are cited have preprints on arxiv. You can look at them and see if Myhrvold's criticisms are justified.

49. **Low Math, Meekly Interacting**
May 27, 2016

"Would that be based on using the thermal model?"

Indeed. There's a lot of heat here, clearly. We'll see if there's light. Tenured professors openly cutting rivals to the quick is hardly surprising, based on what I've observed in my career, and barely warrants a shrug. I normally do expect similar behavior from an "outsider" to be indicative of a crackpot at work. Obviously, Dr. Myhrvold doesn't fit that description. But on the subject of stones, his status as a "billionaire patent troll" of considerable renown does mean that if he's wrong, it's going to be a very, very satisfying experience for some people to point that out, given the current sociopolitical climate. I doubt they will resist the opportunity to gloat in a most public fashion.

50. **JeanTate**
May 27, 2016

Thanks for posting the link to Nathan's response, Peter.

He makes a strong case for some apparent, strange inconsistencies in the published NEOWISE diameter estimates of some asteroids, and at first blush it seems pretty sound. However, despite Anonyrat pointing to many papers being freely available, it's not clear how different the preprint versions are from the actual, published in peer-reviewed journals … some at least are behind paywalls (this points to yet another barrier to outsiders doing front-line, independent research in astronomy; unless you are rich, or have a backdoor, simply obtaining the necessary papers, not preprints, can be prohibitively expensive. Ironic really, as taxpayers, you pay for almost all the published research, yet you have to pay, yet again, to actually read what your dollars resulted in).

I'm a little confused, however; my read of Nathan's paper is that the NEOWISE diameter inconsistencies are a relatively minor part. The main part has to do with the models which are used to produce diameter estimates, and in this regard, it seems that Nathan is doing a dodge of his own.

Finally, Nathan claims that the shortcomings in his equations (etc) are minor, easily fixed, and do not significantly change his main conclusions. That may well be so; however, until he makes the changes, publishes them, and we can all evaluate them for ourselves, his claim has no legs, IMHO.

51. **Scott Church**
May 27, 2016

For what it's worth, this was published today in Slate:
http://www.slate.com/blogs/bad_astronomy/2016/05/27/nathan_myhrvold_claims_nasa_scientists_asteroid_calculations_are_all_wrong.html. Haven't had a chance to read it closely yet, but at first blush it seems thorough, and presents both sides of the debate.

52. **Confused**
May 27, 2016

From the slate paper:
"This is the model Myhrvold claims is wrong. However, the asteroid diameters found by the NEOWISE team agree very well with previous satellite measurements. NEOWISE looked at many of the same asteroids as an earlier mission called IRAS—a couple of thousand of the same asteroids—and found that the diameters calculated for those asteroids matched the measurements using IRAS to about 10 percent. Not only that, measurements using a Japanese satellite called Akari also yielded similar results, and all three agree well with the radar and occultation measurements."
http://www.slate.com/blogs/bad_astronomy/2016/05/27/nathan_myhrvold_claims_nasa_scientists_asteroid_calculations_are_all_wrong.html
—
They cite this paper in support of that claim:
"The mean values of the relative differences are 2.8%, 1.7%, and 7.5% for IRAS, AKARI, and WISE, respectively, and the standard deviations for each are 12–13 %.We found that the size derived by AKARI is closer to that derived by IRAS or WISE. This is not a surprising result, as the beaming parameter adopted in the thermal model calculation in the AKARI catalog is calibrated with well-studied main belt asteroids larger than 90 km, whose size, shape, rotational properties, and albedo are known

from different measurements, as mentioned above. In this respect, the diameters obtained by radiometric measurements based on I–A–W are reliable in a statistical sense, which are smoothed out and averaged over a limited number of observations, even though the sizes obtained by radiometric and other measurements can be discrepant by up to 30%."
http://arxiv.org/pdf/1403.7854.pdf
—
So the 1-sigma uncertainty is >10%, and from figure 7 it looks like the (more usual to report) 2-sigma uncertainty is ~25%. I don't see how Myhrvold's point that claiming "+/- 10% accuracy " is way overconfident is at all controversial from this data.
—
Also, this is apparently for the same asteroids that were used to calibrate this thermal model… Am I understanding that last part correctly? Don't they need to estimate out of sample error in order to assess the skill of the model?

53. **Henry L.**
May 27, 2016

LM MI,
"There's a lot of heat here, clearly."
—
Heat, for sure; clarity, not so much.
🙂

54. **Anonyrat**
May 27, 2016

Since LSST and Ivezic have been brought into the mix by the SciAm article, the "NASA" team have this from April 12: http://arxiv.org/abs/1604.03444 Modeling the Performance of the LSST in Surveying the Near-Earth Object Population
which is from before this controversy hit the airwaves.

Emphasis added:

"We have performed a detailed survey simulation of the LSST performance with regards to near-Earth objects (NEOs) using the project's current baseline cadence. The survey shows that if the project is able to reliably generate linked sets of positions and times (a so-called "tracklet") using two detections of a given object per night and can link these tracklets into a track with a minimum of 3 tracklets covering more than a ~12 day length-of-arc, they would be able to discover 62% of the potentially hazardous asteroids (PHAs) larger than 140 m in its projected 10 year survey lifetime. This completeness would be reduced to 58% if the project is unable to implement a pipeline using the two detection cadence and has to adopt the four detection cadence more commonly used by existing NEO surveys. When including the estimated performance from the current operating surveys, assuming these would continue running until the start of LSST and perhaps beyond, the completeness fraction for PHAs larger than 140m would be 73% for the baseline cadence and 71% for the four detection cadence. **This result is a lower than the estimate of Ivezic et al. (2007,2014); however it is comparable to that of Jones et al. (2016) who show completeness ~70$%.** We also show that the traditional method of using absolute magnitude H < 22 mag as a proxy for the population with diameters larger than 140m results in completeness values that are too high by ~5%. Our simulation makes use of the most recent models of the physical and orbital properties of the NEO populations, as well as simulated cadences and telescope performance estimates provided by LSST. **We further show that while neither LSST nor a space-based IR platform like NEOCam individually can complete the survey for 140m diameter NEOs, the combination of these systems can achieve that goal after a decade of observation.** "

55. **Low Math, Meekly Interacting**
May 27, 2016

One thing that is quite clear: Myhrvold has gone very publicly on the record as stating the NOEOWISE team, et al. should perhaps someday be discussed in classrooms the way we discuss the Piltdown Man. Only the fraud is more obvious. Chutzpah doesn't begin to describe it. If he's wrong he's going to find out what being an 8.4 Tesla shit magnet feels like, and may even deserve it.

56. **Anonyrat**
May 27, 2016

The record of space telescopes operating in the infra-red for detecting asteroids seems unsurpassed. LSST, if it operates per specs, will also be awesome. If I were worried about asteroids that might collide with Earth, I'd want both instruments. If I had to choose one or the other — that is a very hard decision. I hope this goes back to being science and engineering and less the media-circus that it has become. I hope that Myhrvold gets some collaborators and he makes the breakthrough in NEO asteroid detection that he is looking for. Bye-bye for this thread.

57. **Henry L.**
May 27, 2016

LM, MI

I wasn't aware he was on record to have made such a (perhaps) reckless pronouncement. But I can't imagine that he was unaware of the consequences (if he was wrong). So he is either confident that he is not wrong, or he may not care about the consequences. I hear that ~650 mega-bucks can buy a lot of protection against all sorts of consequences.
—
I think that mega-bucks are the keys to clarification for these sorts of controversies. Chercher les mega-bucks if you have a dog in this fight. I don't.

58. **Astronomical Cowardice**
May 28, 2016

I have looked at three of the papers — Myhrvold's arxiv preprint, and (as referenced by Myhrvold) Masiero et al., 2011, and Mainzer et al., 2011c — with some care, and I must say that I find Myhrvold's criticism of the portrayal in Masiero et al. of "direct" diameter measurements (what Myhrvold calls ROS) as the result of the thermal model to be fully legitimate. (Myhrvold reiterates this point in his note, "A Simple Guide to NEOWISE Data Problems," that Peter links to in one of his updates.) (Note, to avoid confusion, that Masiero et al. reference as Mainzer et al., 2011b that which Myhrvold references as Mainzer et al., 2011c.)

I haven't read any of these papers in complete detail, but I have done more than skim them, and I have read through some sections quite closely. Myhrvold complains that 123 of the thermal-model diameter estimates (117 in Masiero et al., 2011) are actually ROS diameters from other sources. On the surface, including such "foreign" diameter measurements in a table of thermal-model estimates is bad science. It would be simply wrong of them to have replaced their model estimates with others' measurements. It would be at a minimum questionable to have somehow baked these benchmark values into their analysis so that their thermal model reproduced those exact values.

Note that Mainzer et al., 2011c analyze thermal models for 50 objects specifically for which ROS diameters are known, and make explicit that they use and report these

ROS diameters. Masiero et al. cite this paper, as I discuss below.

Masiero et al. do cite various ROS papers, but only in the introduction. I find no mention in their paper that they have used these ROS values in any way in their analysis. I find no mention that any of the diameter values in their Table 1 ("Example of Electronic Table of the Thermal Model Fits"), or in the electronic table of which it is an extract, are produced in any way differently than others of the same class. The ONLY clue I see anywhere in the paper itself that those which Myhrvold has identified as ROS values are different is that they are round kilometer values.

Masiero et al. cite a number of other papers, and I have only looked at the few of them that seemed potentially relevant to this issue. Of these, only Mainzer et al., 2011c proved relevant, discussing the explicit use of ROS diameters. Masiero et al. cite Mainzer et al. a number of times in different contexts. The most relevant citation is:

"We obtained our data used for fitting in a method identical to the one described in Mainzer et al. (2011b) and A. K. Mainzer et al. (2011, in preparation), though tuned for MBAs. Specifically …"

In their elaboration of how they collected their data (the "Specifically …" part) Masiero et al. say nothing about requiring any of the objects they analyze to have independent ROS diameters nor do they mention collection any ROS diameters. Although Mainzer et al. could be viewed as a hint that Masiero et al. use ROS diameters, nothing in my reading of Masiero et al. itself states or implies that they use ROS diameters, and in my reading of Masiero et al. and Mainzer et al. together, only the coincidence of the values of a subset of the diameters in Masiero et al. with those in Mainzer et al. indicate that Masiero et al. use ROS diameters.

There are a number of places in the paper, particularly in Sections 3 and 10, where the authors described differing treatment of different classes of object. But, to reiterate what I said above, in no place to I see a statement, or even a hint, that objects for which ROS diameters are available were treated differently.

Table 1 gives thermal-model diameter estimates together with error bars. From text elsewhere in the paper, it would seem that these error bars have been generated with a model-driven Monte Carlo process (but I have not found a description of this process in the paper). However, comparing the error bars for the ROS diameters with, for example, those in Mainzer et al., we see that those error bars are, as are the diameters themselves, input values, rather than results of the model. Again, there is no suggestion in Masiero et al. that these error bars have been put in by hand.

(Myhrvold also complains that the right approach would have been to run the analysis completely blind to the ROS values, and then use the ROS values to measure the errors due to the thermal modelling. I think he's absolutely right about this. Not to have done so is, in my view, poor science.)

Let me note that I have no dog in this fight. Also, you don't have to trust that I'm not making stuff up here or spinning things in some artful way. Look at the papers yourselves. For these ROS values to be presented as results of the thermal modelling with no discussion — or even hint — of where they actually came from is either willfully misleading or incredibly sloppy.

59. **Anonyrat**
May 28, 2016

Sorry, I intrude again. I have to disagree with Astronomical Cowardice.
http://arxiv.org/pdf/1105.0975.pdf
Table 1 has the caption: "Table 1. Spherical NEATM models were created for 50 objects ranging from NEOs to irregular satellites in order to characterize the accuracy of diameter and albedo errors derived from NEOWISE data. The diameters and H
values used to fit each object from the respective source data (either radar, spacecraft imaging, or occultation) are given…..".

Column #1 of the table is the object ID.
Column #2 of the table is the diameter in km and Column #3 is the H value from the (radar, spacecraft imaging or occultation data).
Column #8 is a pointer to the reference to the source of column #2 and #3.

Thus Object #47, with a diameter of 138 +/- 13 km and H of 7.8 comes from reference d, which is Shevchenko, V., & Tedesco, E., 2006 Icarus, 184, 211. Via scholar.google.com one can find this on researchgate.net, where you find Object #147 is the asteroid Aglaja, and it is ascribed a diameter of 138.0 km. You can read the paper and see the details of how that result of 138.0 km was reached (starting with an occultation measurement in 1984.)

It is very clear from the text of the preprint that this preprint describes a calibration of NEOWISE, and that after calibration but with Monte Carlo of measurement uncertainties, NEOWISE gives the diameter of 138 +/- 13 km.

Perhaps the preprint authors should have had two columns, one with the 138.0 km from reference d, and the second with the NEOWISE answer of 138 +/- 13 km. On the other hand, presumably anyone intimately familiar with the literature (or anyone who bothered to read the preprint carefully enough) would know what the condensed table meant.

Yes, the format the authors used will trip up the unwary. On the other hand, it allows their table to neatly fit the width of the page.

My apologies for breaking my promise to exit this thread. I have no stake in these games; I am not a professional scientist, nor affiliated with any science research institution (I am an employee of a telecom company.).

60. **Igor Khavkine**
May 28, 2016

@Anonyrat, your commentary has been very insightful and helpful. Thank you. It seems that the main obstacle to resolving the controversy here is the communication barrier between the scientists who share a common knowledge base related to asteroid astronomy and those who don't, despite being technically competent in other ways. Anyone who has worked in a narrow field would probably agree that such communication barriers are ubiquitous. It's often simply impossible to include all the details of this background information when writing an isolated paper. In fact, including such details can sometimes be seen as tedious repetition by the intended expert audience.

61. **Henry L.**
May 28, 2016

@ Igor Khavkine
—
You make the excellent relevant point "… that the main obstacle to resolving the controversy here is the communication barrier between the scientists who share a common knowledge base related to asteroid astronomy and those who don't, despite being technically competent in other ways." I belong to the latter category, my competency being nuclear physics (LANL, retired). This is why, I believe, such a heated controversy here (in the comments section of the personal blog of an expert in "Quantum Theory, Groups and Representations") seems out of place.

62. **Astronomical Cowardice**
May 28, 2016

In response to Anonyrat's comment, Anonyrat has mixed up two of the papers I discussed.

I criticize Masiero et al.; Anonyrat defends Mainzer et al., the paper I did not criticize.

I apologize for leaving the door open to confusion. I should have been more detailed with paper titles and links in my original comment. Let me correct that now.

I discuss three papers (whose lead authors all begin with the letter 'M'):

The first I refer to as "Myhrvold's arxiv preprint." Its title is:

"Asteroid thermal modeling in the presence of reflected sunlight with an application to WISE/NEOWISE observational data"

and it can be found here:

https://arxiv.org/ftp/arxiv/papers/1605/1605.06490.pdf

The second I refer to as "Masiero et al., 2011" (and in abbreviated form as "Masiero et al."). Its title is:

"MAIN BELT ASTEROIDS WITH WISE/NEOWISE. I. PRELIMINARY ALBEDOS AND DIAMETERS"

and it can be found here:

http://iopscience.iop.org/article/10.1088/0004-637X/741/2/68/pdf

This is the paper I criticize. For completeness, it is cited in Myhrvold's arxiv preprint as:

"Masiero, J.R., Mainzer, A., Grav, T., Bauer, J.M., Cutri, R.M., Dailey, J., Eisenhardt, P.R.M., McMillan, R.S., Spahr, T.B., Skrutskie, M.F., Tholen, D., Walker, R.G., Wright, E.L., DeBaun, E., Elsbury, D., Gautier IV, T., Gomillion, S., Wilkins, A., 2011. Main Belt Asteroids with WISE/NEOWISE. I. Preliminary Albedos and Diameters. Astrophys. J. 741, 68. doi:10.1088/0004-637X/741/2/68"

The third I refer to as "Mainzer et al., 2011c" (and in abbreviated form as "Mainzer et al."). Its title is:

"THERMAL MODEL CALIBRATION FOR MINOR PLANETS OBSERVED WITH WIDE-FIELD INFRARED SURVEY EXPLORER/NEOWISE"
and it can be found here:

http://iopscience.iop.org/article/10.1088/0004-637X/736/2/100/pdf

I did not criticize this paper. Anonyrat defends its arxiv preprint version (see below). For completeness, this paper is cited in Myhrvold's arxiv preprint as:

"Mainzer, A., Grav, T., Masiero, J., Bauer, J.M., Wright, E.L., Cutri, R.M., McMillan, R.S., Cohen, M., Ressler, M., Eisenhardt, P.R.M., 2011c. Thermal Model Calibration for Minor Planets Observed With Wide-Field Infrared Survey Explorer/Neowise. Astrophys. J. 736, 100. doi:10.1088/0004-637X/736/2/100"

and in Masiero et al. as:

"Mainzer, A. K., Grav, T., Masiero, J., et al. 2011b, ApJ, 736, 100"

Anonyrat discusses in his comment:

http://arxiv.org/pdf/1105.0975.pdf

This paper is titled

"Thermal Model Calibration for Minor Planets Observed with WISE/NEOWISE"

and, as indicated above, is the arxiv preprint version of Mainzer et al.

In my original comment I say of this paper:

"Note that Mainzer et al., 2011c analyze thermal models for 50 objects specifically for which ROS diameters are known, and make explicit that they use and report these ROS diameters. Masiero et al. cite this paper, as I discuss below."

That is, I make a point of acknowledging that I find nothing misleading about the use and reporting of ROS diameters in Mainzer et al.

Sorry to be so pedantic about all of these references, but once burnt, twice shy.

To recapitulate, I criticize Masiero et al., and not Mainzer et al. Anonyrat has mixed the two up. I stand by my original conclusion that Masiero et al. "is either willfully misleading or incredibly sloppy."

63. **tt**
May 28, 2016

but they cite the Mainzer articles. this is such a non-issue.
they were not hiding that these values were from other sources.
they are identical to the other sources. Alls it takes is asking the author
and they replied yes its from other sources.

64. **Anonyrat**
May 28, 2016

My apologies if I've confused between papers.

IMO, having seen this kind of thing before, the problem is the lack of trust on either side. We can imagine what each side thought of the other, but let's not got there.

Now that the dispute has gone to the press, attitudes would likely have hardened, and it is going to be difficult to restore trust. In the interest of science, I urge both sides to stop talking to the press, give it a month's break to cool tempers down, and then dedicate a couple of days of face-to-face conference to walk through all the material. Perhaps a mutually respected person should be present, not to decide technical issues but to keep the proceedings parliamentary. Surely doing something like this is within the resource budgets of both sides.

65. **JeanTate**
May 29, 2016

I too have read the key papers Myhrvold cites, in his "A Simple Guide to NEOWISE Data Problems".

"Main Belt Asteroids with WISE/NEOWISE. I. Preliminary Albedos and Diameters" (Masiero+ 2011; doi:10.1088/0004-637X/741/2/68) is not as clear as it could be, re the extent to which the diameters in Table 1 are derived/sourced entirely/solely from "thermal model fits". On its face this seems to support what both Myhrvold and Astronomical Cowardice write (more later).

"NEOWISE Observations of Near Earth Objects: Preliminary Results" (Mainzer+ 2011; doi:10.1088/0004-637X/743/2/156) is quite different. As Anonyrat points out. Myhrvold: "There is no explanation in those papers that diameters were copied, let alone a justification for why it was done." That may be so for doi:10.1088/0004-637X/741/2/68; it is clearly not, for doi:10.1088/0004-637X/743/2/156. Here is an extract from the caption to Table 1, of the latter: "Two calibration papers (Mainzer et al. 2011b, 2011c) discuss the absolute calibration of the WISE data for small solar system bodies and should be consulted before
comparing with data derived from other sources." Note that "Mainzer et al. 2011b" is "Thermal Model Calibration for Minor Planets Observed with Wide-Field Infrared Survey Explorer/NEOWISE", doi:10.1088/0004-637X/736/2/100

Yes, it may be true that, as Myhrvold writes, "What Mainzer and coworkers mean by "calibration" is debatable, but they appear to mean more in the sense of validation — that when they calculate their color correction (to adjust to the properties of the WISE sensor), they get roughly the same observed IR flux from the test objects using the ROS diameters as they see from the asteroids they represent."

However, as I have noted before, astronomers often use conventions, terms, methods, etc which *seem* to be the same as those in other fields of science – and indeed they often are – but may not be (they are sometimes not even consistent, among themselves; "flux" and "extinction" or "attenuation" are notorious examples). Naturally, this can create confusion and misunderstanding when an outsider tries to fully understand a published astronomy paper. Of the three alternatives Myhrvold gives (colossal error, fraud, something else), I think the last is by far the most likely … he simply didn't fully understand what he read.

Returning to "Main Belt Asteroids with WISE/NEOWISE. I. Preliminary Albedos and Diameters". Astronomical Cowardice writes "For these ROS values to be presented as results of the thermal modelling with no discussion — or even hint — of where they actually came from is either willfully misleading or incredibly sloppy." Yes, to a complete outsider this seems a reasonable conclusion. Sadly, I think it's neither; this sort of thing can, IMHO, be found in thousands of published astronomy papers. And many a peer reviewer would not even notice.

I'll end with a hobby-horse: early in his "Simple Guide", Myhrvold cites "Combining asteroid models derived by lightcurve inversion with asteroidal occultation silhouettes" (Ďurech+ 2011) and "Asteroid albedos deduced from stellar occultations" (Shevchenko&Tedesco 2006). Unless you have a cool $71.90 to spare (or a backdoor), you cannot read either. If one wants to get outraged by anything, high up on the list, surely, is why so many Icarus papers are behind paywalls? Personally, I think it's particularly outrageous in these two papers: without the, freely given, observations of many amateur astronomers, neither paper could have been written.

66. **Anonyrat**

Asteroid albedos deduced from stellar occultations

68. **JeanTate**
June 3, 2016

Thanks for digging up these two, Anonyrat.

The second is (almost) certainly what was actually published in Icarus; the first not quite so. In the arXiv abstract (http://arxiv.org/abs/1104.4227), the Comment is "33 pages, 45 figures, 4 tables, accepted for publication in Icarus", which strongly implies it's the same as what (later) was published. However, this is caveat lector; no one is charged with checking that it's accurate, and while authors almost invariably have good intentions, they do sometimes make mistakes. Further, the PDF contains this, at the bottom of the first page: "Preprint submitted to Icarus", making the ambiguity worse.

69. **Peter Erwin**
June 4, 2016

Further, the PDF contains this, at the bottom of the first page: "Preprint submitted to Icarus", making the ambiguity worse.

That's just boilerplate text generated by the LaTeX style file, not something the authors explicitly wrote themselves.

70. **JeanTate**
June 4, 2016

@Peter Erwin thanks for that! Question: how could an outsider ever learn that? Presumably it's something unique to style sheets used by authors thinking of submitting to Icarus, I guess.

71. **Low Math, Meekly Interacting**
June 5, 2016

The divergent accounts of Dr. Myhrvold and the NASA-affiliated investigators make it extremely difficult to figure out who, if anyone, has portrayed the situation with sufficient accuracy to draw firm conclusions from an outside perspective. If there are any uncontroversial statements that can be made, it would appear that Myhrvold's attempts to build a model using basic physics principles is still outperformed by NASA's empirical model, at least in some key instances, though that situation may change with further refinement. Also, the NASA teams' data reporting lacks sufficient clarity to satisfy an outsider that they've been anything but sloppy, at best, and at worst malfeasant.

I am fully in agreement with Phil Plait's article on at least one point: No matter which (if any) of Myhrvold's accusations proves to be correct, they are all quite troubling (with varying degrees of severity), and some publicly-available and well-vetted account of the dispute's resolution is very much in order. I fear that won't happen, given the attention span of modern media, despite the great importance of this story. We have on the one hand an argument for the need for transparency and public accountability of govt.-funded agencies and experiments, and on the other the legitimacy (real or perceived) of the “outsider” scientist as a watchdog. The outcome won’t resolve that age-old tension by any means, but I think it could prove to be a critical bit of history informing the perennial clash of public-vs.-private, insider-vs.-outsider, peer/expert-vs.-well-informed-amateur.

Most unfortunate is the tone, e.g. Dr. Wright’s gratuitous insults. Even worse are the allegations by Dr. Myhrvold that he was compelled to “go public” because of concerns about his work getting fair treatment during peer review. This could legitimately be characterized as “poisoning the well”, and I think he should have waited to see if his suspicions proved justifiable.

To echo Phil Plait, I do very much hope all concerned are as willing to be as vocal and thorough as they have been leading up to peer review of the Icarus article once that process is finished.

72. **Wayt Gibbs**
June 9, 2016

Myhrvold published of the paper to arXiv on June 1: http://arxiv.org/abs/1605.06490

He posted a lay-language explanation of why he finds the NEOWISE group’s use of observations in place of thermal model computations for a few selected asteroids so troubling to Medium on May 25: https://medium.com/@nathanmyhrvold/a-simple-guide-to-neowise-data-problems-a93f41e3bdb4#.kwe9iujo8

He has elaborated in three posts (so far) to the Minor Planets Mailing List on Yahoo on why some of the complaints about his paper in NASA’s press release were off base and has also replied to Herald’s suggestions about using occultation observations: https://groups.yahoo.com/neo/groups/mpml/conversations/topics/32025

He recently gave a talk at the Code Conference on asteroids that briefly touched on the controversy over his paper: https://www.youtube.com/watch?v=CH4k4kNBpN8

73. **Jan Reimers**
June 10, 2016

Maybe someone has already said this, but there seems to be a number of orthogonal issues here
1) Myhrvold’s pre-print has some errors in it. Perhaps already corrected in fourth revision.
2) Myrvold’s bootstrap model predicts some erroneous diameters.
3) Myrvold’s is alleged to have gone running to the press before peer review. Or did the press run to Myrvold?
4) Myrvold makes some harsh accusations about integrity and professionalism.
5) The NEOWISE team do not show what their model predicts for the asteroids for which ROS data are available. Instead they jumble the ROS numbers in same table as the IR model predictions. So we get no indication of how well the NEOWISE IR model works.

As far as I can see the status 1,2,3,4 has absolutely nothing to with whether or not #5 is correct but NASA is using 1,2,3,4 as a smoke screen to deflect attention from #5.

I think a good lesson from this is if you want people to pay attention to something like #5, then don’t do 1,2,3,4.

JR

74. **Wayt Gibbs**
June 11, 2016

Myhrvold put a corrected revision of his article on arXiv on June 1: http://arxiv.org/abs/1605.06490

He posted a plain-English explanation of the reasons that the accuracy of the NEOWISE estimates cannot be determined from their published papers on Medium on May 25: https://medium.com/@nathanmyhrvold/a-simple-guide-to-neowise-data-problems-a93f41e3bdb4#.kb12omv42

He has responded to Dave Herald’s suggestions and some of the misleading statements in the NASA/JPL press release on the Minor Planets Mailing List on Yahoo: https://groups.yahoo.com/neo/groups/mpml/conversations/topics/32025

A story by Scientific American on the debate on May 27 provides some perspectives from astronomers not directly involved WISE or NEOWISE: http://www.scientificamerican.com/article/for-asteroid-hunting-astronomers-nathan-myhrvold-says-the-sky-is-falling1/

Myhrvold gave a short talk at the recent Code Conference on asteroids, and briefly mentioned the debate over asteroid sizes: https://youtu.be/CH4k4kNBpN8

Summing It Up

May 29, 2016
Categories: Book Reviews

There's a new popular book out about number theory by the team of Avner Ash and Robert Gross, entitled [Summing It Up: From one plus one to modern number theory](). This is the third such book that they have written, and I'm embarrassed that it seems that I never reviewed the other two here. All three are highly recommended for anyone who wants a popular book-level introduction to some of the central topics of modern number theory.

- *Summing It Up* is the latest of the three, but it's also the most elementary. It's an introduction to the subject of modular forms, starting at the very beginning. The first half of the book covers in detail some basic ideas about number theory that can be understood in elementary terms, including things like the problems of counting the ways an integer can be a sum of squares or higher powers, or partitioned as a sum of smaller integers. The second half of the book tries to explain in as simple and concrete terms as possible what a "modular form" is, and what some of the properties of such objects are.

  I've just finished teaching a graduate course on representation theory, and ended up the course with a short discussion of the representations of the group SL(2,**R**) (two by two real matrices of determinant one), and what this had to do with modular forms. The relation of modular forms to representation theory (not discussed in the book) is roughly the following. The action of SL(2,**R**) on itself by left multiplication induces an action on functions on the quotient space SL(2,R)/SL(2,**Z**) (elements of SL(2,**Z**) are matrices with integer entries) and one can ask how this representation decomposes into irreducible representations, with modular forms providing part of the answer. How this works is quite basic to our modern understanding of how representation theory and number theory are related.

  In the last few chapters the authors try to explain how modular forms answer concrete counting questions raised in the first half of the book. A problem with trying to do this kind of thing is that while the questions may be straightforward to state, and the basic definitions of modular forms relatively accessible, connecting the two requires invoking some subtleties (half-integral modular forms). The authors several times apologize for not being able to explain exactly what is going on. I've always been quite fascinated by these particular subtleties, since they appear in the basic relationship of representation theory and quantum mechanics. The half-integrality here is related to the half-integer that appears in the ground-state energy of the harmonic oscillator. For quite a bit about how this is related to representation theory, see the [book I've been working on](). I'd love some day to write about the relationship of the ideas that appear in quantum mechanics to the ones that appear in modular forms, but first of all I need to understand myself much better what is going on.

- The first of the three books by Ash and Gross was [Fearless Symmetry: Exposing the Hidden Patterns of Numbers](), published in 2006. It's perhaps the best place to start for a popular introduction to the Langlands program and what it says about the relationship of number theory and representation theory. Modular forms make a brief appearance in that book, where an explanation of them had to be skipped over due to a lack of space. The newest book makes up for that omission.
- The second of the three books was the 2012 [Elliptic Tales: Curves, Counting, and Number Theory](). It covers in detail the topic of elliptic curves and their role in number theory, aiming at a description of one of the main open problems of the subject, the conjecture due to Birch and Swinnerton-Dyer. This is a very active subject of current research, with significant progress being made. If one had to guess which of the Millenium Problems will be the next to fall, this might be a good bet.

While there's a long tradition of popular books about number theory, these typically emphasize elementary methods for solving problems, ones that can be understood without a lot of the modern machinery. The first two Ash-Gross books do a good job of trying to give some insight into this modern machinery, even though a popular book can only do this in a very limited way (just as popular physics books can only give a very limited explanation of quantum field theory). The new one is different in that it makes a serious effort to explain exactly what is really going on, although following this path means that the book can only cover the first steps in the direction of modern techniques for understanding number theory.

Comments

1. **Justin**
   May 29, 2016

   Can someone explain why the Riemann hypothesis isn't related to Langlands? The hypothesis is one of the deepest in number theory, and it just seems to me that Langlands should have something deep to say about it.

2. **John Fredsted**
   May 30, 2016

   Once again your blog has provided me with inspiration as to what book to buy/read next. This time the (third) book by Ash and Gross. Hopefully, a physicist like I will be able to digest it; if not, then no hard feelings, of course. Thanks for your blog.

3. **Andrei**
   May 30, 2016

   "If one had to guess which of the Millenium Problems will be the next to fall, this might be a good bet."

   Funnily, my master's thesis' advisor told me that BSD was like a 27th century-level conjecture or something.

4. **uair01**
   May 30, 2016

   I have the first two books and I find them fascinating. I have studied electrical engineering, so I have some practical math skills, but the books are still challenging. I must applaud the authors for their audacious approach. It is not a light read (like "Love and Math" by Frenkel), but neither is it an academic book (like "Essential topology" by Crossley). But the books showed me some real modern mathematics that I never tasted in university. I will buy the third book when I've finished the second.

5. **uair01**
   May 30, 2016

   Note: If you buy the books you should consider buying the paper version. The Kindle version is not very good with the formulas. The Kindle text is ASCII but the formulas are pictures, so they don't scale with the text. The Kindle version is still readable, but the paper version is much more comfortable.

6. **John Fredsted**
   May 31, 2016

   @uair01: For reading pleasure, there is nothing like a book of paper in your hands. Books should always be read this way, I think, not looking on some electronic screen. But perhaps it is just me that is old-fashioned, or getting old, for that matter :-).

7. **Henry L.**
May 31, 2016

@ John Fredsted
—

Perhaps you are old-fashioned. As for getting old, there is no doubt 🙂

8. **Martin H Krieger**
May 31, 2016

Question: Why is counting up related to scaling symmetry?

One of the recurrent curious phenomena in mathematics and in physics is that counting problems, where we seem to be adding up one-by-one, packaged in a suitable function (such as Riemann's zeta), are then shown to be related (through that packaging function) to a scale invariant function (here the theta functions, which are modular). The Langlands Program is connects a counting function (in a Galois representation) to an automorphic form and representation, meeting in their respective L-functions.
Similarly, the 2d Ising model, solved in many ways by adding up one-by-one the interactions, that is, exp -beta Ei, and packaging them together in the partition function (whose log is the negative of the chemists' free energy), can also be solved by means of renormalization (scaling up from 2 by 2, to 4 by 4, …), as done by Kadanoff and Wilson, and also by Hilhorst, Schick, and van Leuven. And, as pointed out by J-M Maillard, the basic symmetries of that Ising model are embodied in two quadratic forms in the Boltzmann factors (see Baxter's book, chapter 10), whose intersection is an elliptic curve.

9. **former mathematician**
May 31, 2016

It is a happy coincidence that this is published so soon after the Ramanujan biopic opened.

10. **Henry L.**
May 31, 2016

@ former mathematician

I had not heard about the film, "The Man Who Knew Infinity", the Ramanujan biopic. Thanx for mentioning it.

11. **Shantanu**
June 3, 2016

Peter, sad news. Tom Kibble passed away.
Maybe would be nice to hear some tributes from you on him and his impact on particle physics

12. **Peter Woit**
June 3, 2016

Shantanu,
Sorry to hear that. Unfortunately I never met Kibble and am not well-informed about him and his work, so best I leave this to others.

13. **Shantanu**
June 3, 2016

Not even in EW symmetry breaking and his role in discovering the Higgs mechanism?
Around 2012, Frank Close was backing him to win the Nobel for his role in Higgs discovery.

This Week’s Hype

June 4, 2016
Categories: Multiverse Mania, This Week's Hype

One possible reaction to the phenomenon of hype in fundamental physics is to not worry much, figuring that it should be a self-limiting process. While there’s a huge appetite in the media and elsewhere for the “exciting new idea”, overhyped “new” ideas sooner or later should pass into the category of no longer “new”, and less capable of producing “excitement”. The problem is that this doesn’t seem to be happening: favored physics hype keeps getting promoted as “new” and “exciting”, no matter how old it is.

In the case of multiverse hype, Andrei Linde was promoting the idea 34 years ago, back in 1982. That hasn’t stopped many people from heavily promoting it as “new” for quite a few years now. Taking this to a new level, a [talk by Martin Rees] this past week at the Hay Festival advertised the multiverse as not just exciting, but so new as to be one of the main developments in physics of the past year:

> The astronomer will share his excitement about recent cosmic ideas and discoveries. Since last festival there have been new searches for life (even intelligent life) in space. One of Einstein’s greatest predictions has been confirmed with the detection of gravitational waves from colliding back holes. Images of Pluto have surprised us, and astronomers have discovered thousands of planets orbiting other stars, some resembling Earth. And there is speculation that physical reality encompasses more than the aftermath of our big bang: we may inhabit a multiverse.

Lord Rees explains in more detail [in the Telegraph] how exciting this is. It seems that he has been excited about this for more than a quarter century, with a [book on the subject back in 1989]. Since at least 2003 and a Templeton-funded Stanford conference on the multiverse, he has been publicly expressing willingness to bet his dog’s life on the existence of the multiverse, and he repeats that in the Telegraph article (should someone contact the RSPCA?). Luckily for the Rees family pets, there’s no way to ever resolve this issue, so the last couple generations have survived, and so will further ones.

Update: Also this past week, in the category of hype that will never die, Scientific American has [Gravitational Waves Could Finally Help Us Prove String Theory]. This particular hype campaign goes back at least a dozen years. See [here] for a 2004 blog post about a [UCSB press release] featuring claims that LIGO might produce evidence for string theory in 2005 or 2006.

Comments

1. **Peter Woit**
   June 4, 2016

   physicsphile,

   I think it was Weinberg who came up with that, here
   https://arxiv.org/abs/hep-th/0511037
   I never knew what to make of that, not knowing how Weinberg felt about either dogs or Andrei Linde…

2. **Neil**
   June 4, 2016

   Gravitational waves, Pluto pics, and exo-planets. Ergo, the multiverse?

3. **Nick M.**
   June 5, 2016

   How strange! It would appear that some physicists like wagering on a class of ***“Not Even Wrong”*** ideas, producing what can only be described as ***“Not Even A Gamble”***. 😉

4. **Krzysztof**
   June 6, 2016

   The Big Bang term, coined by Hoyle, was used to ridicule Lemaître’s idea.

   It seems that the most illustrious British astronomers keep a habit of ridiculing themselves.

5. **John**
   June 6, 2016

   Will anyone take this bet? Give me \$100 now and when the multiverse is proved I will pay you \$1 million.

6. **Scott Church**
   June 6, 2016

   One small problem John… You may encounter some resistance regarding what constitutes “proof.” Next thing you know you’ll find yourself in a math “beauty” pageant, and if book deals and grants are involved Miss Multiverse’s lawyers might be pretty damn good. 😉

7. **Justin**
   June 6, 2016

   On a related but more positive note, I think your readers will enjoy the latest at Backreaction. http://backreaction.blogspot.com/2016/06/dear-dr-b-why-not-string-theory.html

8. **Harrison**
   June 6, 2016

   Justin, thanks for pointing out that write-up, and site for that matter. Some great stuff.

Short Items

June 8, 2016
Categories: Uncategorized

- String theory continues to make progress. Today the news is from Megan Fox:

  > "Sometimes I just know things," she explains. "I accidentally tap into stuff sometimes. I used to do it as a kid, and I do it as an adult. I crossed over and saw a future string."
  >
  > String, as in string theory. Fox is into stuff like that. She's also spiritual. On her Instagram profile, she describes herself thusly: "Child of the Cherokee Tribe … forest nymph … Lunar Leo mother goddess to 2 bohemian revolutionaries-my kamikaze free spirit & my peaceful warrior."

  A few months ago it was Jaden Smith moving the subject forward:

  > Jaden sees himself as a modern-day prophet and is working on a collection of essays," a pal says in the new issue of Us Weekly. "They're new takes on string theory and chaos theory, but more mystical."
  >
  > After all, he's getting an out-of-this-world assist with the tome. Explains the source, "Jaden thinks he has spiritual ties to people in other dimensions and galaxies, and they are helping him write."

- At some sort of other extreme, Sabine Hossenfelder has very sensible things to say about the string theory phenomenon here.
- If you read Physical Review Letters or the Financial Times you might think that a "key to an unseen portion of the universe" had been found. Luckily for you, Natalie Wolchover is on the case, uncovering the story of why you might not want to take that new fifth force seriously quite yet.
- If you're interested at all in the story of the superluminal neutrinos, you might want to read Gianfranco D'Anna's fictionalized account of the story, 60.7 Nanoseconds, which has just appeared in English

Update: This string theory story is so bizarre I don't know what to make of it:

> While working on String Theory, Kaku, discovered what he sees as evidence that the universe is created by an intelligence, rather than merely formed by random forces. He suggests he can explain it by what he calls, "primitive semi-radius tachyons." We do not yet have a succinct explanation of this idea from Kaku, other than he's referring to tachyons, which are theoretical particles that unbind particles from one another.
>
> Without getting into physics itself, Kaku concludes that we live in a Matrix-style universe, created by an intelligence.
>
> "I have concluded that we are in a world made by rules created by an intelligence", he said. "Believe me, everything that we call chance today won't make sense anymore. To me it is clear that we exists in a plan which is governed by rules that were created, shaped by a universal intelligence and not by chance."

   That first item is effing amazing.

7. **student**
   June 8, 2016

   Dr. Hossenfelder's following remarks are quite too the point:

“So far, string theory has scored in two areas. First, it has proved interesting for mathematicians. … Second, string theory has shown to be useful to push ahead with the lesser understood aspects of quantum field theories. This seems a fruitful avenue and is certainly something to continue.”

The part of the argument that is harder to follow is that other approaches to QG will have a more significant relevance to applications.

“And since that theory underlies all modern technology, this is research which bears relevance for applications.”

Just a casual glance at the arXiv today shows

[arXiv:1606.01893] “Particle-Vortex Duality from 3d Bosonization”
[arXiv:1606.01989] “A Duality Web in 2+1 Dimensions and Condensed Matter Physics”

which is an example of how the rich interplay between ideas in the condensed matter theory, high energy theory, string theory, and even mathematics via mirror symmetry can be applied to problems in condensed matter. This hopefully is an example of the “fruitful avenue” Dr. Hossenfelder suggested and will have an impact on applications faster than “Not in ten years and not in 50 years, but maybe in 100 or 500 years.”

June 9, 2016

Bernhard/Dom,
I’m pretty mystified by the Kaku piece. Quite possibly some of the odd stuff is due to the writer not Kaku (“primitive semi-radius tachyons”???). It’s also true that lots of prominent theorists now sit around publicly debating whether we’re a simulation, which may be what Kaku is talking about, see for instance
http://www.math.columbia.edu/~woit/wordpress/?p=8392

13. **Northern Jock**
June 9, 2016

Just an opinion but I think what you do is important on this blog and that you have good judgement generally speaking, but that it’s a bad idea to go down the road of mocking. It’s important stick with the problems associated with String Theory, it’s theorists, and advocacy with some connection to the community or where there some direct responsibility on the part of the community.
Otherwise…well I mean you could go onto YouTube and find stupendous interpretations and claims about anything you like. And I think that’s an argument that could be thrown back at you, that would have some influences with some people, for a limited interval of time.

14. **David Levitt**
June 9, 2016

I teach an upper level course on medical devices and I show Michio Kaku’s Daily Show interview (pushing his book “The Future of the Mind”) as a classic example of the nonsense that is in this field. Almost every statement of Kaku’s is factually wrong. I suppose I am old fashioned, but I worry about everything I say in lecture, and I am a chagrined if something is not quite right. And here, Kaku can go out before millions of viewers and just spew gobbledygook???

15. **Bernhard**
June 9, 2016

Peter,

I honestly don’t understand the purpose of these debates and to me they are a symptom of how sick our field became. We have plenty of interesting, difficult, down to earth problems to solve and work with.

16. **Peter Woit**
June 9, 2016

Northern Jock,
I understand your point, but the string theory hype machine is still active and I think pointing to the nonsense that it leads to is justifiable. Mostly I do just point without mocking, sometimes I can’t resist temptation.

17. **Northern Jock**
June 9, 2016

Peter Woit – That's entirely understandable and you are very entertaining as well as informative.

18. **Bernhard**
June 9, 2016

Northern Jock,
I wold also add to what Peter is said is that Kaku is not your typical random crank that you would find on youtube. I remember when I was in undergraduate school some people were studying QFT with his book. Not to mention he has a prestigious position as a professor of theoretical physics, so his voice is taken much more seriously by the media and, even worse, by young unwary minds.

19. **Henry L.**
June 9, 2016

Kaku also appears in a Samsung Galaxy S7 Edge commercial, so he is cashing in on some of his notoriety.

20. **zzz**
June 9, 2016

Kaku appears on the morning news shows for anything sciencey.
He doesn't study hurricanes or tornados, but i have heard him speak about them

21. **Northern Jock**
June 9, 2016

Bernard – I wasn't talking about Kaku, who is fair game if he wants to carry on as he does. I was talking about the minor celebrity and the teenage son of a celebrity. I think advocacy of that kind tends to happen randomly wrt the merits of the subject.

22. **Neil**
June 9, 2016

Uh, oh. If Kaku is right, our programmers have been caught out, and we are all in for a reboot.

23. **Rabbit**
June 9, 2016

…"even worse, by young unwary minds." There's no helping unwary minds, young or old.

24. **A**
June 9, 2016

Peter

There are countless crackpots out there who have their own take on relativity, but that does not mean that relativity is wrong. So I don't regard the musings of such people to be any kind of negative statement on strings. Do you?

Regarding Kaku, I couldn't get the video to play. Does he really say that stuff? The organization that published this page doesn' automatically have credibility of course.

25. **Dr. Michelson Moreley**
June 9, 2016

A,

There are countless crackpots out there who have their own take on unicorns, but that does not mean that unicorns exist. So I don't regard the musings of such people to be any kind of positive statement on strings. Do you?

26. **Peter Woit**
June 10, 2016

A,
Of course the views of crackpots about a theory have nothing to do with its value. The tradition though is that celebrity crackpots latch on to successful physics theories that everyone has heard about (e.g. relativity and quantum theory), but the innovation is that now they're latching on to an unsuccessful theory that everyone has heard about, not knowing the difference.

27. **A**
June 10, 2016

@dmm
I don't fully understand your post but I'm going to go with "No".

@peter
Lol.

28. **Narad**
June 10, 2016

> Today the news is from Megan Fox

Oh, dear:

"She and costar Shia LaBeouf [*of Walgreens fame*] were given a tour of of the Great Pyramid of Giza by the Ministry of Antiquities and someone 'high-ranking in that field — I will not say who' told the actors that the pyramid was never actually a tomb.

"'They presume they may have been some type of energy plant at some point,' says Fox."

Even [Phil Lesh](#) was more sophisticated, and I'll bet the shows (which weren't very good aside from Hamza, IMO) at least produced more inquiry into the nature of the observer and the observed, as well as a fair amount of energy.

29. **Richard J. Gaylord**
June 10, 2016

""I have concluded that we are in a world made by rules created by an intelligence", he said. "Believe me, everything that we call chance today won't make sense anymore. To me it is clear that we exists in a plan which is governed by rules that were created, shaped by a universal intelligence and not by chance.". while i admire Kaku's hair much more than i do his books, i think we need to be careful here because this is a quote attributed to Kaku, and many academicians i know have been either misquoted or had their ideas distorted by others with their own agenda. For example, Einstein has often been said to believe in God but for Einstein, God was simply shorthand for nature (or nature's laws). i expect that Kaku realizes that invoking a "universal intelligence" is not a useful scientific explanation of any phenomenon.

30. **Shantanu**
June 10, 2016

Peter: sorry for the OT comment. But looking forward to your report on talks at the LHC conference at KITP, esp. the supersymmetry ones.

31. **Jim Given**
June 10, 2016

Kaku actually says, "a Matrix-style universe"?? Is this a reference to some sort of matrix-valued field theory? Is it a reference to M theory? A reference to the movie, "The Matrix"?

32. **Yatima**
June 10, 2016

When Meedja say "Matrix-style" what they mean is "Matrix-style, like in that Warner Brothers movie from before the War on Stuff with raining green glyphs and Neo and stuff". Using "Matrix" in a technical sense is prohibited as per editor rules (this is an empirical observation though).

Moreover, "M-theory" is not a shorthand for "Matrix theory". My hunch is that the "M" is a quantifier symbol derived from the mirrored "W" as in "Witten".

33. **Parth**
June 12, 2016

Funny string articles..I also think Kaku is referring to living in a simulation by an intelligent being as the 'Matrix-style universe' seems to refer to the common phrase 'living in a Matrix' i.e. living in a simulation like in the movie The Matrix.

34. **Peter Woit**
June 12, 2016

Shantanu,

Sorry, but, just skimming some of the talks, I don't see any real news there. The overwhelming issue right now is the possible 750 GeV state. Total luminosity for this year's run is now at about the level of last year's run (above 3 inverse fb) so soon ATLAS and CMS should have the analysis done to see if a bump is still there in the diphotons. If it is, that's going to completely dominate the subject for the forseeable future (and I'll predict a high-profile event at CERN).

If the bump is gone, then maybe no event at CERN, but talks at ICHEP in Chicago. If there's any remaining ambiguity, it should soon be removed by the data coming in over the next few months.

If no bump, then things should return to the situation things have been in for a long time: overwhelming evidence against heavily oversold SUSY scenarios, with a sector of the physics community refusing to move on and acknowledge what has happened. One conference to wait for might be the one in late September labeled "Is SUSY alive and well?", check out their website with a graphic indicating that SUSY is not only dead, but is haunting the living…

https://workshops.ift.uam-csic.es/susyaaw

35. **Tim**
June 14, 2016

Would it be unwise to read the complete lack of leaked rumors this close before ICHEP as a sign that the bump is most likely dead? Either physicists have gotten several orders of magnitude better at keeping their mouths shut, or this year's run hasn't produced anything interesting …

36. **Peter Woit**
June 14, 2016

Tim,
I think it's just too early. It's only very recently that the experiments have accumulated an amount of data comparable to last year's, and analysis of that data takes a while. I don't know if these are blinded analyses. If they are, it will be a while before they are unblinded.

37. **anon**
June 15, 2016

Regarding result announcements: LIGO collaboration will have a press conference in a couple of hours at the 228th AAS meeting and it looks like they're going to announce new detections of gravitational waves.

38. **Provider of Truth and Factcheck**
June 18, 2016

The story is probably a hoax, at least according to this guy:

http://blog.drwile.com/?p=14864

Kaku never claimed any of these things about "primitive semi radius tachyons".

Some History of Science

June 13, 2016
Categories: Uncategorized

The period of the "String Wars" has now receded far enough into the past that it has become a topic of interest to historians of science. I learned today from Sabine Hossenfelder's round-up of various articles addressing the history and sociology of string theory that Sophie Ritson has published an article on the 2006 "trackback" controversy . It's a fairly straight-forward account of that story, based on publicly available sources, emphasizing the interesting issues raised about science blogging.

While the article deals with the 2006 history, what has happened since then sheds some light on the topic, for example making clear that the "active researcher" business was always a red herring. Within a couple years after 2006 I noticed that arXiv trackbacks were appearing to all sorts of sources obviously not "active researchers" (for example, Slashdot articles). I tried to find out what the new arXiv policy was, but got nowhere. At one point I decided to do some experimental work, setting up a fanboy string theory site, trashing string theory critics and enthusing over the multiverse. An arXiv moderator took a quick look, and decided the anonymous author qualified (see discussion here). I realize this was obnoxious behavior, but thought it at least had a chance of goading the arXiv moderators into revealing their current policy. No dice. Every so often I've tried again to contact someone associated with the arXiv to ask what their policy is, but this has never led anywhere. Sabine describes the current arXiv trackback policy as "one of the arXiv's best-kept secrets". If you look at recent arXiv trackbacks you'll see that the list is dominated by links from the excellent MathOverflow site, but also includes links from a wide variety of other sources that clearly are not "active researchers" (for instance: New York Times stories, press releases on Phys.org, MIT Technology Review weekly lists of arXiv papers, and Quanta magazine stories).

Besides the secret nature of the current policy, the odd way in which the "active researcher" policy came to light is rather remarkable. This all started back in August 2005 (see here) and at that point trackbacks pointing to this blog were appearing. A few months later that stopped and, wondering why, I wasted a lot of time trying to contact people associated with the arXiv to find out what was going on. I finally heard from a Cornell administrator that links to my blog were not being allowed for an undisclosed reason, and I wrote about that here. Sean Carroll picked up the story here, and a former member of the arXiv editorial board revealed the "active researcher" policy in a comment at that blog entry. This I gather forced Jacques Distler into a public discussion of the policy here, which I commented on here. The Ritson article covers this part of the story in some detail.

So, bringing 2006 history up to date, I have no idea what the current arXiv trackback policy is, other than that they've found some new criterion other than the "active researcher" one to justify blocking trackbacks from Not Even Wrong. I guess this will remain "one of the arXiv's best-kept secrets", at least until someone accidentally reveals all in a blog comment somewhere…

Comments

1. **MathPhys**
   June 13, 2016

   It's scary to realize that 'active researchers' can engage in clandestine behavior such as described. The varnish of decency is thin.

2. **Harry Dale Huffman**
   June 13, 2016

   Inevitably, when a "policy" remains strangely a secret, it turns out to be the arbitrary judgment (i.e., personal "likes" and "dislikes") of a single or a few individuals. It means you can't trust the system behind the enterprise.

3. **CIP**
   June 13, 2016

   Using a combination of intuition and certain ESP-like effects inherent in String Theory, I have deduced the arXiv trackback policy: " No trackbacks for Peter Woit."

   That is all

4. **Henry L.**
   June 13, 2016

   Peter,

   Do you have any suspicions about their reason for blocking your blog, which you would be willing to share?

5. **KJ**
   June 13, 2016

   It seems to me that someone determined enough to find out the arXiv trackback policy could do so by exploiting the various sources of public funding they receive and open-records laws. Cornell itself is a sort of public-private hybrid. Several public institutions are "members" and get a seat at the decision-making table. Donations to arXiv are tax-deductible, which makes it subject to certain sunshine laws. Surely at least one source of their money makes them subject to an open-records law that could be used to out the trackback policy if one was willing to put enough time into figuring out which one. I am certainly not such a person, but a science journalist or open-records activist interested in the subject might be.

6. **Peter Woit**
   June 13, 2016

   Henry L.,
   The two people who seem to have something to do with this are Jacques Distler and Joe Polchinski. I've never met either of them personally, but they've both made clear that they are deeply upset and offended by my views about string theory and the multiverse. As far as I can tell, that's the reason behind this. As for what excuse they are now using for the trackback business, now that the "active researcher" one seems no longer being used, I honestly have not the slightest idea. And I think that's intentional, since it means that I can't argue against it…

7. **Peter Woit**
   June 13, 2016

   KJ,
   Personally I've already wasted too much time on this. I'm in the odd position of having spent a lot of time back in 2005-6 in order to find out the "policy", it's hard to get motivated to go through that again, in order to find out the new bogus reason I am unworthy.

8. **Henry L.**
June 13, 2016

I was once proud of Cornell (my undergraduate school). That was half a century ago. Sigh.

9. **KJ**
June 14, 2016

Peter,
I didn't really think you would want to waste any more time. But maybe a science journalist interested in the string theory wars would want to pursue it. I am thinking someone who does that kind of thing for a living could do it much faster than you or I anyway, since we are not familiar with the relevant laws and procedures.

10. **Donald R. Pherson**
June 14, 2016

Hearing the annals of this "trackback" crisis is quite disturbing to me. It seems the "powers that be" at arxiv want no part in the criticism of string theory. String theory has become, at least by the mid-naughtes, more of a way to publish papers, bring in university funds, and maintain faculty than actual legitimate research. To put it differently, it's a racket. There are institutional interests at work that want to maintain the strings status quo. Thankfully the field is drying up however.

Nonetheless, it seems the string theory "wars" are still continuing:

https://www.reddit.com/r/Physics/comments/4o1rk9/im_sick_and_tired_of_the_antistring_theory_bs/

11. **Peter Woit**
June 14, 2016

All,
"Donald R. Pherson= Anonymous Postdoc" is a troll, please ignore. I and others were taken in for a while, leading to a comment thread that I'm afraid you'll never see unless you have been religiously refreshing comments here recently…

12. **Curious cat**
June 15, 2016

You are lucky, the wayback machine didn't catch it up for us 🙂

http://web.archive.org/web/*/https://www.math.columbia.edu/~woit/wordpress/?p=8578

13. **Lindsay Berge**
June 15, 2016

Back when I was involved is Physics research, I would occasionally get referees saying, in effect, "this area is not interesting because I would be working on it if it was". This was no doubt an honest appraisal but unhelpful. Generally another referee could be found who was more open minded or objective.
It would seem the attitude of some String Theorists is that "this area must be vitally important as I would not be working on if it was not". This elevates any fundamental criticism to a personal attack. I also suspect that any questions of legitimacy are deeply threatening after years and years of failure to actually deliver on the original heavily publicised promises (Theory of Everything). Any means possible would seem justified to silence those who would undermine the great and noble undertaking and imperil the reputations, careers, and support of the researchers. A truly productive program (like the original Standard Model) would not be subject to the same fearfulness.

14. **Peter Woit**
June 15, 2016

Lindsay Berge,
People do take criticism of ideas they are invested in personally, I don't think that's really avoidable. What is supposed to happen is that rational criticism of ideas should be met by a rational defense of them, leading to a clarification of what is right and what is wrong. This works very well in mathematics, where it generally is not hard to reach agreement on what is right and what is wrong.

The problem in physics is all about what to do in the "not even wrong" case. Defenders of the multiverse like Polchinski argue that I should not be doing what I'm doing (and thus not linked to by trackbacks), that instead I should be writing scientific papers proving that they are wrong. But the problem with "not even wrong" ideas is that one can never do this, all one can do is point out that their ideas come with no way to ever show that they are wrong. One could try and dress this up as a scientific paper, but it would be a very unusual one, with no equations, not that different from what I write on the blog, and I think people like Polchinski would be no happier with that than with my blog postings.

15. **David Levitt**
June 15, 2016

I am a biophysicist with some background in physics and an amateur's interest in high energy theoretical physics. I find blog sites such as this one extremely valuable in gaining insight into current controversies. What makes these blogs far superior to the general review article or typical newspaper or magazine survey is the presence of the blog comments. For example, if a post by Peter about some string theory argument was factually incorrect, I would expect this to be clearly pointed out by a string expert in the blog comments. (As far as I can tell, Peter does not discriminate against reasonable critics of his posts). The general lack of such responses is, for me, the strongest argument for the correctness of Peter's post. This is the unique strength of these forums. The fact that one or two egotistical physicists controlling the arXiv can deprive the arXiv readers of this valuable link is disgraceful and should illicit a strong response from the physics community.

16. **Brathmore**
June 16, 2016

Wait a minute! If this post is about string theory, and string theory isn't science, then how can this be part of the "history of science?" Shouldn't it be labeled as part of the "history of pseudo-science?" Doesn't the inclusion of non-science in a "history of science" diminish one and elevate the other, or tacitly acknowledge that the non-science actually is science? Me thinks we need some better terminology here.

17. **Peter Woit**
June 16, 2016

Brathmore,

Just to clarify: string theory is science, just happens to be science that didn't work out. The multiverse is pseudo-science. Hope that helps…

18. **Anonymous**
    June 17, 2016

    There is nothing wrong with the ArXiv deciding which sources they want to give the state of a trusted site.
    Neither you nor anybody else has a granted right to get trackbacks approved by the ArXiv administrators.
    I really dont understand why you get worked up about this, as if they were denying you a human right.

19. **Peter Woit**
    June 17, 2016

    Anonymous,
    Sure, it's up to the arXiv to decide this. I'm just trying to find out on what basis they made their decision.

Quick Items

June 15, 2016
Categories: Uncategorized

- In a couple hours, at 1:15 pm New York time, there will be a press conference at the AAS meeting where LIGO and Virgo scientists will discuss “ongoing research” (webcast here). The general assumption is that there will be observations of new gravitational wave sources announced.
- At some other extreme in the space of science talks, the AAS meeting also featured a talk yesterday by Sean Carroll on “Normal Science in a Multiverse”. There’s some discussion of the talk here, and twitter has this. Some counterpoint from Joseph Silk here.

  It seems that Carroll was arguing that the multiverse shows that we need to change our thinking about what science is, adopting his favored “abduction” and “Bayesian reasoning” framework, getting rid of falsifiability. Using this method he arrives at a probability of the multiverse as “about 50%” (funny, but that’s the same number I’d use, as for any binary option where you know nothing). So, from the Bayesians we now have the following for multiverse probability estimates:

  1. Carroll: “About 50%”
  2. Polchinski: “94%”
  3. Rees: “Kill my dog if it’s not true”
  4. Linde: “Kill me if it’s not true”
  5. Weinberg: “Kill Linde and Rees’s dog if it’s not true”

  Not quite sure how one explains this when arguing with people convinced that science is just opinion.

- Among the many summer conferences one might want to take a look at, there’s last week’s Workshop on String Theory and Gender, and this week’s LHCP in Lund. Wilczek will be giving the “Theory Vision” talk at the end on Saturday.
- Today’s Wall Street Journal has an interesting article on the not so great job market for Ph.Ds (to avoid paywall, try Googling, e.g. “Job-Seeking Ph.D. Holders Look to Life Outside School”). I find the claim that the median income for Math/Physics mid-career Ph.Ds dropped 6% over the past 3 years highly remarkable (if true). Yes, US middle class incomes have been tanking, but I that number is pretty extreme, especially since this has been a period of modest economic expansion.

  One other bit of news I learned from the article was what universities (including mine) are doing to help with the situation:

  > at Columbia University, Ph.D.s are taking classes in using Twitter to better communicate their work to nonacademic audiences.

Update: The LIGO news was a second black hole inspiral. I’m sure you can find good coverage of this elsewhere.

I hadn’t realized that the AAS is sponsoring a whole Multiverse Mania Fest, bringing in to promote a new definition of science not just Carroll, but Richard Dawid. Lenny Susskind this afternoon gave a talk (see here) that seems to argue that the Multiverse is a great idea, even though it won’t ever be testable. No news on what his Bayesian percentage is, or whether he’s willing to bet the lives of helpless pets. Sean Carroll made his usual straw man attack on the “Popperazi” (who, despite what he thinks, understand what indirect evidence is), see here.

Update: Another odd multiverse-related item. Laura Mersini-Houghton and collaborators have made well-publicized claims that they have testable predictions based on the string theory landscape. I’ve written about these several times here on the blog, see here, and this posting for one example that includes a response from Mersini-Houghton and Richard Holman.

Their claims are based on two 2006 papers, see here and here. Very recently Will Kinney posted this paper on the arXiv, which has in the abstract:

> we compute limits on these entanglement effects from the Planck CMB data combined with the BICEP/Keck polarization measurement, and find no evidence for observable modulations to the power spectrum from landscape entanglement, and no sourcing of observable CMB anomalies. The originally proposed model with an exponential potential is ruled out to high significance.

See the conclusions section of the paper for the details.

This isn’t particularly surprising or odd, although one wonders if the Kinney paper will get a fraction of the attention that the original claims have gotten. What is odd is that I hear that Mersini-Houghton is asking to have the paper removed from the arXiv, on grounds that have something to do with the fact that she was originally collaborating on the project with Kinney, but is not listed as an author (although he offered to put her name on it). I can’t think of another example of this kind of thing ever happening before, perhaps others are aware of similar controversies.

Update: Much more detail at Backreaction, including comments from Will Kinney explaining the issue with the arXiv.

Comments

1. **KJ**
   June 15, 2016

   I do think that multiverse proponents have abducted the scientific method. But I don’t think that is what Carroll has in mind.

2. **Another Anon**
   June 15, 2016

   Carroll: “About 50%”
   Polchinski: “94%”

   It’s just an absolute nonsense these probability guessing games, aren’t they? I have no idea why highly-regarded physicists are doing this.

3. **Neil**
   June 15, 2016

   When a weather forecaster tells me the probability of rain tomorrow is 50%, I translate it as “I don’t know.” With a greater than 50%, I hear “There is more reason to think it will rain than it won’t” and vice versa with less than 50%. Given Sean Carroll’s past championing of the multiverse hypothesis as an explanation for fine tuning, I’d have thought he’d assign a somewhat higher probability.

4. **Tim**
June 15, 2016

I'm surprised there's so much hostility to these percentage based confidence levels.

Because I'm 99% sure these guys are full of sh*t.

5. **paddy**
June 15, 2016

I do not like to see the very important LIGO results juxtaposed with nonsense (a wee bit more polite Tim, no?).

6. **Peter Woit**
June 15, 2016

I agree with paddy that more politeness would be a good idea. Not good to emulate the tone of a certain other blog.

On the other hand, I'm somewhat fascinated by the juxtaposition of real scientific progress (LIGO) and pseudo-science (the Multiverse) at the AAS meeting. Given the difficult situation of HEP theory, I can understand why string theory meetings sometimes feature Multiverse stuff, but if your field is healthy with serious new advances like this going on, why would you schedule all sorts of pseudo-scientific talks of this kind? The contrast must be quite jarring.

7. **David Nataf**
June 15, 2016

I like to believe that this interest in the multiverse is not permanent. It's likely that a lot of people got now-defunct theoretical training, so this is what they can do. They may have trouble acquiring and training new generations of elite graduate students, who will be more interested in pursuing more dynamic research programs, such as gravitational wave modelling and LHC phenomenology.

8. **Bee**
June 16, 2016

Do you have a link/reference for point 4. and 5. regarding multiverse (Weinberg/Linde)? I hadn't heard of these before.

9. **Jim Baggott**
June 16, 2016

Arguably, Bayesian decision theory (or a subjective, qualitative version of its logic) plays a legitimate role in the scientific method when there are empirical data on which to base prior and posterior judgements. As far as I can tell, the multiverse is really nothing more than an idea or a hunch – I wouldn't even accord it the status of a hypothesis (see http://www.jimbaggott.com/articles/status-anxiety-all-theories-are-not-the-same/). In this regard, Carroll's assertion is surely no more scientific than Pascal's wager.

10. **Bee**
June 16, 2016

Jim,

The problem with using Bayesian reasoning for "theoretical" evidence (as Sean suggests) isn't the priors. The problem is that the supposed evidence isn't about the theory itself, but rather about scientists' beliefs about the theory. Hence, if you use Bayesian inference to take into account non-empirical facts, you are changing the question from "How likely is X to be a correct description of Nature?" to "How likely do theorists think X is a correct description of Nature?" The latter is a quantifiable probability (and not even an entirely uninteresting one) but not actually the one you wanted to know.

This situation can get rather murky in theoretical physics because it's an empirical fact that mathematics works very well. So if you use logical reasoning based on mathematics, that could count as an empirical argument. (Philosophers would disagree on calling it that way, but let's not fight about words.) The problem is though that no proof is ever better than its assumptions. And if you look at what it is that enters these probability estimates, it's primarily scientists' opinion on how likely certain assumptions hold far beyond the regime where they've been tested.

11. **Another Anon**
June 16, 2016

The crux of what you are saying, Bee, is that "How likely is X to be a correct description of Nature? is not a scientific question. "Likely" has no place in science.

12. **Peter Woit**
June 16, 2016

Bee,
See the last paragraph of
https://arxiv.org/abs/hep-th/0511037

13. **Another Anon**
June 16, 2016

I really mean "opinions" have no scientific value.

14. **Bee**
June 16, 2016

Peter,

Thanks!

Another Anon,

I don't know if you did this on purpose or whether it's a copy-and paste mistake, but this isn't what I wrote. "How likely is X to be true?" can be a scientific statement (depending on what X is about), and in fact I would argue that all scientific statements are essentially statements of likelihood (you can never prove any statement about reality to be true). What I said was that statements about likelihood of beliefs of some people aren't normally what scientists are interested in.

(You might actually want to read Sean Carroll's recent book, which I reviewed here. Whether or not you like his opinion about the multiverse, he does a pretty good job explaining Bayesian reasoning and its relevance for science.)

15. **RandomPaddy**
June 16, 2016

> I find the claim that the median income for Math/Physics mid-career Ph.Ds dropped 6% over the past 3 years highly remarkable (if true).

Totally unsurprising. The Great Recession has taken its toll and a lot of these people have been hopping from temp job to temp job over the last 8 years. People wonder why the economy won't pick up, and yet we're talking about prime spending age people who don't have the careers to support anything of the kind. Welcome to Japanification.

16. **Jim Baggott**
June 16, 2016

Bee,
I've actually never been a fan of Bayesianism, because of the difficulty of establishing priors even when there is an abundance of empirical evidence and because I believe it is virtually impossible to be objective. My point is really that all the proponents of Bayesianism that I've read argue for its utility in theory assessment in the light of evidence. I think (I confess I haven't researched it properly) that Dawid and his colleagues are the only philosophers of science advocating Bayesianism in non-empirical theory assessment (see 'String Theory and the Scientific Method', pp. 68-72). Of course, this is a gift to theorists who want to dress opinion in the language of probability. Hence my remark about Pascal's wager.

Whilst I'm mostly in agreement with your view, I do think it's important to avoid what I think is a critical category error. In 'Farewell to Reality' I tried to distinguish between 'correspondence truth' and 'coherence truth'. In science we take something to be true if it corresponds to the empirical facts – for this reason I'd regard general relativity to be 'true', on the understanding that it may one day be superseded by an even more general theory which establishes correspondence with even more facts.

But I can also establish the 'truth' of a network of mathematical relationships which may (or may not) have any relation with empirical facts. Now, establishing the coherence of a set of mathematical structures or a set of logical assertions might give me some confidence that these structures or assertions have something useful to say, but this DOES NOT COUNT as empirical evidence (sorry, this IS about words and I think it's worth fighting for). I would go so far as to suggest establishing coherence truth is no real guide at all to correspondence truth – for this we need predictions (I'll even settle for predictions of existing facts) and so far we have none. The history of science is littered with coherent structures that have nothing whatsoever to say about physical reality.

Another point that these (few) theorists seem to overlook is that new theories are adopted by the community only when they are shown to work better than the established theories they're meant to replace. This isn't even about making testable predictions – it's about making testable predictions which demonstrate that the new theory (string theory or the multiverse) goes further or has greater explanatory power than the standard model of particle physics or big bang cosmology. My opinion (I can put a probability on it, if you want) is that any prediction, for example of some subtle effect in the cosmic background radiation, is likely to be accommodated by tweaking one or more of the many approximations theorists have to make in order to apply the established theories, and Occam's razor will tend to favour the conservatives. In this view the proponents of new theories will have a real uphill struggle to make a convincing case, even if they're ever able to make testable predictions. I'm afraid there's just too much we don't know and so too much flexibility, irrespective of how well the mathematics work.

17. **anonymous**
June 16, 2016

"..and at Columbia University, Ph.D.s are taking classes in using Twitter to better communicate their work to nonacademic audiences.."

I think that courses teaching specific tools used in the prospective industries would be far more useful. What employers seek is practical knowledge and ability to solve problems using the tools they know. They usually don't look for a person who would make for them goundbreaking discoveries.

18. **Peter Woit**
June 16, 2016

Jim/Bee,
I appreciate the serious discussion of the issues of assigning probabilities, but maybe more relevant in this case is that the particular question here seems to me to not pass the laugh test (average expert on the issue thinks the idea is a joke). I take Weinberg's comment about Rees/Linde not as a serious attempt to characterize the "probability there is a multiverse", but as a joke making fun of the whole concept of doing this.

The serious issue is more that of, once you have Carroll, Dawid, Susskind giving prominent talks at this kind of conference, who is the joke on?

19. **adamt**
June 16, 2016

Sean Carroll believes the Multiverse idea is a middling obscure phenomena that indirect evidence could reveal.

Peter Woit and others (myself included) believe the Multiverse is a completely obscure hypothesized phenomena that no evidence (indirect or otherwise) can illuminate at all.

Peter, have you gone through Sean's indirect evidence point-by-point to see why he believes this to illuminate in some way the Multiverse idea?

20. **Peter Woit**
June 16, 2016

adamt,

I don't know what specific point-by-point list of indirect evidence there is, but the arguments for the multiverse have been addressed I think exhaustively and ad nauseam here for more than a decade. Some of this is in the site FAQ, lots more if you poke around in the 125 postings here
http://www.math.columbia.edu/~woit/wordpress/?cat=10
I suppose I should put together a single location of serious arguments about this, but it's hard to get motivated to do this, since my experience has been that the policy of Multiverse proponents is to steadfastly ignore the serious problems with what they are claiming, and instead attack straw men.

21. **Anon**
June 16, 2016

Modest economic expansion can happen while many industries (and perhaps the majority of the middle class) are tanking. The mean can become very different from the median. As conversations most of my long-suffering colleagues, would-be colleagues, and especially students (current and ex-) will attest, the reports of the end of the Great Recession have been greatly exaggerated.

22. **Peter Woit**
June 16, 2016

Anon/RandomPaddy,

I'm not especially surprised by a negative median income trend, it's just that the 6% change seems high over such a short period of time. I did a quick check and couldn't find the real source of those numbers, may take a better look when I find a moment.

23. **Flavio Botelho**
June 16, 2016

I also think Multiverse is a good theory… Just a philosophical one, not a scientific one. Trying to push it as if it were science is a disservice for humanity.

24. **Chris W.**
June 16, 2016

RE: decline in median income for Math/Physics mid-career Ph.Ds

That would be consistent with what's happening to many other white-color occupations. This economy is being driven by the values and priorities of professional investors and Wall Street. They don't want to sacrifice a portion of their returns to compensate well-educated, highly skilled workers any more than anyone else, if they can find ways to avoid it. That attitude is spilling over into areas beyond business, including the administration of colleges and universities.

25. **Curious Wavefunction**
June 16, 2016

Wouldn't the puzzlement at this kind of discussion in conferences go away if we assume that such conferences have two parts: one in a serious scientific vein and one in a lighter, slightly jocular vein? I am not sure Sean Carroll for instance treats the multiverse with the same kind of seriousness he treats LIGO. I think it's ok to put numbers on probabilities like this as long as you make it clear that you are engaging in philosophy and even humor and not science.

26. **Peter Woit**
June 16, 2016

Chris W.,

I'd describe the trends I see differently, with some highly-skilled people doing well, but also fewer mid-range jobs, so more people ending up in poorly paid jobs. At universities, faculty at places like Columbia are doing well, and if you go into university administration your pay has soared dramatically. On the other hand, nationwide there are more teaching jobs being filled by poorly-paid adjuncts. From what I hear of the Silicon Valley world, Google is offering head-spinning sums to some people, and that's probably true of other large successful technology companies. But a few such companies have gobbled up a large part of the economy, with not so much left over for those not working in these few places.

All in all, the pattern in industry after industry seems to be one of "winner take all", with those doing well doing very well (and this is not just Wall street people), but fewer middle-class jobs. More and more cases are visible of middle-aged people who used to have a reasonably well-paid job which they lost as their industry was "disrupted", and now are unemployed or working for much less than they used to.

This trend though isn't new, it has been going on for years, and I'm still suspicious of the size of the claimed effect over 3 years.

27. **Peter Woit**
June 16, 2016

Curious Wavefunction,

I'm sure Carroll knows the difference between serious experimental results like LIGO and speculative stuff like the multiverse, but I've never seen evidence that he isn't quite serious about the multiverse, or has any particular sense of humor about it. When I first heard the Polchinski argument about "94%", I was sure it was a joke, but it seems that he and others take this seriously. What I'm afraid is that conference organizers conceptualize this kind of speculation as, yes, different than solid science, but think of it as "inspirational", as opposed to possibly silly.

28. **Anonyrat**
June 16, 2016

I think the NSF survey on PhDs that you're looking for is here:
https://ncsesdata.nsf.gov/doctoratework/2013/

Median salaries are here (table 53):
https://ncsesdata.nsf.gov/doctoratework/2013/html/SDR2013_DST53.html

To take a pair of data points (2013)

Mathematics/ statistics (11-15 years since PhD) median income: 109,000 standard error 6,000

Physics (11-15 years since PhD) median income 110,000 standard error 4,000

To look for the decline one would have to go to a previous version of this survey.

Here's the 2010 survey:
https://ncsesdata.nsf.gov/doctoratework/2010/html/SDR2010_DST53.html

The 2010 pair of data points reads:

Mathematics/ statistics (11-15 years since PhD) median income: 100,000 standard error 4,500

Physics (11-15 years since PhD) median income 114,000 standard error 7,000

I'm sure other commenters will better be able to slice and dice this data. But on the face of it, it is physics PhDs, not mathematics/statistics PhDs that have had a decline in median income, for this range of experience.

29. **Anonyrat**
June 16, 2016

This article presents some caveats in interpreting the NSF survey of PhDs for newly minted PhDs:
http://www.sciencemag.org/careers/2016/05/employment-crisis-new-phds-illusion

30. **Peter Woit**
June 16, 2016

Anonyrat,
Thanks! Those numbers by age cohort have large "standard errors", not clear whether they're useful. The numbers for all ages are

Math
2003 80,000
2006 81,800
2008 95,000
2010 97,000
2013 98,000

Physics
2003 94,000
2006 99,900
2008 108,ooo
2010 110,000
2013 111,000

These aren't inflation adjusted. Using a CPI inflation calculator I get, in 2013 dollars

Math
2003 101,290
2006 97,570
2008 102,790
2010 103,630
2013 98,000

Physics
2003 119,000
2006 115,440
2008 116,860
2010 117,520
2013 111,000

These do both both show a huge drop 2010-2013, when US median household income was going back up a bit after the recession, see here
https://en.wikipedia.org/wiki/File:US_GDP_per_capita_vs_median_household_income.png
An odd thing about these numbers though is that they show incomes going up significantly from 2006-8 to 2010, but this was the worst of the recession, with median US household income going down quite a bit. So, I'm still suspicious about these numbers, the 2010 ones are unexpectedly high, the 2013 ones unexpectedly low.

31. **paddy**
June 16, 2016

Not to rain on anyone's parade, but those salaries (like mine) are quite a bit over median US incomes. And I enjoy what I do. I would rather complain about the ratio of the salaries of my plumber to that of my banker.

32. **MikeS**
June 17, 2016

Is it possible that the multiverse is indeed string theory playing its end-game? The failure to make useful predictions about our own Universe has been turned into a strong indicator for a Multiverse. Perhaps even going so far, through this odd use of Bayesian statistics, as some sort of proof of a Multiverse.

But where to from here? String theory is no more likely to be able to say anything useful about these alternative realities than it is about our own, and as these alternates will almost certainly remain beyond any hope of our perceiving them then any conjectures will forever remain as conjectures.

Okay, a few more years tinkering with the probabilities of a Multiverse, but that's about it. Pats on the back all around. Multiverse proved. But now what?

The only game in town is playing its final hand. And guess what, it's all aces! Indeed 10^500 of them!

33. **tulpoeid**
June 17, 2016

Peter,
Only indirectly related to today's post, but would you have any article (either yours or others') to recommend on the similarities between strings/multiverse and religion? And I don't mean it as a parody.

34. **Anonyrat**
June 17, 2016

An outsized influx of young PhDs, or retirement of elderly PhDs would have the effect of driving the median salary of (all ages) down.

But yes, it looks like we have 1-sigma results only for 2010-2013.

35. **Peter Woit**
June 17, 2016

tulpoeid,
I can't recall ever seeing any such article and I haven't tried to write such a thing. Religion is a very complex social phenomenon, and so is string theory/multiverse research. It might be possible to say some interesting things about the similarities and differences, but I haven't seen that done.

Sean Carroll is an interesting figure here, he's rather explicit about wanting to replace a religious world-view with one based on theoretical physics, with the multiverse playing a role perhaps closer to theological speculation than to conventional science.

36. **Neil**
June 17, 2016

Re God, Carroll and the multiverse. Carroll addresses some of these questions in The Big Picture, in particular Chapter 36 (Are We the Point?), where he posits his 50-50 ("perhaps") credence figure, and to a lesser extent in Chapter 18 (Abducting God). In Chapter 36 he states that the multiverse is not a theory but a prediction of other scientific theories (string theory and inflation, which he admits are "speculative"), whereas God is not a prediction of any scientific theory.

37. **curious**
June 17, 2016

has there been any discussion that instead of a multiverse, God did it, in terms of Bayesian statistics?

38. **Neil**
June 17, 2016

Curious

In Chapter 18, Carroll discusses whether there is any evidence to update our priors about divine creation (such as, why is there evil then?) and concludes that the concept of God is too imprecise and variable to apply Bayesian updating, leaving us just with our priors. I thought that was obvious all along. Peter is right in thinking that this sort of debate is a monumental waste of time outside of its entertainment value.

39. **Narad**
June 18, 2016

> When a weather forecaster tells me the probability of rain tomorrow is 50%, I translate it as "I don't know."

Not to try to drag things off topic, but my understanding is that such statements denote that rain is likely for 50% of the covered forecast area.

40. **Another Anon**
June 18, 2016

Narad, that works out to the same thing.

https://en.wikipedia.org/wiki/Probability_of_precipitation

41. **Matt Grayson**
June 18, 2016

I understand it's a human compulsion, but why do we persist in thinking that our theories, which are essentially calculation methods to produce numbers that (one hopes) agree with experiments, have ANYTHING to do with reality? Go through history: every time we have thought, "well this theory(n-1) worked well enough at the time, but it was later seen to have nothing to do with the reality we *now* know due to theory(n)." Yet here we are with GR and the Standard Model, and whatever framework is supposed to succeed them, seriously talking about the probability that their implications exist. Well, a Frequentist actually has data, and that probability is Zero.

(I'm resisting the urge to claim proof by induction, but Raoul Bott defined induction as "You work out n=1, you work out n=2, you keep going until you're bored. Then you have a proof." I think the historical record satisfies his criterion..)

Perhaps I misunderstand their claim. Multiverse proponents are NOT, as far as I can tell, claiming probabilities for results of experiments. Or even probabilities that theory(N), for some large N, will make concrete predictions and involve multiverses, are they? But even then, theory(N+1) will show how silly they were to believe such a thing.

42. **Dave**
June 18, 2016

"Argument from ignorance." Have none of these physicists heard of this fallacy? If you don't know something, then all you can conclude from this is that you don't know. So why the assenine guessing games about probabilities? Why the philosophical debates about accepting the reality of something without falsifiability? I don't know, you don't know, point.

43. **Bee**
June 18, 2016

Hi Peter,

Coindidentally I was about to write a blogpost about the Kinney paper, which is now online here.

44. **Bee**
June 18, 2016

@Jim Baggot

I think I agree with what you say. I should check out your book though to get my vocabulary right 🙂

45. **Anonyrat**
June 18, 2016

The American Mathematical Society has some statistics.

The mathematics PhDs awarded by year 2003-2013 in the US are here:
http://www.ams.org/profession/data/annual-survey/2013Survey-NewDoctorates-Supp-TableD3-4.pdf
From there:
2008-09 : 1605
2009-10 : 1632
2010-11 : 1654
2011-12 : 1798
2012-13 : 1843

Median starting salaries for new PhDs 2000-13 in Teaching & Research, Academic Research Only, Government, and Business & Industry categories are available here:
http://www.ams.org/profession/data/annual-survey/2013Survey-StartSal.pdf

The median numbers look like this

Academic teaching & research (11-12 month)
2008: 56.0K
2009: 60.0
2010: 57.0
2011: 55.0
2012: 60.0
2013: 60.0

Research (11-12 months)
2008: 50.0K
2009: 50.0
2010: 51.5
2011: 55.0
2012: 55.0
2013: 54.0

Government:
2008: 81.5
2009: 82.5
2010: 80.0
2011: 70.0
2012: 82.0
2013: 87.0

Business:
2008: 90.0
2009: 90.0
2010: 90.0
2011: 94.3
2012: 95.0
2013: 100.0

I suppose 2011 was the year of government shutdown?

46. **Jeffrey M**
June 18, 2016

Anonyrat,

Wow, I haven't looked at those numbers in a while. I can't believe how many PhD's there are now! I think the year I got mine ('92) there were around 800. And the job market sucked then.

47. **Narad**
June 18, 2016

@Another Anon:

> Narad, that works out to the same thing.

Thanks for the reference. Perhaps I misinterpreted Neil's original comment, but it's neither here nor there in this thread, so I'll just pipe down.

48. **Bayes_or_bust**
June 19, 2016

Regarding the probabilities of the multiverse, you are right that the 'average expert on the issue thinks the idea is a joke'.
.
I've never seen even a sketch of a calculation for e.g. a Bayes-factor for the multiverse vs. universe (or even enough detail to begin a calculation), and suspect that such a calculation would prove deeply problematic.
.
Caroll et al simply seek refuge from accusations that their work isn't scientific in Bayesianism, but their probabilities are just guesses.
.
However, whilst I'm glad you're ridiculing their numbers, I hope it's clear to your audience that there are many important legitimate applications of Bayesian statistics in science.

49. **a l**
June 20, 2016

String Sociology

June 20, 2016
Categories: Strings 2XXX

If you're interested in the various sorts of internal divisions these days among people doing what gets called "string theory", you might want to take a look at [this blog entry]() and the discussion there with string phenomenologist Joseph Conlon.

Back in 2002 or so when I started writing my popular book, it was a lot clearer what the term "string theory" meant and who counted as a "string theorist". If I were writing about this today, there would be a much more confusing situation to try and explain. There's still a conventional "string theory" story about a supposed theory of everything based on quantized strings often told to the public, but it no longer corresponds much to what researchers who call themselves "string theorists" are actually doing.

To get some better picture of this, it might be a good idea to take a look at the big string theory summer conferences. The biggest is Strings XXXX, [this year in Beijing](), about six weeks away. No talk titles available yet, but in recent years one clear pattern has been that most of the talks have little if anything to do with the "string theory" of the textbooks (4gravitons tries to categorize things [here]()) . These conferences have been going on for over 20 years.

Since 2002, there has been a breakaway conference, String Phenomenology 20XX, which I think Conlon characterizes accurately as follows:

> one reason the String Pheno conference was founded was because people working on pheno topics weren't getting a look-in at the Strings conference and so set up their own conference. I think the Strings conference is most accurately regarded as the Princeton view of the world (broadly, every year it reflects subjects popular at the IAS and a couple of other similar places).
>
> Generally, the ratios vary with place. A small fraction do string pheno in the US, a significant number in Europe, almost none in India, quite a few in Korea…

This year's version of this conference has just gotten underway in Greece, you can follow the talks [here](). One big topic this year is the possible 750 GeV diphoton excess. Around the time of Strings 2016 we should hear whether this is real or not. If it is, String Phenomenology 2017 will likely be completely dominated by the topic, if not, it will have vanished without a trace.

Finally, at the other end of the spectrum is String-Math 20XX, which has been going on since 2011, and this year starts [next week in Paris](). Quite a few first-rate mathematicians are involved this year. As with Strings 20XX, most of the talks don't actually have anything at all to do with the theory of a quantized string, and this is more of a "QFT-Math" than "String-Math" conference at this point.

One can read the blog comments mentioned to get some idea of the arguments going on about "phenomenology" vs. "mathematics". The "phenomenologists" argue that they are the ones doing physics and engaging with data, but don't really point out that the models they work with have no known (i.e. not purely speculative) connection to any known physical phenomenon. They're hopeful someday things will be different, but there's no evidence at all of any progress in that direction.

Phenomenologists like Conlon do battle with their Strings 20XX brethren by accusing them of doing "mathematics", not "physics", of in essence really being just an offshoot of the String-Math 20XX crowd. There's an implicit argument that such people don't deserve jobs in a physics department, but should move to a math department. I can report though, that while much of the String-Math 20XX research is more than welcome in the math community, that's not true of most of what goes on at Strings 20XX (a conference that very few mathematicians ever attend).

If you find the current situation confusing, rest assured that you're not the only one…

Comments

1. **Harrison**
   June 20, 2016

   I seem to discern, more or less, an aspirant class of tragicomedy now up-and-running that would completely elude the Greeks. Aristotle more than anyone.

2. **Thomas Müller**
   June 21, 2016

   Peter, are these writers implying that the definition of string theory is "String theory is whatever is done (since 20 years) at the IAS in Princeton"?

3. **Peter Woit**
   June 21, 2016

   Thomas Muller,
   I think what's being made is an even stronger claim, that for now and the future, whatever people at the IAS do, they'll call it string theory. Recall
   https://www.theguardian.com/science/2005/jan/20/science.research

   "Most string theorists are very arrogant," says Seiberg with a smile. "If there is something [beyond string theory], we will call it string theory."

4. **Tim's Mom**
   June 21, 2016

   I've been thinking about this. I think somebody should do a systematic study of exactly how the sociology of a field of science is *different* from the sociology of a non-science field.

   (Also, my hunch is that the field of Mathematics would land on the 'science' side.)

5. **Michael Barany**
   June 22, 2016

   Tim's Mom, a good book to start with is Gordin's recent Pseudoscience Wars http://press.uchicago.edu/ucp/books/book/chicago/P/bo10672063.html
   There is a lively debate among some sociologists of science and more philosophers of science, but the consensus in the former field at least seems to be that you can mainly tell a scientist by looking at who acknowledges her as a scientist and that there are not really robust criteria beyond that.

6. **Tim's Mom**

June 22, 2016

This is what I'm talking about. Compare the sociology of mathematicians, physicists, string theorists and geologists to the sociology of astrologers, art historians, politicians and volleyball players. Even in art history there is a consensus about some things so it's not a priori obvious what's going on. Somebody needs to work on this.

7. **Jonny 5Brane**
June 23, 2016

An early version of the Tim's Mom's abject nihilism surfaced after Kuhn's work first came out. I am happy to observe Woit *is not* taking that stance – Conlon has 45 publications and yet his ressentiment is palpable. I feel like I can see the face he makes when he says "Princeton". Strings-Math 2016 does indeed look awesome! Looks like I'll be hosting all night watch parties next week. Enjoy!

Rumor Mongering

June 21, 2016
Categories: Experimental HEP News

Since I don't see why Resonaances should have all the fun, I guess I'll post something here about the big upcoming news of the summer: is the 750 GeV diphoton bump still there in the 2016 LHC data? We're very soon about to hit a major fork in the road for high energy physics: if the bump is there, the field will be revolutionized and dominated by this for years, ft it's not, we're back to the usual frustrating grind.

Last year's tentative signal was based upon 3.2 inverse fb of 2015 data, and as of today the experiments have over 6 inverse fb of new 2016 data. One can guess that within ATLAS and CMS, plots have started to circulate of preliminary analyses of some sizable fraction of the new data, and some number of people now know which fork we're headed down, a number that will grow to 6000 or so in coming weeks.

If you're not one of those, you could try accessing this data indirectly, using a model of how the CERN administration works. According to this presentation at LHCP this past weekend

> the next major update of physics results from the LHC is at the ICHEP 2016 Conference, August 2016, Chicago

and

> CERN management is in regular contacts with the experiments' Spokespersons. It is agreed that any significant (i.e. discovery-like) result (such as the 750 GeV bump becoming a signal or other) has first to be announced in a seminar at CERN.

No detailed schedule yet for ICHEP, but the first day of plenary talks there is scheduled for Monday August 8. My CERN-modeling suggests that the two forks in the road will correspond to the following two possibilities

- A "special seminar" in Geneva mid to late July, where a "discovery-like result" will be announced jointly by the CERN DG and the two experiments.
- A pair of seminars in Chicago on August 8 or shortly thereafter showing off bump-less plots. Much of the drama will be gone by then, since not all 6000 physicists will have kept quiet, and everyone will realize that if "discovery-like" was going to happen, it would have happened earlier.

It may become clear which fork we're taking relatively soon, since the "special seminar" route takes some planning and will get announced in advance. If there's no such news by mid-July I think it will be clear we're headed down the boring fork in the road.

Unfortunately, life being what it is, that's the most likely one anyway. To supplement this CERN-administration-modeling, you can watch the comment section at Resonaances, where rumors of no bump have already started to appear…

Update: Now, it's an official rumor (since it's on Twitter). I can add to this that, of the rumors I have heard, there have been no rumors that this official rumor is not an accurate rumor.

Comments

1. **Another Anon**
   June 21, 2016

   Yeah, I was going to say the rumour is that the bump has gone.

2. **anonymous**
   June 21, 2016

   Jester has hinted in the comments on his blog that the bump is indeed going away:

   "Many papers, including some written by the winners, made interesting contributions that will live longer than this particular bump. So this post is self-irony through the tears, rather than slut shaming as interpreted by some."

   On the bright side, the LHC is coasting along magnificently, churning out 2/fb/week despite the dump leak in the SPS. ICHEP could be presenting 15/fb of data in total, 30/fb in total by the end of 2016 assuming no more curious fouines.

3. **Henry L.**
   June 21, 2016

   Peter,

   I am interested in how your "CERN-modeling" works. Would you be willing to share some details, or are your algorithms proprietary?

4. **Peter Woit**
   June 21, 2016

   The model is quite simple: it just says that if there's a "discovery", they will reveal this at a special seminar at CERN, announced a week or so in advance. If there's a let-down non-discovery, they will announce at a previously scheduled conference outside CERN. This modeling is based on past observations and basic understanding of how a good PR operation works. I do think it's a pretty powerful model: once you know the announcement plan, you know the result.

   Of course my confidence level in the model may depend on proprietary algorithms, although these are more relevant to evaluating rumors…

5. **anon**
   June 21, 2016

   "One can guess that within ATLAS and CMS, plots have started to circulate of preliminary analyses" – do we even know reliably whether the data has been unblinded?

6. **Neil**
   June 22, 2016

Dismaying for BSM hopes, but still just a rumor. Perhaps disseminated to put the bloodhounds off the scent trail?

7. **M**
   June 22, 2016

   anon, ATLAS had a meeting on June 16 at 13:00 and CMS on June 20 at 17:00: it’s impossible to keep information private among 3000+3000 persons, especially when not everybody agrees on a selective policy for announcing data. They risk that somebody could go beyond a tweet and post the digamma spectra on a blog. Anyhow, another rumor is that a few years ago, in one analysis, higgs to gamma gamma disappeared for a while, until it reappeared with more data. Diphoton data are growing fast, already now they have twice the data analysed so far.

8. **anon**
   June 22, 2016

   @M, should I take that as confirmation that the data have been unblinded from someone inside an experimental collaboration?

9. **Dan D.**
   June 22, 2016

   In regards to M’s comment above, I, too, seem to recall that at one point, the Higgs digamma signal in CMS fluctuated downward quite a bit in one batch of data. I can’t remember if this was before or after the 2012 discovery announcement.

10. **Alex C**
    June 22, 2016

    My little bird in CERN told me the bump has gone in 2016 data

11. **Confused**
    June 22, 2016

    I am wondering if it is commonly understood amongst particle physicists that this is the expected behavior of p-values. If there is no signal, the p-value should not be expected to converge onto any specific value as more data is collected. It will random walk between 0 and 1; ie if the null hypothesis is true the p-value is a sample from a uniform distribution. See for example the simple simulation output in figure 2 here (you can easily run your own simulations as well):
    http://pss.sagepub.com/content/22/11/1359.full

12. **Peter Woit**
    June 22, 2016

    Confused,
    Particle physicists do have a quite sophisticated understanding of these issues, this is a central part of what they do, you’re mistaken if you think they’re not quite aware of this. The problem is that they do this a lot: a huge number of very different analyses get performed, so it is tricky to characterize probabilities of seeing a certain size fluctuation at a certain location. Then there are two independent experiments, if they see something at roughly the same location, how do you take into account the significance of that?

    The bottom line here is that, however you quantified it, last year’s data contained a potentially significant signal, although one not large enough to be convincing. With this year’s data, the situation is just about binary: with pretty high probability,if there’s something there, the signal should get larger and become convincing, if not its significance should recede. The rumor is that the latter has happened, with details still to come.

13. **Bayes_or_bust**
    June 22, 2016

    I’d like to have seen a Bayesian analysis of the combined data. My feeling is that the complicated statistical analyses (local vs global and LEE, and the lack of a reliable combination of ATLAS and CMS data) contributed to the hype and confusion about a new particle. I think this mess would have been partially avoided with e.g. Bayes-factors for a diphoton toy model vs the SM.

14. **Peter Woit**
    June 22, 2016

    Bayes_or_bust,

    I don’t think a Bayesian or other analysis would have changed anything, other than giving people yet more different inconclusive ways of characterizing the significance of the bump.

    What has surprised me about the LHC results has been how rare things like this are. If you look back at the history of HEP experiments you can find a long list of interesting looking, but not quite convincing effects that have appeared and then disappeared. This is just part of how this kind of science works. Given the huge number of different analyses going on at the LHC, I’d have expected more such stories. The experiments have done an unusually excellent job of trying to be rigorous about their statistical methods.

    The reaction of the theory community is a different story, see the discussion at Resonaances. There the way the field is intensely starved for anything new led to this getting an unusual (and, it seems, unjustified) amount of attention.

15. **db**
    June 22, 2016

    @Peter Woit

    Of course the real question is whether or not you would be prepared to kill someones dog if your CERN PR model was falsified. 🙂

16. **G. S.**
    June 22, 2016

    Bayes_or_bust,

    Before calculating the Bayes-factor for a diphoton toy model, you have to decide which toy model(s) to consider. How would you do this?

I would think that you would want to use one that existed and was deemed "reasonable" prior to observation of the diphoton excess. That would be to avoid models that have since been tuned or selected to fit the observation. However, I'm not sure any such models existed.

17. **Sal Rappoccio**
June 22, 2016

The statistical methods we've developed are robust to all of this… that oft-decried 5-sigma standard of evidence is a pragmatic way to get around the trickiness of the 3-sigma jumps and bumps that should happen occasionally when performing hundreds and thousands of analyses. We just need to stick to the decision! Instead, we collectively lost our minds over a tantalizing hint, and will subsequently pay the price if it is falsified.

It's like playing Texas Hold'Em. You've got a pocket pair of aces. Yes, it's a good hand pre-flop. But, it's not enough to bet your house on, there are 5 cards to play. At least wait until the turn! In science, we should really wait all the way until the river in order to call the game ;).

18. **S**
June 22, 2016

Actually, Sal, you kind of want to push people off those pocket twos before the flop, just in case, which does justify a pretty aggressive bet pre-flop.

Maybe this explains string theory PR?

19. **Bayes_or_bust**
June 22, 2016

@GS I think a toy model could have been made. @Peter it's not a lack of rigour that I dislike. It's the complicated frequentist techniques and lack of an official combination of ATLAS and CMS data.

Even now @jester's blog you can see confusion about this. No one knows the combined global significance for that search. And they worry they've been fooled by the sheer number of analyses.

Suppose we knew the Bayes-factor and it said: diphoton toy model 5 times more plausible after 2015 data. Don't you think that would alleviate confusion? No global/local/LEE to contend with.

That said, the decisions people make to to e.g. make a paper or get excited, are based on many factors beyond the plausibility of the new physics model.

20. **Peter Woit**
June 22, 2016

Bayes_or_bust,
No, "diphoton toy model 5 times more plausible after 2015 data" would add to, not reduce confusion, by introducing a host of new complications (which toy model? how do you get the "5 times"?).

The experiments I think do a good job of quantifying what can be quantified. Beyond that, it's a matter of judgment and experience, the importance of which can't be eliminated by more sophisticated statistical analysis. My impression is that a typical expert reaction to the diphoton plots and to the kind of numbers quoted for statistical significance is something like "yes, looks like there could very well be something there, but I can think of several cases in the past when bumps like that went away with more data". You can assign all sorts of numbers to this situation, but the bottom line is that the 2015 data was not convincing evidence, especially not convincing evidence for an extraordinary claim (completely new, never before seen physics not part of the standard model). Extraordinary claims require extraordinary evidence, and that wasn't there.

What's interesting about this situation is that the new data should with high probability resolve the issue. If there really is a state with that kind of cross-section, we should see convincing evidence soon. If there isn't, the new data should sizably reduce the significance of the bump. Landing in the middle zone isn't especially likely.

21. **Bayes_or_bust**
June 23, 2016

The Bayes-factor (I said 5 times for an example) would be calculated in the usual way. I agree there would be questions about which toy-model was tested against the SM, but even in the frequentist log-likelihood ratio methods currently used for the diphoton analyses, one has to make an alternative model to test. So I don't see it as problematic. But we'll have to agree to disagree, I think.

22. **anonymous**
June 23, 2016

Peter and others,

Is there any known plausible theoretical reason for the existence of a heavy resonant state at 750 GeV ? That would certainly make it a-priori more likely to exist.

After all, the Higgs discovery was extremely well-motivated theoretically around *half a century* before it was discovered.

23. **M**
June 23, 2016

Dear anonymous, the Theory of Anything univocally predicts 10^500 different vacua. About 10^350 of them are indistinguishable from the Standard Model, and about 10^345 of them have a diphoton resonance at 750 GeV.

24. **Another Anon**
June 23, 2016

One thing that bugs me a bit is why all the particle physicists got so thrilled by the news of the bump. How can it be good to discover something we don't understand? Effectively, that increases our ignorance about the world. Surely the aim is to decrease our ignorance, by making sense of the data we already know. A new particle just pushes us further from that goal. I appreciate a new particle would have given them something to work on, but that's not the point – there's already plenty of stuff to work on: go solve the hierarchy problem, or dark matter if you're short of something to do,

25. **MikeS**
June 23, 2016

Another Anon

Unexpected findings do not increase our ignorance they reveal our ignorance. Which is the first step in reducing our ignorance.

26. **Another Anon**
June 23, 2016

Good point. But I don't think I'd be so happy to discover I was ignorant.

27. **Martin S.**
June 23, 2016

@ Another Anon: Then you apparently do not have a soul of scientist.

PS Thinking about new unexpected stuff may help you to find clues to other difficult phenomena.

28. **Low Math, Meekly Interacting**
June 23, 2016

At one time, wouldn't something like 2/3 of the particles we already observe have been completely unexpected? Of course, I suppose today we have much better constraints on where something unforeseen might be lurking. Still, I'm surprised and chagrined at how risible some in the blogosphere seem to think the activity and excitement around the 750 GeV bump has been. It's not like HEP theorists have had much else that was obviously better to do lately.

29. **Peter Woit**
June 23, 2016

LMMI,
The main blog making fun of this has been Resonaances, whose author himself has papers on two different models explaining the bump. There's a reason he calls himself "Jester", and I think a sense of humor about this whole situation is not out of place…

30. **Low Math, Meekly Interacting**
June 23, 2016

I do get the humor, sort of. Given the abject starvation for new data theorists are experiencing, it's certainly better for one's sanity to laugh than to cry. But there's also some accusatory chatter about schlock being dumped into the arXiv to drive up citation counts, people ruining their own Christmas, etc., and all that seems kind of cruel to me. I mean, HEP theorists may be treading a path into the driest desert imaginable. The way things are going, there may literally be nothing for the next Feynman or Gell-Mann or Weinberg or Wilczek to sink his or her teeth into…EVER. So, for pity's sake, why look askance at people burning a few hours and electrons on a potentially vanishing dream. At least they're theorizing about an actual result. Spurious result or not, it's no anthropic landscape.

31. **DrDave**
June 23, 2016

"I do think it's a pretty powerful model: once you know the announcement plan, you know the result."
So you are saying that you can make predictions based on observation, and that the results are falsifiable.

32. **chris**
June 24, 2016

this aligns nicely with the rumors i have been hearing.

33. **Peter Shor**
June 24, 2016

I think this can all be explained with sociology/game theory.

If I remember properly, before the LHC came on, physics departments increased the number of phenomenologists they were hiring, because they thought there was a substantial probability that with the LHC, this field would become more important.

So now we have all these untenured phenomenologists, all of whom are desperate to write a significant paper in the next few years. It would be foolish of them *not to* publish explanations for any possibly significant bump discovered at the LHC, on the off-chance that the bump is real and their paper is correct, winning them the tenure lottery.

34. **wb**
June 24, 2016

>> all these untenured phenomenologists

In seems that the 'worst case scenario' is becoming reality: The LHC saw the Higgs but nothing else.
So what now?

35. **John Baez**
June 24, 2016

Another Anon wrote:

> But I don't think I'd be so happy to discover I was ignorant.

Opinions may vary, but I already feel extremely ignorant about particle physics. There are lots of mysteries in this subject, from why such a complicated theory as the Standard Model seems to work so well, to what's the explanation of dark matter (a new particle not in the Standard Model?), inflation (another new particle?), dark energy, etc. etc. Since I'm completely stuck on trying to figure these things out, any further clues would be great.

36. **Jonathan Tooker**
June 26, 2016

When will they announce the spin of the Higgs-like particle that got announced in this way in 2012?

37. **Karibe**
June 27, 2016

I was hoping the bump won’t go away, but grow into a signal.

Some Ancient History

June 27, 2016
Categories: Uncategorized

A couple months ago there was a session at an APS meeting with the topic Sidney Coleman Remembered. Slides are available for talks by Coleman's student Erick Weinberg and colleague Howard Georgi. Georgi has recently posted a written version of the talk here. He also a few years ago wrote this biographical memoir about Coleman for the National Academy of Sciences.

David Derbes and collaborators are putting together a book version of Coleman's famous lectures on quantum field theory, hope to be finished with this by the end of the summer. I've helped out in a very small way by sending them a scan of my notes from when I took Coleman's course very long ago.

This will be a great resource for anyone learning QFT and, in the meantime, if you don't have a copy of Coleman's Erice lectures, Aspects of Symmetry, you should get one. The period of these lectures spans the late sixties and seventies, and at the time they were required reading for everyone, giving every couple years a lucid explanation of the most important new ideas in the field. The last (1979) lectures are about the 1/N expansion, and I notice that Coleman extensively credits Witten, who was a postdoc at Harvard at the time. A couple years later, Witten in some sense took over from Coleman, lecturing about supersymmetry (a topic Coleman never warmed to) at Erice in 1981.

Last Friday at CERN there was an event devoted to the 40th anniversary of supergravity. Coleman makes a couple appearances, with Sergio Ferrara claiming he was responsible for the name "gravitino" and Peter van Nieuwenhuizen quoting him as saying

> I am uninterested in gravity, and superuninterested in supergravity.

One reason for this was surely the ferociously technical difficulties of constructing supergravity, with Coleman not interested in difficult calculations. Another was likely a lack of interest in topics with no known relation to experiment, which likely had to do with his comments about both gravity and supergravity. At the CERN event, Albert De Roecke's presentation, Desperately Seeking SUSY, reviews the long story of the failure of SUSY and supergravity to make contact with experiment, including a New York Times 1993 article about the failure to find SUSY at the Tevatron. It has extensive detail about the unsuccessful searches at the LHC.

De Roeck also includes a copy of David Gross's 1994 bet with Ken Lane that SUSY will appear at the LHC (when at least 50 inverse fb have been accumulated). Gross will likely have to pay this off next year, but another such bet just came due on June 16th, so a group of theorists should by now be buying expensive cognac for their more prescient colleagues.

Comments

1. **Tony Smith**
   June 27, 2016

   How would the Derbes et al version of Sidney Coleman's lectures on quantum field theory compare with the 1999 Cambridge University Press book by Robin Ticciati Quantum Field Theory for Mathematicians in which the preface says that Ticciati
   "… had audited Sidney Coleman's outstanding Harvard lectures
   and had taken very good notes …[and]… had Robert Brandenburger's official solutions to all the homework sets. …".

   Tony

2. **Peter Woit**
   June 27, 2016

   Tony Smith,

   Ticciati's book is quite different, although in places one can certainly see Coleman's influence. Probably quite a few modern QFT books were influenced, directly or indirectly, by Coleman's course. Picking up a few at random, I see that in their introductions Tony Zee and Michael Peskin mention learning QFT from Coleman.

3. **Jeff M**
   June 27, 2016

   I notice that Peter Orland is a NO on the linked bet, which should be paid off now. Enjoy the cognac Peter 🙂

4. **susy**
   June 27, 2016

   how many inverse fb is needed before any conclusions about SUSY can be made at LHC energies?

5. **David Derbes**
   June 27, 2016

   Hi, Peter.

   Thank you very much for the plug, and also for the xeroxed notes, which have been invaluable. But I want to be sure that my colleagues' names are front and center. First and foremost, none of this would have happened without Brian Hill's notes. Brian was a friend of Sidney's and a grader of Sidney's QFT course for three years. His handwritten notes were the closest thing to a textbook that the course had for at least fifteen years. About three years ago, Bryan Ging-Ge Chen and Yuan-Sen Ting LaTeX'd Brian's notes for the arXiv (and you can get them today, if you like). I got in touch with Brian, Bryan and Yuan-Sen and asked about the second semester. They hadn't any notes for that. I emailed a former high school student of mine (I'm a high school teacher, but I have a PhD in theoretical physics), Matt Headrick, who had a set of second semester notes by a grad student who prefers to remain anonymous. Yuan-Sen made the initial suggestion that we try to turn the notes, the videos and all the rest into a book. Yuan-Sen suggested I get in touch with Richard Sohn, who was very helpful to him and Bryan when they were LaTeX'ing Brian's notes. Richard has taken over the job of the second semester, I'm about done with the first. Richard has done more work on the book than anyone. I mentioned this project to Peter about two years ago, and he sent me his notes. As most of your readers know, Harvard videotaped Coleman's lectures in 1975-76, and these are on the web. Richard and I have transcribed nearly all of them. In addition, we hope to have a foreword by David Kaiser, a former Coleman grad student (though he finished with Alan Guth), who has also edited a big chunk of the first semester. He also got copies of Sidney's own notes from Diana Coleman, Sidney's widow. When Richard and I had been at it for a few months, David Griffiths (of textbook fame, and also a Coleman PhD student) emailed Yuan-Sen to ask about the second semester. Yuan-Sen told him to get in touch with me. David has provided unbelievably wonderful criticism, great suggestions and rewording, and generally improved the manuscript's quality by a factor of at least 2 and probably 3. There ought to be at least seven names on the cover: Brian Hill, Yuan-Sen Ting, Bryan Ging-Ge Chen, Richard Sohn, David Griffiths, David Kaiser and me. (I would also include the anonymous grad student, but that's not in keeping with his wishes.) At present only Bryan's, Yuan-Sen's, Richard's and my names are on it (tentatively) (very probably David K will be credited on the cover for the foreword), but I'm going to ask Brian, David G and the anonymous grad student again once we're nearly done. I should also add that all proceeds are going to Diana Coleman. We're all doing this work for free, out of affection and respect for Sidney Coleman. Harvard's IP people are OK with it, nobody asked for royalties (not even Harvard), and I hope the community will be reasonably happy with the result. It isn't going to be the book Sidney would have written, no one should be fooled, but we hope it will be a reasonable approximation, and we think Sidney's voice is clearly heard. Finally, we're also including problem sets and solutions; these were supplied by Matt Headrick, Peter Woit, Brian Hill, and the graders Nathan Salwen and David Lee. At present we're not including final exams and answers, but maybe we should. This is a big book, perhaps 900 pp. We hope to deliver the finished manuscript (LaTeX source and illustrations) to World Scientific by September 1.

6. **Peter Woit**
   June 27, 2016

   susy,
   To get some rough numbers, Tevatron gluino mass bounds were something like 350 GeV. Naively scaling to the LHC at a factor of 6.5 higher in energy, one would expect to be able to reach up to something like 2300 GeV. Results from 3 inverse fb reported late last year give (see De Roeck) something like 1700 GeV bounds. Measured in logarithmic terms, there's not that much space left between 1700 and 2300 GeV, most of the increased reach expected from the LHC has already happened. I don't think David Gross would be making his bet with Ken Lane today…

   There are of course lots of different SUSY particles one can look for, and higher luminosity is more relevant to states that are not strongly interacting. There will be a very long story of slowly rising bounds of different sorts, best to leave more discussion of this to August, when we'll see what gets announced at ICHEP (and whether that starts to cause SUSY enthusiasts to finally give up…)

7. **Peter Woit**
   June 27, 2016

   Thanks David for the details, I think this is a great project, congratulations to all of you on getting near the end!

8. **Lee Smolin**
   June 27, 2016

   Dear Peter,

   I was told that "I am uninterested in gravity, and super-uninterested in supergravity…but…" was most of Sydney's letter of recommendation for me. Perhaps he used it for others as well.

   Lee

9. **Peter Woit**
   June 27, 2016

   Thanks Lee,
   That's consistent with another version of the talk by Peter van Nieuwenhuizen, see here
   media.scgp.stonybrook.edu/presentations/20140109_vanNieuwenhuizen.pdf
   where he tells the story this way:

   I remember a recommendation letter from Sydney Coleman that began as
   follows: "I am uninterested in gravity, and superuninterested in supergravity".

10. **Harrison**
    June 28, 2016

    "If you tell yourself something over and over again, right or wrong, it becomes intuitive."-Sidney Coleman

    Thanks very much for that biographic item on him.

11. **Peter Orland**
    June 28, 2016

    Jeff M,

    Thanks for the good wishes. For some reason, an earlier bet (from 2000) was extended, without consulting most of the signers.

    I drink milliliters of alcohol per year, but I look forward to getting a contact high from other winners (if the bet is ever paid off).

12. **David Appell**
    June 28, 2016

    A few years ago I wrote an article about the discovery of supergravity, including the night Peter van Nieuwenhuizen verified by computer that a prominent term vanished:

    "When supergravity was born," Physics World, September 2012, pp 32-36.
    http://www.davidappell.com/articles/PWSep12appell-supergravity.pdf

    He told me that right afterwards he was depressed for days. And he told me that he got emotional while reading my article about it, 36 years later.

13. **Alan**
    June 29, 2016

    In the De Roeck presentation, he suggested 1500GeV was a limit to gluino mass for SUSY being natural. If mass of gluino is already constrained for >1700GeV, does it mean that naturalness has already be lost?

14. **Peter Woit**
    June 29, 2016

    Alan,

The problem is that there is no well-defined definition of what "naturalness" precisely means. It is now widely recognized though that the LHC results are in stark contrast to pre-LHC expectations based on such "naturalness" arguments.

15. **lzp**
June 29, 2016

Ouch, these are strong words, quoted from Peter van Nieuwenhuizen's presentation linked above–but in line with the feelings/beliefs/preferences of the majority of the readers of this blog:

"The reader may ask why in this book [Facts and Mysteries of Elementary Particles, 2003] string theory and supersymmetry have not been discussed. . . The fact is that this book is about physics and this implies that theoretical ideas must be supported by experimental facts. Neither supersymmetry nor string theory satisfy this criterion. They are figments of the theoretical mind. To quote Pauli, they are not even wrong. They have no place here. . ." (M. Veltman)

16. **Alan**
June 29, 2016

Ok, more precisely, when will 84% -1 sigma- of pMSSM models be discarded, taking the prior as experimental constraints which where in 1977 -when MSSM was created-.

17. **Peter Woit**
June 29, 2016

Alan,
The problem with that formulation is that there's no obvious way to choose a measure on the space of pMSSM models. You want "naturalness" to mean that this measure falls off at higher masses, but how to do this is ill-defined.

18. **GoletaBeach**
June 30, 2016

Perhaps the most successful endeavor in broader particle physics in the past 20-or-so years was… the LHC detector collaborations argued for very challenging and expensive calorimeters… far better than D0 or CDF… at a time when Higgs to gamma gamma was largely disbelieved for two reasons…. 1)the bias of experimentalists to believe new particles are usually very heavy, particularly a fundamental scalar (with the well known theoretical support for the Higgs)…. that was why the no-lose Higgs theorems were attractive for SSC experimental advocates…. 2)Higgs to gamma gamma is just too darned hard, experimentally speaking.

ATLAS and CMS pushed for fantastically expensive calorimeters anyway, and they were right. Of course Higgs to Z0 Z0 is excellent too. But once again, seeing that is another testament to the quality of the detectors… good coverage, excellent systems, etc. All the while, ferocious downward pressure on budgets, and ATLAS and CMS came through.

Not much connection with Sidney Coleman, who was a delightful guy… in fact ATLAS and CMS (and LIGO, and maybe LSST, Planck, LZ, etc) are collectives where single great personalities aren't particularly effective… endless institutional reviews and internal assessments drive the modern big science collaborations. Celebrating that rather boring process isn't as fun as the celebrating the 40th anniversary of supergravity, and a good party is always good, even if it celebrates 25 years of not seeing dark matter or SUSY.

Big science collaborations are sometimes called the last refuge of communism. Nobody wants to laud that. Maybe we should.

July 6, 2016

Peter,

Having recently struggled to review some of Karl Popper's works on the philosophical problem of induction, I'm totally in favor of placing a deadline on proving a theory. The bet, be it a bottle of cognac or a set of Encyclopedia Britannica, puts the unfalsifiable theory to rest so that science can continue to advance along other fronts. I have great respect for the theorist who is willing to set an end date and a bottle of France's finest on the table to either connect their theory with empirical experiment or set it aside in favor of others willing to take the same challenge.

20. **zzz**
July 7, 2016

they have bet like that, what they need is a bookie to enforce it.

21. **Andrew Porter**
July 9, 2016

I knew him as someone I saw at science fiction conventions, often at in the Boston area, but also at the annual World Science Fiction Conventions, held at various places around the world. His help for SF writers struggling to put real and logical physics into their stories and novels was legendary.
.
In the SF field, he was long known as "the best physicist to have never won a Nobel Prize," as detailed here:
.
http://fancyclopedia.org/sidney-coleman

22. **Richard A. Lupoff**
July 9, 2016

As a onetime science fiction fan and sometime science fiction writer, I knew Sidney Coleman in another, and non-technical, context. When I was grappling with a scientific concept that was vital to a story I was writing, I would ask Sid for help. He was endlessly patient and generous in this regard. Importantly, he was utterly lucid, explaining concepts in terms that I–very much a layman!–could understand. Sid is fondly remembered in the literary field, and it is gratifying to see the attention he is now receiving among his former colleagues. He deserves to receive great credit and to be fondly and warmly remembered!

23. **Gregory Benford**
July 9, 2016

I'm a physicist at UCI and wrote a memoir about Sid in 2012 that focuses on the man, an old friend:

Short Items

June 30, 2016
Categories: Uncategorized

- Erica Klarreich at Quanta magazine has a wonderful profile of Peter Scholze. Scholze has been busy revolutionizing various parts of arithmetic geometry in recent years, and the article does a good job of giving some of the flavor of this. I noticed this morning that Scholze has a new preprint out, about a q-deformation of de Rham cohomology, so that may be the latest, hottest news in the subject.

  The new paper was written for the occasion of his acceptance of the 2015 Fermat Prize. Another Quanta piece makes the obvious point that we already know who one winner of the 2018 Fields Medal will be. While Scholze has been awarded a fair number of prizes already, it's interesting that he's not universally in favor of the prize phenomenon: see here for some discussion of his decision last year to turn down one of the 2016 Breakthrough Prizes.

- In addition to being a great mathematician, Scholze also seems to be a fine human being. The AMS Notices this week has an interview with another such mathematician, Robert Bryant, who is now the AMS President, recently head of MSRI. Unlike Scholze, I've had the pleasure of getting to know Bryant a little bit, since he was a visitor one semester here at Columbia. The Notices article explains his interesting background, which is somewhat unusual for an academic mathematician. The math community is lucky to have leading figures like him combining mathematical talent and excellent personal qualities.

  I first heard about him back when I was a post-doc at Stony Brook, trying to learn more about mathematics and the math community. At some point I asked Claude LeBrun (a young geometer then, now an older one, with a conference in his honor next week in Montreal) who he thought the best young geometers were. He told me about Robert Bryant, and when I asked "why him?", his answer was "He's read and understood all of Cartan". I wasn't sure whether to take that seriously, but from the AMS interview, he was quite right about that.

- For one last piece of mathematics news, fans of geometric Langlands may want to take a look at the new preprint by David Ben-Zvi and David Nadler on a Betti form of geometric Langlands.
- Turning to physics, last week UCLA announced a $11 million donation to fund a Mani L. Bhaumik Institute for Theoretical Physics at UCLA. As NSF funding for theoretical physics stays flat or declines, at least in the US it is private funding like this that is becoming much more important.
- At CERN the LHC has reached design luminosity, and is breaking records with a fast pace of new collisions. This may have something to do with the report that the LHC is also about to tear open a portal to another dimension. Not clear why people are worrying about the 750 GeV state with this going on.

Soon heading North for a week-long vacation, blogging likely slim to non-existent.

Update: For geometric Langlands fans, this and this on the arXiv from Dennis Gaitsgory tonight.

   June 30, 2016

   I sometimes wonder if there is an upper limit for mathematical prodigy. Hardy gave himself a score of 25, Littlewood 30, Hilbert 80 and Ramanujan 100. Are people like Scholz, Bryant or Tao close to 80? Maybe even close to 100? Better?

2. **Peter Woit**
   June 30, 2016

   Heiko242,
   I don't think mathematicians can be usefully ranked like that. If one looks at the best work of mathematicians like Scholze, Bryant and Tao, I think one sees both different, incommensurable, technical talents, as well as different backgrounds that come into play. Bryant's story about his engagement with the works of Cartan is a good example. If he hadn't pursued that, but had gone in some other direction, would he have accomplished as much? Scholze's story about starting with the Wiles proof and working backwards is another example of a very special way of entering mathematics that worked out for him. It's possible that if Scholze had devoted himself to reading Cartan, and Bryant to trying to understand the Wiles proof, neither would have had anything like the same success.

   Great new mathematics comes out of a complicated mixture of having learned the right things, having the right talents, being in the right place to talk to people who can help, having the time and dedication to focus on something, and choosing the right thing to focus on. As mathematics progresses, in some sense easier things get done and what is left is harder. On the other hand, the way the community is organized and the way mathematicians are trained also evolves, making it possible for them to effectively specialize and attack problems beyond what their predecessors were able to deal with.

   To the extent that some isolated notion of raw talent is part of the story, I don't know of any reason to believe that the best mathematicians of today are particularly different than those of other eras.

3. **David Hansen**
   June 30, 2016

   I'm just writing to strongly endorse Peter's response to Heiko. Like all human endeavors, math has context, and any simplistic ranking of mathematicians is essentially meaningless.

Physics and Math News

July 11, 2016
Categories: Uncategorized

Now back from vacation, here's the latest on revolutionary developments in physics and mathematics:

- On the high energy physics front, the good news is that the LHC is performing remarkably well, with already over 13 inverse fb of luminosity, far above that expected at this time, on track to end up with a lot more than the targeted 25 inverse fb for the year. The bad news however is that new reliable rumors (together with the non-observation of any sign of a "special seminar" at CERN, see here) confirm non-existence of the 750 GeV state that would have killed the Standard Model and revolutionized the field. As far as I know, the plan is still to present these results publicly the first week of August at ICHEP, it looks like this will be on August 5.

  For some interesting discussion of the statistical analysis issues that come up when trying to quantify how significant the 2015 evidence is for the supposed 750 GeV state, see the comment section of this blog entry. These subtleties it seems will be made irrelevant by the arrival of new data.

- In mathematics there has also been an unconfirmed claim of something revolutionary, but the problem is that there's nothing analogous to new data coming in to help decide the issue. This is the claim first made four years ago by Mochizuki to have a proof of the abc conjecture, using new methods he calls "Inter-Universal Teichmuller Theory". The current situation is an extremely unusual one, with experts still unable to understand and evaluate the purported proof. For the best summary of the situation, see Brian Conrad's detailed explanation from last December here.

  Not much seems to have happened since then, but one very recent development has been the appearance of a new survey of the theory. Unfortunately, my guess is that this is not likely to address the issues raised by Conrad and provide what he and other experts are looking for: precise checkable arguments. Instead the new survey is another attempt by Mochizuki to communicate his general high-level vision, often in very metaphorical terms. The last section of the survey is a remarkable attempt to position his ideas in the landscape of modern mathematics, which includes setting these ideas in opposition to those of the dominant research program (and thus of great value if they work out).

  What's really odd here is the way that usual mechanisms for transmitting understanding have failed. Mochizuki has worked to transmit understanding of his ideas to a small number of others, but the transmission has stopped there, with understanding of the abc proof not moving from them to others. For a while the hope was that Go Yamashita would be the one to move this forward, but he has not produced a promised document, or succeeded in communicating by his talks. More recently, last year Yuichiro Hoshi produced a document that is supposed to explain crucial ideas, but it is in Japanese, so inaccessible to most experts. Why this has not been translated remains very unclear.

  Next week in Kyoto there will be another workshop trying to further understanding of the IUT theory. I hope this works out better than the last one. There's a preparatory document here which to me seems to ignore the fundamental problem of figuring out what has gone wrong so far. In particular, its last point appears to be explicitly aimed at discouraging anyone in the audience from confronting speakers that are not successfully communicating ideas and insisting that they try to do better. It would be more fruitful to encourage this instead.

3. **Another Anon**
   July 12, 2016

   These sigma significance levels need reevaluation. 2.5 sigma supposedly means a result is correct over 99% of the time – in other words, hardly ever wrong. But we know that's nowhere near the reality.

4. **Peter Woit**
   July 12, 2016

   Another Anon,
   That's the topic being discussed at Tommaso Dorigo's blog (which would be a better place to discuss this than here). The subtleties of going from such a "local" number to a number reflecting the actual probability of something new are well-known in HEP physics (and the reason behind the very high "5 sigma" standard). This is nothing new, but has always been part of this subject.

5. **sdf**
   July 12, 2016

   Is this on anyone's radar? http://www.ihes.fr/~lafforgue/math/NoriMotivesInformation.pdf

   Re. Y. Hoshi, he gave ~4 hours of lectures in Paris on his mono-anabelian ideas, he has superb English so that is not a reason for lack of translation. One frustrating thing he does is give a new name to everything e.g. say A is an 'isomorph' of B if A is isomorphic to B; say that a morphism is 'multiradial' if it is not injective… etc etc. this sort of thing seemed to cause a lot of raised eyebrows in the theatre of IHP—this appears to be the m.o. in Mochizuki's writings too.

6. **Chris Austin**
   July 12, 2016

   On page 3 of the new overview, ("Alien Copies"), Mochizuki says, (slightly paraphrased):

"Let N be a fixed natural number > 1. Then the issue of bounding a given nonnegative real number h \ge 0 may be understood as the issue of showing that N h is roughly equal to h."

This is an absurd statement, because h factors out of the approximate equality. It is not a typo, because he then repeats it in a formula.

7. **Peter Woit**
July 12, 2016

Chris Austin,
In the text you mention Mochizuki is explicitly pointing to sections 2.3 and 2.4 for an explanation of what this is supposed to mean (i.e. what does "roughly equal", or "=" mean), so you need to go there to interpret what he is writing. The problem is not that he is making trivial, easily identifiable mistakes.

This does however give some idea of the problem with this survey and with similar things he writes. All sorts of things are in quotes (or analogies, not equalities) and even when they're not (e.g. roughly equal), it's often hard to track down a precise definition, or figure out what precise claims are being made. This then makes it impossible not only to check for flaws in the argument, but even to understand exactly what the argument is.

The 2012 IUT papers are supposed to contain the precise statements, but these are 600 pages long and have resisted the efforts of experts to understand them. Mochizuki claims that four mathematicians have, with his help, gone through these and checked them. Normally what should have happened is that, armed with a detailed understanding, these mathematicians should have been able to transmit this to others, and to write up an independent version, one that would help others understand the papers. Besides the possible example of the Hoshi document in Japanese, this has not happened.

8. **Michael**
July 12, 2016

Chris Austin,

A clearer version of that statement appears at the bottom of page 11: The point is that 'roughly equal' is in the sense of the 'absolute error' not the 'relative error'. For instance, if h and 101h differ by at most 1, then h can't exceed 0.01. (By contrast, the relative error between Nh and h is fixed by N and, as you assert, would tell us nothing about h itself.)

9. **Chris Austin**
July 12, 2016

Peter and Michael, thank you for the clarifications.

10. **anon**
July 12, 2016

Regarding Hoshi's document, Brian Conrad wrote in January in a comment on the same page that has his summary of the December workshop that Hoshi is hoping to make an English translation of his notes available around the time of summer workshop.

11. **Peter Woit**
July 12, 2016

anon,
I've heard that such a translation is under way, but one of the mysteries of the subject is why this is taking so long. With the workshop less than a week away, it's already pretty much too late to be useful to people preparing for the workshop.

12. **Peter Zbornik**
July 12, 2016

Peter, you write that "Mochizuki has worked to transmit understanding of his ideas to a small number of others, but the transmission has stopped there, with understanding of the abc proof not moving from them to others."

I would like to comment on that. There actually seems to be substantial "transmission" of IUT "to others" from Taylor Dupuy. Dupuy is the guy that Felipe Voloch "felt" "was the one that made the most progress learning the stuff" on the Oxford workshop (https://plus.google.com/106680226131440966362/posts/UHoetkZ7XXK).

You will find Dupuy's has published several series of IUT-related videos on his vlog:
https://www.youtube.com/channel/UCHWnZ1NtJ4WvE5AHmNVXziw/playlists

The playlist "IUT strategy" seems to be a good starting point:
https://www.youtube.com/playlist?list=PLJmfLfPx1OednuaMHywSDgaDzRa0MiaOf

Then seems to be other relevant playlists too, like:
The geometry of Frobenioids, Anabelian Geometry, Etale Theta, Hodge Theatres, etc.

It seems that Taylor Dupuy is making an effort to "transmit" Mochizuki's work to a wider audience.

Dupuy will be a speaker at the RIMS conference. It seems that the conference is going to be recorded on video, although maybe not streamed.
https://twitter.com/DupuyTaylor/status/744999080229765120
https://twitter.com/DupuyTaylor/status/744999335092436992

Otherwise, part of the confusion around this proof seems to come from the fact, that Mochizuki has worked on IUT for a long time and few professionals had done their homework before the Oxford workshop. Imagine you attend a class in some branch of maths you haven't studied before and that you have ignored studying the required prequisite literature. I think that's what happened at Oxford and that is really not very surprising.

I for sure experienced this quite some times during my math studies, when I had skipped my homework before class. The worst thing I could do in this situation would be to ask impertinent and not-so-very-clever questions.

The second issue worh mentioning is the fact that Mochizuki is Japanese and seems to be value that highly (someone wrote he is from a samuraj family).

Thus, when Mochizuki asks people to do their homework, to be polite and not to interrupt if it is not absolutely necessary, then this might be an other way to ask that the visitors to respect the "the Japanese language-based mathematical culture that exists" "at RIMS".
http://www.kurims.kyoto-u.ac.jp/~motizuki/students-english.html

To quote Mochizuki in full:
Especially with regard to (1), the prospective applicant should be aware that Japanese
is the official language in which mathematical and administrative affairs are conducted here at RIMS. Some individuals may tend to regard this state of affairs as a sort of "unpleasant obstacle". On the other hand, at the present time, there is no shortage of institutions throughout the world at which one may obtain a quality graduate education in mathematics in English. By contrast, the Japanese language-based mathematical culture that exists here at RIMS [and indeed at other Japanese universities] is, in my opinion, a precious cultural asset, both for Japan and for the world.

There has been more written about this:
"Despite mathematics being a universal language, culture clash could be getting in the way, says Kim. "In Japan people are pretty used to long, technical discussions by the lecturer that require a lot of concentration," he says. "In America or England we expect much more interaction, pointed questions coming from the audience, at least some level of heated debate."
https://www.newscientist.com/article/dn28682-mathematicians-left-baffled-after-three-year-struggle-over-proof/

I am certainly not an expert in Japanese culture, but I know so much, that they tend to put more emphasis on politeness and respect, than in the West.

Well in any case it seems that Dupuy has done his homework and is actually "transmitting" IUT to the West.

If Dupuy's videos on IUT would get wider publicity, that might actually constructively contribute to transmitting IUT to a wider audience and thus to further mathematical knowledge and development :).

13. **Dan**
July 12, 2016

As a physics person, it's hard to imagine that people are so invested in even trying to read Mochizuki's paper. Given this kind of difficulty, it seems like a similar document in physics would have been abandoned and forgotten after a day or two, let alone years (Verlinde's entropic gravity paper comes to mind). Maybe it just shows how different the goals are: here one can still hope to extract precise technical statements/proofs, whereas in a physics paper that would often be, at most, a secondary goal. Still, it seems strange… I guess Mochizuki must have some serious cred/social capital in his field?

14. **Peter Woit**
July 12, 2016

Dan,

I don't think there really could be a physics analog of this, since what's at issue is whether a very complex set of new ideas is powerful enough to provide a proof, a kind of question physicists don't deal with. Mochizuki is a well-known, accomplished and talented mathematician, and the fascination of this is that he clearly has new ideas, but the complexity of what he is doing and the way he has chosen to explain them has left experts unsure of how much can be gotten out of them.

The "entropic gravity" business is quite different. There was nothing at all complicated about that. It was a simple, but vague idea (not much different than ones other people had discussed in the past). Experts could immediately read Verlinde's paper and see what he had. Different people would have different judgments about whether pursuing that kind of vague idea would ever lead anywhere, but that's a different question.

15. **Dan**
July 12, 2016

I guess that's part of my confusion- how vague/non-vague is Mochizuki's work? Trying to parse the intro of his new paper is impossible for me; it sounds very vague, but obviously it's above my pay grade. Maybe I can ask a sharper question: do people seem to agree that his paper is technically sound, but they just aren't sure how it connects to standard literature? Or is there any possibility that he is "wrong"/any of this is jibberish?

16. **Peter Woit**
July 12, 2016

Peter Zbornik,

I'm sorry, but I really don't buy at all the "Japanese culture" explanation for the problem. Mochizuki grew up here in New York City (from age 5), went to school at Exeter, then got his undergraduate and graduate degrees at Princeton. His upbringing is more American than mine (I spent 5 years as a kid in France).

I also don't buy the "didn't do their homework" explanation for what happened in Oxford. Brian Conrad's article I think does an excellent job of explaining the problems with the talks, and looking at the slides confirms what he has to say. He and others who were there are the best in the business, and claiming that the problem was that they were asking stupid uninformed questions is just ridiculous.

From what I can tell, Taylor Dupuy's efforts are very enthusiastic (I've looked at some of them), but at a similar level of vagueness to Mochizuki's surveys (or even much more so), and suffer from the same problems of being disconnected from the rest of solid mathematics, and being too imprecise to be checkable. Maybe I'm wrong, but as far as I know, he's not claiming to fully understand the details and have checked them.

17. **Peter Woit**
July 12, 2016

Dan,
The problem is twofold: the shorter "survey" papers are very vague, the 600 page 4-part IUT paper series more precise but bafflingly complex and invoking a completely new universe of mathematical objects. A lot of that complexity is likely irrelevant to the heart of the supposed proof. What's needed is something in between: a detailed outline of the proof, with precise, checkable statements. The mystery here is why, four years out, such a thing seems to still not exist.

This kind of highly complex proof is inherently difficult to check: the mathematical objects involved can have subtle, often unintuitive behavior. To check such a proof, you need an expert, one who has some pretty deep insight into the behavior of the mathematical objects being manipulated. My impression is that we're still unfortunately far from anyone (other than Mochizuki), being able to carry this out with confidence in the result.

18. **Zoviyer**
July 12, 2016

I think is clear that the way of transmitting IUT has not been efficient. But on the other hand it may be that this theory is enough original and has been developed for such a long time that it would be as if Grothendieck presented to the world the EGA or SGA volumes in one stroke and thinking that in three years we could understand his proof of the first parts of the Weil conjectures.

19. **Peter Woit**

July 12, 2016

Zoviyer,

Sure, that's in principle possible. My guess though is that in such a hypothetical case it would take people a significant amount of time to understand the whole thing, but you would see progress taking place as this happened, and you wouldn't see the odd phenomenon of people close to Grothendieck supposedly mastering the ideas, but unable to write up their own version and explain it to others. This is a really peculiar situation that I know of no historical analog for.

20. **Jeffrey M**
July 12, 2016

Zoviyer,

Thing is, while it took a bit for people to catch on to what Grothendieck was doing, they did, and in a few years. With the IUT the best people just have no clue. When Perelman proved Thurston's geometrization conjecture, I was at a conference with many of the best geometric analysts in the world. Perelman had posted some work, and everyone was reading it, and within weeks they had a very good idea of what he had done. When Wiles proved Fermat, the same thing. The hole in his original argument was picked up quickly, took him a year to fix. What's going on here is you have someone claiming to have essentially invented an entirely new branch of math, with little connection to other branches. It's like Newton and Leibniz with calculus, more or less. People were using calculus almost immediately to do all sorts of amazing things, though of course it took more than a hundred years to put it on a good foundation. But people understood it, and used it, lots and lots of people. No one really seems to understand IUT, at least well enough to explain it in any fashion to very very smart people. No one has used it for anything. It could be correct, but I somehow doubt it. 600 pages of heavy duty math has probably tens of thousands of little things that could be wrong, and any one of them would likely blow the whole thing up.

21. **Zoviyer**
July 12, 2016

Peter,

I agree with your points. From the outside looks as if both Hoshi and Yamashita had no internalized the crucial ideas and how they relate as steps of the proof, and that's why it has not been communicated efficiently in the workshop or afterwards. The document that has not been translated to English is "just" an Introduction to IUT

22. **kbot**
July 13, 2016

With regards to the statistics issue – another point is the so called "look elsewhere" effect. The LHC experiments do hundreds of searches looking at a large number of final states. It is not just the probability of this particular search one has to consider but also what the entire experiment sees as a whole to properly compute the probability of having these results. This is why it often appears that results that taken on their own in isolation would indeed be perplexing if there were 3 sigma deviations coming and going all the time. However, what is neglected in this discussion is that people forget that there are hundreds of searches that land spot on the SM. Just like one expects that if one has a bunch of experimental points that you expect to fall on a line you don't expect all of them to be within one error bar of the line. You expect a certain fraction of them to be 1 sigma, 2 sigma, 3 sigma, etc to be off just from the statistical nature of the measurement process. Unfortunately statistics and p-values are often misunderstood or misrepresented so people can easily get the wrong impression of what the real probability of seeing deviations is…

23. **Peter Zbornik**
July 14, 2016

Peter, I agree with you, there is no proof published in a peer-reviewed journal.

But then we have a unique situation, where there is a claim, that Mochizuki has changed the foundations of mathematics.

Quoting the Nature article:
"Fesenko has studied Mochizuki's work in detail over the past year, visited him at RIMS again in the autumn of 2014 and says that he has now verified the proof. (The other three mathematicians who say they have corroborated it have also spent considerable time working alongside Mochizuki in Japan.) The overarching theme of inter-universal geometry, as Fesenko describes it, is that one must look at whole numbers in a different light — leaving addition aside and seeing the multiplication structure as something malleable and deformable. Standard multiplication would then be just one particular case of a family of structures, just as a circle is a special case of an ellipse. Fesenko says that Mochizuki compares himself to the mathematical giant Grothendieck — and it is no immodest claim. "We had mathematics before Mochizuki's work — and now we have mathematics after Mochizuki's work," Fesenko says.
http://www.nature.com/news/the-biggest-mystery-in-mathematics-shinichi-mochizuki-and-the-impenetrable-proof-1.18509

Talking about the lack of examples: refering to Fesenko above, it would be interesting to get an example, where in "non-standard multiplication" 2*3=5

I would not agree with progress not being made at Oxford, quoting Conrad in his posed referred in your post:
"Despite the difficulties and general audience frustration that emerged towards the end of the week, overall the workshop was valuable for several reasons. It improved awareness of some of the key ingredients and notions. Moreover, in addition to providing an illuminating discussion of ideas around the vast pre-IUT background, it also gave a clearer sense of a more efficient route into IUT (i.e., how to navigate around a lot of unnecessary material in prior papers). The workshop also clarified the effectivity issues and highlighted a crucial cohomological construction and some relevant notions concerning Frobenioids.

Another memorable feature of the meeting was seeing the expertise of Y. Hoshi on full display. He could always immediately correct any errors by speakers and made sincere attempts to give answers to many audience questions (which were often passed over to him when a speaker did not know the answer or did not explain it to the satisfaction of the audience)."

The main problem for the participants in Oxford was, that they did not understand the big picture and thus it was not easy to dig into the details. Conrad wrote in the post you refered above, that: "Many are willing to work hard to understand what must be very deep and powerful ideas, but they need a clearer sense of the landscape before beginning their journey." Dupuy and Mochizuki have now laid out the land whith their vlog resp. last paper. I believe this deserves some recognition.
There are several more papers with surveys ot IUT in the conference programme: https://www.maths.nottingham.ac.uk/personal/ibf/files/iut-kyoto-pr.html
At the conference there seem to also be some "transmission made".

The end of your post was not very polite nor correct:
"There's a preparatory document here which to me seems to ignore the fundamental problem of figuring out what has gone wrong so far. In particular, its last point appears to be explicitly aimed at discouraging anyone in the audience from confronting speakers that are not successfully communicating ideas and insisting that they try to do better."

The problem at the Oxie conference was that the interruptions made things worse, "party crashing-style", quoting Conrad:
"The fact that the audience was interrupting with so many basic questions caused the lectures to fall behind schedule, which caused some talks to go even faster to try to catch up with the intended schedule, leading to a feedback loop of even more audience confusion, but it was the initial "too much information" problem that caused the

many basic questions to arise in the first place. Lectures should be aimed at the audience that is present."

As for the doing the homework before the conference at Oxie. It really seems that all these esteemed experts did not study the IUT and other papers before the conference. Specifically: Voloch wrote in the last comment of his blog post, that:
"I prepared some but did not put 100s of hours as some had suggested but neither did most people I talked to."
Conrad: "It was reasonable that participants with advanced expertise in arithmetic geometry should get something out of the meeting even without reading any IUT-related material in advance, as none of us were expecting to emerge as experts (just seeking basic enlightenment)."
Contrast this with Fesenko and Mochizuki in the nature article:
"Mochizuki has estimated that it would take a maths graduate student about 10 years to be able to understand his work, and Fesenko believes that it would take even an expert in arithmetic geometry some 500 hours. So far, only four mathematicians say that they have been able to read the entire proof."
Contrast this with Conrads post, quote:
"At multiple times during the workshop we were shown lists of how many hours were invested by those who have already learned the theory"
Well, sad to say, "basic enlightenment" is seldom effortless. I think we can agree on that :o)

Yes, these guys were experts in their field, but they were faced with an other new field of maths and in this case, like it or not, you have to do your homework, because they cannot by definition be experts in this new field.

Now we have some Japanese and a Russian having spent considerable time with Mochizuki. Maybe some of the English-speaking "expert" community would also venture to do the same? That would certainly prove fruitful.

But then there definitely is a culture barrier here, undeniably, since Hoshi's IUT introduction has not been translated to English and evidently the Japanese do not consider it to be a priority to translate it to the English-speaking mathematicians :o)

Please allow me a personal reflection. I believe we have been stuck with an outdated number system based addition and multiplication. At the same time there really has been almost no work on alternative construcions of the natural numbers or on generalizing multiplication (the only serious one I know of are the surreals) since Hilbert's program. So from that point of view, for me, it is difficult not to see the work of Mochizuki as a possible "light in the tunnel". There is no work on "un-ordered" "numbers" (whose cardinality exceed that of the largest possible ordered field). On the other hand we have all those wierd stuff with connections to quantum mechanicsa around the Riemann hypothesiss, which all point to the need to widen the notion of basic concepts like "number", "addition", "multiplication" and "order".

Now let's see if the new workshop will bring "order out of chaos" :0). It seems to be invitation-only, where the applicant has to state his or her "knowledge of IUT" (https://www.maths.nottingham.ac.uk/personal/ibf/files/iut-rims16.html), so party-crashers may be stopped at the gates. It is organised at Mochizuki's home turf (he has stopped travelling outside of Kyoto, last years) by Mochizuki, Fesenko and Taguchi. So it seems that the scene is set for some "transmission" of knowledge, provided that the participants have done their homework, will be polite and will not crash the lectures.

Somewhere I read, that Mochizuki estimated it would take like until, I believe, 2020 before IUT was understood and accepted.

Maybe in 2020 we will have the abc proof and some less rigid foundations of mathematics to go with it too, if Mochizuki doesn't go Perelman playing ping pong with himself after all the hate thrown at him in the mean time.

Maybe it would be suitable to end this comment by quoting some "laws" from Fesenko's website:
"Everything takes longer than you think [including learning IUT – comment by PZ]."
"When all else fails, read the instructions [of required reading for the conference – comment by PZ]."
"Abrams's Advice: When eating an elephant, take one bite at a time [i.e. learning IUT takes time, there is no short-cuts – comment by PZ]."
https://www.maths.nottingham.ac.uk/personal/ibf/some.html

24. **Peter Woit**
July 14, 2016

Peter Zbornik,
I think you're selectively quoting Conrad, who was being exceedingly polite (despite being repeatedly insulted as a rude party-crasher who hadn't done his homework). I hope the organizers of the Kyoto workshop think carefully about his analysis of what went wrong at Oxford and why Mochizuki's work is not getting understood by experts. That they think the problem was experts asking questions and that they are trying to discourage questions is not confidence inspiring. When no one in the audience of a talk is understanding the speaker, it is much better for everyone if someone interrupts with questions than if the speaker is allowed to continue unimpeded.

25. **Narad**
July 14, 2016

> Brian Conrad's article I think does an excellent job of explaining the problems with the talks….

Speaking as layperson, but with at least pretty rigorous undergraduate training, I also found it invaluable in understanding things well beyond just "drama + mystery proof." Thanks for leading me to it.

26. **hmm**
July 19, 2016

IUT Kyoto Summit seems is progressing constructive discussions.
Christelle Vinsent (@ xl772) 's tweets is very convenient.
and this site is very nice. https://storify.com/xl772

27. **Peter Zbornik**
July 23, 2016

Peter, for completeness, here is Fesenko's take on the proceedings of the Oxford workshop and on the reasons for the relatively slower pace of knowledge transfer of IUT to a wider international audience: https://www.maths.nottingham.ac.uk/personal/ibf/files/iut-i-rep.html

28. **Peter Woit**
July 23, 2016

Peter Zbornik,
I wrote about that at the time here:
http://www.math.columbia.edu/~woit/wordpress/?p=8195
Fesenko kept changing the part of it blaming Brian Conrad (which I think is absurd), I see the latest version is

” Some participants who had ignored recommendations to study the theory before the workshop did not always behave considerately towards the speakers, interrupted the flow of talks by asking shallow questions and felt free to exhibit negative emotions without any concern to the other participants. ”

There’s an ongoing problem with how these ideas are being communicated, and instead of addressing it, Fesenko here tries to shoot the messenger. This isn’t helpful.

29. **anon**
July 25, 2016

This whole saga just sounds unprofessional on the part of the principal actor. Blaming it on some inherent problem with an idea of Japanese culture derived from orientalist Hollywood minstrel shows seems insulting to Japanese culture.

30. **marshall Flax**
July 25, 2016

@anon Don’t think it is fair to call anyone “unprofessional”. Simpler explanation is that it is *very very very hard* to simplify the work of a decade or two into digestible pieces. Not only is it hard work, but it is work that might require the surrounding community to help. Perhaps the struggle we’re observing is actually the only way to clarify things. Perhaps this really is the best of all possible worlds.

This might actually be the most efficient way to actually share a breakthrough, even if it is painful for all those directly involved?

31. **Peter Woit**
July 25, 2016

Marshall Flax,
This is an unusually difficult situation, both for Mochizuki and for those trying to understand his ideas. We’ll see what emerges from the Kyoto workshop, but reports I’ve heard are not very encouraging, with the same obstructions to progress obvious at the Oxford workshop still there. I strongly disagree that this is the best of all possible worlds, in particular, better possible worlds exist in which
1. Hoshi’s survey exists in English
2. Fesenko took to heart criticisms of what happened in Oxford, encouraging people to demand better explanations of material no one is understanding, instead of attacking people for doing this.
3. Mochizuki paid attention to explanations from experts of what was needed for them to follow him, and wrote up a version of the proof addressing their concerns.

I agree with anon that blaming problems on Japanese culture makes no sense. From what I can see, part of the story here is something not that uncommon in mathematics: an author writes up his ideas in a way that is impossible for others to follow. What is supposed to happen then is that journals tell the author to rewrite. The author may not agree and be willing to do so, and then others need to step in, figure out what is going on, and write something readable themselves. What is highly unusual here is that we haven’t seen that happen, and the central question is why that is.

32. **Snowman**
July 26, 2016

I think it’s pretty obvious what’s going on with Mochizuki. He wants to sell his theory, but others want to buy the proof for Vojta/Szpiro/ABC only. I think he sees the proof more as a motivational example for his theory, thus he has little interest to publish a more compact version that cuts out all unnecessary generality. I suspect in reading his papers in reverse chronology, concentrating only on the parts relevant to the proof, one would find more success than in trying to digest his published works of the last 10 years or so.

33. **marshall Flax**
July 26, 2016

@Snowman … don’t think that’s precisely true either … at least some of the participants in the seminar are imagining that the theory might be extendable one day to address even deeper questions like BSD or Riemann.

34. **Peter Zborník**
July 27, 2016

Some assorted tidbits on this mesmerizing topic:
—
1) The publication of the proof might be on the way:
It seems, that Mochizuki’s ABC papers are being refereed, some say that probably by a Japanese journal:
“These papers are currently being refereed, and, although they have not yet been
officially accepted for publication, the refereeing process is proceeding in an orderly,
constructive, and positive manner.”
http://www.kurims.kyoto-u.ac.jp/~motizuki/Questions%20and%20Comments%20on%20IUT.pdf
—
2) Replacement for Japanese IUT introduction:
Maybe Hoshi’s Introduction to IUT, might in large be replaced by his lecture notes from the Oxie and RIMS workshops? Someone mentioned they were good.
—
3) Intellectual theft in the mathematical community:
Fear of stealing the proof “Perelman”-wise, and of confronting frustrated, impertinent mathematicions, might also play a role in the slower pace of knowledge transfer. After all, the Mathematical community is a jungle, according to Grothendieck, with whom Mochizuki compares himself (see the article in nature above) and who just couldn’t care less for his work to go through standard peer reviewing.

This is what Wikipedia has to say on Grothendieck: (https://en.wikipedia.org/wiki/Alexander_Grothendieck):

“While not publishing mathematical research in conventional ways during the 1980s, he [Grothendieck] produced several influential manuscripts with limited distribution, with both mathematical and biographical content.”
…
“In the 1,000-page autobiographical manuscript Récoltes et semailles (1986) Grothendieck describes his approach to mathematics and his experiences in the mathematical community, a community that initially accepted him in an open and welcoming manner but which he progressively perceived to be governed by competition and status. He complains about what he saw as the “burial” of his work and betrayal by his former students and colleagues after he had left the community.[13] Récoltes et semailles work is now available on the internet in the French original,[36] and an English translation is underway. Parts of Récoltes et semailles have been translated into Spanish[37] and into Russian and published in Moscow.[38]”
…
“He […] criticized what he saw as the declining ethics of the scientific community, characterized by outright scientific theft that, according to him, had become

commonplace and tolerated."
https://en.wikipedia.org/wiki/Alexander_Grothendieck

—

4) Speculation:
We might also speculate, that Mochizuki might considers other things more important, than making "PR" for his theory and fraternizing with the mathematical community, like for instance, using IUT to prove Riemann's hypothesis. What then is a decade of slower acceptance of IUT and ABC compared to proving Riemann's hypothesis?

—

5) Cultural speculation
For some reason, I believe that the Japanese might not mind all that much, that IUT becomes a Japan-dominated field of study, centered at RIMS lead by Hoshi and guru Mochizuki :o) What these guys mind is not PR and marketing, but doing some fine new maths. Someone good at PR and marketing in the mathematics community should help them.

—

6) My own take:
Personally I am more interested in the mathematics, that comes with the proof, than the proof itself, so therefore I see as the biggest problem the unvillingness of the experts to invest the 500 hours or more to study the problem.

35. **e. ehrenweist**
July 28, 2016

Peter writes: "reports I've heard are not very encouraging, with the same obstructions to progress obvious at the Oxford workshop still there".

Taylor Dupuy wrote on twitter: "Great conference, we got way way farther than Oxford".

36. **e. ehrenweist**
July 28, 2016

Following up on my last message re @DupuyTaylor 's comments, some more twitter feedback on the IUT Summit: Artur Jackson (@arturj) wrote "I am impressed with … the depth of the discussions. Better results than Oxford". Ivan Fesenko wrote "A successful and rewarding workshop (see @math_jin feed; n.b. of course Ivan is an organizer) . Christelle Vincent (@xl772) has a number of tweets on the conference as well, see generally the hashtag #iutsummit . The tone of the feedback I have read appears generally, contra Peter's comment, to be positive and encouraging than at Oxford.

37. **Peter Woit**
July 28, 2016

e.ehrenweist,

I hope we'll get some serious public reports from experts who were there, now that the workshop is over. The twitter traffic made clear that that's not a good way of transmitting tricky arguments in arithmetic algebraic geometry. That things went better than Oxford (maybe due to Mochizuki himself playing a major role) is not inconsistent with the same problems still being there. Fesenko thought Oxford went great, so one might take that into consideration in reading his take on Kyoto.

Will likely write more about this once there's more serious information available.

38. **Peter Zbornik**
July 28, 2016

First report in by Nature: http://www.nature.com/news/monumental-proof-to-torment-mathematicians-for-years-to-come-1.20342

39. **Peter Zbornik**
July 28, 2016

Christelle Vincent sums up the "mood at the conference" in a series of replies to a tweet here:

Ghostbusters

July 14, 2016
Categories: Film Reviews

Last night I went to a preview screening of the new Ghostbusters film. This isn't a review, all I'll say is that if you liked the first one, you'd probably like this one too.

In the first film, an early scene was set here at Columbia University, with Bill Murray an experimental psychology professor (you can watch it here). Academia doesn't come off too well… In the new film, again an early scene is set at Columbia, but now the protagonist is a theoretical physicist played by Kristen Wiig. She first appears in a lecture hall with a huge blackboard filled with equations relevant to GUTs and supergravity. For some explanation of how that came about from Lindley Winslow, who provided this and other advice, see here.

Theoretical physics comes off better in this version of the film than experimental psychology did in the first version. Academia is still made fun of though. The chair of the Columbia physics department is portrayed as telling Wiig's character that if she wants to get tenure she needs to do better than to have a letter from Princeton, since that department is well known to no longer be what it once was.

Update: For more about the physics background, see here. The Lindley Winslow piece doesn't mention that Janet Conrad took over from her when she had a baby, and it was Conrad's stuff that went into the Kristen Wiig character's office. I'd somehow missed that the bad guy had a string theory paper:

> Meanwhile, an antagonist named Rowan North got a string theory paper on Feynman ghost diagrams, which offered the opportunity for a little interdisciplinary ribbing. "Of course we made the woman a neutrino theorist and the bad guy a string theorist," Conrad says.

String theorists really do get no respect these days…

Update: More here, including

> Conrad made Wiig's character a neutrino physicist. She decided the bad guy would probably be into string theory. There's just something sinister about the theory's famous lack of verifiable predictions, Winslow says.
>
> String theorists can also be lovely people, though, Conrad says, and "I wanted to make as evil as possible." In the scientific paper she wrote for his desk, "he doesn't acknowledge anyone. He just says 'The author is supported by the Royal Society of Fellows,' and that's it."
>
> Also, she wrote for him "an evil letter where he's turning someone down for tenure."

Update: There's a profile here of Kate McKinnon, the most entertaining of the new Ghostbusters, emphasizing her interest in physics.

Comments

1. **Douglas Natelson**
   July 14, 2016

   I think you really wanted this clip for commentary about academia: https://www.youtube.com/watch?v=RjzC1Dgh17A

2. **Peter Woit**
   July 14, 2016

   Douglas Natelson,
   Thanks! I had forgotten about that part of the earlier film. Lovely sentiments and footage of the campus here (the new film has no such footage, just a quick exterior shot).

3. **Peter Woit**
   July 14, 2016

   For the new film, I don't think there was any actual filming here at Columbia, and in general most of the places supposedly in New York were actually locations in and around Boston.

4. **Mark Callaghan**
   July 15, 2016

   I liked the first one – but i was 15 at the time! , I used to find ' Carry on' films funny , but now they make me cringe. Thanks for the clip though – very funny.

5. **Low Math, Meekly Interacting**
   July 15, 2016

   I have no plans to ever see this movie.

   That said, I'm curious enough to ask: Are these amazing details something any moviegoer (expert or otherwise) is likely to be able to apprehend, or would it require one's nose be pressed against their 60″ flat-screen while their itchy trigger finger hovers over the Pause button?

6. **Peter Woit**
   July 15, 2016

   LMMI,
   A huge blackboard is the background for an early scene. No pause button, but I could recognize the standard graph of GUT coupling constant unfication, as well as some SUGRA equations.

   The scene in the office with Conrad's stuff lasts a little while, but I wasn't paying attention to the books or other things in the office.

   You need more of an experimentalist than me to recognize things in the lab scenes.

   As for the string theory paper mentioned, I didn't see that, quite possibly it ended up on the cutting room floor.

7. **Doug McDonald**
July 15, 2016

I'm a chemical physicist. I very strongly recommend the film Real Genius. It too has pertinent equations on the blackboard. The lab laser is a real one, and would actually burn holes in (very thin) ceramic plates. I'm told that a larger version of the same ideas has burned a hole through the Pacific Coast range (comment from a very very drunk ex-student in a position to know, and apparently too drunk to worry about classified information) and is admittedly now militarily operational.
And even better, the main professor protagonist is the very perfect image of a very real Professor of Electrical Engineering here at the time, who worked in the "Gaseous Electronics Lab" building (I'm not making up the building name.) This guy ran the exact same kind of jokes for real.

8. **Low Math, Meekly Interacting**
July 15, 2016

Thanks for the summary! Amazing the amount of work that must have gone into those minute details, and too bad some of them didn't make the final cut. Also somewhat ironic, given the premise.

9. **srp**
July 16, 2016

A second to the motion for Real Genius.

10. **String postdoc**
July 17, 2016

last night I saw ghostbusters with some string theory postdocs here at Princeton. Two of them are women and found the film hilarious. One remarked that Lubos has no place now that physics departments hire men based on looks. 😀😀

11. **Chris W.**
July 18, 2016

From what I've seen of Kate McKinnon's performances in other things, including SNL skits, she seems smart as hell and naturally inquisitive about a lot of things.

That said, it sounds like her interest in science and engineering was almost still-born. Maybe she should take a sabbatical from acting and comedy sometime and make a serious run at it, at least as a self-taught amateur. Her lack of a mathematical background will require a very serious commitment to work through, however.

12. **Andreas**
July 20, 2016

Hey Peter! There is the IUTT Mochizuki workshop going on since monday (https://www.maths.nottingham.ac.uk/personal/ibf/files/kyoto.iut.html). Did you hear some news from there yet? I can't find any sources – usually your blog is a pretty good one 🙂

13. **Peter Woit**
July 20, 2016

Andreas,
Yes, I know, see the previous posting. I have been hearing some news from there, will likely write something after its over. I do hope a well-informed take on the workshop will emerge from one or more of the participants, as happened with Brian Conrad's summary of the last one.

14. **Chris W.**
August 6, 2016

The New York Times has another profile of Kate McKinnon:

> **Did you consult with any real-life scientists?**
>
> I've been a big astrophysics nut since I was 12. I have always had a real soft spot for the bizarreness of quantum mechanics. But I gave up on being a scientist in high school — I'm just not that good at math. So that ticks me off, that I've limited myself and my life choices in that way. I will never be a theoretical physicist.

WIMPs on Death Row

July 21, 2016
Categories: Experimental HEP News

One of the main arguments given for the idea of supersymmetric extensions of the standard model has been what SUSY enthusiasts call the "WIMP Miracle" (WIMP=Weakly Interacting Massive Particle). This is the claim that such SUSY models include a stable very massive weakly interacting particle that could provide an explanation for dark matter.

According to the "WIMP Miracle", evidence for such a particle is supposed to show up as they get produced at the LHC, and at underground detectors designed to look for ones traveling through the earth. Like all other predicted SUSY particles, no evidence for such a thing has appeared at the LHC. A sequence of more and more sensitive underground experiments has also come up empty.

One of the latest of these, LUX, announced results today, see here, press release here. These are the results from the final 20 month run of the LUX detector and they are conclusively negative: no candidate events were seen, putting four times smaller bounds on the cross-section for any such particle. New Scientist has it right I think, with a story headlined Dark matter no-show puts favoured particles on death row. Ethan Siegel has a very good article, Dark Matter May Be Completely Invisible, Concludes World's Most Sensitive Search, which includes:

> The null detection is incredible, with a fantastic slew of implications:
>
> 1. Dark matter is most likely not made up, 100%, of the most commonly thought-of WIMP candidates.
> 2. It is highly unlikely that whatever dark matter is, in light of the LUX results, will be produced at the LHC.
> 3. And it is quite likely that dark matter lies outside of the standard mass range, either much lower (as with axions or sterile neutrinos) or much higher (as with WIMPzillas).

Enthusiasts are not likely to give up so easily though, with Sean Carroll tweeting that the news is only "we're not seeing it yet, stay tuned." Not sure what one is supposed to stay tuned to, this is pretty much a final result from LUX. There will be a next generation experiment, LZ, but that's for after 2020. There are other competing experiments now operating, including Xenon1T, now being commissioned, which will be somewhat more sensitive. There seems to be no serious reason though to expect WIMPs to appear at somewhat lower cross-sections if they haven't appeared yet.

With SUSY and the "WIMP miracle" now dead ideas, perhaps that will lead to focus on more promising ones. There is still a great deal that we don't understand about neutrinos. A few days ago I saw this intriguing news about the PTOLEMY project, which I hadn't heard about before.

Comments

1. **M**
July 21, 2016

   "WIMPs on Death Row" is hype, altought negative. What gets more in trouble is WIMP interacting with nucleons at tree-level and in s-wave. WIMP that interacts through electroweak loops is ok. WIMP with a p-wave non-relativistic suppression is ok.

2. **Peter Woit**
July 21, 2016

   M,
Thanks. But is there any motivation for such models, at a level visible with another order of magnitude sensitivity, or would such things always be likely invisible to this kind of experiment?

3. **Douglas Natelson**
July 21, 2016

   I will ask this because I'm too lazy to read extensively to figure out the answer: Is the LUX result directly incompatible w/ the DAMA claims?

4. **Peter Woit**
July 21, 2016

   Douglas Natelson,

   Even the earlier LUX results were incompatible with DAMA, see for instance
http://arxiv.org/abs/1406.5200

5. **Jeffrey M**
July 21, 2016

   OK, I'm confused. DAMA observed changes in dark matter flux based on the earth's orbit, right? But LUX says no such thing could have happened? Or only that it couldn't be WIMP's?

6. **Peter Woit**
July 21, 2016

   Jeffrey M,
If you believe DAMA's interpretation of the periodic effect in their data as due to a WIMP, that implies a WIMP cross-section (probability of interacting with a nucleon) so large that LUX should be seeing a sizable signal. In this sense, LUX rules out the idea that DAMA is seeing WIMPs.

7. **Marc**
July 21, 2016

   Peter–Often the DM experimental results show, in the plot of cross-section vs mass, a large gray area in the lower right which corresponds to the predictions of typical SUSY models. While this experiment takes out a big chunk of it, it only looks like about 1/2 of the gray area. So doesn't Death Row seem a tad bit premature?

8. **Peter Woit**
July 21, 2016

Marc,
The problem is that the meaning of "typical SUSY model" and the associated grey blobs are ill-defined and move as the experiments get more sensitive. For example, a few minutes research turned up some 2001 SUSY "predictions", see
http://arxiv.org/abs/hep-ph/0106148
where the conclusion is
"When CDMS is moved to the Soudan mine, its sensitivity will drop to between 10^-8 and 10^-7 pb and GENIUS claims to be able to reach 10^-9. At those levels, direct detection experiments will either discover supersymmetric dark matter or impose serious constraints on supersymmetric models.

The LUX result is below 10^{-9} pb over a very large range, down to 2.2 x10^-10 at 50 GeV. So, it is very much "imposing serious constraints" on SUSY, but of course there will always be SUSY models with smaller cross sections. I don't think there's a sensible way to put a measure on such things.

9. **Jeffrey M**
July 21, 2016

Thanks Peter. So DAMA was explicitly claiming WIMPS, which LUX rules out. Got it. Should we expect a surge of papers explaining DAMA in some different way?

10. **Peter Woit**
July 21, 2016

Jeffrey M,
The interpretation of the DAMA signal as being due to dark matter was already ruled out by earlier experiments, including early data from LUX. So, there's nothing new about that here. I haven't followed the latest in attempts to explain the DAMA signal, but, since it is just an annual modulation, one can imagine all sorts of non-fundamental sources due to a subtle seasonal variation in the environment of the experiment.

11. **M**
July 22, 2016

One example of an alive&healthy WIMP is (in SUSY langauge) an umixed Wino. Or, more generically, a weak triplet with zero hypercharge. It interacts only with heavy electroweak vectors, giving a loop-level direct detection cross section below present bounds and a little above the neutrino background.

12. **Tom Andersen**
July 22, 2016

Peter,

Theorists should not diminish experimental results they don't understand, based solely on the fact that they can't predict them.

Don't you think that the DAMA team has used various techniques to improve any seasonal environment variations? Despite all efforts at this the signal amplitude remains the same. Is it a WIMP dark matter signal? No. Is it real? Looks likely.

There are now a few direct reproductions of the DAMA experiment. Let the experimenters decide this one.

13. **Peter Woit**
July 22, 2016

Tom Andersen,

You're reading things into what I wrote that aren't there. Of course I'm aware that the DAMA people (and others) have done their best to identify environmental sources of the signal. They are seeing something, but my understanding is that the results from other experiments show that it's not the hoped for WIMP signal, and that currently no one knows what it is. Given this, an environmental source remains a possibility, as well as something much more interesting. I have no idea what relative probabilities to assign to those two alternatives, was not implying anything about that issue at all.

14. **Chris Austin**
July 22, 2016

M,

"One example of an alive&healthy WIMP is (in SUSY langauge) an umixed Wino. Or, more generically, a weak triplet with zero hypercharge."

Do you mean just the electrically neutral component of the triplet?

15. **Peter Woit**
July 22, 2016

Chris Austin,
If it's not electrically neutral, it's not a WIMP…

16. **Bernhard**
July 22, 2016

If not DM directly, there is still hope to find evidence on the existence of other stuff from the dark sector at the LHC (like dark photons).

17. **piscator**
July 22, 2016

Tom: talk off-line to experimenters involved in other WIMP DM searches and ask them their opinion of DAMA's claims. It is not just theorists who are sceptical about DAMA's results.

18. **paddy**
July 22, 2016

Peter,
My reading of Chris Austin's comment is that he was pointing out exactly what you said. Perhaps he could phrased it better: "Do[n't] you mean just the electrically neutral component of the triplet?"

19. **M**
July 23, 2016

Chris, yes. Its direct detection cross section is ≈ 0.3 10^-46 cm^2

20. **tom joad**
July 23, 2016

Interesting news, but in what sense are SUSY or WIMP DM dead ideas? There exists parameter space that wasn't excluded by any experiments. They are alive.

I suppose you mean that they're less plausible in light of LUX latest results? Can you elaborate on your reasoning? In the past you dismissed inductive (Bayesian) reasoning in science, but now you suggest that the plausibility of particular models has changed in light of data.

Have you changed your mind? If so, very good. If not, OK, but don't argue that the status of SUSY DM or WIMP was affected – it has the same status as before, unfalsified.

21. **Yatima**
July 23, 2016

it has the same status as before, unfalsified

The correct adjective here is (still) "unjustified".

That being said here is report on the possibility that Dark Matter is mainly formed by a large population of primordial black holes (thus, a galactic halo of black hole "gas"). I am not sure whether this fits the (AFAIK) sparse observations of lensing events.

22. **Peter Woit**
July 23, 2016

tom joad,
The last thing in the world I want to get into is a debate over Bayesian reasoning, but I'll point out that my criticisms and mocking of it had to do with its misuse (things like Polchinski's calculation of probability of a multiverse), not with its use to characterize the significance of experimental results.

Obviously SUSY is unfalsifiable due to its huge parameter space,, always has been, always will be, and John Ellis I think has stated that he'll never abandon it. Equally obviously the "WIMP miracle" is not working out, and in that sense the idea is on its way to the graveyard of failed ideas.

23. **tom joad**
July 23, 2016

Fair enough, that makes sense to me. These DM results are pretty cool, and I enjoy reading your blog. Enjoy the weekend.

24. **DP**
July 23, 2016

Hi Peter, you might be interested in the new announcement from the PandaX Dark Matter Experiment.

25. **Andreas**
July 24, 2016

Hey Peter! Thanks for this news, i haven't seen it yet. Concerning dark matter, what did you think about Adam Riess' recent investigation:
http://journals.aps.org/prl/abstract/10.1103/PhysRevLett.116.201301 ?

26. **Peter Woit**
July 24, 2016

Andreas,
Sorry, but you really need an astronomer to evaluate that idea, not me.

DP,
Thanks! I took a quick look at
http://pandax.physics.sjtu.edu.cn/files/pandax_ii_idm.pdf
and their new result seems to be quite similar to the LUX result (best limit 2.7 x 10^{-10}pb at 40 GeV, vs 2.2 at 50 GeV). Not sure why LUX is getting all the atttention. Perhaps combining the two results one might get even more stringent exclusion limits.

27. **MikeS**
July 25, 2016

Until we have some better explanation of Dark Matter, WIMPs of some form must remain a contender. We either have to establish a theory that Dark Matter does not exist, or we have to find where it is hiding. And in the case of the latter, there are precious few theories.

I suspect it is simply the hitching of WIMPs to the SUSY bandwagon, and the rather circular logic whereby one seems to promote the probability of the other that people object to.

28. **Doug McDonald**
July 25, 2016

There are no pointers to papers above, and a quick search didn't find what I want.
Question from an experimentalist: I read the Panda Powerpoint. It quotes a
maximum cross section versus energy.

BUT … such an experiment measures the PRODUCT of a cross section times a flux.

There is no measurement of a flux! They must be assuming something … is it something astronomical?

29. **Syksy Räsänen**
July 25, 2016

Doug McDonald:

The experiments measure events per time in each energy bin. A simple discussion of WIMP direct detection can be found on pages 116-117 of my lecture notes.

http://www.courses.physics.helsinki.fi/teor/cos1/cosmo2015_07.pdf

30. **Tim**
July 26, 2016

Doug,

The "WIMP Miracle" mentioned in the post is that if you assume a certain cross section and mass that are compatible with a particle that interacts via interactions at the "weak" scale, then the standard model + big bang nucleosynthesis produces it in the right amounts and with the right energies to explain both the amount and spatial distribution of observed dark matter. You can calculate the expected flux from that.

Once the expected flux * expected cross section is not observed, it's still possible that dark matter exists with other smaller values, but the connection to a particle (potentially supersymmetric) interacting at the weak scale is lost.

So there you go. The assumptions come from theoretical predictions of formerly popular models that seemed to explain our dark matter observations quite nicely. Unfortunately this + LHC bounds now suggest that the right answer now seems to be something other than a weak scale lightest supersymmetric particle.

31. **GoletaBeach**
July 26, 2016

Peter, wow. Just within the realm of SUSY models, plenty, plenty of models predict WIMPs with cross sections lower than LUX, XENON1T, or even LZ sensitivity.

Some questions only have empirical answers, and thank goodness that particle experimenters have traditionally only lightly paid attention to theorists' hype.

There was tremendous disrespect for Ray Davis and his neutrino experiment from theorists… I remember it well. There was disrespect for all the many, many searches for neutrino mass/mixing, because, there was no good theoretical prediction for delta-m-squareds. Or the mixing angles. Thank goodness experimentalists soldier on.

I even remember when the weak interaction was agreed by all theorists, Fermi too (who died in 1954) to be S+T. It turned out to be V-A with no theoretical prediction of that, although Lee and Yang eventually followed up on Ernest Lawrence's admonition, `Who the he** cares about parity violation, this is experiment!' in response to the tau-theta puzzle.

Declaring the `WIMP miracle' dead is so obviously premature that you have just joined the scammers and hype-meisters that you often criticize. I guess you are jealous of them, that their scamming gets publicity and your doesn't.

32. **Chris Kennedy**
July 26, 2016

So how could neutrino mass be a possible explanation for dark matter? Seems to me that since galaxies come in a variety of baryonic mass distributions from center to edge, the neutrino mass distribution would always (and conveniently) have to be such that it is arranged to produce near-flat rotation curves for all varieties of galaxy. In my opinion, the odds of that are off the chart.

33. **Peter Woit**
July 26, 2016

Goleta Beach,
No disrespect to these experiments intended. They're doing an impressive job of repeatedly pushing down limits by large factors. It's great that people are doing them, they're looking somewhere no one has ever looked, and if they find something it will revolutionize physics. Yes, such experiments should be done, no matter what theorists say about the likelihood of them seeing something.

That said, I still think it's important to admit that these huge improvements on the limits carry implications for certain theoretical ideas. I just googled for more info about the GENIUS proposal that Ellis et al. mention. The 1998 proposal, see
http://arxiv.org/abs/nucl-ex/9801004
states in the abstract:
"The entire MSSM parameter space for prediction of neutralinos as dark matter particles could be covered already in a first step of the full experiment ". If I'm reading figure 3 properly, the entire region of points plotted as such "predictions" is now ruled out by LUX. For twenty years I've been seeing plots of this kind and claims of various kinds that SUSY dark matter models imply a WIMP in this region. Now that such things are ruled out, acknowledgement of previous "predictions" that have been falsified would be a good idea, before moving on to new models and new "predictions".

The "miracle" in the SUSY "WIMP miracle" was always hype, but one reason it got attention was that it appeared to make a specific claim that something would be seen at the LHC and in experiments with sensitivity like that of LUX. Sure, of course WIMP dark matter isn't dead, maybe it's there at lower cross-sections. But it seems to me the "miracle" is dead, and it should be given a proper public burial.

Chris Kennedy,

My understanding is that right-handed (sterile) neutrino models can readily provide dark matter.

34. **GoletaBeach**
July 26, 2016

The `miracle' was that weak interaction order-of-magnitude cross sections + thermal equilibrium in the early universe easily accommodate the observed dark matter density… noticed by Ben Lee and Steven Weinberg in the 1970's. Has not a thing to do with SUSY, and lasting interest in the WIMP being a right-handed neutrino (or left-handed antineutrinos) is traceable to that `miracle'. Maybe couplings to the right-handed sector were appreciable in the weak interaction in the early universe.

Your opinion, if based on anything related to SUSY, won't influence any serious scientists' opinion about the WIMP miracle. Maybe you'll help grow some anti-WIMP feelings among popular science hobbyists, though.

As for the SUSY connection, there is and will always be hope that SUSY is related to the weak interaction, and so that is the connection that seems to mainly be in your crosshairs.

Referencing H.V. Klapdor-Kleingrothaus doesn't raise the level of the discussion. He discovered neutrinoless double beta decay, although nobody else agrees with his discovery.

Perhaps take a look at https://arxiv.org/abs/1604.07336 . Figures 2 and 5, and, the paper seems to indicate that scalar and gaugino masses were only scanned up to 2 TeV. It may be that scanning to 100 TeV or more yields a lot more low-cross section neutralino likelihood. Those plots are for the fewest free parameter CMSSM.

The 2 TeV limits? Motivated by only scanning where the LHC can see stuff. It is entirely possible that SUSY is there, unobservable a the LHC, but detectable by direct detection experiments. Or, detectable only by indirect detection (Veritas, CTA, Pingu, etc).

More parameters than the CMSSM? No problem, figure 3 of https://arxiv.org/abs/1503.00599, in the 9-parameter MSSM.

Of course we all want to see revisions after Run-2 LHC results are presented.

35. **Peter Woit**
July 26, 2016

GoletaBeach,
Maybe this is my lack of education, but all the public discussions of the term "WIMP miracle" that I remember seeing claim as a big part of the "miracle" the LSP in SUSY, I had assumed that when people referred to the "miracle", they had in mind the "miracle" of SUSY predicting a weak-scale stable particle. For an example of what I have in mind, see
http://www.symmetrymagazine.org/article/july-2015/miraculous-wimps

"When researchers use the properties of the lightest supersymmetric particle to calculate how many of them would still be around today, they end up with a number that matches closely the amount of dark matter experimentally observed—a link referred to as the "WIMP miracle.""

I'm curious if you know who first used this term, did Ben Lee or Steve Weinberg call it that way back when? I always assumed it was part of the SUSY/String theory hype (who else calls a very rough coincidence good only within several orders of magnitude a "miracle"?)

I don't doubt that there's plenty of room in SUSY parameter space and that you can find recent plots with susy models "predicting" some region to the lower right of the latest exclusion. What I'm objecting to is ignoring all the similar plots I've seen over the years, put forward by people promoting SUSY. If you Google "wimp miracle", the first two things that turn up are
https://en.wikipedia.org/wiki/Weakly_interacting_massive_particles
which has a 2004 plot of the area SUSY is supposed to show up at that is now disallowed, and then this from 2009
http://www.ps.uci.edu/~jlf/research/presentations/0912upenn.pdf
which (page 9) has a plot claiming a "universal prediction" of a 10^{-44} cm^2 cross-section (also now completely disallowed).

As for what this does to the public perception of science, I don't think 20 years of heavily hyped "predictions" based on a "miracle", followed by "oh, just forget those, we've got new ones" when they're conclusively falsified is a healthy situation.

Theorists and experimentalists who want to communicate with the public about the implications of these results (together with those from the LHC) for theory it seems to me should tell a straightforward and accurate story: experimental results have not shown what was expected, so these ideas are pretty much dead. This is what scientific progress looks like. Yes, there are always more models, and very good reasons to keep looking, but the general ideas behind SUSY extensions of the SM are no longer a particularly plausible motivation for anything. Abandoning these and moving on to other more promising ideas (let's hear more about right-handed neutrinos, less about neutralinos) would be a good idea.

36. **GoletaBeach**
July 26, 2016

I'm not an etymologist… appears that the earliest (1985) reference to WIMP, has no mention I see of SUSY…
http://ac.els-cdn.com/0550321385905371/1-s2.0-0550321385905371-main.pdf?_tid=4ae66064-538d-11e6-a255-00000aab0f26&acdnat=1469577879_0f1061aceb68f51962bd19520d599e70

And earliest WIMP Miracle (2007, possibly from Feng alone) is on the first 4 slides of:
http://theory.fnal.gov/jetp/talks/feng.pdf

Note that the SUSY stuff in that 2007 talk is *after *the WIMP miracle.

The logic is (thermal equilibrium) + (weak interaction) = WIMP miracle.

SUSY only chases that ambulance. If some people get it wrong, that is their mistake.

As experimental data accumulates, simple scientific principles require any well-defined phenomenology to adapt to respect the new experimental data. And so it goes with SUSY phenomenology… the very simplest SUSY phenomenology, the CMSSM, still has plenty of room for an LSP that is the WIMP, even after all known data (through LHC run 1) is accommodated. But even if someday experimenters doing good science eliminate all viable CMSSM parameter space, all they will do is prove the CMSSM LSP is not the WIMP. The WIMP miracle will remain untouched.

Of course the MSSM has less simple parameterizations than the CMSSM. As I pointed out, in those less simple parameterizations, there is even more room for an LSP that is the WIMP.

The above is just: SCIENCE!!! SUSY has loads of parameters. Ruling it out is a lot of work. Just as proving global warming was man-driven was a lot of work. Welcome to real science.

The LUX results are entirely consistent with what is expected under both SUSY and the separate and distinct WIMP miracle. There is no "conclusively falsified" anything here.

In the talk you link, and the plot you refer to, Baltz and Gondolo's predictions went off the bottom of the plot. Feng took a specific category of models and pointed at 10^(-44) cm^2. Obviously other models weren't covered by his pointing. And Feng ain't a consensus Snowmass or NAS report. If you don't like Feng's hype, take it up with him. Tainting a whole field with one (possible) hypester is not good. And Wikipedia? Seriously?

Real science is a complicated, messy thing. It clearly frustrates you that simple stories you have decided are true are not. What frustrates me is that good experimental science effort is likely to be impeded by your cartoonish simplifications.

37. **Peter Woit**
July 26, 2016

GoletaBeach,
Interesting that the terminology is that recent, I had no idea. I would have thought it went back to SUSY enthusiasts of long ago. Whoever it's due to though, I think it's a bad idea, misleading hype. Would be better to find another one.

While doing a bit of looking at old papers/slides to see where the "miracle" came from, just about every one of them has a plot of susy predictions that are now conclusively falsified (often the range of the LUX results isn't even plotted). This isn't just Feng.

Look, experimentalists should do what they can do: design and build the best experiments to look where no one has looked before. I don't see why they should get into questions about complicated BSM models that have no good motivation. Theorists should be the ones evaluating such models, and they are the ones I'm claiming need to look at the long, sorry tale of SUSY extensions of the SM, draw the conclusion it's no longer a promising idea, and not continue down the rabbit hole of promoting ever less motivated corners of SUSY parameter space.

I'm well aware this is a complicated story (actually I wrote a whole chapter in my book long ago about SUSY, precisely because it is a complicated subject). I should have realized that I didn't write about the "miracle", because it wasn't called such back when I was writing (2002-3). But, despite all the complexities, there are now a lot of very good reasons to call SUSY extensions of the SM a failed idea. I wrote about a bunch back in 2002-3, the LHC has given us a bunch more, and so have experiments like LUX. No, you can't ever completely rule out something like the SUSY framework, but you can get to the point where its original motivations haven't worked out and it has become highly implausible. We're there now.

38. **GoletaBeach**
July 27, 2016

The original (thermal equilibrium) + (weak interaction) = currently observed relic density is very compelling, and independent of SUSY. That is the `hype' that most serious speakers point to. Feng named it the WIMP miracle. Weinberg and Lee pointed it out in the 1970's, and in the 1980's that connection lead to the first WIMP searches… when the big idea was to test whether the WIMP had V couplings like heavy Dirac neutrinos… in the 1980's that was ruled out. No-one called it the WIMP miracle but everybody knew what was going on. SUSY didn't matter at that time, although the attraction of the LSP (then called the photino) being the WIMP started to be discussed.

Only recently has WIMP sensitivity of experiments achieved the expectation for A couplings like Majorana neutrinos. People in the thick of things know this, you don't, you keep projecting SUSY BS onto the field.

And guess what… long before you were around the usual experimental introduction to anything w/r to SUSY was… `There is no experimental evidence that supports SUSY. But SUSY has withstood the test of time.' It is sardonic.

That SUSY might be restored at a mass scale a bit higher than accelerator folks want is not important for a possible LSP/WIMP connection. The cancellations that SUSY provides to regulate infinities work just fine even if a 500 TeV collider would see absolutely no evidence of SUSY, so the original motivation for SUSY is intact.

39. **Peter Woit**
July 27, 2016

GoletaBeach,
Thanks, I'd love to hear more about the possible role of Majorana neutrinos here. I think those working in this area would do well to discuss such topics when describing publicly motivation for these experiments, rather than trying to emphasize SUSY motivations that have not worked out.

40. **GoletaBeach**
July 27, 2016

Most experienced experimentalists are fairly ecumenical about SUSY. It is another good reason to look for stuff, but not the only reason. Phenomenological SUSY provides serious numerical modeling and serious model building. Lots of phenomenologists work hard on scanning its super-big range of parameters. That is all good science…

Sure, people oversell SUSY. One of those people is you, who want to portray the testing of SUSY as a straight up and down test, like the Michaelson Morley experiment. It is not.

It is perfectly possible that a peculiar corner of SUSY parameter space out of reach of LHC or the Great Collider or Veritas or CTA or LZ is what Nature chose. If eventually some experiment 500 years from now figures that out, I'm sure theorists 500 years from now will say that Nature's solution is beautiful and natural.

But that is not a serious argument to cease experimentation and returning to theological debates over naturalness or the anthropic principle or the nature of transubstantiation.
Doing the best experiments we can afford remains a better use of our time. Sometimes we do the wrong experiments and sometimes indelicate hype gets used to justify the correct experiment. I wish we were all perfect but we are not.

41. **GoletaBeach**
July 27, 2016

A/Majorana… something published is Fig. 1 in:
https://arxiv.org/pdf/astro-ph/0509269v2.pdf shows where the Majorana line was.

Latest LUX among others blew through that line over much of the mass range
https://arxiv.org/pdf/1602.03489v3.pdf

42. **Peter Woit**
July 27, 2016

GoletaBeach,

You're missing the context of what I write about SUSY here. I'm very aware of the complexities, have been following the story since the very early 80s (when I was a graduate student at Princeton, Witten was telling students they should learn about supersymmetry, Julius Wess was a visitor, giving a series of lectures that ended up as the book with John Bagger). When I was a postdoc at Stony Brook during the mid 80s, SUSY/supergravity was something hard to ignore.

From the beginning though, I found that SUSY didn't provide any convincing explanations about the SM. Over the years it has become a hugely oversold subject, partly by making claims (e.g. "SUSY solves the hierarchy problem, so superpartners will be seen at LEP, Tevatron, LHC, etc..") that have always failed. My impression of the way most theorists felt about SUSY a few years ago was increasing skepticism, with the LHC results to come the final and last hope. Now that those have come in, I think people need to draw the appropriate conclusions, not go on for the rest of all our lives saying "still a great idea, just have to go to higher masses"

So, sure, you're going to see me keep arguing that new LHC results are nails in the coffin (I think we'll see more in a week or two at ICHEP) of a bad idea that never worked. The long sad story of how we got to this point though is too complicated to keep retelling.

43. **GoletaBeach**
July 27, 2016

Well, the very high energy cancellations above the SUSY restoration scale are the bedrock prediction of the SUSY endeavor, and Nature doesn't check in with any of us as to where to place that restoration scale. Nature also doesn't care about the LHC or experimental budgets.

Burt Richter has always been right: theoretical physics is by and large a sociological activity, only a little different than theology or philosophy. You are making sociological observations. Only when incontrovertible data from experimentalists or observers test the theoretical guesses do theorists take notice, and often theorists find one of N wild papers they published and assert that they predicted it all. We're going through an episode with Gordon Kane etc and everyone who went out on a limb about SUSY at the LHC. Oh well, the human drama.

As to your experience in the 1980s, well, you move in theoretical circles. You got sucked into the groupthink. Experimentalists were never anything but skeptics about SUSY… poor Mohammad Mohammadi and his SUSY discovery in the 1980's at UA1.

Experiment also has sociological aspects, of course, and the drive to higher energy colliders has by and large been based on planning with a rear view mirror. Higher energies have worked before, so why not try again? There are of course other ideas… WIMP searches and indirect WIMP searches among them.

SUSY will always remain a reasonable motivation for all of them, forever.

As a field (including astrophysics) we've been interrogating dark matter since Opik in 1915 or so. Again, Nature doesn't give a darn about human life scales. Secrets will be revealed when they are. Sociological sniping based on impatience is irrelevant.

As to nails in the coffin: it is a very large coffin and your nails don't begin to cover its perimeters. You're free to get bored with it, of course, but others may be more durable than you.

And on several occasions the search for neutrino mass/mixing was declared worthless and `over' too. Thank goodness solid scientists carried on.

44. **Chris Kennedy**
July 28, 2016

I had this friend who called me a few months ago and said: "I ran some calculations and I'm pretty sure I have a ghost in my house." Of course I thought he was kidding but he continued: "In exactly two weeks, I'm going to start hearing noises, and several items are going to get knocked onto the floor when no one is in the room." So I went over to his house, we did a stakeout and we never heard a sound. He then said: "Well next week for sure" and this went on for three more occasions after that.

Even though he was the one who gave me the dates and times of all of the predicted supernatural "events" he then started saying things like: "Look, it's a ghost, it's going to come out when it feels like it – it's certainly not obligated to our timetable." I then asked him: "Did you ever consider the possibility that your house is not haunted after all?"

45. **Low Math, Meekly Interacting**
July 28, 2016

Forgive the naïve outsider, but the story of the search for neutrino masses doesn't seem to me to be remotely like the story of SUSY. When you have a particle that demonstrably exists, a third of those particles emitted by the Sun are completely missing, there's no particularly deep reason for it to be massless, and mass solves the missing neutrino problem, you've got some serious "motivation". SUSY solves naturalness problems that might not even be problems, at the cost of an extravagant number of new particles that we've never seen, and which can remain forever hidden by breaking the symmetry at whatever scale remains conveniently unprobed. Where is the analogy?

46. **Tim**
July 28, 2016

I don't know that a doubling is extravagant. In fact I'd personally say it's more likely than a handful of new particles. Nature just sort of likes to do that.

Remember that antimatter doubled the number of known particles; generations tripled them for no obvious reason. Any broken symmetry is inevitably going to result in "… and this is the other half of the universe you didn't previously know about."

47. **paddy**
July 28, 2016

I can't be the only who remembers Glashow's answer to the likes of Tim's argument. To paraphrase: SUSY must be right…after all we have already found half the particles it predicts.

48. **Peter Woit**
July 28, 2016

Tim,
What's really suspicious here is that the theory says "all particles" will come in pairs of a specific kind, but if you look at the complicated structure of the many known particles, there are no pairs this kind. Not one. Another way of saying this is that the theory claims a new symmetry of nature. Symmetries tell us something by relating different states. SUSY provides no relations between any known states, it acts trivially on the space of known states (supposedly taking them to a different space).

And, unlike antimatter, introducing SUSY breaking to make the partners invisible means you're not just postulating a doubling of the state space, with a Z2 symmetry, you're also adding in a huge extra number of random parameters to deal with the SUSY breaking.

49. **GoletaBeach**
August 1, 2016

to Chris Kennedy… the only technique that guarantees certainty is to not look for new physics. They you are absolutely sure of the result… that nothing new will ever be discovered. If you want something new, there will always be risk of coming up emptyhanded.

to Low Math… the parameter space that describes possible neutrino masses and mixing angles is vast. No theorist had any prediction of which parameters Nature would pick. The solar neutrino experiment didn't start as a neutrino oscillation experiment, it started because a clever experimentalist devised a technique with sufficient sensitivity to observe solar neutrinos. Most of the theoretical community didn't support the experiment, and when there was a deficit, most of the theoretical community thought that poor solar models, not neutrino oscillation, was the explanation. A similar sequence played out with atmospheric neutrino oscillations. The heart of the matter is… experimentalists are generally at least as good and usually better at finding new physics than theorists. A good reason to keep doing WIMP and other dark matter experiments.

To Tim: yes, the tripling into three generations is an entirely unpredicted phenomenon, little considered. It often feels like there is a pattern of excitations underlying that one, but no substructure theories have ever been devised that help describe it. The usual contemporary attitude is that quantum field theory masks any underlying pattern so completely that it is pointless to look for a pattern. A good argument to complete the one pattern that is incomplete… the neutrino mass template. Maybe an interesting pattern will show up.

50. **Low Math, Meekly Interacting**
August 1, 2016

Hi, Goleta Beach,

Thanks for your reply. I'm far from expert in the matter, nor am I as knowledgeable as you about the history, by my understanding is that the first experiments back in the 1960s were designed to observed solar neutrinos because that's an interesting thing to do. Beyond the related nuclear physics, theory didn't really need to come into it. but they found the discrepancy (should have said 2/3, not 1/3 of the electron neutrinos missing), and that got the ball rolling in the right direction in short order. Of course people first suspected an astrophysical explanation. My understanding is that those speculations were dispatched without much difficulty, perhaps ironically by the temperature of solar neutrinos, which, among other results, showed that you couldn't explain away the deficit through poor solar modeling. Reactor experiments, etc. gave a pretty tight upper bound on neutrino masses, the lower bound was assumed, so by the time people were looking seriously at neutrino mass, there were already very tight constraints.

Again, an experimentally verified particle, an experimentally verified and sizable deviation from theory, experimental elimination of the alternatives, and fairly inevitable experimental validation of the best explanation for the discrepancy. Which, perhaps to no surprise, has fostered advances in the field of neutrino physics that may provide the best hope for BSM theorists.

SUSY, rather, looks to me like the theoretical tail wagging the dog to death, and then continuing to wag the mutilated corpse in hopes flailing will resuscitate it. There's no experimentally-validated anything to show unequivocally that it's necessary, just a lack of understanding of the hierarchy problem. Which, as many smarter people than me continue to point out, we can't say for certain is even a problem. And there's no upper bound on the scale. There likely would have come a time when we could have said that the neutrino mass is so small that, if it exists, it couldn't explain the solar neutrino problem. No such luck with SUSY. It's already failed the "naturalness" test, LSP WIMPs are looking ever more implausible, etc., etc. It can live comfortably forever in the anthropic multiverse, which great for SUSY, I suppose, but hopeless scientifically. I just don't see any comparison to neutrino masses at all.

51. **GoletaBeach**
August 5, 2016

To Low Math, well, not quite.

SUSY has a vast parameter space of possibilities that all are, (IMO) "Natural". Naturalness is a completely subjective judgement, and I have no doubt that should SUSY show up experimentally *anywhere*, theorists will eventually proclaim the situation "Natural". What else can they do? Call *Nature* un-*Natural*??

The space of possible neutrino parameters was and is also vast. That *any* experiment happened on the true neutrino parameters is a minor miracle.

That is the analogy: 2 vast parameter space with really no guidance as to where nature is hiding.

The resistance to the Ray Davis Homestake result was much, much stiffer than you portray. By far the strongest resistance was: people thought his experiment was just flat wrong. It was a radiochemical experiment more akin to Rutherford & Soddy than to 1960's particle physics. The experimental community were just utterly skeptical… thought the `missing neutrinos' were just a bad calibration. And then lots of theorists referred back to the vast parameter space, and shrugged. A few took Davis seriously…. John Bahcall… then the MSW effect showed up in the 1980's, and Davis got more respect. Turns out the MSW effect is not the origin of the Davis effect, but, still, that MSW can stimulate neutrino transitions really turned peoples heads at the time, and helped stimulate new experiments that verified Davis.

There is an excellent, excellent argument for SUSY… stabilizing quantum field theory at very high energies. How high do you need to go to see SUSY restored? Anybody's guess. There will never really be a serious argument that any scale is `natural' until we have empirically discovered it.

Sure, we all wish that a very clever $10,000 experiment will discover SUSY in some incredible series of unlikely events. Believe me, the experimental community probes ideas like that all the friggin' time. And lots have something to do with Dark Matter. No matter what, though, WIMPs ain't dead. They don't need SUSY to still be right.

Quantum Theory and Representation Theory, the Book

July 26, 2016
Categories: Quantum Theory: The Book

For the last few years most of my time has been spent working on writing a textbook, with the current title Quantum Theory, Groups and Representations: An Introduction. The book is based on a year-long course that I've taught twice, based on the concept of starting out assuming little but calculus and linear algebra, and developing simultaneously basic ideas about quantum mechanics and representation theory. The first half of the course stuck to basic non-relativistic quantum mechanics, while the second introduced free quantum field theories and the relativistic case. By the end, the idea is to bring the reader to the point of having some appreciation of the main elements of the Standard Model, from a perspective emphasizing the representation theory structures that appear.

The discussion of quantum field theory I think is rather different than that of other textbooks, taking a Hamiltonian point of view, rather than the Lagrangian/path integral one in which most physicists are now trained (myself included). One basic idea was to try and work out very carefully the quantization of a finite-dimensional phase space in all its representation-theoretic glory, with the idea that free quantum field theories could then be developed as a straightforward extension to the case of taking solutions of a field equation as phase space. While this point of view on quantum field theory is fairly well-known, writing up the details turned out to be a lot more challenging than I expected.

As part of this, the book attempts to carefully distinguish mathematical objects that usually get identified by physicist's calculational methods. In particular, phase space and its dual space are distinguished, and the role of complex numbers and complexification of real vector spaces receives a lot of attention.

At the same time, the book is based on a relatively simple philosophical take on what the fundamental structures are and how they are grounded in representation theory. From this point of view, free relativistic quantum field theories are based on starting with an identification of irreducible representations of the space-time symmetry group using the Casimir operator to get a wave-equation. This provides a single-particle theory, with the quantum field theory then appearing as its "second quantization", which is a metaplectic (bosonic case) or spinor (fermionic case) representation. These are some of the specifics behind the grandiose point of view on how mathematics and physics are related that I described here. For some indications of further ideas needed to capture other aspects of the Standard Model, there's this that I wrote long ago, but which now seems to me hopelessly naive, in need of a complete rethinking in light of much of what I've learned since then.

The manuscript is still not quite finished, and comments are extremely welcome. While several people have already been very helpful with this, few have been willing to face the latter chapters, which I fear are quite challenging and in need of advice about how to make them less so. The current state of things is that what remains to be done is

- A bit more work on the last chapters.
- A rereading from the start, bringing earlier chapters in line with choices that I made later, and addressing a long list of comments that a few people have given me.
- An old list of problems (see here) needs to be edited, with more problems added.
- I need to find someone to make professional drawings (there are some funds for this).
- An index is needed.

Optimistically I'm hoping to have this mostly done by the end of the summer. Springer will be publishing the book (my contract with them specifies that I can make a draft version of the book freely available on my web-site), and I assume it will appear next year. To be honest, I'm getting very tired of this project, and looking forward to pursuing new ideas and thinking about something different this fall.

Comments

1. **tulpoeid**
   July 26, 2016

   Impressive. Congratulations and may you pursue new ideas very soon 🙂

2. **Marcus**
   July 27, 2016

   Hi Peter,

   The content of your books look really good. Congrats for (almost) finishing!

   I'm interested in what you think is the unique difference of your book to existing books that seem to cover similar ground (e.g. Zee's new Group Theory book, Schwichtenberg's Physics from Symmetry or Robinson's Symmetry and the Standard Model Reference)? At a first glance I would guess maybe mathematical rigor?

   Best wishes,
   Marcus

3. **Asaint**
   July 27, 2016

   Any disclosures as to what those "new ideas" are?

4. **StrangeRep**
   July 27, 2016

   Hi Peter,

   1) On p240 you seem to say that Kepler's 3rd law is associated with the LRL vector. I believe this is not correct. Rather, the 3rd law arises from a dilation-like symmetry. In coordinate form, it is t -> kt, q -> k^{2/3} q. See section 10.2 of Stephani, i.e.,

   H. Stephani, "Differential Equations…", CUP 1989C, ISBN 0-521-36689-5

   (I find this extra dilation-like symmetry interesting because it is not associated with a conserved quantity. Not sure how/whether it's relevant in the quantized version.)

   2) What units are you using in the Hamiltonian and LRL vector on p240? Your expressions seem dimensionally invalid, at least superficially.

   3) Your expression W on p241 for the quantized LRL vector seems to have a typo. Your denominator |Q|^2 should be just |Q|, shouldn't it?Also, you don't seem to mention that the main reason why Pauli chose that modified version was in order to have an Hermitian operator. The GvH thm is less of an issue here, since one just looks

for Hermitian versions of the classical quantities.

And btw, do you want further comments delivered here on your blog, or would email be more convenient?

5. **fg**
July 27, 2016

To follow up on the point 1 in StrangeRep's comment:

The existence of the LRL conserved vector is responsible for the fact that all the bounded orbits a 1/r potential are closed. The conservation of LRL is specific to this potential, and is not related to the usual geometrical symmetries (such as angular momentum, from rotational invariance). It may (but I am not sure) be in fact related to the scaling symmetry pointed out in StrangeRep's comment.

At the quantum level, I think it is related to the degeneracy of the energy levels of the hydrogen atom (all states with the same n and different l have the same energy).

The only other rotationnally invariant potential whose orbits are all closed is the harmonic oscillator. Again, this property can be attributed to the existence of an extra conserved quantity, besides the geometrical ones.

6. **Peter Orland**
July 27, 2016

Hi Peter and Commenters,

After the comments above, I took a look at page 240. It is never actually stated which of Kepler's laws follows from which property of the Coulomb problem. It probably would be good to clarify this.

It's nice to have an explicit solution of the hydrogen atom done this (Pauli's) way in a textbook. I always preferred Fock's method of stereographic projections (it's somewhat more elegant and quicker, esp. for Coulomb scattering), but what you are presenting is probably more suitable for a course at this level.

7. **Peter Woit**
July 27, 2016

StrangeRep,
Thanks! Such comments are greatly appreciated, in general better to send them to me via email.

Thanks to others for comment about the Coulomb potential calculation. One thing one realizes when writing something like this is that even quite a few hundreds of pages is not enough to do more than scratch the surface of the topics one wants to explain. The main goal in this case was the Lie algebra calculation of the hydrogen spectrum, which is both very important physics and a great demonstration of representation theory techniques.

Marcus,
I think there's a detailed answer to your question in the introduction. I'm trying to cover different material not so readily available elsewhere, and also to develop a certain unifying point of view about the relationship of QM and representation theory.

The level of rigor is higher than typical physics books, less than that of typical math textbooks. I've described it jokingly as a level of rigor of the kind one sometimes sees in Russian math textbooks. Unlike many math textbooks, the aim is generally to develop specific central examples, rather than to develop theory and make general statements. The goal is to simultaneously be precise enough to keep mathematicians happy, while still writing something that physicists might be willing to read and try to follow

Asaint,
One project is to get back to work on Dirac cohomology. The book actually develops a lot of the basic elements needed for going farther with that.

8. **Justin**
July 27, 2016

Woit,

What exactly are the prerequisites for working through your book? I understand linear algebra from Serge Lang's famous text, but it does not mention anything about Hilbert spaces and I've never studied them. I also know some algebra from Fraleigh's classic text. I have a very minimal amount of physics just now learning some quantum mechanics from a text geared towards freshman undergraduates so it's below the level of Griffith's text.

9. **Peter Woit**
July 28, 2016

Justin,
You should be able to read the book. It avoids getting into the serious analysis of Hilbert space theory. A warning to anyone though is that more mathematics and more physics come into it as the book goes on, while the treatment gets sketchier, so the later parts will be much more challenging.

10. **D R Lunsford**
July 30, 2016

Book looks like a valuable addition to the canon, thanks for the effort.

-drl

11. **Chris Oakley**
July 30, 2016

Roger Penrose writes the wave equation for a free helicity *s* particle as ∂^{AA'}Φ_{AB…} where there are 2*s* LH SL(2,C) indices on the field. It may have been obvious to him why this followed from Wigner's irreducible reps of the Poincare group, but as it was not obvious to me, I did the analysis in section 3.3 here: maybe there's a quicker way. This equation is the massless Dirac equation for spin 1/2, source-free Maxwell's equation for helicity 1 and linearised GR for helicity 2. So it gets you from your chapter 42 to chapter 46 without needing to invoke pre-quantum physics, and I would have thought, especially if you are aiming the book at the mathematical end of the physicist market, it would be a welcome addition.

12. **Peter Woit**

July 30, 2016

Chris,
Thanks for the pointer to the notes. I wanted though to do something different than the SL(2,C) spinor formalism, for various reasons (one is to keep separate the different ways complex numbers occur). As in a lot of other places in the book, I also wanted to focus on the structure of specific examples, as opposed to a more general formalism. So, while the SL(2,C) formalism is of great generality, covering all spins, I wanted to instead concentrate on the specific cases of field equations for fields occurring in the Standard Model.

13. **Auntiegrav**
August 5, 2016

Do you have a notification list for when the book is published? I look forward to it. Sounds like just what this old nutjob needs.

Monumental Proof to Torment Mathematicians for Years to Come

July 28, 2016
Categories: abc Conjecture

Davide Castelvecchi at Nature has talked to some of the mathematicians at the recent Kyoto workshop on Mochizuki's proposed proof of the abc conjecture, and written up a summary under the appropriate title [Monumental proof to torment mathematicians for years to come](). Here's the part that summarizes the opinions of some of the experts there:

> Mochizuki is "less isolated than he was before the process got started", says Kiran Kedlaya, a number theorist at the University of California, San Diego. Although at first Mochizuki's papers, which stretch over more than 500 pages1–4, seemed like an impenetrable jungle of formulae, experts have slowly discerned a strategy in the proof that the papers describe, and have been able to zero in on particular passages that seem crucial, he says.
>
> Jeffrey Lagarias, a number theorist at the University of Michigan in Ann Arbor, says that he got far enough to see that Mochizuki's work is worth the effort. "It has some revolutionary new ideas," he says.
>
> Still, Kedlaya says that the more he delves into the proof, the longer he thinks it will take to reach a consensus on whether it is correct. He used to think that the issue would be resolved perhaps by 2017. "Now I'm thinking at least three years from now."
>
> Others are even less optimistic. "The constructions are generally clear, and many of the arguments could be followed to some extent, but the overarching strategy remains totally elusive for me," says mathematician Vesselin Dimitrov of Yale University in New Haven, Connecticut. "Add to this the heavy, unprecedentedly indigestible notation: these papers are unlike anything that has ever appeared in the mathematical literature."

Kedlaya's opinion is the one likely to carry most weight in the math community, since he's a prominent and well-respected expert in this field. Lagarias has a background in somewhat different areas, not in arithmetic algebraic geometry, and Dimitrov I believe is still a Ph.D. student (at Yale, with Goncharov as thesis advisor).

My impression based on this and from what I've heard elsewhere is that the Kyoto workshop was more successful than last year's one at Oxford, perhaps largely because of Mochizuki's direct participation. Unfortunately it seems that we're still not at the point where others besides Mochizuki have enough understanding of his ideas to convincingly check them, with Kedlaya's "at least three years" justifying well the title of the Nature piece.

Organizer Ivan Fesenko has a much more upbeat take [here](), although I wonder about the Vojta quote "now the theorem proved by someone in the audience" and whether that refers to Mochizuki's IUT proof of the Vojta conjecture over number fields (which implies abc), or the Vojta conjecture over complex function fields (such as in Theorem 9 of the 2004 paper http://www.kurims.kyoto-u.ac.jp/preprint/file/RIMS1413.pdf), or something else. The reference to Dimitrov as discussing "applications of IUT" might be better worded as "would-be applications of IUT".

There will be a [conference at the University of Vermont]() in September, billed as "An introduction to concepts involved in Mochizuki's work on the ABC conjecture, intended for non-experts."

Update: Fesenko has updated his report on the conference (see [here]()) to include a more accurate characterization of talks by Vojta and Dimitrov (you can see changes to that report [here]()). Between this and the Nature quotes, there seems to be a consensus among the experts quoted (Kedlaya, Dimitrov, Vojta, Lagarias) that they still don't understand the IUT material well enough to judge whether it will provide a proof of abc or not. Unfortunately it still seems that Mochizuki is the one person with a detailed grasp of the proof and how it works. I hope people will continue to encourage him to write this up in a way that will help these experts follow the details and see if they can come to a conclusion about the proof, in less than Kedlaya's "at least three years".

Update: New Scientist has [a piece about this]() which, as in its typical physics coverage, distinguishes itself from *Nature* by throwing caution to the wind. It quotes Fesenko as follows:

> I expect that at least 100 of the most important open problems in number theory will be solved using Mochizuki's theory and further development.

Fesenko also claims that "At least 10 people now understand the theory in detail", although no word who they are (besides Mochizuki) and why if they understand the theory in detail they are having such trouble explaining it to others, such as the experts quoted in the *Nature* article. He also claims that

> the IUT papers have almost passed peer review so should be officially published in a journal in the next year or so. That will likely change the attitude of people who have previously been hostile towards Mochizuki's work, says Fesenko. "Mathematicians are very conservative people, and they follow the traditions. When papers are published, that's it."

I think Fesenko here seriously misrepresents the way mathematics works. It's not that mathematicians are very conservative and devoted to following tradition. The ethos of the field is that it's not a proof until it's written down (or presented in a talk or less formal discussion) in such a way that, if you have the proper background, you can read it for yourself, follow the argument, and understand why the claim is true. Unfortunately this is not yet the case, as experts have not been able to completely follow the argument.

If it is true that a Japanese journal will publish the IUT papers as is, with Mochizuki and Fesenko then demanding that the math community must accept that this is a correct argument, even though experts don't understand it, that will create a truly unfortunate situation. Refereeing is usually conducted anonymously, shielding that process from any examination. Lagarias gives some indication of the problem:

> It is likely that the IUT papers will be published in a Japanese journal, says Fesenko, as Mochizuki's previous work has been. That may affect its reception by the wider community. "Certainly which journal they are published in will have something to do with how the math community reacts," says Lagarias.

While refereeing of typical math papers can be rather slipshod, standards have traditionally been higher for results of great importance like this one. A good example is the Wiles proof of Fermat, which was submitted to Annals of Mathematics, after which a team of experts went to work on it. One of these experts, Nick Katz, finally identified a subtle flaw in the argument (the proof was later completed with the help of Richard Taylor). Is the refereeing by the Japanese journal being done at this level of competence, one that would identify the sort of flaw that Katz found? That's the question people will be asking.

In some sense the refereeing process for these papers has already been problematic. A paper is supposed to be not just free of mistakes, but also written in a way that others can understand. Arguably any referee of these papers should have begun by insisting that the author rewrite them first to address the expository problems experts have identified.

Update: Fesenko is not happy with the Nature article, see his comment [here]().

Comments

1. **Scott Lange**
   July 28, 2016

Can anyone give some insight as to how someone can create something in one lifetime that is so complex it cannot be explained to other experts in that field in less than three years? From a non-mathematician's perspective, it is incredibly hard to imagine such a situation. If I start from the same knowledge base as someone else, and then spend a day or two creating something new on top of it, I can't imagine it taking more than 20 or 30 minutes to explain to that other person- a creation-to-explanation ratio of perhaps 50:1. I would also think that ratio would increase with scope of the creation, due to the various dead-ends that a larger project would have to have encountered that then would not need to be explained.

Thanks in advance for any insight anyone can offer!

2. **Peter Woit**
July 28, 2016

Scott Lange,
Well, Mochizuki hasn't spent all his time since the proof came out explaining to experts, and they haven't spent all that time listening. On the other hand, it is four years, not three… This really is an extremely unusual situation, I know of no other like it. One thing that I think is fascinating about it is that by understanding what has gone wrong, you get insight into the complexities of how things work normally, when things go right, and understanding gets transmitted.

3. **eggcrook**
July 28, 2016

It sounds like the plot of the Taming of the Shrew where the father (Mochizuki) won't allow any of the suitors of his popular daughter (ABC proof) to marry her until they find a husband for his unpopular and difficult daughter (IUT theory). If he wants as many people to put the effort into learning IUT as possible, a reduction of the ABC proof to existing mathematics would be a disaster for him.

4. **Thomas**
July 29, 2016

Two properties of Mochizuki's texts repel people: First, his too frequent and too often repulsive terminology, much of which is about things one usually does not need new words for – mathematicians usually have a better sense for words and take better care on them (esp. Grothendieck and his school). Then, a lack of expository structure – usually one gives an overview what is done where and with which ideas, so that readers can decide which parts they read in which order with which way of reading.

5. **Davide Castelvecchi**
July 29, 2016

I think that Mochizuki's case has some (distant) similarities with Louis de Branges' claim to have proved the Riemann hypothesis. He also had a track record of solving important problems. and he too developed his own, nonstandard mathematical language that other mathematicians found indigestible. Although contrary to de Branges' case, people are taking Mochizuki's proof seriously and some are putting a lot of effort into reading it. See this story from several years ago:

http://www.lrb.co.uk/v26/n14/karl-sabbagh/the-strange-case-of-louis-de-branges

In the past, there have been cases of theories that (even though much less grandiose and elaborate) took a long time for people to understand — and eventually had to be reformulated in a different language. When I wrote my profile of Mochizuki back in October, some of my sources mentioned Newton's Principia as an example. And just the other day, one source told me: "It was mentioned at the conference that sometimes things take a long time to be accepted. Two examples mentioned at the conference were Galois theory and Class Field Theory, each of which took about 40 years."

6. **e. ehrenweist**
July 29, 2016

Cohen's proof of the independence of the continuum hypothesis using forcing seemed at first nearly incomprehensible, and alien, to most mathematicians. It took several years before its ideas were distilled and made accessible. (I still find forcing to be somewhat magical for that matter.)

7. **mahmoud**
July 29, 2016

ehrenweist,

Cohen's proof was quickly judged as correct by Gödel (as well as other prominent logicians in the US) and in a few years after Cohen's breakthrough there was an avalanche of new applications of forcing. In fact Shoenfield's 1967 textbook contains an exposition of forcing, just 3 years after Cohen's papers, so how is this in any way similar to Mochizuki's case where experts can't understand even the overarching strategy after 4 years?

8. **Aatu Koskensilta**
July 29, 2016

ehrenweist,

as mahmoud says, Cohen's proof was understood very quickly, and what confusion and misunderstanding there was, mostly had to do with the fact that it was so unexpectedly "mathematical", involving, in its more natural, non-syntactic form, surprisingly little particularly logical machinery in any substantial sense. It took a while, but not very long, before set theorists and logicians sorted out what was essential, what was just idiosyncratic technical scaffolding, and so on, resulting in the now familiar unramified partial order and Boolean valued formulations. There were plenty of easy cases to try forcing on, and a vast array of immediately apparent possibilities for further application and refinement — collapsing cardinals, iterated forcing, class forcing, and so on, and so on — so that people were able to quickly develop a sense for the sort of mathematics that the new stage of set theory would turn out to be. As Kreisel (who apparently was somewhat miffed he hadn't come up with forcing himself, and even, somewhat implausibly, suggested it was nothing new, really, pointing to all manner of in hindsight analogous technical whatsits in constructive and intuitionistic mathematics) and others were at pains to point out, the basic ideas and proofs were very simple and straightforward by any mathematical standards, even if they did at points give out a slight whiff of magical out-of-hat-pullery, and there certainly wasn't years worth of new terminology, visions, grand theory, to digest. Indeed, it was all positively pedestrian in comparison to, say, what proof theorists back in the day were up to.

9. **Peter Woit**
July 29, 2016

All,
Please, no more comments using this as an excuse to discuss a completely unrelated topic.

10. **sdf**
July 29, 2016

The thing stopping me from going near his papers are the language and notation as highlighted by Dimitrov in the quote you have. Faltings said that he didn't think that Mochizuki's work would be taken seriously until "he wrote a readable paper"—recall that Faltings was Mochizuki's advisor.

11. **Peter Zbornik**
July 29, 2016

There might Be a need for a "Rosetta stone" or a dictionary in order to speed up IUT learning. Fortunately such a stone sesms to be around. Mochizuki writes the following in his paper "Bogomolov's proof of the geometric version of the Szpiro conjecture from the point of view of inter-universal Teichmüller theory" (Res. Math. Sci. 3(2016), 3:6), that:
"
aspects of inter-universal Teichmüller theory may be thought of as arithmetic analogues of the geometric theory surrounding Bogomolov's proof. Alternatively, Bogomolov's proof may be thought of as a sort of useful elementary guide, or blueprint [perhaps even a sort of Rosetta stone!], for understanding substantial portions of inter-universal Teichmuller theory."

http://www.kurims.kyoto-u.ac.jp/%7Emotizuki/Bogomolov%20from%20the%20Point%20of%20View%20of%20Inter-universal%20Teichmuller%20Theory.pdf

12. **mahmoud**
July 29, 2016

I think Castelvecchi is quite right in his comparison to de Branges, what he did not mention is de Branges earlier and correct(!) proof of Bieberbach's conjecture, which also was presented in form of a lengthy and mostly indigestible manuscript that most mathematicians dismissed at the time.

So the Mochizuki affair could be summarised by asking: are we dealing with another case of de Branges' proof of the Riemann hypothesis, or of his proof of Bieberbach's conjecture?

13. **Radioactive**
July 29, 2016

For the interested non-mathematician – what even are the objects or concepts involved in IUT? What are the universes that are supposedly inter-connected by Teichmüller theory? I suppose a more basic question would be about Teichmüller theory itself… but has anyone constructed any examples of these spaces and the relations between them in terms of more familiar things?

14. **Michael Barany**
July 29, 2016

Davide's comparisons to Newton and Galois seem spot-on from my perspective as a historian and sociologist of mathematics (though it will take a very long time indeed to say whether IUT has anything approaching the importance of the calculus or Galois theory). Some historical references for those who are interested: on Galois, if you read French you should definitely track down the recent work of Caroline Ehrhardt, who has come up with some real breakthroughs in how historians understand the interpretive history of Galois's very confusing texts. On Newton, Niccolo Guicciardini's Reading the Principia is an accessible and insightful place to look. A now-canonical comparison-point for sociologists is the classification of finite simple groups, though that was a large collective project rather than a proposal from an individual; see Alma Steingart's important article "A Group Theory of Group Theory."

15. **Peter Woit**
July 29, 2016

Radioactive,
The problem here is that such questions as "what are the basic new objects and concepts" have baffled experts, so the non-expert doesn't have a chance. Knowing anything about the usual Teichmuller theory I don't think helps.

16. **Dale C.**
July 29, 2016

Apparently the 500+ page introductory material is too complex and time-consuming to digest. Is the only way out that someone (or a group of people) digest the material and re-write it to more closely follow mainstream mathematics? And should they re-write just the parts essential to the ABC proof, or the whole material? In the beginning, there was not enough motivation to do that, as no outsider knew if the re-write was worth the effort. It appears that the attitude might be changing.

17. **Peter Woit**
July 29, 2016

Dale C.,
I'm not sure what "introductory material" you mean. The problem I think is basically that
1. Mochizuki refuses to rewrite material, on the grounds that this should not be necessary, people should just spend the time it takes to understand what he has written.

2. The small number of people who were supposed to have digested this material, and rewrite it in this manner (e.g. Go Yamashita), have not been able to complete this task.

3. Others have been unable to digest the material. If you can't understand yourself why a proof works, you're not going to be able to rewrite it for others to understand.

That, four years later, no one else has been able to write up their own version of the proof is the central mystery here.

18. **Dale C.**
July 29, 2016

With the "introductory material" I was referring to "Mochizuki, S. Inter-universal Teichmüller Theory I-IV", that apparently the ABC proof is based on. It looks very much like no outsider understands the material despite 4 years since the release of the claimed proof.

I suppose Mochizuki re-writing material has its own problems, as probably according to his understanding the material is complete already. If this is the case, then somebody else has to invest time to make the translation to a more mainstream formulation. The problem might be that the material is so large and so far away from mainstream mathematics that it will take years to understand and re-write it.

19. **Bernhard**
July 29, 2016

Peter,

What do you think about Lagarias' comment that Mochizuki's work has "some revolutionary new ideas," ? This seems really odd. Aren't they still trying to figure out if the alleged proof is right or wrong still? How do they than separate a possible collection of crackpotish ideas from "revolutionary" ones? Is this a case where no matter what the outcome the tools he invited (which?) are already useful?

Also shouldn't be on Mochizuki's shoulder the burden to try to prove his work is worthy? Why aren't these guys reacting like "You have a proof? Make it readable" His refusal to do so, sounds a bit he's hiding behind formalism.

It's not like they can do an experiment to verify it so…

20. **Peter Woit**
July 29, 2016

Dale C.,
Those papers are where the details of the proof are supposed to be, and it's exactly those that everyone is having trouble with.

Bernhard,
There are definitely lots of "new ideas", the problem is understanding them and whether they really are powerful enough to give a proof. They are not being just dismissed, partly because Mochizuki has a serious track record, partly because as people work on them, they are not finding that they are wrong.
I think there is a strong feeling among a lot of people in the field that it is Mochizuki's responsibility to do a better job of communicating his ideas, so they're not going to spend more time on this now.

21. **Peter Zbornik**
July 30, 2016

Here is what Mochizuki thinks of the situation, December 2014:

"Indeed, I have been participating for over 20 years now, as author, referee, editor, and editor-in-chief, in the refereeing of countless papers for math- ematical journals, and, as far as I can see, the verification activities on the part of the three researchers discussed above already exceed, by a quite substantial margin — i.e., in their content, thoroughness, and meticulousness — the usual level of refereeing for a mathematical journal. Moreover, although I have received com- ments not only from the "core three" researchers, but also from other researchers as well, concerning numerous superficial technical oversights that may be repaired immediately (i.e., a routine aspect of the refereeing process),
I have yet to hear of even a single problem that relates to the essential thrust or validity of the theory."
…
"My understanding, at present, concerning the verification of IUTeich is that
at least with regard to the substantive mathematical aspects of such a verification, the verification of IUTeich is, for all practical purposes, com- plete; nevertheless, as a precautionary measure, in light of the importance of the theory and the novelty of the techniques that underlie the theory, it seems appropriate that a bit more time be allowed to elapse before a final official declaration of the completion of the verification of IUTeich is made.
On the other hand, I should also state that, although such precautionary measures may serve a meaningful role for a limited amount of time, I am not of the opinion that such precautionary measures should be maintained for periods of, say, the order of 20 ~ 30 years. That is to say, although there are perhaps numerous approaches to the issue of computing an appropriate length of duration for such precautionary measures, my current sense is that the length of duration of such precautionary measures should not exceed 10 years, i.e., counting from the time of the first oral presentation of the theory (i.e., in October 2010) and the posting of the series of papers on the theory (i.e., in August 2012). Put another way, my current sense is that some date during the latter half of the 2010's would be an appropriate time for the termination of such precautionary measures."

http://www.kurims.kyoto-u.ac.jp/~motizuki/IUTeich%20Verification%20Report%202014-12.pdf

22. **Radioactive**
July 31, 2016

From reading that it does sound like, if he hadn't claimed to solve a famous problem, the refereeing process would have been done and dusted a long time ago. And it does seem that he has made quite a bit of effort to disseminate and teach the theory to people and recognizes the need for more exposition. Thus it must be frustrating to him to see such statements as the title of this article.

I suppose the proliferation of specialties in math can lead to situations like this – especially when important proofs come from unexpected sources – and rather than exposing some fault of Mochizuki it exposes some weaknesses in the mathematical community. With everyone an expert in their own subdomain, and with no time to carefully examine new approaches, if the one with a revolutionary result is, understandably, not willing to drop everything and publicize then a state of confusion will persist.

Though I suppose someone with a good expository style will eventually learn what a Frobenoid is and write a textbook.

23. **David Roberts**
July 31, 2016

Peter,

Is there likely to be a high-level blog post from someone who was there this time around? Or perhaps an interview with such a person with a serious mathematical audience in mind? (i.e. not merely educated layperson-level coverage, nice though that is)

24. **Peter Woit**
July 31, 2016

David Roberts,

I agree that that would be a great service and really helpful for the field and for the math community in general. I hope it will happen (and hear rumors it might…).

25. **Timothy Chow**
August 1, 2016

I am curious about your comment that Mochizuki is "the one person with a detailed grasp of the proof and how it works." What about Hoshi and Yamashita? Admittedly they have not produced expositions that satisfy others, but then again neither has Mochizuki.

You also said, "That, four years later, no one else has been able to write up their own version of the proof is the central mystery here." This does not seem so mysterious. Writing up your own version requires a lot of talent in its own right. Perhaps Hoshi and Yamashita don't have that particular talent. As for others, few if any made any concerted attempt to understand the papers for the first three years.

26. **Joe Yang**
August 1, 2016

As someone who has left the filed of mathematical research many years ago, I only recently started following the ABC conjecture/Mochizuki saga and found it to be absolutely fascinating. Given that several mathematicians have claimed to have gone through the IUT theory thoroughly and Mochizuki's reputation of being a detailed and bright mathematician, it is unlikely that IUT theory is complete rubbish. Of course, it is still possible that there are technical mistakes in the proof of the ABC conjecture that have not been caught due to the massive amount of new ideas and technique/concept/terminology.

One interesting point I have seen raised in another thread of discussion is the lack of HARD analytical number theory type of argument in Mochizuki's claimed proof. This seems to be addressed in the most recent survey (though 100 pages long) article by SM:

http://www.kurims.kyoto-u.ac.jp/~motizuki/Alien%20Copies,%20Gaussians,%20and%20Inter-universal%20Teichmuller%20Theory.pdf

Section 1 is accessible to anyone with basic calculus background and makes for very interesting reading as SM explains how to do Gaussian integral to a fictitious high school student . Through section 1, one can get some cursory sense of what SM is trying to do with IUT and perhaps also understand his frustration. The following passage on page 7 in particular is clearly meant to address some of the criticism pointedly:

"the idea that meaningful progress could be made in the computation of
such an exceedingly difficult integral simply by considering two identical
copies of the integral — i.e., as opposed to a single copy — struck the
student as being utterly ludicrous.
Put another way, the suggestion of Step 3 was simply not the sort of suggestion that
the student wanted to hear. Rather, the student was keenly interested in seeing some
sort of clever partial integration or change of coordinates involving "sin(–)",
"cos(–)", "tan(–)", "exp(–)", " 1
1+x2 ", etc., i.e., of the sort that the student was
used to seeing in familiar expositions of one-variable calculus."

27. **Peter Woit**
August 1, 2016

Timothy Chow,
I disagree that writing up a proof requires unusual talent, this is what mathematicians are trained to do. This is what we do with students: try and teach them why something is true, then see if they understand it by asking them to give the argument in their own words. Until they can do this we don't recognize them as someone who understands the argument.

To apply this to the current situation is of course oversimplifying and being rather harsh on Yoshi and Yamashita. The situation with this proof is quite unusual due to its complexity and use of unfamiliar concepts. But, it seems to be a fact that they have not been able to either write out a version of the proof that others can understand, or give lectures that transmit understanding. Why this is is a big mystery, I just don't believe that the problem lies with laziness of the audience.

28. **Peter Woit**
August 1, 2016

Joe Yang,

The Gaussian integral business is I think a good indication of the problem with Mochizuki's survey (the latest one, and similar early documents). It is advertised as an explanation to other mathematicians of his ideas, but the Gaussian integral explains nothing at all about them since it's just a very vague analogy. Bringing in the high school student makes explicit that what this is is a parable, and in the parable experts in the subject are being compared to ignorant, unsophisticated high school students. I think experts trying to get something out of this document find this beginning part of it not only useless, but insulting, it doesn't exactly encourage them to read on.

29. **Joe Yang**
August 1, 2016

Peter,

Yes, the tone used in the high school student analogy can certainly be taken as insult to some. On the other hand, I don't see anything wrong with using Gaussian integral as a motivating analogy (even if a "vague" one as you put it) in a survey paper to explain the concept behind "mutually alien copies". It should not be "useless" if indeed the idea behind mutually alien copies is similar to taking two identical copies of integrals. Having met / worked with"experts" in various mathematical fields, I find it common occurrence that many who are brilliant in understanding ideas close to their own research to be not necessarily so fast at grasping "alien" concepts. More often than not, the "experts" would like to see an analogy from concepts that they are familiar with and as such a simple analogy can often be a good starting point.

30. **Peter Woit**
August 1, 2016

Joe Yang,
I'm actually normally a big fan of mathematicians including more motivational material in what they write, including even vague analogies like this one. Too much of the math literature is only readable by experts, including no help to the nonexpert about how to get oriented, how to get the general picture of what is happening. The problem here is a very unusual one, that there's plenty of such motivational material, but the more precise material experts need to understand exactly what is going on is missing from the survey, and in the long IUT documents buried in a huge array of new definitions and formalism, often depending on earlier papers. There's somewhat of a standoff here, with Mochizuki's attitude: "it's all there, you just have to work harder", a lot of experts saying: "we've tried that, couldn't get anywhere, you need to write this up in a more conventional form, an outline of the proof with precise, checkable statements". I can't recommend Brian Conrad's blog post highly enough as a serious explanation of what the problem is.

The workshops at Oxford and Kyoto have been the best attempt so far to overcome this standoff. This is a difficult situation and I think lots of people are honestly working hard to understand the potential new mathematics here. I do think though that it would help if Mochizuki (or those close to him) made more of an effort to write something that would address the concerns experts have pointed out. Responding to these with even implicit insults is not helpful.

31. **Timothy Chow**
August 1, 2016

Peter, I may have misunderstood what you meant by "writing up their own version of the proof." Hoshi and Yamashita have, after all, given lectures and produced written text that is not simply a verbatim reproduction of Mochizuki's writings. I took you to mean producing a fundamentally new exposition that meets the popular demand for a high-level sketch that conveys the main ideas of the proof in more conventional language that the experts are already accustomed to. That sort of thing requires talent and doesn't always happen within a few years. Consider, for example, the account of etale cohomology in SGA4, or Hironaka's paper on resolution of singularities. These have a reputation for being formidable and inaccessible texts, and it took a very long time for alternative expositions to appear.

32. **Peter Woit**
August 1, 2016

Timothy Chow,
As far as I know the only English-language written texts available from Hoshi and Yamashita are sketchy slides from presentations (Yamashita is supposed to be writing a conventional document but it hasn't emerged, Hoshi has some notes on IUT in Japanese which I gather he is translating into English). Among those slides, I don't see anything like an outline of the abc proof, they appear to be addressing more specialized topics that are somehow part of the proof. They're meant to complement lectures, undoubtedly those in attendance at the lectures could get more out of them. But the bottom line seems to be that no one in attendance at those lectures, or readers of those slides, has come away saying "now I understand the proof, at least in outline".

I wasn't asking for the kind of thing you describe, readable by many mathematicians. That would be great, and hopefully someday we'll have such a thing, but, sure, that's the result of often a lot of time boiling down the initial version. What doesn't seem to exist is something readable by experts.

SGA4 is maybe a good example. When it came out (1972?)[*actually much earlier, see Brian Conrad's comment*] it was already the product of not just one person, but multiple experts who had absorbed Grothendieck's ideas.
A more readable version SGA 4.5, did take 5 years to appear, and something like that for IUT is still a long ways away. By the way, my guess is that if we ever do have a version of Mochizuki's ideas, integrated with the rest of mathematics, he may be as unhappy with the way they are written up as Grothendieck was with SGA 4.5…

33. **Brian Conrad**
August 2, 2016

Peter:

Roughly speaking, SGAn was the seminar in 196n (so SGA1 in 1961, etc.). The Springer-Verlag edition of the SGA4 volumes was widely published in the early 1970's, but the original copies were distributed to a more limited set of math departments in the mid-1960's (e.g., in the Harvard math library the original SGA's are massive volumes in yellow binding consisting of typewriter-generated text on paper that must by now be very brittle; laid end to end, these volumes occupy much of an entire shelf and constitute a very daunting sight!)

But your main point about others in geographical vicinity to Grothendieck picking up the ideas and pushing them into new terrain is apt: in those days one had to be in one of a handful of places (e.g., Paris [Serre/Grothendieck/Deligne/etc.], Moscow [Shafarevich/Manin], Princeton [Katz], Bonn [Harder], or Boston [Artin/Mazur/Mumford/Tate]) to acquire a "working knowledge" of the new concepts by talking with local experts, that being much more efficient than trying to read on one's own, and things really spread that way. (I have been told by a top expert from those days that much was learned through seminars and talking with people, rather than by direct study of EGA on one's own, etc.)

For example, already by the late 1960's the students of Mike Artin, Barry Mazur, David Mumford, and John Tate were making very creative use of the ideas of SGA4 (e.g., Knutson's 1968 PhD thesis on algebraic spaces, Jim Milne's 1967 thesis using etale and crystalline methods to prove BSD for constant abelian varieties, Tadao Oda's 1967 thesis on Dieudonne theory for abelian varieties, Larry Roberts' 1968 thesis on flat cohomology of finite group schemes, Friedlander's 1970 thesis on etale homotopy theory). And that's just the PhD students in Boston, to say nothing of what was being done by the senior faculty there (Deligne-Mumford, Artin-Verdier, Artin-Mazur, Artin-Tate, etc.) and by both PhD students and senior faculty elsewhere.

The publication of more accessible references such as SGA 4.5 in 1977 (let alone Hartshorne's textbook at a more basic level in the same year, the impact of which on the explosion of the subject probably cannot be overestimated) helped tremendously in spreading the understanding of these ideas for those who weren't able to attend lectures by Katz, Deligne, etc. But well before the huge increase in accessibility of the subject through written alternatives to the foundational references, within a handful of years after SGA4 a growing number of people were picking up the principles through the oral tradition and producing high-level research based on these ideas.

In more recent times one can see something similar happening with perfectoid spaces (which were introduced only in 2012 and have already led to tremendous advances in many directions never anticipated at the inception), thanks in no small part to the creator of the subject traveling early on to numerous places to give substantive lectures and producing insightful surveys on the basis of which (along with original papers) seminars have been run all over the world. Of course, the available options for dissemination of ideas are far greater now than in the 1960's.

34. **sdf**
August 2, 2016

New Scientist article here reports I. Fesenko as having made the absurdly ambitious statement (2nd paragraph from end):

"I expect that at least 100 of the most important open problems in number theory will be solved using Mochizuki's theory and further development."

35. **mahmoud**
August 2, 2016

Unless New Scientist has fabricated the "100 problems"-quote by Fesenko it seems high time to put him in the crackpot camp together with de Branges. Also, didn't Mochizuki himself say before that IUT is likely to be a one hit wonder without any major applications besides abc?

36. **Brian Conrad**
August 2, 2016

mahmoud: It is correct that when an audience member asked Mochizuki during one of the Q&A Skype sessions at the Oxford workshop whether he was aware of other applications of his IUT work to other problems in mathematics, his reply was a forthright "No" (which is of course quite fine).

He also explained in very reasonable terms why he had explored trying to use it to attack RH. The point is that his notion of Frobenioid was inspired by the search for a replacement for Frobenius maps that is useful in characteristic 0, and the IUT work provided a context for applying that notion in some specific instances. Hence, it seemed quite natural to follow up the IUT work by considering if Frobenioids could be applied to characteristic-0 versions of problems for which Frobenius maps have been very fruitful in characteristic p, such as RH.

He was very straightforward in then saying that after trying this for some time (maybe a couple of years?) and not making much progress, he wasn't looking into that approach to RH anymore.

37. **Alan**

August 2, 2016

On Go Yamashita's page (http://www.kurims.kyoto-u.ac.jp/ja/list/yamashita.html) you can find this:

近年は,望月新一氏による宇宙際幾何学のさらなる発展の方向性で同氏と共同研究をしている.望月新一氏の計算においてabc予想の誤差項にRiemannゼータ関数との関連性を示唆する1/2が現れる.一方,同氏の宇宙際Teichmüller理論においてテータ関数が中心的役割を果たすのであるが,テータ関数はMellin変換によってRiemannゼータ関数と関係する.さらに,宇宙際Teichmüller理論において宇宙際Fourier変換の現象が起きている.これらのことから,長期的な計画であるが"宇宙際Mellin変換" の理論ができればRiemannゼータ関数と関係させることができるのではないかと期待して共同研究を進めている.

I have a translation:

Recently, I am researching in collaboration with Shinichi Mochizuki, the perspective of future development of Inter-Universal Geometry, of his authorship. According to Mochizuki's calculations, on the abc conjecture "error" there appears a 1/2 as an indicator of the relationship that can exist with the Riemann zeta function. On the other hand, on Mochizuki's Inter-Universal Teichmüller Theory, the theta function presents a fundamental role, that by its turn is related to the Riemann zeta function by the Mellin Transform. Moreover, in the Inter-Universal Teichmüller Theory appears the occurrence of Fourier Transform. Based on this facts, although it's a long term project, I am advancing the collaborative research in expectation that if the "Inter-Universal Mellin Transform" is completed, then the relationship with the Riemann zeta function can be proved.

38. **David Roberts**
August 3, 2016

Sadly the second link to what I gather is Fesenko's Facebook feed (in the sentence "you can see changes to that report [here]") requires a FB account. Can anyone with access let us know what it says?

39. **Peter Woit**
August 3, 2016

David Roberts,
That's not very important, just the edit history of that post, showing the half-dozen or so different versions as the author edited and added some material, most substantively clarifying what Vojta and Dimitrov had to say (I assume you can see the latest version).

40. **mahmoud**
August 3, 2016

Conrad and Alan,

Glancing at Mochizuki's papers the connection to RH is actually discussed at some length in IV: Log-volume Computations and Set-theoretic Foundations: Remark 2.2.1 on page 47 is essentially an elaboration of what Alan translated from Yamashita. Despite his answer over skype that Conrad reported it appears he hasn't given up on that approach yet (it isn't clear when that remark was written, he has added new remarks to the paper in June 2016 so 2.2.1 might be a new addition).

Anyway, this suggests a way forward for experts in number theory who are unwilling to go through the whole terminological mayhem around IUT: study the computations (especially the "log-volume estimate" 1.10) and take Mochizuki on faith that it should apply to (arbitrary Dedekind) zeta functions; if anything emerges that contradicts known bounds on these functions this would throw serious cold water on the reliability of (this application of) IUT.

41. **Brian Conrad**
August 3, 2016

mahmoud:

Thanks for the clarification; perhaps something changed between December and June. Due to discussions I've had with some who have looked in detail at the computations (including around IV.1.10), it seems that those computations are not going to shed much light in the direction you mentioned. Hopefully there will eventually appear an essay by an audience participant at the Kyoto meeting who can address what mathematical insights from the IUT papers were communicated to the audience.

In case you may have wondered, the question and answer at http://mathoverflow.net/questions/245438/mochizukis-gaussian-integral-analogy has essentially no mathematical content and does not address statements which are precise. Nothing helpful is likely to come out of Math Overflow Q&A's at this stage (not that one should have expected otherwise, given the circumstances).

42. **marshall Flax**
August 3, 2016

@Brian Contrad, perhaps what's changed is the last two slides from https://www.maths.nottingham.ac.uk/personal/ibf/files/dimitrov.pdf ?

43. **Brian Conrad**
August 3, 2016

marshall flax: No, that definitely has nothing to do with it (and I recommend not to spend time wondering what someone else may or may not achieve in the direction of RH). The appearance of an L-function there is related to Siegel zeros, and the connection between a suitable formulation of ABC and Siegel zeros has been known for some time since work of Granville & Stark (as Dimitrov notes on his slides too), well before 2012. Those slides reflect considerations of Dimitrov done on his own, treating the methods of IUT as a black box (as one can see from how the slides are written); the core arguments in his slides are applications of the standard methods of Diophantine analysis.

44. **Gowers**
August 4, 2016

I'm not the first to say this by any means, but I sometimes wonder whether a change in culture is needed, a change particularly highlighted by this example. Proofs have two functions: to certify the truth of mathematical statements, and to give insights into why they are true. If one mathematician provides a long and almost incomprehensible, but correct, proof of a statement (perhaps checkable by only a handful of experts), we tend to say that that mathematician has solved the problem, but if another mathematician comes along and finds a shorter proof that everybody understands, that is often much more valuable. I think there's a case for saying that Mochizuki hasn't really solved the abc conjecture even if his proof is correct. However, if someone uses his ideas to produce a comprehensible proof, then obviously Mochizuki will have played a major — probably *the* major (but that depends on the details of how the comprehensible proof is found) — role in the solution.

45. **Jeffrey M**
August 4, 2016

Just a quick comment, Fresenko is wrong about publication and what it means. Plenty of things have been published which no one in the field treats seriously. It depends on where it appears, which essentially has to do with how good the refereeing is. Annals for Wiles is the classic example, but there are plenty of others. Incorrect stuff gets published plenty, but experts usually know it's wrong and just ignore it. The fact that no one can (yet) explain this to people who should be able to understand it is a giant red flag, in my opinion. Nothing has ever been like that, ever. Grothendieck confused plenty of people, but as brian Conrad points out, quite a few people were using his stuff to generate all sorts of amazing results within a short period.

46. **Peter Woit**
August 5, 2016

I'm closing comments on this for now, since I'm on vacation and don't have time to moderate them. In addition, this has become kind of depressing, with some people seemingly intent on choosing pro or anti Fesenko or Mochizuki positions and arguing them. I'd urge everyone to stop this and stick to the question of whether or not this is a proof. I've seen what can happen to your field when, lacking such a standard, people start choosing sides and arguing. It's not pretty, and mathematics should not go there.

HEP Physics News

July 31, 2016
Categories: Strings 2XXX, Uncategorized

- ICHEP 2016 starts in Chicago this week. Talks about the new diphoton results are scheduled for 9am (Chicago time) Friday. There will also be talks later in the day at CERN (5pm Geneva time), scheduled as part of this summer's TH institute. Consulting my prediction here (although I had the plenary vs. parallel wrong), I think it's very clear that these will be negative results for the supposed 750 GeV bump. See Resonaances for discussion of the significance of this.
- Last year I heard Nima Arkani-Hamed talk here about "Nnaturalness". The paper is now out.
- There's a very interesting profile in Nautilus of Fotini Markopolou, who left theoretical physics to work on a startup in England.
- At Quanta magazine, Natalie Wolchover has a nice article about intriguing new neutrino results. With nothing unexpected showing up at the energy frontier being explored by the LHC, in coming years it may very well be the neutrino sector, which can be explored at much lower energies, where one should look for something new.
- Strings 2016 is starting in Beijing in a few hours. Schedule here, talk titles here.

Update: Videos of the Strings 2016 talks are becoming available here. The talks of the first day featured little string theory (except for a historical talk by John Schwarz). A major theme was 3d quantum field theory, with Witten and Costello talking about the same new ideas starting with Chern-Simons theory, and Seiberg talking about dualities in 3d qft.

Update: Slides are here. Tuesday started off with entanglement entropy and tensor networks. I confess that not only do I not see what this has to do with string theory, but have trouble seeing what it has to do with anything. The connection with quantum gravity using tensor networks seems vaguely to recall the much more well-motivated spin networks of LQG, which string theorists always denounced as not exhibiting a Lorentz invariant ground state. Now it's the string theorists promoting this kind of network structure, noticing the same problem they used to denounce as convincing evidence their competitors had it all wrong. The world is a strange place.

Update: New Scientist has a quote from me saying the obvious thing about Nnaturalness. Blogging likely light to nonexistent for the next week, I'll be traveling, listening to music in Nashville, as well as up in the mountains of Virginia/Tennessee,

Comments

1. **David**
   July 31, 2016

   Will the Strings 2016 talks be available for streaming anywhere?

2. **Peter Woit**
   July 31, 2016

   David,
   I assume so, they always have been in the past. Presumably links to videos will appear at some point on the Strings 2016 website.

3. **Tim**
   August 1, 2016

   I am amazed Strings 2016 and ICHEP happen at the same time. I guess they're working under the assumption that no one who is interested in string theory is also interested in experimental results?

4. **Peter Woit**
   August 1, 2016

   Tim,
   The main part of ICHEP is next week (the only overlap with Strings 2016 is the first two days, Thursday and Friday this week), and it is largely an experimental physics conference, with experimentalists usually not going to theory conferences, and vice versa. The Strings schedule leaves plenty of time for participants to head to Chicago on Friday and catch most of ICHEP (although I don't think a lot of that will be going on).

5. **Szilard**
   August 1, 2016

   Natalie Wolchover is one of the best science journalists out there, IMO.

6. **vmarko**
   August 3, 2016

   Peter,

   The tensor networks are not really being used in the similar context to spin networks of LQG. String theorists are studying tensor networks in order to apply them to holography-related ideas. AFAICS, a lot of ST has now mutated into the study of holography and AdS/CFT, so I am not really surprised that tensor networks are so prominent at the conference.

   Also, the entanglement entropy is tied into the issue of black hole information problem, which is of course a very popular toy-topic for ST folks. So no surprise there either.

   Of course, one can always challenge the relevance of holography and BHI problem to quantum gravity (and I often like to do it), but that's a different issue.

   🙂
   Marko

7. **Peter Woit**
   August 3, 2016

   vmarko,
   I understand that this work is motivated by issues to do with holography, I'm just having trouble seeing a plausible scenario for how you get from this sort of thing to any

new insight about fundamental physics (as opposed to the hundredth claim to “solve the black hole information paradox”). To some extent the idea seems to be that this is going to lead to some completely new understanding of QFT, or even of quantum theory itself, but I just don’t see it.

Yes, these are different networks in a different context, the similarity is just in the idea that one is going to construct quantum gravity states using some discrete combinatorial gadget, and it’s amusing to see that this encounters the same problem as the (to my mind much better motivated) LQG attempt. I’m curious what Gross and Witten think of this. They were quite critical of such things when motivated by LQG, wonder if they think this is anything better.

August 8, 2016

Peter,

I vaguely recall some purported connection between entanglement in tensor networks and AdS/CFT, whereby spacetime itself could be constructed. I believe, this was the piece Nature did on it last year: http://www.nature.com/news/the-quantum-source-of-space-time-1.18797

With regards to spin networks, I found Roger Penrose’ original papers on them, quite insightful, but markedly different wrt the above. Incidentally, today is Penrose’ 85th birthday, so congratulations to him.

The summer of null results continues:

Sterile Neutrinos not an element of this universe with p > 0.99: via the red-top press

17. **martibal**
August 9, 2016

Does this rule out only a fourth generation of neutrinos, or also right-handed neutrinos for the known generations ?

18. **Low Math, Meekly Interacting**
August 9, 2016

Despite the frustratingly vague wording in many of these popular articles, it appears that the IceCube collaboration largely ruled out low-mass sterile neutrinos of the 4th kind. If it has anything to do with chirality, type of fermion, see-saw mechanism, etc. that’s nowhere made explicit in what I’ve seen.

Natalie Wolchover does her magic at Quanta Mag: What No New Particles Means for Physics tl;dr Just keep on trucking! (Although nothing is said about the significance of “the desert” for the prospect of financing a next generation colliders)

The Nightmare Scenario

August 10, 2016
Categories: Uncategorized

Now back from a short vacation, and there seems to have been a lot happening on the debate over fundamental physics front. From the experimentalists, news that the Standard Model continues to resist falsification:

- At ICHEP, as expected, new data from ATLAS and CMS ruled out the supposed 750 GeV state that would have indicated new physics.
- Also at ICHEP, significantly stronger bounds on SUSY: gluinos ruled out up to 1.9 TeV, stops up to 900 GeV.

Recall also the recent results from LUX and PandaX (discussed here) putting stronger bounds on the sort of WIMP dark matter supposedly a feature of SUSY models.

In addition, there was news from IceCube ruling out the possibility of certain models of light sterile neutrinos (paper here, a Nature news story here).

For what it all means, you should of course consult Resonaances (and read a profile of Jester, The Rogue Blogger Who Keeps Spoiling Physics' Biggest News) as well as Tommaso Dorigo (and some coverage from Physics World featuring him).

From an even wider perspective, see Sabine Hossenfelder for The LHC "nightmare scenario" has come true and Natalie Wolchover's piece on the "nightmare scenario", What No New Particles Means for Physics (by the way, congratulations to Wolchover on some well-deserved awards, including this one). My own views on this are well known: this was in some sense a major theme of my book, and among other places I've written about this, see for example a 2013 Edge essay.

My perspective on this is in some ways similar to Hossenfelder's, but I draw very different conclusions, strongly disagreeing with her criticism of "reliance on gauge symmetry", and "trust in beauty and simplicity". This hasn't been what theorists have been doing for 30 years. The string theory unification ideology has led to an emphasis on extremely complex and ugly models, with gauge symmetry not a fundamental feature at all. Yes, she's right to point to "A failure of particle physicists to uncover a more powerful mathematical framework to improve upon the theories we already have", but I'd argue that that failure is due to an insistence on looking in the wrong place.

Wolchover's piece captures some of the current angst well, for instance quoting Maria Spiropolu about SUSY as follows:

> "We had figured it all out," said Maria Spiropulu, a particle physicist at the California Institute of Technology and a member of CMS. "If you ask people of my generation, we were almost taught that supersymmetry is there even if we haven't discovered it. We believed it."

Arkani-Hamed is as quotable as ever, saying the lesson of all this failure is

> "There are many theorists, myself included, who feel that we're in a totally unique time, where the questions on the table are the really huge, structural ones, not the details of the next particle. We're very lucky to get to live in a period like this — even if there may not be major, verified progress in our lifetimes."

I suspect that there are quite a few physicists, of my generation and later, who don't necessarily feel "very lucky" to get to live in a period of no significant progress in the past 40 years, with the prospect of none in our lifetimes. It would be great if the "huge, structural" questions really were on the table, but I've seen little interest among theorists in such questions, beyond whatever the fad of the day related to AdS/CFT might be.

Also finishing up while I was away was the Strings 2016 conference, and for the state of the subject you might want to watch David Gross's "Vision" talk (video here, I had to download the whole thing to watch it, streaming was unusable). I think Gross was right in pointing to work on the so-called "Sachdev-Ye-Kitaev" model as perhaps the most interesting thing being discussed at the conference. This is an exactly solvable large-N quantum mechanical model exhibiting features of holography. A good place to start learning about it is Kitaev's KITP lectures here and here.

Gross also went over some history, noting that some current topics in string theory echo back to 1967 work of Mandelstam (and that Gross himself had written a paper at that time on this material, so next year will be a 50th anniversary of his engagement with the subject). As for the current state of the theory, his take is much the same as that he has talked about at many earlier Strings conferences: string theory is now a "framework" encompassing QFT and most of the rest of fundamental physics, but we don't really know "what string theory is". To me it's very unclear why one is supposed to believe so strongly in the overarching role of a set of ideas that aren't well-defined and have been an utter failure at explaining anything about particle physics. Soon he'll have to pay off his SUSY bets, but this doesn't seem to have changed his conviction that superstring theory unification is on the right track. He ended with his usual sign-off "The best is yet to come", but this time added a parenthetical "I hope it comes quick".

Another new Wolchover piece well worth reading is about Miranda Cheng and her work on modular forms and string theory on K3 surfaces. I think this sort of work on the boundary of mathematics and physics makes clear the problem with string theory and mathematics: things are complicated and ugly if you try and make the theory look like the real world. You get beautiful ideas and great mathematics when you ignore the supposed connection to the real world and go in another direction. The problem is that often, instead of pursuing good mathematical ideas where they lead, people doing this feel the need to stick to some connection to the failed idea. Here's what Cheng has to say:

> I personally always have the real world at the back of my mind — but really, really, really back. I use it as sort of an inspiration for determining roughly the big directions I'm going in. But my day-to-day research is not aimed at solving the real world. I see it as differences in taste and style and personal capabilities. New ideas are needed in fundamental high-energy physics, and it's hard to say where those new ideas will come from. Understanding the basic, fundamental structures of string theory is needed and helpful. You've got to start somewhere where you can compute things, and that leads, often, to very mathematical corners. The payoff to understanding the real world might be really long term, but that's necessary at this stage.

For another physicist still enthusiastic about string theory, see this interview with Brian Greene, somehow motivated by a sci-fi horror series, Netflix's "Stranger Things".

Comments

1. **Justin**
   August 10, 2016

   As the most influential string theorists like Witten approach retirement, should we expect to see a whole new generation of independent research ideas coming from the young theorists? Or will the influence of strings carry over into the next generation preventing research in other ideas? And how are we supposed to ever make progress if we are limited in what we can work on? Also, is this a problem unique to the US or do strings have a stranglehold in Europe as well?

2. **Bob**
   August 11, 2016

   To me, that fact that people are disagreeing about what should be fundamental and what we have too much of really means we need a period where everything is challenged and everything is explored.

Here's hoping we move into a period where wild speculation and exploration of new ideas is actually encouraged rather than sticking to paradigms that may be leading us nowhere fast.

When you reach a dead end in a maze, you have to take a few steps back to find another branch, no matter how gold-gilded the walls are.

3. **Bee**
   August 11, 2016

   Peter,

   I suspect the reason you are disagreeing with me is that I am not referring to string theory, but primarily to all the hep-ph clutter you find on the arXiv. If the diphoton story has demonstrated on thing it's that you can cook up hundreds of models to fit any bump that comes up as a fluke. This type of construction is hence arguably seriously underdetermined.

4. **Thomas Larsson**
   August 11, 2016

   Has anybody considered the possibility that the reason why the LHC found no trace of BSM physics might be that there is no BSM physics? Except for gravity, which is a separate story. With the Higgs mass right at the edge of the stability region, there seems to be no compelling theoretical reason why there has to be anything beyond the SM. On the contrary, the fact that the SM is living on the edge makes it more compelling to me than if it were deep inside the stability region.

   The standard counter-argument is that visible matter only makes up 5% of the universe's mass. However, recall that medieval astronomers knew that the universe was a clockwork with at least thirteen epicycles. Experimental data are always interpreted within some framework, be it epicycles or QFT+GR. QFT and GR are of course on much stronger footing than epicycle theory ever was, but we know that their marriage is an unhappy one, and if they break down anywhere , the large-scale structure of the universe is as likely a place as any.

5. **Bee**
   August 11, 2016

   Thomas,

   The problem with your idea is the statement that the "unhappy marriage" of QFT and GR is as likely to break down on (cosmologically) large scales as anywhere. On cosmologically large scales joining GR and QFT works just fine. The problems only become noticeable at very short distances, or high energies respectively. This doesn't mean that a combination of GR and QFT does *not* lead to long-distance modifications, but at least it isn't presently clear how or even why that should be so. And in any case, that would also constitute new physics.

   Having said that, of course it's been considered that there isn't any new physics until the Planck scale, it's called the "big desert". But you don't read much about it in the pop sci media because there isn't much to be said about it.

6. **Dave Miller**
   August 11, 2016

   Peter,

   It sounds as if you agree with Miranda Cheng's comment?

   Personally, it sounds sensible to me: the basic ideas of string theory are sort of intriguing, and it will be interesting to see them explored and fleshed out. Alas, connecting them to experimental physics seems to be a project for the distant future.

   Maybe the "string wars" will end in a truce along the lines Cheng suggests.

   Dave Miller in Sacramento

7. **Navneeth**
   August 11, 2016

   > **Thomas Larsson**: Has anybody considered the possibility that the reason why the LHC found no trace of BSM physics might be that there is no BSM physics?

   Why are so many people so quick to dismiss BSM physics so soon, despite the experimentalists' repeating that we have so far gathered only a fraction of the data the LHC was designed to generate?

8. **Maurice Carid**
   August 11, 2016

   The crucial question is "what do we learn from the unholy mess that the particle physics community got itself into?".
   I agree with Peter that I cannot comprehend the lessons Sabine suggests.
   Neither do I comprehend her answer to Peter:

   >I suspect the reason you are disagreeing with me is that I am not referring to string theory, but primarily to all the hep-ph clutter you find on the arXiv.

   Sabine, do you consider the "hep-ph clutter" you're referring to, to rely overly on gauge symmetry or to be beautiful and/or simple?! If not, it is no example for cases of too much "reliance on gauge symmetry" or "trust in beauty and simplicity" in the last decades, that Peter challenges you to cite.

9. **Jan Reimers**
   August 11, 2016

   Hi Peter, I am curious if you think the recent progress on amplitudes is a counter example to pessimistic statements like:

   Yes, she's [Sabine's] right to point to "A failure of particle physicists to uncover a more powerful mathematical framework to improve upon the theories we already have", but I'd argue that that failure is due to an insistence on looking in the wrong place.

   It would be great if the "huge, structural" questions really were on the table, but I've seen little interest among theorists in such questions,
   beyond whatever the fad of the day related to AdS/CFT might be.

In particular we can now calculate complex gluon tree amplitudes using a starting point (Grassmanian + twistor variables etc) that has no locality or unitarity and we see these features emerge in the final answer. At least for tree level we can't just wave this off as only applying to a toy model (planer N=4 SYM). For me this really does seem to be uncovering a more powerful mathematical framework to improve upon the theories we already have. At least it is a definitive step in that direction which can be rigorously checked against known results. Does this work also not count as a step towards the huge structural questions (emergent space-time and emergent QM)?

Thanks
JR

10. **Low Math, Meekly Interacting**
August 11, 2016

Hi, Naveenth,
Based on my read of the popular literature on the subject, while the quoted experimentalists are maintaining an admirably agnostic stance, the theoretical picture is pretty grim. Since the LHC has turned on (and arguably well before), the favored theory for BSM physics, SUSY, has been shown to be all-but-irrelevant to the major problems it was purported to solve. If SUSY kept the Higgs mass "natural" and supplied a candidate for WIMPs, at the very worst a credible bump should have appeared somewhere by now. Instead there's NOTHING. If anything like SUSY exists in nature, it either has to be horribly ugly to meet its original demands, or it's fine-tuned. The former seems unlikely, and the latter just adds exponentially to the mystery of nature's apparent "unnaturalness". There's little reason to think that SUSY will appear at energies accessible to any conceivable experiment. At best, there's no reason to think that feasible experiments are probing nature at energies that are in any way special. We would simply have to be extremely, incredibly, ludicrously lucky to live in a universe where BSM physics is accessible.
Presently, there's simply no compelling reason to think the LHC will see anything deviating from the SM. Maybe it will, but why should it? And if we are to build another, more powerful collider, what would it be for? Perhaps all we can hope to do is learn more about the SM Higgs. Is that enough to justify the tens or hundreds of billions of dollars that will be needed to build this machine? Can a vibrant field of theoretical and experimental particle physics be sustained by such an endeavor? I guess these are the major, and deeply troubling questions that need to be faced even now. Unless, again, we are very, very, very, VERY lucky.
Do I have this right?

11. **Radioactive**
August 11, 2016

Thomas – there is all that Dark Matter floating around in space…

Peter – Ads/CFT is a very long lived fad, going strong since 1997. And I am not sure what you expect theorists to do when there's a popular and promising direction, other than to pursue it and then give talks about it at conferences.

12. **Anonyrat**
August 11, 2016

IMO, we have to figure out "beautiful and simple" rather than "arbitrary and underdetermined" symmetry-breaking, if the fundamental theory is built with symmetries and dimensions that aren't apparent in our world.

13. **Peter Woit**
August 11, 2016

Justin,
There are now many generations of string theorists of all ages, the problem isn't Witten (whose influence is not what it used to be). Actually, Witten and those of his generation had a much wider training than many younger theorists, who often ended up with a rather narrow perspective.

These days, even "string theorists" mostly don't work on actual string theory. The faddishness of the field remains an ongoing problem, even as the fads evolve. The nature of the fads and prospects for doing other things vary a lot from place to place, hard to generalize much about "US vs. Europe" for instance.

14. **Peter Woit**
August 11, 2016

Bee,
We agree about hep-ph. I think a problem may be that lots of hep-ph work starts with a motivational claim about how beautiful SUSY is, how beautiful GUTs are, but then goes on to extremely complicated and ugly constructions (because the simple, beautiful ones don't look at all like nature).

15. **Peter Woit**
August 11, 2016

Dave Miller,
I don't agree or disagree with Miranda Cheng's comment, I quoted it as a good example of how string theorists working in that area think about their work. They realize there is no hope of doing something that connects with experiments (which is good, keeping them from working on failed ideas), but at the same time, the goal of getting such a connection to string theory motivates their research direction. The danger here is that this keeps them from pursuing directions that are mathematically promising (because they clearly don't lead to anything related to physics), while at the same time encouraging research directions that are mathematically unpromising, but promise some sort of physics connection (although I think these are mirages).

A good example of what I mean is Cheng's recent talk at the Strings 2016 conference, where one of her topics was counting IIB flux vacua, a subject motivated by dubious physics, and leading into a thicket of complicated mathematics.

16. **Peter Woit**
August 11, 2016

Jan Reimers,
Some of the amplitudes ideas you mention are an example of new structural ideas, and I'm sure that's something Arkani-Hamed had in mind. So, yes, that's a good example of an interesting research program. At the same time, there's a huge disjunction between what is actually going on in that subject, and claims that one is going to get something like "emergent spacetime and QM" out of it. Arkani-Hamed himself acknowledges that the long hype-filled motivational intros to his talks about this are something he does to keep himself from getting discouraged, more than actually grounded in reality. At the latest Strings, his technical talk was "Towards deriving string theory as the weakly coupled UV completion of gravity", and, like the Cheng example above, I suspect this is an example of devotion to string ideology sending someone in a direction quite different than where the actually interesting things being learned about amplitudes might be pointing.

17. **Peter Woit**
August 11, 2016

Radioactive,
I don't know if "fad" is the right word for something going on for nearly 20 years (or, even more so, something like SUSY extensions of the SM, at over 40 years). What I meant to indicate is a huge overemphasis on one idea, partly because everyone else is working on it. After 20 or 40 years, claims about "promising" are highly problematic, arguably one might instead take the point of view that once tens of thousands of papers and decades have been devoted to an idea, if its initial promise hasn't worked out, it never will.

18. **John**
August 11, 2016

The real life reason it's called the nightmare scenario is because the funding dollars will start to dry up and jobs will be lost. Governments and taxpayers will start to question why we need to keep funding the LHC if there is nothing else to find.

On the bright side some funding should free up for new concepts and ideas that are different from the direction that has been pushed for 20+ years.

19. **Cormac O'Raifeartaigh**
August 11, 2016

Hi Peter,
as I said elsewhere, I remember Dad used to worry quite a bit about the possibility of a 'desert' in accelerator physics after the discovery of the Higgs (unlike his colleague Julius Wess, who felt that the first SUSY discovery was just around the corner).
The frustration is understandable from a theorist's point of view but the situation is a little different for the experimentalist. After all, it's reasonable to explore the next energy frontier and see what shows up, at least for a while. As my old supervisor used to say, experimental physics works primarily by ruling things out.
Of course, it's possible particle physics may find itself in the same situation as GR in the 40s and the 50s for some years. After all, we can't expect experiment to always track faithfully, there will always be periods of drought. And maybe it won't be such a bad thing if more theoreticians and experimentalists focus on other areas such as condensed matter physics for a while. Many important breakthroughs were made there before, as you know.
My feeling is that the next big discoveries may come in observational cosmology – hopefully these will show the way for the next generation of particles
Regards, Cormac

20. **WLM**
August 12, 2016

It would seem that one aspect of this "ultimate catastrophe" is that, as recently as a couple of years ago, almost everybody in hep-ph thought that finding the proverbial needles in the haystack would be easy: you just had to sit down on that metaphorical haystack (the energies at the LHC) and the needles (new particles) would poke you in the ass. Turns out that was wrong. Super-symmetry isn't just harder to find, it may not even exist. So BSM physics got much harder to identify; if the LHC is going to expose anything, it will probably be fairly subtle, maybe not at all obvious. One of the things that David Gross said recently applies here (paraphrasing): If we are now going to find maybe only a single needle hidden within a single straw somewhere within that haystack, we need to understand the haystack very, very well. That's what the LHC can help to provide, including the Alice experiment, not just CMS and ATLAS.

On the other hand, the push to investigate N=4 super-symmetric, non-interacting, infinite color charge, conformal versions of QCD, as something that's sort of close to the real world if one could only somehow insert quarks into it and break super-symmetry to get it back to reality, seems like the "more of the same" that both you and Bee are referring to. The main reason that this approach is "interesting" and "shows promise" seems to be that it looks like it may someday have some connection to a version of String Theory, not that it is actually about physics. Seems like what an old federal judge friend of mine used to refer to as "mental masturbation" — something that used to appear to be more common in the law and in philosophy than in physics :-).

21. **Radioactive**
August 12, 2016

I guess I would agree with that Peter. However if you dislike hep-ph and hep-th 'clutter' then the academic environment is much more at fault than any perverse desire on the part of the average researcher to doggedly pursue failed ideas. The non-stop treadmill of competition for new PhDs, new postdocs and new staff with very little flow out the top and the pressure to publish 2-3 papers a year and get cited means no time to start whole new research directions or take risky decisions. With a healthy experimental situation – eg. the 70s in particle physics, right now in gene editing – this environment probably works quite well for making rapid progress.

Regarding switching from elementary particle theory to condensed matter. Many people, young and old, I have interacted with seem to view theories about fundamental particles as not just intellectually, but morally superior. I think the continued existence and even growth of apparently moribund ideas will continue as long as this view persists.

22. **anon**
August 12, 2016

I wouldn't consider the situation in life sciences (e.g., gene editing) as quite that good. There's a huge oversupply of recent PhDs who are slaving in low-paid (usually a paid a lot less than in physics) postdoc positions for years. And there's no shortage of of bad (inconsequential, plain wrong or in worst cases downright fraudulent) papers.

23. **Mitchell Porter**
August 12, 2016

WLM, see e.g. arxiv:1607.02843 for fruits of N=4 research.

24. **Thomas Larsson**
August 12, 2016

Navneeth:
Yes, the LHC have only gathered a fraction of the data at full energy, but IIRC statistical errors only decrease with the square root of the integrated luminocity, so error bars will only go down with one order of magnitude or so. Besides, there are other experiments, like PEDM and proton decay, which also point at no BSM physics.

Radioactive:
As I said, 95% of the universe's mass is dark, *if* you interpret the observations within the framework of QFT+GR. But my impression is that most plausible models of dark matter lead to BSM physics at LHC scales, so there is a cognitive dissonance with the null results from LHC. But a modification of the QFT+GR framework would of course also be a kind of BSM physics.

Bee:
People talked about the Big Desert back when I was a student, but nobody believed in it then. And it is incompatible with the standard interpretation of dark matter and energy, right?

My argument against BSM physics, apart from the obvious fact that it is disfavored at the LHC, was the criticality of the Higgs mass. This is not my idea – the authors of arXiv:1307.3536 call it the principle of living dangerously.

25. **Jonas**
August 12, 2016

Thomas Larsson,
As far as I understand things the non-zero neutrino mass is BSM, so we already have such data. It's just not related to SUSY or similar things.

26. **NoGo**
August 12, 2016

Perhaps one more direction where BSM physics might come from (apart from colliders, comsology, and neutrno detection):

http://arstechnica.com/science/2016/08/researchers-orbit-a-muon-around-an-atom-confirm-physics-is-broken/

27. **Shantanu**
August 12, 2016

Thomas, forget dark matter. But don't neutrino oscillations already tell us there must be BSM physics? After all that's why last year's nobel was given

28. **Peter Woit**
August 12, 2016

All,
The neutrino mass story is complicated, I don't think "BSM/non-BSM" is very useful. One project planned for when I have some time is to get unconfused about some aspects of that story, maybe will write about it here if I manage that.

NoGo,
For, this, there's the ever reliable and topical Natalie Wolchover, with
https://www.quantamagazine.org/20160811-new-measurement-deepens-proton-radius-puzzle/
which includes

"Still, Pohl is highly skeptical that the puzzle is evidence of new fundamental physics."

29. **Anonymous**
August 12, 2016

"I suspect this is an example of devotion to string ideology sending someone in a direction quite different than where the actually interesting things being learned about amplitudes might be pointing."

What is the direction that the actually interesting things being learned about amplitudes might be pointing? Is there any technical reason for this comment?

30. **Peter Woit**
August 12, 2016

Anonymous,
I'm no expert on amplitudes, so,it would be silly of me to claim to know technically what people studying amplitudes should be doing. It seems to be a rich subject with many possibilities. The point of the comment was just that using the subject to try and find a way to make a dubious nogo argument for string theory is the kind of thing you get into if you are enthralled by a dubious ideology rather than the logic of the subject itself.

31. **tommaso dorigo**
August 15, 2016

Hi Peter,

thanks for the link. Maybe something that other commenters have not pointed out here is the importance of the present status of things for the next forty years. We are in a difficult situation as we need to plan the next big machine now, and we do not know what is the right thing to do. Since experiments are not giving any hint of what direction to take, it seems natural to go for a precision machine that will measure the Higgs boson properties in detail – an e+e- collider reaching several hundred GeV but not more. That thing will improve our knowledge of what we know already, but will most likely not discover anything new, like the much glorified LEP and LEP-II.

If no investment is made in the near future in a big new hadron collider (which should have one order of magniture larger energy to make any sense) or an entirely new-concept muon collider (which is very challenging and probably as of yet unmotivated), we risk that humanity remains stuck for a long while; in the meantime, we will lose a whole generation of machine developers and detector builders, without a chance of transferring their know-how to the new generations.

(I must say that regardless of the above threat, I remain of the opinion that no choice should be made now, as we should rather keep waiting for new developments in the neutrino sector and in other related fields of experimental physics before committing to building some new big toy that might not be the right thing).

In summary, the situation may look good to NAH, but experimentalists have little to rejoice here.

Cheers,
T.

32. **vmarko**
August 15, 2016

Hi Tommaso,

"Since experiments are not giving any hint of what direction to take, it seems natural to go for a precision machine that will measure the Higgs boson properties in detail"

It seems to me that the experimental results from the LHC are actually giving a very strong hint which direction to take next — study IR physics, maybe also Higgs precision measurements, and abandon high energies for now. Certainly, it's a gloomy prospect, but a precision-measurements machine can maintain the knowledge base and the craft of building particle colliders until there is a development suggesting there is something to be found at higher energies.

In my opinion, we are better off developing methods to study the high energy frontier by catching cosmic radiation. Only there we stand a chance to find out that there is something interesting to look for, and at which energy scale to expect it. And only once we find that out, it makes sense to build another collider, at the appropriate energy scale to study it. I know, it's tough, luminosity from cosmic rays sucks, but the no-new-physics situation at the LHC leaves us little choice, IMO.

Best, 🙂
Marko

33. **Peter Woit**
August 15, 2016

vmarko,

My impression is that it's not just that the luminosity from cosmic rays sucks, but that, at center of mass energies above the LHC scale, it's useless for since you're highly unlikely to see any events probing very short distances.

To get more precise information about the Higgs, one needs a new high-energy machine. A lepton collider that could produce and study Higgs particles would have lower beam energy than the LHC, but still would be higher than LEP, extending collider technology to higher energies.

34. **NoGo**
August 16, 2016

Peter,

Thanks for the link to Natalie Wolchover's piece. Indeed, it is very informative, and is far more level-headed than other coverage of these experiments I've seen.

Still I wonder, perhaps naively, if some significant progress towards BSM can be made by improving sensitivity of detectors, and increasing calculation power of computers used, rather than "smashing things harder". (I confess that the sensitivity achieved by LIGO still blows my mind… Of course it's a different area of research, but demonstrates how far one can go). Isn't it true that the effect of "heavier" quantum fields can be in principle detected even if colliders lack the energy to actually create particles of such fields?

I admit that what made me jump up and down about muonic deuterium experiment is that, if it turned out BSM physic, it might shed some light on generation problem. As a non-physicist, again perhaps naively, I find the generations to be the most unsatisfactory part of SM, evidence for something else. I can in principle buy (with cringed nose) anthropic explanation for the rest of SM feathers, but not that one…

35. **Peter Woit**
August 16, 2016

NoGo,
In essence what these experiments are doing is creating a highly excited state (by colliding protons), then looking at the long-lived states this decays to, and using this to study the physics at a high energy scale (in principle one might indirectly even get information about scales higher than the accelerator is producing). The detectors are quite sensitive in the sense of identifying the decay products, more sensitivity of this kind I don't think would help much. The problem is the large number and complexity of the decay products, making it very challenging to extract useful information about the processes that produced them. So, the sensitivity challenge is that of extracting a small interesting signal from a much larger uninteresting one. This is what HEP experimental analyses are all about, and their methods are highly sophisticated, using as effectively as they can a huge amount of computational power.

Yes, the generations are a great mystery and in principle a different behavior than expected of muons could shed light on it. But it's very hard to think of what could plausibly explain such different behavior, at low energy scales that we think we understand well. Thus the skepticism about a non-Standard Model explanation of this.

36. **GoletaBeach**
August 17, 2016

Nature is natural by definition, and if there are no thresholds of new physics crossed at the LHC, that must be perfectly natural.

It is perfectly fine for the neutralino of SUSY to be far lighter than all the other superpartners. The photon, mostly the neutralino superpartner, is far lighter than all the normal partners.

A 1 TeV neutralino is perfectly fine for even the absolutely simplest SUSY phenomenologies, with all other superpartners out of reach of buildable colliders. That neutralino might be seen in the direct dark matter experiments or the indirect ones.. no problem.

https://idm2016.shef.ac.uk/indico/event/0/contribution/32

Or it might not. Whichever it is, all perfectly natural, because natural always is what nature chooses.

37. **TS**
August 17, 2016

I am reading the exchange to say that no one around believes that B-factory experiments will discover anything worthwhile? Well, make that singular, as there's only going to be Belle II. Anyway, did the biggest new particle accelerator experiment slip everybody's mind?

I can't help wondering what B-physics could achieve if as much brain power was devoted to it on the theory side as is to high-energy phenomenology or string theory.

Various News

August 19, 2016
Categories: Uncategorized

Before turning to other topics, congratulations to my Columbia colleague Wei Zhang, who was awarded the Gold Medal at the recent ICCM in Beijing.

On the HEP physics front, some news is:

- On Monday at 1:30pm Danish time, at the conference on Current Themes in High Energy Physics and Cosmology that is part of the Simons Program at the Niels Bohr International Academy, there will be an event adjudicating the bet on SUSY first made in 2000 (described here, the wager is here).

  Nima Arkani-Hamed will act as referee, a bit unconventional since he's on one side of the bet. On the other hand, it's clearly the losing one and I have no doubt he'll concede graciously. Others who may be heard from as part of the event include David Gross and Gerard 't Hooft.

  Video streaming should be available at this site, I guess the time is 7:30am New York time, maybe I'll be up and watch during breakfast…

- In related news, Frank Wilczek has conceded loss on a similar bet he made back in 2009 with Garrett Lisi, see here.
- As for other similar bets I'm aware of, Lubos Motl is about to lose his bet with Adam Falkowski, and David Gross should be losing his with Ken Lane within the next year (perhaps he'll comment on this on Monday). The interesting story to watch here will be whether this changes anyone's behavior. Will Gross, Wilczek and others continue to point to SUSY extensions of the Standard Model as the promising future of the field, or will they acknowledge that this is an idea that hasn't worked out?
- In other HEP news, the "nightmare scenario" seems to have driven physicists at CERN to try human sacrifice to propitiate the angry Gods who are tormenting them in this manner.
- There's a conference going on in Banff organized by FQXI, and you can follow it to some extent on Twitter. I'm somewhat of a skeptic about claims to have deep new insights into physics based on what seem like simple, vague natural language arguments. Not clear if the 140 character limit of Twitter is a good or bad thing in trying to capture such arguments.
- Another of the vague sort of claims I'm dubious about is the "ER=EPR" one described here. On the other hand, this at least appears to have important applications.
- Also on the dubious HEP news front, there have been lots of news articles recently about a supposed new "Fifth Force", generated by a press release from UC Irvine promoting a PRL paper by UCI theorists. This story had been debunked a couple months ago by Natalie Wolchover at Quanta (see here).

  The usual hit on science journalism is that the work of scientists is hyped and misrepresented by journalists, but I think this shows an all too common example of the real problem: hype from physicists and their institutions (egged on by PRL), with journalists trying to hold the line against it (and not always succeeding).

- Finally, there's a wonderful interview with Edward Witten (part of a TV program in Dutch) that I would guess was filmed in ~~1999-2000~~ and is available here. Witten is there quite optimistic about the prospects of string theory, and of course I'm curious whether and how the intervening years have changed his point of view. On other topics the interview is quite fascinating, doing an unusually good job of getting the normally reticent Witten to talk a bit about life and wider issues (as well as demonstrating an admirable refusal to get provoked into pontificating about various questions he's not expert in).

Update: For a detailed explanation from one of the theorists working on the supposed "fifth force", see here.

Comments

1. **NoGo**
   August 19, 2016

   Well, if I correctly understand Natalie Wolchover's article, the fifth force "discovery" is not completely dead yet:
   [[Their history "is reason for pause," Thaler said, but "I still think follow-up studies on this intriguing anomaly should definitely be performed."]]
   Although given the history of Atomki group as described in the article, I am not holding my breath…

2. **Peter Woit**
   August 19, 2016

   NoGo,
   I think if one reads the full article, there are some devastating comments from experts, with "Their history "is reason for pause," " a polite version of "this is almost certainly nonsense".

3. **Peter Woit**
   August 19, 2016

   NoGo,
   By the way, at least one of the authors has a history with this kind of press release, see
   http://www.math.columbia.edu/~woit/wordpress/?p=335

4. **Shecky R**
   August 19, 2016

   FWIW, John Horgan noted in a recent column that Witten had told him in a 2014 interview that he still thought string theory was "right" and would be validated in time.

5. **Peter Woit**
   August 19, 2016

   Scheky R,
   I know Witten is still optimistic that string theory will in some sense work out, but I'm curious what effect the negative results of the last nearly 20 years have had on how he sees this. The Dutch interviewer did a great job of getting him to talk about various things, maybe he's willing to go back to the IAS for an update…

6. **Robert Garisto**
   August 19, 2016

   > egged on by PRL

• The experimental paper is subtitled "Possible Indication of a Light, Neutral Boson," not evidence or observation. That is a weak claim.
• The abstract says that it "could possibly be due to nuclear reaction interference effects or might indicate that, in an intermediate step, a neutral isoscalar particle".
• The first phrase is not present in the preprint for the paper…
• We did not highlight either paper or issue a press release on them.
• Editors get to, in the end, accept or reject.
• We do try to be sure claims match the evidence, as in this case. Did they discover a new boson? Possibly, but probably not. The paper does not claim discovery of a new boson.

7. **Tim M.P. Tait**
August 19, 2016

Peter,

In addition to Robert Garisto's comments, which are all accurate and fair, as far as I can tell, I am deeply disturbed by the way you choose to portray the experimental results by Krasznahorkay et al which appeared there or our theoretical interpretation. Both are suitably cautious and do not claim a discovery. I defy you to find a quote or interview by any of the scientists involved in which the need for verification is not stressed. So where is the hype? It's not coming from the scientists.

You are grossly mischaracterizing the article by Natalie Walchover in Quanta magazine, which, while it does contain several sobering quotes from experts, by no means "debunks" anything. All but one had nothing more to say than that there were earlier reports at a different mass. Are those earlier results inconsistent? We don't even know because no one has mentioned the uncertainty on the earlier determination. Particle and nuclear experiments recalibrate their energy measurements all of the time. One of the experts she quoted from the Michigan State cyclotron said much stronger things, but backed them up with no specific detailed criticism. That's hardly convincing.

Extraordinary claims require extraordinary evidence. No one has made such a claim, and the scientists involved have all agreed that more evidence is needed. Before you start declaring it all to be hype and assigning blame, it would be more convincing if you actually had a clear idea of who has said what and presented the situation as it is, not as you think it should be.

8. **Peter Woit**
August 19, 2016

Tim Tait,
I strongly disagree with you about the Wolchover article, which I think is an excellent piece of reporting and makes a devastating case that this is an experimental result that one should be extremely skeptical about. I won't go through what I think you have wrong, but here's one specific example: you say "no one has mentioned the uncertainty on the earlier determination" but if you look at the paper it says 13.45(30) MeV (compare to the latest claim of 16.70 +/-.35+/-.5 MeV).

Given such skepticism, experts can argue about whether PRL should have published the experimental result, but I don't think anyone can seriously argue that the stories all over the press about a new fifth force of nature are anything other than highly misleading. And they're all due to the "UCI physicists confirm possible discovery of fifth force of nature" press release. Do you really think that press release with that headline was a good idea?

Robert Garisto,
Maybe I'm wrong, but I was under the impression that PRL encourages authors to have their institutions issue press releases like the UCI one when a paper is published. If I'm wrong I apologize. If I'm right, what do you think PRL should do about misleading press releases about PRL papers? What if this is a repeated phenomenon? I'm referring to the Northeastern press release discussed here:
http://www.math.columbia.edu/~woit/wordpress/?p=335

9. **Tim M.P. Tait**
August 20, 2016

Peter,

To be clear, I do not have any problem with the Wolchover article, just with your mischaracterization of what it says.

Furthermore, the claimed uncertainty on the curren mismeaurement is not what is relevant here. What is relevant is the claimed uncertainty on the previous claim.

Finally, again, if you wish to claim that the scientists are the "bad guys" here, point to one place where they overhyped the situation. If you have no example, then concede that this part of your statement is unfounded.

10. **Peter Woit**
August 20, 2016

Tim,
The most egregious and problematic example of hype here is UCI putting out a press release with the headline "UCI physicists confirm possible discovery of fifth force of nature". It seems to me that scientists have some responsibility for this kind of thing. In particular, given the long history in this field of such overhyped press releases, anyone dealing with their institution's press office should be well aware of the potential problem and take steps to make sure this doesn't happen.

11. **Frans Langelaan**
August 20, 2016

A big thank you for the link to the Witten interview, which in turn lead me to a DVD box of "Van de schoonheid en de troost" (dutch for "Of beauty and consolation) which consists of 14 dvd's with interviews (each appx. 1.5 hours long, by Wim Kayzer, the same who interviewed Edward Witten) with Wole Soyinka, Roger Scruton, Jane Goodall, George Steiner, Vladimir Ashkenazy, Steven Weinberg, Martha Nussbaum, Karel Appel, Edward Witten, Elizabeth Loftus, Rutger Kopland, Gary Lynch, Stephen Jay Gould, Dubravka Ugresic, Simon Schama, Catherine Bott, John M. Coetzee, Richard Dufallo, Leon Lederman, Rudi Fuchs, Tatjana Tolstaja, Freeman Dyson, Richard Rorty, György Konrád, Germaine Greer, Yehudi Menuhin.

It must have aired here in the Netherlands some years ago, but I suspect, as is often the case with programs of this quality, at a time when I was fast asleep in bed. I wasn't aware of the existence of the show, but Wim Kayzer has a pretty terrific reputation and I could not resist ordering the box right away, looking forward to long winter nights…

12. **Anon**
August 20, 2016

If you listened carefully to –all of– the interview with Witten you'd have immediately concluded this *could not* possibly be 99-00, but *significantly* earlier. It is amusing to see his consistency regarding consciousness…

13. **Frans Langelaan**

August 20, 2016

The series of which the Witten interview was part of dates to 2000.

14. **Peter Woit**
August 20, 2016

Anon,
The video was broadcast in 2000. Witten at some point refers to the current situation as three years or so after a big breakthrough, with understanding of that now consolidating, (I'm paraphrasing from memory). At first I thought he might be referring to AdS/CFT, but more likely he was referring to M-theory and 1995. So, my best guess would be 1998 or 1999, but if anyone has a source for the actual date, that would be interesting.

15. **Anon**
August 20, 2016

I wonder if Kane will also be giving conceding defeat on SUSY?

He wrote on Tomasso's blog in December 2015:
http://www.science20.com/a_quantum_diaries_survivor/supersymmetry_is_about_to_be_discovered_kane_says-160367

"Now that we can predict the gluino mass from compactified M theory we know that superpartners should not have been expected in LHC Run 1 because the gluino mass is about 1.5 TeV, and it will appear in Run 2 once the luminosity gets over 15-20 fb-1."

16. **A Nony Mouse**
August 20, 2016

I didn't know that the death of a model was dependent on bets.

17. **Anon**
August 20, 2016

"So, my best guess would be 1998 or 1999, but if anyone has a source for the actual date, that would be interesting."

It was probably around 1996 judging by his discussion of the CC problem –clearly pre-1998– and the age of his children…

18. **Michael Shain**
August 20, 2016

Regarding the CC, in the interview Whitten says "suspecting the answer is zero guides a little bit my choice of attempts to solve problems". I wonder how approach to problem solving changed after 1998?

19. **Nope**
August 20, 2016

In the same video series there one with Freeman Dyson
https://www.youtube.com/watch?v=rBSnCfAcaek
and shortly after the 30 minutes mark it is stated that this interview happened in 1997. It seems reasonable to assume Witten's interview is from the same year.

20. **anon**
August 21, 2016

I found the interview with Witten very embarrassing to watch at the end: Witten would give a complete answer, the interviewer couldn't think of anything further to immediately to ask, long awkward silence with the camera still focused on Witten, Witten squirming with embarrassment.

The interviewer then got very personal by asking Witten about whether the holocaust affected him, which it obviously did looking at how uncomfortable he was with even thinking about the question. Again, awkward pause from interviewer.

21. **Peter Woit**
August 21, 2016

anon,

I think you're misunderstanding what the interviewer was doing. Witten is often quite reticent in conversation and the interviewer was trying to push him to say more. The interviewer's tactics made for some awkwardness, but I think he did get Witten to say more than he usually would have on some topics, which was interesting to hear.

22. **Anonymous Coward**
August 21, 2016

According to this webpage of the Netherlands Institute for Sound and Vision, the air date of the Witten interview is Feb 27th 2000.

http://zoeken.beeldengeluid.nl/internet/index.aspx?chapterid=1164&filterid=974&contentid=7&searchID=2169206&columnorderid=-1&orderby=1&itemsOnPage=10&defsortcol=12&defsortby=2&pvname=personen&pis=

23. **MathPhys**
August 21, 2016

I agree with anon that watching the interview was embarrassing in the sense that I felt that Witten was less than well treated. Witten made it perfectly clear that he has nothing to add regarding the Holocaust. Then there were these long pauses during which I'm fairly confident that Witten expected either a change of topic, or a cut in the filming. Instead, the filming crew pressed on. They were no doubt expecting to be able to film him get emotional. Witten's performance was impeccable. As a scientist, he was obviously happiest whenever he could steer the discussion away from personal matters and manage to talk about the universe which is "a wonderful place" that filled him with "awe", etc.

24. **Robert Garisto**
August 22, 2016

Peter:

The most important thing we do is to try and ensure that the claims in the published PRL itself are responsible and reflect the evidence presented. The paper is the version of record, not anything in the press.

There is a generic statement in our acceptance letter to authors suggesting they contact their press people. After all, dissemination of physics is one of our mission goals. It goes without saying that we do not encourage public statements that over-state results. When we are involved in the publicity ourselves, either through our outlets such as Physics (physics.aps.org) or through collaborating with the authors' press offices, we do our part to ensure that the message is scientifically accurate and not overhyped. Of course, we do not have control on the message when it does not involve us.

I did try to combat this particular instance: https://twitter.com/RobertGaristo/status/766331929348145152

25. **Tim M.P. Tait**
August 22, 2016

Peter,

To be honest, I hadn't noticed the title of the UCI press release before now. (I was asked to look over a draft of text before it was posted, which I think is fine as it is, but not the title, and I overlooked it when it appeared on line). Even in the era of click-bait titles running rampant, I am not in favor of that phrasing. I can ask for it to be changed, but that article (like any piece of scientific journalism) is the property of its author, and I have no standing to demand anything of it.

I still think your blog entry does a disservice by accusing many people of many things which they are not responsible. Robert has addressed PRL's role as far as the press is concerned, and has only touched on the fact that the articles which appear in PRL are subject to peer review involving at least two anonymous referees. That process is hardly fool-proof, but compare the track record of PRL with something like Science or Nature, and you'll find that over-statements leading to retractions are not the norm in PRL articles. Similarly, the scientists themselves have been measured and cautious in every communication that I have seen, and you have not provided an example to the contrary.

Finally, what I consider the most serious problem with what you wrote is in regard to the work of the Hungarian group led by Krasznahorkay et al. The article by Wolchover (which apparently both of us thought was well done) does not "debunk" anything. You saying that it does is not fair to her, nor to its subject matter. It contains one very negative comment (and several cautious ones), but that comment itself does not offer any informed indication as to why one should discount Krasznahorkay et al.'s work. So either it is his uninformed opinion, or somehow the reasoning was not included in the text of the article. I have no way to know which it was, but given the over-all thoroughness I see in other parts of that article, I suspect the former. If there are any serious flaws in the work of Krasznahorkay et al., someone should point them out. Taking random potshots at them without being informed of what they did or did not do wrong does nothing to advance scientific understanding.

So while I concede that there is a certain amount of hype in the title of the UCI press release, I would suggest that by over-stating the evidence against the result, you are engaging in a different kind of hype. I would be in favor of reducing over-statements on all sides.

26. **Peter Woit**
August 22, 2016

Tim,
It was not my intention to criticize here the PRL papers (in particular I have zero competence with regards to evaluating the experimental one). I think we're just going to have to disagree about the implications of Wolchover's story on one's evaluation of the credibility of the experimental result. Yes "debunk" is strong, but as a short characterization of the situation I think it's defensible.

Obviously what I wrote about this is motivated by a pet peeve, due to seeing way too many examples over the years of highly misleading press stories like this latest series. These things almost always come from the same mechanism: PRL paper generates problematic press release generates misleading stories. For HEP theory PRL papers that generate press releases, it seems to me the majority lead to misleading stories (unless they're completely ignored). This is not good at all for the public understanding of science. One can argue that the fault is that of the journalists who write the misleading stories, which is part of the problem, but I do think the phenomenon of bad press releases is a big part of the problem, and both PRL and physicists involved need to be aware of this and think about what they can do about it.

One starting point would be to first think twice about whether a press release is really a good idea. PR people have an agenda, and it's not caution and scientific accuracy. Once a piece is written, quite likely an editor is going to read it quickly and put the most attention-getting headline on it that they can think of, this is their job. Some non-expert journalists getting the press release are going to pay more attention to the headline than to the content, and are going to miss carefully hedged caveats. It seems to me that this case shows what goes wrong pretty clearly, would be a good idea if people involved, from PRL on, think about what can be done to improve the situation.

Not Ever Wrong

August 22, 2016
Categories: Uncategorized

The "SUSY Bet" event in Copenhagen took place today, with video available for a while at this site. It appears to be gone for the moment, will put up a better link if it becomes available. An expensive bottle of cognac was presented by Nima Arkani-Hamed to Poul Damgaard, conceding loss of the bet. On the larger question of the significance of the negative LHC results, a recorded statement by Gerard 't Hooft (who had bet against SUSY), and a statement by Stephen Hawking (not in on the bet, but in the audience) claimed that if arguments for SUSY were correct, the LHC should have seen something, so they think nature has spoken and there's something wrong with the idea.

The losers of the bet who spoke, (Arkani-Hamed, David Gross and David Shih) demonstrated the lesson about science that supersymmetry and superstring theory have taught us: particle theorists backing these ideas won't give up on them, no matter what. They all took the position that they still weren't giving up on SUSY, despite losing the bet. In more detail:

- Arkani-Hamed was not a signatory of the original bet in 2000, but signed on to the later 2011 version. He explained today that at the time he thought chances of SUSY visible early on at the LHC were just 50/50 (with his 2004 work on split SUSY motivated by realizing that pre-LHC the conventional picture of SUSY at the electroweak scale was already ruled out). He attributed his decision to take the pro-SUSY side of a 50/50 bet to "optimism", implying that this took place at a conference dinner where there may have been too much to drink. In his split-SUSY scenario, SUSY may yet show up at the LHC, or it could even be invisible there, requiring a higher energy accelerator. So, he's not giving up on SUSY based on LHC results.
- David Gross also is not giving up, arguing that fine tuning of a factor of 100 or 1000 is not a problem (invoking the large ratios that appear in the fundamental Yukawa couplings). He did say that young people might want to take this as reason to look for new ideas, but, for himself, felt "I'm too old for that".
- David Shih isn't giving up either, arguing that there still was lots of data to come, plenty of room for SUSY to appear at the LHC, still believes we'll discover SUSY, at the LHC or elsewhere.

One piece of misinformation promoted by several of the speakers was the idea that "everyone" back around 2000 believed in SUSY as the next new physics to be found. In my book (written in 2002-3) I wrote a long section about the evidence against SUSY, and, of course, if you look at the bet under discussion, in 2000 many more people (16 vs. 7) were taking the anti-SUSY vs. pro-SUSY side (at least in Copenhagen, but I think this reflects the general range of opinions).

No one today asked the obvious question "Is there any forseeable experimental data that would cause you to decide that SUSY was an idea that should be abandoned?". I'm now not seeing any prospect in my lifetime of anything that would cause these or other SUSY proponents to give up (John Ellis has also announced that no matter what the LHC says, he's not giving up). Unfortunately "Not Ever Wrong" is clearly the slogan of the (minority) segment of the particle theory community that long ago signed up for the vision of fundamental physics in which SUSY plays a critical part.

Update: There's a blog entry from Natalie Wolchover about this. She has more detail about the final remarks from Gross that I mentioned:

> "In the absence of any positive experimental evidence for supersymmetry," Gross said, "it's a good time to scare the hell out of the young people in the audience and tell them: 'Don't follow your elders. … Go out and look for something new and crazy and powerful and different. Different, especially.' That's definitely a good lesson. But I'm too old for that."

Update: Video of the Copenhagen event is available here.

Update: I happened to be looking at Michael Dine's 2007 Physics Today article on string theory and the LHC, noticed the side remark that "The Large Hadron Collider will either make a spectacular discovery or rule out supersymmetry entirely." I wonder if he still thinks this, and whether we'll ever see Physics Today publishing something updating its readers.

Update: Yet another news story about this, from Science News.

Comments

1. **GoletaBeach**
   August 22, 2016

   So… what experiments should experimentalists do, Peter? Should we fold up shop and give up because some theorists lose bets?

   I think there has never been doubt that going to the energy frontier is always the best experiment to perform. Mel Schwartz used to emphasize this point; he did lots of clever experiments, from being the prime mover in the nu_mu discovery to (pi mu) atoms to very clever exploitations of the SLAC facility in doing K0L physics.

   The argument for the energy frontier among experimentalists never depended on some theoretical bets… primarily it depended on discovery potential for something completely new. To the extent theorists have enabled marshalling resources through hype to get the machines built, they are useful. If they are wet blankets they should be ignored.

   If they overhype… well… James Watson's rule kicks in… if you overhype and are wrong, the only penalty is embarrassment, and there is always a chance your wrong hype will stimulate the right idea. If you underhype you risk 1)the right idea might never germinate and 2)the needed experimental work might very well never get performed.

   How hilarious it has been to read "Tunnel Visions" and read some of the rationale in 1993 for killing the SSC. The need to focus on economically remunerative research was a big argument. Meanwhile, the single biggest economic force since 1993… the world wide web… was invented at CERN to assist particle physics. Irony factorial.

   The non-signals at the LHC tell us that a proton collider should be the next energy frontier machine, not a lepton machine. Precision Higgs studies are the role of e+e- in the future. Prepare, Peter, for all the hype from people you find frustrating to get those projects done. It will take decades, but the allure of the energy frontier will never die.

   Meanwhile lots of clever low energy experiments are underway. Likely, though, that there will be the usual fights to cease basic research and spend all scarce research funds on a new Facebook or something. Perhaps that is what the result of your negativity might be, Peter.

2. **Urs Schreiber**
   August 22, 2016

   It is good to remember the difference between the variants of "low" energy susy checked at LHC, and high energy susy, namely supergravity. No known mechanism exists which would force a supergravity theory to settle in a vacuum that preserves a global supersymmetry (which is what the LHC could see), while there are excellent theoretical arguments for supergravity itself, i.e. for high energy susy: Besides sugra being a prediction of spinning strings (the spectrum of the spinning string miraculously exhibits spacetime supersymmetry) there are some strong general mathematical arguments, such as Deligne's Tannakian theorem on tensor categories and its implication for supersymmetry.

3. **Low Math, Meekly Interacting**
   August 22, 2016

   Hi, Goleta Beach,

   I don't think you're being realistic here, and Watson's nonsense about overhyping is directly refuted by the example of the SSC. In retrospect, it actually took outrageous hype to defend the thing, and it still got killed. By the standards of any other field in science, SUSY has completely and utterly failed as a "natural" explanation for the Higgs mass, and it has failed equally to supply a realistic WIMP. It's only in HEP, apparently, that a theory can crater so dramatically and still be tweaked in such a way as to receive endless and unconditional support. One never encounters anywhere else such boundless trust in "beauty", as judged by a miniscule fraction of the overall physics community.

   They may be right. The universe may indeed be supersymmetric. But at what energies should it be sought for, if not the TeV scale? The LHC got funded because there was such a high degree of confidence that the Higgs (be it fundamental or composite) would be discovered at accessible energies. And there was a ton of hype about SUSY to ice that cake. Now the Higgs has been discovered, and it's not supersymmetric. Rather, it's super-standard. If SUSY exists, it's fine-tuned to at least some degree, we now know that much. But by how much? How can anyone answer with confidence anymore, except to say it could be any value up to energies we will never be able to probe? Has anything of the scale of the next-generation collider been funded based on such uncertainty of discovery?

   I personally would gladly vote to build such a machine anyway, just in case. Sadly, people like me aren't in charge, and the example of the SSC tells me HEP researchers have a vertically-steep uphill battle ahead of them to convince those who hold the purse strings to commit to such an expense. And they will need a better argument than "well, you never know…" The overhyping of SUSY will likely factor directly and powerfully into the skepticism of the funders those future researchers will face, and I'm inclined to predict it will be the field's undoing unless a much better idea is discovered, and soon.

4. **Peter Woit**
   August 22, 2016

   Goleta Beach,
   I think what experimentalists should do is pretty much ignore unconvincing beyond the SM models, and go about the business of exploring the energy frontier as best they can. Such models may have some useful role in motivating ideas about what searches to do, but, especially given how they haven't worked out, people should be careful to not let them have too much influence over what searches get done and what don't.

   As for the next collider, I do think there should be one, but that considerations of what to build should not be significantly influenced by arguments like "this machine is better because it will have better reach for superpartner X". In terms of selling a machine to governments, some hype is unavoidable, but if you're going to engage in over the top hype, you should avoid blowback to your own community, not engage in it at technical conferences for instance. The main problem I'm concerned about is theorists believing their own hype.

   The politics of a new collider are going to be very tricky. All that's clear to me is that this is hopeless in the US right now, there's no way that is going to happen, no matter how much hype you engage in. I have zero understanding of what the Japanese and Chinese situation is. In Japan, with negative interest rates, you might think that building a very expensive machine would make money, not cost money… As for CERN, I also don't know much, but if I had to guess, I'd guess any project that could fit in the envelope of the current level of funding should be salable, anything that would cost a lot more will likely be hard to sell (no matter how much hype…). More specifically, I'd guess that a new 100km ring is going to be hard to get, but anything you can imagine putting in the LHC ring (ep machine, HE-LHC) much more plausible.

5. **GoletaBeach**
   August 22, 2016

   To Low Math… well, "Tunnel Visions" tells a quite different story of the demise of the SSC. A bit more realistic about how things actually work, as opposed to a theoretical guess as to how US funding works.

   The theorists (as serious as Steven Weinberg) were hardly listened too… meaning, overhype didn't kill the SSC. Much stronger budget winds, the demise of the Soviet Union, and the reconciliation of HEP v. billion dollar project management styles in the US forces were all way more important than the hype was. Basically the theory hype has to be there but in politicians minds the difference between Steven Weinberg saying "This is important" and him saying "If you fund this you will get the Starship Enterprise built before Russia does" is squat. Both arguments saturate the "science good" meter.

   As for SUSY being unnatural, I disagree, as I said earlier:
   "A 1 TeV neutralino is perfectly fine for even the absolutely simplest SUSY phenomenologies, with all other superpartners out of reach of buildable colliders. That neutralino might be seen in the direct dark matter experiments or the indirect ones.. no problem.

   https://idm2016.shef.ac.uk/indico/event/0/contribution/32

   Or it might not. Whichever it is, all perfectly natural, because natural always is what nature chooses."

   My decades in physics have taught me how right Watson was. His view is not nonsense at all… the reason being, the path to truly important discoveries is usually circuitous and not linear at all. Thinking that it is easy to predict the serendipity of discovery the real nonsense.

   Increasing beam energy is always the best route to a fundamentally new discovery, whether it is SUSY or not. Integrated luminosity at a hadron machine does help because in essence (the parton distribution functions) it does slowly increase the available energy. But slowly. Getting more energetic beams in the long run is needed, no matter what.

   Thanks Peter. Probably the kind of thinking that is needed… if the field can think of a way to get, say, 3X the energy for the same cost as the LHC, that should trigger a new collider. Innovation is essential to achieve that. That the direct work product of collider physics has economic value has always been a ruse.

   On the other hand, the indirect work product, from every light source in the world to the world wide web, are rather powerful arguments to keep the endeavor going.

6. **Lino D'Ischia**
   August 22, 2016

   Remember what Planck said.
   "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

It was true a hundred years ago; and, it is true now. David Gross is onto something with the remark you attribute to him.

7. **srp**
August 22, 2016

Goleta Beach:
1) The U.S. got the benefits of the web without tossing the additional billions that were still needed into the SSC.
2) Glad you may be seeing the light on the need for accelerator innovation. It would be encouraging to this non-physics taxpayer if the particle community would stop trying to build scaled-up versions of what they already know how to do and invest at least a few hundred million dollars in advanced accelerator concepts, if only to rule them out. Both rational and sales-oriented considerations make it desirable to pursue new technologies offering the potential to drastically cut the cost of the energy frontier.

8. **Low Math, Meekly Interacting**
August 22, 2016

Hi, Goleta Beach,

I'm pretty familiar with the sad story of the SSC, though I'm sure not as much as yourself. What I meant by "in retrospect" is that anyone looking back will think themselves justified in ignoring the eggheads with their expensive toys and killing the thing even when, back then, the scientific argument looked substantially better. Because those eggheads got it rather wrong anyway.

As for the question of naturalness, I'm also looking at history and seeing decades of vehement arguments in favor of SUSY appearing long, long ago, and ever since. Clearly there's always a place where "natural" SUSY can hide, and, if I understand correctly, that will be true forever, given how many knobs SUSY has to twist. I imagine it must be possible to craft a SUSY theory in which SUSY is perfectly natural and 100% undetectable by the LHC, just by having an extreme version of the model in the Quanta article. But why, then, were so many incredibly smart people (including several Nobelists) so thoroughly convinced that the LSP simply had to appear in the LEP? Then the Tevatron. Then in the first run of the LHC? Then they talk about one-part-in-a-thousand fine tuning as being perfectly OK, obviously. And, hey, what does it really mean to be "natural" anyhow? Etc. This has been going on literally for decades. I know of no parallel in science, anywhere. I've seen wrong ideas. I've seen failures. I've seen outright fraud (embarrassing amounts in my own field, in case anyone thinks I lack any perspective at all). But the failure-proofing of the SUSY paradigm seems outlandish. I'm perfectly aware of my own limited intellect; that's why I rely on the testimony of those much smarter people. But their story keeps changing, and my ability to trust their judgment is simply gone.

I don't think it's reasonable to expect continued financial support based on an infinite regression of models "explaining" why the sure bet wasn't, and why we should look just a little bit harder, over and over again. Much better to use your other argument, which is simply "push the frontier".

That said, if I understand correctly, an order-of-magnitude increase in energy will be staggeringly expensive even by the standards of "big science", barring some revolutionary technological breakthroughs (I fantasize about the muon collider, which I'm told is likely a pipe dream). I think without a much more compelling argument for a new discovery than the SSC had going for it back in the day, I'm with Peter: Zero chance in the USA of it passing the laugh test in Congress. The next generation hadron collier will probably have to be in China, mostly for nationalistic reasons. So let's hope the PRC stays stable over the next 40 years or so.

9. **Peter Woit**
August 22, 2016

Lino D'Ischia,
One problem here is that SUSY enthusiasm isn't just something common in Gross's generation. Several generations of theorists since have been trained from their student days in this ideology. Of the comments from the bet losers, it was David Shih who seemed most unconcerned about not seeing SUSY so far, and he is the youngest of them.

10. **Giotis**
August 22, 2016

Jesus, the same story again and again.

SUSY is there; it is alive, well and unbroken at some high energy scale. It's almost a necessity of Nature to be there for strong *fundamental* theoretical reasons.

It is just that along the way people thought that the presence of the Symmetry (if appropriately broken at certain scale) can be justified also from effective field theory point of view using some bottom-up arguments based on naturalness.

So what people are trying to see in LHC now is how much it is broken using bottom-up low energy effective field theoretic arguments based on naturalness.

It is naturalness that is failing here (to the extend that it is failing at the specific LHC scales), but naturalness is just a general strategy used to guess at which scale new Physics is expected to appear; it is unrelated to SUSY per se.

The fact that no new Physics (not just SUSY) seems to appear at LHC just means that the effective field theory doesn't have a clue why Higgs is so light and it's a question for the fundamental theory to answer (this also depends on how much fine tuning someone is willing to accept).

So be it, all it's nice; SUSY should not carry the burden to justify the usage of naturalness by Physicists as a working hypothesis to construct BSM phenomenological models.

I'm sure this is what Gross had in mind and reporters must stop misleading the public with similar eye catching hype.

11. **Peter Woit**
August 22, 2016

Giotis,
"SUSY is there; it is alive, well and unbroken at some high energy scale."
The problem is that such a statement is a religious one, not a scientific one. Gross and the other losers of the Copenhagen bet were betting that SUSY was science, with particular testable experimental implications. Unfortunately for that point of view, they lost. This really is now the question for the future of HEP theory: is it really all right if the field becomes based on a series of untestable claims like yours (which, by the way, I strongly disagree with)?

I think you will find that, post LHC results, your religious views are now those of a small minority of the field.

12. **Michał Pawlak**
August 22, 2016

In 1986 I attended a summer school of physics, where John Ellis was one of the tutors, and had a lecture on SUSY. Asked about experimental prospects of finding it he responded, quote “I will not commit suicide if SUSY is not found at LEP. But if it is not found at the SSC then maybe…”. OK, LHC is lower energy than the SSC, but I’m a bit afraid…

13. **Giotis**
August 22, 2016

I feel I repeating my self so for the last time I will state the obvious.

SUSY as a fundamental symmetry doesn’t make any top down low energy BSM predictions or the scale at which it is broken.

It is naturalness that makes these predictions and not just for SUSY but for any potential new Physics that can be used to explain the Higgs lightness.

These are two completely unrelated issues.

14. **Anon**
August 22, 2016

On a more mundane level, we can at least test David Shih’s optimistic claim that by spring, the LHC will have up to five times the data it had at ICHEP giving 12×5 = 60\fb. Personally, I believe David’s being overly optimistic as with SUSY based upon how things are going right now, and it will be a rather more modest 35\fb.

Also, despite the optimism of Nima and David Gross about this being a great opportunity for newly minted PhDs to come up with new ideas to challenge SUSY, the main problem remains: No new physics has shown up at the LHC to show the way and we need to wait until then.

15. **GoletaBeach**
August 22, 2016

srb… of course no-one predicted the web would come from the expenditures justified for CERN between 1954 and 1993….

What no-one knows is… what innovation did we miss out on by *not* pursuing the SSC… and would it have been as lucrative as the web was? The point is…. serendipity.

Of course much of the condensed matter community was vociferously opposed to the SSC as impractical, focused on wasteful intellectual curiosity that would never lead anywhere. Not one of those SSC antagonists credit high energy physics with inventing the web, though.

There have been intense efforts in accelerator innovation for at least 30 years. In fact, the LHC did benefit from some of the very practical magnet innovations developed for the SSC…. and the LHC ignored some other of the SSC lessons; had they paid attention to them the magnet problems the LHC experienced might have been avoided.

But accelerator physicists are often prevented by practical matters from innovation… they must deliver the beam and aren’t always given enough freedom and support to play with instruments like the LHC and benefit from some serendipity.

Low Math… doesn’t the argument for the SSC look even stronger today? At first glance, the LHC didn’t have sufficient energy to discover new physics. The SSC might have had sufficient energy.

As to why Nobelists predicted evidence for SUSY at PEP-I, SppS, KEK, LEP, Tevatron, LHC… they are optimists. Optimists have a huge evolutionary advantage over pessimists, because optimists make things happen. And sure, we’ll need innovations to keep future collider costs within a reasonable envelope. I’m optimistic that we’ll get them.

As for fine tuning… the universe is already amazingly fine tuned… see
https://en.wikipedia.org/wiki/Fine-tuned_Universe

which omits the surprising fine-tuning of G_fermi, which controls the rate of pp fusion in the Sun.

The only sensible definition of naturalness is: if nature chooses it, it is natural.

16. **wimp**
August 22, 2016

@GoletaBeach, if dark matter consists of 1 TEV neutralinos, wouldn’t LHC, Lux, PandaX, or upcoming Xenon1T detect it?

@Peter Woit – what about neutron and electron EDM measurements? it is conceivable they can find a EDM consistent with SUSY or rule out EDM to SM values, ruling out SUSY, and do not require multibillion dollar colliders.

best

17. **Peter Woit**
August 22, 2016

wimp,
The problem is that these are just two numbers, and if you manage to measure a value too large to be the SM value, you have found evidence for BSM physics, but very little information about what it is, in particular no evidence that it is SUSY.

On the other hand (and this is where we are now), when you find a lower bound on an EDM inconsistent with “generic” SUSY models, SUSY proponents will just say that this doesn’t rule out SUSY, only puts a single constraint on the large parameter space of SUSY models. These EDM numbers have been inconsistent with generic SUSY models with TeV-scale superpartners for a while, but that has had little effect on getting anyone to give up on looking for SUSY at the LHC (although it was one of the motivations for split SUSY).

This is the general problem with low energy experiments that give very indirect access to high mass scale physics. So far all they give is a small number of complicated constraints on BSM models, and if you observe something non-SM you may justifiably get a Nobel prize, but the only information you’ll have about BSM physics is one number, a complicated function of the huge parameter space of BSM models.

18. **wimp**
August 22, 2016

Peter Woit,

i understand what you are saying, but what about an exclusion? finding EDM does not prove SUSY, but a sufficiently low EDM might be able to falsify it.

is it possible in principle that a sufficiently low measured value of electron/neutron EDM – both- on the order of 10^-32 or less, can rule out SUSY, since SUSY generically predict values of EDM much higher than this? i.e if electron, neutron, proton EDM – all three- are measured to less than 10^-32, would that falsify SUSY (assuming no other evidence of SUSY in LHC, rare decays, dark matter searches)?

regards

19. **Peter Woit**
August 22, 2016

wimp,
The problem is that you are falsifying a particular notion of "generic" SUSY model. Given the kind of EDM limits you mention, SUSY enthusiasts could just say
1. SUSY might be "generic", at high enough energy scale.
2. SUSY might be at lower energy scales but "non-generic", or "fine-tuned", just happening to be such that the EDMs are much lower than expected by dimensional analysis.

In any case, the main point I was trying to make is that ruling out SUSY models at higher mass scales might be something you can do with a new collider, but it's not a good motivation for building one. We already know all sorts of problems with such models, and they don't really explain anything, so ruling them out is not an interesting goal. Understanding what physics looks like at multi-TeV scales (and whether it is SM or non-SM) is a good motivation.

20. **Lino D'Ischia**
August 23, 2016

Peter, your response only points out the wisdom of Planck's statement; i.e., only now, after two unsuccessful attempts to see anything of SUSY, will the younger generation begin to distrust this approach. And it will have to be the generation behind the present one. This might take some time. OTOH, I believe that at least some of the youngest generation will begin to look in unchartered areas, and should something prove promising, who knows,maybe the whole field will latch onto that. I think the problem in modern-day science is that opposing viewpoints are so quickly suppressed.

But I can't help feel that all of this should be part of some learning curve for scientists.

21. **Claudio Merati**
August 23, 2016

Urs,
you say that supergravity might be the way to go. How many parameters (instead of the about 20 of the standard model) does it have? Are they fewer than the 105 of usual supersymmetry?

22. **MathPhys**
August 23, 2016

Nature didn't read the paper of Wess and Zumino. Too bad.

23. **Peter Woit**
August 23, 2016

Claudio Merati,
The SUSY models under discussion are generally assumed to be supergravity models, this aspect of them doesn't solve the fundamental problem Urs and Giotis want to ignore: the supposed beauties of the models are wrecked by the necessity of breaking SUSY since you see no evidence of it in the observed particle spectrum.

24. **M**
August 23, 2016

There are good motivations for SUSY. But the main motivation, that weak-scale SUSY makes the weak scale naturally small, is dead. If future data will show evidence for sparticles, it would be like discovering a dead body.

25. **chris**
August 23, 2016

I am a HEP theorist myself and about 30% of my published work deals with new physics searches.

If I had to decide, I would not fund a new collider today.

I am surprised that many of my colleagues still would. They seem to be blinded by some strong observational bias or put sociology over interest in nature. Because if the LHC has told us one thing it is that everything points towards a "dessert" (i put the word into quotation marks as I am again quite surprised that the working of our theories over many orders of magnitudes should be labeled by a derogatory term).

So, let us look at the big picture. Aside from all speculative thoughts there was one big argument why the LHC had to be built: In its energy range there had to be the Higgs or otherwise S-matrix unitarity would be violated. And remember, when we started out the upper mass bound for the Higgs (from triviality) was ~600-800GeV. That is a solid reason to sink O(10) billion.

What has happened now? The Higgs is found and its mass indicates that our vacuum is metastable and something will happen at ~10^12GeV. So again we are in a situation where there is a new energy where we have to see some sort of new physics, just like before. Only this time around it happens to be 9 or so orders of magnitude beyond our current technical capabilities.

Leaving egos, careers, technical expertise and all these aside, what can one conclude from that? I think the logical decision would be that accelerator physics should start confronting the challenge of bridging the gap of 9 orders of magnitude in energy and while they are busy doing that the big money should go to other areas of fundamental physics where progress is just happening at breakneck speed like e.g. cosmology.

As individuals – especially those stuck in the field – we might not like it, but that seems to be the only logical conclusion. Some people seem to prefer to hype their specific model and want to convince the public to commit substantial resources towards investigating if their ideas are correct. But in all honesty, a scientist should know better and clearly separate established fact (like someting new has to show up at around 10^12 GeV) from fantasy (like "SUSY is around the corner").

26. **MathPhys**
August 23, 2016

AGT tells that Nekrasov's instanton partition functions in 4D N=2 SYM can be used to compute conformal blocks in non-supersymmetric 2D critical systems, including the humble Ising model.

These surface critical systems are studied since decades in many different ways, using various analytic methods including 2D conformal field theory, numerical methods, as well as experimentally. The AGT correspondence, which originates in very stringy ideas, leads to results that are in perfect agreement with everything that we know. 4D SUSY is absolutely necessary to obtain these results in 2D non-SUSY systems, and no SUSY-breaking or any approximation of any type is involved in these computations.

If only for this reason, 4D supersymmetry cannot be a totally wacko idea. However, SUSY simply does not appear in high energy physics.

27. **Peter Woit**
August 23, 2016

chris,
Arguments like "we know there's no BSM physics up to 10^12 GeV" from theorists are just as worthless as the "we know from naturalness there has to be BSM physics at the TeV scale" ones. I hope experimentalists have the sense to ignore both of them.

Mathphys,
I agree that d=4 N=2 SUSY is a fascinating theory, (besides the AGT stuff you mention, this is the theory that gives Donaldson invariants and a very deep connection between 4d geometry and topology and physics). People should study SUSY theories like this, while noting that the ones leading to beautiful mathematics are different than the ones used in the failed program to connect SUSY to experiment (e.g. N=2, twisted, vs N=1). I wouldn't be at all surprised if thinking about SUSY and QFT led to some new classes of theories providing new insights into the world, I just think it's clear that the particular class used so far doesn't work.

28. **anon**
August 23, 2016

As someone who worked on SUSY for years, and even did my Ph.D. on a SUSY model, I have to admit that I never was able to see anything particularly compelling or beautiful about the whole idea. I know, I know, the square root of the Poincaré group and all that, but as beautiful and inevitable as I find the mathematics of gravity or gauge theories, SUSY always seemed ugly to me. Personal esthetics, I guess.

29. **anon**
August 23, 2016

Chris, though it would be very nice for this glutton if everything pointed to a dessert, I think you meant to say desert.

30. **Low Math, Meekly Interacting**
August 23, 2016

With SUSY, you really can have your cake and eat it too.

31. **GoletaBeach**
August 23, 2016

To chris… I don't really agree that cosmology is proceeding at breakneck speed. A simple cosmological constant fits the dark energy just fine… B-modes promise to be a long hard slog. Maybe we'll get the average neutrino mass out, that will be good. But hardly breakneck speed.

The arguments you mention about the Higgs & LHC were really arguments for the Higgs & SSC. The LHC got interesting when precision electroweak indicated a light Higgs. The no-lose theorem never applied to the LHC and a heavy higgs.

What you miss is the exploratory aspect of high energy physics. A prominent motivation for experimentalists and machine builders is the unexpected. No theorist predicted the muon, parity violation (actually seen in the 1930's, it is a wonderful story), strangeness, CP violation, neutrino flavor, the bottom quark, the tau lepton… well, the charm quark, the Z0, the W, the top quark, and CP violation in the B system, the Higgs and its mass (roughly)… they did get predicted by theorists.

A requirement of theoretical prediction would, in the past, have resulted in missing about 1/2 of particle physics discovery. Luis Alvarez wrote a wonderful essay in the early 1970's about the necessity to politely and congenially disregard theory regularly (but not always).

Sure, $10 billion ain't easy. But accelerator builders haven't figured out how to get factors of 10 or 10,000 in beam energy because they are lazy. Nobody has figured out economical flying cars either in the past 50 years. Some technological problems are rightfully hard.

There has been however a very nice adiabatic continuous improvement in accelerator abilities. The field needs to support machine guys and not burden them with ideas of flying cars… and don't ever think that innovation is not intensely pursued in the accelerator business. It is, but often theorists are a big ignorant about it.

32. **anon2.**
August 23, 2016

Just a quick question about your book. Are you going to keep the latest free PDF version of the final draft online, even after it is printed? Would the publisher permit that, since it might just reduce sales? (On the other hand, seeing what you're getting like this may be a way to promote and popularise the book, just as browsing in bookstores works.)

33. **Peter Woit**
August 23, 2016

anon2,
My contract with Springer specifies that I retain copyright, as well as the right to make the final draft version available on my web site, which I intend to do (I did learn something from the experience of my first book…)

Right now rereading from beginning, fixing minor things and making various improvements based on comments and suggestions from readers. Pretty thoroughly sick of working on this, hope it's over soon.

34. **Peter Woit**
August 23, 2016

All,
I'm deleting further tired general discussion of topics like particle accelerators and their funding, and hoping for a return to the topic of the posting.

35. **Low Math, Meekly Interacting**
August 23, 2016

I actually was curious about what the current state of SUSY and general BSM physics betting might be, in light of the current LHC results. Maybe the dust hasn't settled enough yet, but it was quite entertaining a few years ago to see all the personal odds estimates being thrown around, as well attempts at generating aggregates for different outcomes. Useless scientifically, of course, but a very interesting sociological exercise.

36. **GoletaBeach**
August 23, 2016

Well, the accelerator discussion (as well as EDMs) was targeted to the topic of "in your lifetime". But it is your blog and if it is tiresome to you, that is alright.

To stay on topic: "Not Ever Wrong" and "Not in Your Lifetime" are inequivalent. Ever is forever. Your lifetime may be forever for you, but it is not forever for everyone else.

Not Ever Wrong makes current particle theorists sound like theologists. I don't think they are. I think that their belief is that eventually empirical evidence will decide whether SUSY is wrong or right, it is just that the time frame may be 1000's of years, or however long it takes to do a complete set of experiments up to the Planck Mass. Speculation about how long it will take to perform that set of experiments is… well… tiresome to you.

The current particle theorists view is not the same as theology. In theology the concept is that the theology is correct independent of empirical evidence.

37. **johnnythelowery**
August 23, 2016

Congratulations to you too on this in recognition of you standing up to the Zeitgeist of the day. Bravo!!

38. **Jonathan Miller**
August 24, 2016

As an experimentalist in HEP, I think the community should focus on testing the SM and not on testing unmotivated theories. It is entirely natural that sometimes theory needs to wait for some hint from experiment and this is the current case.

And there is no reason to be pessimistic about the field, there are a lot of obvious areas to test the SM such as neutrino masses, CP violation in the lepton sector, proton decay, confinement and muon g-2 to name just a few. These don't require a bigger collider, but that doesn't make them any less important or likely to provide the necessary hint.

And it would be best if theorists create theories to fit these new hints, not only look for some version of an old, no longer motivated, model that is not ruled out by the new 'constraint'.

If all the obvious places to test the SM result in trivial extensions and no hint about future physics, then it might be time to become pessimistic.

39. **WLM**
August 24, 2016

I had a slightly different take on David Gross's comments, following on those of 't Hooft, than Peter. I understood him to be saying that the emphasis on SUSY as a central issue is actually misplaced [except perhaps for some String theorists], and a distraction from dealing with our lack of understanding of some true fundamentals of particle physics and of space-time in general. (From 't Hooft: The resolution of whether super-symmetry exists or not isn't just about whether some new particles show up at a particular energy in a particular experiment, but rather about the nature of space and time: is space-time super symmetric?) To summarize:

– The underlying issue is one of "naturalness", or the lack thereof, in the heirarchy of masses and their couplings with the Higgs field.

– There have been a whole series of issues with "big numbers" and "small numbers" during the development of the Standard Model, all of which appeared to be completely "unnatural" at the time. Some have been dealt with in the theory, in QCD, and are calculatble (if you understand the dynamics properly) and some have just been accepted as "just the way it is" — such as the heaviest quarks having 50,000 times the mass of the quarks that make up the proton. There's no fundamental explanation for that – just measurement. In 1960, that would have been considered insanity. Today, it's "So what?"

– We should not try to apply the same methods to other, perhaps totally unrelated "problems of large numbers" just because they worked before. Every such problem is its own separate case and will probably require its own particular solution, as we better understand the underlying physics. E.g., the Cosmological Constant problem is probably unrelated to the hierarchy problem, and will need its own separate solution, to be able to calculate anything.

– Super symmetry offers the possibility of handling the hierarchy problems by turning them into logarithmic effects, just like we learned from QCD that couplings vary logarithmically with energy, not linearly. Some type of super symmetry still seems like the best hope for doing that.

– So super symmetry doesn't show up at the LHC, or only shows up very tentatively over the next few years? That's probably just a sign that there are small numbers involved, just like there were in the quark-lepton mass spectrum. So what? It's likely that we don't understand the parameters of super symmetry buried in the couplings with the Higgs just like we don't understand other paramters of the Standard Model: we are missing something fundamental.

– This doesn't mean that it's right, just that it's the only explanation we have come up with so far that addresses this particular large number issue. So he's sticking with it, as something that will need to be considered in more fundamental explanations.

– What we really should be worrying about is identifying the underlying dynamics of more fundamental physics, that better explains those unexplained parameters in the Standard Model and lets us do actual calculations in regimes where we currently cannot. And the younger generation should not be shy about throwing out the preconceptions of the prior generation of physicists in order to do so.

While I can't claim to agree with "believing in" SUSY just because it's the only game in town, this seems like a much more nuanced, rational approach than Peter suggests.

40. **Another Anon**
August 24, 2016

Yeah, as johnnythelowery says, congratulations. This is probably the nearest you're ever going to get to official confirmation that SUSY is dead.

41. **Andreas**
August 24, 2016

Don't worry Peter, that's exactly what Thomas Kuhn descriped. Some theory only dies when their participants die. It would be worrying if many new people join SUSY/Strings, but i guess that doesn't happen. At our universities, string theoretists are not taken serios anymore, and the groups mainly consist of a few old guys, and senior-postdocs which cant find permanent positions. no PhD students mainly.

I guess thats a good sign. 🙂

42. **Bernd**
August 24, 2016

Peter,
I strongly disagree with the statement that arguing for the desert is the same as arguing for low-energy BSM physics on grounds of naturalness. First of all, the desert is not a thing, but actually the absence of a thing (BSM physics below the GUT scale). Hence, the default assumption should be to stick with the SM and put the burden of proof on anyone who claims there are violations just round the corner.

43. **Peter Woit**
August 24, 2016

johnnythelowery and anon,

Thanks, but in this case I don't think my skepticism about SUSY at the LHC is a "standing up" to anything, since I think most HEP theorists have always shared this skepticism (as I keep pointing out, it's the losers of this bet who were in the minority). So, on this one I'm in the majority, now kicking the losers while they are down…

WLM,
I didn't discuss Gross's comments about SUSY/naturalness getting too much attention, while our complete lack of understanding of the SM parameters at all gets very little. I completely agree with those comments.

I do though also completely disagree with his argument that one should have faith in SUSY, because it promises a solution to the naturalness problem, even if you have to fine tune things somewhat. This argument claims to solve a conceptual "fine-tuning problem" by extending the SM by something complicated, adding in over a hundred new parameters. And then you find it doesn't really solve the problem, you still need some fine-tuning. I've always been of the opinion that this never was a solution to the problem (adding a huge number of new parameters is not a plausible explanation of a puzzle about one parameter), but the LHC could have vindicated this. It didn't, so now the disturbing situation is that proponents of this have decided to stick to a bad "solution to a problem" and keep promoting it, without any hope now of experiment resolving the issue.

44. **Mr Anon Anonymous**
August 24, 2016

The bet I'm really looking forward to is the Lubos-Jester one. Boy, am I looking forward to that one!

The LHC has recorded ~20\fb making ~30\fb by mid-October a realistic possibility. Make the blog post a good one, Peter 😉

45. **Peter Woit**
August 24, 2016

Mr. Anon Anonymous,
I think that bet was a good indication that skepticism about SUSY at the LHC was always very widespread (Jester offered 100 to 1 odds, betting it wouldn't show up).

I hear Lubos is doing his best to refuse to admit defeat, now claiming he won't pay up until all analyses in all channels by CMS/ATLAS based on 30 inverse fb are completed, which could be quite a while.

One reason I never got interested in searching out such a bet was that I suspected I'd never see the money if I won. I would have predicted that some sort of anomaly would show up in LHC data that SUSY enthusiasts could point to as a possible SUSY signal, have been surprised that that hasn't happened.

46. **Ming the Merciless**
August 24, 2016

Opinion: Nature has spoken on more than one level here, for example on the matter of which speaks the most for human naturel, neo-philosophical notions of Critical Rationalism as exemplified by Karl Popper and currently David Deutsch on Karl Popper; or is it the more traditional mixture of common experience with a peppering of self-honesty and awareness of the facts of history.
We don't change our minds. It may not even be possible to change our mind. Not about core hard-won whole-life insights. The reason this is not apparent to us is because it's a relatively tiny subset of the fulsome summary of all the real or possible things we think we have (or had, or would've).
Everyone is [usually] more-than-happy to abandon, or switch sides, on the vast majority of our opinions because we attach little real value to them. So it looks like changing our minds is something humans do all the time, when in reality we do not, ever.
Science on the theoretical side is almost always about the hard-won insights and whole-life lessons. It cannot, and has never, depended on this sort of notion. What has changed relatively recently is the level in scientific affairs at which positions are decided. Everywhere else the positions that really matter are attributes of groups not individuals. Science uniquely managed to heave this trait in the direction of the individual far enough that the consensus and ultimate course became on-balance, and ultimately settled objectively by objective reality, via measurements.
That has now changed, it has reverted back to the base-energy state of human nature in which it is relative power that has the final word, not truth. Not because humans are cynical or attach little value to the virtue of objective truth, but because that is the objective truth in human affairs.

47. **Anonymous**
August 24, 2016

I assume people are aware of this: at collaborations like ATLAS, the limits on BSM physics can move to publication quickly; however, unexpected/expected excess could take much longer to go through the internal review and politics. This is just the reality of the life in big collaborations. With this in mind, you might want to hold your bet for a little longer and it is very sensible to me that you do want to see majority of the results with full 2016 LHC data.

48. **anon**
August 24, 2016

Dull discussion accompanying the bet. Just a load of big shots (who in this case were proven categorically wrong) exchanging platitudes about new physics and naturalness. The final speaker literally agreed with everything said previously. With respect, what was he there for? I wanted something more adversarial. Unfortunately, these kinds of discussions are somewhat ceromonial and reverential, and don't challenge the ideas or the logic of their special esteemed guests. As a result, we hear the same old things and nothing changes. I suppose at least they had the video message from 't Hooft.

49. **Peter Woit**
August 24, 2016

anon,
I think the idea was to just have as panelists those who had lost the bet, with the idea that they might have something interesting to say about how losing the bet had changed their point of view (winners of the bet were likely to not have much to say except "told you so"). This didn't really work out, since the attitude of the losers was pretty uniformly "So what? I still believe SUSY rules, no matter what experiment says".

50. **NoGo**
August 24, 2016

Can you explain this attachment to SUSY? What is so compelling about it?

51. **WLM**
August 24, 2016

Peter,
I completely agree with you re. the "ugliness" of super symmetry as a solution to a hypothetical "naturalness problem", and that we should not just have faith that it will ultimately somehow turn out to be correct after all (despite needing fine tuning to reduce fine tuning). [One should note, however, that "ugliness", just like "beauty", is not a valid criterion for deciding the correctness of a theory. :)]

I was just giving Gross the benefit of the doubt in his statement that we don't understand the parameters of super symmetry buried in the couplings with the Higgs, yet, just like we don't have a clue about other open issues with the SM itself. And we need to.

My interpretation is that he hopes/wishes/fantasizes [take your pick] that, once we understand what is really going on, those 100+ parameters will not just be explained, but will most likely disappear. His analogy was that, just like the morass of hadrons and their constituents was clarified once we understood gauge theory and asymptotic freedom in QCD, a more basic understanding of the underlying dynamics of Higgs interactions is what is required to clear up what is really going on in the morass that is super symmetry and the naturalness "problem" — and perhaps other SM issues as well. And that will require understanding those Higgs couplings much better.

Of course, a fundamental difference is that the issues in the 1960s with hadrons and quark confinement were the results of multiple experiments. The issues thrown up by super symmetry are strictly theoretical, solving a theoretical problem, with essentially no experimental guidance or even confirmation of the problems themselves, other than negative ones. But my interpretation of his current approach is to say, OK, we don't know what's going on, but let's start by assuming some kind of super symmetry effectively exists and see if that can lead us to the deeper understanding where we can explain it away.

That's obviously just my interpretation from several of Gross's talks. It's very different from just "believing in SUSY" (like some of those panelists apparently still do). And it could be considered increasingly foolhardy as decades of experiments accumulate against that hope. It would be interesting to hear his actual thoughts spelled out.

52. **TS**
August 25, 2016

I had a stint with theoretical particle physics a long time back, I did some supersymmetrical calculations, then switched to experimental particle physics. To my understanding, the best argument for SUSY was that if supersymmetry were realized in nature, there would be a Nobel for my university (well, until Julius Wess's untimely passing). The second best argument was the pure ingenuity of QFT that forces you to discover supersymmetry if you are creative and study its mathematics hard enough. I always felt that these arguments were more convincing than "it gives you dark matter (once you assume an additional symmetry)" and "it cures a mathematical-aesthetical problem that you have when you extrapolate to arbitrarily large energies assuming that there are no unknowns on the way there." This skeptical point of view may have been reinforced by my very pragmatic advisor, who never bought the hype, and who is still at the forefront of pure standard model calculation, but who at the time wanted to do a few SUSY calculations in order to learn the formalism himself. (BTW I would like to remind everyone that recent progress in SM calculations has been tremendous, so it's not at all like theoretical particle physics is not making progress, and the progress is actually very much related to better understanding of the mathematical structures even though generalized polylogarithms and numerical-analytical methods probably aren't as sexy as amplituhedra.)

Anyway, what I originally wanted to point out is that talking about hundreds of parameters as a deficit of SUSY is not attacking one of its weak points. The idea, as I understood it then, was that we need all these parameters because we don't understand how supersymmetry is broken, so they parameterize our ignorance and if we keep them, we avoid prejudice about the unknown: if you assume that SUSY is a fundamental symmetry, you also assume that, say, the mass of the electron and the selectron are related by the same mechanism that relates the mass of the muon and the smuon. Thus nobody who believes in SUSY believes that the masses of selectron and smuon are independent parameters (provided of course that the SM parameters are known inputs). The large number of parameters is a convenience, and allows very general experimental exploration, exactly because it doesn't require to specifiy the mechanism of SUSY breaking.

This seems to imply that someone should keep track of which models of SUSY breaking have been excluded, but I don't think I've seen anything like that. Maybe even with SUSY breaking there's more freedom left than I could possibly imagine?

53. **Peter Woit**
August 25, 2016

TS,
It's true that the huge number of new parameters problem is not fundamental, in the sense that one can always claim that "all that is needed is to figure out the mechanism of supersymmetry breaking". On the other hand, despite 40 years of effort, no one has come up with any compelling such mechanism (i.e. one that explains something about known physics, or does anything other than multiplying entities and adding complexity on a scale larger than the number of phenomena one is trying to explain). The extra parameters issue is a quick way of referring to that problem, since examining in detail all the possible mechanisms for susy breaking and their problems leads to absurd complexity (such that this is an issue that theorists appear to have pretty much abandoned, as far as I can tell, few people still work on it). And, these mechanisms completely torpedo claims to have a "beautiful" or "elegant" theory.

54. **Robert Matthews**
August 25, 2016

Seems like 't Hooft and Peter W should have placed side-bets on the "We lost, but we could still win" reaction from the usual SUSYpects.

The debacle also seems to leave Popper's idea of refutation looking pretty underpowered when it comes to theories like SUSY, with so many tunable parameters.

Maybe this week we've seen the emergence of a new criterion for such theories: "aleatory refutation" – aka Death by Wager.

55. **MathPhys**

" John Ellis has also announced that no matter what the LHC says, he's not giving up "

A man has declared his mind closed. I have respect for self-knowledge.

56. **Emil**
August 26, 2016

There were always many arguments against low energy supersymmetry, both empirical and aesthetic. The searches for superpartners at the LHC coming up empty is only the latest, strongest empirical argument against low energy supersymmetry. The aesthetic is as soon as one took the beautiful idea of supersymmetry and tried to match it to nature, it rapidly became ugly. It is a solution in search of a problem, like a cave man finding by chance a shiny MacPowerBook and after puzzling over what to do with it, uses it as a hammer.

That doesn't mean that supersymmetry has no place in physics, any more than that the laptop has no use good use. Solid mathematics has a way of finding a realization in physics. It's that aesthetic appeal of supersymmetry that leads to its advocates not giving up on it. It's just that we haven't yet found that proper place, and in the meantime we should probably give up viewing it as a hammer.

More seriously, the most compelling argument against low energy supersymmetry was always that although it was advocated on the basis of 'naturalness' to cancel quadratic cutoff dependence and explain the light Higgs vs. the Planck mass, it provided and still provides no answer to the biggest naturalness problem of all–namely the smallness of the vacuum energy in Planck units. By itself this is telling us with certainty that supersymmetry cannot solve all naturalness problems associated with the Planck scale, which will require a much better understanding of how quantum theory and Einstein's gravity fit together.

57. **Anonyrat**
August 26, 2016

Uses of supersymmetry – am under the impression that the BRST formalism relies on supersymmetry? So, mathematically, not physically, supersymmetry is realized in every non-abelian gauge theory?

58. **Peter Woit**
August 26, 2016

Anonyrat,

It depends what you mean by "supersymmetry". If you mean generically use of a Lie superalgebra, then BRST is an example. But usually "supersymmetry" in this context means a specific Lie superalgebra, a non-trivial extension of the Poincare group. BRST treatment of gauge symmetry doesn't involve space-time symmetries.

I agree with Emil that probably what's going on here is that "supersymmetry" has some different role in fundamental physics. I'd guess that you want to use Lie superalgebras in the context of space-time symmetries, but the particular extension of the Poincare group and the representations of this that people have been trying to connect to reality don't work (and I think the problem is not just a low energy one). Perhaps you want something more like the way superalgebras appear in BRST.

59. **anon**
August 26, 2016

Anonyrat, BRST and SUSY are very different.

In BRST y0u have a single Grassmann-odd operator that squares to zero and is used to conveniently encode and impose the gauge constraints on the state space. The constraints can generally be imposed in other ways that are more complicated in practice but don't require the BRST formalism. BRST doesn't add any physical states that are not in the original gauge theory. The whole point of BRST is that the "ghosts" we introduce should factor out of the state space and in addition cancel out gauge-redundant degrees of freedom. So BRST reduces the state space as opposed to increasing it.

In SUSY you have a set of Grassmann-odd operators that, when "squared," give spacetime translations (not zero as in BRST). SUSY can thus be seen as an extension of spacetime, adding Grassmann-odd "directions" besides the usual 3+1. Field vibration modes in the new odd directions provide superpartners to the usual particles in ordinary spacetime. So, in contrast to BRST, adding SUSY to a model provides extra physical states.

60. **Cormac O'Raifeartaigh**
August 26, 2016

NoGo: I think the main attraction of SUSY is that it offered a way around certain problems in the construction of a consistent unified field theory of all four interactions. Plus, as the last possible symmetry of the Poincare group, it would seem a pity that Nature might not avail of it!
Re the zeitgeist, it seems to me that many commentators such as Johnnythelowery have things the wrong way around; the current zeitgeist is SUSY skepticism, not SUSY optimism (at least if judged by blogs, media articles and pop science). Which is strange because only low-energy SUSY has been ruled out so far.
Indeed, it seems to me that most commentators have misunderstood the nature of the bet – it was whether SUSY particles would show up by a certain energy range. A silly bet to be sure, but to interpret the negative result as 'SUSY dead' rather than 'SUSY looking less likely' is simplistic..

61. **Peter Woit**
August 26, 2016

anon,
That's a good explanation of the usual point of view. I find it interesting though that there are contexts where these things are not so different, with one of them Witten's N=2 (twisted) SUSY YM theory that gives Donaldson invariants. In that case, among the supercharges is one that can be interpreted as a BRST differential

Much more generally, the interesting mathematical applications of SUSY theories often just look at "BPS states", using a construction closer to the BRST one. It may be that the right perspective on SUSY theories is that most of the states are more like "ghosts", not physical. And at the same time, I'm suspicious that BRST is more fundamental than people think, really needed to properly understand what is going on with gauge symmetry.

62. **Low Math, Meekly Interacting**
August 26, 2016

Hi, Cormac,

I think many of us outsiders understand (to the extent our brains allow) that there many ways to look at SUSY and what it might do. As an outsider, I've been surprised at the relative lack of discussion in the popular literature about the unique ability of SUSY to combine space-time and internal symmetries. I'd love to see more popular exposition about that aspect of the theory and why it is or isn't compelling on its own. Then again, the relevant energy for that idea (in isolation) appears to be around the Planck scale, so maybe that's why it's not so interesting.

The other idea, the one where the superpartners that come with this unification have anything to do with the Higgs mass or a viable dark matter candidate? That idea seems to be bad shape, given the empirical evidence. It's not clear to me what optimism or pessimism has to do with it anymore. Experiment has told us that if SUSY is relevant to these aspects of nature, it's reportedly "very cleverly hidden". That seems to be a nice way of saying it's no longer plausible, if it ever was.

63. **Peter Woit**
August 26, 2016

LMMI,
SUSY doesn't really combine space-time and internal symmetries, it's an extension of the space-time symmetries, commutes with the internal ones.

64. **Low Math, Meekly Interacting**
August 26, 2016

Hi, Peter,

Yes, thanks for correcting my imprecise description. I'm pretty much directly quoting another source directly, which delves into just what you said in detail that rapidly starts flying over my head (I'm not at all qualified to even get into the Coleman-Mandula no-go theorem and the nitty-gritty of why SUSY is the one-and-only non-trivial way to circumvent it, except to say I recognize this is important and interesting in its own right).

65. **Nakanishi**
August 26, 2016

I would like to comment that there is a supersymmetry other than SUSY or BRS, but yet consistent with the unitarity of the physical S-matrix. I believe that it is natural to supersymmetrize only the local Lorentz symmetry of the Einstein gravity, because it commutes with the spacetime symmetry. The Lorentz symmetry SO(3,1) is extended to the orthosymplectic superalgebra OSp(N, 2; C). In this extension, {Q, Q} and {Q^(bar), Q^(bar}} are identified with M_(mu, nu), but {Q, Q^(bar)}=0.

66. **John Baez**
August 27, 2016

From a mathematician's viewpoint, spacetime supersymmetry is just one aspect of "supermathematics", namely the replacement of vector spaces, manifolds, Lie groups, Lie algebras, commutative algebras and so on by their Z/2-graded versions. This is a remarkably potent idea – for example, it provides new improved proofs of the Atiyah-Singer index theorem, the positive mass theorem in general relativity, and a new outlook on differential forms.

Moreover, supermathematics is not an *arbitrary* generalization of ordinary mathematics: there are plenty of theorems explaining how this Z/2-graded generalization is uniquely singled out. For an example, I recommend Urs Schreiber's post on Deligne's theorem, but can't resist mentioning the closely related result that I proved earlier.

I'm sure all this is somewhere in the back of the minds of physicists who think supersymmetry is "the only game in town": there are few other principles with such wide-ranging connections to beautiful mathematics – except of course for those that have already been widely adopted in physics, such as gauge invariance, diffeomorphism-invariance, or the principle of least action.

The problem, of course, is that spacetime symmetry focuses our attention on a collection of staggeringly beautiful physical theories – such as 10-dimensional superstring theory and 11-dimensional supergravity – which seem to describe worlds *utterly unlike our universe*. And when people try to tweak these theories to make them physically realistic, they – so far – become ugly and complicated.

So, back when I was interested in figuring out the fundamental laws of nature, I avoided having anything to do with supersymmetry. Only after I quit that and took up pure math for a while did I come to appreciate its beauty! I especially enjoy how superstrings and supergravity are connected to n-categories and normed division algebras, with the octonions being closely connected to 10- and 11-dimensional spacetime supersymmetry.

I think it's possible to take a balanced attitude and enjoy the beautiful mathematics of supersymmetry while taking an agnostic or even jaundiced attitude to whether it's relevant to particle physics. But this is, of course, nearly impossible for people who hae staked their careers on it.

67. **Marc Nardmann**
August 27, 2016

John Baez,

when you say that supersymmetry is a remarkably potent idea that provides for example a new improved proof of the positive mass theorem in general relativity, are you just referring to Witten's 1981 article "A new proof of the positive energy theorem"? Its fourth section starts as follows: "In this section a few speculative remarks will be made about the not altogether clear relation between the previous argument and supergravity." Has this become clearer later?

Independently of the answer (which I'm really interested in), my point is this. There are many examples in differential geometry where spinors are important to solve problems whose statements do not already involve spinors. The positive mass theorem is certainly such an example. But is it an example for the usefulness of supersymmetry? Would a Z_2 grading on geometric objects make the spinorial proof easier or more elegant in any way? Knowing the analytic details of the proof quite well, I doubt that. So, while I agree with you that one should "enjoy the beautiful mathematics of supersymmetry", I think there is a danger of overhyping supersymmetry as a panacea already in pure mathematics.

I see an analogy to the discussion of physics we are having here. Obviously fermions (i.e., spinors) are needed to describe the universe we live in. But do we need supersymmetry to describe the universe? Even if we ignore (absence of) experimental evidence, would a Z_2 grading that puts bosons and fermions on the same footing really make our description of fundamental physics easier or more elegant? Everyone has to judge for themselves, but I doubt this one, too. From a purely geometric and representation-theoretic viewpoint, I find the Standard Model quite elegant the way it is; and the few aspects that lack elegance would not be remedied by supersymmetry.

68. **Peter Woit**
August 27, 2016

Marc Nardmann/John Baez,
Once you expand the term "supersymmetry" to include all uses of Z2-graded mathematical structures, it doesn't make sense to argue about whether it is related to physics. Of course it is, very fundamentally (the Dirac operator is the supercharge of a supersymmetric QM theory). The problem though is "which Z2-graded mathematical structure"? There a huge universe of them, as big or bigger than the universe of all more conventional mathematical structures. It becomes impossible to say anything true but non-trivial about such a universe.

A more useful discussion is to distinguish between what parts of this general Z2-graded universe reflect something deep about physics and/or mathematics (certain SUSY

QM models) and what parts don't seem to (SUSY extensions of the SM)

69. **Marc Nardmann**
August 27, 2016

Peter Woit,

you said: "A more useful discussion is to distinguish between what parts of this general Z2-graded universe reflect something deep about physics and/or mathematics […]" That is closely related to the point I wanted to make: I agree that there are many places in differential geometry where spinors and Dirac operators can be used in "deep" ways, in contexts that do not a priori involve spinors. Does this already justify — probably by definition — to say that "supersymmetry" is used there in a nontrivial way? If so, then I will not argue with that definition. If not, then I argue that the positive mass theorem is not a good example of a deep application of supersymmetry. This is roughly analogous to the fact that we would not call the plain Standard Model (which involves spinors and Dirac operators) a "supersymmetric" theory.

70. **John Baez**
August 27, 2016

Marc Nardmann wrote:

> When you say that supersymmetry is a remarkably potent idea that provides for example a new improved proof of the positive mass theorem in general relativity…

It's late at night here in Singapore, so I'll try to answer your questions later, but for now let me just note that I didn't say that. I tried to be quite careful in how I expressed myself, saying:

> From a mathematician's viewpoint, spacetime supersymmetry is just one aspect of "supermathematics", namely the replacement of vector spaces, manifolds, Lie groups, Lie algebras, commutative algebras and so on by their Z/2-graded versions. This is a remarkably potent idea…

Maybe it wasn't clear, but "this" refers to "supermathematics", not supersymmetry.

71. **Marc Nardmann**
August 27, 2016

John Baez wrote: "Maybe it wasn't clear, but 'this' refers to 'supermathematics', not supersymmetry."

That was indeed not clear to me. I apologise for mis-paraphrasing. So, which Z_2-graded objects were you alluding to in the context of the positive mass theorem?

You mentioned the application of "super" concepts in proofs of (versions of) the Atiyah-Singer index theorem. This seems to me to be a good example of the potency of "super" ideas. I still do not see how the positive mass theorem is an example. To me, it is just an example of the usefulness of spinors in differential geometry — which is profound, but not "super" in a technical sense.

72. **Urs Schreiber**
August 28, 2016

The fact that the worline theory of an ordinary spinning particle (such as the electron) is 1d supersymmetric (see here for details and references) is interesting mostly because it is a precursor of the fact that the worldsheet theory of the "spinning string" (as it was originally called) just so happens to be 2d supersymmetric (and called the "superstring" only once this was realized), which in turn is interesting because it miraculously implies that the effective spacetime theory of which these strings are quata is locally 10d supersymmetric. This is interesting because, while the automatic worldline supersymmetry of the electron does not imply that the spacetime theory is supersymmetric, just assuming that the electron is the point particle limit of a string (and nothing else) does imply local spacetime supersymmetry. This is a key prediction of the assumption of strings:

strings & fermioms => supergravity

This of course does not prove that local spacetime supersymmetry (supergravity) is realistic, but it is one of the theorems that miraculously imply local spacetime supersymmetry and thus make it a plausible possibility. Of course this particular argument does require the assumption that particles are limits of strings, which might be wrong, and if so then the conclusion wouldn't follow, of course.

On the other hand Deligne's theorem needs no assumption beyond established principles of quantum physics (that elementary particles are labled by irreducible linear representations of the local spacetime symmetry group), but as a payoff it does not imply that the local spacetime symmetry group is the super-Poincare group, it only implies that among all imaginable modifications of local spacetime supersymmetry (e.g. non-commutative groups, aka quantum groups or more bizarre possbilitities) all except precisely the class of super-symmetry groups are excluded on mathematical grounds.

Combined with the observavation made in 1922, that the world does contain fermions, and the realization, a little later, that hence the phase space of every realistic physical theory (such as the standard model) is a supermanifold (the fermions constituting the odd-graded coordinates) it makes it rather plausible that the local symmetry group acting on this supermanifold in general mixed bosons and fermions, hence be a supersymmetry group. Of course this is not logically implied and could well be wrong, but the point to notice is that given the above circumstances, it would almost seem to require _more_ explanation why it shouldn't, than the other way around: experiment shows that phase space is a supermanifold, and Deligne's theorem says that the most general local spacetime symmetry group may be a supergroup, so why on earth would Nature then choose to constrain this possibility and have an ordinary group act on the supermanifold, if it could choose a supergroup.

Again, this does of course not prove local spacetime supersymmetry, but it serves to show that there are good reasons to expect that it might be: Because conversely, if the world were not locally supersymmetric, then there would be reason to ask: why this constraint? Why, if provided with the possibility to choose from the class of all super-groups, and with phase space of verified physic already being a supermanifold, why would Nature choose a purely bosonic symmetry group? It's possible, but it shows that it is not insane to suspect that fundamentally (i.e. at high energy) it might be different.

That all said, recall again that all this is about high energy local supersymmetry (supergravity). There is no comparable argument from first-principles which would force that a theory of supergavity should settle in a vacuum where at the weak scale there is a global supersymmetry left (which is the kind of supersymmetry that is invoked for those arguments about naturalness, gauge coupling unification, dark matter etc.). In contrast, a global supersymmetry (a global Killing spinor) in a solution to the equations of motion of supergravity is about is unlikely as a global translation symmetry (of which the supersymmetry is a "square root"). We don't expect the universe to be globally translation invariant in any one direction, even though locally it is, and analogously it would be surprising to find a global supersymmetry, even if locally everything would be supersymmetric.

In conclusion, the main question of interest seems to be a question rarely discussed at the moment:

Theoretically, the real question is: given a theory of supergravity (or some UV-completion thereof) what are the compactification mechanisms, what can one say about its effective "low" energy (say weak scale) vacua. Is there any actual mechanism, besides prejudice, that would prefer Calabi-Yau or G2 compactifications? Or maybe better: at which scale would such these be effective?

Experimentally, a good question would be: what would be experimental checks not of low energy supersymmetry, but of supergravity. For instance [these authors here](#) argue that plateau inflation (such as Starobisnky-inflation) — which is the model of inflation presently preferred by experiemtal data — gives a still better fit to experimental data after embedding into supergravity. Now, that particular argument will have its loopholes, but generally more experimental arguments for or against high energy supersymmetry (supergravity) would be interesting to have.

73. **Peter Woit**
August 28, 2016

Urs,
You are trying to derive from an extremely general abstract theorem (that Tannaka duality works for not just groups but also Z2-graded groups) an argument for a very specific supergroup, a rather ugly one with no experimental evidence at all for it. I just don't see any argument at all for this.

"All groups" covers almost all of mathematics, and adding in Z2-graded groups makes this even more general. I'm a big fan of the idea that quantum mechanics is fundamentally representation theory, and (see the book I've been writing) I think there's a huge amount to say about how highly non-trivial and specific basic structures in representation theory govern quantum theory. But, you can't get something from nothing: an extremely general piece of abstraction applying to almost the entire mathematical universe cannot possibly do the job of distinguishing the very specific mathematical structure that seems to govern the physical universe.

Urs Schreiber wrote: "[T]his does of course not prove local spacetime supersymmetry, but it serves to show that there are good reasons to expect that it might be: Because conversely, if the world were not locally supersymmetric, then there would be reason to ask: why this constraint?"

That's a good question, and I cannot resist to offer a thought. Most people (including me) assume that the Standard Model (or whatever BSM model you want to replace it with) is an effective theory at large length scales of some underlying theory U. This underlying theory does not even have to be a quantum field theory. The bosonic and fermionic fields in the effective theory are effective degrees of freedom that arise in a possibly complicated way from the degrees of freedom of U. In this situation, should we expect that the effective theory allows local spacetime supersymmetry transformations that can mix the effective bosons and fermions?

I think there are essentially two possibilities we have to consider: Either there exist *many* theories U that induce effective theories with bosons and fermions that look roughly like the Standard Model; or there is essentially only one possible U with this property.

In the second case, not having any a priori information about U, I would assign a 50% prior probability (or much less, but I'll be generous here) to the statement that the effective theory allows local spacetime supersymmetry. I.e., I would answer Urs' question with a counterquestion: Why should this constraint *not* exist?

In the first case, however, the situation is different. If bosons and fermions can arise in many different ways from an underlying theory, we should expect that the absence of transformations that can mix them is a pretty generic property in the class of possible theories U. After all, the bosonic fields could appear effectively by a mechanism quite different from the mechanism that produces the fermions. Then we would not expect a symmetry that can mix them, because they are just quite different objects, like apples and orangutans. (In the Standard Model, the bosons and fermions do not look similar at all. I take that as a hint that they arise indeed in quite different ways from the underlying theory, whatever it may be.)

Hence, no matter whether we are in the first or (as I hope) second case or something in between, I do not find it particularly puzzling that the effective theory that describes our universe shows no sign of spacetime supersymmetry. If we would see supersymmetry, that would be an extremely strong clue about the underlying theory: it would have to induce fermions and bosons as effective degrees of freedom in very similar ways, so that the effective theory could mix them. But we do not see it. Why should anyone be surprised? For the stated reasons, I even find it very likely that supersymmetry does not occur at *any* length scale at which the effective theory is valid. And in the underlying theory, the question "Is there spacetime supersymmetry?" might conceivably not even be well-defined.

Maybe SUSY enthusiasts do not like this idea — that the bosons and fermions in our universe arise effectively from an underlying theory U in completely different ways — because they assume that then U would have to be an inelegant, complicated theory? I do not see any argument that would support this assumption.

Peter wrote:

> You [Urs Schreiber] are trying to derive from an extremely general abstract theorem (that Tannaka duality works for not just groups but also Z/2-graded groups) an argument for a very specific supergroup, a rather ugly one with no experimental evidence at all for it.

I don't think he's doing that. For starters, he didn't mention any specific supergroup, much less a specific "rather ugly one". Which supergroup are you talking about, anyway? Whatever it is, Urs never mentioned it.

I think the only reasonable attitude is to realize that we are missing many pieces of the puzzle, both experimental pieces and conceptual pieces: that is, ideas we need, that we don't have yet. So, people motivated primarily by mathematical elegance should not expect their work to make contact with experiment in the next few decades, or indeed at all. The time is not ripe for that. They should instead try to do good math. Good math can be recognized independent of any applications to physics, and it has its own inherent value.

I think Urs is doing good math. He's not spending his days working on the minimal supersymmetric extension of the Standard Model or any other specific ugly attempt to ram our current theoretical thinking down the throat of the experimental data we have now. He's instead inventing fundamental new ideas in geometry, topology and algebra – indeed, so fundamental that breaking math into these separate subjects doesn't do justice to his work. Some of his work is on particular theories that string theorist like (showing how they fit into a single structure, the "brane bouquet"), but a lot of his work is more general than that, and thus of more general interest. I'm talking about things like infinity-categories, infinity-topoi, and how these permit a new much more general approach to old topics like Lie groups, Lie algebras, gauge theory, prequantization and so on. These are worth studying *regardless* of any application to physics. In fact, trying to connect them prematurely to particle physics runs the risk of screwing up their natural development, by making us focus on the theories we know and not on the ones we don't.

Marc Nardmann wrote:

> I still do not see how the positive mass theorem is an example. To me, it is just an example of the usefulness of spinors in differential geometry — which is profound, but not "super" in a technical sense.

Okay – I was trying to give examples of "supermathematics" (Z/2-graded mathematics), not supersymmetry, but I guess this was a bad example. I was in grad school in the early 1980s when Witten was starting to wow mathematicians with his new arguments for known results. His "physics proofs" of the Atiyah-Singer index theorem and positive mass theorem came out then. Both involved the Dirac operator in ways that surprised mathematicians, so I tend to mentally lump them together.

But you're right, his argument for the positive mass theorem doesn't use Z/2-graded ideas, at least not explicitly. Wikipedia says his argument was "inspired by positive energy theorems in the context of supergravity", and the fourth section of [Witten's paper](#) discusses the connection to supergravity. But he says the connection is "not altogether clear". I don't know if anyone ever nailed it down!

A much better example, from around the same time, would be [Witten's approach to Morse theory](#). I took a course on that with Raoul Bott, and at one point he said, eyebrows wagging mischievously: "So we think about this, and we get stuck. So we need to *super*think!"

Around this time I also took a course from Quillen on Witten's proof of the Atiyah-Singer index theorem. Quillen was trying to make it rigorous using "high-school calculus" and lot of elementary superalgebra. He got scooped by Getzler.

So, I think of this as the era when mathematicians realized the importance of supermathematics.

77. **Peter Woit**
August 29, 2016

John,
I think we agree about strategy: step back and look for new mathematical insights that may later find applications in fundamental physics. Even if you don't get what you want for physics, you'll learn more about deep mathematics, which is all to the good. And sure, Z2-graded mathematics may very well be part of those insights. Now that I'm wrapping up work on the book, I'm looking forward to going back to doing precisely that, thinking about Dirac cohomology.

My problem with Urs is that while he's often doing this sort of thing, at the same time he finds it necessary to try to use this to defend the central failed research program that has dominated (and done a huge amount of damage to) theoretical physics for over 30 years. His argument starting with Z2-graded Tannaka duality ends up with the specific endpoint of an argument for supergravity, in ten dimensions (whatever you want to call the local supergroup there, that's the one I'm referring to). I don't think there's a serious argument there. You can't get to that kind of specific theory from general ideas about the relation of QM, representation theory and Tannaka duality. When you try and do it, you're just adding in lots of unexamined assumptions and eliding distinctions that are exactly the ones you need to be looking at to figure out where this train of inference goes wrong.

Defending 10d superstring theory and supergravity as the fundamental theory while arguing that any possible actual experiments are irrelevant is very dangerous, the "Not Ever Wrong" danger I'm trying to point out. Bringing very abstract not relevant mathematical statements in to help do this is a really bad idea. I think in this year we're going to finally see the collapse of any hope that supersymmetric extensions of the standard model will ever see a test or get experimental support. I hope the community reacts to this by challenging the assumptions that led to enthusiasm for these models, not by permanently seeking refuge in excuses ("only visible at high energy") and dubious invocations of abstract mathematics.

Peter Woit wrote: "I'm suspicious that BRST is more fundamental than people think, really needed to properly understand what is going on with gauge symmetry."

Yes, I remember BRST seeming very ad hoc to me, until I realized I could think of the Faddeev-Popov ghosts as differential forms in disguise, with Q being essentially a version the exterior differentiation d constrained to the gauge directions. It's been a while since I worked on this but I seem to remember convincing myself that the path integral over the ghost action expresses a coordinate-invariant volume form on the gauge surfaces like we would normally do with differential forms. Since then I've thought of BRST as about as fundamental and well-motivates as differential forms are.

I know there are cases where BRST gets a little more complicated and I am not sure how far the correspondence with differential forms can be taken.

79. **Jeff M**
August 29, 2016

John,

Wow, you're giving me memories of grad school 🙂 That Witten paper on Morse theory was the basis of my orals, I had to present it. Honestly, could never work out what Witten was talking about until I read Roe's book on it.

80. **M. Nix**
August 29, 2016

This is nothing new. Kuhn's Theory on the Structure of Scientific Revolutions predicts exactly this sort of response. Individual scientists rarely change deeply-held views, no matter what evidence they're faced with (as with most humans). Rather, as the evidence mounts to discount old theories and promote new ones, new scientists adhere to the newer theories while the adherents of the old theories eventually retire and leave the field. Thus, while individual scientists don't change their views, the outlook of the field as a whole shifts over time.

Peter wrote:

> I think we agree about strategy: step back and look for new mathematical insights that may later find applications in fundamental physics. Even if you don't get what you want for physics, you'll learn more about deep mathematics, which is all to the good.

Agreed.

> And sure, Z/2-graded mathematics may very well be part of those insights.

Not "may very well be" – *is*. Let's face it, the realization that particles with half-integer spin obey canonical *anti*commutation relations, and that more generally you need to insert minus signs whenever you switch two odd objects, is precisely Z/2-graded mathematics. Z/2-gradings permeate mathematics, from Clifford algebras and K-theory on up. It's crucial to understand them.

That's a different question from whether particle physicists should care about supergroups that mix bosonic and fermionic physical degrees of freedom. In my opinion there's no sign from Nature that they should.

> My problem with Urs is that while he's often doing this sort of thing, at the same time he finds it necessary to try to use this to defend the central failed research program that has dominated (and done a huge amount of damage to) theoretical physics for over 30 years.

I fought hard against string theory for quite a while. I only started working on it after I gave up on fundamental physics and decided to enjoy some of the math for its own sake. So I'm a weird case. But I completely sympathize with how tough it is for people who work in the string theory community to break free of its core beliefs. I know because I broke free of loop quantum gravity.

Once you spend a few years working with people, pursuing the same majestic dream, going to conferences with them, becoming friends with them, it really feels tragic to throw in the towel and admit they're probably on the wrong track. For a while you feel life is pointless – because nothing else feels as exciting as the dream you once had. And then you have to make a decision: you can either stay in close contact with your former colleagues and spend your time arguing with them, casting doubt on their dreams, or – as I did – you can leave them behind, staying friendly but not talking much about your new work.

So we should never expect string theorists to admit in a public announcement that they lost a bet because they were wrong. They will either succeed someday… or gradually fade away.

> … dubious invocations of abstract mathematics.

On a wholly separate note, not related to this supersymmetry business, I wish people would stop saying the phrase "abstract mathematics" in a critical tone of voice. Mathematics is abstract, and it's been so at least since 1600 BC when Babylonians were solving some cubic equations. Abstraction is fundamental to mathematics. It's good. If people said "mathematics I don't understand", I'd be perfectly sympathetic and try to help.

I think your real complaint has nothing to do with Deligne's theorem being "abstract": it's that after applying it to see particles should form a representation of some supergroup, Urs goes the extra mile and throws in a plausibility argument that maybe, despite the experimental evidence, this supergroup should not be a mere group:

> Again, this does of course not prove local spacetime supersymmetry, but it serves to show that there are good reasons to expect that it might be: Because conversely, if the world were not locally supersymmetric, then there would be reason to ask: why this constraint? Why, if provided with the possibility to choose from the class of all super-groups, and with phase space of verified physics already being a supermanifold, why would Nature choose a purely bosonic symmetry group? It's possible, but it shows that it is not insane to suspect that fundamentally (i.e. at high energy) it might be different.

The reasoning here is hand-wavy, but the conclusion – that it's *"not insane to suspect"* the existence of supersymmetries – is so weak that I couldn't possibly argue against it. If nobody were working on supersymmetry, I'd say we should definitely put some people on it. The problem, in my mind, starts when a research community devotes a huge amount of time to studying this possibility and not as much to studying the alternatives.

83. **Urs Schreiber**
August 30, 2016

Peter, for one, it's not "Z/2-graded Tannaka duality" in Deligne's theorem. It's plain Tannaka duality for tensor categories in characteristic zero. That's the force of the theorem and the point for the present discussion: Starting with something god-given that does not mention super-symmetry, the theorem says that it secretly is governed by super-symmetry.

I'll leave it at that here. If anyone feels like discussing aspects of what I explained, let's do so in it's own comment thread here.

84. **JE**
August 30, 2016

Urs said, "so why on earth would Nature then choose to constrain this possibility and have an ordinary group act on the supermanifold, if it could choose a supergroup".

Because she is whimsical enough to dislike susy?

As forceful and mathematically appealing as it may seem, the fact that susy is now known to be nonexistent or totally out of experimental reach should suffice to abandon the idea that it (in its present form and unless miraculously proved otherwise in some foreseeably distant future) plays a key role in fundamental physics.

85. **Urs Schreiber**
August 30, 2016

High energy supersymmetry (supergravity) need not necessarily be experimentally out of reach. The Starobinsky model of cosmic inflation, preferred by the PLANCK satellite data, is argued to work even better after embedding into supergravity. See here for more discussion.

86. **Marc Nardmann**
August 30, 2016

John Baez wrote: "A much better example, from around the same time, would be Witten's approach to Morse theory."

I agree, that's another good example.

John: "[Witten's] argument for the positive mass theorem doesn't use Z/2-graded ideas, at least not explicitly."

They do not even occur implicitly. Not even the Z_2-grading of the Clifford algebra (i.e., its superalgebra structure) is used in the proof.

It's amusing that Witten's motivation for the spinorial proof of the positive mass theorem was a "not altogether clear relation" to supergravity. There would have been a much more natural and quite obvious motivation: the 1963 work of André Lichnerowicz about obstructions to nonnegative scalar curvature on closed manifolds. (Witten cites this work in this article, but only in passing, as an example that "spinors have been used in the past to prove various results that are at least roughly related to the positive energy theorem".) The path from Lichnerowicz' work to the spinorial proof of the positive mass theorem is straight and seems in hindsight hard to overlook. I could explain it here in a few paragraphs, but that might be off-topic. At least from the late 1960s on, there must have been people who knew both, Lichnerowicz' work and the (then open) positive mass conjecture. No outburst of ingenuity would have been necessary to find the spinorial proof. It's remarkable that nobody discovered it before 1981, and that even then the motivation was not the obvious one.

87. **Peter Woit**
August 30, 2016

Urs,
You're just ignoring the problem I'm pointing out, that of a huge leap of logic from this theorem to 10d supergravity. If you're going to make huge leaps of logic, they should at least land you somewhere new and interesting.

As for Planck data providing evidence for supergravity, I'm unfortunately an expert on indefensible claims about experimental evidence of this kind, but this is a new one to me, taking this kind of claim with nothing behind it to a new level.

88. **Giotis**
August 30, 2016

I'm not sure why we have to motivate mathematically SUSY when we have a very strong physical motivation to begin with.

The primary reason is that SUSY necessitates fermions and relates bosons and fermions in a deep way.

A five-year old will tell you that if you extend bosonic space-time to supersymmetric space-time you get fermions (a QM concept really) and if you make global SUSY local (as you ought to) you get gravity within the general context of Supergravity. Of course the only known way to make SUGRA UV finite is to UV complete it via String theory.

So you can think SUSY as the only consistent extension of special relativity, SUGRA as the only consistent extension of GR and String theory as the only consistent extension of QFT that can incorporate Gravity and give you Gauge Symmetry as a free bonus.

Or in another language you extend the Poincare group (SR) to Super Poincare (SUSY), the local Poincare (GR) to SUGRA and you make SUGRA consistent via String theory.

This is the bottom up approach; top down you can start with a bosonic String, follow consistency and you get the same picture and eventually the known Physics as an approximation.

89. **Urs Schreiber**
August 30, 2016

Giotis, this is a tautology:

> if you extend bosonic space-time to supersymmetric space-time you get fermions

Similarly this is a tautology:

> if you make global SUSY local (as you ought to) you get gravity within the general context of Supergravity.

I know that some sources make advertisements of this sort, but just repeating them doesn't make these statements less empty. Supersymmetry in physics by definition is an extension of the Poincare Lie algebra by fermions (check it out here), so of course it gives fermions and of course its local gauging gives gravity, that's by design, not by miracle. The miracles of supersymmetry lie elsewhere.

90. **Noboru Nakanishi**
August 30, 2016

I would like to summarize the theoretical reasons why the supersymmetric extension of Poincare algebra (SUSY) is not expected to be a correct physical theory.

1. Many people misunderstand the no-go theorem of Coleman-Mandula and Haag et al. It is a proposition for the observable symmetry, that is, it refers only to the symmetry of the physical S-matrix. Since unbroken SUSY is not realized in the real world, what we want to have is the proposition for the symmetry of Lagrangian. But nothing can be claimed for the Lagrangian symmetry; indeed, one can construct a counter-example. Thus, SUSY is not a privileged symmetry.

2. If SUSY is spontaneously broken, there must exist the Nambu-Goldstone fermion, but it is not observed. If one appeals to the super-Higgs mechanism, one must give up the important hypothesis that in the low energy region the quantum effects 0f gravity are completely negligible. If one does so, the brilliant success of SM must be regarded as merely accidental.

3. Quantum supergravity does not contain the global SUSY, that is, quantum supergravity is not a natural extension of SUSY. In classical supergravity, internal local symmetries can be easily translated into spacetime local symmetries by means 0f vierbein. But the same is no longer true for the global quantities because vierbein is a local field. Indeed, {Q, Q^(bar)} cannot have the spacetime index (mu) of the translational generator P_(mu), that is, SUSY is not reproduced.

4. In Einstein gravity, the general-coordinate-trasformation (GCT) algebra already contains not only the translation algebra but also the Lorentz algebra, that is, the Poincare algebra is a subalgebra of the GCT algebra. And the local Lorentz algebra is completely independent of it. In quantum Einstein gravity, the globalized versions of both symmetries are spontaneously broken; the unbroken physical Poincare algebra arises as a special combination just like the electromagnetic symmetry of the electroweak theory. Thus the physical Poincare algebra is a symmetry at the representatkon level. Therefore, it is quite unnatural to supersymmetrize the Poincare algebra at the Lagrangian level.

91. **Giotis**
August 31, 2016

Urs,

They are tautologies of course, that's the whole point; even so textbook tautologies are much better than often repeated, self-advertised, grandiose esoteric claims about miracles and novelties that nobody seems to pay attention to (in theoretical physics side at least)

92. **random reader**
August 31, 2016

Urs,

there are a couple of problems with the arguments from Deligne's theorems.

First, there is some fine print that you overlook in those theorems such as group vs group scheme, and algebraic groups vs pro-algebraic groups, that means the objects can be materially different from the smooth (super) Lie groups and Lie algebras as those terms are understood in physics. It would be interesting in the non-supersymmetric case to understand whether this more algebraic type of structure, such as a group scheme, is useful anywhere in the physics, and also whether the theorems like Deligne's hold in smooth or complex-analytic settings.

Second, the standard model (and most other non-SUSY QFT) uses an ordinary, non-supersymmetric, finite dimensional, gauge group, but some of the irreducible representations of that group are fermions. Having fermions in the theory therefore does not imply anything about the group being Z/2 graded. Deligne's theorem tells us that supergroups are complicated enough to accomodate any experimentally observed tensor product rules for particles (i.e., irreducible representations). To make a case for supersymmetry using Deligne's theorems, you would need some no-go theorem for ordinary Lie groups, explaining what limitations on the allowed sorts of tensor products are imposed by the absence of SUSY.

93. **Doug McDonald**
August 31, 2016

On topic: other SUSY bets. In particular Lubos Motl and Gordon Kane. I note that the two LHC main detectors are now both above 25 inverse fb for this year. That adds up to above 50, plus the bits from last year. Lubos's bet says 30, but does that mean combined detectors or just one? You (Woit) quote Kane as saying 300 inverse fb, but Tommaso Dorigo quotes Kane "Now that we can predict the gluino mass from compactified M theory we know that superpartners should not have been expected in LHC Run 1 because the gluino mass is about 1.5 TeV, and it will appear in Run 2 once the luminosity gets over 15-20 fb-1." which while not a bet is a very confident numerical prediction.

At a total of over 50, despite the total lack at the recent meeting, the analysis people and their stable of leakers would surely have leaked something as important as a SUSY-ascribable bump.

Presumably CERN has computerized autoanalysis constantly updating the
data plots and their bump standard deviations.

94. **Peter Woit**
August 31, 2016

Doug McDonald,
A problem with many of these bets is that they were made before the LHC turned on, and ran into trouble, forcing Run I to be at lower (8 TeV) energy. So, the people on the SUSY side of the bet might argue that only the data at full energy should count (actually, design energy was 14 TeV and they are running at 13 TeV, but nobody thinks that difference matters).

Putting together this year and last year's data, they're at about 30 inverse fb of 13 TeV data. So, when this data is analyzed, Lubos's bet is lost. I gather he'll hang on and not give up for a while, since there are lots of ongoing analyses. No, I've heard no rumors of SUSY signals in Run 2 data.

That "prediction" of Kane's is just the latest one in a long list of falsified ones. He's never in the past acknowledged that a prediction being wrong has any implication for the theory he is pushing, don't see why he should start now.

95. **random reader**
September 1, 2016

Another thing about the argument for SUSY using Deligne's theorem(s) on tensor categories is that Deligne refers to bare linear representations whereas the representations used to represent elementary particles involve unitary or projective structure on the representations, or positive-energy conditions.

OK, one might think that if supergroups are enough to accomodate general categories of finite-dimensional linear representations, then any extra structure on the representations must come from some extra data decorating the supergroups, in a way that would not change the basic idea of supergroups being the structure dictated by tensor categories. But having such a straightforward picture is only a hope, not something that would have to occur. Or if it does occur, the extra data could beef up the supergroups into more exotic categories of objects that we were hoping to avoid (as a flight of fancy to illustrate the idea: take a quadratic form to give the unitary structure, from that try and construct a Poisson bracket, which happens to be deformation data to form a quantum group… and if that is too constrained then deform in the even more exotic quasi-quantum category).

It is easy to glibly think of super Lie groups and algebras as some sort of next-more-complicated thing after Lie groups, but they are actually qualitatively more complex and Deligne's theorem is an indication of that. Another one is that the finite dimensional simple Lie superalgebras are not classified by discrete data, there are continuous moduli for some types of them.

p.s. In the preceding comment I wrote "gauge group" where I should have written (super)Poincare group, which is the thing whose representations are particles that are tensored together. But the same point applies, that having fermionic things among the representations does not by itself imply Z/2 grading.

96. **bk**
September 1, 2016

Urs,

while I sympathize with your standpoints, in full contrast to other's,
for sake of correctness I need to point out that your statement

"….) just so happens to be 2d supersymmetric (and called the "superstring" only once this was realized), which in turn is interesting because it miraculously implies that the effective spacetime theory of which these strings are quata is locally 10d supersymmetric.."

is misleasing if not wrong, despite it has been claimed so for zilli0ns of times.
Take as counterexamples the "other" 10 dim string theories that are not spacetime susy inspite of having world-sheet susy. Eg the heterotic string with O(16)xO(16) symmetry.
These theories are almost never mentioned when talking about the grand scheme of things, for some reason.

97. **GoletaBeach**
September 5, 2016

On Dine's quote… it is buried in a popular article, certainly it is not the banner headline… even the 2 sentences before are: "Despite those successes, good reasons exist for skepticism. Some are experimental: Apart from coupling unification, no direct evidence yet argues for supersymmetry." Not denying that Dine went overboard in the next sentence, but I don't think that quote is a main thrust of the article, or, within a light year of the consensus view of the experimental particle physics community.

Just have to go back a few months in Physics Today for a sober article by Fabiola Gianotti and Chris Quigg… quoting from that one "theorists have advanced many extensions of electroweak theory—supersymmetry and technicolor, for example—that compel additional new phenomena near 1 TeV." They get totally right, 4 or so years in advance: "An essential first step toward decoding electroweak symmetry breaking is to find the Higgs boson and learn its properties. One promising channel for an early discovery is H → ZZ → 4 charged leptons. Backgrounds are very small, so even a handful of events would suffice for a claim of discov- ery. Establishing the signal will require efficient electron and muon reconstruction and identification down to a few GeV."

On Kane, "That "prediction" of Kane's is just the latest one in a long list of falsified ones. He's never in the past acknowledged that a prediction being wrong has any implication for the theory he is pushing, don't see why he should start now."

Well, I've heard him acknowledge just that many times. He is an honest guy. I don't really understand what data you have used to support such a strong statement.

I can't think of any useful reasons to beat up optimists, except if they have directly suppressed good science. I don't think Dine and Kane have done so; optimists generally don't suppress good science, they encourage too promiscuously.

Their enthusiasm has pushed the field forward, and the personal embarrassment they suffer from wrong predictions is a sociological issue, and irrelevant for getting good physics done. If any thing, making predictions that prove to be wrong and that embarrass in the long run is helpful to the progress of physics…. the right idea might well eventually be stimulated by the wrong prediction.

Only in retrospect does physics seem to be sort of linear… the advance of physics is always more like diffusion, with lots of backward and forward motion. Sideways too. Overly enthusiastic ideas are just part of the diffusion process.

98. **Peter Woit**
September 5, 2016

GoletaBeach,

One problem with writing a prominent article/book saying "SUSY will either be discovered at the LHC or is wrong", and then refusing to acknowledge that SUSY is wrong when the LHC doesn't see it is that you destroy your own credibility if you do this. Kane already has passed the point where anyone thinks his "predictions" are credible, and while Dine has been more circumspect, if he tries to make more such claims about SUSY at higher energies, few will take them seriously.

Unfortunately, when this kind of behavior is widespread, it becomes a problem not just for certain people's credibility, but for the general credibility of the field, and that has serious implications. In another comment thread, someone pointed out that CN Yang has publicly come out against the proposed Chinese collider. One of his main arguments is that SUSY is being put forward as a reason for building such a machine, and that this motivation lacks credibility. He's probably aware of pre-LHC arguments like those of Dine and Kane, not willing to tolerate them any more, and this will have implications for those trying to make the case for a new collider.

September 6, 2016

FWIW, I have many middle-aged colleagues who grew up in mainland China. None of them have a physics background beyond the requirements to get their degrees in other areas, like medicine or biochemistry. They all know who C.N. Yang and T.D. Lee are and can tell you in impressive detail what they shared the Nobel for, K mesons, parity violation, the whole deal. If I ask one of my contemporaneous American colleagues who our most famous physics laureate is, I would likely get an answer like "um…Einstein?" (technically correct, but…) For reasons I don't claim to fully understand, these Chinese folks had it drilled into their heads during their pre-graduate educations that Lee and Yang were exemplars of Chinese civilization, and are worthy of reverence. If Yang is going around saying SUSY is a waste of time and money, I'd guess it would exert oversized influence, at least on the generation that now is predominantly represented in the Party of the PRC.

100. **GoletaBeach**
September 7, 2016

As I said, in the sentence prior to the one you quote in the Dine article, he points out a good reason to be skeptical of SUSY… "Despite those successes, good reasons exist for skepticism. Some are experimental: Apart from coupling unification, no direct evidence yet argues for supersymmetry."… yes, his subsequent sentence that LHC will be deterministic for SUSY is simply wrong, and in no way (ever) represented the consensus view of the experimental community. And was not a sufficient portion of the article to warrant a retraction, in my opinion.

The Fabiola Gianotti and Chris Quigg article that same year is much closer to the consensus view of the community.

I don't think any of the LHC technical documents (yellow books, technical design reports, etc) say anything like ""SUSY will either be discovered at the LHC or is wrong". If you know of anyplace those documents support your assertion, I'm all ears.

Everyone serious knows that even the simplest implementations of SUSY, like the CMSSM, are not close to eliminated by LHC data. See for example, Leszek Roszkowski's talk at IDM 2016: https://idm2016.shef.ac.uk/indico/event/0/timetable/#20160719.

Any claim that "SUSY is wrong" is not currently supported by data or phenomenology. Pointing to a few people who said that is sort of like pointing to a few glaciers that are expanding and claiming that global warming is wrong.

Do any theorists, whether Gordon Kane or Frank Yang, have any significant credibility with their predictions? Einstein himself was wrong about a lot, from the cosmological constant to quantum mechanics, and he was even childish and petulant in his errors about gravity waves, as Barry Barish has been pointing out in his recent talks.

The mistake is ever to attribute credibility *for sweeping predictions* to theorists. If they can bat 0.001 that actually an amazing record on the "big questions". Batting 0.300 has never been realistic.

I think the mistake is to get snide and dark over the 0.999 of the time theorists are wrong about big stuff. Because… first of all, it is too easy, it is like shooting fish in a barrel. Second of all, being snide and dark only suppresses the speculation that is necessary for the occasional right theoretical idea to pop up.

101. **Peter Woit**
September 7, 2016

GoletaBeach,

The Frank Yang problem I was pointing was not bad predictions from him, but he's a good example of the danger you face when you choose to overhype an idea about physics (and lots of people did this with SUSY and the LHC, not just Dine and Kane). Serious physicists like Yang will notice you're doing this, and after your "predictions" don't work out, and you try and pull the same thing again, they'll call you on it. And some of them may be extremely influential with the government officials you need funding from.

By the way, there's yet another news story about this https://www.sciencenews.org/article/supersymmetry%E2%80%99s-absence-lhc-puzzles-physicists

I'll add an update to the posting.

102. **GoletaBeach**
September 7, 2016

Nice Science News article… actually the Frank Yang comment has harmed his reputation with me, now that I look carefully at it. I am getting repetitive, but if you choose a subset of the community (say, Kane, Dine, some others you bring up) and then color everyone with their comments, *and*, if you ignore the measured consensus documents like all the technical design reports, yellow reports, Snowmass process, etc…. well… you are doing the same thing climate deniers do.

Maybe climate deniers are in the end correct, but their application of the scientific method is unconvincing.

Building the highest energy machine is always a good scientific idea. In fact we have learned that the SSC had more discovery potential than the LHC, ex post facto (I know you didn't want any more collider discussion, but you reintroduced with Frank Yang's comment about the Great Collider).

The only issue is cost. If we could do 100 TeV for the cost of the LHC, we should do so, independent of SUSY or technicolor or multiverses or any theoretical fashion.

Because discovery is an empirical science in the end. But the LHC cost has been a kind of wall that governments cannot get beyond, maybe fairly.

If Frank Yang is anti-discovery, well, his reputation suffers with me.

103. **Peter Woit**
September 7, 2016

GoletaBeach,

I agree that a new energy frontier machine is desirable. My only point is that if you try and make the case for it with the argument "a 100 TeV collider will tell whether or not there is SUSY" (I've already seen this argument made publicly, in this form, will see if I can remember the source), you're handing over to those who disagree with you excellent evidence that you lack credibility.

104. **GoletaBeach**
September 8, 2016

Sure, there are always people who overstate the case for anything… most politicians, most fitness gurus, some scientists.

For the LHC, the serious case was made in DOE technical design reports, CERN yellow reports, etc. I don't think you'll find a statement like "the LHC will either confirm or refute SUSY" in any of those reports, but if you can point to an example, I'm interested in knowing. Quigg and Gianotti in their 2007 Physics Today seem to me to have respected the foundational LHC reports, and Dine did not.

Similarly for any serious 100 TeV proposal… there will be lots of careful scientific projection and effort that will be documented very responsibly, and that is the corpus of work that will form the foundation of the proposal.

I'm not comfortable with replacing all that good science with the overenthusiastic or exaggerated claims of some theorists, or some promoters, or whoever. Maybe in the superficial media world things like that happen all the time… the glib talking heads get to drive the bus.

At least within the world of science, the real science should matter. However, there is freedom of speech and opinion… if Nima Arkani-Hamed or David Gross or Gordon Kane or Michael Dine wants to try to give their personal spin, I see no way to stop them.

Well, maybe if China chooses to build the collider they could imprison anyone saying something not consistent with all the design reports…. China certainly does that on other political issues. I'm not being serious, of course.

Even if China did that, any talking head with an opinion could always just hide out in the Ecuadoran embassy and Skype their opinion to the world (not serious about that either).

In the end Hollywood rules are probably about as practical as anything: 1)if your name gets publicized, your first concern should be if they spelled it right, not what the nature of the publicity is; 2)the only bad publicity is your obituary.

Templeton News

September 1, 2016
Categories: Uncategorized

Looking at my list of items to blog about, I see most of them have some relation to the Templeton Foundation, so this will be a blog post just about those. To get some idea of the scale of Templeton's activities, at the end of 2014 they had about \$3.2 billion in assets, and during 2014 had given away about \$185 million. For comparison, the NSF budget for FY2014 for physics was $267 million and for mathematics \$225 million.

One of the main goals of the foundation is to bring together science and religion. Among the many things they are funding to accomplish this is a \$871,000 grant to Arizona State University to fund Think Write Publish Fellowships in Science and Religion. If you're a hard-up writer, these people will give you the opportunity to get $10,000 to write "creative nonfiction stories about harmonies between science and religion" and help you get them published.

Over the next few years, as you see things like this make it into the media, realize that this is not evidence of an intellectual trend, but a reflection of Templeton money and their agenda. ASU's Lawrence Krauss is, for good reason, not happy.

To give an idea of the range of Templeton's influence, just at ASU they're funding several other large grants, including $745,000 for Representations of God (this and this), and $544,000 for emergent gravity. When you notice conferences, seminars, public lectures, etc. about "emergent gravity" in coming years, realize that some of them are happening because of Templeton's agenda (one of the PIs is a Templeton Prize winner).

One of Templeton's largest recent grants has been \$4.7 million to FQXI for research into "Physics of the Observer". Among other things, this funded a recent conference at Banff.

A major interest of Templeton's over the years has been "Genius". Another of their large recent grants has been to the World Science Foundation for its Cultivating Genius Initiative.

Finally, there will be an interesting mathematics conference related to quantum field theory at Harvard October 8-10. I'll likely be up in Boston visiting my brother and hope to maybe attend some of the talks. Funding for this is coming partially from the "Templeton Charity Foundation Switzerland". I guess this is these people, some off-shoot of the Templeton Foundation, with exactly the same interests, They say they have made \$85.2 million in grants, a list is here.

Update: I was thinking of commenting that Templeton at least seemed to have slowed down its efforts to promote multiverse mania. But then I noticed this. If you want to know why Ira Flatow on NPR keeps bringing up the multiverse, \$150,000 in Templeton money might have something to do with it…

Update: I keep on finding out about more of these Templeton-funded things, they are endless. Templeton is funding an Institute for Cross-Disciplinary Engagement at Dartmouth. Themes to be investigated are "Can science alone explain the nature of reality?", "Is there free will?" and "Is there purpose in the universe?". Among their many activities will be an event featuring a dialogue between Sean Carroll and a Buddhist Scholar in San Francisco in February.

Comments

1. **Thomas Larsson**
   September 2, 2016

   I'm all in favor of studying physics of the observer. After all, every real experiment is an interaction between a system and an observer, and the outcome depends on the physical properties of both. Studying an aspect which is present in all experiments and which has been hitherto rather ignored seems like a promising approach to make progress.

   Of course, an "observer" does not have to be conscious or even alive. Perhaps "probe" is a better word, or "test particle" in the context of GR.

2. **Bernd**
   September 2, 2016

   Is "emergent gravity" somehow related to "intelligent falling"?

3. **Jess Riedel**
   September 2, 2016

   As someone who attended the Banff conference, whose thesis was ~20% funded by Templeton, and who is applying for a grant, I strongly agree with Peter's wariness and the danger of interpreting forthcoming fads as meaningful intellectual trends rather than just the effect of funding incentives. This is important to highlight. That said, I think the Templeton funding is a definite net positive for the world (my own work aside, of course). They aren't a lone nefarious bias in an otherwise pristine academia, they are just one of many, many distortionary incentives, created by mostly well-meaning human beings.

   Yes, if Templeton really was an O(1) fraction of the funding for physics (or any other subject), what would be serious cause for concern, but the numbers given above are misleading. The large majority of Templeton money is *not* going to math and physics research, so it's not fair to compare all $185M to the $492M total NSF math and physics funding. Take a look here for the Templeton Foundation's Math & Physical Science grant winners. They gave $12.2M in 2014, $17.4M in 2015, $7.5M so far in 2016. I encourage concerned folks to go read the grant descriptions for signs of nefarious religious influences.

   Ultimately we have to reply on the marketplace of ideas. If the marketplace breaks (say, because physicists are more dysfunctional than mathematicians when unconstrained by experimental data), it can't be saved by rallying the group to exclude certain funders.

   Thanks for the very useful post, Peter!

4. **Jonathan Miller**
   September 2, 2016

   They have a lot of money, I should make a grant application.

5. **Peter Woit**
   September 2, 2016

   Thanks Jess,

The numbers were meant more to give an idea of the overall scale of the resources Templeton is devoting to its agenda. To compare the impact on physics and mathematics you'd have to look at different numbers. Templeton does very little to support mathematics research, so has just about no impact there. For physics research (unlike the NSF) they do very little on the experimental side, which is the most expensive.

6. **sebastian**
   September 2, 2016

   Judging from the invited speakers, the conference is mainly about the operator algebra approach to 2 dimensional conformal QFT.

7. **Jess Riedel**
   September 2, 2016

   > For physics research (unlike the NSF) they do very little on the experimental side, which is the most expensive.

   Yep, that's a good point.

8. **Matt Leifer**
   September 2, 2016

   I am not completely comfortable with taking Templeton money, but on the other hand there really is nobody else funding work on the foundations of physics, so if you want to work on that where are you supposed to go?

   I do think we need a private funding body that has a skeptical agenda as a counterpoint to Templeton. In an ideal world, the NSF would be doing that, but in the current political climate that is not going to happen.

9. **Kevin Henderson**
   September 2, 2016

   It appears Templeton will continue to fund research which will likely never match their aspirations. It is innocuous to apply and accept grants from them as it only benefits the researcher.

10. **Peter Shor**
    September 3, 2016

    If, on the religion side, the Templeton Foundation supplies a balance to the creationists and the other virulent anti-science religious types, it may end up doing much more good than harm.

    Of course I, and most readers of this blog (I suspect) can only judge what effects the Templeton Foundation is having on the science side, where it seems to be doing things like putting more emphasis on emergent gravity than is really justified.

11. **Dragster**
    September 4, 2016

    > For physics research (unlike the NSF) they do very little on the experimental side, which is the most expensive.

    Is that still true? Looking at the 2016 grants, their second largest is $1.5M for this project:

    A tabletop-scale experiment to probe for new particles and forces responsible for the predominance of matter over antimatter in the Universe

12. **Tim May**
    September 4, 2016

    I recall that a semi-crackpot organization called the "Gravity Research Foundation," or something similar, funded some important GR work in or about the about the 60s, maybe as late as into the 70s.

    They were interested in anti-gravity stuff, but they funded some important GR things.

    Didn't seem harmful. Everyone knew the funding was coming from some near-crackpots, but, hey, it was there money.

    –Tim May

13. **Peter Woit**
    September 4, 2016

    Tim May,
    They're still around, see Wikipedia or their web-site for more of their story and what they're up to. As far as I can tell, they've got about $1 million in assets, and their only expenses going to further physics are about $10,000/year for their essay awards. So, we're talking .01% of Templeton.

    Actually, doing a little investigation of that Foundation, there are some analogies with Templeton. It appears to be run by the son (George M. Rideout, Jr.) of the guy who, together with Roger Babson, started the thing (and a large chunk of the Foundation income goes to him). The founders were, like Templeton, in the investment advisory business. Also like Templeton, there is an associated Foundation supporting religion, the "Open-Church Foundation"), also run by George M. Rideout, Jr.

14. **Peter Woit**
    September 4, 2016

    Dragster,
    From their grant descriptions it appears that support of experimental research is still quite unusual and a small proportion of what they do. On the other hand, at NSF physics, I believe more funding goes to experiment than theory (although a quick search hasn't turned up numbers categorized that way).

15. **Daniel**
    September 4, 2016

    An off-topic news, CN Yang just officially opposed to the building of the large collider. This may have important effect on Chinese government's decision.

16. **Peter Woit**
September 5, 2016

Daniel,
Thanks, but I want to discourage discussion of this here since it is off-topic. For those interested in this, there is more here
http://www.sixthtone.com/news/china-should-not-build-particle-collider-says-nobel-winner
and surely Chinese speakers can find other sources.

17. **Larry Lurio**
September 5, 2016

We (NIU) just had a colloquium from Alexey Burov on "Genesis of a Pythagorean Universe" which was based on an essay that won an FQXi award http://arxiv.org/abs/1411.7304. The talk claimed to disprove the unconstrained multiverse hypothesis since there was an infinite probability of each universe containing the seeds of its own destruction. The resolution was a constrained multiverse constructed by "The Mind" which wished to be observed. I was a little surprised that religious based philosophy of science would win an award from a foundational questions institute, but after reading your information about the source of funding, I am less surprised.

18. **Mozibur Ullah**
September 10, 2016

I just reread the beginning of Feynmans lectures on physics, and his polemics against philosophers which I enjoyed when I was younger now just make me feel a little annoyed; the same went when I looked at Susskinds lectures where he suggested, for example, that Aristotle supposed F=mv – which quite missed the point of Aristotles subtle analysis what change requires.

So I'm all for a dialogue between philosophy, religion and physics – and oh, mathematics.

If the Templeton organisation is over-funding emergent gravitation it certainly suggests that they ought to have input from more physics-wise physicists; but how can this happen if they're eyeing each other nervously/reluctantly?

Weapons of Math Destruction

September 6, 2016
Categories: Book Reviews

Cathy O'Neil's important new book [Weapons of Math Destruction](), is out today, and if you're at all interested in the social significance of how mathematics is now being used, you should go out and get a copy. She has been blogging for quite a while at [Mathbabe](), which you should be following, and is a good place to start if your attention span is too short for the book.

Cathy has had an interesting career path, including a period as my colleague here in the math department at Columbia. She left here to pursue excitement and fortune at a top hedge fund, D.E. Shaw, where she had a front-row seat at the 2008 financial industry collapse. A large factor in that collapse was the role played by mathematical models, and her book explains some of that story (for another take on this, there's [Models.Behaving.Badly]() from another Columbia colleague, Emanuel Derman). As far as I've ever been able to figure out, the role of mathematical modeling in the mortgage backed securities debacle was as a straightforward accessory to fraud. Dubious and fraudulent lending was packaged using mathematics into something that could be marketed as a relatively safe investment, with one main role of the model that of making it hard for others to figure out what was going on. This worked quite well for those selling these things, with the models successfully doing their job of obscuring the fraud and keeping most everyone out of jail.

While this part of the story is now an old and well-worn one, what's new and important about *Weapons of Math Destruction* is its examination of the much wider role that mathematical modeling now plays in our society. Cathy went on from the job at D.E. Shaw to work first in risk management and later as a data scientist at an internet media start-up. There she saw some of the same processes at work:

> In fact, I saw all kinds of parallels between finance and Big Data. Both industries gobble up the same pool of talent, much of it from elite universities like MIT, Princeton and Stanford. These new hires are ravenous for success and have been focused on external metrics – like SAT scores and college admissions – their entire lives. Whether in finance or tech, the message they've received is that they will be rich, they they will run the world…
>
> In both of these industries, the real world, with all its messiness, sits apart. The inclination is to replace people with data trails turning them into more effective shoppers, voters, or workers to optimize some objective… More and more I worried about the separation between technical models and real people, and about the moral repercussions of that separation. If fact, I saw the same pattern emerging that I'd witnessed in finance: a false sense of security was leading to widespread use of imperfect models, self-serving definitions of success, and growing feedback loops. Those who objected were regarded as nostalgic Luddites.
>
> I wondered what the analogue to the credit crisis might be in Big Data. Instead of a bust, I saw a growing dystopia, with inequality rising. The algorithms would make sure that those deemed losers would remain that way. A lucky minority would gain ever more control over the data economy, taking in outrageous fortunes and convincing themselves that they deserved it.

The book then goes on to examine various examples of how Big Data and complex algorithms are working out in practice. Some of these include:

- The effect of the *US News and World Report* algorithm for college ranking, as colleges try and game the algorithm, while at the same time well-off families are at work gaming the complexities of elite college admissions systems.
- The effects of targeted advertising, especially the way it allows predatory advertisers (some for profit educational institutions, payday lenders, etc.) to very efficiently go after those most vulnerable to the scam.
- The effects of predictive policing, with equality before the law replaced by an algorithm that sends different degrees of law enforcement into different communities.
- The effects of automated algorithms sorting and rejecting job applications, with indirect consequences of discrimination against classes of people.
- The effects of poorly thought-out algorithms for evaluating teachers, sometimes driving excellent teachers from their jobs .
- The effects of algorithms that score credit, determine access to mortgages and to insurance, often with the effect of making sure that those deemed losers stay that way.

Finally, there's a chapter on Facebook and the way political interests are taking advantage of the detailed information it provides to target their messages, to the detriment of democracy.

To me, Facebook is perhaps the most worrisome of all the Big Data concerns of the book. It now exercises an incredible amount of influence over what information people see, with this influence sometimes being sold to the highest bidder. Together with Amazon, Google and Apple, our economy and society have become controlled by monopolies to an unparalleled degree, monopolies that monitor our every move. In the context of government surveillance, Edward Snowden remarked that we are now "tagged animals, the primary difference being that we paid for the tags and they're in our pockets." A very small number of huge extremely wealthy corporations have even greater access to those tags than the government does, recording every movement, communication with others, and even every train of thought as we interact with the web.

These organizations are just starting to explore how to optimize their use of our tags, and thus of us. Of the students starting classes here today in the math department, our training will allow many of them to go on to careers working for these companies. As they go off to work on the algorithms that will govern the lives of all of us, I hope they'll start by reading this book and thinking about the issues it raises.

Comments

1. **amz review**
   September 6, 2016

   read this customer review at Amazon (3 stars)

   https://www.amazon.com/Weapons-Math-Destruction-Increases-Inequality/product-reviews/0553418815/ref=cm_cr_dp_text?ie=UTF8&showViewpoints=0&sortBy=helpful#R1HO7IVVTLX9VL

   I struggled with the star rating for this book. There are certainly aspects of the work that merit five stars. And it is VERY thought-provoking, like a good book should be. But there are flaws, significant ones, with the biggest flaw being a glaring over-simplification of many of the systems that O'Neil decries in the book. I don't know if O'Neil has personally ever had to take a psychology test to get a job, worked under the Kronos scheduling system, lived in a neighborhood with increased police presence due to crime rates, been victimized by insurance rates adjusted to zip codes, and endured corporate wellness programs. But all of those things have been a part of my life for years, and even I have to admit the many positive aspects of some of these systems. A few examples:

   –Kronos. Despised by the rank and file of companies that I've worked for, Kronos software contains many aspects and automates things that previously were done by people, mostly managers. I hated it, but I have to admit overall it made things more fair. Why? Well, say you have a workplace policy that mandates chronically-late employees be written up for tardiness and eventually fired if they don't shape up. What tended to happen at multiple companies I worked for was that managers would look the other way when their buddies were tardy, and write up people they didn't like. Kronos changed that, because the system automatically generated write-ups for any employee that clocked in late too many times. Kronos has no buddies. Popular, habitually-late people suffered, but it was more "fair" in the true sense of the word. Some systems, like Kronos, have both aspects that level the playing field and aspects (like increased scheduling "efficiency") that can victimize workers. O'Neil tends to harp on the negative only, and if you have not personally seen both sides of system, you might not realize there was another side at all.

–Increased police presence in high-crime areas. This one really grated me the wrong way. O'Neil positions this as something that victimizes the poor. Well I have been poor, or at least this country's version of it, and I have lived in very high crime areas where if you didn't shut your window at night chances were good you would hear a murder. And believe me when I say I was DEEPLY grateful for the increased police presence. But then, I wasn't committing crimes. Now I live in a very wealthy neighborhood (though I am not wealthy) where I have not seen a single police car drive down my street in the past four months. O'Neil argues that many crimes, like drug use by affluent college students, go unpunished because the police are busy in the poorer neighborhoods. I agree, but police resources are limited and for mercy's sake they should be sent where people are being killed, not where a college student is passed out in his living room. My current neighbors many be committing as many crimes as O'Neil implies, but I'm not terrified to walk down the street, so I don't mind the lack of police presence. I know officers have to go deal with the more life-threatening stuff, and I am grateful to them. It all depends on your perspective.

–Corporate Wellness programs. These programs have never done anything for me except shower me with gift cards and educate me on behavioral sleep therapy. I love them. But, again, perspective. I am not overweight, I love to work out, and I eat healthy. The programs were a source of income for me and my family when we needed it most. I just would have liked acknowledgement that wellness programs really do have benefits for some people, instead of a chapter painting them as some sort of 1984-style nightmare where we are all forced to be thin. It's more complicated than that.

–And the best for last: The psychology tests. Those things are pretty bad. Despite winning multiple Employee and Student of the Year awards in my life, I can't pass those tests. Not to save my life. I didn't think much of it, until I heard about another star employee how couldn't pass them either. Then I met a third star employee (and I am talking about an employee who won two JD Power Awards in two years) who couldn't pass them. Why? Picture holding a hundred quarters in your hands and then throwing them at a wall. Some will go off to one side and some to another, but most will probably cluster in the middle. Those tests keep the quarters in the middle, weeding out people who aren't typical. Sometimes that's good (deadbeats) sometimes that's bad (talented employees that think different). Here O'Neil misses an opportunity to convince owners of companies that the tests can cost them highly desirable employees. Offering real, concrete ideas of how the tests could be improved to benefit both workers and company owners would have been a harder book to write, but a much more useful one.

A lot of the ominous implications made in the book have to do with what MIGHT happen in the future, if certain systems become more common. O'Neil often uses blanket statements to imply that certain outcomes are inevitable, but that is far from true. Irritate enough people, and the systems change. Legal challenges are made and won. Some companies, eager to lure star workers, throw out some of the more punishing aspects of commonly-used systems (that happened at a company where I worked, where "life-style" scheduling that forbid clopening and gave you two days off in a row was used in conjunction with Kronos. Worked great, people loved it.). The biggest weapon against abuse is, as O'Neil repeatedly states, transparency. Having been in the industry that creates these algorithms, she is in a unique position to expose the finer details of how they work. But the book is short on the kind of details I personally crave and long on blanket statements and generalizations, the same kind of generalizations she denounces companies for making. Not all automated systems victimize the poor, not even the ones spotlighted in this book. I know because I lived them and I was poor.

I hovered on the edge of a four star rating for this book, until a chance conversation with a Japanese woman a couple days ago. Her grandmother had lost most of her possessions and land after World War II because of land redistribution. My friend was not complaining, she thought the reforms overall a good thing, though her family had lost a lot from it. "Something may benefit 99 people of of 100," she told me,"but there's always that one person…". Exactly. There's always that one person. These systems that have come to permeate our culture need to be tweaked to minimize injustice. Unlawful algorithms need to be outlawed. Bad ideas need to be replaced with good ones. And Cathy O'Neil does discuss this, especially in the conclusion, but for me the focus of the book wasn't on target. It was too slanted against systems I have seen both harm AND help. It over-simplified issues, at least for me. It's a mess out there, and solutions that work for everyone wickedly hard to come by.

Because there's always that one person.

2. **anon**
   September 6, 2016

   I am constantly surprised that people continue to choose to use Facebook daily in all its awfulness. If this is how most our society chooses to squander this wonderful thing called the internet, maybe our society deserves the consequences, whatever they may be.

   We tend to forget that people can delete their accounts. (I did.) Participation isn't mandatory.

   September 6, 2016

   amz review (and others),
   Please do not spam this blog with copied content from other places. That's what links are for, and, in any case, anyone who wants to read Amazon reviews will see them if they follow the link to the Amazon book page included in the posting.

4. **srp**
   September 6, 2016

   There are often two contradictory strands of these critiques of modern operations research (which is really what all this stuff is about). One is that it doesn't work, the other that it works too well. So you end up with all this spaghetti being thrown at the wall, as in Peter's synopsis.

   Moreover, most of the drawbacks of pervasive personal data also have advantages. A machine that invades our privacy is also an alibi machine for the innocent for example. Pervasive video surveillance makes it hard to sneak around but it also makes it harder for police to abuse suspects. And so on.

   Personally, having seen the really primitive ability of current Big Data marketing tools to predict my interests and send me appropriate ads and offers, I think the biggest issue is hype. These things are much weaker in application than in breathless accounts, and when they do work it seems mostly a good thing.

5. **Bee**
   September 7, 2016

   Thanks for pointing out, sounds very interesting. Will totally put this on the reading list.

6. **Eiger**
   September 7, 2016

   @srp

   Your argument in favour of pervasive data collection seems to be the same as that used for state mass surveillance: 'it'll keep you safer, and if you're not doing anything wrong you've got nothing to worry about.'

7. **Navneeth**

September 7, 2016

Bee & Peter,
If you're interested, the theme from one of the 'MLConfs' from a few months ago was on the ethics in machine learning. You can find the videos of the talks, here: https://www.youtube.com/playlist?list=PLrbAIdPI69PiyfmA-TzKpWkmYTmuck5wS

And a summary of the conference itself: http://www.kdnuggets.com/2016/06/ethics-machine-learning-mlconf.html

8. **Bernald**
September 7, 2016

I saw the headline "Math is racist" at CNN, and correctly guessed there'd be something more reasonable at this blog.

But I have to say this seems like a classic case of out of touch elites. If you have a perfectly fair and objective algorithm (or more broadly, any human-made system), some people in positions of influence, and with their own personal biases, will deem the results unacceptable and unfair, and will act to modify things to strongly push the results in a direction they find desirable. Often this tampering is done in the name of egalitarianism, to make things superficially appear more equal by actually making them less fair. This generally does more harm than good, including to the intended beneficiaries.

While the author may make many legitimate arguments, some other arguments have things exactly backwards. Instead of the problem being that "algorithms" (more broadly, any human-made systems and decision making processes) have an unintended or intended bias against certain parts of society, allegedly causing some purported social injustice, it is rather the case that some pseudo-egalitarian elites have actively rigged and tampered with the systems so as to direct favor towards those who the elites deem to be deserving recipients of some compensatory social justice.

It's often not the algorithms/systems that are the problem, but rather it is the actions to counteract the supposed problem that are the real problem.

9. **KMS**
September 7, 2016

Actually I think there are at least two somewhat more fundamental problems concerning the social context and consequences of mathematical models, which one should think about before discussing the questions, wether the outcomes are beneficial or not.
First, one should be aware of the fact, that modelling in itself is a descriptive activity: Models try to capture the important aspects of some part of reality, necessarily leaving out "small" factors, that will not influence the outcomes (mostly average quantities) significantly. When relying on them to initiate activities, they however cease to be purely descriptive tools and acquire normative aspects.
But in the realm of normative questions there are – at least in most parts of the western world – different standards, by which rules are judged. One important aspect is, that once people are concerned it is not in general acceptable to just look at averages outcomes and _ignore_ those individuals who happen to suffer a serious disadvantage for the greater good of the majority. This does not mean that such situations do not also occur without the involvement of machines and algorithms – but in the end they are (or rather should be) handled in the context of legal decisions by courts who always have to take individual rights and general legal principles into account. This is very much in contrast to the "Utilitarian" position cited at the end of amz review's comment. So relying on algorithms for social decisions tends to promote a certain ethical position, which I consider to be at odds with some of the more fundamental principles of western societies. In any case, if one would like to base our society on such a position, one should openly discuss this using arguments from the relevant realms (ethics/philosophy/…) – and not just accept such a position, because it happens to harmonize well with the way models work.
Related to this is the point, that many algorithms at their core are nothing but statistically vamped up prejudices: Correlating e.g. zip codes to credit default risks is not fundamentally different to forming prejudice about people in certain neighbourhoods based on "everyday observations". But in constrast to plain old prejudices they now claim to be serious (even scientific) answers to practical (and often pressing) questions.
This leads me to my second point: There seems to be a serious problem in the perception of what models can and can not do, both in the general population and among many of those involved in the modelling.
Talking to people outside academia and looking at statements in the media, mathematical models seem to have an almost magical status: Mathematics is seen as very complicated, so the people building the models must be very clever and consequently their models have to stand above "normal" reasoning. Of course, models are not more and not less than a precise version of ordinary reasoning in a framework (mathematics) which allows the application of a lot of machinery to make precise reasoning easier and quantitative.
As a result, the importance of the modelling proper and the huge freedom one has when setting up a model is massively underestimated (if perceived at all). And this last point I suspect to also be true for many of the mathematicians doing the modelling.
There are systematic factors for that – one of the most important being, that at least those coming from pure mathematics usually have no experience at all in modelling. This is not just a question of maybe having learned and numerically implemented one or two well establied models, but of having made the experience that one can come up with loads of models for a given phenomenon, which are mathematically consistent and at first sight might seem plausible, but later just turn out to be wrong in important aspects.

In general I do think there are by now quite a few important questions about the consequences of increasing reliance on mathematical models and the responsabilities of those involved in building them. I therefore consider it high time that Mathematicians abandons their "we are disconnected from the world outside" attitude (as expressed e.g. in Hardy's "Apology") and start talking about their responsabilites – just like Physicists had to do 70 years ago.

10. **Peter Woit**
September 7, 2016

Bernald,
The "Math is racist" headline is a really stupid take on the book. Countering that kind of stupidity with "the problem is out of touch social engineering elites" is just as stupid. Neither has anything to do with what's actually in the book. All, the internet has quite enough of this kind of stupid reductive argument, please don't do this here.

11. **Barbara Duck**
September 7, 2016

I have followed her since day one on her blog. I was already over in healthcare writing the same type of blog posts as I could see how financial models were just being tweaked to be used in healthcare. Do pay attention as our current Medicare/CMS acting director is all into this with stats and numbers and came from United Healthcare where modeling was his expertise, as he's a former McKinsey Consultant and Goldman banker. WMD are really being pushed at HHS and CMS. It's scary indeed and I've been writing about it for about 8 years with the incest of United Healthcare that exists there.

I go a bit further and talk about "excess scoring" as a result of the WMDs and if most folks only really knew and would educate themselves on what goes on at the prescription counter, well it might be too much for folks to take when they see the reality of how you are scored with medication prediction adherence 300 metrics based on behavior, not drug compliance really. I chat with pharmacists all the time that keep me updated in that arena. Here's a link below that has a video and goes into detail, but in summary, Cathy is correct on the WMDs as they are everywhere, scoring people into oblivion. I'm glad she did this book.

http://ducknetweb.blogspot.com/2016/06/the-truth-about-pharmacy-benefit.html

12. **Jan Galkowski**
September 7, 2016

@KMS,

Regarding “First, one should be aware of the fact, that modelling in itself is a descriptive activity: Models try to capture the important aspects of some part of reality, necessarily leaving out “small” factors, that will not influence the outcomes (mostly average quantities) significantly. When relying on them to initiate activities, they however cease to be purely descriptive tools and acquire normative aspects.”

That depends upon one’s perspective. There is an entirely defensible program of statistics which acknowledges the subjective elements of any inference, and provides a framework for incorporating it. Moreover, it is possible, even if practically difficult, to bring loss estimates into inference and adjust them accordingly. These are necessarily based upon judgment. So, I would very much challenge whether modeling in any practical application can remain purely descriptive.

Among other assertions, to my thinking, WMD reemphasizes the need to bring forward our assumptions, *all* of them, and acknowledge them.

13. **MikeS**
September 7, 2016

One or two here seem to be suggesting that Big Data is fine so long as the algorithms are good.

In the hands of a benevolent state committed to the equal distribution of its bounties that may be true – although there are still contrary arguments to that idea.

However, does this not miss the point of the book? That Big Data is largely in the hands of large corporate self-interest groups have no motivation to establish the fair distribution of anything.

14. **Low Math, Meekly Interacting**
September 7, 2016

The author of this book was in the room, and only she truly knows how much she was made, wittingly or unwittingly, into a con artist. I tend to suspect hubris more than fraud on the part of the actual quants (not sure about their bosses), i.e. another cohort of geniuses brought low by the messy complexities of the real world. The entire field of economics suffers from the same delusions, as far as I’m concerned. They weren’t the first, and won’t be the last. In my field, the promises of the “omics” du jour is plagued by similar hype, and the data collected has the potential for even more harm, if misused, which it almost certainly is and will be. Perhaps it’s how I get myself to sleep at night, while acknowledging I’m just another corporate whore; but I like to think the individual players at least started off hoping to simply make a good living and provide a useful product. That, and having surveyed the abuses of academia, they thought the stench maybe wasn’t any worse on the outside.

To me the folly of the quants is just a symptom of the larger problem of trying to optimize systems before first optimizing incentives. The quants did the job they were asked to do. Probably a lot of them even believed their own dazzling bullshit. They were rewarded handsomely, nand probably broke few if any laws, the legal disincentives having been gutted long before. While people were still making billions playing the securities shell game, they were the heroes of investers, from the richest fund managers to saps like me, happy to get a cheap mortgage and a growling 401K.

The system was well primed, they just helped lubricate it. I’m far too much of a cynic now to believe adding some more ethics to the graduate maths curriculum will accomplish much without some major structural corrections to the financial sector, among many others, corrections that only sweeping govt. action can compel. It’s good to be wary of certain algorithms, but clever people will always find a new trick for the right price, and one can only be so vigilant. We must admit that nearly all of us, sadly, have our price. If we could do a better job of acknowledging that at the societal level, I think the talents of the quants could be reliably channeled to far better uses. I’d like to think the vast majority of them were fundamentally as decent as most people, and got swept up in it all.

15. **Anonyrat**
September 7, 2016

I think the new class of methods of concern have to do with machine learning, which can produce predictions without a model in the usual sense of the word. The mathematics is in the model of learning, but not in the particular model that resulted from the data that was used as the training set. I think this class of methods is the most liable to the spiral described in the review: ” if a poor student can’t get a loan because a lending model deems him too risky (by virtue of his zip code), he’s then cut off from the kind of education that could pull him out of poverty, and a vicious spiral ensues”.

16. **Low Math, Meekly Interacting**
September 7, 2016

Hi, Anonyrat,

From the perspective of a lender, whose fiduciary responsibility is to maximize return on investment for their shareholders, such a model might be performing quite optimally. The lender isn’t in the business of “pull(ing) him out of poverty”, they’re in the business of collecting interest. The fundamental problem, then, isn’t a bad algorithm, though that might exacerbate things considerably if it contributes to unsustainable trends, i.e. bubbles, it’s what we as a society deem to be fair game in the student loan sector. It could be that giving people loans for a song in affluent zip codes when there isn’t the collateral to back them up, then packaging these things in such a way as to conceal risk from investors is a really crap way of performing ones fiduciary duty, but the plight of some kid on the wrong side of the tracks isn’t technically relevant until post-collapse.

Sure, big data and the algorithms to exploit it may hurt us, but they’re designed to give us the answers we want, after all. As far as I can tell, they didn’t entirely fail the financial sector. They do appear to have been phenomenally successful, over an appropriately finite duration. Microbial populations mindlessly exploit a fundamentally similar approach in a closed system; they just lack the foresight and ability to know when to exit the log phase voluntarily, so as to better reap the rewards of their success. From a brutally pure financial standpoint, investors didn’t miscalculate what to buy so much as when to sell.

I think we have to ask ourselves, while we’re mulling how we got here, why, when things don’t go so obviously wrong, the underlying status quo is still OK.

17. **A.J.**
September 7, 2016

LMMI:

The author of this book was in the room, and only she truly knows how much she was made, wittingly or unwittingly, into a con artist.

What do you mean by this? Are you under the impression that O’Neill was involved in pricing mortgages?

18. **Peter Woit**
September 7, 2016

LMMI,
As AJ points out, ONeil wasn't involved in pricing mortgage backed securities, so had nothing to do with the specific fraudulent practice I mentioned in the posting. She has written some fairly detailed postings about her time at D.E. Shaw, for example, take a look here
https://mathbabe.org/2011/06/15/working-with-larry-summers-part-1/
and at other postings in that series that are linked to from there.

19. **Low Math, Meekly Interacting**
September 7, 2016

Yes, yes, and quite sorry, Peter and AJ. Got mixed up on sectors. But one might ponder the same questions of ethics when considering the relevant quants.

I think in general the idea here is to be appropriately nuanced, but as the "math is racist" nonsense makes amply clear, it's apparently too easy to make "big data" and "algorithms" into bogeymen, and caricature quants as some new, insulated, coldly metrics-driven rentier class, instead of people with a particular skill set getting paid to do a particular job the way they were asked to, much like the rest of us. The manifestation of the problem is fairly novel and sophisticated, but the underlying causes and motivations are rather more perennial and prosaic, in my opinion.

20. **Anonyrat**
September 7, 2016

LMMI,

I'm not asking the lender to be a social activist; but a lender might trust a human where an algorithm might not. A lender might come up with microlending, and so on.

Then there are some of the concerns expressed here, that are relevant to this post: http://sites.ieee.org/spotlight/ai-ethical-dilemma/ (IEEE, On the Use of AI – the Dependency Dilemma)

"What started out as Internet technologies that made it possible for individuals to share preferences efficiently has rapidly transformed into a growing array of algorithms that increasingly dictate those preferences."

21. **Cgh**
September 7, 2016

I don't see how her extremely limited tenure at a (systematic) trading firm and subsequent rants makes her any more than a slactivist.

Peter, sorry, the content in your link to her blog is just non-specific and childish ranting, a small step down from her book. I actually approached her book really excited to get her perspective. From a rigorous and fact-based perspective her book was very thin. I realize that she's tapping a narrative that people feel very passionate about but I disagree with your earlier use of the word "important". It could have been important. Had she leveraged her job-hopping and intellect as opposed to what is clearly an ax she has to grind she could have started a nice converasation based on factual reporting to support her hypotheses.

22. **srp**
September 7, 2016

Eiger: No, that's not what I'm saying. Pervasive data can protect you AGAINST the state at times, as well as against false accusations. Not having the video can be as damaging to justice as having lots of video around.

In general, if a mathematical model is functioning in place of a human being (or being used by a human to supersede his own judgment) in making decisions that affect people, then as noted by others above the math aspect doesn't really change any of the value-oriented policy or ethical issues. Police officers have traditionally been trained to look for what seems "out of place" in a situation and investigate that, a heuristic which has much merit but also leads to excessive stopping of motorists traveling outside "their" perceived communities. A drone programmed or trained to do the same thing would be no better and no worse in terms of fairness and public safety than the human. The same goes for loan officers, admissions officers, etc. The advantage of the mathematical model is that it is in principle easier to audit it (unless it is a neural net) and to get it to operate consistently in the way its designer intended. But if the designer has the wrong incentives, and if in practice the auditing aspect does not occur because reading the code of the model is difficult for those who might care, then you're back to the same old problems. I don't see how they would be worse than if the human were doing the "wrong" thing unassisted by a model but based on his incentives and perceptions.

23. **Low Math, Meekly Interacting**
September 7, 2016

Hi, Anonyrat,

Microlending strikes me as fairly activist in the current climate. If I've learned anything about corporate behemoths, it's that they reflexively seek to minimize time, overhead, and risk. This quaint notion of two people building a mutually-beneficial relationship through engagement and trust will just take too damn long. And this trust thing is pretty subjective. Too hard to measure, too hard to track and hold accountable. That's why these algorithms are invented. It's not that big lenders are evil so much as impatient and risk-averse. What's the most reliable way to close a good deal fast and get the money? That they actually wind up increasing risk and losses in the process is a considerable irony, but data and algorithms only serve as an amplifier of a flawed ethos. We lost the benefits of more deliberative practices because we valued them less than rapid returns.

24. **Mat Noir**
September 8, 2016

The problem with social-algorithm based decision-making is that despite their short-comings (assumptions that are incomplete, false, agenda-driven, …) they are held in awe and almost beyond reproach as they are inaccessible to 99.9 percent of the population. Furthermore, such models are impersonal, veil profit motive or criminal intent, and are almost never challenged. A loan is denied, and all a loan officer has to mouth is, "it is policy, I would love to help, but my hands are tied." And the kicker is that those who have the will and means (read governments, corporations, the Beverly Hills Zipcode) to disassemble the algorithm du jour can handily subvert it for fun and profit. It is man against the machine – and the machines are winning!

25. **Q. Austin**
September 8, 2016

Paul Wilmott, has been warning of abuse of math in finance for a long time. Despite himself being a quantitative financial analyst and having written several books in this area.

http://rsta.royalsocietypublishing.org/content/358/1765/63

Big Data is not just about obscure algorithms and machine learning. Visualization is an important part of it. And, newer methods of visualizations, which harness certain insights from data, have helped many in decision making. Unfortunately, that is not an aspect that is usually attributed to Big Data.

Big Data and Data Science, the way it is practised today, is mostly statistics + computer science. Mathematicians and physicists need to develop better understanding of these two fields to contribute more in this space.

26. **Roderic C Deyo**
September 8, 2016

It's even worse than people think. Having worked for many years on "big data" and machine learning at a very large software company, what became apparent was that careful and statistically reliable data analysis was eventually thought to be too stodgy since it often didn't immediately lead to revenue gains. Instead, conclusions were hastily drawn and tried out at massive scale in the hope of randomly producing a winner. The resulting "lottery" winners moved up and the losers moved on.

27. **Mozibur Ullah**
September 10, 2016

I've followed her column occasionally, and its good to see someone take this seriously whose background is in modelling. How does one audit complex mathematical models in high finance where secrecy is important? As well as traders motivations, incentives and so on.

28. **RandomPaddy**
September 16, 2016

Sociologically, the algorithms are a replacement for religious precepts.
They allow the governing class to impose its values on the rest of society, and regulate their actions, behaviour, and social class. You don't need religion to impose a belief system.

Various and Sundry

September 8, 2016
Categories: Uncategorized

A few unrelated items:

- Maybe Multiverse Mania in the popular press is fading. The Atlantic has The Multiverse Idea is Rotting Culture, where the author points out

> In 2014, the New Scientist published an article called "Multiverse Me," revealing that various lonely boffins take succor from the fact that alternate versions of themselves are leading fun lives full of emotional and sexual fulfillment, instead of solitudinous slogs through the stupid infinity of high-level algebra.
>
> They're not jealous; they want the best for their alternate selves, they want them to be happy. How can you help? The answers given are all cop-outs; the scientists have decided to keep on living as if the multiverse didn't exist ("The multiverse," one says, "tells us that we should behave as if we were valuing the risks according to probabilities in a classical universe"), because if it does exist the implications are horrifying. Right now, infinite versions of yourself are dying in really horrible ways, not in spite of the fact that you're lazily giving answers to a New Scientist reporter, but because of it. Every second you live, their suffering increases. If you stand on a cliff-edge and decide not to die, how many billions are smashed on the rocks? Jump now, and save them all.

- Over at Scientific American, Lee Billings has a story about dark matter and the lack of evidence for WIMPS.
- At CASW Showcase, an interesting interview with Natalie Wolchover.
- Carlo Rovelli has posted on the arXiv The dangers of non-empirical confirmation, his contribution to the *Why Trust a Theory?* meeting discussed here and here.
- Next week there will be a Natifest at the IAS, celebrating Nati Seiberg's 60th birthday. I'll try and get down there for the first day, leaving on a trip (more about that to come) later in the week.

  There's a wonderful discussion with Seiberg arranged by Hirosi Ooguri that is well worth reading.

- Denny Hill wrote recently to tell me about an interesting article on the history of the study of gravitational wave solutions, by him and Pawel Nurowski, now on the arXiv here.

Update: One more. Congratulations to Nigel Hitchin, whose 70th birthday celebrations are now ongoing. See here, here and here.

Comments

1. **Richard**
   September 9, 2016

   Is the content of the gravitational waves paper discussed in Janna Levin's "Black Hole Blues" book?

2. **Prof CJ**
   September 9, 2016

   It's Denny Hill and Pawel Nurowski

3. **Robert Levine**
   September 9, 2016

   Isn't Kriss (following the New Scientist piece he refers to) conflating Everett's many-worlds interpretation of QM with the landscape-type multiverse more recently promoted as a rationale for the vast space of vacuum states compatible with string theory? The two concepts *seem* to have very little to do with each other…

4. **Peter Woit**
   September 9, 2016

   Richard,
   Not really (from what I remember of the Levin book). There's a well-known story about Einstein's early mistake about gravitational waves that is in both places, but otherwise the Hill/Nurowski paper mostly discusses mathematical history not covered by Levin.

   Prof CJ,
   Thanks, fixed.

   Robert Levine,
   Yes, they're two completely different things, but physicists promoting multiverse mania often conflate the two. The article is not about the physics but about the mania.

5. **bayes_or_bust**
   September 9, 2016

   Whilst I don't quite agree with everything, Rovelli's rebuttal is excellent.

   Dawid's ideas weren't ever very interesting. They gained traction because they supported string theorists at a time when many are questioning their modes of reasoning.

   I'd be curious to know historical examples of scientists acclaiming particular new ideas in philosophy at moments of (real or perceived) crisis or change.

6. **Douglas Natelson**
   September 9, 2016

   Peter, Robert, how do we know they're different? Many worlds has to do with entanglement, and from enthusiastic theorists we learn that EPR = ER, and Einstein Rosen wormholes could connect different spacetimes or causally disconnected regions of our infinite universe…. (I kid, I kid. But you know Kaku will have a show on TV about this within a month.)

7. **Prof CJ**
   September 9, 2016

One more time, it's Pawel Nurowski. True,
Americans are typically monolingual so they
have little insight into how other languages
function but this cannot be that difficult

8. **Peter Woit**
September 9, 2016

Prof CJ,
Fixed. I think the problem here is not the number of languages I speak (two pretty well, a couple more badly) but distraction due to busyness of first week of classes. And also sleep deprivation due to time spent downtown watching Kieslowski's(sp?) Dekalog (4 hours down, six to go…)

9. **Jeffrey M**
September 9, 2016

Peter,

Dekalog is worth it. Also, if you haven't already, go see Red, White, and Blue.

10. **John**
September 10, 2016

"In 2014, the New Scientist published an article called "Multiverse Me," revealing that various lonely boffins take succor from the fact that alternate versions of themselves are leading fun lives full of emotional and sexual fulfillment, instead of solitudinous slogs through the stupid infinity of high-level algebra."

What is this repugnant rubbish? Multiverse theories are discredited because they are totally unsubstantiated by experiment, not because they may reflect fetishes and fantasies of individual researchers, or because they contradict peoples' moral sensibilities. Sorry to be insulting to the blog author – I've had one drink too many, but you *are* mocking the piece, right?

The original article makes some fair points at certain places, but dresses them in an unacceptably mocking rhetoric that, on top of everything, makes no sense. It invokes everyday experience to discredit ideas in a field where everyday experience goes out the window anyway.

Again: multiverse theories are not rejected because they contradict our sensibilities, but because they are unsubstantiated by our data. At this point I wonder if it is better for certain people to believe that unicorns are possible rather than reject the existence of horses, because for some people this seems to be a dichotomy…

11. **Tim May**
September 10, 2016

I think you are correct: the multiverse/multiple worlds fascination seems to be a somewhat sterile dead end.

(Understand, I read Larry Niven's SF about multiple worlds with fascination around 1972 or so. And then Bryce DeWitt came out with his articles and his book on the same, circa around 1973 or so. I might be off by a year or two. Heady stuff. But even as I was taking a class in General Relativity from Jim Hartle himself, it never seemed appropriate to ask things like "But what if we're just one of 10 to the 1427 power realities?"

In my opinion, Peter's "Not Even Wrong" moniker deserves something even stronger for this whole idea of many universes. However, as he notes, it seems to be running out of steam. (This doesn't make it wrong, just not of much interest.)

I often think in terms of many worlds to clarify my thinking in QM, but I don't assume these other possible worlds have any tangible existence, application, etc.

— Tim May

12. **Yatima**
September 10, 2016

Completely off-topic, but Tim May writes: "I read Larry Niven's SF about multiple worlds with fascination around 1972 or so."

May I enquire which SF that was? Larry Niven was always talking about Big Engineering and Exploration with Magical Physics thrown in as needed in order to play around. We had: Transport Booths, Hyperdrive Shunt engines coming in quantized speed increments (with the Mark II extremely large and extremely expensive), General Products Indestructible Ship Hulls, Bussard Ramjets working with finely managed electromagnetic fields OUTSIDE the ship (how?), Scrith Ringworld Construction Material with supernatural tensile strength and able to stop neutrinos, Stasis Fields inside which time stops, Non-Newtonian drives, Sinclair wire that is practically indestructible and can cut anything, Autodocs, Longevity Drugs and more stuff of Pulp Magazine Wonder, but we didn't have multiple worlds. Indeed, Quantum Mechanics wasn't even mentioned once as far as I can remember.

13. **Dom**
September 10, 2016

Regarding Kieslowski, "Red" and "Double life of Veronique" both starring Irene Jacob are two of the best films I've ever seen.

14. **Peter Woit**
September 10, 2016

Please, enough about Larry Niven.

John,
Just about none of the popular discussion of the multiverse has any scientific content whatsoever. What I found interesting was just that this latest example was countering the usual "Gee whiz, isn't this cool?" with "This is awful!". I think it may be some indication of the (to me) long-awaited moment where people get sick of hearing the same nonsense about this.

15. **paddy**
September 10, 2016

Peter: Damn! And I was just typing up my critique of L. Niven. Actually just commenting to thank you for the Rovelli link.

16. **Prof CJ**

September 10, 2016

Kieślowski's Dekalog is indeed powerful. I was going to recommend "Red" (one theme is Jungian synchronicity) and "Double Life of Veronique" but Dom beat me to it. "Blind Chance" is not bad, and at least conceptually is related to physics.

I hope I wasn't too harsh in posting my correction.

17. **Low Math, Meekly Interacting**
September 11, 2016

I conjecture such new-found disdain for the anthropic principle in the pop-sci press is connected to the failure to find experimental evidence for weak-scale SUSY. We've been hearing for literally decades that SUSY is part of a grander framework that implies a multiverse, and part of what makes it so grand is SUSY's many testable virtues. With the latest crop of null results, it can no longer be avoided: the amount of baroqueness needed to keep weak-scale SUSY alive is past the "psychological threshold" of even many ardent supporters. Bottles of fine cognac have publicly changed hands. Since long-cherished ideas now face the likely prospect of failure, reliance on the speculative judgment of their proponents also seems questionable.

I'd rather they pointed out anthropism's obvious problems on their own much earlier, instead of finally dropping an argument from authority only when it's become impossible to do otherwise and remain credible. But I suppose it's a step in the right direction.

18. **Douglas Natelson**
September 11, 2016

Yatima: short story, "All the Myriad Ways". (Sorry Peter.)
Regarding the very nice SciAm piece about dark matter: Am I correct that the amount of microlensing that is seen/not seen places a strong limit on primordial blackholes as a possible dark matter explanation?

19. **IMHO**
September 12, 2016

Regarding MACHOS: it's my understanding (and please correct me if I'm wrong) that the yet to be ruled out mass ranges overlap with the masses seen by LIGO. I think primordial black holes as dark matter is still breathing, if only barely.

20. **Mehmet Jon Jonnerson**
September 12, 2016

seems to me Rovelli's Bayesian argument against string theory is

PosteriorP(string theory | not SUSY pheno at LHC scale) = (1/P(not SUSY pheno at LHC scale))*P(not SUSY pheno at LHC scale | string theory)*PriorP(String Theory)

am I right?

But this seems to require knowledge of P(not SUSY pheno at LHC scale | string theory), which, I don't think, is at all well known. Like, sure, you can find a guy (e.g. Kane) who will tell you he has *a* model in which the conjunction of clauses (string theory) && (SUSY pheno at LHC scale) is true. But nobody has done the *model counting*.

So, to even know how to update P(string theory), you have to do SMT on a very complicated Domain Specific Language in which the state explosion problem is very real. Like, 10^500 real.

So, the problem is, Rovelli's making an argument which,* given more information about the string theory landscape/multiverse than is known to any string theorist*, may very well discredit string theory. This is, ironically, an argument to *do more string theory*.

Or, maybe, when Rovelli complaint about string theory's flexibility, he means there's a Bayesian parameter estimation problem, where we would like to infer a probability distribution on the parameter space of string theories from our probability distribution of observables. The flexibility problem is that the observability grammian, so to speak, has tiny eigenvalues, at least for the observables available to us thus far- or, truth be told, we don't even actually know that observability grammian. So, again, we must *do more string theory*.

For the record, I think Rovelli's a smart guy who has better things to do than post polemics to the arxiv. Here's hoping someone sees something at that 7/6 r_{s} region him and Hal were talking about.

By the way, regardless whether or not the multiverse is a bad idea, the fools in the multiverse me article aren't fools because they believe in the multiverse, they're fools because they don't understand what independent and identically distributed random variables are.

21. **Anonyrat**
September 12, 2016

@Mehmet: Rovelli wrote: "From a Popperian point of view, these failures do not falsify the theory, because the theory is so flexible that it can be adjusted to escape failed predictions. But from a Bayesian point of view, each of these failures decreases the credibility in the theory, **because a positive result would have increased it.**" {emphasis added}.

We do not require further knowledge of string theory for Rovelli's argument to work.

22. **Peter Woit**
September 12, 2016

Mehmet Jon Jonnerson and anyone who wants to argue with him,
Enough, I have serious trouble making sense of lots of arguments of this kind, and here I'm failing completely, so, while leaving this here in case others can, I'll delete any more of it, on the simple grounds that I can't moderate a discussion I can't make sense of.

23. **Anonyrat**
September 12, 2016

Peter,
Though the apriori probability of string theory being true and the conditional probability of seeing SUSY at LHC given string theory are both unknown, if we accept the proposition that seeing SUSY at LHC boosts the a posteriori probability of string theory, that gives us a simple inequality,

Bayesian a posteriori > a priori;

from which it is two minutes of symbol manipulation to prove that not seeing SUSY at LHC decreases the a posteriori probability of string theory.

24. **Peter Woit**
September 12, 2016

Anonyrat,
Yes, but I don't see how dressing this up in Bayesian probability and manipulating symbols does anything but encourage obfuscation of the obvious: if somebody tells you (or publishes a piece in the Wall Street Journal saying) "experiment X seeing Y will be evidence for theory Z" and then experiment X sees not Y, this is negative news for theory Z.

Exactly how bad the news is for theory Z of course depends on the details of the original argument. If, in retrospect, it was a very weak argument since theory Z can give you pretty much anything, including Y or not Y, then attention should shift from theory Z to why in the world people are discrediting science by making very weak arguments for theory Z in the Wall Street Journal.

Fashion, Faith, and Fantasy

September 12, 2016
Categories: Book Reviews

Roger Penrose's Fashion, Faith and Fantasy in the New Physics of the Universe is finally being published this week. This is a bit of a landmark event, since the book has a long history, going back to a series of lectures that he delivered in 2003 at the university and IAS. At one point I remember watching videos of these lectures hosted by Princeton here , but these no longer seem to be available.

In giving these lectures, Penrose was walking into the lion's den, bringing a forceful critique of string theory to the academic institution where it is most popular. Congratulations to Princeton University Press for publishing this despite it challenging the hegemonic viewpoint at Princeton (I had less luck with them: when my British publisher sent them my book for consideration way back when, they hired Lubos Motl to write an evaluation of it…).

Besides a mathematical appendix, the book is divided up into four parts:

- **Fashion**: This is the section that deals with string theory, and Penrose's central objection is to the use of extra spatial dimensions as a crucial part of the theory. When trying to use string theory as a unified theory, an assumption is made that one can take four space-time dimensions very large, and the rest very small, decoupling the large and small dimensions. Penrose argues that there is no reason to believe one can consistently do this, that there should be couplings between these degrees of freedom that cannot be ignored, leading to instability of the theory, rather than a stable ground state with large dimensions.

  The problem is that one doesn't actually have a non-perturbative string theory in which one could properly study this issue. There's no consistent theory, so Penrose can't rigorously prove there's a problem of this kind. He faces the generic problem of arguing not with a well-defined theory, but with people's speculative hopes of what kind of theory might exist. I agree with him though that the extra dimensions are a deadly problem for the theory. Even if you accept the most optimistic hopes that Penrose's and other problems will go away, you are still going to be left with the landscape problem. Everything known about conjecturally stable states with 4 large dimensions indicates an infinite complexity of such conjectural things, capable of giving you any physics you want, leaving the theory able to predict nothing and empty of explanatory power.

- **Faith:** In this section Penrose addresses the measurement problem of quantum mechanics, pointing out correctly that our standard story about quantum mechanics introduces an "ontological shift", indicating that something more is going on than a well-understood consistent framework. He favors the idea that perhaps the introduction of gravity into the usual framework could resolve this problem, backing this up with a dimensional analysis argument that a relevant effect could come from gravity, while being too small to be observable so far.

  Here I think he does an excellent job of explaining the usual story and why there's a problem, but personally I've never been convinced that this problem requires new physical laws, non-linearities, or the introduction of gravitational effects. To me the "ontological shift" has always seemed due to the standard story being not a full theory of what happens in a real measurement process, but being a phenomenological approximation of what happens, with approximation needed to get a tractable description. As people build and study more complicated and larger fully quantum systems, the inadequacies of the standard story about "measurement" I think will become clearer, and we'll get a better understanding of how classical behavior emerges from quantum laws, with no need to change those laws.

- **Fantasy:** Here Penrose describes in detail some basic problems in the theory of cosmology, and how they are supposedly resolved by the theory of inflation. He explains that characterizing this as "fantasy" is not meant to be purely critical, that "fantasizing" about the moment of the big bang is what theorists do in the absence of compelling evidence, and that he just has other fantasies he thinks worthwhile.

  I don't think I can do justice here to the depth and complexities of his arguments in this section. This is a topic involving subtle questions about the behavior of general relativity where Penrose is one of our deepest thinkers and greatest experts. While acknowledging some of the achievements of inflationary theory, part of his critique is related to that of Paul Steinhardt and others, showing that the theory doesn't accomplish what it sets out to do, with the exponential expansion not providing a way to get observed homogeneity from arbitrary initial conditions. At the same time there is a lot more there, and this section seems to me that it should be required reading for anyone trying to make sense of fantasies of the description of the big bang itself.

- **A new physics for the universe?:** In a final section, Penrose describes some of his more positive ideas addressing the problems pointed out in the earlier sections. This begins with a wonderful summary of the theory of twistors, and I strongly suspect that he's right that this very different way of thinking about space-time geometry will ultimately be part of any successful integration of our understanding of quantization and geometry. That this geometry is very specific to four space-time dimensions provides yet another reason for skepticism about the fashion of theories with more spatial dimensions.

  I'm less convinced by his speculation about quantum state reduction, and by what he refers to as his "Conformal Crazy Cosmology", although the emphasis on conformal invariance may very well be a correct one.

  In a final "Personal Coda" he explains that he sees himself not as a "maverick", but as rather embodying an "inner conservatism", somewhat allergic to the appeals of fashion. In particular:

  > So when I heard that string theory – to which I had been distinctly attracted, partly because of its early use of Riemann surfaces – had moved itself in the direction of requiring all those extra spatial dimensions, I was horrified, and far from being tempted by the romantic attractions of a higher-dimensional universe. I found it impossible to believe that nature would have rejected all those beautiful connections with Lorentzian 4-space – and I still do.

A wonderful aspect of the book are Penrose's many and detailed graphical illustrations, which have been made available separately by Princeton here. At their website you can also read the Preface, and an interview. Unfortunately I'll be in Germany next week, missing Penrose's book tour events here in New York, at the American Museum of Natural History and MoMath.

The range of non-crackpot speculative ideas about fundamental physics that normally get much attention is unfortunately quite narrow. In this environment Penrose is a breath of fresh air, providing here a different point of view on several topics, backed by serious and detailed argument. In some ways this is a popular book, but in others it is something else, deserving the attention of experts in the subject. I can't recommend it too highly to anyone with a serious interest in fundamental questions about physics.

Update: A somewhat different version of this review is up at MAA Reviews.

Comments

1. **Will F.**
   September 12, 2016

   Peter,

Would you recommend the book to a somewhat well-read layman?

2. **Peter Woit**
September 12, 2016

Will F.,
Yes, especially one not afraid of a little mathematics. This is not another "Road to Reality", which was more technical. There will be sections though where I think a layman will likely get lost (an example is the discussion of twistors), but only few of those.

3. **DrDave**
September 12, 2016

" they hired Lubos Motl to write an evaluation of it…"
I know I shouldn't be curious, but was the evaluation ever published?

4. **Peter Woit**
September 12, 2016

The full story is that parts of Lubos's review first appeared as a review on Amazon, see
https://www.amazon.com/gp/customer-reviews/R3PGUGKCPHDI39/
and I wrote a little about this here
http://www.math.columbia.edu/~woit/wordpress/?p=401

At the time I was perplexed by what version of the manuscript he was writing about. He later explained about the PUP story, see
http://www.math.columbia.edu/~woit/wordpress/?p=438
and
http://motls.blogspot.com/2006/08/seventeen-pages-of-problems-with-book.html

The original link to his full review no longer works, but you can find this via the wayback machine, for instance at

https://web.archive.org/web/20060827005045/http://schwinger.harvard.edu/~motl/new-report-edited.doc

Enough though about this history, further comments should be about Penrose's book, a much more interesting topic than Lubos's reaction to mine over ten years ago.

5. **Richard Gaylord**
September 12, 2016

Penrose's entire 10 video lecture series is available on YouTube. start with https://www.youtube.com/watch?v=5jXj1TwiFys and you can locate all the lectures from there.

6. **Al**
September 13, 2016

@Richard that youtube link goes to his lecture at Penn State given many years after his Princeton lectures (even though it has the same title).

7. **bayes_or_bust**
September 13, 2016

Anything about consciousness/QM? That was one of his pet topics.

I'm looking forward to this book. I met Penrose a few years ago; he was extremely pleasant, and of course, extremely insightful about physics.

8. **Peter Woit**
September 13, 2016

bayes_or_bust,
As far as I can tell, there's exactly one and only one sentence about consciousness/QM in the book, basically noting that he has written about this and giving a reference.

9. **wimp**
September 13, 2016

Peter

in the book,
if Penrose thinks that the extra dimensions can cause instability
does Penrose discuss the KKLT construction for stabilizing the extra dimensions? does it in fact work, in creating 3 large spatial dimensions and 6 curled up and stable?

does Penrose discuss the latest results from LHC on SUSY i.e no-show?

10. **Peter Woit**
September 14, 2016

wimp,
One reason I find the book refreshing is there's not much about such tired topics. He's got a couple pages on SUSY and the fact that it hasn't appeared, as well as the danger that proponents will just argue that higher energies are needed. He discusses the moduli stabilization problem, but in the context of explaining that the problems he sees with extra dimensions are much wider than that, with the freedom to vary parameters characterizing Calabi-Yaus the least of the problems introduced by the huge number of new degrees of freedom coming with extra dimensions.

11. **Ken**
September 14, 2016

Anyone else try buying directly from Princeton University Press and run into problems with the shopping cart? I am using the most up to date version of Chrome. If it is not an intermittent thing then I will have to go to Amazon I suppose.

12. **adamt**

September 14, 2016

Peter, thank you for the wonderful review. Based upon it I've picked up the book and reading through Chapter 1 now. One minor nitpick is that Penrose takes issue not with the huge number of degrees of freedom involving the extra dimensions, but rather the *much* larger number of functional freedom that is involved. He emphasizes this in the last paragraph of Appendix 2:

"The phrase 'degrees of freedom' is frequently used in the context of physical situations and, indeed, I frequently make use of that terminology in this book. It should be emphasized, however, that this is not the same as 'functional freedom.'"

… where he goes on to explain the difference in that "degrees of freedom" are associated with the components of the field in question whereas the "functional freedom" is far greater and completely swamps the "degrees of freedom" when extra dimensions are involved.

13. **Peter Woit**
September 14, 2016

adamt,

To my mind, the "number of degrees of freedom" here is infinite-dimensional, since the configuration spaces are function spaces, and I didn't mean anything more precise than that by my usage. I didn't want to get into explaining exactly how Penrose quantifies "functional freedom" since a short attempt at that would likely just be confusing.

For exactly what this means, if you have a copy of "The Road to Reality", see section 16.7. The argument Penrose is making against extra dimensions is not a new one for him. He developed it in detail quite a while, see for instance his paper "On the instability of extra space dimensions" in the Hawking 60th birthday celebration volume, published in 2003.

14. **adamt**
September 14, 2016

Peter,

I see, thanks. The degrees of freedom available to a theory with extra dimensions is "utterly unassailably" vastly larger because of the functional freedom as Penrose says. In his book, Penrose states that he does not think anyone has really responded in good faith and detail to his "functional freedom" objections to string theory and now I see this objection really has been out there for some time. While I'm reading the book it would be nice to see some counter-argument. Do you know of any attempt to rebut or explain away his objection in good faith and earnest?

15. **Peter Woit**
September 14, 2016

adamt,
I'm not aware of any, and I recently talked to Penrose about this, and he said he hadn't gotten any counter-argument.

My guess is that string theorists approach this question like a lot of possible arguments against what they are doing, figure it is best to just push forward, assume that things decouple in some way to avoid the problem, and see what you can do. To my mind the deadly argument against string theory is not any argument like Penrose's, but that, even if you optimistically ignore all such problems, you end up with an empty theory that can't predict anything.

Put differently, if string theorists ignored Penrose's problem, then went on to find a calculational framework that was vindicated by success in explaining the real world, that would be fine. His problem would be an interesting issue to think about in terms of better understanding string theory, but it would not be a compelling argument against string theory. On the other hand, if you have a good argument that something is not going to work, and it doesn't, you should take that argument quite seriously, it might show you where you're going wrong. Some string theorists I've talked to actually do say that they're not interested in the higher dimensions, believe that string theory needs to find a proper 4d formulation.

16. **Thomas**
September 14, 2016

I don't understand this supposed argument against extra dimensions. If there was an argument that implies that the 3+1 d standard model cannot be an EFT for a higher dimensional theory, how does the same argument not rule out 2+1 Chern Simons theory as an EFT for 3+1 electrons in a quantum hall state? Or, how does it not imply that 2-d domain walls in 3d broken symmetry states must be unstable?

17. **wimp**
September 14, 2016

thanks for replying

i posted this question and a string theorist replied. In his view Penrose objections were satisfactory resolved in 2002 with the KKLT paper, and is no longer an issue for string theory. the string theorist then updated the string FAQ

18. **Peter Woit**
September 15, 2016

wimp,
Penrose explicitly explains in the book that the problem of fixing the finite-dimensional moduli that KKLT is supposed to solve is not the problem he is discussing.

Thomas,
Have you tried reading his argument? I don't see how your objection has anything to do with it.

19. **Urs Schreiber**
September 15, 2016

It's a little unfortunate for the scientific discourse that the argument is hidden behind a paywall. Looking around, I find this old video recording of a talk by Roger Penrose, which from 3:55 on explains what "functional freedom" is meant to refer to. (Go to 6:56 to see the key slide.)

The presentation there is aimed at non-experts, but what it says in technical paraphrase is that if a physical field takes values in a manifold V, then a field configuration is a section of a V-bundle over spacetime, hence locally a function from spacetime to V. The point of the slide is to highlight that the space of functions to V (field configurations) is an infinite-dimensional manifold (and in fact that's true only if the local domain is compact, otherwise things become more wild still). So if the pointwise degrees of freedom of a field are parameterized by a finite dimensional manifold V, then the actual spacetime-wide degrees of freedom are parameterized by an infinite-dimensional mapping space.

What I wonder is in which way this basic fact is meant to be something not appreciated in traditional literature. What is traditionally meant by moduli stabilization is precisely the argument that on-shell the dependency of those V-valued functions along the compact dimensions disappears due to them picking up a potential, in direct analogy to how the Higgs field has a constant (absolute) value throughout spacetime (at least locally) since it sits at the bottom of a potential well.

Possibly there is room to argue that the existing arguments for moduli stabilization in string theory (Acharya 02, KKLT 03, Buchbinder-Ovrut 03) are lacking in rigor, but I don't see how one would argue that they are based on an elementary misunderstanding of what the problem is.

20. **Peter Woit**
September 15, 2016

Urs,
For the N'th time, Penrose is not talking about the moduli stabilization problem. Why do you insist he is? If you want to know what his argument is, find a copy of the book, or lookup up his article "On the instability of extra space dimensions" in the Hawking 60th birthday volume. If you can't be bothered to read his argument, why post things on the internet saying it is wrong?

21. **Jeffrey M**
September 15, 2016

FYI, Penrose's paper is (mostly) available via Google, a few pages missing. More than enough to see what he is talking about. Which is NOT moduli stabilization. Very interesting stuff, I have to go back now and read the original Cartan paper. Penrose also has interesting things to say about ADS/CFT.

22. **Urs Schreiber**
September 15, 2016

In "On the instability of extra space dimensions" section 10.2 focuses on vacuum solutions of Einstein gravity:

> Let us consider the case where our field equations are just Ricci-flatness for M, as is the case in string theory, where one takes just the first-order term in the string constant a'.

This is the assumption that is shown to be false by the stabilization mechanisms from 2002/03 by Acharya, KKLT, and others cited above: they work with two extra ingredients present in string theory but not in KK-gravity: effective potentials introduced by the presence of higher form fields (fluxes) and non-perturbative effects.

I suppose it would be worthwhile for mathematical physicists to have a closer inspection of these string theoretic arguments, but what is discussed in "On the instability of extra space dimensions" is the problem without string theoretic effects.

Now, of course "On the instability of extra space dimensions" was written for a meeting in 2002, hence just a moment before string theorists presented their solution to the stabilization problem.

23. **Peter Woit**
September 15, 2016

Urs,
Yes, there's nothing in there about KKLT, which is irrelevant to his argument. If you now have access to his paper, why don't you read it and try and understand his argument, instead of insisting that it is something it isn't, and which he explicitly says it is not (in the latest book)?

24. **Shantanu**
September 15, 2016

Peter, something OT. videos of talks at Cosmo-16 including on particle physics subjects
http://cosmo16.physics.lsa.umich.edu/talks.html

25. **adamt**
September 15, 2016

Urs,

To be clear, Penrose also declares that the responses he's seen to his talk on Hawking's 60th birthday have been, "dismissed with what would appear to be a somewhat hand-waving quantum-mechanical argument of a general nature that I regard as basically fallacious." He goes on to restate the argument, "in a more forceful form" in section 1.10 of his new book which I am just getting to read now.

The general tone I see is one of frustration that string theorists have not addressed the overall geometrical and physical considerations he sees as obvious. Coming from Penrose with his manifest expertise in geometry and general relativity I'm surprised that his concerns haven't been taken more seriously. Here is some flavor:

"It is my impression that many of the most obvious geometrical and physical issues arising from the perspective of string theory are never really properly discussed at all!"

and

"I find this curious lack of a coherent geometrical picture of how string theory is to be viewed in ordinary physical terms to be very odd."

and

"The acceptance, by a highly knowledgeable section of the physics community, of such a hybrid of great geometrical sophistication on the one hand and a seeming disregard for an overall geometrical coherence on the other is something that I find extremely puzzling!"

26. **adamt**
September 15, 2016

Thomas,

FWIW, in section 1.10 of his new book he brings up your objection regarding the quantum hall effect as a 2-space quantum phenomenon taking place within ordinary 3-space. Penrose says it is a "completely false analogy" because the quantum hall effect is an example where the lower-dimensional space is a "subspace" of the higher one rather than the "factor space" in String Theory's 10 dimensional spacetime with the 6-space and regular 4-spacetime in an M x X factor space. He then goes on to say that the analogy is better suited to "very different brane-world picture" which he is going to discuss later. But please read the book as I am probably botching something.

27. **David Roberts**
September 15, 2016

@adamt

more useful than quoting passages about Penrose's puzzlement and reactions to reactions, would be to quote some actual mathematical or physical arguments (or, gasp, even a sketch proof), so everyone can see what all the fuss is about. I'm not about to pop out and buy a book (or rather wait for international delivery, or else find a bookstore to order it for me) to check what might be one page of proof in an area which is not my own, but I am interested to know what the various arguments are.

If we all had the relevant passage in front of us people wouldn't be trying to second-guess what it might contain based over lectures over a decade old, and could make progress.

28. **Thomas**
September 15, 2016

@adamt

Thanks for pointing me to this section. I only skimmed the book and missed it.

I think the question is relevant. Penrose argues (in the same chapter) that the motion of the sun will excite extra-dimensiona modes. If this was true, I would expect that a two-dimensional current excites three-dimensional electronic states, which contradicts standard EFT arguments (and experiment).

I fail to understand Penrose's claim that this is a false analogy, and the distinction he makes between subspaces and factor spaces.

29. **adamt**
September 16, 2016

David,

If I thought I could do his argument justice in just a few well-placed quotes I might try, but I have no such belief. Penrose wrote a chapter of a book about it so I think you would be best advised to read it when you get the chance if you are interested rather than have a layman try and paraphrase his argument in a blog comment.

I will note that he also devotes a considerable bit to throwing shade on AdS/CFT as well using some of the same types of arguments. Seems he respects the mathematical tools, but finds the possible connection to our actual physical universe tenuous at the very best. Mostly, I think he is just frustrated that no one bothers to respond other than Lenny Suskind basically telling him that his reservations are well founded, but please hush up about it so as not to discourage the kids working on string theory.

30. **Curious Mayhem**
September 16, 2016

It's always refreshing to hear from Penrose. I don't always agree with his criticisms or answers to questions — but he's asking the right questions and raising important issues.

My main problem with Penrose's arguments is his weird prejudice against inflation. Surely, he's right that deeper questions need to be addressed about the connection between gravity and thermodynamics, or why the inflationary universe starts in the first place in a low- or zero-entropy state. I doubt if gravity or consciousness plays a fundamental role. Rather, I think gravity, quantum mechanics, and thermodynamics have a basic relationship that we don't fully understand but that we can reasonably guess is important, on the basis of gravitational event horizons and singularities, for example.

Similarly, consciousness is a prime candidate for an essentially quantum phenomenon at the macroscopic scale. But it's the quantum that's fundamental, not consciousness. Free will is fine, too, if we're careful to define it without recourse to dualism. Aristotle comes in handy here, as he answered a similar difficulty, in a different context, in his disagreements with Plato. In fact, modern physics, with quantum mechanics, thermodynamics, and gravitation, is in a position to sensibly ask ontological and teleological questions not legitimate in a scientific framework since the death of Aristotelianism three or four centuries ago. But we're asking these questions in a completely different context, not within exploded philosophical and theological frameworks. Maybe that's what Templeton is after, in a misguided way. Nice try.

It's likely in the next decade that the evidence in favor of inflation will become decisive. So it's important to keep up the effort to stop the false association in lay people's minds (and even the minds of scientists) between inflation and the multiverse (in the string or "landscape" sense). The two are logically and historically unrelated. Technically, it's difficult to get inflation to work in string-infused QFT models. If a future BICEP or Planck nails the case for inflation, it should be viewed as a highly prejudicial against string theory.

31. **David Roberts**
September 20, 2016

@adamt

Then surely *someone* who has access to the book can supply the concrete mathematical/physical arguments in enough detail so that those familiar with the necessary technical bits and pieces can see what he's getting at? If in these discussions so far experts are misunderstanding what the issues are that Penrose claims, then insufficient detail has been given.

32. **adamt**
September 22, 2016

David Roberts,

Ok, with the risk that I am probably grossly simplyfing or misrepresenting his argument I'll try.

Penrose's biggest critique – but by no means sole critique – of String Theory's cavalier attitude towards extra spacial dimensions is presented in chapter 1.10 of his book. The argument goes that the extra spacial dimensions will necessarily entail a (vast!) functional freedom above and beyond those of our familiar four dimensional space-time. He explains this in detail, but here I just take it as acknowledged. Penrose says that String Theorists usually dismiss this and say it will never come into play because of the huge energy required to excite these 6 small dimensions and activate their degrees of freedom.

To be clear, he is not talking about *zero-modes*, but rather excitations that *do* require energy. In the types of String Theory which purport to address quantum gravity in a serious way he says the energy necessary to excite these degrees of freedom would be on the order of the Planck energy.

Here, he says String Theorists usually argue that to excite them would need a process involving individual particles accelerated to this approximate Planck energy. Penrose finds this argument utterly unconvincing for many reasons, but the chief being that the space-time presented in this picture – at least in the ground state – is a *product space* M x X. In this space, M represents our familiar classical 4-space-time and X is represents the extra spatial dimensions. Were X to be excited, then the 'excited mode' as opposed to the ground state, would be given by M x X` and this is to be thought of as representing the space-time of the *entire universe.* In this context, the Planck energy is not large at all.

He goes on to explain the nonlinear instability involved when considering this 10-space as representing a space-time where some Einstein equations are presumably taken to be controlling the evolution of both sets of degrees of freedom in the 6-space of the small dimensions and the regular 4-space.

That's the nut of the biggest critique I think, but he explains in far more detail than I can provide here. I really recommend if you are interested to go to amazon and get his book which is available on kindle right now.

33. **David Roberts**
September 23, 2016

Ok, arguments that assume a compactification is just a product always seemed slightly fishy to me. This is not fatal, though, if the argument is really local in nature, but the fibres should probably be some sort of interesting orbifolds, and the fibration may not be locally trivial etc etc.

I realise there is yet more detail, but it's not going to be forthcoming here at the present rate. I'm not going to buy a Kindle book any time soon, so perhaps I'll take a peek if and when my local shop gets it in, or some kind soul gives a thorough breakdown of the relevant material.

October 3, 2016

A buddy of mine with some friends at Princeton found the following links to these lectures. You can even download them.

https://mediacentral.princeton.edu/media/Fashion%2C+Faith+and+Fantasy+in+the+New+Physics+of+the+universe+-+Lecture+2A+FAITH/1_7n9wzmi0/13468321

https://mediacentral.princeton.edu/media/Fashion%2C+Faith+and+Fantasy+in+the+New+Physics+of+the+universe+-+Lecture+1A+FASHION/1_kgs8jsyq/13468321

https://mediacentral.princeton.edu/media/Fashion%2C+Faith+and+Fantasy+in+the+New+Physics+of+the+universe+-+Lecture+3A+FANTASY/1_xbikovdr/13468321

They are just hard to find, I guess.

This Week's Hype

September 15, 2016
Categories: This Week's Hype

Quanta Magazine has over the past couple years been establishing a well-deserved reputation as the smartest and best science journalism around. At the opposite extreme, over many years of interacting with science journalists, the most embarrassingly incompetent one I've run across has been KC Cole, so I was surprised today to see that Quanta has published a piece by her.

Back in 2006 she wrote a review for the LA Times, basically explaining that Lee Smolin and I shouldn't be listened to because we were incompetent embittered failures who didn't understand the beauties of string theory. When I contacted her and the LA Times to complain that her review had completely misrepresented what I wrote in my book about neutrino physics, she wrote back to explain to me that I didn't know what I was talking about, whereas she was an expert on neutrino physics. Her other main evidence for my ignorance was this:

> As for Woit's claim that string theory has "absolutely zero connection with experiment," experiments already planned for a new European particle accelerator will look for the existence of extra dimensions and extra families of particles — both predicted by string theory. In fact, many statements about string theory in these books are plain wrong.

The topic of her new article is The Strange Second Life of String Theory, which makes the claims that string theory has failed as a theory of quantum gravity (which will be news to a lot of string theorists), but that "it has blossomed into one of the most useful sets of tools in science."

The article has all sorts of interesting quotes from experts about the state of string theory these days, mostly indicating that people have given up on it and are trying to figure out how to move on. For instance:

> David Gross: "After a certain point in the early '90s, people gave up on trying to connect to the real world," Gross said. "The last 20 years have really been a great extension of theoretical tools, but very little progress on understanding what's actually out there."
>
> Robbert Dijkgraaf: "But now we have this big mess." "Things have gotten almost postmodern."
>
> "Nobody knows whether to say they're a string theorist anymore," said Chris Beem, a mathematical physicist at the University of Oxford. "It's become very confusing."
>
> At last year's big annual string theory meeting, the Stanford University string theorist Eva Silverstein was amused to find she was one of the few giving a talk "on string theory proper," she said.
>
> Juan Maldacena jokingly defines "string theory" as "Solid Theoretical Research in Natural Geometric Structures."
>
> Like many of his colleagues, Simmons-Duffin says he's a string theorist mostly in the sense that it's become an umbrella term for anyone doing fundamental physics in underdeveloped corners. He's currently focusing on a physical system that's described by a conformal field theory but has nothing to do with strings.

I'm amused to hear that according to Maldacena and Simmons-Duffin, it appears that I'm a string theorist. One thing Cole gets right is that most theorists are now working on questions about quantum field theories. Sean Carroll objects to this:

> It's the kind of work that makes people such as Sean Carroll, a theoretical physicist at the California Institute of Technology, wonder if the field has strayed too far from its early ambitions — to find, if not a "theory of everything," at least a theory of quantum gravity. "Answering deep questions about quantum gravity has not really happened," he said. "They have all these hammers and they go looking for nails." That's fine, he said, even acknowledging that generations might be needed to develop a new theory of quantum gravity. "But it isn't fine if you forget that, ultimately, your goal is describing the real world."
>
> It's a question he has asked his friends. Why are they investigating detailed quantum field theories? "What's the aspiration?" he asks. Their answers are logical, he says, but steps removed from developing a true description of our universe.
>
> Instead, he's looking for a way to "find gravity inside quantum mechanics." A paper he recently wrote with colleagues claims to take steps toward just that. It does not involve string theory.

Cole tells us that

> Like many a maturing beauty, string theory has gotten rich in relationships, complicated, hard to handle and widely influential. Its tentacles have reached so deeply into so many areas in theoretical physics, it's become almost unrecognizable, even to string theorists.

According to her, string theory has made "essential contributions to cosmology" (this likely is news to cosmologists), especially by revealing the multiverse, which is now "taken for granted by a large number of physicists", one of whom you might think is David Gross, since she writes:

> Inflationary models get tangled in string theory in multiple ways, not least of which is the multiverse — the idea that ours is one of a perhaps infinite number of universes, each created by the same mechanism that begat our own. Between string theory and cosmology, the idea of an infinite landscape of possible universes became not just acceptable, but even taken for granted by a large number of physicists. The selection effect, Silverstein said, would be one quite natural explanation for why our world is the way it is: In a very different universe, we wouldn't be here to tell the story.
>
> This effect could be one answer to a big problem string theory was supposed to solve. As Gross put it: "What picks out this particular theory" — the Standard Model — from the "plethora of infinite possibilities?"
>
> Silverstein thinks the selection effect is actually a good argument for string theory. The infinite landscape of possible universes can be directly linked to "the rich structure that we find in string theory," she said — the innumerable ways that string theory's multidimensional space-time can be folded in upon itself.

The piece ends with a different genre of hype:

> Arkani-Hamed believes we are in the most exciting epoch of physics since quantum mechanics appeared in the 1920s.

I actually spent much of the day down in Princeton at the IAS, attending some of the talks at the Natifest in honor of Nati Seiberg's 60th birthday. Lots of different ideas were discussed by the speakers, with essentially no mention of string theory. A serious journalist who talked to all the people Cole did would likely have noticed the obvious and framed the same material quite differently: string theory hasn't worked out and theorists have moved on to other things, with the center of gravity of the subject now the deeper study of quantum field theory.

Update: I took a look again at the KC Cole review of my book, the second page of it is here. It was even more dishonest and unethical than I remember. She takes my

> superstring theory has had absolutely zero connection with experiment,

and turns it into

> Woit's claim that string theory has "absolutely zero connection with experiment,"

Note how pulling a phrase out of sentence, you get to do fun stuff like change the tense of the sentence.

On the neutrino issue, Cole writes:

> To say, as Woit does, that fundamental mysteries about neutrinos are being ignored will come as news to the dozens of physicists who've been working on these problems for years.

This is based on the fact that on page 93 of the US edition I write, after giving a description of the things the standard model leaves unexplained, including a parameter count that ignores neutrino masses:

> One complication that has been ignored so far involves neutrinos.

and then go on to explain about the experimental evidence for neutrino masses. The "ignored so far" obviously means "ignored so far in this chapter", not "fundamental mysteries about neutrinos are being ignored" by physicists.

When I contacted her to complain about this, her response was that there was nothing wrong with what she had done, and that, unlike me, she was an expert on neutrino physics.

The Quanta article has lots of her characteristic "quotes", words or phrases pulled out of context. I'll bet that lots of those misrepresent what the person being quoted actually said. I'd urge the Quanta editors to re-fact check this piece, asking for full quotes, in context.

Comments

1. **Johannes**
   September 16, 2016

   A Natifest without string theory? Is Seiberg now the only string theorist remaining on Earth?

   More seriously: Peter, what ideas were presented? What are people at the IAS doing exactly?

2. **David Appell**
   September 16, 2016

   K.C. Cole has a BA in political science. Snarf.

   https://en.wikipedia.org/wiki/K.C._Cole#Personal_life

3. **Another Anon**
   September 16, 2016

   "String theory hasn't worked out". This is it in a nutshell. It's not like it was ever going to die overnight, we're seeing it slowly morphing and fading.

4. **cgh**
   September 16, 2016

   As someone who has been quoted in the press more than a few times, it has been my experience that quotes will be used contextually, and sometimes practically altered, to support a larger narrative or theme that you're unaware of at the time the question is asked. Just a couple of months ago I agreed to an interview, which I agreed to be attributable, on two different subjects. Granted, this stuff is complicated, and the job of reporting and conveying clearly is not easy, but I was very surprised by subsequent published piece as 1) it conflated the two separate responses as if they applied to the same topic and 2) the context of the story rendered their usage non-sensical.

   It sounds like KC Cole approaches this stuff with a bias.

5. **TS**
   September 16, 2016

   Nowadays, string theory is cited as an example of science gone wrong to explain failure in other fields. Here (PDF) you will find recent economics research being compared to string theory, and that is not meant as a compliment.

6. **Asaint**
   September 16, 2016

   Can someone explain what Nima means by:
   "Every aspect of the idea that we understood quantum field theory turns out to be wrong. It's a vastly bigger beast."

7. **Peter Woit**
   September 16, 2016

   David Appell,

   But she told me she was an expert in neutrino science?

   More seriously, a lack of formal training in science isn't necessarily a problem, some of the best science writers I've met don't have this. On the other hand, lacking any interest in accuracy and being in love with ridiculous hype are problems. Someone back in 2006 pointed me to this account of Cole's advice to other science writers, which encourages them to eschew objectivity and quote out of context

   https://web.archive.org/web/20061002142756/http://www.ncswa.org/archive/workshops/2004/3cole.html

“Really good science writers need to lie, cheat, and steal, said K. C. Cole in the first plenary of the workshop. She outlined 15 rules for writing in her talk, but focused most on the value of lying.”

8. **Peter Woit**
September 16, 2016

Johannes,
You can follow the conference via a live-streaming link here
https://www.ias.edu/events/natifest-celebrating-science-nathan-seiberg-0
and I would guess that slides from talks will be posted.

The talks are covering a lot of different topics, many with some relation to Seiberg’s work on getting non-perturbative information about supersymmetric qfts (with the Seiberg-Witten work on N=2 d=4 SUSY a high point of that subject).

My impression is that there has been a lot of interest recently at the IAS in problems of low-dimensional QFTs related to condensed matter physics. Some of this started with attempts to use AdS/CFT to say something about condensed matter, but seems to have moved on from there to more basic questions purely about QFT, often with some relation to topological quantum field theory.

9. **John**
September 16, 2016

“Really good science writers need to lie, cheat, and steal, said K. C. Cole in the first plenary of the workshop. She outlined 15 rules for writing in her talk, but focused most on the value of lying.”

This seems to apply to about 90% of all journalists in any field or subject. Problem today is journalism isn’t reporting anymore. It’s telling of a story and that requires a bias, else the story is too boring most of the time. This is how journalism is now taught in most universities.

10. **Peter Woit**
September 16, 2016

John,
I don’t know about journalists in general, but my experience with science journalists is that the great majority of them do try and get things right, in an unbiased way, with Cole an unusual exception. This is especially true of the writers at Quanta, since that publication is not advertising driven, and thus more focused on producing high quality content, not clickbait.

11. **Bernhard**
September 16, 2016

It’s been a while since I last read so many embarrassing statements about science in the the same piece. Wow.

12. **Curious Mayhem**
September 16, 2016

Who *is* working on string theory, as such, these days? Wasn’t all the progress, such as it was, using quantum field theory and funky symmetries, some new, some not?

This stuff from KC Cole (whom I never paid much attention to) is astonishingly ignorant. String theory isn’t a maturing beauty, but a bad idea that died some time ago and no one wants to talk about too loudly and in public — like those embarrassing Facebook pictures from Florida spring break you wish you hadn’t posted.

The crap about the multiuniverse is deeply ignorant. Inflation is consistent with, but does not require, a universe of multiple domains. It has nothing to do with causally disconnected or disjointed realities — no “landscape” of “realizations.” The technical implementation of inflation (the long e-folding needed) is quite difficult to pull off in string-inspired QFT models. The only cases I know of involve a new, extra symmetry. Otherwise, actually, it’s impossible. If the evidence for inflation ever becomes decisive, that would be another nail in the string theory coffin.

Cosmologists and astrophysicists who understand the QFT side of inflation know this, but they’re generally careful not to say it too loudly. It’s like tripping the archbishop during high mass. Maybe now that string theory has died an overdue, quiet, and deserved death, more people can talk about this openly.

13. **Bai Xiao**
September 16, 2016

Many years ago I attended a workshop at KITP, which ran in parallel with another one on String Theory. KC Cole had been invited by the director (David Gross) as the “in-house journalist” and was invited to lecture us about how to write science better and hype up (I presume) our field.

This was in 2004 and the field was just starting to take off and attracting more and more attention, especially from condensed matter and HEP theorists.

After reading the post and the above comments, I am under the impression that some people in the community may have taken private lessons with her. Since then, the field has become increasingly dominated by hype and nonsensical theoretical proposals.

Unlike String theory, there is still much degree of experimental input, but it is dressed in a heavy cloud of hype and wild speculation. With a few exceptions, experimental results are often reported as “ground breaking”, when they often are textbook demonstrations of well understood quantum mechanical phenomena, or simply new realizations of phenomena that had been already observed in other systems.

14. **Narad**
September 17, 2016

“Like many a maturing beauty…. Its tentacles have reached….”

That’s quite the mixed metaphor.

15. **David Metzler**
September 18, 2016

This is OT, but some might enjoy a pretty decent write-up by the LIGO people of the process they went through to validate their first detection:

https://www.ligo.caltech.edu/news/ligo20160914

Careful and important science, written up well for a general audience.

16. **Paul**
September 19, 2016

Peter Woit says:
"David Appell,
But she told me she was an expert in neutrino science?
More seriously, a lack of formal training in science isn't necessarily a problem, some of the best science writers I've met don't have this. On the other hand, lacking any interest in accuracy and being in love with ridiculous hype are problems…"

Peter, you're a Gentleman and a Scholar. One of the many reasons why I enjoy your blog.

17. **kwwrona**
September 20, 2016

There are at least two possible explanations for Cole's expertise in neutrino physics. She once lived in Shaker Heights, OH. And since Frederick Reines was chairman of the Case Tech physics department while he was working on the detection of gamma-generated neutrinos in the atmosphere, who knows? It's only a couple of miles away.

And, Shaker Heights isn't very far from the Irvine-Michigan-Brookhaven neutrino detector at Fairport Harbor on Lake Erie. It's just off I90.

So maybe something rubbed off.

18. **Peter Woit**
September 21, 2016

kwwrona,
I think she believes she's an expert in neutrino physics since she wrote an article about a neutrino experiment for the New Yorker.

19. **GoletaBeach**
September 22, 2016

A bit too snarky for me… "not even wrong" is as snarky a comment itself as anything KC Cole wrote into her review… I can't see anything about neutrino physics in that LA Times review she wrote of "Not Even Wrong". I didn't even feel was she was particularly negative to you, Peter.

Meanwhile, a certain segment of the neutrino community (double beta decay, direct neutrino mass) was up the hill from me this week… nice talks. Wonderful "Livingston" plot of the improvement in sensitivity to direct neutrino mass as a function of time, predicting that around 2020/2030 direct sensitivity will start to get to the level of delta-ms measured in oscillations.

There is a mild fissure in the experimental community, I think… DUNE is not always appreciated by the LHC guys, and maybe vice versa. A story too true and important to be delved into, I guess. But the DUNE neutrino community is distinct from the nuclear-side neutrino folks up the hill from me this week.

20. **Peter Woit**
September 22, 2016

Goleta Beach,

I think you probably weren't seeing page 2 of the review, see
http://articles.latimes.com/2006/oct/08/books/bk-cole8/2

I went back and looked at the LA Times review again, it was even more dishonest than I remember. Besides the outrageous neutrino business, the way she used another quote, deleting a word to change its meaning, was a piece of sleaze I don't think I noticed before. I suspect that most of the quotes in this piece are also seriously out of context (often she just quotes a couple words of a sentence, surrounding them with her own). The Quanta editors might want to go back and re-fact check this piece, asking Cole to provide full, in context quotes to check against the quotes she uses.

21. **Peter Woit**
September 22, 2016

I added an update to the posting explaining some of what was going on in Cole's LA Times review, for the vanishingly small number of readers who might care…

22. **Low Math, Meekly Interacting**
September 22, 2016

Just makes me more and more grateful for Ms. Wolchover.

23. **Roy**
September 22, 2016

I think you're making too much of the journalist's error. Doubtful that it's malicious.

24. **Peter Woit**
September 23, 2016

Roy,
In the case of ten years ago, there was definitely malice involved (towards Lee Smolin and myself). In the case of the new article I don't think there's malice, just incompetence.

Heidelberg Laureate Forum

September 19, 2016
Categories: Uncategorized

This week I'm in Heidelberg, attending the Heidelberg Laureate Forum, where I'll be writing some blog posts for their website (which should appear here). You can follow talks on their website, either in real-time as streaming video, or by watching a talk video later on.

This event brings together mathematicians and computer scientists. More specifically winners of the Fields Medal, Abel Prize, ACM Turing award and Nevanlinna Prize come to give talks and interact with a large group of young researchers (and various hangers-on such as myself).

Update: I wrote blog entries for the HLF about Faltings, Ngo, Wiles, Atiyah and Voevodsky. Now on my way to London, will spend the next week in England, mostly in Oxford.

Still Not Even Wrong

September 24, 2016
Categories: Not Even Wrong: The Book

A while back Tushna Commissariat of Physics World came to talk with me at Columbia, partly to discuss the topic of “Not Even Wrong, ten years later”, and that has now been turned into a podcast available as Still Not Even Wrong.

I’ve now forgotten what I said then, but presumably I still agree with it. This coming week I’m traveling and won’t have much time to deal with the blog, so comments from me may be few and far between.

Update: There’s an appreciative blog post about this here from ZapperZ.

Comments

1. **Shantanu**
   September 26, 2016

   Peter something OT
   Jim Gates’s colloquium at CFA
   https://www.youtube.com/watch?v=n64-koDcCqs

2. **Shantanu**
   September 26, 2016

   I think his punchline in answer to Giovanni Fazio’s question is “string theory still does not exist”

3. **Shantanu**
   October 3, 2016

   Peter any rumors/guesses for this year’s nobel prize?

4. **AcademicLurker**
   October 3, 2016

   @Shantanu,

   Gravity wave detection? Maybe it’s too soon and they’ll wait a year or two.

5. **N.**
   October 3, 2016

   Jeez, 10 yrs…
   I read your book after Lee’s Trouble and I remember thinking, now well, this must be a conspiracy, strings rule, don’t they…
   I remember I read your book twice. And Lee’s as well.
   It was my serious intention to read it again one of these days, but it is unfortunately impossible.
   Moral of the story: do not lend good books to good friends. 🙁

6. **AcademicLurker**
   October 4, 2016

   Well that was a surprise. I remember studying the Kosterlitz–Thouless transition in grad school.

7. **CWJ**
   October 4, 2016

   Heck, I had Thouless as a professor in grad school. I always thought of him as being on the long list for the prize, but after this many years I assumed it wasn’t going to happen. Congratulations to the winners!

   (And my bet for next year is gravitational waves…)

8. **Thomas Larsson**
   October 4, 2016

   It was a long time since I thought about the KT transition. IIRC, there is a continuum of inequivalent critical points depending on the coupling constant, which is possible because the relevant CFT does not belong to the unitary discrete series but to a continuum of unitary models with c=1.

   The Wikipedia article already mentions the 2016 Nobel prize.

9. **Rob**
   October 6, 2016

   I think it was wise not to give the prize for gravitational radiation this year. I’m nervous about the reliability of the result. I don’t doubt that the experiment has done a great job. However, experimental science rests on reproducibility. Ideally this would come from other experiments. However, this is some way off. Therefore, at the least I’d like to see Advanced Ligo collect a more substantial sample of gravity wave “events” than it presently has.

10. **pie inskee**
    October 9, 2016

    Good interview…your voice/manner is very much as suggested by your blog/mission.

May I ask a question. I 'feel' like things are going your way. This last year or so seems to have seen significant rise in hard criticism of Strings. The question is whether you concur with this perception.

11. **Peter Woit**
October 9, 2016

pie inskee,

The lack of any evidence for supersymmetry over the past year or so, given that the LHC is now running at nearly full energy, I think removes the last hope for some sort of experimental vindication of the ideas behind string theory as a unified theory. This may have an effect, I'm not sure that I've seen much of a change recently. I do think though there has been a big change over the last ten years, as string theorists themselves have given up on the idea of getting predictions out of the theory. The embrace of the multiverse as an excuse is a move that doesn't convince most people.

Back

October 4, 2016
Categories: Uncategorized

Now back from traveling, regular blogging will resume. Here are a few items:

- I was going to write something yesterday, explaining that this year's physics Nobel would surely go to the LIGO trio who have gotten every other major physics prize this year. Luckily I was too lazy to do that yesterday, since this morning's news is that it instead went to Haldane, Kosterlitz and Thouless, work going way back to the early 1970s. When I was doing my thesis work trying to figure out how to find a lattice version of topological invariants of gauge fields, I started out looking at the case of the 2d XY model which they had studied, where the topology is much simpler.

  Congratulations to them, probably next year for the LIGO guys…

- My colleague Daniel Litt has started up a really nice blog.
- Some sort of time warp back to the days of pre-LHC hype of the last decade seems to have occurred while I was in Germany, leading to lots of media stories like this one.
- In Heidelberg among the people I met were Dirk Huylebrouck, who reminded me that there's lots of great material in the Mathematical Intelligencer, including his "Mathematical Tourist" column, and Barry Cipra, one of the authors of the AMS's What's Happening series.
- John Baez is involved with a new project, funded by DARPA, that he describes here.
- Last week there was a conference in Madrid devoted to the question Is SUSY Alive and Well?. Of the talks I looked at, the only one with a sensible answer to the question was that of Alessandro Strumia.
  Update: A commenter points to this very interesting survey of the participants.
- In case you haven't heard what's going on in Leicester, Tim Gowers explains here.
- I was very sorry to hear of the passing last Saturday of Joseph Birman, a theorist at CCNY, and husband of my colleague Joan Birman. Some information about one aspect of Joe's work is here, perhaps more about other aspects will appear soon.

Comments

1. **Bernd**
   October 5, 2016

   The Leicester story gets a sad ironical twist with this year's Nobel prize going to three Brits who left the country during the Thatcher madness. Doesn't seem they have learned anything. To make matters worse, the "good citizenship" requirement nowadays includes spying on your students to spot potential "terrorists". A colleague of mine grew up in the GDR and finds these practices eerily familiar.

2. **anon**
   October 5, 2016

   The survey results from that conference are interesting

   https://workshops.ift.uam-csic.es/susyaaw/Survey

3. **Peter Woit**
   October 5, 2016

   anon,
   Thanks, very interesting. I've added a link to that to the posting. Interesting to see that even among experts on SUSY still working on it, "alive and well" is the opinion of less than 30%.

4. **MikeS**
   October 5, 2016

   There may actually be some wisdom in giving the LIGO discovery another year to mature. Not least because that gives a clear opportunity for another clear event or more to be identified.
   The first event GW150914 is always associated with that slight niggle because it was almost immediately seen on switch on, nothing so clear since, and no corroboration from any other observation type. The subsequent GW151226 event is so buried in the noise that a skeptic may believe that reverse engineering the result cannot be entirely ruled out. And again no corroborating gamma ray burst or the like. Yes I realise that some very sound statistics have been employed, but in the end we still have only two events.
   The room for doubt may be tiny, but hopefully this time next year it will be non-existent.

5. **KJ**
   October 5, 2016

   "Alive and Well" is the opinion of less than 30%, but on the other hand, "Alive" in some form is the opinion of over 85% of those surveyed. A survey question not asked, to which I would have liked to see the results, is "Under what circumstances would you be likely to consider SUSY dead?" with options for not seeing any evidence from various runs of the LHC or other future events.
   I wonder how many would pick "I will never agree that SUSY is dead"?

6. **Yatima**
   October 5, 2016

   And again no corroborating gamma ray burst or the like.

   If these are black hole collisions happening hundreds millions of LY away, one might suppose that there would never be anything to put on a photographic plate (these are blacks holes, after all). On the other hand… Modeling the afterglow of the possible Fermi-GBM event associated with GW150914

7. **anon**
   October 5, 2016

   More information about the survey included many comments here https://workshops.ift.uam-csic.es/files/205/Survey.pdf

8. **Low Math, Meekly Interacting**
October 6, 2016

What's this "suppressed SUSY" business?

9. **Jeffrey M**
October 6, 2016

LMMI,

Well, curiouser and curiouser. If you Google "suppressed SUSY" you hit a ton of papers by a John Dixon. If you check these papers, the recent ones have no affiliation listed for him. Go back a bit, and the affiliation is a law firm. Back further, and he was at Texas A&M. Anyone care to explain?

10. **Low Math, Meekly Interacting**
October 6, 2016

In the comments from that survey, it appears to be the most-cited reason to continue to expect natural SUSY. Or, at least, the notion of "suppressed SUSY" is deemed to be both sufficiently promising, despite being poorly understood, to not dismiss the notion of SUSY being a viable solution to the hierarchy problem. From what little I can understand, "suppressed SUSY" seems to provide a "natural" explanation for why sparticles have not been, will not be seen by the LHC. It also seems qualitatively different than other ideas (e.g. sparticles "hiding in plain sight" because the masses of the LSP and the next-to-LSP are nearly equal) explaining away the non-appearance of SUSY.

Lacking the needed expertise/IQ/what-have-you, I'm unable to determine if my limited understanding is correct. I'm also unable to determine how desperate a measure" suppression" is to rescue "naturalness", compared to the others in the SUSY field.

11. **Peter Woit**
October 6, 2016

LMMI,
The problem with those comments is that you don't know whether they reflect anything other than the views of one particular participant. In this case, John Dixon is listed as a participant at this conference, and the comments about "suppressed SUSY" may just be his enthusiasm for his own idea.

12. **Low Math, Meekly Interacting**
October 6, 2016

Got it. Didn't factor in such a powerful, uh, selection bias. Rather, figured those comments might reflect a broader sample.

13. **JG**
October 6, 2016

Speaking of "Alive and Well" can anybody confirm whether the LIGO "trio" (Rainer Weiss (age 84), Kip Thorne (76) , Ronald Drever (85)) need to survive until the end of nominations in January or if they have to still be alive next October at the time of the award of the Nobel?

14. **John Dixon**
October 6, 2016

I am the John Dixon of whom you are speaking, in relation to Suppressed Susy, and the recent Madrid conference on `Is SUSY alive and well'. A friend pointed out these remarks to me. This is a test to see if this gets online. If it does, then I will probably make a short reply to your remarks about the conference, and also about my own work.

15. **John Dixon**
October 6, 2016

Well OK then. I tend to agree with Peter Woit, that the talk of Alessandro Strumia, which gave a short answer NO to the question `Is SUSY alive and well?' made some valid points. Alessandro did get a lot of flack for that answer at the conference. But SUSY is certainly in trouble, using the usual ideas, in my opinion.

The purpose of a conference of course is to create a venue where people can exchange ideas. The Madrid conference did that, and I enjoyed it.

The problem for SUSY, at present, is that the popular view at the conference was that SUSY can get spontaneously broken in an invisible sector, which is then manifested in the visible sector (our world) by some unknown messenger sector. The trouble is that this is supposed to give rise to some hundred and fifty new undetermined parameters.

Much of the conference was a discussion of these parameters, and how the present experiments constrict the huge space that these occupy. It does not look very good for the theory in my opinion. Also I do not think that the theory makes much sense anyway. It is rather like the Emperor's new clothes as things stand–you can't see the invisible sector, and that is where everything important is supposed to happen.

It is true that I do not presently hold an academic position. Recently I was at Oxford for six months or so as a visitor. My recent papers have been published however by a reputable refereed journal, Physics Letters B. It is also true that these are not yet widely known or cited. They are very new and the ideas are new too. However, this does not mean that they are necessarily wrong or crackpot. I went to the conference and also the SUSY 2016 conference in Australia in July, to discuss these ideas with colleagues. I did give a talk at SUSY 2016. People at the conferences seem somewhat interested, but as the comments above note, the thing is complicated, and I expect progress to be slow.

Suppressed SUSY is an idea that amounts to a way of splitting SUSY masses without spontaneous breaking of SUSY. The next step is to calculate the one-loop corrections.
So I do not know yet how successful it will be. It depends on the Master Equation for the BRST formulation of SUSY, as explained in the papers.
Other papers are in preparation.

16. **Jeff M**
October 7, 2016

JG,

I believe, but someone correct me if I'm wrong, that you have to be alive when the prize is awarded. You don't have to make it to the presentation ceremony.

17. **Thomas Larsson**
October 7, 2016

More precisely, the Nobel committee must think that you are alive when the prize is awarded. On 3 October 2011, the laureates for the Nobel Prize in Physiology or Medicine were announced; however, the committee was not aware that one of the laureates, Ralph M. Steinman, had died three days earlier. The committee was debating about Steinman's prize, since the rule is that the prize is not awarded posthumously. The committee later decided that as the decision to award Steinman the prize "was made in good faith", it would remain unchanged. [Wikipedia]

18. **NotPhysicist**
October 7, 2016

I tried to post this earlier but it didn't show up, possibly due to the spam filter, so I am trying again. I mean no annoyance if it did not show up due to being considered off topic. I would like to see some discussion of this issue somewhere though.

>MikeS: "Yes I realise that some very sound statistics have been employed"
–
I'm not so sure the headline stats (that really small p-value) were interpreted correctly:
–
"We present the analysis of 16 days of coincident observations between the two LIGO detectors from September 12 to October 20, 2015.
[…]
The significance of a candidate event is determined by the search background—the rate at which detector noise produces events with a detection-statistic value equal to or higher than the candidate event. Estimating this background is challenging for two reasons: the detector noise is nonstationary and non-Gaussian, so its properties must be empirically determined; and it is not possible to shield the detector from gravitational waves to directly measure a signal-free background. The specific procedure used to estimate the background is slightly different for the two searches, but both use a time-shift technique: the time stamps of one detector's data are artificially shifted by an offset that is large compared to the intersite propagation time, and a new set of events is produced based on this time-shifted data set. For instrumental noise that is uncorrelated between detectors this is an effective way to estimate the background."
http://journals.aps.org/prl/abstract/10.1103/PhysRevLett.116.061102
–
"Even though the routine data quality checks did not indicate any problems with the data, in-depth checks of potential noise sources were performed around the time of GW150914…No data quality vetoes were active within an hour of the event.
[…]
Following the event, the detectors were maintained in the same configuration to ensure that detector changes would not cause unanticipated consequences which might bias the background estimation for the event."
https://arxiv.org/abs/1602.03844
–
So the hypothesis being tested is that their model of background noise accurately describes what the detectors were sensing at the time of GW150914. Also, note the model of background noise is based on data collected primarily after the detection. However, members of the LIGO team have described that this was not the case, the processing pipeline was changed in response to GW150914:
–
"At 11:23:20 UTC, an analyst follow-up determined which auxiliary channels were associated with iDQ's decision. It became clear that these were un-calibrated versions of h(t) which had not been flagged as "unsafe" and were only added to the set of available low latency channels after the start of ER8. Based on the safety of the channels, the Data Quality Veto label was removed within 2.5 hours and analyses proceeded after restarting by hand."
http://www.ligo.org/magazine/LIGO-magazine-issue-8.pdf
–
So that statistical test doesn't mean much to me, the hypothesis it tested was rendered false by altering the configuration. That numerical relativity simulations could easily reproduce the signal is far more convincing than their statistical argument.

19. **Harry Dale Huffman**
October 7, 2016

This comment is off-topic for this post, but it's the easiest way to bring it to your kind attention:

I just, for the first time, came across a blog by Sabine Hossenfelder called "backreaction", and there is a post there on "Demystifying Spin-1/2"

I didn't think the discussion there demystified spin-1/2 particles at all. Hossenfelder first wrote that spin-1/2 particles are "…particles that have to be rotated twice to return to the same initial state." She then made a statement I readily agreed with: "I don't know if anybody who didn't know the math already has ever been able to make sense of this explanation – certainly not me when I was a teenager."

But then, instead of "demystifying" anything, she merely doubles down on the idea of "particles that have to be rotated twice to return to the same initial state", by introducing how rotations (or, more generally symmetry transformations) act upon quantum states. She writes, "A symmetry transformation acting on a quantum state must be described by a unitary transformation …. And the full set of all symmetry transformations must be described by a 'unitary representation' of the group." Then, "Symmetry groups, however, can be difficult to handle, and so physicists prefer to instead work with the algebra associated to the group. The algebra can be used to build up the group…. But here's where things get interesting: If you use the algebra of the rotation group to describe how particles transform, you don't get back merely the rotation group. Instead you get what's called a 'double cover' of the rotation group. It means – guess! – you have to turn the state around twice to get back to the initial state." So she's gotten back to that original definition of a spin-1/2 particle. But in my view, she hasn't "demystified" spin-1/2 particles, she has merely given a quick summary of why mathematical physicists define them that way (in other words, it's just the mathematics used, not the physics). For anyone interested in what spin-1/2 particles are physically, surely it is simpler to say they are particles that are always (can only be) observed to have either "spin up" or "spin down" along any given axis. That doesn't really explain what "(quantum) spin" is either, physically, but it captures the observable reality where "double cover of the rotation group" does not.

Why didn't Hossenfelder give the traditional definition I just gave, and why did she call her post "demystifying spin-1/2", when she did not do that at all? I would like to see a post by you on this, to see where you and your readers stand on it.

20. **Peter Woit**
October 7, 2016

Harry Dale Huffman,

That is highly off-topic, and I don't want to have a discussion of it here, not because it's not interesting, but because it's too interesting, and deserves something more serious. I did look at that blog posting, and it struck me as running into the standard problem such discussions always run into: you can get from knowing how SO(3) rotations act on vectors (which is what we have lots of intuition about) to all sorts of interesting things, but you can't get the spin 1/2 representation this way. In particular, you can motivate the fact that \pi_1(SO(3))=Z_2, but this isn't enough to tell you about the spinor representation.

I think this is an example of something I disagree with lots of physicists about. Yes, if you really understand something you should be able to explain it to your grandmother, but in cases like this you're just going to confuse her (or mislead her into thinking she understands something she doesn't) if you try and explain things in terms of her intuitions about rotating objects in 3-space. Granny is going to need to sit still and pay attention for quite a while, as you first explain to her some new ideas she has no intuition for. One of various ways of going about this is to start by telling her about complex numbers and show how you can use them to study rotations in the plane, then introduce quaternions and show how to think of rotations in terms of them. At that point you have the spinor representation, not just the vector representation (for the details of what I'm talking about, see chapter 6 of http://www.math.columbia.edu/~woit/QM/qmbook.pdf).

Retraction at Annals of Physics

October 8, 2016
Categories: Uncategorized

Retraction Watch reports that *Annals of Physics* has removed a recently published article by Joy Christian, replacing it by a publisher's note that just says:

> "This article was erroneously included in this issue. We apologize for any inconvenience this may cause."

The paper is available on the arXiv here. Christian's affiliation in the abstract is listed as "Oxford". This refers to the Einstein Centre for Local-Realistic Physics which is not at Oxford University, but at a location in the town that I think I unknowingly walked past on my way to go punting last week. The only person involved with the centre who lists an academic affiliation is Dr. Jay R. Yablon (MIT), who appears to be a patent attorney in Schenectady.

This story brings back memories of the Bogdanov affair of 2002, one aspect of which was the publication by the Bogdanovs in *Annals of Physics* of a paper that, as far as I could tell, made little sense. That paper was never removed or retracted. The editor-in-chief when the Bogdanov paper was accepted was Roman Jackiw. Frank Wilczek took over from him and said at the time that he was hoping to improve the journal's standards. The current editor-in-chief is my Columbia colleague Brian Greene.

Comments are off since I would rather not host a discussion involving the merits of this paper. I haven't tried to seriously read it, and don't want to spend time doing so. In the Bogdanov case I spent (wasted…) a lot of time reading their papers, so felt comfortable discussing them, not about to do the same in this case.

YITP at 50

October 11, 2016
Categories: Uncategorized

The past couple days the YITP at Stony Brook has been celebrating its 50th birthday. It was started back in 1966 by C. N. Yang and has been an active center for theoretical physics ever since. The ITP at Stony Brook was as some point renamed in honor of Yang, now it's officially the "C. N. Yang Institute for Theoretical Physics". I was a postdoc there in 1984-87, when it was just the ITP, and Yang was still the director. I had been hoping to go out to Stony Brook for at least one day of the event, but unfortunately other things have kept me here in New York.

Luckily, with today's technology one can watch the talks online (see here) and follow what happened at the conference. I've watched a few of the talks, and they give a good survey of the kind of work that has been going on at the institute over the last 50 years. One aspect that isn't emphasized in the talks (although there's a little bit in Fred Goldhaber's talk) is that the institute is in the same building as the mathematics department with, at least back in my day, some physicists and some mathematicians even having offices nearby on the same floor. Being able to talk to and learn from some great mathematicians (soon after Yang, in 1968 Jim Simons came to Stony Brook and brought together a world-class mathematics department) was a big influence on me during my postdoc years. These days, with the Simons Center for Geometry and Physics, Stony Brook is one of the great centers of mathematical physics.

The last talk of the event was a public talk by Ashoke Sen on What is String Theory? (slides here), one which made me think that maybe it wasn't a bad thing that I hadn't made it out to Stony Brook, since I might have been there for this. Sen's talk was a depressing compilation of ancient hype and misleading claims about string theory, with the standard multiverse excuse for why it predicts nothing at all about particle physics.

My time at the ITP coincided with the early years of this kind of string theory hype, which got started in late 1984, about the time I got there. By my last year there (exactly 30 years ago, 1986-87), everyone in the physics community had already been subjected to a couple years of this kind of thing, so much so that Ginsparg and Glashow had published in spring 1986 their Desperately Seeking Superstrings article, noting that

> …years of intense effort by dozens of the best and the brightest have yielded not one verifiable prediction, nor should any soon be expected.

They worried that

> Contemplation of superstrings may evolve into an activity as remote from conventional particle physics as particle physics is from chemistry, to be conducted at schools of divinity by future equivalents of medieval theologians.

which many at the time thought was kind of harsh, but in retrospect looks quite prescient. I doubt that even they thought that anyone in the physics community would sit still 30 years later to listen to a talk like Sen's.

My own attitude at the time was that superstring theory was just one in a sequence of fads that had gotten the attention of particle theorists, with one to two years the usual decay time for such things. So by 86-87, I figured this one was now past its sell-by date and would soon be on the way out. How wrong I was.

Comments

1. **Jeffrey M**
   October 11, 2016

   Peter,

   Am I wrong that string theory was kind of on the way out, not in 87, but by the early 90's? As I sort of remember it, there were major issues with various singularity sort of issues, and then Witten figured out ways around them, and things took off again, getting much worse when Malcedena came along. I of course never knew the details, being a mathematician, but I followed it a little since I knew Witten as a mathematician, a very good one.

2. **Tim Nguyen**
   October 11, 2016

   Pardon my sense of humor Peter but if string theory died out long ago, you wouldn't have your book, your blog, and your readers. In this other sector of the multiverse, who might you be in 2016?

3. **Peter Woit**
   October 12, 2016

   Jeffrey M,
   Interest in string theory was starting to die down in late 80s, early 90s (and during a lot of this period Witten was working on TQFT/Chern-Simons, topics not related to string theory). M-theory in the mid-90s really revived and changed a lot the nature of what string theorists were doing. It didn't at all though address the problems of connecting string theories of unification with reality.

   Tim Nguyen,

   An interesting question. Quite likely I wouldn't have a blog or popular book, maybe my book about QM and math would have been finished long ago (instead of maybe next week…). I'd like to think that in such a universe we'd have learned a lot more about quantum field theory by now, and I'd hope about questions that always have motivated me. So, I think I'd be much less well-known, but maybe much more content…

4. **A.J.**
   October 12, 2016

   * I'd like to think that in such a universe we'd have learned a lot more about quantum field theory by now.*

   I don't really understand this claim. You can say whatever you want about string theory as a model of particle physics. We haven't had any progress in that subject since the 70s; indeed, any progress beyond the Standard Model was at best premature. But it seems odd to me to dismiss what we've learned about QFT by studying strings, just because you find it unappealing as an approach to particle physics. The study of string theory, especially after 1995, has been the single most fruitful source of new toy models, new mechanisms, and new ideas in QFT.

5. **John McAllison**

October 12, 2016

Peter, while what you claim about interest in String theory declining in the late 80s and early 90s is true, it doesn't tell the whole story from the information on page 20 here: https://workshops.ift.uam-csic.es/files/205/Strumia.pdf

There's a huge x10 jump in interest beginning in 1984 after the first String revolution, falling sharply to half this level in early 1990 and remaining fairly constant up to early 2000.But the general picture is a decline, as you say, compared to its glory days of 1986.

6. **Peter Woit**
   October 12, 2016

   A.J.
   I'm not dismissing what has been learned about QFT as a byproduct of string theory, I'm just pointing out that, if effort devoted to string theory had instead been devoted directly to questions about QFT, quite possibly we'd have learned more about QFT. Making QFT research an appendage to string theory research means that certain aspects of QFT have gotten a lot of attention and made progress (e.g. 2d CFTs), whereas other questions about QFT have gotten little attention, because they have no connection to string theory.

   As an example of what I mean, I was referring above to the amazing breakthroughs in our understanding of QFT that Witten came up with (especially Chern-Simons, TQFTs) during the late 80s, early 90s, many of which had nothing to do with string theory. What if there had been no M-theory "revolution"? Yes, you would lose all sorts of things that came out of that, but perhaps the QFT research directions that people followed instead might have been even more interesting. We'll of course never know.

   John McAllison,

   I think that slide does a good job of measuring the popularity of string theory. It was at its height in 85-86, reached a local minimum around 1994, revived for a while, and has been steadily decreasing since 2000.

7. **A.J.**
   October 12, 2016

   Peter,

   It's true (by definition, really) that when we learn something about QFT by working on string theory, we can understand it independently of string theory, although usually at some cost in intuition. (Sometimes we can even reduce it to something mathematicians can work with.)

   But just because something is logically independent of X, doesn't mean we'd have come up with it without having worked on X. Witten was working on topological QFTs because he was looking for simplified models that exhibited background independence, so that he could better understand string theory! His first paper on the subject, "Topological Quantum Field Theory", is quite clear about this; he even says straight out that the core arguments should be familiar to string theorists. Other lines of inquiry on topological sigma models and mirror manifolds are explicitly string theoretic. The 1989 Chern-Simons theory paper is something of an odd man out, since it's a Schwarz-type TQFT and because he was trying to write something mathematicians could digest. (But it didn't take long for string theoretic work to spark further developments in Chern-Simons theory, like the connection Gopakumar-Vafa invariants.)

   Likewise, the Seiberg-Witten revolution in differential topology was really spin-off of spin off of non-topological string theory calculations. S&W were trying to understand dualities in string theory, and they came up a calculable model of 4d confinement. To my mind, that's of far greater importance to physics than any of the topological baubles we mathematicians get distracted by.

   The things you're suggesting might have been better to study than string theory, came from string theory.

   Note: I'm not advocating making QFT research an appendage to string theory research. There's a lot of good stuff out there that didn't come from string theory. But I think it's important to dismiss the origins of ideas, and it looks to me like a world where we didn't discover string theory is just a world where we don't know as much.

8. **A.J.**
   October 12, 2016

   Heh. I meant to say 'not to dismiss the origins of ideas', but my inner mathematician interfered.

9. **Peter Woit**
   October 12, 2016

   AJ,
   Your claims about history really are just not true. I was there at the time, and later I spent a lot of time carefully researching the details of this history before I wrote about it in my book. One place where Witten tells the story in his own words is here:
   http://www.ims.cuhk.edu.hk/~ajm/vol3/3_1/witten.ps
   Note that there's nothing about string theory there. Yes, this was (87) exactly the period when it had become clear that initial hopes for string theory weren't working out. Witten was undoubtedly hoping that the ideas about QFT he worked out in the TQFT paper would lead to some new insight about string theory. The flow of information though was opposite to the one you suggest: he wasn't at all using ideas from string theory to find the TQFT that Atiyah had suggested existed (based on Witten's ideas about supersymmetry and Morse theory, applied to the space of connections). Once he had found the right TQFT undoubtedly he was hoping it would help him overcome the roadblock he was facing in string theory (it didn't).

   As for his Chern-Simons paper, sorry, that had nothing to do with string theory either (although it did have to do with the WZW cft). The idea that that came from string theory, but Witten just didn't mention this in his paper because it was aimed at mathematicians is nonsense.

10. **paddy**
    October 12, 2016

    Am awaiting LMMI's always informative questions so I can glean more from the discussion. PS Apparently, Peter, we overlapped there at Stony Brook–tho I was not in the 'tower' but in the dungeon labs.

11. **A.J.**
    October 12, 2016

    It's not surprising that string theory isn't mentioned. Witten says explicitly in the linked article that he's leaving it out of the discussion, presumably because he's writing for an audience of mathematicians. Then he skips over the details of how he came to write down the twisted N=2 theory, saying only that he had the 'good luck' to notice how to do it. (He similarly elides the story of how he & Seiberg had the 'great good fortune' of looking at electric/magnetic duality in N=2 theories…) So, no, I don't think that article gives a complete picture of what was in his mind and motivating him when he cooked up the Donaldson theory. Fortunately, we do have the original article, where he points out that the core arguments are analogous to ones already known in string theory. Forgive me if I take Witten's word here.

You can divide TQFT from string theory logically, but you can't split up the intellectual histories of the two subjects. I don't even know why you'd want to, given how much explanatory power you lose.

12. **Peter Woit**
October 12, 2016

Just realized I've been through this same discussion before, with Lubos Motl. For those who care, see
http://www.math.columbia.edu/~woit/wordpress/?p=99

13. **No Math, Meekly Interacting**
October 13, 2016

Hi, paddy,

I got nothing. I'm just astonished at the "Desperately Seeking…" article. If they added a paragraph on the 10^500 vacua, seems like it could have been written 30 minutes ago instead of 30 years and still been quite topical. Philosophically, nothing's been settled, despite the best efforts of the Bayesians to make it seem otherwise. Plus ça change…

14. **A.J.**
October 13, 2016

One correction to the history you give in your link: You say that by '89, Witten "has completely abandoned the idea of relating Jones polynomials to topological sigma models" and that "New ideas about relations between branes, topological strings, and Chern-Simons appeared about ten years later". In fact, the next big step in the story comes in '92, with Witten's "Chern-Simons Gauge Theory As A String Theory", where he explains how to realize Chern-Simons theory as the spacetime physics of a topological string theory, more or less as he'd anticipated in the first TQFT paper. That's only a 3 year gap, which doesn't seem like much to me, given that it's a substantially more difficult paper.

15. **Tim Nguyen**
October 13, 2016

"I knew Witten as a mathematician, a very good one."

I was actually fortunate enough to have Witten come to my talk on quantum Yang-Mills at the IAS earlier in April:
https://www.youtube.com/watch?v=3lEgEGCH2cg

of which are more up to date and entertaining account of my work can be found here:

https://www.youtube.com/watch?v=hHXavKP6EmI

I was a bit surprised that the only question Witten had during question time at the end of my talk was matters pertaining to higher genus – a question only a mathematician (or a string theorist?) would ask! Ironic, since I myself as mathematician/physicist, the motivation behind my work was much more along the lines of fundamental physics/QFT and I was hoping Witten would have something to say about those issues.

Based on this isolated experience, I suspect speculations about Witten's true motivations may not be so cut and dry.

16. **student**
October 13, 2016

How do you think Montonen-Olive duality would have fared without the work of Sen, whom you just managed to be breathtakingly disrespectful to.

17. **Peter Woit**
October 13, 2016

student,
I think Montonen-Olive duality would have fared fine without Sen. And what's breathtakingly disrespectful here is not my (accurate) characterization of his talk, but his decision to deliver a talk full of misleading hype and pseudo-science to the audience at Stony Brook.

18. **adrian**
October 13, 2016

Dear Peter,
echoing a bit here what the commenters "student" and AJ wrote. You know I usually do not comment in this forum, but the discussion is interesting in this case.

–About Ashoke Sen's talk: true, the first part of his seminar is a bit disappointing. Except for the analogy with the phases of water, there is not much. But may be that is his view of that part of String Theory. If one reads the second part, the thing takes a much more interesting perspective. In particular, Sen discussed the virtue of the black hole as an ideal system. This lead to remarkable progress. It is a counting problem that 'knows' about quantum gravity. Far from trivial are Sen's and collaborators papers on this topics.

I just felt that your comment about his talk was unfair. May be I am biased by the fact that knowing Sen, having discussed with him in few occasions, I clearly have the perception that he is a very deep thinker, who truly cares for his research and the truth in it. Aside from a very nice person. I know I am mixing things here, so just wanted to stress that the second part of his seminar was much more insightful.

–About QFT and all we missed to learn because of the efforts being focused on string theory: You are saying in one of your responses to the commenter AJ that:
" I'm not dismissing what has been learned about QFT as a byproduct of string theory, "

On which we agree. The bit about "many more things about QFT would have been learnt if the effort on strings had been dedicated to QFT" I think i disagree. Of course, we do not know and we cannot know. But, I know you appreciate the fact that the theory of strings, dealing with very symmetric systems, has a high chance of striking a discovery.

There are various examples in "stringy times' ' of QFT progress that happened 'independently' of String theory (though many of the discoverers are string people): Seiberg duality, the Seiberg-Witten solution are such examples (though not so good, as there is a stringy taste to them). Importantly, these ideas found a very nice and intuitive realisation in stringy language (brane set ups, etc). Other important advances in QFT—like the Maldacena conjecture–seem harder to come by if one is not working on strings.

All I am trying to say (a bit obvious, I believe) is that being so symmetric, String Theory suggest ideas that then might find interesting applications in QFT in general. It 'geometrizes' the Physics problems. I believe we will agree on this virtue of the theory of Strings.
About the String Theory being a description of physical Nature, I am saying nothing here. Just about its ability to struck on interesting aspects of QFT in general.

thanks for the posting and the links

October 13, 2016

adrian,
The problem is that I don't think there's anything meaningful one can say about the intertwined relationship of string theory and QFT research in a sentence or two, and attempts to do so lead to stupid ideological posturing, not insight. The problem starts with the fact that "string theory" is not a specific thing (in particular, you say it is "very symmetric", but we don't know what the symmetries of non-perturbative string theory might be), but a name attached to a huge area of research into some very disparate things. There are lots of interesting specific things one could discuss, but just arguing "string theory" this or "string theory" that doesn't capture anything non-trivial. My comments about this were about two very specific advances in QFT made by Witten in 1988 where the situation is rather simple: they had little to nothing to do with string theory (under any sensible definition of the term).

I've never met Sen, and everyone I know who has tells me he's a very nice person and a serious scientist and I'm sure they're right. Of course I don't think his plan was to write a talk full of misleading hype and pseudo-science, and the talk he gave wasn't much different than a hundred other similar ones delivered over the last 30 years, many of which he's probably sat through himself and thought they were all right. That he is likely not aware of them does not change the problems with the talk.

20. **paddy**
October 15, 2016

Hi L(N)MMI,
I read that 30 years old article by Ginsparg/Glashow article many years ago (and god don't I feel old). Not sure when I read it though I suspect via a PW link at least a decade ago. But thanks to you and PW I have reread it. 'Tis somewhat prophetic, eh? (Glashow was my favorite professor during my brief foray into HEP-th 40 years ago.)

21. **Low Math, Meekly Interacting**
October 15, 2016

Somehow I missed that one. Prophetic indeed. Like Cassandra, unfortunately.

22. **Ravi Sinha**
October 16, 2016

In nearly a decade of my occasional visits to "Not Even Wrong" I feel, for the first time, sufficiently provoked to key in a comment. Ashoke's talk at YITP 50 is a model of clarity and comprehensiveness, especially for a public lecture. Even those who are dismissive of String Theory will have to grant that. Anyone who knows Ashoke even faintly knows that he cannot be associated with the word "hype" in any sense of the term. He, as someone commented above, is undoubtedly a deep thinker. But beyond that he is an unassuming and self-effacing person of a truly rare kind. Only other physicist with similar qualities who comes to my mind is perhaps Jeffrey Goldstone – my teacher at MIT nearly four decades ago.
Ashoke believes that potentially deep theories must be explored thoroughly to see what they have to say about the world. It is a fortunate thing that he has decided to deploy his remarkable talents to this end, as must also be said about Witten. Everyone knows that the twin goals of String Theory – understanding the success of the Standard Model and arriving convincingly at Quantum Gravity – have not been realized so far. I am sure leaders of the field including Ashoke are more aware of this situation than anyone else. One may remember Witten's assessment of the difficulties when he remarked nearly three decades ago about the fortuitousness of 21st century physics and 22nd century mathematics falling into the lap of 20th century.
There may be many string theory enthusiasts who may be prone to hype. But names like Ashoke Sen and Edward Witten should not be dragged into the mud.

23. **Peter Woit**
October 16, 2016

Ravi Sinha,
I don't agree at all that the lecture was "a model of clarity and comprehensiveness" (for one thing, comprehensiveness would require explaining the problems with the ideas one is promoting). Why do you engage in hype as an argument that someone else isn't?

You seem to think that criticizing the content of an academic lecture is a personal attack on someone, "dragging their name through the mud". I think that my characterization of this talk is accurate, and that it has nothing at all to do with Sen's personal qualities, which are quite possibly highly admirable. I also don't know why you bring Witten into this since he wasn't mentioned. I have written critically about things Witten has said in quite a few places, but from everything I've written it should be clear this is not inconsistent with great admiration for him personally and intellectually. That I'm "dragging his name through the mud" is a ridiculous accusation

Smart, nice, unassuming people can be wrong about things, and, at times, this needs to be pointed out. That's all I'm doing here.

24. **Jeff M**
October 16, 2016

I was looking at Sen's slides. Two things. He seems to describe compactification as the shrinking of 6 dimensions. Is that actually what physicists mean by compactification? It's not correct mathematically, mathematically compactification has nothing to do with the diameter, it's just whether every open cover has a finite sub cover. Am I misreading the slides? Is he saying that we shrink the dimensions by turning them into circles? But the circles could still be big, even though they're compact. Second thing, he makes a big deal of ADS/CFT, and how this shows that string theory is obviously going to give us a correct quantum theory of gravity. Except ADS/CFT lives in a universe where the sign of the cosmological constant is opposite to the sign in the universe we actually live in. So how is it relevant?

25. **Peter Woit**
October 16, 2016

Jeff M.,
Physicists don't use "compactification" in quite the same way as mathematicians. They use this just to mean you are looking at a theory on a pseudo-Riemannian background manifold that is Minkowski space or some cosmological background times some Riemannian manifold M. M is generally assumed to have dimensions very small with respect to observed distance scales (to explain why we don't see evidence of it). It may be smooth and compact, but also could be singular and non-compact. Typical models also add lots of other structures to M (e.g. choices of cohomology classes).

AdS/CFT solves none of the problems of string theory unification, so no point to discuss it here.

Please, keep in mind this is not a general discussion board, I don't want to moderate such a thing.

26. **GoletaBeach**
October 16, 2016

Looked up Mencken for some solace/wisdom about democracy to sooth myself from the current national election… bumped into curious Mencken viewpoints about science, about how he trusted empiricism but was harshly skeptical of even minimal mathematical intrusion… somewhat applicable to the everlasting string theory back-and-forth…. Mencken was caustically cynical about atoms, quantum mechanics, and relativity…

https://en.wikipedia.org/wiki/H._L._Mencken#Science

I am kind of "Anglican" on the string theory of the moment… that is, I think current practitioners do respect empiricism, eventually, and are conveniently hopeful that LHC etc might find something soon in their favor.

Old topic… I see your point Peter about KC Cole.

27. **Jeff M**
October 16, 2016

Peter,

Sorry, didn't intend to open a can of worms with ADS/CFT. It just really confuses me, why anyone cares about it. And thanks for clarifying about compact.

28. **Tim Nguyen**
October 16, 2016

Peter,

As someone not knowledgeable enough to have an opinion of what is/isn't a fair characterization of Sen's lecture, perhaps a suggestion for future criticisms of such lectures would be some sort of time chart of the lecture paired with corresponding specific rebuttals to make more tangible what exactly you find disagreeable. I imagine the specific objections to string theory have not changed much over the years and so have been thoroughly discussed in the annals of this blog. Which means that you could probably just link the time frames to old threads. It would take a bit of work, but if you're already watching the video, I think the extra amount of time would be worth the amount it would strengthen your objections. Just my two cents.

(As someone who's written a paper/made a video critical of the way physicists do perturbative QFT, I myself made a very precise criticism of Peskin-Schroeder by highlighting specific passages and explaining what goes awry. Thus far, I've had no one object to this analysis and I do not anticipate anyone being capable of doing so. This is quite different than the vague "physicists aren't rigorous" throwing in of the towel by nearly all mathematicians, which has never deterred physicists from doing what they do and has not increased mathematician's understanding of QFT.)

29. **Tim Nguyen**
October 16, 2016

I might as well illustrate precisely what I meant by a specific criticism of Peskin-Schroeder, here is a link to the video at the precise moment (the 1:11 mark):

https://youtu.be/QTjmLBzAdAA?t=1m11s

Of course, you don't need to be as technologically fancy as I was, but a link to the video to be analyzed, lists of specific time frames, and your rebuttals would get the job done.

30. **Peter Woit**
October 16, 2016

Tim Nguyen,
Sorry, but I'm not going to spend time doing that kind of thing. I spent a couple years writing a book addressing these issues in detail and explaining what the problems were with the conventional string theory hype. Sen is just repeating pretty much the same hype the book was aimed at. If he had a new argument, maybe I'd discuss that, but he doesn't. No sensible person wants to read yet another explanation from me of why string theory unification has failed and why the string landscape multiverse is pseudo-science.

I should point out that references to the problem of continuing string theory hype like the ones in this blog posting are not really aimed at explaining the problem to non-experts, for that there's the book. Knowing how these things go and from the little I could see and hear of the audience in this video, I'd suspect that physicists who had heard all this many times before made up most of the audience. In some sense what I write here is aimed at them: why do you put up with this? It's done a huge amount of damage to your field and its credibility, why schedule talks like this, then sit there politely and listen to them?

31. **Tim Nguyen**
October 16, 2016

Peter,

Of course, you know how best to spend your time rather than me. It just seems that there is enough energy spent going back in the forth in the comments that a pre-emptive investment along the lines I suggested might be worth considering. It was just a thought.

"It's done a huge amount of damage to your field and its credibility"

Well, "my field" is mathematics and I'm actually under the impression that mathematicians are at worst agnostic about string theory, but at best, they are willing to hire them since string theory has inspired a lot of rich mathematics. I'm unusual in that I'm motivated in trying to understand QFT. I haven't gotten into string theory because my time and energy are finite and so I've chosen to focus on something more grounded (in fact, it's already risky/suicidal enough to pursue QFT as a mathematician, so I don't need to further up the stakes with string theory).

I can sympathize with you to one extent which is that I do feel that there is a great deal of work done on mathematical "QFT" that may as well be classified as "damaging", e.g. works in which the mathematical formalism itself supplants the substance of the subject (e.g. imagine if in learning "general relativity" one became preoccupied with tensors and how one could make them more complicated, adding more indices, making things noncommutative, invoking higher categories only for the sake for their mathematical consistency, but then left out the underlying geometry and gravity itself; the consequence is research that is much ado about nothing insofar as

GR is concerned and I do find talks along these lines hard to "sit politely" and listen). One of the reasons I invested time in my videos was to provide a no-nonsense account of the mathematical accounts of QFT, one which gets straight to the point and avoids all the "damaging" detours I went through before finding my way.

As this was a completely avante garde thing to do and only undertaken recently, I don't know how much of an influence/difference this will make. But it seems to me, as with all social/political changes, the voice of reason needs constant rekindling and repetition. I myself read your book some time ago, it was a good read, but I can't remember the exact arguments or details any longer. Just as no two protests over the latest outrage over police violence/etc. are the same, I imagine no two "damaging string theory lectures" will be completely identical or redundant either. But if your goal is to get people to see your point of view (I imagine you desire this to some extent), perhaps creative forms of reinforcing what you've already claimed, along the lines I've suggested, might work. This is of course up to you, but it's a suggestion that at least is backed up by what I'm trying to do in my own terms.

In any case, I suspect this thread shouldn't degenerate into suggestions on how your blog should be run, unless of course, you are open to polling readers on this idea 🙂

32. **Ming**
October 17, 2016

I attended Sen's lecture in Stony Brook, and while I mostly agree with you on the assessment of String Theory, I think I should share some observations I have regarding Sen's lecture. I was quite surprised at the turnout, since it wasn't really widely promoted (e.g. the poster for the event was only distributed a few days before the event). There were at least 300 people in the audience, including people from on and off campus. I think even the university president was there. What also surprised me was the almost-rock-star status of Sen in the eyes of some participants. Most of the audience seemed in awe of him, never mind that most probably didn't understand what he's talking about (made worse by his heavy Indian accent), almost nobody left in the middle of the lecture, and at the end I even saw people asking Sen for autographs! As a physicist myself I have to say I'm pretty impressed but also baffled. Granted Sen is a rather famous theoretical physicist in his field, but even some physicists may not know him outside his field. I guess we have Yuri Milner and his glitzy Breakthrough Prizes to thank for elevating Sen to physics superstardom in the eyes of the public…

33. **Peter Woit**
October 17, 2016

Ming,
Thanks for the report. From the video one couldn't tell what the size of the audience was. It is remarkable that one can get that large a crowd to come hear a not so well known string theorist give a promotional talk indistinguishable from many others given over the past 30 years.

34. **Boundary graviton**
October 21, 2016

It's amusing for you to say that a very highly cited Dirac medalist physicist to be not so well known. When non physicists writing nay saying books on physics can be popular, it may be better to remain not well known. But nevertheless… It's amusing to see your comment

35. **Peter Woit**
October 21, 2016

Boundary graviton,
The "not so well known" referred to "not so well known" to the public, which was the audience for this talk. I think it's quite accurate to say that Sen is not well known to the public, certainly in the US. The same is true of the Dirac medal.

Actually, I think the same is even true for physicists in general, leaving aside theorists, who would generally know about him.

36. **Boundary graviton**
October 21, 2016

Right. I get the sense which you told it now. Stony Brook is where he did his PhD. That might have contributed.

37. **Boundary graviton**
October 21, 2016

*in which

By the way, when Maldacena visited India, lectures were filled to full capacity. Same was the case with Witten but Witten is much more known to the public perhaps.

Math Items

October 17, 2016
Categories: Langlands, Uncategorized

A few mathematics items:

- David Ben-Zvi's overview talk about *Representation Theory as Gauge Theory* given last month at the Clay conference in Oxford that I attended is now available online, as slides and video. Other talks from the conference are here.
- My fantasy that I might try and understand arithmetic algebraic geometry by reading Tate's collected papers keeps getting delayed as the AMS puts off publication (now scheduled for January 18 of next year). While the books are not available, at least Milne's review is.
- A couple weeks ago there was a Beyond Endoscopy conference at the IAS, at the same time I gather functioning as an 80th birthday celebration for Langlands. There's a write-up by Langlands of his talk here. I think it can be described as the current Langlands take on "Geometric Langlands".
- No recent news I'm aware of concerning Mochizuki and the the abc conjecture, but Inference magazine has just published a long article by Ivan Fesenko giving his take on "Inter-universal Teichmuller Theory".
- The Breakthrough Prize symposium this year is scheduled for December 5 at UCSF, so I guess that means the prizes will likely be announced and awards ceremony held December 4, if things go like in recent years. I have no idea who will get the $3 million math prize since it's a relatively new prize and there is a whole world of accomplished mathematicians who would make good candidates. One can be pretty sure though who won't get it, arguably the most accomplished young mathematician around, Peter Scholze (since he turned down the junior version last year).

  I have a modest proposal for whoever is awarded the prize: if you're financially pretty well set already, how about doing the math community a huge favor? Donate the money to your university to endow a faculty position, then use the influence and moral high ground this will buy you to try and convince the Breakthrough Prize people to make this a policy. In the future, the winner gets a $3 million check made out to their institution to endow a position in their name. Then they could even try again with Scholze and perhaps get him to accept.

  At the same time, there will also be a $3 million physics award. For a while these things were going pretty uniformly to string theorists, then they turned around and started giving them to experimentalists. I have no idea what they'll do this year.

Comments

1. **David Derbes**
   October 17, 2016

   Breakthrough Prize in Physics to the LIGO guys? Kip S. Thorne, Rainer Weiss and Ronald Drever? I thought they were a lock for the Nobel. Then again, Higgs and Englert had to wait a year after the CERN announcement.

2. **Peter Woit**
   October 17, 2016

   David,
   They already gave those three (and the rest of LIGO) a Special Breakthrough Prize earlier this year.

   https://breakthroughprize.org/News/32

3. **Michael Weiss**
   October 17, 2016

   "Like many budding number theorists," writes Milne, "Tate's favourite theorem when young was Gauss's law of quadratic reciprocity."

   John Tate shared with our undergraduate number theory class in the spring of 1977 (then designated Math 101) that as a teen he came across Quadratic Reciprocity and immediately closed the book to attempt a proof himself. For several months, Prof. Tate recalled, he persevered but without success.

   Prof. Tate wistfully noted to the class that by contrast the young Gauss had developed four different proofs. He then passed around Disquisitiones Arithmeticae in Latin. John never spoke to us of his own enormous contributions to generalized reciprocity laws.

4. **Tom DeLillo**
   October 18, 2016

   Good idea, Peter, to endow new positions. Let's keep this suggestion alive! We've got money coming in at my state university to support a chair in honor of a deceased colleague. However, we would need permission to hire into an existing tenure line and there's a hiring freeze due to state budget problems. There seems to be money around for other things. (I discreetly avoid giving the name of my institution, but you could probably track me down.)

5. **random reader**
   October 18, 2016

   Peter, you may be interested in the recent arxiv posting by Kevin Costello, with what I think is the first mathematically rigorous construction of a particular type of (perturbative) M-theory. http://arxiv.org/abs/1610.04144

6. **Richard**
   October 18, 2016

   I would not be surprised if Maryna Viazovska — whose pioneering work* on sphere-packing in dimensions 8 and 24 (The latter being a collaborative effort.) has caused something of a sensation — is the recipient of the $3-million Breakthrough Prize.
   Her status as a potential future Fields Medalist ought also not to go unremarked-upon….

   * Of which I understand only the occasional punctuation mark.

7. **Coxeter Todd**
   October 18, 2016

I would guess Yitang Zhang for his work on bounded gaps between primes.

8. **anon**
October 18, 2016

I'm not sure if some people, Scholze for example, would like to endow a professorship in 'their name'.

9. **Peter Woit**
October 18, 2016

anon,
Yes, a better idea would be for the winner to choose the name of the chair, perhaps with a default suggestion that the name would become that of the winner at their retirement. It would also be fine to just name these things "Breakthrough Prize" or "Milner-Zuckerberg" chairs. The suggestion of using the winner's name is just that the main idea behind these prizes is to get more public recognition of the prize winners.

10. **Richard**
October 18, 2016

P.S. Thanks much for the link to the article by Ivan the Arithmetical. (I can hardly wait for the English translation.*)

* A remark that should * not * be taken as a dig at Fesenko: rather, it is my way of expressing my own bewilderment in the face of ideas whose depth, subtlety, and complexity will likely render them impregnable to any and all efforts on my part to understand them!

11. **Tom Andersen**
October 18, 2016

Peter,

I am not sure that doing anything more than making the endowment an option would work. Not all universities are run by honest people. The winner may choose to do something better with the money, like a school or charity in another country.

12. **Anon**
October 18, 2016

I don't know if this is off-topic. I wonder what the intended audience of Inference magazine is. As someone who is moderately educated in math, I find the article by Ivan Fesenko very hard to follow when he starts talking about class field theory. Likewise, another article in the same issue about linguistics is almost incomprehensible to me as a lay person to the field. I suppose the magazine is not for a "broad audience"?

13. **jsm**
October 19, 2016

Michael Weiss: Your story of Tate and quadratic reciprocity reminds me of another. Tate learned about the K2 of fields from Hyman Bass when both were in Paris in Fall 1968. Bass asked Tate if he could compute K2(Q). According to legend, Tate was working on the question in the presence of Bass late one night when what he was doing reminded him of something in one of Gauss's proofs of quadratic reciprocity. The two went out and found a copy of Gauss's Disquisitiones in a second-hand book store, and sure enough Tate was able to find in Gauss's work what he needed to complete the calculation.

14. **Jim Given**
October 19, 2016

I am an educated non-specialist in number theory (a physicist). Fesenko's paper claims that IUT "settles the abc-conjecture". Is Fesenko claiming that in fact Mochizuki has a proof of abc? Or is he just serving as a reporter and repeating Mochizuki's claim? I believe that the consensus at present is that one should not claim that Mochizuki has a proof. Is that wrong?

15. **G. S.**
October 19, 2016

I like the idea of the endowed chair, but I think arguments would erupt over where that endowed chair should be. Would the endowed chair be at the university where the recipient of the award currently resides, or at the university where the recipient did the bulk of his/her award-winning work?

I'm not sure how things tend to go in math, but in physics those are often not the same.

16. **Peter Woit**
October 19, 2016

Jim Given,
The current consensus among experts is that Mochizuki has not yet produced an acceptable proof, since no one seems to be able to explain his proof to others in a convincing way (Fesenko's article for example does not do this). Many experts tell me they think it is plausible that Mochizuki does have a proof, but the way he has written it up means experts cannot follow it or check it. Things seem to be at a standstill, with progress possible only if Mochizuki writes a less problematic version of the proof that others can follow, or someone else manages to see their way through what he has written and explain it to others.

17. **Peter Woit**
October 19, 2016

G.S.,
I think questions about the details of the chair could be left up to the winner. The important point would be that the funds in the long term support mathematics research by endowing support for a permanent position for a mathematics researcher, rather than ending up as personal assets of the winner.

This would most affect winners with financial problems who need the money. But winning the prize would automatically increase their value in the job market and likely the salary they could command. If the terms of the endowed position are up to them, this would also put them in a very strong negotiating position with whatever institution they work for, or any interested in hiring them (they could bring the endowment with them).

18. **ronab**
October 20, 2016

So would it be ok for them to occupy their own endowed chair?

19. **Peter Woit**
October 20, 2016

ronab,
Sure, that might even be the default arrangement.

20. **PedroJVM**
October 21, 2016

Don't quit yet on arithmetic algebraic geometric. My minimal suggestion is: start (and keep on with) with Silverman+Tate's "Rational Points on Elliptic Curves", and whenever you feel bored switch to Hindry+Silverman's "Diophantine Geometry: An Introduction". (Checkout Silverman's W^3 pages on both books.) There are many other options but my suggestion was minimal.

21. **Chris Austin**
October 21, 2016

Peter, if the Breakthrough Prize Foundation informed you that in recognition of some outstanding results you had achieved, they wanted to award a large prize *to someone else* in your honor, wouldn't you feel that a nasty joke was being played on you?

22. **Peter Woit**
October 21, 2016

Chris Austin,
Exactly my point is that such a prize should not go to a person, but to an institution for support of mathematical research. At this point, at least in the US, I think the best way to do that would be to endow permanent positions at research universities. If the Breakthrough Prize people want to endow such a position somewhere in my name, that would be great. I'd even consider dressing up in a monkey suit and attending their ceremony (by the way, I'm free Dec. 4 and was even thinking about a trip to the Bay Area around then, so they just have to let me know where and when to show up).

Better though would be if they endow the position here at Columbia, because then the administration and my colleagues would treat me even better than they do now. I might finally get a new carpet and paint job for my office…

23. **Peter Woit**
October 22, 2016

PedroJVM,
Thanks! That looks like excellent advice.

A New 30 GeV Particle?

October 21, 2016
Categories: Experimental HEP News

Last night a preprint appeared on the arXiv, with a re-analysis of old 1992-5 LEP data, looking at the dimuon spectrum for b-tagged (identified as involving a b-quark) events. An excess around 30 GeV was found, which would indicate a possible new particle around that energy. The author quotes various significance numbers for the bump, with look-elsewhere effect included, of 2.4 to 2.9 sigma.

Thinking a bit about the look-elsewhere effect here, something very funny is going on. To properly compute the look-elsewhere effect, one really should know how many other channels the author looked at and found nothing, but there's no mention of looking at other channels. Why did this particular physicist decide to go and reanalyze LEP data, looking only at the b-tagged dimuon spectrum (and it seems he's doing this by himself)? It's hard to understand why anyone would do this, unless perhaps they had heard that one of the LHC experiments might be seeing something in the b-tagged dimuon spectrum, say, around 30 GeV.

We'll likely find out more about this story soon. If the LHC experiments haven't been looking closely at this particular channel, they will do so now. 30 GeV is low enough that I don't see why you would need the Run 2 13 TeV data, this should be in the older Run 1 data.

I should make the obvious remark though: this is an extraordinary claim, and the evidence for a new particle is very far from the extraordinary level. So, at a high confidence level, the probability is that there's nothing there.

For much more about this, Tommaso Dorigo and Matt Strassler have just put out blog postings.

Update: Tommaso has an update with more about this: the author was not a member of ALEPH and that collboration does not support this but thinks this is bogus. It appears that the signal is spurious, with the muons coming from semileptonic b decays, not a new particle. Still a mystery: why was this physicist looking at this old data for one very specific signal?

Update: The talk today by Nate Odell of CMS at the LPC Physics Forum at Fermilab is not public, but the title is: "Dimuon 29 GeV analysis". Any guess whether that has something to do with this story about 30 GeV dimuons?

Comments

1. **tommaso dorigo**
   October 21, 2016

   Hello Peter,

   nice post. I am thinking that even CDF and DZERO (leave alone DELPHI and OPAL) could look for something similar in their own oldie but goldie data. In fact, this whole business of looking for signals of anomalous particles in LEP data reminds me of the sbottom quark search of CDF, which returned an excess of multi-lepton dijet events, and the summer 2000 crisis. The signature of dijet events with leptons was sought by ALEPH, who initially found a 3-sigma signal, and then by the other LEP experiments, that found nothing. Will history repeat itself ?

   On a second though I should not derate the wannabe signal, and rather put out a bet on this one signal too – it looks like a nice way to earn my daily bread.

   Best,
   T.

2. **Balazs Vagvolgyi**
   October 21, 2016

   I don't get it. Why did scientists come up with 5-sigma, if they ignore it all the time.
   Why even bother publishing anything under 5-sigma, when it's not up to the standards of modern physics?

   Some say 3-sigma still means that there is a 99.7% chance that it's not a fluke, but I disagree. Look elsewhere should be applied not only within individual experiments but in the set of all the experiments being performed:
   Let's say physicists in the world perform 1000 experiments a day. If all their data is just random noise, then there will still be 3 experiments every day that has a 3-sigma signal.
   To me, that just means that 3-sigma results are worthless.

3. **Peter Woit**
   October 21, 2016

   Balazs Vagvolgyi,

   As I wrote in the posting, something funny is going on here and I think it's very likely there's more to this than meets the eye. I doubt the author of this preprint randomly picked this analysis of old data to do, finding and publishing a 3 sigma effect. A possible explanation is that ATLAS or CMS has an unreleased analysis of b-tagged dimuons with a bump around 30 GeV, with a large enough significance to get people excited (e.g. 4 sigma or more). Put such an ATLAS or CMS result together with this new one and by some measure you have 5 sigma (and, a lot of ATLAS or CMS people pretty annoyed at this guy…).

4. **anon**
   October 21, 2016

   The author seems to be, or at least has been, a member of LHCb collaboration (at least his name is one of the 700 or so on their author lists). But going rogue would seem like sure way to leave the collaboration…

5. **Peter Woit**
   October 21, 2016

   anon,
   Yes, I think we can be sure that inspiration didn't come from unreleased LHCb results. It looks like this guy used to be in CMS, for what that's worth.

6. **hronir**
October 21, 2016

What’s the timescale (knowing how things go in collaborations common practice) for any (official) statement from ATLAS/CMS about it? I mean, roughly in… days? weeks? more?

7. **Peter Woit**
October 21, 2016

hronir,
If ATLAS/CMS haven’t already done this analysis, I’d guess it would take them a couple months to get it done and internally vet the results. If they already have something they’re working on, depends how far along that is. These people really don’t like to release results until they’re very sure about them.

This year’s pp run is ending right around now. Results from the full dataset for this year’s results I’d assume will start to appear early next year, at the usual winter HEP conferences.

8. **anonymous**
October 21, 2016

Perhaps you want to take it in a slightly different way. As this guy released something like this, ATLAS or CMS might have some “pressure” to move ahead. This might be good for the guys working on the unreleased analysis. It will be interesting. As a side remark, why can’t he study the “bump” around 24-25 GeV, too. Following similar analysis to extract significance, he might have some sigmas in that region as around 30 GeV. Instead of one, he could have two or more.

9. **Dale C.**
October 22, 2016

So I guess shortly we are going to see a lot of preprints describing a theoretical model containing a 30 GeV weakly interacting “dark sector” particle, as in the 750 GeV diphoton excess case.

10. **katzeee**
October 22, 2016

I would not leave out the possibility of some kind of hoax: After the 750-GeV-Experience, some experimentalists decide to get people excited by reexamining old data and finding sth. around 3 sigma. Most of the known hep-bloggers get excited too (or at least spread the news) and speculate if there is sth. in the LHC-data to be seen. Things get on and theorists try to explain these mysterious bump by dozens of models in various preprints… Then the experimatalists share a good laugh.

11. **Harry Dale Huffman**
October 22, 2016

An (over-)ambitious overachiever, trying to break out? As “katzee” noted just above, “after the 750Gev experience”, hope springs eternal in some. ‘Twas ever thus. (The term used in criminal investigations comes to mind: A copycat crime. Or that well-known phenomenon, of strange occurrences happening in bunches.)

12. **Dale C.**
October 22, 2016

According to Tommaso, the signal is clearly spurious, as the muons are collinear with the b-jets emitted in the Z decay. Waiting for the next fluke…

13. **Low Math, Meekly Interacting**
October 22, 2016

I’ve tended to favor “Hanlon’s Razor” in most circumstances, but too often lately I’m finding out instead I’ve been terribly naive. Could katzeee be right?

14. **Verissimo**
October 22, 2016

Poor Jester got so fried from the 750GeV hype that he has no take on this

15. **Peter Woit**
October 22, 2016

Verissimo,
He may just be showing his good judgment by ignoring it…

16. **Nick M.**
October 23, 2016

@Peter,

Ignoring it indeed! I submitted a comment, on Jester’s blog, asking if anyone there had any thoughts on this possible 30 GeV particle. He didn’t even bother to post it….
😉 I guess he’s done getting excited over these 3-sigma, gaussian looking, bumps that have the word “fluke” written all over them!

17. **NotPhycsist**
October 24, 2016

>”Some say 3-sigma still means that there is a 99.7% chance that it’s not a fluke”

I saw a lot of this surrounding the LIGO results. No, this is wrong in the most insidious way. The error you are making is called the “fallacy of the transposed conditional”: http://rationalwiki.org/wiki/Confusion_of_the_inverse

In short, the probably of observing something assuming the model is correct does not equal the probability the model is correct given the observations. The sigma value refers to the former, you want it to refer to the latter but it does not. In this case, “the model” refers to whatever background only, no signal, “chance” model is being tested.

18. **Balazs Vagvolgyi**

October 24, 2016

@ NotPhycsist

> The error you are making is called the “fallacy of the transposed conditional”

I don’t agree with it, that’s why I wrote “Some say”.
Thanks to you, now I know the name of this fallacy.

19. **NotPhycsist**
October 24, 2016

@ Balazs Vagvolgyi

Thanks for clarifying. It is just an additional problem on top of what you and Peter identify as the “look elsewhere effect”. Btw, I think that problem can be better understood as using an incorrect model for the background. The correct model would automatically account for the actual researcher behavior.

I know it is common practice across many fields to do post-hoc “adjustments” for multiple comparisons, but to me that is a misleading way to conceptualize the problem. The “adjustments” should be baked into the null model to begin with, so that it is as correct as possible.

Another way of putting it is that the “bump” is real. The model being tested is known to be wrong though, it apparently assumes the researcher only looked at 10 sets of data, or whatever, that is less than reality. Rejecting this null model would be the right thing for the statistical machinery to do, but is rather pointless scientifically.

20. **RandomPaddy**
October 27, 2016

I don’t think all these swirling rumors do much for the credibility of particle physics.

A lot of this could be completely avoided by just putting the data up on a publicly accessible server. It’s 2016 and these experiments involve more people than the average aircraft carrier. Just release the data and stop all these bump in the data murder mysteries .

21. **JD**
October 28, 2016

RandomPaddy

Go to Tommaso Dorigo’s blog to clarify your thinking. I agree with him that the data should be out there for general use, and apparantly it is. But that will not solve the problem, obviously. The problem lies in the culture of todays science.

22. **Peter Woit**
October 28, 2016

JD,

You’re right that this has nothing to do with public availability of data (except to show problems that can occur when doing this). I don’t think though it has to do with the culture of today’s science, rather, this is a quite unusual situation, where a single physicist, for reasons that it seems he’s not revealing and that would be interesting to know, has decided to go back and look for something very specific in old data from another experiment.

23. **Shantanu**
October 29, 2016

Peter and others ,
I slightly disagree with this. I think HEP experiments should make their data public
and individual folks should be encouraged to analyze this data, not just the collaborations. In fact in astronomy it is mandatary to make all data public and many people outside the collaboration have analyzed the data and written good papers.
But for some reason this is not the norm in HEP. So its heartening to see individual
folks analyzing experimental HEP data.

24. **Peter Woit**
November 3, 2016

I’ve added an update noting the title of a talk today (Nov. 3) by someone from CMS…

Final Draft Version

October 24, 2016
Categories: Quantum Theory: The Book

I finally have finished a draft version of the book that I've been working on for the past four years or so. This version will remain freely available on my website here. The plan is to get professional illustrations done and have the book published by Springer, presumably appearing in print sometime next year. By now it's too late for any significant changes, but comments, especially corrections and typos, are welcome.

At this point I'm very happy with how the book has turned out, since I think it provides a valuable point of view on the relation between quantum mechanics and mathematics, and contains significant amounts of material not well-explained elsewhere. I'm simultaneously rather unhappy with it, very much aware of a long list of ways in which it could be improved. Any of these though would require putting more time into the project, and right now I'm thoroughly sick of it, desperately wanting to think about other things. So, this is pretty much it.

I've learned a huge amount by writing this, and I hope to apply some of this in work on several different new projects. As I work on these, perhaps I'll do some more writing that would partially take the form of new chapters extending what's in the book. We'll see…

Comments

1. **Anonymous Pedant**
   October 25, 2016

   "on the the behavior" page 141

2. **mikemm**
   October 25, 2016

   congratulations! I've been quietly following this as you've worked on it over the last few years and am delighted it's now 'complete enough' and you can focus on other things. Also, thanks for making it available before it's hidden behind a paywall. I'm looking forward to having the time to get into it..

3. **Shantanu**
   October 25, 2016

   Peter, congrats for finishing the book

4. **Jim Holt**
   October 25, 2016

   Let me add my own congratulations–and also hearty thanks, since I've learned so much from working through the early chapters of your draft. You've managed to convey the mathematical structure of quantum mechanics in a way that's refreshingly elegant and clear.

5. **another anonymous pedant**
   October 25, 2016

   page 547, "include a a connection"

6. **Harry Dale Huffman**
   October 25, 2016

   I downloaded the file and skimmed through sections of it, and seen that it is very much mathematics, while I am very much into physics now. The only thing that jumps out at me is the so-far hand-drawn illustrations and your stated desire to "get professional illustrations done"; having authored my own book, with well over 200 color illustrations I designed and made myself, I would say the illustrations in your book are not hard to do yourself, using only the "Paint" program in Windows for example, and you could take real pride in doing so, and also have no one else to blame if you are unhappy with the "professional" versions (choose your own fonts and line thicknesses, for example, and extend axes to your liking). (Most of my illustrations came from the interactive graphical software I developed myself, about 18 years ago, to do my unprecedented research — into what turned out to be the single objective origin of all of the world's "ancient mysteries" — and so were churned out "ready-made"–with that software cookie cutter, as it were–but a fair number were done from scratch, or just finished, using Windows Paint, as yours could be.) I am my own "professional", or craftsman, in every aspect of my book, and the result is complete satisfaction.

7. **Lino D'Ischia**
   October 25, 2016

   Peter: What an accomplishment! Congratulations. And give that mind of yours a little time off!

8. **Eric Weinstein**
   October 25, 2016

   While I haven't read the whole book, I've read parts of earlier drafts quite closely. I've been amazed at how much there is to recommend this contribution. In many texts one reads the same lines (almost verbatim) that one has read in earlier works. This means that if the original phraseology confused you, you have the illusion that you can't learn the material because the same phraseology occurs repeatedly and seemingly independently.

   As a famous example of this kind of phenomena, many years ago Atiyah and Singer had to explain what an anomaly was mathematically to those of us geometry minded folks who had swallowed the mystical physicists description "An anomaly is what prevents a classical symmetry from surviving quantization." Many physicists claimed this work of A&S was "nothing new", but it showed me in an instant how important a change in pedagogy can be to those of us who cannot understand the standard descriptions.

   This book excels at this most important task in my opinion. People may claim that it breaks no new ground, but this will be incorrect. It is a pedagogical innovation to be able to explain things from a new viewpoint so that those who were mystified by the original descriptions can find a new path to understanding. This book has repaid close reading every time I have invested in resolving a long-standing confusion.

   Well done.

9. **Peter Woit**
October 25, 2016

Thanks to all for the kind words. Especially to Eric, since he's praising what I would like to think is the best feature of the book, not different results, but a somewhat different viewpoint than the usual one. While teaching the course, I did try and rethink for myself the subject from the ground up rather than following closely other texts.

Anonymous pedants,
Thanks!!

10. **amz review**
October 25, 2016

Technical comment about harmonic oscillator: "If we start off with a state |0> that is a non-zero eigenvector of N with eigenvalue 0, we see that the eigenvalues of N will be the non-negative integers, etc"

Actually one must argue that this MUST be the case (see Dirac book): if we start off with an eigenstate |c> with fractional eigenvalue c, then by repeated applications of the annihilation operator a we obtain a sequence of eigenstates of N with eigenvalues c-1, c-2, … which will eventually take negative values. This is impossible (as proved earlier in the text), hence the sequence MUST terminate with a state "x" such that a|x> = 0. It follows that the eigenvalue of N is zero for this state, and we may label the state |0>. Then by repeated applications of the creation operator, we derive that the eigenvalues of N are the non-negative integers.

11. **Another anonymous pedant**
October 25, 2016

Page 15 "…2 by two matrices…"

12. **Peter Woit**
October 25, 2016

amz review,
An earlier version had that argument, but I decided it best to leave it out. The problem is that if you try and make general statements about ALL representations of the algebra of annihilation and creation operators you have to worry about various possible pathologies, whether operators are defined, etc. In general the philosophy of the book is to avoid trying to prove general theorems about what MUST happen, since getting those exactly right typically requires making explicit a complicated set of assumptions. Better to not get involved if it's not something I need for what I want to explain.

13. **John McAllison**
October 25, 2016

It looks great; I like the way it starts at an elementary level, gradually increasing in difficulty. The important thing now is to not worry too much about it being perfect, but that the number of mistakes are minimized, laying the foundations for a later second edition if successful.

It has the potential to be a classic like 'Tensor Geometry: The Geometric Viewpoint and its Uses' which all the reviews rave about it laying the foundations clearly:
https://www.amazon.com/Tensor-Geometry-Geometric-Viewpoint-Mathematics/dp/354052018X

14. **struwwel**
October 25, 2016

You write (page 100) that CP^1 is C^2 quotiented out by C^*. Actually it is C^2 minus the origin which must be quotiented out by C^* : no point in CP^1 has homogeneous coordinates (0:0).

15. **Sam Dolan**
October 25, 2016

Congratulations, and thank you for making this final draft freely available.

In the 2nd ed., perhaps Chap. 41 could also touch upon the (less well-known) isomorphism between SO+(3,1) [the standard matrix representation of the orthochronous proper Lorentz group] and SO(3,C) [the group of 3×3 complex orthogonal matrices with unit determinant]. The latter representation is convenient for (e.g.) transforming the Faraday tensor F between orthonormal frames, or transforming the Weyl tensor W.

[It goes something like this: As F is a bivector, it can be expressed as a complex 3-vector, and as the Riemann tensor R is (in some sense) the symmetric product of two bivectors, it can be expressed as a complex 3×3 matrix. The Weyl tensor W is a symmetric and trace-free 3×3 complex matrix. Under Lorentz transformations, F' = A F and W' = A W A^t, where A is the appropriate matrix in SO(3,C)].

16. **Peter Woit**
October 26, 2016

struwwel,
Thanks. Fixed.

17. **Richard**
October 26, 2016

Shouldn't the expression "Planck's constant" show up somewhere in Section 1.2.1?

18. **Peter Woit**
October 26, 2016

Richard,
A good point. I seem to have discussed this constant without ever using its name, will fix that.

19. **regex**
October 26, 2016

The topological reason for this this is that
The relation between between the quadratic

angular momentum of an object spinning about about some axis

20. **regex**
October 26, 2016

If you have a Knuth style $1 per typo policy, I'll write some more regex and find others 😉

21. **Peter Woit**
October 26, 2016

regex,
Thanks! This inspired me to run a full check for repeated words on my .tex file and found a couple more. Fixed.

No, no bounty for typos, I seem to be doing very well getting them found for free!

On the other hand, if people can find sign errors in equations, I might think about it. Current plan is to check all the equations one last time once this thing is in proofs, and I'm not looking forward to that…

22. **Narad**
October 27, 2016

If Springer doesn't have any TeX-savvy manuscript editors, I'm always looking for freelance work (just looking at chapter 1, that $\langle\cdot ,\cdot\rangle$ construction could use some touching up, and just above section 1.3.3, "i.e. " should be "i.e.,\ " [or "i.e.\ " if you insist] along with a comma after the equation). Whether they outsource, I don't know.

23. **Narad**
October 27, 2016

^ Whoops, "i.e., ". Probably not the best advertisement.

24. **Narad**
October 27, 2016

Anyway, "Choosing local coordinates on G, π will given by" (between the definition of a representation and an irreducible representation) doesn't really read right. I'm also unclear on the meaning of the subscript $|W$ introduced just below.

25. **Mateusz Wasilewski**
October 28, 2016

Near the end of page 325 it should be "One thus sees that on C^n, as in the symplectic case, up to change of basis there is only one non-degenerate **symmetric** bilinear form.".

26. **Peter Woit**
October 28, 2016

Mateusz,
Thanks! Fixed.

27. **Anonymous**
October 29, 2016

The letter font for some of the SU(, SO(and Spin(like in the title of 21.2 or the last paragraph of page 246 is different from the rest. Is that correct?

28. **Narad**
November 1, 2016

> The letter font for some of the SU(, SO(and Spin(like in the title of 21.2 or the last paragraph of page 246 is different from the rest. Is that correct?

@Anonymous: Fraktur denotes the algebra, italics the group.

The $\frac{1}{2}$ instances on page 246 "should be" \tfrac, but I'm doing my level best to STFU about such things.

29. **Narad**
November 1, 2016

But, seriously, don't do, e.g., $\dot{p_j}$. Springer's never going to catch the horizontal misplacement (even directly compared with $\dot{q_j}$). Use ${\dot{p}_j}$, etc.

30. **Johan**
November 18, 2016

Congratulations on finishing the book! Just a small comment: I was surprised not to see a mention of or reference to Jean-Marie Souriau, who was (pretty much simultaneously with Kostant) the first to introduce the general notion of momentum map as we now know it, as well as introducing geometric quantization (again, independently but essentially simultaneously with Kostant). His book "Structure des systèmes dynamiques" (published in English as "Structure of Dynamical Systems – A Symplectic View of Physics" by Birkhauser in '97) is still a worthy read.

31. **Peter Woit**
November 18, 2016

Johan,

Thanks! Souriau was one of the places I first started learning about symplectic geometry. In general my references are just a selection of expository things I happen to have looked at in recent years. I try not to get into references related to who originated ideas, since that gets very complicated very fast. The Kostant reference is an anomaly.

Various Links

October 27, 2016
Categories: Uncategorized

- The 2016 LHC proton-proton run is now over, with delivered (41.07 CMS/38.4 ATLAS) and recorded (37.82 CMS/35.5 ATLAS) luminosities (in inverse fb) far above the goal for this year of 25. Together with last year's data, the experiments now have 41.63 (CMS) and 39.4 (ATLAS) inverse fb recorded at 13 TeV, close to the LHC design energy of 14 TeV. It is likely that preliminary results will be reported at an "end-of-year jamboree" in mid-December, with more to come at the winter conferences.

  I'd guess that these new results will see improved bounds on SUSY particles, and that David Gross and Lubos Motl will have to pay off their long-standing bets that the LHC would find SUSY (Gross's bet with Ken Lane is here, it says 50 inverse fb of LHC data, sum of CMS and ATLAS now about 80). Unfortunately, I'm afraid that losing these bets won't affect their devotion to SUSY.

- Paul Steinhardt gave a colloquium at Fermilab last month with the title Simply Wrong vs. Simple. In it he explained "why the big bang inflationary picture fails as a scientific theory" (it doesn't work as promised, is not self-consistent and not falsifiable). This is a complicated topic, but Steinhardt is an expert and one of the originators of the theory, so if you want to understand the problems of some common arguments for inflation, watching this talk is highly recommended. Steinhardt's talk was part of a Fermilab workshop, Simplicity II.
- On the multiverse front, Sabine Hossenfelder's Mom has Sabine to set her straight. For professional physicists, instead of getting set straight there's the usual Templeton funding for the opposite, in this case a workshop on Fine-tuning, the Multiverse and Life.
- Paul Ginsparg discusses various issues having to do with the arXiv here and here, with an emphasis on the question of how to decide which preprints to reject (they have my sympathy on the difficulties involved). Ginsparg notes that they decided not to have comments/discussion of papers there, but to have "trackbacks" to discussions hosted elsewhere. Still no indication of why trackbacks here are banned.

- Theoretical physicist Walter Greiner passed away a couple weeks ago. He was the author of a series of textbooks, one of which in particular, Field Quantization, I found very helpful when I was trying to figure out some details for the book I was writing.

Update: I just noticed that Witten's Commemorative Lecture for the Kyoto Prize is available here. It's a very interesting account by him of his career and point of view.

Update: In case you think fine-tuning is a central question in physics, besides the Templeton-funded workshop in Sydney, you can consult the website of a Templeton-funded program, or buy this book by a Templeton-funded author. There's also a talk by Aron Wall, given to a Rutgers University apologetics club. Wall's conclusion is that either God or the Multiverse did it, and he comes down on the side of God (because of the Resurrection of Jesus business).

Update: Also on the Templeton front, they are funding a new $7.2 million Black Hole Initiative, which advertises itself by

> The BHI will be the first center worldwide to focus on the study of black holes, and as such it offers a unique naming opportunity for potential donors.

Templeton is paying for the first three years of this. To get some idea of the scale of this project, the yearly grant is roughly half the size of the NSF grant to each to the two largest US centers in pure math and in theoretical physics (MSRI and the KITP).

Comments

   October 28, 2016

   Interesting quote: "Each problem here involved applying physics ideas to a problem that traditionally would have been viewed
   as a math problem, not a physics problem. These were all problems that I would not have seriously considered
   working on until String Theory broadened our horizons concerning the relations between mathematics and physics"

   In particular because he talks about his paper on QFT and the Jones polynomial.

2. **Bee**
   October 28, 2016

   The field quantization textbook was mostly written by Joachim Reinhardt. Who, sadly, enough passed away a week before Greiner. And thanks for the link. My mom appreciates it 😉

3. **curious**
   October 28, 2016

   Together with last year's data, the experiments now have 41.63 (CMS) and 39.4 (ATLAS) inverse fb recorded at 13 TeV, close to the LHC design energy of 14 TeV. It is likely that preliminary results will be reported at an "end-of-year jamboree" in mid-December, with more to come at the winter conferences.
   ^

   if LHC sees no evidence of SUSY after recording and analyzing that many inverse fb recorded at 13 TeV, and possibly reported by dec- 2016, what are the probability LHC will ever see SUSY over its entire lifetime i.e after it collects 3000 inverse fb? with 5-sigma being discovery?

4. **Peter Woit**
   October 28, 2016

   curious,
   There's no well-defined answer to that, since there is no sensible notion of probability distribution for different susy parameters. One can say thought that by the standard "naturalness" arguments, SUSY was supposed to show up at the (masses 100-200 GeV), and definitely early on at the full energy LHC (masses around 1 TeV). That's what David Gross was willing to bet money on. I think we'll soon see gluino mass bounds above 2 TeV. Much later on the LHC may be able to get bounds up to say 3 TeV. I'm pretty sure though that Gross would turn down an offer of a "double or nothing" bet that superpartners will show up later on at the LHC.

5. **Peter Woit**
   October 28, 2016

   Anonymous,
   One thing about the Witten piece is that he is rather defensive about string theory (very explicitly in the last part), not surprising given how things have not worked out.

The comment you quote is interesting in that he credits string theory more with causing a change in point of view and change in culture that led to some of his great work. It's certainly accurate that string theory and the way Witten pursued it with a lot of mathematical firepower changed a lot how physicists looked at mathematics (I think there has however been a backlash more recently, as many physicists blame mathematics for the failures of the research program).

But, ignoring that, I think his comments about the relation of math and physics in his work (as well as the role of string theory) are really fascinating. One thing that has always struck me about him is that, even when he was revolutionizing some fields of mathematics, it always seemed that he was leery of getting too much involved with the mathematics, wanted to stay grounded in physics. My own reaction to some of his great work was quite different, as it led me to want to learn more about the mathematical context in order to better understand how mathematics and physics were interacting.

On the one hand I think he has always been aware that his strong suit is that he can do things mathematicians can't, by exploiting what physicists know. It's also true that he is driven ultimately by a deep motivation to solve certain problems in physics, which is quite different than the motivations of mathematicians. He mentions explicitly something usually not mentioned, that from the beginning of his career, a deep motivation has been that of trying to solve QCD, and because of this, trying to better understand non-perturbative QFT. In particular striking to me was his comment:
"I am not sure that there is any such thing as being an expert on how quantum systems behave for strong coupling, and in any event certainly I myself never have become such an expert. I have learned quite a bit while always feeling like a beginner."

6. **milkshaken**
   October 28, 2016

   I really enjoyed Paul Steinhardt lecture – accessible to nontechnical audience (like me) – and I admire his plain-speaking courage (given that he is one of the founders of inflationary cosmology).

7. **Miki Weiss**
   October 29, 2016

   Thanks for the reference to Aron Wall lecture. He shows the logical absurds in the Anthropical principle and the String Landscape with the shortest and most elegant reasoning.
   Why the Anthropic Principle is absurd? – see slide 38.
   Why the String Landscape is absurd? – see slide 41.
   But he still gives the Inflation Multiverse the benefit of doubt, if inflation is proven by experiment to be correct….

8. **jonW**
   October 30, 2016

   I thought Steinhardt's talk was excellent, too, and I find it a very commonsensical approach to really examine the degrees of freedom available to inflationary theories and what this means for their notability as predictions. Just for the sake of balance, though, does anyone know of a paper or lecture (pitched at a similar level) that gives as strong a rebuttal as possible to Steinhardt's criticisms? I know those criticisms aren't exactly new.

9. **Ben**
   October 31, 2016

   I think many people are aware of Steinhardt's criticisms, which mostly boil down to the fact that inflation doesn't really solve problems so much as kick them down the road a bit. Instead of flatness/horizon problems, you now have questions about initial conditions or bubble nucleation in eternal inflation, etc.

   But to the extent that developed alternatives even exist, they don't seem much better. Ekpyrotic/bounce scenarios really just shift the question to "how do you propagate density perturbations through the bounce". And since the methods used to do so have to violate something or other (usually the NEC), there's skepticism that a clever theorist will eventually figure out how to get any prediction you want out of that model, too.

   So it's not so much that people rebut Steinhardt or don't believe him, it's just that nobody knows what else to do. I will say that I think that many observational people will start eyeing inflation with a lot more skepticism if B-modes don't start showing up soon (i.e. if limits get down below 10^-3).

    October 31, 2016

    Peter,

    I know Aron Wall, and I can tell you that between God and the multiverse he does not consider God to be the better answer to fine tuning because of "the Resurrection of Jesus business." What he does believe is that given the current state of cosmology and QFT, *demonstrated* physics + God is a more robust and less ad-hoc explanation than that offered by the inflation/string theory multiverse + Materialism… a conclusion I agree with. His reasons for thinking so can be found in more detail at his blog. He mentioned the resurrection in that talk only to to point out that because he *already* has other reasons to believe in God including that one, the former is a viable option for him whether science progresses further on the matter or not. As such, he can objectively weigh both alternatives because he has no prior commitment to either outcome, whereas, materialists who wish to claim scientific authority are stuck with the latter whether they like it or not , and have little choice but to go to whatever lengths are necessary to make it work… up to, and including dispensing with the need for testable predictions in science. For more on all this, see Aron's post about that talk and the resulting comment thread, pro and con.

    For better or worse, physics has brought us to a place where we're knocking on the door of ultimate origins where the delineations between it and metaphysics are starting to blur, and it's becoming increasingly important to understand how the two relate to each other. To date many, if not most scientists have been reluctant to do so and now the chickens are coming home to roost. Thirty years ago it was commonplace to see philosophers and theologians addressing scientific topics with little or no training in the relevant fields (case in point, creationism). Today we're starting to see the reverse as well… physicists practicing metaphysics while professing themselves to be above doing so, and as such doing so unconsciously, and therefore *badly*. Aron, who is well-trained in both, is one of the more notable exceptions to that disturbing trend.

11. **Peter Woit**
    October 31, 2016

    Scott Church,
    I wasn't pretending to do justice to Aron Wall's views with that off-hand remark, thanks for giving a more detailed explanation of his views . My views on all this are tediously simple: "God did it" and "the Multiverse did it" are equally vacuous non-explanations and those who want to debate them are doing something I'm not interested in and that I don't think qualifies as science under even a generous interpretation of the term. And I think most physicists agree.

12. **Lars**
    November 1, 2016

    "God did the multiverse"

God did the multiverse
And string theory too
Cuz after the universe
He'd nothing to do

13. **Goose Gossage**
November 1, 2016

Thanks for the link to Fermilab, Peter. Paul Steinhardt's talk was exciting. The headline: there are now two types of bounces that have been worked out — one quantum and one classical. One involves a quantum violation of the null energy condition, and the other a stable classical violation. That's clearly a very big deal. For each, one can now compute what effect there is on the perturbations. Odds are there is no effect on the large scales that cosmologists measure — too early to say what that the prediction will be until a careful computation is done. But Steinhardt said there WILL be a definite prediction, unlike inflation which has turned out to be dependent on extremely unlikely initial conditions (as proven by Planck) and the multiverse, which produces every darn thing imaginable. It's no secret that Steinhardt's argument has long been that inflation makes no predictions (because you always wind up with a multiverse, which means it predicts….everything). At Fermilab, he was saying it's not right to compare a fundamentally unpredictive idea (inflation) with a scientific idea (a bounce) that WILL be able to make a prediction. I think that was the real point of his lecture.

Vote!

October 30, 2016
Categories: Uncategorized

Normally I avoid politics here, but these are not normal times. What follows is a request to my US readers, followed by some general remarks about the disturbing state of US democracy. Sorry, but if you want to discuss any of this, it will have to be elsewhere (internet comment sections are part of the problem…).

To those not planning on voting for Donald Trump:

- If you're planning on voting for Hillary Clinton: please be sure to get out and vote, by early voting if available in your state or on Election day. This is extremely important, with the election likely decided by who cares enough to turn out and vote.
- If you're planning on not voting: please rethink this. One can in many elections make a reasonable case that the differences between the candidates aren't great, so, why bother? If there ever were a US election where that was not true, this is it.
- If you're planning on voting for a third-party candidate: again, that might make sense if the differences between the two viable candidates were not great, but that is absolutely not the case here. More specifically, if you're a progressive planning on voting for Jill Stein, please look at what happened in 2000. People who did the same thing in Florida (voting for Nader then) gave us George W. Bush as president, which was a disaster for the progressive cause. I also urge you to look deep within your heart and ask yourself whether your behavior is a realistic engagement with the world, or self-involved moral posturing.

To those planning on voting for Donald Trump:

Please don't. I see two main arguments for doing this and I think they're both misguided.

- You agree with Trump more than Clinton on important policy issues. Whatever policy issue you have in mind, I think if you look into it you'll find that whatever Trump says now, at some other point he was saying something different. There's little evidence Trump has fixed views on any policy issue (other than the desirability of better tax treatment for real estate development projects). If you think Trump will, for instance, appoint Supreme Court justices that share your moral values, note that he has reportedly told Peter Thiel that he would like to appoint him to the Court. Thiel is a gay, radical libertarian Silicon Valley billionaire from San Francisco with highly eccentric views. I doubt you share his moral values (since virtually no one else does, right, left or center).

  Note added: This same argument applies to those opposing Clinton and supporting Trump's election on grounds such as "she's a war-mongerer, unlike Trump", since (on some days) Trump claims to oppose US military interventions abroad. If you really believe that "Make America Great" means Trump will institute a policy of restraint on the use of the US military, I think it will likely be just a few weeks into the Trump administration before you find out that you, like your right-wing brethren in flyover country, have been conned.

- You're angry at well-off coastal elites who you feel look down on you and your culture, and you want to spit in their face by voting for Trump. If so, you are quite right to feel the way you do. From a lifetime spent among such elites I can tell you that, yes, they do look down on you. Most people here in New York City probably do think you're an ignorant racist. Your problem though is that Donald Trump is one of us. He's a well-off New Yorker through and through, looks down on you every bit as much as others. If elected he will govern in the interest of his tribe, not yours. If you think otherwise, you've been conned. All you will accomplish by a vote for Trump is to convince people in New York, Washington D.C. and California that you really are even more ignorant than they thought, a racist fool taken in by an obvious con.

How did we end up here?

Whatever happens, I think the huge question facing US democracy is that of how, in an election contest between a competent, honest centrist candidate and an unqualified con artist, we've ended up with the majority of the electorate convinced that the first of these is the one with serious ethical problems. American politics has become a reality TV show, with the plot line all about convincing people that a contestant is unethical and dislikable, and so should be voted off the island.

That the right has pursued this tactic against the Clintons since the early 90s is not surprising, since it's much more effective than arguing the issues. What's destroying US democracy though is not just one side's decision to do this, but that the other side, instead of fighting back, has been joining in. The most outrageous example of this is the Clinton email server "scandal", which is and always has been an absurdity. The attacks on Hillary Clinton's character based on this have not come just from the right, but also from the left. I every so often look at the Drudge Report, as well as lefty sources (The Intercept, Firedoglake=Shadowproof, Naked Capitalism, etc), and, on this topic, you can't tell the difference between right and left.

Most damaging though is the behavior of the mainstream media, in particular that of the New York Times, whose coverage of this issue has been atrociously unfair to Clinton. This is not new behavior for them, it goes back to the first Clinton administration, during which they promoted endless similar nonsense (Travelgate, Whitewater, etc., etc.). At the time I found it hard to understand why they were doing this, with one conjecture that it had to do with reporters and editors harboring some sort of resentment, intent on taking down the Clintons a notch ("they think they're so great, we'll show them, expose their dirty laundry").

More recently I've come to the conclusion that what's going on here has to do with the world-view of much of the liberal, educated class that I'm a part of. After some success at addressing ancient problems of racism, sexism, homophobia and the like, many have become impossibly self-righteous and devoted to moral posturing, intent on ferreting out reasons to "call out" others and show their moral superiority.

When political arguments are about issues, they're often not very rational and it has always been thus. What has changed in the US is that political arguments are now dominated by obsession with the supposed moral failings of others. We're experiencing a perfect storm of the demagoguery of the right meeting the obsessive self-righteousness of the left, all mediated by journalists who see their primary role as taking down and exposing the supposed moral failings of our leaders. I don't think we've seen this before in our history, and it threatens to upend the basic premises of a working democracy.

It's very hard to know what kind of craziness we'll have to deal with if Trump is elected. His agenda is purely that of getting attention for himself and "winning", I doubt even he has any idea what he'll do if he wins. On the other hand, unfortunately it's all too clear what's going to happen if Clinton is elected. The Republicans will launch endless investigations and attacks on her character in an attempt to make sure her presidency is not a success. The left will join in, and the New York Times and much of the rest of the media will nearly every day feature a new story about what is wrong with Hilary Clinton and with whoever joins her administration and attempts to govern the country in the best interest of its citizens. I don't see see how this fever breaks, and it's very hard not to see bleak days ahead for this country.

Update: From talking to various people I realized that one reason some Democrats and those on the left don't see the "top secret email" business as being as absurd as I do is that they have no idea what these emails were. For that story, see this from the Wall Street Journal and this from the Washington Post.

One reason many people may not be informed about this is that they get their news from the New York Times, where the only mention of this I can find is a snide remark in this story.

Update: Based on some emails from people misreading this posting, it seems I have to make the following clear

- I DON'T think Trump supporters are ignorant racists.
- I DON'T think Peter Thiel is immoral (eccentric ≠ bad).

I DO think that

- Left-wing news and commentary sites
- New York Times political reporters and editors, together with others at mainstream media outlets
- Jill Stein and people who support her candidacy

have joined the right in an unholy alliance to try and discredit Clinton, based on completely absurd accusations regarding her use of email. This has led to a serious danger that the US will elect a con artist and fascist demagogue as President next week, or, failing that, destroy hopes for a successful Hilary Clinton administration.

Update: A correspondent points out that I haven't addressed one reason some on both the Left and the Right (including those at the lefty websites I mentioned) are supporting Trump and trying to destroy Hilary Clinton. They believe that the advent of Trump will "break open the current oligarchy's Pandora's box", with the destruction of the US democratic system making way for a wonderful new system that will grow and flourish in the wreckage. I didn't mention this nihilist argument for Trump because there is no rational argument against the desire to deal with a problem by smashing everything around one. Sure, that will work, it will get rid of what is bothering you, you'll feel better and, as long as you're well enough off, other people will be the collateral damage hit by the debris, as well as those that have to clean up the mess.

Those who think this way though should at least be honest that that's what they want, and not hide behind dishonest demonization of Hilary Clinton over bogus accusations about her email. The left's joining with the Republican party to weaponize dishonest accusations about ethics and use those to bring down whoever they disagree with is something that will live on and make sure that what emerges from the wreckage will be even uglier than what was destroyed.

I also added something above, making clear that the arguments to Trump supporters also apply to his Leftist ones.

The Day After

November 9, 2016
Categories: Favorite Old Posts, Uncategorized

The last few months have not been helpful for my sanity (and I think for that of a large number of other Americans). My three-point program to return to better mental health is to:

- Write one last blog post about what has been going on in the US (with comments off, again for mental health reasons).
- Stop thinking about this topic and stick to thinking and blogging about math and physics.
- Get out of this country for a while, heading to Paris the day after Thanksgiving and hiding out there for a week or so. While there, may do some research into what the current French policy is on political refugees.

On the question everyone is asking themselves (what will Trump do?) I have no idea and suspect he doesn't either. Many around him and in the Republican party do have definite ideas about this. Their agenda will be to use their party's unparalleled control of the US government at all levels, together with his executive power, to force changes dictated by their ideology. Either Trump will go along with this, or he'll change and come up with his own agenda going beyond just that of getting more attention for himself.

On the question of how we got here, I think my [previous blog post] stands up well given what data I've seen from the election returns. Most of the explanations one hears of Trump's success don't hold up if you look at exit polling numbers:

- Sexism: more white women voted for Trump than for Clinton.
- Racism: many counties that went solidly for Obama in the past went to Trump this election. Many Trump voters last voted for an African-American President.
- Revolt of the rural poor whites: While New York City went heavily to Clinton, nearby Suffolk County on Long Island, with a median family income of $100,000, went for Trump.
- Ignorance, lack of education: Most white college graduates voted for Trump.

There is however a common thread in most stories I've read that let Trump supporters say why they were voting for him: they hated Hillary Clinton and found her dishonest. Polls show that back in early September, when asked "who is more honest and trustworthy?" Clinton and Trump were tied (45/45). By the week before the election, the numbers were (38/45): eight percent more of likely voters thought Trump was honest than thought Clinton was. Whatever you think of Hillary Clinton, the idea that Donald Trump is more honest is quite simply insane. The central question of how we got to a Trump presidency is to understand how this destruction of Clinton's reputation was accomplished. What makes this tricky is that there was such a huge campaign from all sides to do this, including not just the usual Republican politics of personal destruction machine (Drudge Report, Breitbart, Fox News), but a wide array of actors on the center and the left, including:

- Julian Assange and Wikileaks, quite likely fronting for Russian secret services.
- All sorts of lefty news sources, too many examples to pick. Susan Webber who runs *Naked Capitalism* today is gleeful at the Trump win, and hopes that this is what we'll soon see:

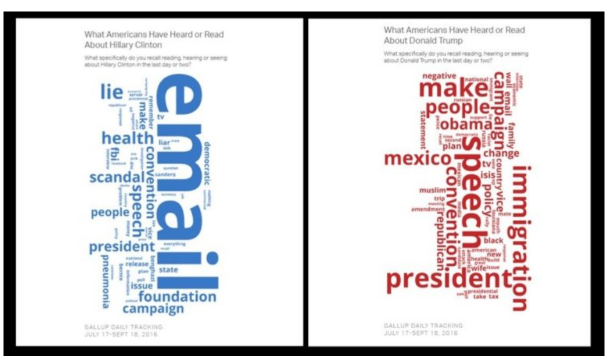
  > There is one more Trump campaign promise that will serve as an important early test of his seriousness as well as his survival skills: investigating Clinton. Even if Obama pardons her, as our Jerri-Lynn Scofield has predicted, it will be critical for Trump to carry out a probe of the Clinton Foundation's business while Clinton was Secretary of State.

- The New York Times, which for months nearly every day published an above-the-fold front page news article attacking Clinton's ethics, with several reporters (Amy Chozick, for one) tasked to make it their full-time assignment to produce such stories. While their opinion writers were mostly more restrained, there's the bizarre case of Maureen Dowd who for 25 years has been writing literally hundreds of pieces about what she feels is ethically wrong with Hillary Clinton. On the Sunday before the election the Times ran not one but two pieces by Dowd attacking Clinton: a shorter one in the op-ed section, and a longer one in the Magazine section.

Together with the onslaught of right-wing "News" attacking Clinton's honesty, it is not surprising that more voters decided Trump was the honest one, or that this likely was enough to get him elected (with a minority of the popular vote).

One way to describe what has happened is that this was the first real social media election, with most people getting the information they used to decide who to vote for from Facebook and other internet sources. Many if not most of these have no interest in what is actually true. Many are dominated by a reality TV ethos of picking out someone for others to attack, appealing directly to the ugliest part of the monkey brain we are all descended from. This is not just the province of the Right, with the Left just as happy to join in the ugliness. Everyone can play and get satisfaction of their darkest needs. The winner will always be the con artist monkey with the best dominance displays.

Trump was always going to win an election campaign fought on these grounds, and that's what this one was. I have no idea of how to stop this from being the future of US democracy. If you're not from the US, maybe you can take action to ensure that your society does not follow ours down this path.



Source

Update: I'm not seeing many other analyses of what happened this election that I agree with. Here's one.

Entanglement, the Multiverse and the Universe

November 10, 2016
Categories: Multiverse Mania

“Entanglement” is the current buzzword of physics, here are two new stories featuring this:

Back in 2013 one could read lots of claims in the media that “Hard evidence for the multiverse” had been found, based on “effects of quantum entanglement between our horizon patch and others”. These claims were discussed on this blog (with a response from the authors here). A new paper by Will Kinney has now been published in JCAP, including the following conclusion about such claims:

> It is worthwhile to discuss in general the “concrete predictions” originally claimed by the authors of refs. , since several key claims do not survive even cursory scrutiny. For example, the discontinuity in the effective potential claimed to be correlated with voids and the CMB cold spot does not appear to in fact exist: for all physically relevant values of the parameters V_0, λ, and b, the modulation F(ϕ) is a smooth function, with no characteristic discontinuities which would explain features in the power spectrum. Perhaps more importantly, the form of the effective potential resulting from landscape entanglement is completely dependent on the choice of inflationary potential V(ϕ), which is itself an arbitrary free function. One could just as consistently choose the underlying inflationary potential in the absence of landscape corrections to be the same as the effective potential (2.7)! In this sense, the landscape model is no more (or less) predictive than single-field inflation itself, and most of the claimed predictions of the entanglement model turn out not to have been
> predictions at all. However, any considerations of theoretical consistency are a moot point: even if one takes the claimed predictions at face value, almost all of them are ruled out by Planck. Experiment always supersedes theory, and the model does not match the data.

This paper has an unusual story behind it, with an author of the work it criticizes trying to keep it off the arXiv. For more about this, see here and here.

Another entanglement story that is getting some press attention this week is this paper by Erik Verlinde, with its associated press release, explaining that we may be “on the brink of a scientific revolution”. I’ll have to avoid trying to give an explanation of the physical argument of the paper, on the grounds that I don’t understand it, partly because there seems to be no underlying physical model here. The basic idea is stated as replacing dark matter by

> an elastic response due to the volume law contribution to the entanglement entropy in our universe.

but someone else will have to explain exactly what that means. Maybe I’m missing it, but I don’t see anywhere in the paper a suggested experimental test of the theory. Someone much more expert than me is needed to explain whether the picture of this paper is consistent with the known astrophysical and cosmological evidence usually interpreted as dark matter/dark energy.

Comments

1. **paddy**
   November 10, 2016

   Peter, Thank you for a post of ideas with which I can distract myself. Have a nice Thanksgiving.

2. **Abbyyorker**
   November 10, 2016

   WRT Verlinde – I understand very little although I tried to read it. The takeaway for me was that there is a fundamental emergent theory of gravity that explains dark matter observations without the need for, well, dark matter. If true, it would be great but I guess the physics community needs to digest it.

3. **physicsphile**
   November 11, 2016

   One problem with the Verlinde theory as it can’t yet explain dynamical situations like the bullet cluster. Nor the cosmic microwave background observations, which arguably provide the most compelling evidence for dark matter.

4. **Erik**
   November 11, 2016

   You cannot imagine the media coverage of Verlinde’s paper here in the Netherlands. It’s really incredible. Every big Dutch news paper featured him as “being the one overthrowing Einstein” and quoting him saying that “this is going to be a new scientific revolution”. I am quite amazed by the media offensive that Verlinde and the university of Amsterdam have taken. Probably the paper is an interesting avenue, but hailing it as the next big thing seems too much.

5. **Another Anon**
   November 11, 2016

   Verlinde has been pushing that idea for years, and the dark matter idea. This just sounds like his university has a new publicity department.

   If Gravity is an entropic force, then how come it’s perfectly reversible (unlike entropy)? Lift a stone, drop it, you get the same energy back.

   I was at a talk with Erik Verlinde and Frank Wilczek, and Frank Wilczek was sooo dismissive of Verlinde’s idea it was almost rude.

6. **Peter Woit**
   November 11, 2016

   Abbyyorker,
   Yes, that’s what he’s claiming to do. Unfortunately all I see in the paper is a bunch of wordy vague analogies claiming a revolutionary new fundamental physics, and little in the way of how to confront these ideas with experiment, or any examination of whether or not they’re already disconfirmed (or even self-consistent). I haven’t computed a John Baez crackpot index for this, but I’d suspect it’s pretty high. Prominent physicists tend to be polite in terms of their public response to things like this, even when privately highly dismissive. Verlinde has been giving lectures about these ideas for several years now, and as far as I can tell his peers have just ignored them. Likely they’ll do the same with this paper, no matter how much press it gets.

7. **Entropic gravity**
   November 11, 2016

@ Erik
I guess the huge media coverage of the paper in the Netherlands can be understood as a way to justify the 6.5 million euros in fund given for the entropic gravity thing in 2012.
http://www.math.columbia.edu/~woit/wordpress/?p=5334

8. **Zack Yezek**
November 11, 2016

I actually read most of his paper, and it looks like his model is worth real investigation even if it proves to be wrong. Yeah, he's certainly not at "Einstein 1915" yet- that's hype. But its not impossible either. It wasn't like anybody in 1900 saw Einstein himself coming, or that most physicists in 1900 correctly guessed that junking the Ether model entirely was the correct path forward.

Basically, the idea is that the Holographic principle does NOT hold exactly in de Sitter space (AKA the real universe) like it does in Anti-de Sitter space. Instead, dS obeys a more general law in which the entropy of the volume is encoded in both horizon and non-vanishing 'volume' terms. He then has a considerably more tenuous/vague argument invoking ER=EPR (among several things) that associates the presence of matter-energy within a space-time volume w/ a decrease in the value of these 'volume entropy' terms within it. The 2nd Law of Thermodynamics then requires this loss of entropy be balanced (or over-balanced) by a compensatory growth of entropy on the horizon, which through a long argument he claims can be modeled well in the same way solid state physics models stresses & displacements on a chunk of material. From there he claims that at Newtonian/GR gravity is replicated at solar- to local-interstellar scales, but at galactic scale you get a new 'displacement' or 'backreaction' gravitational effect that explains why the MOND model works there (and only there) w/out new dark matter, and a non-local effect that explains apparent Dark Energy.

I don't know how much of this is justified, but in principle he sounds like he's asserting:
1) The Equivalence Principle is an EXACT law of nature. That means any experimentally observed deviation would invalidate Verlinder as well as Einstein.
2) Black holes should have no firewalls.
3) The canonical Holographic principle does NOT apply to our universe- only an extension of it does. Don't know how to test this, exactly, but if that research was EVER science the concept should be testable in principle.
4) The apparent inferred distribution of 'dark matter' is really entirely due to the distribution of Baryonic matter. That should be observationally distinguishable from numerous DM models like Bose-Einstein condensate Axions or 'hidden sector force' DM, which have non-gravitational dynamics.

9. **Peter Woit**
November 11, 2016

Zack,
Of the four things you see Verlinde as asserting as implications of his ideas, only the fourth seems to be substantive, and I don't see in what he writes any evidence that "entirely due to distribution of Baryonic matter" better explains the data (astrophysical and cosmological) than other dark matter models. But I'm pretty ignorant about these issues, so I'd love to hear from someone expert on what the data says about whether or not it's consistent with what Verlinde is claiming. Hopefully the public attention to his claims will get some experts to weigh in on this.

10. **Shantanu**
November 11, 2016

Peter interesting that now string theory can also predict MOND. I thought existence of dark matter is strong evidence for string theory.

11. **Peter Woit**
November 11, 2016

Possibly relevant:
http://xkcd.com/1758/

12. **Luis**
November 11, 2016

"Verlinde has been giving lectures about these ideas for several years now, and as far as I can tell his peers have just ignored them."

His paper on the entropic origin of gravity has about 579 citations. Maybe his peers don't agree about it but hardly one could say they ignored it. I wish my work would received that kind of indifference!

On the CMB, he says his model behaves like a pressure-less fluid like cold dark matter so, if I understood correctly, at early stages it shouldn't show differences with current models …

My first impression is that people modeling structure formation in the Universe would be able to test these ideas.

13. **Peter Woit**
November 11, 2016

Luis,

I was referring to his arguments about dark matter, which now have been around for a long time. If you can point to a reference which takes them seriously and discusses their testability and consistency with observation, I'd like to hear about that.

14. **Thomas**
November 12, 2016

The work of Kobakhidze (2011) (https://arxiv.org/abs/1108.4161) disproved the earlier version of Verlinde's theory. Unfortunately, the work of Kobakhidze (2011) is not even cited in this last Verlinde's paper.

15. **jd**
November 12, 2016

I believe that PRL 117,201101(2016), in the latest PRL, is in the neighborhood of this discussion. There already is a simulation that claims a nonMOND explanation. I do not have that reference. I am not really a fan of complex models and simulations.

16. **Robert Delbourgo**
November 12, 2016

For a nonMOND explanation of galactic rotation curves and without invoking dark matter, I have suggested that Born reciprocity might be working at the cosmic level. See my paper on Born reciprocity and the 1/r potential. Of course I might be utterly wrong but the idea might be worth a second look, especially if somebody can see how to relativize it properly. It could also benefit from proper investigation by a professional astrophysicist.

17. **Kazek Kurz**
November 13, 2016

@Zack Yezek – this is something I've thought too. I see this Verlinde paper as interesting. At macroscopic level he argues that it restored galaxy acceleration curves. So it probably takes some insight into something important. But as Kobakhidze shows, microscopic ideas below this calculations are wrong.
It starts with holographic principle and he denied it in order to include some additional degrees of freedom excited in the bulk. It looks somehow in relation to holographic principle like Gibbs paradox in relation to classical computation of entropy.

18. **Alex**
November 14, 2016

This new theory seems to depend on Verlinde's original work that argues for gravity as an entropic force (https://arxiv.org/abs/1001.0785). However, the original paper is fundamentally flawed. He mixes up the Unruh temperature that a uniformly accelerated observer experiences in flat spacetime with the Hawking temperature that a constant radial observer sees outside of a black hole. The two temperatures are not equal.

In the JHEP version of the paper equation equations (5.3), (4.1) say that the temperature of some closed surface enclosing a mass distribution is equal to the temperature proportional to the proper acceleration of some static observer (analogously to the Unruh effect). But this totally incorrect. A static observer outside of a black hole would experience Hawking radiation which would not be proportional to that observer's proper acceleration. The only place a static observer outside a black hole sees a temperature proportional to their acceleration is exactly at the event horizon where the temperature goes to infinity. However, both temperatures go to infinity in the same way. So the whole theory seems completely incorrect to me.

19. **Peter Woit**
November 14, 2016

Alex,

An odd thing about the Verlinde paper is that it's not clear (at least to me) what the relation is to the earlier one. I haven't bothered trying to follow carefully what he does, but he seems to me to be invoking different very vague speculative ideas in the new one than the old one (although, at this level of vagueness, presumably there is some relation between the new and old ideas).

20. **Alex**
November 15, 2016

Peter,

I think it is the same idea. If you look at page 10, and the text surrounding equation (2.12) he states:

"Our hypothesis is that this [horizon] entropy is evenly distributed over microscopic degrees of freedom that make up the bulk spacetime."

So the horizon entropy is the entropy of the gravitational degrees of freedom and the tendency to maximize this entropy forms the 'elastic response' (previously 'elastic force').

Actually in reading this in more detail I'm even more confused. He says that the volume of "a ball of radius r centered around the origin" is basically 4/3*pi*L^3. But in the coordinate patch he's using the volume of this "ball" of radius L calculated using the induced metric would, I think, give an infinite volume. So there's a lot of problems here.

But I agree with you in that the idea is so vague that any attempt to disprove it might be futile.

21. **MathPhys**
November 16, 2016

In an earlier version given in talks (not so sure whether that's the case also in the paper), dark matter is interpreted as degrees of freedom in the matrix model of M theory, degrees of freedom that so far have no other interpretation. But in the string theory limit of M theory, gravity is a fundamental force on equal footing with all other forces. So what's going on? Is gravity emergent or not emergent?

String theory might be about to finally be killed off

November 13, 2016
Categories: Uncategorized

News site TechEye is reporting that String theory might be about to finally be killed off, with a story that starts off

> The world's top boffins are debating finally killing off one of the more elegant scientific theories about the nature of reality.

This isn't exactly the most reliable information source, with one problem that the story is about supersymmetry, with the only connection to string theory this:

> For ages the world's cleverest physicists have been divided over the concept of supersymmetry – a theory which stipulates that all known fundamental particles have heavier, supersymmetric counterparts called sparticles. It appears to be based on the theory that the universe is made out of string which was teased into shape by cats which are potentially dead or alive

The writer seems to have gotten the material for the story from a more reliable source, the Economist, which recently had A bet about a cherished theory of physics may soon pay out. That story starts by explaining about Ken Lane's 1994 bet with David Gross that the LHC would not see supersymmetry. As mentioned here, this year's data should be enough to resolve the question they were betting about. It is likely that results from SUSY searches using most of this year's data will be presented at the usual mid-December LHC Jamboree at CERN, and unless there's dramatic news my sources are keeping from me, these results will be negative.

The bet was for an expensive dinner at Girardet's, a three-star Swiss restaurant which has now closed, and

> Dr Lane says it is time for Dr Gross (who won the Nobel prize in 2004) to cough up—if not with dinner at Girardet's then at another suitably ritzy venue. After receiving no response to several e-mail prompts, however, Dr Lane is growing impatient. "David appears to be welshing on our bet," he says.

but

> Dr Gross is not ready to concede quite yet. The data are in, but their analysis is not complete. "It looks like I will lose this bet by the end of the year," he says, "but we should await the word from the experimenters themselves." (Dr Lane says the original terms have been met and Dr Gross should throw in the towel.)

As for whether this really kills off SUSY, there's a pithy quote from Sabine Hossenfelder:

> Sabine Hossenfelder, a theoretical physicist at the Frankfurt Institute for Advanced Studies, is one of many who think it is time for theorists to focus on other problems—how gravity behaves at the very small scales of quantum mechanics, for instance. If the LHC finds no trace of sparticles in this year's data, she believes the last thing the field needs is another round of Susy model adjustments. "That's not science," she says. "That's pathetic."

Comments

   November 13, 2016

   I agree with Gross on this: wait until ICHEP 2017 when the recorded 40fb from 2015-2016 has been fully analyzed. The news coverage will be far greater on the demise of SUSY, than on the the state of the diphoton excess at ICHEP 2016.

   Talking of bets… I'm hoping Jester does a series of blog posts over the coming months on how his bet with Lubos is finally being concluded at long last.

2. **Another Anon**
   November 14, 2016

   If SUSY dies, surely string theory dies as well?

3. **Another Anon**
   November 14, 2016

   There's no fermions in bosonic string theory without SUSY.

4. **Jeff M**
   November 14, 2016

   Being a mathematician, not a physicist, I'm curious – any story about what the first bet like this was? Also, isn't SUSY essentially unkillable, I mean can't you adjust the energy up by at least several orders of magnitude?

5. **Kenneth Lane**
   November 14, 2016

   1)From my iMac's built-in dictionary:

   welsh |welSH| (also welch)
   verb [no obj.] (welsh on)
   fail to honor (a debt or obligation incurred through a promise or agreement): banks began welshing on their agreement not to convert dollar reserves into gold.

   Sorry, my Welsh friend. As far as I know, it is not meant as a national slur, but I don't have my OED handy.

   2) At ICHEP, in Chicago in August, the largest statistical support for supersymmetry was about 3-sigma; see the plenary talk by Dave Charlton. At that time, the LHC had delivered a total of about 55 inverse femtobarns to ATLAS and CMS, of which about 90-95% was recorded by each detector. There is now about 65 inverse femtobarns delivered to them. There is no way on God's green earth that the additional 1o inverse femtobarns can turn a 3-sigma fluctuation into a 5-sigma discovery. As any decent physicist knows.

6. **Kenneth Lane**
   November 14, 2016

p.s. For those unfamiliar with the LHC: Those 55 and 65 inverse femtobarn refer to EACH detector. The bet called for only 50.

7. **Peter Woit**
November 14, 2016

Kenneth Lane,

I think you're counting both 8 TeV and 13 TeV data. Presumably David's argument is that the 8 TeV data doesn't count, only data at or near the design energy counts. In any case, he's only got a month left before (negative) results with 50 inverse fb at 13 TeV appear, so you should be able to collect soon.

As in many etymology questions, the one here may be not so clear, but online one finds explanations like this:

".Even worse is the verb 'to welsh,' meaning 'to renege on a bet,'…The term welsher became common in Britain during the eighteenth and nineteenth centuries in the argot of race-track bettors. But from a reader came a comforting word for all Welshmen, one which gives a touch of logic to the use of the term: 'It was ENGLISH bookies who, having too many long shot winners against them, fled over the border to 'boondock' Wales to become the original welshers and escape irate bettors looking for their payoff.'"

8. **Eric Weinstein**
November 14, 2016

[This is really weird. Something must have changed for me to be writing a pro-SUSY comment.]

To state the obvious, nature either uses SUSY, or it does not. So, let's leave that aside at first.

What irritates so many about SUSY, is that SUSY supporters often act like it just HAS to be true and then somehow get an indulgence from the usual standards of science to take a massive advance on experimental reality.

So while it is really satisfying to see the most strident of the SUSY cheerleaders lose their bets, this isn't really about SUSY. It's a morality play about representing a particularly insufferable flavor of triumphalist group arrogance in speculative physics.

But what if, for argument's sake, SUSY is real, yet nature instantiated in a totally different framework than the one expected? It's not SUSY which should be on trial. Instead, it's really the specificity with which the current top physics echelon claimed it could specify the future of the field.

SUSY is one of the few areas in which physicists pointed mathematicians at something that mathematics should have seen but even now can't really intuit. Sure you can write down axioms, but the SUSY structures are surprisingly rich and difficult to motivate.

If we lose SUSY, we are going to lose a lot of genius thinking about spinors that has not yet been fully incorporated into the core of pure mathematics. I for one hope that SUSY is real but that the current instantiation will come to be seen as wildly off. That will end up, in practice, seemingly vindicating both the cheer-leading David Grosses of the world and their grumpy critics. In truth it will validate neither.

I don't believe in the sparticles we are supposed to see at LHC. I also don't believe that SUSY is nowhere to be found in nature. My guess has been that we did something brilliant and then messed it up. And this is why SUSY won't die and also isn't progressing to confirmation. Let's let the morality play finish, but realize that it is triumphalism rather than SUSY which is about to have its comeuppance.

9. **Peter Woit**
November 14, 2016

Eric,
I agree that there's a problem here, since the term "SUSY" can mean several different things. Particularly a problem to my mind is that what doesn't get distinguished are

1. SUSY = use of super Lie algebras (i.e. Z2-graded Lie algebras)

2. SUSY = Extension of the Lie algebra structure of the Standard Model by a specific extension of the Poincare Lie algebra by a Z2-odd spinor (N=1 minimal supersymmetric extension of the SM).

The second of these has been problematic from the beginning (no superpartners= states you would get by acting by the Z2-odd spinor operators on known states, theory gets ugly very quickly if you try and introduce new physics to push these states to unobservably high masses). The first is a very general idea, and I think likely will be part of any deeper understanding that goes beyond the SM.

10. **Barry Badge**
November 14, 2016

I obviously don't know, but a phenomenon like String Theory looks to me more historically similar to a political movement than a scientific theory, in that the key to the status of that community is very much to do with the dominance it holds in key institutions and the links it has to the major sources of funds.

I am hopeful String Theory will die off but the signal will, I think, be that of the funding drying up. Even then, with institutions like Templeton in play, String Theory will leave the mortal coil of science very much like the proverbial 'old hippy'.

That said, the last couple of years feels like a sea change with many more people coming out against it. You're obviously much more informed and in-touch with events and if you think it's a maybe, maybe it is.

11. **Peter Woit**
November 14, 2016

Barry Badge,

The real news is the failure of the 13 TeV LHC to see supersymmetry, with the way the TechEye story brings string theory into it kind of silly. It is true that no SUSY at the LHC removes the best hope that those devoted to string theory unification models had for seeing some sort of experimental vindication. Other than SUSY, hopes for an experimental result indicating string theory are now pretty much "maybe a miracle will happen." This isn't at all though a new situation.

I don't want this to turn into the same discussion as usual of the state of string theory, but I'll just comment that funding has never really been the way to look at this: amounts of money going into theoretical physics, string theory or otherwise, have always been and always will be rather small compared to other topics.

12. **Barry Badge**

November 15, 2016

"amounts of money going into theoretical physics, string theory or otherwise, have always been and always will be rather small compared to other topics."

Sure but that surely translates the allocation of resources up the list of what determines outcomes. Presumably the problem is not String Theory in itself, in that if there were 20 string theorists worldwide on a shoe string budget, there would be no problem.

13. **Anon**
November 15, 2016

The December CERN jamboree is cancelled to preserve the sanity of the experimentalists. Expect the 40 fb-1 results for Moriond early next year.

14. **Peter Woit**
November 15, 2016

Anon,
Thanks for the news. So, the likely date for the funeral of SUSY and fine-dining for Ken Lane now seems to be four months away, mid-March.

15. **Entropic gravity**
November 15, 2016

We'll enjoy the event better during the spring break… 🙂

16. **NumCracker**
November 16, 2016

BTW, one can not experimentaly kill SUSY or even superstrings, they can survive even this ridiculous limits: https://arxiv.org/abs/hep-th/0503249

17. **Ford**
November 16, 2016

Dear Peter

I would like to see your comments on approaches like this, where SUSY disapears from observable spectrum: https://arxiv.org/abs/hep-th/0105155
Regards

Ford

18. **Peter Woit**
November 16, 2016

Ford,

I think Sabine Hossenfelder's comment was aimed at this kind of thing, and I agree with it.

19. **Kenneth Lane**
November 17, 2016

To Peter Woit and what data at what energy counts: As you can see from the original bet (whose picture I believe you posted) there is no mention of what energy the 50 inverse fb must be. There is not even mention of whether it is 50 inverse fb per detector of 50 total for the two. A reasonable interpretation is that it is 50 inverse fb for each detector and all the data from Runs 1 and 2 count toward the 50. (After all, the Higgs boson was discovered in 2012 with — as I recall — somewhat less than 20 inverse 5b of 8-TeV data.) The job of interpreting the bet is on the other three physicists, and they agree that the conditions of the bet have been met. BTW, I do not think there will be a total of 50 inverse fb of 13 TeV data; it is more like 42 or so.

As for the ethnic slur, I was unaware of its origin and I sincerely apologize for using it.

20. **Peter Woit**
November 17, 2016

Kenneth Lane,
Unfortunately the terms of your bet are somewhat imprecise, and I can see a technical argument from Gross's side to wait a bit more before conceding. He has though clearly lost the bet, with the only thing that could save him a SUSY discovery in this year's data, and that doesn't seem to have happened (although we'll have to wait until March it seems for fully analyzed, released, results). It sounds like you'll be able to collect, on a time scale of months from now.

I'm more interested though in whether we'll see a consensus in the HEP community that SUSY is dead, or whether it will continue to live on as a zombie form of physics. One question is whether Gross will admit not just that he lost a bet, but that this was a wrong idea. Another thing I wonder about is whether the field will keep training students in this subject, even after it is dead. One thing to watch will be the upcoming IAS summer school on particle phenomenology, see
https://pitp.ias.edu/
Will there be lectures there aimed at training the grad students and postdocs in the lost cause of SUSY phenomenology, or will there be an acknowledgement that this was a failure, and a move on to other topics?

21. **Nakanishi**
November 17, 2016

SUSY is dead: Nature is natural!!
Since some decades ago, I have continuously claimed that SUSY should not be a correct symmetry. The reason for this belief is that SUSY as a symmetry at the Lagrangian level is inconsistent with quantum Einstein gravity, which implies that the Poincare symmetry cannot be a primary symmetry but is a secondary symmetry derived as a consequence of spontaneous breakdown, just like the electromagnetic U(1) symmetry in the electroweak theory.

22. **Scott Church**
November 20, 2016

Peter, forgive me if this is a naive question but…

What's being killed off here is *minimal* SUSY. We can of course keep looking for it at ever-higher energy scales. Now IMHO searching for increasingly massive sparticles to preserve increasingly lop-sided symmetries with their lighter Standard Model partners only makes it more subject to Occam's Razor. But a string theory enthusiast could respond by playing the "elegance" card, and say that a theory this "beautiful" justifies doing that… indefinitely (quoting Einstein, "If the facts don't fit the theory, then so much worse for the facts…").

It seems to me that questions of "beauty" vs. Occam's Razor are about as objective as arguing about who's wife is hotter. I've seen Sean Carroll go so far as to refer to the AdS-CFT duality as "our best *understanding* of quantum gravity…" even though it's a toy model duality based on an AdS universe we *don't* live in. If the word "understanding" can be stretched to limits like these it's difficult to see what *would* be ad-hoc enough to offset what's "beautiful" to string theory enthusiasts.

So… how can we be sure it's even *possible* to kill off string theory? Is this really any different than trying to convince Linus not to waste yet another Halloween night waiting in the cold for the Great Pumpkin to appear…?

23. **Peter Woit**
November 20, 2016

Scott Church,
Yes, string theory unification is compatible with anything, and so is SUSY, by pushing the SUSY breaking scale up to unobservably high values. But, for the last 30 years or so, whenever asked about how string theory was going to connect to experiment, the standard answer has been by finding SUSY at the LHC (and a SUSY dark matter particle). Now that that has collapsed, there is nothing left as justification for string theory unification except claiming that ugly scenarios are really beautiful, and hype about AdS/CFT (which has nothing at all to do with string theory unification).

The point is not that seeing nothing at the LHC falsifies string theory/SUSY, but it falsifies the one viable heavily sold scenario for connecting these ideas to experiment.

What Math Do You Need For Physics?

November 17, 2016
Categories: Uncategorized

Chad Orzel has a very sensible piece at Forbes, headlined What Math Do You Need For Physics? It Depends, which addresses the question of what math a physicist like him (experimental AMO physics) really needs. I'm glad to see that he emphasizes the same basic courses my department offers aimed at non-majors:

- Multivariable calculus
- Differential equations
- Linear algebra

together with statistics (which here at Columbia is handled by a separate department). He disses complex analysis, for reasons that I can understand. That's a beautiful subject, and the results you can get out of analytic functions and contour integration are often unexpected and seemingly magic, but they're not of as general use as the other subjects.

One subject he doesn't mention that I would argue for is Fourier Analysis, which is the class I'll be teaching next semester. That's an incredibly useful as well as profound subject which every physicist should know, but it is true some of its basics often gets taught in other courses (for example in ode courses as a method for solving differential equations).

Orzel starts off with an amusing discussion of a physics version of "Humiliation", admitting that he's never used or really worked through a proof of Noether's theorem, widely considered "the most profound idea in science". I've argued here for the Hamiltonian over Lagrangian method, in which case a different set of ideas about symmetry is fundamental, with Noether's theorem playing no role. In the Hamiltonian case symmetries are generated by functions on phase space, and finding the function that generates any symmetry is a matter of Poisson brackets (as an experimentalist, maybe Orzel has never calculated a Poisson bracket either though…).

One says that a function F on phase space generates an infinitesimal transformation if such an infinitesimal transformation changes the function G by {G,F} (the Poisson bracket of the functions G and F). A basic example is the Hamiltonian function, with {G,H} the infinitesimal change of G by time translation, or in other words, Hamilton's equation
dG/dt={G,H}
When {H,F}=0, we say that the infinitesimal transformation generated by F is a symmetry, since H is left unchanged by such transformations. Using the antisymmetry of the Poisson bracket, this can also be read as {F,H}=0, with Hamilton's equation then the conservation law that F doesn't change with time.

All this seems to me much more straightforward than the Lagrangian Noether's theorem approach to symmetry transformations and conservation laws. My own analog of Orzel's admission would be admitting (which I won't do) how long it took me in life to understand this fundamental point (I blame my teachers).

For lots and lots more about this, see chapters 14 and 15 here.

Comments

1. **sflammia**
   November 17, 2016

   To me, complex analysis and Fourier analysis are inseparable. For example, theorems like the Paley-Wiener theorem give direct, explicit, and important connections between complex analytic concepts like analyticity and Fourier analytic concepts like smoothness or rapid decay of Fourier coefficients. Perhaps the problem is that the two subjects are not taught in a way that synthesizes the most useful features for a physics audience.

2. **Jeff M**
   November 17, 2016

   Interesting. Back when I was a physics major, I did more math than most (ended up a mathematician of course). What about group theory? Lie groups. Had a course in that as an undergrad, which I guess is pretty unusual. Did it instead of Galois theory. And you need some complex. The only mathematical physics course I took was all complex analysis, mostly funky contour integrals. I agree about hamilton, and Fourier analysis. Of course, I guess it really depends on what sort of physics you do. Differential geometry is helpful, and nowadays graph theory. I guess you need enough time to take some physics courses….

3. **Bee**
   November 18, 2016

   I managed to misread Humiliation for Hamiltonian! As Jeff says above, I'd think you pretty much can't do quantum mechanics and quantum field theory without group theory, Lie groups, representations thereof, and so on. But you can go a pretty long way without differential geometry.

4. **Bobito**
   November 18, 2016

   In practice it is hard to directly measure momenta (we don't "see" phase space easily). For this reason the Lagrangian description is fundamental. Sometimes one has to think like an experimentalist.

5. **cthulhu**
   November 18, 2016

   I'm an engineer, not a physicist, but wouldn't you need tensor calculus for general relativity? Or is GR a specialized enough field that you would only take that math when you needed it?

   Looking back at my college years and knowing what I know now, I would have traded my second semester of PDEs for a half advanced linear algebra, half advanced Fourier analysis class; I use those every day but haven't dug out those fancy PDEs in decades.

6. **Chris Oakley**
   November 18, 2016

   I am probably pushing at an open door here, but I would vote for the theory of continuous groups as well. In 1980, as I was finishing my undergrad physics course, there were a lot of talks and TV programs on high-energy physics aimed at the general public (remember those days?) SU(3) would come up a lot. This was fascinating to me as I had no idea what it was. When, as a graduate student, I actually found out, I was almost disappointed. Continuous groups should, IMHO, be taught alongside quantum mechanics at undergrad level.

7. **anon**
November 18, 2016

GR is very much a specialized field. I don't think many physicists, apart from those working directly on GR or related subjects, know the mathematics needed for that.

I agree that parts of group theory are needed for QM, but still I wouldn't say it's something necessary for all physicists.

8. **vskrin**
November 18, 2016

@sabine: I've also misread Humiliation for Hamiltonian, professional deformation I suppose.

@peter: You're probably familiar with DeWitt's book (well a series of books actually) on QFT. In there he advocates various approaches which are not standard in the HEP community. In particular there's a lot of mentioning of the Pereils bracket, and thing like that. Now, as much as I wanted to read that book cover to cover I still didn't find time for it, so I was wondering if the approach that you're describing here in the post has any relation to DeWitt's approach?

Cheers!

9. **Yatima**
November 18, 2016

Any thoughts on (no, not Trump, but):

https://www.quantamagazine.org/20161115-strange-numbers-found-in-particle-collisions/

10. **Dave Miller**
November 18, 2016

Peter,

I've worked in engineering as well as physics: Any decent engineer needs to be very comfortable intuitively with Fourier analysis. To be sure, they do not have to remember the difference between the Dirichlet kernel and the Fejer kernel, but they need a strong physical sense for what is happening.

And, I once solved an important engineering problem using the Schwarz-Christoffel transformation. To be sure, most engineers do not remember enough complex analysis to handle that (perhaps that is why the company hired a physicist).

Dave Miller in Sacramento

11. **Dave Miller**
November 18, 2016

cthulhu asked:
>I'm an engineer, not a physicist, but wouldn't you need tensor calculus for general relativity? Or is GR a specialized enough field that you would only take that math when you needed it?

I recently worked out the Schwarzschild solution without using tensors: I ran with the approach Feynman lays out toward the end of volume II.

So, it's possible to do some basic things in GR without tensors, though I have to admit it is quite a mess: I consider my little exercise to be justification as to why one really needs to learn the tensor apparatus.

Tensors are also used in various fields of engineering (stress, strain, and all that), although not in the same way as in GR. Anyway, I personally do not think someone should call himself a physicist if he does not understand the math and physical ideas underlying GR.

Dave

12. **Jeff M**
November 18, 2016

When I did GR as an undergrad, I taught myself tensors along the way. I had some differential geometry before that, but not a lot. But I was lucky enough that I was doing the GR as an independent study with a great professor, so I had a lot of help.

13. **Josie Altzman**
November 18, 2016

I kind of wish I had this type of thing when I was an undergrad physics major at CU back in the 80's. I did take the Fourier Analysis course, along with a whole course on Calculus of Variations (not sure if it's even still taught).

I ended up swallowing Morse&Feshbach in graduate school for fun.

14. **Low Math, Meekly Interacting**
November 18, 2016

I'm acquainted with a former GR post-doc who made the jump to medical imaging and does some freelance coding for VR gaming. Given the role tensor maths play in the diverse subjects, and how well-versed he also is with QM and the basics of QFT, I'm guessing he'd be appalled to hear most physicists don't need tensors.

15. **Miki Weiss**
November 18, 2016

Lagrangian dynamics is a very usefull tool in Mechanical engineering, enabling to write equations of motion of very complex rigid body systems, including translations and 3d rotations, with generalized coordinates and complex boundry conditions (see the book "Lagrangian Dynamics" by A.D. Wells)
Fourier Analysis (in the complex plane), in continuous and discrete time, along with Hilbert space techniques, are among the most usefull tools of modern Electrical Enginnering – Communication &Information theory Information theory, Signals analysis, synthesis and processing (Audio, Cellular systems, Radar, Sonar), detection &

parameter estimation of signals buried in noise, e.g., "Digital Signal Processing" by Oppenhaim, "Digital Communication" by Proakis and the classical 4 volume series of Van Trees. The communication and Internet revolution of the 1990's was not possible without those tools, used daily by hundred thousands engineers worldwide.
Finally, Green function methods together with Fourier analysis are used by RF Antennae designers, solving Maxwell equations from the EM fields induced on the antenna surfaces, as means of calculating the far field Antenna gain pattern (which actually is a tow dimensional Fourier analysis with complex boundary conditions.
Hurrah for those 17-18 century French mathematicians!

16. **Matthew Foster**
November 18, 2016

In condensed matter theory, we are importing more and more abstract/modern mathematics to deal with topological insulators, superconductors, and topologically ordered phases. In my view the standard undergraduate training that focuses mainly on pre-20th century mathematics is leading to an increasing gap between what is taught and what is used in research. I'm not sure what the solution is, though, because if you want to apply category theory notions to (e.g.) non-abelian anyons in fractional quantum Hall states, learning category theory from math texts or courses is from my perspective a big circumnavigation around what a physicist really needs: intuitive grasp of the rules and algorithms for applying them. (Of course there are many exceptions–I take it that Greg Moore learned category theory overnight.)

My own small contribution has been to elaborate on R. Cahn's Lie algebra book, to try to write course modules that could be accessible to an undergrad. My argument (that I made in a grant application at least) was that Lie algebras are kind of the "gateway drug" to many more advanced notions, such as affine Lie algebras and 2D CFT, braiding and fusion in anyon systems, Bethe ansatz solvable systems and quantum groups. Thus if students who want to do theory can learn LA representation theory as undergrads, maybe it further opens the door to assimilating these more modern topics in graduate school. It's a work in progress, but what I have is available here:
http://mf23.web.rice.edu/

17. **Thomas Larsson**
November 18, 2016

My first year in college ended with a class in vector calculus, including Cartesian tensor calculus. Once you understood how to juggle those indices, you didn't have to struggle to remember in detail how to deal with those divs, curls and nablas – it all popped out automatically. It was like knowing about the Euler formula, when people taking "simpler" classes had to memorize tons of trig formulas. A real time-saver.

From the viewpoint of my later non-career, however, I would said that group theory is the most important. In particular, tensor calculus and differential geometry are secretely the same as the classical representation theory of the diffeomorphism (or Poincaré, in flat space) group. This just says that tensor calculus deals with objects that have a meaning independent of the coordinate system.

18. **AcademicLurker**
November 18, 2016

Orzel's list sounds much like my undergraduate maths curriculum. 3 semesters of calculus, 1 semester of linear algebra, 1 semester of differential equations, and one of those grab bag "mathematical methods" courses. All the rest of the math I learned was either taught piecemeal in various physics courses of picked up on my own as needed.

A sometimes wish I had taken a proper complex analysis course.

19. **Manfred Requardt**
November 18, 2016

Dear all, I think the core observation of the field theoretic Noether theorems (I and II) is the existence of conserved currents comong from symmetries. The second theorem even includes gauge theory (infinite dimensional Lie groups). In this sense it is very fundamental.

20. **Tim**
November 18, 2016

Two thumbs and ten toes up for Fourier Analysis. I'd encourage you to include at least an overview of how Shor's Algorithm works. The implementation of a fourier transform as a series of phase rotation quantum gates is quite elegant. It's a nice example of how being able to quickly measure periods of functions leads to some clever and unexpected results.

21. **Peter Woit**
November 18, 2016

Bobito,
I'm not convinced that thinking simultaneously about position and momentum is that hard, even for an experimentalist (and often, momentum is easier to measure than position, e.g for light). What is deep and unintuitive is the Poisson bracket, one can argue more so than the Lagrangian (although my point is that once you understand the Poisson bracket, you have conserved quantities for free, while with the Lagrangian you have non-intuitive work to do to find them).

vskrin,

In my earlier discussion of this that I linked to, there's a link to this article
https://arxiv.org/abs/1402.1282
which is the best explanation I know for the relation of the Peierls bracket and de Witt's approach to more conventional Hamiltonian methods.

Yatima,
That's an interesting topic, but I don't know much about it, nothing useful to say here. The mathematical structures that are begin discussed come up in looking at terms in a series expansion, they're interesting mathematics, and potentially quite useful, but not clearly part of the deep structure of the theory, rather than an artifact of the approximation.

All,
I obviously am quite devoted to the idea that Lie groups and their representations are the way to understand quantum mechanics (and can recommend a good book…). A problem though is that any young physics student who wants to learn this math is going to find that math department courses covering it only are offered at an advanced level, and not really accessible.

As for GR and geometry, yes, they should be studied together. But, for most physicists GR is disconnected from what they do and they can happily live without knowing anything about it.

22. **Matthew McIrvin**
November 18, 2016

My impression was that when physicists talk colloquially about Noether's Theorem, often they really are thinking about a Hamiltonian picture, not the Lagrangian one in which Noether's Theorem was literally derived.

More specifically, a *quantum* Hamiltonian picture, really. Some quantum operator commutes with the Hamiltonian, therefore it's obviously a conserved quantity, and the transformation you get by exponentiating it must preserve the Hamiltonian as well, so there's your symmetry. It's all very simple once you're used to QM.

23. **vmarko**
November 18, 2016

Peter,

I'm slightly confused by you emphasizing the Hamiltonian over the Lagrangian approach, over and over. Purely at the math level of ODE's, it is simply a theorem that N second-order ODE's are equivalent to 2N first-order ODE's (of course, given certain assumptions), which is all there is to say really regarding the relationship between Lagrangian and Hamiltonian approaches. Naturally, each of the two approaches has its strengths and weaknesses, and every physicist should be familiar with both, and use one formalism or the other as needed, the right tool for the job. But fundamentally, what is all the fuss about?

Regarding Noether theorems, their true power lies not in the discussion of the conserved charges, but in the discussion of gauge symmetries. And in the Hamiltonian approach, the presence of gauge symmetries requires one to understand the Dirac analysis of constrained Hamiltonian systems, first- and second-class constraints, Dirac brackets, Castellani's construction of the symmetry generator, the proper boundary behavior of variables to construct conserved quantities, the whole shebang.

In other words, in the Lagrangian framework, the consequences of gauge symmetries are neatly packaged into two Noether theorems. On the other hand, in the Hamiltonian framework, one discovers that the evolution is not described by a single phase-space trajectory but an infinite family of trajectories (connected by a gauge transformation), and all hell breaks loose…

As an example, just try to explain the "problem of time" to a student, using the Hamiltonian framework. I just don't know of any easy way to explain (without appealing to Noether thms) how come the Hamiltonian of a diff-invariant system is always zero, and how one is supposed to work out anything in the Hamiltonian framework if the actual Hamiltonian vanishes.

One always needs to understand some context — Emmy Noether was asked by Hilbert, Einstein and others to clear up the fuzziness around conservation laws in general relativity. That's how the two theorems arose, and they explained away this fuzziness with two pure and beautiful pieces of math. Hamiltonian description of GR came much later, with the development of the ADM formalism, and it is confusing a lot of students to this very day. On the other hand, in QM the Hamiltonian approach was dominant from the very beginning, but there were no gauge symmetries involved. They came in as an afterthought (and gained mainstream importance only with the development of the Standard Model), but Hamiltonian formalism was never really well-suited to the study of gauge symmetries. The complexity of the Dirac formalism of constrained systems is a testament to that.

It seems to me that you are emphasizing the triviality of the first Noether theorem, while completely ignoring the second one, where all the power really lies. Let me suggest a challenge — try to derive the Bianchi identities in GR using the Hamiltonian (or ADM) formalism and moment maps, and then say it is better, clearer and easier than the Lagrangian approach. I just don't believe that the Hamiltonian framework could ever possibly be superior there.

Best, 🙂
Marko

24. **Peter Woit**
November 18, 2016

Matthew McIrvin,
Yes, I do think that when physicists invoke Noether's theorem, often they're misspeaking, having in mind the Hamiltonian rather than Lagrangian formalism. And I completely agree that, in the Hamiltonian formalism, the relation of conserved quantities and symmetry group actions is even simpler in quantum mechanics than in classical mechanics (as you say, because the group action is just given by exponentiating the operator corresponding to the conserved quantity).

Marko,
My comments were really motivated by Orzel's pointing out that he doesn't use or really understand Noether's technique for finding conserved quantities, and I was arguing that for simple physical systems, how conserved quantities work is much clearer in the Hamiltonian formalism.

Yes, for something like GR the Lagrangian formalism and Noether's second theorem come into their own (and that's why she developed this). But the issue of gauge and diffeomorphism symmetry is a subtle and thorny one no matter how you deal with it (since it is so hard to cleanly separate out physical and gauge degrees of freedom). I'm not convinced the Lagrangian formalism doesn't obscure parts of the problem that the Hamiltonian formalism at least brings to the fore.

25. **Some guy**
November 19, 2016

The Lagrangian version of Noether's theorem typically is preferred because there are important symmetries which are manifest at the level of the Lagrangian but not in the Hamiltonian. The most obvious example are the symmetries corresponding to Lorentz transformations. Here the Poisson bracket/Hamiltonian formulation suffers from the fact that the transformations on the phase space variables depend on the precise form of the Hamiltonian, in contrast to the Lagrangian formulation where the transformations depend only on representation content and not on the precise form of the action. To convince yourself of this, try proving the Lorentz invariance of non-abelian gauge theory in the Hamiltonian formulation. It is quite an ordeal, whereas in the Lagrangian formulation it follows by inspection.

26. **santarakshita**
November 19, 2016

I think the importance of complex analysis is much less subjective than claims of its beauty (or perhaps, what I write next is possibly an expression of that beauty): it is absolutely vital as a source of intuition and motivation for a vast amount of modern mathematics; given that function theory of the 19th-20th century led to the foundational papers in algebraic geometry (ex: Riemann's Abelian function paper), algebraic topology and number theory. Covering spaces and (co)homology (via Cauchy's theorem) arises naturally in a first course of complex analysis. One cannot master algebraic geometry at any level without some understanding of Riemann surfaces.

While it is possible to repurpose a machine for a variety of uses, I feel it is vital to at least have a sense of its original context.

27. **ComplexIsPunny**
November 19, 2016

I'm a mathematician, not a physicist, so I am not really qualified to comment, but
to my mind a bit of complex analysis is fundamental. (I had to review this material for physics students recently so it's on my mind.) Fourier series is of course necessary

for physics but you can't legitimately teach
Fourier series without Euler's formula (e^i\theta=…) since it simplifies the formulas and proofs so much, and once you are doing that, how can you not make the connection between power series (Laurent series) restricted to the circle and Fourier series? I'm talking about intuitive connection, proofs not needed, as the details of when what converges in what sense are subtle.
But for the basics you at least need the idea of radius of convergence of a complex power series, the complex expansion of exp, sin and cos. Euler then gives you the polar form of a complex number and the connection with rotation matrices. Once you have the idea of complex derivative the Cauchy-Riemann equations fall out of that. Now Cauchy's theorem and formula et al are so closely related to vector calculus that it just reinforces that material which is so crucial for E and M. That may be all that is really needed. I agree that computing complicated contour integrals could be largely a waste of time. My favorite Complex Analysis text is Lang (surprisingly given some of his other books, this one is excellent). Marsden, Knopp I and II, and still Ahlfors are all excellent as well. For the professor to delve into more deeply for themselves, Katznelson's book on Harmonic Analysis is remarkable.

If Fourier transforms are necessary, that's tougher to do it rigorously, as you ideally need some measure theory and functional analysis. But at least they should have the intuitive ideas that the transform of a sin wave is a point mass at that frequency, and that the transform of a Gaussian is a Gaussian, with a thin one getting spread out and vice-versa.

28. **paddy**
November 19, 2016

My (winding down) career has been applied/experimental (coincidentally starting with AMO) ; however, I had earlier undergraduate/graduate theoretical pretensions. I was exposed in that phase to a number of areas that have been concretely helpful throughout my career, most notably complex/Fourier analysis (only somewhat also Group theory). I see from above many posters concur. I also see the mention of Marsden–which sits almost pristine on my shelf from 40 years ago. Perhaps it is my own taste, but the book I pull down the most on these issues is Carrier, Krook and Pearson. Mainly because without over-simplification it introduces and addresses techniques like Weiner-Hopf by demonstration and application. Lighthill, for all its skimpiness, is another useful text.

29. **David**
November 19, 2016

Highly recommended: D. Neuenschwander, "Emmy Noether's Wonderful Theorem." A marvelous little book.

30. **Peter Woit**
November 19, 2016

Some guy,

My current favored way to think of this is that it is the equations of motion and the symplectic structure on the space of solutions (=phase space) that is fundamental. Lagrangians give a nice way of producing such things (as solutions of the variational problem), although often with a degenerate or singular symplectic structure (and thus descent into "constrained Hamiltonian dynamics").

This point of view sometimes is called "covariant" phase space, with some names attached to it Crnkovic-Witten and Zuckerman, who wrote down the Yang-Mills case. It's a point of view that ends up relating Noether's theorem to the Hamiltonian point of view and Poisson brackets.

Typically one parametrizes solutions of equations of motion by initial values at t=0, and when you do this you get a problem describing some of the Lorentz generators (boosts). These aren't really symmetries in the usual sense though (don't commute with the Hamiltonian).

I think historically the preference for Lagrangian methods arose in the development of perturbation series methods in relativistic QFT (Schwinger, Feynman), since understanding renormalization is much more difficult without explicitly Lorentz-invariant terms in such series. Gauge symmetry leads to its own problems with Lorentz invariance, which are though quite fundamental (inherent conflict between positive Hilbert space and covariant elimination of the gauge degrees of freedom).

31. **Peter Woit**
November 19, 2016

About complex analysis:

santarakshita: no question you should understand Riemann surfaces and complex analysis to have any idea what is going on in algebraic geometry, but physicists can (and do) almost all happily go through their careers knowing nothing about algebraic geometry.

Complexispunny: To discuss Fourier analysis you clearly want to talk about complex valued functions of a real variable, but you can mostly avoid functions of a complex variable and the notion of a holomorphic function (although that may be the best way to understand some facts).

paddy: I second the recommendation of Carrier, Crook and Pearson, which is full of wonderful applications of the subject. That's actually the book I first learned complex analysis from, in an applied math course. Later on I learned a less applied point of view by teaching the subject in a math department.

32. **paddy**
November 19, 2016

Peter: might not be a coincidence on Carrier, Krook et al. My handwriting in inner leaf says '74 and I am sure for a course in DEAP (?). Cannot recall the name of the professor.

33. **paddy**
November 19, 2016

PS: I've always felt that my preference for the Hamiltonian formalism (as more intuitive ?) was do to my not proceeding further into relativistic QFT than I did. Perhaps someday I will revisit.

34. **Peter Woit**
November 19, 2016

paddy,
That's very funny, not a coincidence. I just dug up my old course notes, seems I took Applied Math 201 Fall 1976, my sophomore year. I have written on the notes as instructors Richard Lindzen and John Hutchinson, but don't remember much about them. Lindzen went on to fame (notoriety?) in climate science, Hutchinson I guess is still there, see
http://web-static-aws.seas.harvard.edu/hutchinson/

Applied Math 201 was the complex variables class and used Carrier, Krook and Pearson as one of the texts. Presumably this had something to do with the authors having taught this course at Harvard in the 60s

There was also a second semester of the class, Applied Math 202, about PDEs, which I took spring 1977. That used the book "Partial Differential Equations" by Carrier and Pearson, presumably also written based on that course.

35. **paddy**
November 19, 2016

OT a bit I know…but. The professor in '74 in whatever the course was using CK&P would finish his lecture and, as students funneled out (and some forward to ask him questions), he would–as if rationing–begin unwrapping a pack of Players.

36. **Peter Woit**
November 19, 2016

paddy,
I don't remember this, but could easily have been Lindzen, who was there in 74. There's this from a 2001 Newsweek interview

"Lindzen clearly relishes the role of naysayer. He'll even expound on how weakly lung cancer is linked to cigarette smoking. He speaks in full, impeccably logical paragraphs, and he punctuates his measured cadences with thoughtful drags on a cigarette."

37. **paddy**
November 19, 2016

Peter: I looked up Lindzen and you are correct. 'Twas he. Good course and good teacher. I hope he (unlike I) has stopped smoking.

38. **Jonathan Miller**
November 19, 2016

I had a double major in physics and math and continued to take math in my first year of PhD study when I intended to become a theorist (I was also accepted into math PhD programs). I left theory for experiment, but have continued to work with theorists. I have observed that most theorists and experimentalists could have used more computer science courses and, probably, less mathematics courses.

39. **Ilyas**
November 20, 2016

Group theory – right up there in my view as a "preferred" topic to be taught to physicists. Whilst i am here, I'll say thanks for hosting such an interesting and engaging blog for so long.

40. **anon**
November 20, 2016

Jonathan Miller: I agree that some more formal training in programming would be good for many or even most physicists. The reputation 'self-taught scientist programmers' have among software engineers is not entirely undeserved.

41. **Trailmut**
November 21, 2016

Peter, thank you for this illuminating and at times entertaining blog. I did a lot of math and physics years ago at the undergrad level and then dropped out for the outdoors and environmental activism. I would love to revisit some of this stuff. What would you recommend as a good textbook these days on calculus, on differential equations, and on linear algebra. Thank you, again.

42. **Peter Shor**
November 21, 2016

About complex analysis –

Is an area of math that comes up everywhere in other mathematics also likely to come up lots of places in physics? My inclination is to say "yes", but quite possibly I'm wrong.

43. **Mike Weiss**
November 21, 2016

Peter, thanks for reminding us that you took Applied Math 201 in the fall of 1976, our sophomore years at Harvard. By coincidence, I attended the first week of AM201 but then switched to Math 213a, the Math version of the graduate course in complex analysis. Math 213a in the fall of 1976 was the first and only time that John Tate ever taught complex analysis, and he saw it as a grand opportunity to provide his own perspective (not using Lars Ahlfors classic text). At the time we did not know what a privilege it was.

44. **anon**
November 21, 2016

Complex analysis, definitely. You can't even have a coherent discussion of common Green's functions and common Fourier transforms (in electrodynamics, scattering theory, solid state physics, or QFT propagators) without knowledge of contour integrals.

Same goes for group theory and QM. Even a basic discussion of QM conservation laws in my intro grad QM class stumbled when it came to light the students had no background in groups. SO I had to introduce basic Lie groups (as in translation and rotation) ab initio, at grad level. Quite shocking.

45. **Peter Woit**
November 21, 2016

Trailmut,
Sorry, but in my little experience with books for these courses, none stands out as unusual and worth specially recommending. Here at Columbia and many other places, Stewart's Calculus is the text we use. I've always thought that calculus and introductory physics should be taught together, haven't ever seen a book that does that though.

Mike Weiss,

Thanks for that story. Probably it's very good that I didn't do what you did. I got a fair amount out of the Applied Math version, although struggled a bit with that since I wasn't exactly over-prepared for it. I suspect I would have gotten little out of Tate's version, which later in life though would have been great to experience.

All in all, physicists should be wary of the fact that complex analysis can be taught very differently, depending especially on whether the emphasis is on applications (which are marvelous and something physicists should know) or theory (which leads to many deep areas of pure math, but less necessary for physicists).

anon,
I agree completely, and the problem you mention is one motivation for the book I've just finished. The material about translations/rotations and what they have to do with momentum/angular momentum should though be part of the standard physics undergrad courses on mechanics and QM.

46. **Matt Grayson**
November 21, 2016

Mike,
I took 213a the preceding year taught by Ahlfors. That actually seemed like a privilege at the time. Of course, I didn't understand much of it until I taught the stuff ten years later.

Peter,
I was a TA for Math 22 taught by Bamberg and Sternberg. That made a serious attempt to combine second year calculus and linear algebra with physics. I remember them applying cohomology to resister networks and expressing Maxwell's Equations in differential forms.

47. **Michael Comenetz**
November 21, 2016

Trailmut and Peter,
I hope you won't mind if I quote from the Zentralblatt MATH (now zbMATH) review of my own elementary calculus book, "Calculus: The Elements" (World Scientific, 2002): "A mathematician's first reaction to the book may well be, Is this a text by a physicist, or by a mathematician. After delving further, one has the feeling that it is a work by a mathematician still in close touch with physics. … The author succeeds well in giving an excellent intuitive introduction while ultimately maintaining a healthy respect for rigor." A fuller review by Roy Smith of the University of Georgia can be found at the World Scientific website.

48. **Frederick**
November 22, 2016

One of the reason why few undergraduates know about group theory is the relative lack of a good group theory book designed for physics majors. They could have taken a course on abstract algebra, but then they would have to spend time learning about rings and fields, which are not quite connected to physics.

Even the currently available material seems to be too rigorous. It is well known that physicists apply Stoke's theorem on non-compact spaces; physicists are reckless folks indeed.

49. **Jeff M**
November 22, 2016

When I was an undergrad, there was a book, "Group theory in quantum mechanics" or very similar title. I just checked, and it's now Dover, so you can get it for less than $20. It's listed as graduate level, but I used it as an undergrad (I was taking a mathematics modern algebra course at the same time). I remember it being a wonderful book.

50. **paddy**
November 22, 2016

On Group theory: Hamermesh was text I first learned from. Proved to be quite useful even in a mundane area like understanding fluorescence of transition metal ions in crystals. Once again my fly leaf indicates '74 and this time I remember the professor: Glashow.

51. **jc**
November 23, 2016

Frederick,

A very nice "dumbed down" group theory textbook for non-math majors which I found very readable, is:

"Lie Groups, Physics, and Geometry: An Introduction for Physicists, Engineers and Chemists" by Robert Gilmore.

http://www.physics.drexel.edu/~bob/LieGroups.html

A few pre-Thanksgiving items:

- International Journal of Modern Physics A has a new issue with "Featured Topic" part I of a discussion of the proposed Chinese supercollider project. The high profile contributions are from C. N. Yang, China should not build a supercollider at this time, and a response from David Gross: Why China should build the Great Collider. Both I think do a good job of making the case for and against the project, with the central question that of the high cost. If this was a $1 billion project there would be no question it would get done, and if it was a $100 billion project it could never happen. The problem is that the order of magnitude is $10 billion.

  There are some other contributions to the debate, including sensible pro-collider pieces by Yifang Wang and Weimin Wu. There's also a bizarre piece by Henry Tye, making an ad hominem argument against Yang, based on the fact that in 1980 Yang was skeptical about the future of high energy physics. I'm afraid that this doesn't work very well as an argument against Yang, whose prediction of no post-1980 breakthroughs looks unfortunately prescient these days.

- According to the New York Times, one possibly imminent non-HEP breakthrough is a Microsoft quantum computer. Their project grew out of one they funded led by topologist Mike Freedman.
- Last weekend there was a celebration at Caltech of John Schwarz's 75th birthday. No slides or video of talks it seems. I've wondered what Susskind's take on supersymmetry is these days, so curious what might have been in his talk entitled "Supersymmetry and the Limits of What We Know".
- Howard Burton was the founding director of Perimeter, helping to get it off the ground and turn it into the success it has become (Sabine Hossenfelder here notes that the term of the current director Neil Turok is up and wonders who is next). In recent years Burton has been running something he calls Ideas Roadshow, and now has a new blog called In Search of Refinement. He writes about a recent event with Roger Penrose, discussing his new book, and has kind things to say about my review of the book. Ideas Roadshow now has accumulated a significant number of interesting interviews, worth your while if you're looking for high-quality but not free internet content to support.

Update: One more. Yet more private funding for US scientific research. The New York Times reports on the Simons Foundation Flatiron Institute, a planned $80 million/year, 200 employee research institute. The focus will be on computational work, and doing better science by freeing scientists from having to apply for grants.

Comments

1. **Another Anon**
   November 23, 2016

   Neil Turok's term "about to run out" means May 2018. He'll probably just get renewed.

   https://www.perimeterinstitute.ca/news/neil-turok-appointed-second-term-perimeter-s-director-and-lazaridis-bohr-chair

   November 23, 2016

   Paywalled, the whole thing which is strange as its public commentary drawn from unpaid sources. I'd like to see what yang says.

   How come he didn't win two Nobel prizes?

3. **Narad**
   November 24, 2016

   > Paywalled, the whole thing which is strange as its public commentary drawn from unpaid sources.

   The IJMPA? I haven't checked all of the papers, but the Yang was just nagwalled (one has to register).

4. **curious**
   November 24, 2016

   " Chinese supercollider"

   Peter do you think a Chinese supercollider should be funded, or is that money better spent elsewhere?

   From what i read elsewhere they are hoping to achieve 50km radius and perhaps 50-70 TEV collision, which for the price doesn't sound like a large leap over LHC of 14 TEV.

5. **Peter Woit**
   November 24, 2016

   curious,
   I don't know enough about the situation in China to have an informed opinion on this. Yang's argument is that China is still too poor a country to do this, but the situation there is changing rapidly. I would support such a project in the US, don't want to engage in the usual simplistic arguments about government spending on anything (please anyone who wants to do this, resist the temptation).

6. **Jeff M**
   November 24, 2016

   Peter,

   Is there any expectation that you would see anything new at 50TEV? What would the point be of that sort of collider? When people were considering the superconducting collider in the states, or the LHC, the expectation was that you would find the Higgs. I don't see any expectation that anyone is going to find anything at 50 TEV, for that matter, I don't see anything at 500TEV, no?

7. **Peter Woit**

November 24, 2016

Jeff M,
Plans for such a collider typically involve two stages: an electron positron collider in the large tunnel that would be a “Higgs factory” allowing a much more detailed study of the Higgs properties than at the LHC, and a higher energy proton-proton collider. The second one would explore a higher energy range than the LHC, and that’s of value in itself, there might be something unexpected, but also allow measurement of the Higgs self-coupling, again telling us something about the Higgs that the LHC can’t.

8. **Bobito**
November 25, 2016

Private funding for math research may be a poison pill. Someday the government might perceive that there’s no need for public funding …

9. **Casey Leedom**
November 25, 2016

“The New York Times reports on the Simons Foundation Flatiron Institute, a planned $80 million/year, 200 employee research institute.”

Woah, really? That’s an insanely high Burdened Employee Rate. It used to be about % Full Time Equivalent employees per $1M several years ago. In Silicon Valley it’s getting close to 4 FTEs/$1M. Even with that higher rate, $80M/year should fund 320 employees. So they apparently are getting a lot of salary … or there’s a lot of overhead …

Casey

10. **Casey Leedom**
November 25, 2016

[[Sorry, no ability to edit: That should have been “_5_ FTEs/$1M several years ago” …]]

11. **Parisian**
November 25, 2016

Casey,

You need things such as computer clusters, postdocs, etc. to do research. $80M should cover all those things, including paying for electricity. I’m surprised that the budget is not bigger.

12. **Bernhard**
November 25, 2016

I just read both Yang’s and Gross’ papers on the CEPC. It would be interesting if Yang would write a response, as I think Gross made a better job arguing in favor than Yang did against it.

13. **curious**
November 25, 2016

how does chinese collider compare with proposals of a higher energy 28 tev LHC using more powerful magnets?

14. **GoodAndNotSo**
November 25, 2016

It’s wonderful the way Jim Simons chooses to spend his money. Aside from the
math/physics projects, all of which seem to be innovative and well thought-out
(rather than the huge prizes which usually go to make the rich richer and cause a huge media splash), he built a beautiful park near Stony Brook.Those are the only projects I happen to know about, partly because he doesn’t seem to care about getting publicity.

In contrast, his Renaissance Technologies co-founder (and now CEO Robert Mercer
is who we can thank for bringing us Ted Cruz, Breitbart, Bannon, Kellyanne, and Donald. The damage to math/physics in particular, education in general (not to mention 1000 other things) caused by the latter may well outweigh all the good done
by our guy… But who knows? we shall see….

15. **Bill**
November 27, 2016

Special presenter in the math category at Breakthrough Prize Ceremony, https://breakthroughprize.org/News/33 , seems to indicate that the prize will go to a number theorist. Could it be Andrew Wiles, or Yitang Zhang?

16. **anon**
November 27, 2016

I don’t think that having Jeremy Irons as a special presenter necessarily tells anything. I would have been surprised if they didn’t have any actors from The Man Knew Infinity present, no matter who gets the prize.

17. **Marco Renzi**
November 29, 2016

Gross claims that the Higgs could have a substructure. Is there any hint that the Higgs has non-zero size?

Why is looking for substructure f the Higgs a reason to build a collider, whereas looking for substructure of the electron is not?

18. **Peter Woit**
November 29, 2016

Marco Renzi,

There are some reasons to believe the Higgs may not be an elementary particle like others. For example, the Higgs phenomenon is quite analogous to what happens in superconductivity, and there the analog of the Higgs field is a composite one. Also, unlike other elementary particles, the Higgs has self interactions not due to gauge interactions. At this point these self-interactions have not been observed, and doing so would be one goal of a 100 TeV collider.

Electrons are much simpler and much better understood, with purely gauge interactions (+coupling to the Higgs). Their short distance behavior has been measured at LEP to be that expected of an elementary particle down to very short distances. A new collider would likely have a first stage involving an electron positron machine of higher energy than LEP. This would check for substructure to even shorter distances than LEP, but since, unlike the Higgs, the electron is so well understood, it seems very likely that we know how this will turn out.

19. **My MilkShake**
    November 29, 2016

    Hi Peter, I ran across this fascinating article that you will like:

    http://phys.org/news/2016-11-quantum-physics-factor.html

    … will it turn out that one can prove the Riemann hypothesis using techniques from quantum mechanics?…

    December 1, 2016

    I saw this intriguing tweet from Peter Koppenberg via Jester, but I haven't heard anything else. Any ideas on the significance of this possible finding?

21. **Anon**
    December 3, 2016

    The Simons Foundation has recently joined the CMS experiment. I'm not sure if this is directly the institute mentioned in the NYT article, but it seems likely.

Breakthrough Prizes 2017

December 4, 2016
Categories: Uncategorized

The 2017 Breakthrough Prizes have just been announced, here are the winners and a few comments. Note that I'm leaving the usual singing of praise of the many virtues of the laureates to others, since there should soon be a lot of such stories appearing. Instead I'll concentrate on issues that aren't getting as much attention.

Already announced back in May, there is a special Breakthrough Prize for the LIGO collaboration: \$1 million to be split by Drever, Thorne and Weiss, \$2 million to be split by the other 1012 members of the LIGO collaboration. Quite likely Drever, Thorne and Weiss will get the Nobel Prize next year (the LIGO result was published too late for consideration this year). A very good thing about the Breakthrough Prize though is that it is given to the entire collaboration, with awards going to every one. They have done similar things in the past, with awards to the LHC experiments, to neutrino experiments and to the accelerating universe supernova experiments.

The Nobel Prize in Physics and most other such prizes are never awarded to a group, just (at most three) individuals. In an era of large scientific collaborations this isn't fair, with all the recognition and prize money going to some small set of people, nothing to anyone else. I'm glad to see that, for these experimental prizes, the Breakthrough Prize has been following a different model.

The 2017 \$3 million Breakthrough Prize in mathematics goes to Jean Bourgain of the Institute for Advanced Study in Princeton. I'm not particularly familiar with his work, you'll have to read about it elsewhere. He is a well-known figure in the math community, already a recipient of many prizes including the Fields Medal, Shaw and Crafoord prizes.

I've never been convinced that this mathematics $3 million prize is a good idea, since it typically goes to someone like Bourgain who, besides being an essentially randomly chosen lucky winner from a sizable pool of similarly distinguished mathematicians, already has prize money and a very well paid position with minimal responsibilities. This isn't going to help him do better mathematics. A much better way to spend the money would be on endowing new permanent academic positions in mathematics, allowing more talented young people to have a career in mathematical research.

The philosophy behind the Breakthrough Prizes, very visible in the glitzy award ceremony (you can watch it on the National Geographic channel this evening, 10pm EST), is that scientists don't get the kind of fame and stardom they deserve, so Milner and Zuckerberg are going to help fix this. What motivates good mathematics though is something very different, and bringing to mathematics more of the Hollywood star system is not going to improve mathematics research. In recent decades much of US society has moved to a brutal winner-take-all system. While our Silicon Valley overlords have flourished under this, I don't think their bringing more of it to scientific research is a good idea.

While one can argue that the huge checks to mathematicians don't have any particular negative effect, the situation in theoretical physics is quite different. Since the original laureates chosen by Milner, the yearly prizes that have gone to theorists (as opposed to the experimental prizes mentioned above) have all gone to string theorists (there was also a special prize given to Hawking). First there was Polyakov, then Green and Schwarz, and this year the $3 million Breakthrough Prize in Physics goes to three more string theorists: Joe Polchinski, Andy Strominger, and Cumrun Vafa.

In the case of string theory, I don't think one can seriously argue that the field suffers from a lack of public attention. Mountains of hype about string theory have been produced in the last 32 years, seriously damaging the field of theoretical physics. This year's prize adds to that mountain, with hype-ridden ~~citations~~ backing the glitzy ceremony and million dollar checks. The language tries to turn physics research Hollywood: for instance, relativity and quantum theory are "the two superstar theories of modern physics".

Perhaps the worst aspect of these prizes and ~~citations~~ is that they often hype and reward failed theoretical ideas: if your ideas work maybe you'll get part of a \$1 million Nobel Prize, but if they fail, as long as they're about string theory, you'll get part of a \$3 million Breakthrough Prize. The ~~citation~~ for Strominger includes this about string theory:

> Andrew Strominger played a major role in its emergence when he showed that it not only reconciles quantum mechanics with gravity, but can also contains within it the other observed particles and forces.

This refers to Strominger's early work on Calabi-Yau compactifications, while not mentioning that this idea has never worked out.

These prizes are often awarded for ideas about the black hole information paradox, independent of whether these ideas work. Maldacena's citation from 2012 tells us that he got the award partly for "resolving the black hole information paradox", and the Strominger ~~citation~~ tells us that "His work hints at a solution to the famous 'black hole information paradox'". Polchinski is rewarded for a

> big idea, deriving from the principles of quantum mechanics: 'firewalls' –blizzards of high-energy particles around black holes. The existence of firewalls would signal a fault line in the foundations of physics: at least one of the two superstar theories of modern physics – relativity theory and quantum theory – would have to be incomplete at a fundamental level.

Anyone reading this is unlikely to figure out that the significance of Polchinski's "big idea" is that it purports to show that the solution to the paradox supposedly given by Maldacena actually doesn't work (not surprising, since it was never more than a speculation). If you're a string theorist, you don't actually need to solve a problem to get a prize: speculation about what the solution to a problem might be is good enough, as is finding problems with the speculations of other string theorists. This sort of thing does nothing to improve the difficult situation of current theoretical physics, quite the opposite.

Tomorrow there will be a symposium at UCSF featuring 15 minute "TED-style" talks giving "pragmatic versions" of what could be done during the next ten years. For string theory, the blurb for the talk or talks is

> Medium-term goals of string theory, from resolving the paradoxes of black holes to estimating the lifetime of the universe.

After a cycle of two prizes for resolving the information paradox and then unresolving it, I suppose it's a reasonable goal for string theorists to go through another cycle or so during the next ten years. The idea of using string theory to "estimat the lifetime of the universe" anytime soon goes beyond any of the usual hype, so we'll have to see what that's about tomorrow.

Update: Smaller \$100,000 "New Horizons" prizes, some split in various ways, went to 6 theoretical physicists (Asimina Arvanitaki, Peter Graham, Surjeet Rajendran, Simone Gombi, Xi Yin and Frans Pretorius) and 4 mathematicians (Mohammed Abouzaid, Hugo Duminil-Copin, Ben Elias and Geordie Williamson). Congratulations to all, especially to the Columbia contingent (Mohammed is a faculty member now, Ben was a grad student here, and TA one year for my representation theory course).

Update: Some of the language quoted above as part of the citations for the string theory awards was actually in a separate section of materials distributed to the press called "Contributions", which gave more specifics of what the award was being made for. I've changed the wording above to more accurately reflect this.

Update: Just watched the Breakthrough Prize ceremony on TV. Very nice short portrait of Jean Bourgain and his work, and remarks by him. The string theorists were right at the end, and the DVR cut off in the middle of a clip of outrageous hype from them (I guess the ceremony went slightly longer than scheduled).

Update: Nature has coverage of the prizes here, emphasizing the award to Polchinski for firewalls, with some justification from Milner.

Update: Livestream of the symposium is here. Polchinski and Strominger will be talking about black hole information paradox/string theory, Vafa will describe "a research program for putting rigorous bounds on the lifetime of our universe, by studying the range of possibilities permitted by the laws of string theory."

Comments

1. **anon**
   December 4, 2016

   A nice detail that shows how much Breakthrough Prize ceremony really is about scientists is that National Geographic Channel managed to misspell Vafa's first name as 'Comrum' in its tweets.

2. **Jeff M**
   December 4, 2016

   Back when I was a young mathematician I used to tell people I was glad there wasn't a Nobel in math, since the Nobel's only harmed the sciences. The Breakthrough prizes are of course much worse. Terrible use of the money, all around.

3. **CIP**
   December 4, 2016

   Leo Szilard wrote a story in which a guy who was thawed out after many years frozen, finding, himself now immensely rich, pondered the problem of how to spend it. He decided that he wanted to slow down scientific progress, and concluded that the best way would be to fund a bunch of scientific prizes that would get all the promising scientists chasing them. I think the story appeared in his book, The Voice of the Dolphins.

4. **David Roberts**
   December 4, 2016

   I wonder if Bourgain will donate his prize money to the Breakout graduate fellowships?

5. **Bee**
   December 5, 2016

   Great, then when do I get my prize for showing that the firewall argument is wrong? I mean, I feel like I'm starting to sound like one of the cranks in my inbox. It's demonstrably a wrong derivation. The four assumptions they claim are inconsistent are not inconsistent. It's an unnecessary fifth assumption, hidden in the text, that makes them inconsistent. It's mathematically provably wrong. I even have a counterexample. And it's all published. Hello, hello, anybody? We can stop talking about it.

   (This isn't to say that Joe doesn't deserve a prize, but maybe the firewall wasn't exactly the thing to highlight.)

   Leaving aside my puzzlement about the world of theoretical high energy physics, I've heard various rumors that LIGO was nominated in time for the Nobel last year. Not sure what to conclude from that if true.

6. **Jess Riedel**
   December 5, 2016

   What is the point of dividing an award up among 1k people? Each one gets $2k and…something on their CV which is immediately worthless by dilution? It resembles a useless cum laude distinction.

   Prizes are meant to give folks status, but status is zero sum. Yes, it may not make sense to give an award to the leaders of a huge collaboration if those leaders did nothing extraordinary. But why not simply refrain from giving an award out if no one did anything extraordinary?

   The only explanation I can think of is that such awards would function as a way, not to incentive physicists, but to highlight to outsiders the best achievements by physicists as a group.

7. **Manfred Requardt**
   December 5, 2016

   I also showed that the firewall argument is wrong.

8. **M**
   December 5, 2016

   The possibility of adding D-branes here and there gave the final shot to the hope of getting predictions from string theory. This was an important development that deserves a prize.

9. **anon**
   December 5, 2016

   Regarding LIGO and Nobel, I have also heard that the three LIGO pioneers were nominated. It would be strange if they hadn't been, there are a lot of people who can nominate and LIGO is a big collaboration; I would think that some possible nominators already knew about the coming announcement before the deadline.

   It's hard to imagine LIGO not getting a Nobel. Maybe the committee just likes to avoid the appearance that they consider nominations based on rumours or inside information, so they want the results to have been public before the nomination deadline.

10. **Peter Woit**
    December 5, 2016

    Jess,
    I'm sure the LIGO people do each appreciate the $2000, and the small amount of personal recognition. What's wrong with it?

    To the extent that you're right that status is zero-sum, that's part of the problem with giving huge awards to a couple people, nothing to everyone else, what I was trying to point to by calling this a "winner take all" reward system. By deciding to inject these huge awards into the status system, Milner and Zuckerberg are not just making a few people "stars", but simultaneously lowering the status of everyone else (while at least making some effort to ameliorate the situation in the case of experimental awards).

11. **Peter Woit**
    December 5, 2016

    Bee,
    Thanks, I should have at least pointed out that there's no consensus about what this argument even means. About the huge check though, I'm afraid I have to point out to you and Requardt that you're not string theorists, and thus ineligible.

12. **Peter Woit**
    December 5, 2016

    M,

    Yes, you've got it right. In his acceptance remarks

    https://breakthroughprize.org/Laureates/1/L3795

    Polchinski lists "D-branes, the string landscape, and the black hole firewall" as his contributions to the subject, and states that a unified theory is the main motivation. He explains that since the landscape shows things are "veiled by the randomness of the Multiverse", that's why you can't make predictions.

    Interestingly, the people who awarded him the prize don't seem to agree. While he thinks he deserves the prize because of the landscape, that work is not mentioned at all in the details about his "Contributions" given to the press.

13. **Bill**
    December 5, 2016

    Wow, Breakthrough Prize in Science Fiction?

    Sad to see math prize becoming another lifetime achievement award. Although Bourgain has been very active in recent years, the award is clearly not for some particular work. Obviously, previous winners do not have the courage to pick among recent real breakthroughs.

14. **masmadera**
    December 5, 2016

    Status is a zero-sum game within the community. The award however focuses on outside-community recognition and in this regard I believe that it is working moderately well. The prize is almost as well advertised as a Nobel. The winner-take-it-all is very widespread in American mentality. If this is a necessary/sufficient lure to attract young bright students that otherwise would pursue other careers I don't know, but the prize is a good addition in that it seeks to provide celebrity status to working scientists, as opposed to the so many science communicators and popularizers that already have this status. Hence, no wonder that many winners (particularly physicists) share in some regards the hype- or over-simplification characteristics of their fellow "science" (communicators) stars.

15. **Bill**
    December 5, 2016

    The idea of attracting bright young students into science is a bit ridiculous. This and all other awards do more damage at much later stage by disrupting natural development of ideas. People get awards, get positions at top universities, attract better Ph.D. students and postdocs, while publishing mediocre papers in top journals, etc. This is how some areas get overemphasized and overdeveloped, while some perhaps more interesting long term research gets marginalized.

16. **Marco**
    December 5, 2016

    As much as I appreciated the idea of a prize given to all members of a collaborations (and I know for a fact that the colleagues of my lab working on LIGO/VIRGO do appreciate both the money and the recognition), I'm afraid I have to correct you. There was no award given to the LHC experiment collaborations in a way even close to what is done in 2016 with LIGO/VIRGO. The 2013 Special Breakthrough Prize was directly given to a few individuals (current and former ATLAS and CMS Spokespersons) but not to the collaboration members (then some of our beloved spokespersons decided to use that money to fund a scholarship so that the collaboration "at large" can profit, but this is another – enlightening – story).

17. **Peter Woit**
    December 5, 2016

    Marco,
    Thanks. I had forgotten that it was only for the two experimental prizes after the LHC one that any money/recognition went to the bulk of the collaborations.

18. **anon**
    December 5, 2016

    Some of the criticism is getting a bit unreasonable. I agree that there would be better ways to support science with the millions they are spending, but it seems that some people are claiming that these awards are the worst threats to science.

    Bill, I'm getting curious: who would've been a (much) better recipient of the mathematics award than Bourgain?

19. **Peter Woit**
    December 5, 2016

    anon,
    I'd rather not host a discussion here of the relative merits of all research mathematicians. I think Bill was just making a comment about an interesting question: what is the criterion for choosing a math prize winner? The description of the prize just says "rewards significant discoveries" making it sound like it is aimed at rewarding specific results ("breakthroughs") and that fits with last year's award to Ian Agol, but the Bourgain prize looked more like an award for a body of work. So, still unclear what their plan is…

20. **Bill**
    December 5, 2016

    Bourgain is not a bad choice, his (even recent) research is clearly at the absolutely highest level. The best choice would be not to have the award. Second option would be to give instead 10 Horizon prizes worth 300K each. If you must have current format — Yitang Zhang, Scholze, Hacon-McKernan, … many many more come to mind.

21. **anon**
December 5, 2016

For what it's worth, I think that if a very big award must be given to someone, a life-time award to a senior figure is less damaging than rewarding some new breakthrough. For new breakthroughs I think smaller awards, like the "New Horizons" prizes make more sense.

22. **anon**
December 5, 2016

I didn't notice Bill's last comment; I actually agree with what he says.

23. **masmadera**
December 5, 2016

As much as attracting young bright students into science might feel ridiculous to someone (!?) this is one of the main purposes of popularizing science and the role of beloved science programs in TV in luring the attention of bright (or ambitious) kids is well attested. With regards to "People get awards, get positions at top universities, attract better Ph.D. students and postdocs, while publishing mediocre papers in top journals, etc." I think that Bill has the order totally reversed, at least with respect to the Breakthrough Prizes. I didn't know that Joe Polchinski, Andy Strominger, and Cumrun Vafa were in need of a position in a top university.

24. **Lars**
December 5, 2016

"The Breakthrough"

The Breakthrough Prize
Has broken through
It's on the rise
And in the view

Though Nobel tolls
For just a few
The Breakthrough prize
Awards a crew

25. **Lars**
December 5, 2016

Though Nobel tolls
For just a few
The Breakthrough doles
To quite a crew

26. **Bill**
December 5, 2016

masmadera, I wasn't talking about these life time achievement awards. And when some field gets hyped, even lesser people end up at top universities. But actually I agree with you — prizes at every level often go to people and students of people at top universities because of connections.

I am kind of glad they gave it to string theorists again. The prize is discredited before it had a chance to take off the ground.

27. **Michael Hutchings**
December 5, 2016

It would be nice if they had a million dollar prize for people who haven't previously won some other million dollar prize.

28. **Gregor Samsa**
December 5, 2016

anon,
better recipients in mathematics would have been Atiyah, Deligne, Manin, Milnor, Suslin, Tits or Serre. (And as two of my candidates show, my choice is not dictated by Bourgain's Belgianness…)

29. **David Appell**
December 5, 2016

Jess Riedel says:
"What is the point of dividing an award up among 1k people? Each one gets $2k…."

$2k isn't trivial, for graduate students and postdocs.

Plus, they get to put it on their resume.

30. **Jess Riedel**
December 5, 2016

David Appel: Building LIGO was a multi-decade project, so $2k is really like $100/year. Insofar as graduate students are getting $2k, that just speaks against awarding everyone in the collaboration equally; it's like a participation award, or the "cum laude" on a Harvard degree. Lots of people get it, so it's mostly ignored.

Peter Woit: I think it would take us too far afield to argue about the foundational purpose of awards, on which we probably disagree. But it seems to me the much important criticism here is what sorts of accomplishments the awards are recognizing, rather than the inequality in award amounts.

31. **Mike**
December 6, 2016

Its an interesting general question how to recognize scientific achievement in a large collaboration. The spokespeople are often too narrow a set and are not always the ones who made crucial technical breakthroughs. On the other hand, not all 1k+ members made equal contributions. This problem is only going to get worse as science becomes more of a team effort so maybe one has to rethink some basic assumptions. Perhaps some kind of two-tier authorship structure is possible, although that of course can also lead to conflicts.

32. **anon**
December 6, 2016

"The prize is discredited before it had a chance to take off the ground."

So accurate. With both the senior and the junior prizes (in physics), it is easy to trace very short intellectual paths to a very small number of people at the Institute for Advanced Study in Princeton.

33. **Conrad**
December 6, 2016

Who has recently (late 2015!) proved the fairly famous outstanding Vinogradov main Conjecture from the 30's? (while it's fairly technical, the gist of it is that a very general of set of Diophantine equations have the expected bounds on the number of solutions – expected by the same heuristic randomness arguments "integers do not conspire subtly" that underlie all the main conjectures in NT – integers obviously conspire since if n is even positive, n+2 cannot be prime but the heuristic says that such are essentially only conspiracies around)

Clearly qualifies for a recent breakthrough I think

34. **Bill**
December 6, 2016

Why Guth and Demeter are not getting part of this award then?

35. **P = NP (Peace = Nobel Prize)**
December 6, 2016

As a Nobel Prize winner (Peace Prize 2012, 2.5*10^-9 part) I certainly support awards distributed to groups. I have not yet received my portion of the award money, I'm sorry to report.

On a more serious note, I do, however, not agree that scientific prizes should be used to lure young people into attempting a career in science. It doesn't seem quite ethical.

36. **Lars**
December 6, 2016

"What is the point of dividing an award up among 1k people? Each one gets $2k…."

If any of these folks thinks that $2K is a mere pittance, I would be happy to take said pittance off their hands. I'll even pay the taxes on it.

They can leave their name and contact information on this blog and I will get in touch.

37. **Low Math, Meekly Interacting**
December 6, 2016

In the (albeit ethically challenged) for-profit world, when the company does well, they often give everyone some kind of a bonus. Not everyone deserves to get anything. Almost no one who deserves something gets a bonus that is commensurate with their contribution, high or low. People complain about this bitterly. If I know a single person who has returned the money or donated it all publicly to a worthy cause in protest, I will eat an earthworm, raw and without condiments.

Something typically is better than nothing. Token recognition isn't worthless, however irksome the inequities of real life. I think it's great to put more pressure on the Prizes to do a better job of recognizing big teams than they're doing, but I think that aspect of the Breakthrough Prize is a big step in the right direction.

38. **anon**
December 6, 2016

I think you guys here are a bit deluded concerning the fundamental physics prize. The people who won these awards this year and in the past (both junior and senior) are highly respected for their fundamental contributions and the intellectual fertility they have brought to the fields of cond-mat, hep-th, hep-ph, astro-ph and gr-qc. They are known and respected by almost everyone active in the field, and these are tens of thousands of people, surely not all of them with direct links to Princeton. If you don't believe this you can try to setup some opinion polls. And this is what matters. You can't argue that there is conspiracy which involves 10000 people. It's true that there are many other deserving people who have not yet gotten the prize but people who got are truly top (and hopefully other deserving people will get their prizes in the future).

39. **Peter Woit**
December 6, 2016

anon,
I think if you poll groups of physicists and ask them whether they would choose six string theorists for the first three $3 million prizes in theoretical fundamental physics, you're only going to get a non-zero number in agreement if you are polling a string theory group (or, maybe a group of initial award winners chosen by Milner and dominated by string theorists…).

40. **Bill**
December 6, 2016

Q1: Do the winners of the 2017 Breakthrough Prize in Fundamental Physics, interpreted as a lifetime achievement award, deserve the prize as much as any other physicist you can think of (excluding previous Nobel prize laureates)? Vote here:

http://vote.pollcode.com/75474954

Q2: Do the winners of the 2017 Breakthrough Prize in Fundamental Physics, interpreted as an award for work in the last 10-15 years, deserve the prize as much as any other physicist you can think of? Vote here:

http://vote.pollcode.com/64254698

41. **anon**
December 6, 2016

Bill: Your poll in incorrect, on two counts. First, you must poll the experts in fundamental physics, which are people regularly publishing in cond-mat, hep-th, hep-ph, astro-ph and gr-qc. Amateurs are excluded, sorry. Second, it might be that every one of us has a personal hero who we would put higher than this year's prize winners. This proves nothing, as these sets of personal heroes might be highly nonoverlapping. I only claimed that this years winners are highly respected and it's totally non-controversial in the community that they got it – this is what needs to be polled.

42. **anon**
December 6, 2016

Peter: it just so happens that this prize is called "fundamental physics prize", and that string theory is grappling with fundamental physics questions. It would be surprising if you found 6 atmospheric scientists among the winners, but 6 people who worked on string theory is OK. Also you can't dismiss as 'string theorists' people like Witten or Polyakov or Maldacena who command all of theoretical physicists. Working from time to time on string theory is their choice, just like at other times they can be seen working on issues in condensed matter physics or QFT or cosmology or what not. There are also many people in the group of winners who have nothing to do with string theory nor IAS, certainly more than half by now. Since this years winners were presumably chosen by majority voting, you can't dismiss it as Princeton people who vote for their friends.

43. **Jeff M**
December 6, 2016

I am really curious what the "fundamental contribution" are that were made by the winners? What was the last experimentally verified prediction in HEP? The top quark? In 1973? The winners this year probably weren't even in high school then. Sure, they spit out papers, but what from those paper is established physics? It's certainly possible something done by one of the winners might eventually become real physics, but personally I'm willing to bet very little does. Maybe nothing. I have a feeling 100 years from now they will all be a footnote, sort of like all the theorists who spent decades working on the aether.

44. **Peter Woit**
December 6, 2016

anon,
The first nine winners were chosen by Milner personally, and given his own lack of expertise he made an understandable choice to choose a lot of IAS people. The six theorists chosen since then (Polyakov, Green, Schwarz, Polchinski, Strominger) are not so much Princeton-centric (Princeton now has a shortage of string theorists without million-dollar checks), but are uniformly strongly self-identified string theorists. I don't think polling is needed to know that it's an absurd claim that it's "totally non-controversial in the community" of people in fields like hep-ph, cond-math, astro-ph and gr-qc that choosing only string theorists so far makes sense.

I don't know what the voting system being used is, but obviously there now is only one very large homogeneous block amongst the people voting, and it looks like they've decided to vote for their own tribe. Put differently, for instance, among this large group I think there's at most one condensed matter theorist (Kitaev), so not surprising that condensed matter theorists are not being chosen.

Your conviction that well-known string theorists "command all of theoretical physics" and do the best work in fields like condensed matter and cosmology is one you might want to discuss with theorists in those fields to find out what they think.

45. **anon**
December 6, 2016

Dear Jeff M. May I ask you, are you are a practicing physicist, and in which field? I am, for example, a staff member of the CERN theoretical physics department. So I can presumably tell a valuable theoretical contribution from nonsense. Concerning your questions about verified predictions and when they were made. Inflation was developed in early 80's, Weinberg's discussion of nonzero cosmological constant was in 1987. MSW effect was first discussed in the 80's. There are tons of less dramatic predictions in HEP which are made and verified every day at LHC and other colliders.

46. **anon**
December 6, 2016

Correction: "command all of theoretical physicists"->"command all of theoretical physics" 🙂

47. **Johannes**
December 6, 2016

Peter,

when will the results of this year's LHC searches for supersymmetry be announced? Are there already rumors?

48. **Bill**
December 6, 2016

anon, that's why I included "close enough" option. If you have a personal hero but think that the winners are deserving and highly respected, vote close enough.

If the Fields Medal was almost always given to, let's say, algebraic geometers then it would have no credibility, although it would still be a much more reasonable situation than giving all fundamental physics prizes to string theorists. Give me an example of one great idea of Polchinski that is relevant in physics in some proven way, or at least some great theoretical calculation or technique that influenced other developments that are relevant in physics in some proven way? Or even genuinely influenced great developments in mathematics?

49. **Peter Woit**
December 6, 2016

Jeff M,

There's a case to be made that because of the lack of experimentally verified advances, you now need to be rewarding the best ones that are promising but not yet verified. I don't see though the justification for what the Breakthrough Prize people are sometimes doing, which is rewarding failed ideas, ones that are much less promising now than when they came out.

A very odd thing about these prizes, especially this year's physics prizes, is that there is no explanation publicly given of what the prizes are rewarding (just a meaningless hype phrase "transformative advances in quantum field theory, string theory, and quantum gravity"). The Nobel Prizes (and most others) come with a very detailed and carefully written extensive description of the work that is being rewarded by the prize, but there is nothing like that here. The press did receive before the announcement a document that described "Contributions" for each physicist. I quoted a bit of this, and I've seen some of it appear in places like the UCSB press release about Polchinski. But this material was very poorly written and hype-ridden, with no detail. This is an odd situation, I would have expected that part of the job of the committee choosing these people was to write up an explanation of why they were chosen.

50. **anon**
December 6, 2016

Bill: I'm not gonna vote because I don't want to see my vote drowned in the tons of amateurs frequenting this blog. Make another poll where the participants will have to testify, on honor, that you published say more than 10 papers in the above-mentioned arxiv categories over the course of your life.

I won't enter into a discussion of Polchinski's contributions because any blog discussion of this type will not do justice. But you can easily go to INSPIRE, look up the list of his papers, check out the better cited ones and you will see that many of them don't even have to do with string theory, but with various aspects of QFT.

51. **Peter Woit**
December 6, 2016

Johannes,
This is off-topic. Results should be announced in March at the Moriond conference. I've heard no rumors of any results indicating SUSY.

52. **anon**
December 6, 2016

This is anon replying to anon (just to clarify matters).

I did a quick count. Of the 22 junior winners in particle (excluding the 3 CMT people), I count 19 where (if you are in the subject and know the intellectual/social connections) it is easy to draw a short line to Princeton.

With the senior people, almost everyone who has won the prize has made significant, deep and lasting contributions to fundamental physics. But it's a narrow and impoverished view of fundamental physics that would weight prizes so heavily to string theory and allied topics (and I work on string theory, so I'm not anti- the subject).

The statements 'people who get these prizes are respected in the subject' and 'the prizes are part of a patronage network' can both be true (and are).

53. **anon**
December 6, 2016

Bill: for one example, look at Polchinski's work on effective field theory in condensed matter (for one example)

anon: being slightly mischievous, I am trying to think whether you are uniquely identifiable from being (a) a staff member at CERN-TH and (b) willing to list Weinberg's anthropic discussion of the cosmological constant as on a par with inflation and MSW

54. **Bill**
December 6, 2016

Why Phil Anderson didn't get the Breakthrough prize for Anderson-Higgs mechanism? Of course, we will quickly run out of such obvious examples, but I am sure there are many more good ones. Take this year's Nobel prize winners, for example.

In string theory, it seems that the rules are quite different from the rest of physics. If you have large enough theoretical toolbox to play with and a good imagination, you can keep proposing various "fundamental physics" ideas. There is no formula or mechanism to test in experiments or in simulations, or even for mathematicians to break their back with. You propose some paradox, and come up with many not necessarily compatible ways to "solve" it.

55. **Bill**
December 6, 2016

anon, if you give "Effective Field Theory" as an example, one can come up with a long list of people in condmat and related fields who are by an order of magnitude more deserving. This just proves my point.

56. **anon**
December 7, 2016

Bill: because no prize was given for the Higgs mechanism. Also: Anderson seems to be confused about the difference between the Higgs boson and the W-boson (see the discussion in his "Basic Notions…" book).

anon who replied to anon: I'm not sure how you counted. For the record I believe Hartnoll, Casini, Huerta, Ryu, Takayanagi, Flauger, Graham, Arvanitaki, Rajendran, Yin have no particular connection to Princeton. As a connection I count PhD, postdoc or a job. I don't count vague `intellectual connections' because this is not well defined, and if you start stretching it too far, we are all related to Eordos, to Hilbert, to Adam and Eve and perhaps even to Rovelli and Smolin in just a handful of steps. I might be wrong on one or two of the above winners, still, this makes it close to 50% total outsiders. Not bad at all, given that the rest 50% is also top and it would be unfair to exclude them just because they happened to do their PhD or one of their postdocs at top institutions as Princeton or IAS. I have to stress once again that the selection committee by now includes so many physicists from so many fields that string theorists and Princetonians do not hold a majority. Just nominate (many people complain but don't nominate) your top choices and hopefully they will be among next year's winners. And it's excluded you can identify me from the verified predictions I mentioned. At CERN-TH we are proud to be universalists.

57. **anon**
December 7, 2016

Bill : "There is no formula or mechanism to test in experiments or in simulations, or even for mathematicians to break their back with." There are tons of formulas that came out from string theory that mathematicians are breaking their back with now as we speak.

58. **anon**
December 7, 2016

tulpoeid: why boosted? If everyone hates this prize as much as the readership of this blog seems to suggest, then having been awarded it is going to be a handicap, not a boost, in the race for a Nobel. Surely the Swedish Royal Academy is going to side with you guys and will punish LIGO.

59. **anon**
December 7, 2016

Peter:
I did not say they do their "best" work in cond-mat or cosmology. But they do do very important work in those fields as well. Pity that you assume that I don't talk to people in those fields. Not only do I do, but I also regularly attend seminars and follow the literature on these subjects. It's a very rewarding experience and I recommend it to everyone. I hope you can say the same about yourself. Now, concerning QFT which was also on my list but which you dropped (is it because it does not fit your narrative?), some of the very best work of Polyakov, Witten, Maldacena is in QFT. They are as much field theorists as they are string theorists. Had they not written a single string theory paper, still they would have more than deserved the fundamental physics prize. It might be that from the point of view of this blog the moment you start thinking about strings, you get negative points which cancel even your previous achievements. But the community does not think the same.

60. **anon**
December 7, 2016

Just to be concrete. Here's a recent paper by Maldacena, Shenker and Stanford which is valued by cond-mat researchers as much as any other recent paper in that subject: http://arxiv.org/abs/1503.01409. Proof? It has been featured this month on http://www.condmatjournalclub.org, a site run by cond-mat researchers for cond-mat researchers.

61. **Peter Woit**
December 7, 2016

I've just resisted the temptation to respond to the flood of misinformation from anon at CERN-TH and urge everyone else to do so. This discussion with him has become an unenlightening waste of time so I'll cut it off. Other discussions with something new to say are encouraged.

62. **Hans.Neumaier**
December 7, 2016

In 1912, Nils Gustaf Dalén won the Nobel Prize in Physics "for his invention of automatic regulators for use in conjunction with gas accumulators for illuminating lighthouses and buoys". His predecessor was Wien (of Wien's law) and his successor was Kamerlingh Onnes (discovery of superconductivity). Fermi got the prize in 1938 for a mistaken publication – but deserved it. Also the Nobel Prize has strange sides.

But still, they are much less strange than the Breakthrough prize, where dozens of string theorists get prizes for a theory that predicts supersymmetry – which, as data show and Veltman writes, is "a figment of imagination". Yes, string theorists are influential, very much so. Nobody denies this. Not even Woit… But this influence does not make string theory correct or the prize deserved. We are back in times where influence (authority!) is valued more that experimental data. Didn't physicists fight for centuries against the misuse of authority and in favor of experiment?

63. **Bernhard**
December 8, 2016

"A very good thing about the Breakthrough Prize though is that it is given to the entire collaboration, with awards going to every one. "

Although they didn't do this with the special prize for the Higgs they gave to Gianotti and Incandela in 2012. Back then, they said the prize would be donated to support a grant or something like that but in the end they decided it was best to keep in their pockets, as far as I know.

64. **Bill**
December 8, 2016

Bernard, wasn't it given to 7 or 8 people, not 2? So only ~375K per person, although it's a shame if they kept it in their pockets…

65. **Bernhard**
December 8, 2016

Bill,

The special prize due the Higgs was shared by F. Gianotti, J. Incandela, P. Jenni, T. Virdee, G. Tonelli and L. Evans. As far as I remember, this was a 3 million prize shared among these people, so actually 500k.

Whatever the sum though , I think it was substantial and shameful that they did not return this money back to young people at their collaborations, even though some like Gianotti, claimed they would.

It's unjust enrichment if you ask me.

66. **Bill**
December 8, 2016

Bernard, is it possible they used the money to to fund some research activities, students, postdocs, etc., and this information is just not on the internet?

67. **Peter Woit**
December 8, 2016

Bernhard and Bill,
It looks like there was some use of the prize money for scholarships, see
https://breakthroughprize.org/News/5
and
https://breakthroughprize.org/News/10
about an ATLAS PhD Scholarship program (Jenni and Gianotti), a CMS Fundamental Physics Scholarship (Incandela) and training for African high school teachers (Virdee). There's also mention that

"Virdee is working on, along with the other CMS recipients of the FPP, is setting up a series of prizes to recognize and assist young people within the CMS collaboration who have made significant contributions."

I don't know if that ever happened or if anything similar was planned for ATLAS.

68. **Peter Woit**

December 8, 2016

More about the CMS part of this here, which includes a 20,000 franc scholarship to pay for someone to come to CERN for a year.
http://cms.web.cern.ch/news/cms-fps-new-scholarship-support-young-scientists

69. **Bernhard**
December 8, 2016

Peter,

thanks. I looked for it before (long time ago) on their site and didn't find it . It's good to see that at least part of the prize was put to good use by at least some of the contenders.

70. **Rob Meyer**
December 26, 2016

Anomaly!

December 6, 2016
Categories: Book Reviews

Tommaso Dorigo's new book [*Anomaly! Collider Physics and the Quest for New Phenomena at Fermilab*]() has just become available. I highly recommend it to anyone with an interest in high energy physics who wants some insight into how collider experiments are done. Dorigo is a well-known blogger, with the [best (as well as most entertaining) blog]() there is about the experimental side of high energy physics. If you're not following his blogging, you should be.

The nominal topic of the book is research conducted at the Tevatron by the CDF experiment during the 80s and 90s, into the early 2000s. Some of the specific well-known CDF results discussed in detail include measurement of the Z mass and the discovery of the top quark. The material about the top quark discovery comes closest to the kind of thing you find in other books. It's a very well-done insider's account of the story of an important discovery. I don't know of a better place to read about the top quark search and how it finally succeeded.

One of the most unusual aspects of the book, in evidence in the top quark section and throughout the rest, is that it goes much deeper into an explanation of how collider experiment physics analyses are actually done than is usual in a popular or semi-popular book. Besides the insider's local color and insights into the personalities involved, there's quite a bit of discussion of the technical issues of the subject. This is a subject involving thorny issues of how best to reconstruct the properties of particles coming out of collisions, and finding clever new ways to deal with these while avoiding subtle pitfalls is a central problem, one outsiders normally don't get to hear about.

The other unusual aspect of the book is that it doesn't just discuss success stories of striking discoveries (of which there hasn't been much between the top and the much later Higgs discovery at the LHC). One of the main activities of the field has been the search for "anomalies", experimental results that disagree with the Standard Model and point to new physics. The problem is that finding anomalies is common, but they almost certainly will turn out to be due to some problem with the experiment or its analysis (such problems are always much more likely than revolutionary new physics).

One of the stories of an anomaly described extensively is that of an excess of high transverse energy jets, something that one might expect to see if quarks had some substructure ("preons"). Here the problem turned out to have a lot to do not with the experimental result, but with the theoretical modeling of what to expect from QCD. Another example is the story of "superjets", events involving a W and 2 or 3 jets, with unusual properties.

For the "superjets" and for other anomalies, a favorite explanation was to invoke supersymmetry, since supersymmetric models predict a large range of different kinds of new particles, and one might hope that any anomaly is due to one of them. Dorigo has a few stories about theorists I hadn't heard, in particular that of a fall 1995 letter signed by many prominent theorists (except Howard Georgi, who refused to sign). Despite ongoing efforts to look for superpartners, all of which had been unsuccessful, the feeling of the theorists was that the Fermilab experimenters weren't trying hard enough. The letter was sent to the Fermilab director as well as the CDF and DZERO spokespersons. It explained what a great idea supersymmetry was, and ended with

> We, the undersigned, believe that Fermilab has unique detection possibilites for supersymmetry, and urge you to direct your laboratory's efforts in that direction, and ask the leaders of the collider detector collaborations to intensify their search for massive superpartners.

For more than two decades now, such searches for superpartners have been one of the dominant activities of collider experiments, with well-known negative results.

Finally, another important and unusual theme that runs through the book is the question of how to statistically characterize the significance of an anomaly. This is a topic where Dorigo is very much an expert, recently heading the CMS Statistics Committee.

Anomaly! is both a great tale of how science is really done, and an unusually insightful exploration of the crucial question of how one evaluates the significance of hints of new experimental discoveries. This question is of central importance now as the LHC gathers and analyzes data in a previously unexplored energy range. There are undoubtedly anomalies galore being studied by the LHC scientists, almost all of which will never be heard of by the public, as the experiments cautiously work to eliminate every possible conventional physics explanation for the anomaly. The 750 GeV diphoton bump of the past year is one example of an anomaly that made it out to a public announcement, with its disappearance in this year's data making clear why the experiments are so cautious. You can't find out about these ongoing stories, perhaps for good reason, due to the policies of how collider experiments are run, but now you can buy a copy of *Anomaly!* and at least read about how things played out in the previous generation of such experiments. This background should be helpful to make sense of what is going on if and when (March?), the next LHC anomaly gets reported.

Comments

1. **David Appell**
   December 6, 2016

   Peter, thanks for noting this. But the price, yikes! $50 for a paperback on Amazon…. Will need to get it through my library.

2. **tommaso dorigo**
   December 7, 2016

   Many thanks Peter for this excellent review!

   To David Appell above: if you buy the book through World Scientific (at http://www.worldscientific.com/worldscibooks/10.1142/q0032), by quoting the code WSSLPS20 you get a reduction of 20% on the cover price until December 31st.

   Best,
   T.

3. **Mike Hall**
   December 7, 2016

   Tomamaso, does the discount apply in the UK (where worldscientific.com's paperback price on its website is the same as Amazon's, at £40, and thus practically equal to the USA's $50)?

   Currently, the cheapest easily findable price, as is often the case, seems to be on Amazon marketplace

4. **tommaso dorigo**
   December 7, 2016

   Dear Mike, I wouldn't know. Perhaps the best is currently CERN, where the book is offered for 40 swiss francs.

Best,
T.

5. **Alex Karev**
December 8, 2016

David Appell, using WS16XMAS35 discount code on World Scientific website you will get 35% off (also until December 31)

HEP Theory Letter

December 8, 2016
Categories: Uncategorized

A couple weeks ago a large group of US HEP theorists wrote a letter to the DOE High Energy Physics Advisory Panel (HEPAP) (available at page 7 here) expressing alarm at trends in DOE funding of HEP theory, ending with

> We formally request that a subpanel of HEPAP be formed to investigate and better understand this damaging trend and to make recommendations to address its consequences and restore a thriving Theory program, and we strongly urge that HEPAP support measure to rebuild and maintain the prominent and world-leading standing of US High Energy Theoretical Physics.

The letter claims that since 2011 the overall DOE HEP Theory program has been cut by 17%, with the university component of this cut by 30%. It also claims that 25% of DOE-supported university theorists have had their funding cut off in the last four years, with the number of postdocs going down by about 30%.

At last week's HEPAP meeting there was a discussion of this, but I don't know what was decided. Some numbers presented there indicated that from FY2013-2015. the DOE theory budget went from $51.2 million to $49.32 million. The net number of funded PIs was reduced by more than 10% (25 out of about 230), with 52 PIs dropped, 27 new ones coming in. The conclusion of that presentation was that "The theory program in its current state cannot be described as thriving." The emphasis in the letter and this presentation on "thriving" is a reference to one of the P5 recommendations that is supposed to be governing how the DOE HEP budget is allocated:

> The U.S. has leadership in diverse areas of theoretical research in particle physics. A thriving theory program is essential for both identifying new directions for the field and supporting the current experimental program.

The most detailed recent information I can find about the DOE HEP theory budget is in this presentation from August. It shows a decline from FY10 to FY16 from $53.09 million to $46.69 million, with most of this in the component going to university groups, which went from $27.25 million to $21.765 million. The current number of postdocs supported is listed as about 125 (100 at universities, 25 at the labs), the number of graduate students is about 120.

Concern about this decrease in funding first became public two and a half years ago (see my blog post here) with Sean Carroll's blog post describing a "calamity". Various HEPAP presentations warned physicists about the dangers of public complaints and these died down for a while, but the continuing cuts to the university component of theory funding seem to have led to the decision to send this new letter.

An odd part of this story is that it's unclear why this decision to reduce DOE HEP theory university funding significantly was made. It's true that the overall DOE HEP budget has been cut over the same period (from $810.5 million in FY10 to $795 million in FY16) but unknown why the university theory component was cut 20% over this period while the overall cut was only 2%. Note that none of these numbers are adjusted for inflation.

It would be very interesting to hear comments from anyone who knows more about what is going on here. The usual generic comments that government spending is bad will be deleted. Keep in mind that the amount of money at issue here is (2.7% of the HEP budget, .00058% of the total federal budget) very small on the scale of government funding of science, and now ever small on the scale of private science funding (the Simons Foundation alone last year gave out $233 million in grants).

Update: A full copy of the letter with all signatures is here. An explanation of where the numbers in the letter come from is here.

Comments

1. **Peter Shor**
   December 8, 2016

   I assume you mean the overall cut was 2% rather than $2.

2. **Peter Woit**
   December 8, 2016

   Peter Shor,
   Thanks. Fixed.

3. **NoGo**
   December 8, 2016

   Might it be "because strings"? — all the "over-selling and under-delivering" by String theorists caused "powers that be" to loose their interest/trust in HEP theorists in general? Or such things are below the radar of the government?
   I have no idea how such decisions are made, and curious.

4. **Peter Woit**
   December 8, 2016

   NoGo,
   Most DOE grants aren't going to string theory, but to other subfields, and I haven't seen any evidence that string theory grants are being cut more than non-string theory grants. One could equally well speculate that it is phenomenology that it is the problem: with the LHC finding nothing to vindicate any BSM phenomenology, maybe someone has decided that less funding for that area is needed.

   One can find many plausible speculative reasons for why someone might think it a good idea to cut theory funding, but I've seen no evidence for any of them. Perhaps even the authors of the letter are in the dark (note that they don't seem to be responding to a particular argument against their field), with one goal of the letter to find out why this has happened.

5. **John**
   December 8, 2016

   I know you like deleting comments from me but I'll try one more time to answer your question with the facts even if you don't like hearing them.

   The reason for the change is due to sequestration. Instead of individual appropriation bills the government was funded with CR's (continuing resolutions). Now the sequestration deal required additional cuts. For FY 2013 there was a reduction that was going to impact the LCLS II upgrade project along with some other large planned programs.

Congress no longer controlled the allocation process but did agree to shift funds to make sure the LCLS II project would continue. They took the funds from staffing related funds.

Even last year on November 2nd 2016 a deal was reached by Obama and Congress that would modify the Budget Control Act of 2011. It raised funds for FY 2016 and this is why the overall dollars are not that large. DOE got a decent increase with this agreement. However, the agreement went to projects as it was only going to last for one year and therefore would not make sense to increase funding for staffing.

So the answer to your question comes down to all the deals that were made by the administration and Congress in dealing with sequestration. The agreements to restored some funding were for specific projects and short term. Funding for HEP related felt the full weight of sequestration. Hence the difference in overall budgets and the larger cut to the area you mentioned.

And finally there is one additional area that caused this difference. Fermilab has seen reduced funding each year as core research has shifted to the LHC. This funding is part of the reduction you see in HEP related projects. You can look up the FY 2013 budget act for more detail surrounding the Fermilab funding cuts.

If you want to know more about the details you can research the Budget Control Act of 2011 and the yearly CR’s since then.

6. **Peter Woit**
December 8, 2016

John,
I deleted the previous version of your comment only because all it contained was a simple unsupported claim (that sequestration was the reason) that seemed of no relevance to the issue (why a larger DOE university theory cut?) Thanks for the more detailed version, although I’m still having trouble understanding this well enough to be sure that the reasons you give explain what is going on.

Two and a half years ago when this first came up there were arguments given that this was a technical problem (change in dates grants started, change in policy about later-year commitments). It seemed that if that was true, in later years the cuts should be restored, but instead they have gotten more severe.

If the problem is just sequestration, presumably it should go away when there’s a final budget, no? If so, the response to the theory letter should just be a simple “this is a temporary problem, will go away when we have a budget”, right?

7. **JE**
December 8, 2016

Sorry if this is exactly what you meant by “generic comments that government spending is bad”, but maybe it’s just that, with such little recent progress and such big prospects of a desert ahead for HEP, someone at DOE (mistakenly) decided that cutting down HEP funds was a reasonable thing to do, with HEP Theory fund cuts being perceived as less unpopular than HEP experimental fund cuts.

8. **Peter Woit**
December 8, 2016

JE,
I think that’s a reasonable speculation, but I’ve seen no evidence in any public statement coming out of DOE that that’s the explanation for the cuts. Maybe the theory letter will lead to a response from DOE that will clarify whether that’s what is going on or whether it is something else.

9. **Dragster**
December 9, 2016

Is it possible that recent high-profile private funding, such as the Simons Foundation and Breakthrough Prizes, makes superficially informed DOE bureaucrats more comfortable with reducing the government funding?

10. **Fred**
December 9, 2016

Is there any statistics on the fraction of DOE HEP theory funds spent on summer salaries? Since the DOE introduced a summer salary cap not long ago, I’m wondering if this is the main reason for the decline in HEP theory funding?
I don’t want to start a discussion about adequate salaries, but I do think that research grants should be used to support young researchers (postdocs and Ph.D.s) rather than to pay for the summer retreat of a well established (and typically reasonably well paid) Professor at Lake Winnebago.

11. **anon**
December 9, 2016

I’m not sure if funding young researchers, especially PhD students, more is a good idea. I don’t work in HEP, but in my field doing that has lead to overproduction of PhDs with not nearly enough permanent positions.

12. **Peter Woit**
December 9, 2016

Dragster,
Maybe, but again, no known evidence that this is a factor.

Fred,
The number of grants, postdocs, students is going down, it’s not just a reduction in some summer salaries. The cap was put in to keep other reductions from being even larger.

anon,
HEP theory has always had a very unhealthy situation of far more phds and postdocs than permanent jobs. This situation isn’t any worse than usual right now, maybe even slightly better, so this doesn’t explain recent cuts. Cuts in grants funding senior tenured people don’t exactly encourage universities to create more permanent positions in this area, so on that end won’t help the job situation.

13. **Anon**
December 9, 2016

Off topic but I hope interesting, this seminar at CERN yesterday:

https://indico.cern.ch/event/592392/

The "unexpected results" are not yet published, only on Ting's slides and seem only to be documented in Turkish, but are potentially very interesting:

http://esrap.physics.metu.edu.tr/duyuru/ams-02-basin-aciklamasi

In particular the positron fractions and especially the proton-antiproton ratios.

14. **NotAPhycsist**
December 9, 2016

"Various HEPAP presentations warned physicists about the dangers of public complaints"

What are these dangers? Can you link to a presentation?

15. **Jonathan Miller**
December 9, 2016

I think that there are a number of factors.

First, and maybe most importantly, a significant (temporary) cut of support for theory does not have the same cost as a significant (temporary) cut of support for experiment. This is because cutting an experiments funding (beyond some threshold) can cause some, most or all previous funding to that experiment to be wasted and can cost the entire scientific program. Even a radical cut to a theoretical program allows it to be pursued in 2, 5 or 10 years time at low cost. In fact, if the theoretical funding was geared to maintaining the same number of awards for tenure-tracked theorists, there would probably be minimal harm to theoretical programs even with significant (temporary) cuts.

Second, my experience at University of Maryland is that HEP theorists were much more likely to be supported as students and at postdoc level by the University than HEP experimentalists. This was via teaching assignments, which decreased the time spent on research but still resulted in many more students and postdoc level theorists being supported than would be the case otherwise.

Finally, I would argue that HEP theory as a whole needs some experimental input right now. It isn't just string theory. For example, there has been a ton of theoretical and experimental effort put into WIMPs. And due to the recent experimental results in astronomy, collider physics and direct detection, I don't think extensive further theoretical effort without experimental guidance is well motivated in this sector. Yes, one could argue that the recent AMS results support 1 TeV DM, but they could also support many other interpretations as the results also change our understanding of Cosmic Rays.

All of these points hopefully point to just a short period of temporary cuts and a bright future. If the third factor continues to grow in significance, then probably the full field (HEP theorists and experimentalists alike) can expect further cutbacks.

16. **Peter Woit**
December 9, 2016

NotAPhysicist,

See for instance
http://science.energy.gov/~/media/hep/hepap/pdf/201403/Siegrist_FY15_HEP_Budget_HEPAP_Talk_v2.pdf
"Bickering scientists get nothing"

Jonathan Miller,

Those are all possible factors, but again I don't see evidence that they are the explanation for recent cuts (or any evidence or reassurance from DOE that this is a temporary situation).

17. **John**
December 9, 2016

Peter,

Sequestration is supposed to last till FY2021 unless reversed by Congress. The first large cuts that were noticed over two years ago were directly related to the FY 2013 CR deal as this was the first year that would see full implementation of sequestration as agreed to in the BCA of 2011. They shifted funds to cover existing projects from pure HEP theory funds given directly to universities.

The deal reached last year on November 2nd increased overall DOE funds and even restored some HEP related funds. But once again it was a deal for just a single year and most of the monies were spent on projects and not university grants related to full time positions.

The reason DOE says it is a temporary situation is because sequestration will eventually go away. And each year the various CR's might restore some funds that were previously cut. Even now Congress is debating and will vote on a new CR for the rest of this FY. Details are not yet out on DOE related funding so I have not read how it might impact this issue.

But please note that the entire cause of these cuts were 100% directly related to sequestration and then the shifting of funds within DOE to projects and away from hiring's at universities and research centers.

I know it's Wikipedia but they have a decent explanation of the process. It doesn't get down to the level you want which is only found in the various budget acts approved by congress. https://en.wikipedia.org/wiki/United_States_budget_sequestration_in_2013

18. **Peter Woit**
December 9, 2016

Thanks John,

I guess what I'm still not understanding is the "we can't cut projects, so we'll cut university grants, especially in theory" justification of why overall cuts are hitting university theory grants much harder than other parts of the HEP program.

19. **ronab**
December 9, 2016

Does all this mean I can look forward to an imminent 30% reduction in pop-sci articles about the multiverse? Cool.

20. **John**
December 9, 2016

Here is the actual budget presentation submitted by the DOE for FY 2016

http://science.energy.gov/~/media/sc-1/pdf/2012/Dehmer_2016_Budget_Presentation

Not sure how much this helps but it does show HEP is flat while most other areas are seeking an increase. I can't answer the "why are they doing this" as no one has explained their motive for why they shift funds around.

21. **jd**
December 9, 2016

I support what John has written above. First read the Wikipedia explanation of sequestration; sequestration does not end with a final budget. Then read and understand the slides of Jim Siegrist, Office of High Energy Physics. At most it takes only a very little reading between the lines to understand what is going on. The letter written by the group of theorists may have been a mistake; to me it smells of bickering. But I am not in HEP so what do I know? I recommend that HEP get its internal politics quietly in order. But then again what do I know?

22. **Anonymous mathematician**
December 10, 2016

I only have anecdotal information, but I have talked to a few graduate students who have decided against careers in HEP because of the lack of new experimental findings at the LHC (nothing to do with string theory; graduate students still seem excited about that).

I don't think this is related, because the money started being cut before it was clear that the LHC wasn't finding anything beyond the Higgs. But it's probably less of a disaster than it would be if there were exciting new experimental results from the LHC.

23. **Shantanu**
December 10, 2016

Peter, most of the people who have signed this letter are string theorists.

24. **Peter Woit**
December 10, 2016

Shantanu,
The slide does say there are "many more" on another page, not reproduced. But that list is dominated by string theorists, few phenomenologists, which is odd.

The oddest thing about the letter that I noticed was that its first reason given for why the field should not be cut is
"These cuts come at a time of continued public fascination with particle physics, cosmology, and gravity".
It's unclear why success at getting public attention (often with fairly outrageous hype) is a good argument for federal research dollars. This is also not a great argument to be making to gain support from physicists in other subfields that are doing important work, but don't enjoy the same public attention, and may not be so happy about that.

25. **Doug McDonald**
December 12, 2016

Peter, the pointers already here do include a vastly larger list of signers.

https://drive.google.com/file/d/0B3IXprj4oX2sU0VvczR6VzdheDQ/view

26. **Peter Woit**
December 12, 2016

Doug McDonald,
Thanks, I've updated the posting with a link to that full version of the letter, as well as to a document justifying the numbers in the letter.

27. **GoletaBeach**
December 28, 2016

As best as I can tell, there is serious downward budget pressure… John's explanation that the origin of it might be right… but to document the Office of Science funding, FY1999 appropriations are at: http://science.energy.gov/~/media/budget/pdf/sc-budget-request-to-congress/fy-2000/Cong_Budget_2000_Overview.pdf … can compare with John's link above, and look at the change in funding levels during this period for the "big 6" portions of the Office of Science mission:

Basic Energy Sciences …. +52% (that accounts for the effect of inflation)
Computing …. +140%
Bio/Env…. -4.7%
Fusion…. +48%
High Energy…. -23%
Nuclear…. +25%

Overall OS Funding…. +25%.

I picked year 2000 just because it was a round number for the budget… all years from 1987 are at: http://science.energy.gov/budget/ . But I do believe that HEP has been a big loser for a decade or two… not sure it is the SSC, either.

My impression is that Basic Energy Sciences does more quantifiable, more easily defended activities. They can say that in FY 2015 8,988 samples were quantified in 93% beam uptime at their 5 facilities, and in FY 2016 they increased to 9,611 samples in 94% beam uptime. The private sector sends samples to Basic Energy Sciences facilities. So, BES have been the big winners for quite some time.

That is what our government wants these days. HEP theory activities like… our group got deeper insight into the nature of symmetry as it relates to unification of the fundamental forces, well… not easy for bean counting to deal with that, or support it.

The experimental HEP community has adopted a layer that interfaces to the way the DOE wants to understand things. Seems to me that the theoretical community is off the mark a little… agitation helps, but in the end, when in Rome.

Various Links

Categories: Langlands, Multiverse Mania, Uncategorized

A grab-bag of unrelated topics and links:

- Continuing the subject of budget cuts from the last posting, I heard today that the NSA is not funding this year the grant program that the AMS has been running for it, called the NSA Mathematical Sciences Program. In typical NSA fashion, no real reason given:

  > after much deliberation our senior management has decided that the MSP will not have the resources to make new awards in FY2017.

  Even less information is available than in the case of the similarly mysterious DOE HEP Theory cuts, since all information about the NSA budget, even the total, is classified (although from Snowden and others, it seems that it's about $10.5 billion).

- The IHES has a new website.
- This spring Peter Scholze will give a series of six lectures at the IHES on the latest about the local Langlands conjectures.
- Via David Roberts, the LMS has some videos about mathematicians here. Kevin Buzzard explains Langlands:

  > The Langlands philosophy? Yeah, that's like Birch-Swinnerton-Dyer on crack, isn't it?.

- Tate's collected works are finally available from the AMS.
- Turning to physics, there's a very good new article at Quanta from Natalie Wolchover about the unsuccessful search for proton decay and what this means for grand unification ideas. Glashow has now given up, with the simplest GUTs now conclusively ruled out:

  > Glashow, for one, largely lost interest in the whole affair when SU(5) was ruled out. "Proton decay has been a failure," he said. "So many great ideas have died."

  Not everyone has given up though, with fans of the "flipped SU(5)" SUSY GUT explaining things this way:

  > Barr, one of the originators of the still-viable "flipped SU(5)" GUT model, compared the situation to waiting for your spouse to come home. "If they're 10 minutes late, there's simple explanations for that. An hour late, maybe those explanations become a little less plausible. If they're eight hours late … you begin to worry that maybe your husband or wife is dead. So the point is, at what point do you say your theory is dead?"
  >
  > Right now, he said, "we're more at the point where the spouse is 10 minutes late, or maybe an hour late. It's still completely plausible that grand unification is correct."

  Besides the current wishful thinking, this particular model has a strange history. You can read here about how it follows from Vedic Science. Over the years it has been about to come home many times, see this from 2012, which assures us that:

  > The CMS and ATLAS experiments have also observed tantalizing hints of the unique signature predicted by the Flipped SU(5) model.

  At this point, it seems to me to be way more than an hour late, time for its nearest and dearest to admit that it's dead (or maybe has run off with its TM instructor).

- Also in Quanta, you can read about Janet Conrad and sterile neutrinos here.
- I don't always agree with Sabine Hossenfelder about math, but I very much agree with the conclusion of this posting:

  > In lack of experimental guidance, what we need in the foundations of physics is conceptual clarity. We need rigorous math, not claims to experience, intuition, and aesthetic appeal. Don't be afraid, but we need more math.

- There's a Recent Developments in Fields, Strings, and Gravity conference going on this week at the new Center for Quantum Mathematics and Physics at Davis.
- Videos of the talks at the recent John Schwarz 75th birthday conference at Caltech are available here.
- Multiversal Journeys is an organization devoted to promoting theoretical physics, with a heavy dose of multiverse mania as part of their story. They have a new book coming out, Quantum Physics, Mini Black Holes and the Multiverse, supposedly "Debunking Common Misconceptions in Theoretical Physics". It seems that one of these common misconceptions is that the multiverse is pseudo-science. To fight this, they've also produced a promotional video.
- Bert Schroer has an interesting preprint with a lot of material about Rudolf Haag and algebraic quantum field theory.
- Another intriguing preprint recently out is from Arkani-Hamed and collaborators. In the past Arkani-Hamed has been vehement about gauge symmetry just being a worthless redundancy in our description of physics, for instance stating:

  > What's as a misnomer called gauge symmetry, whose beauty is extolled at length in all the textbooks on the subject, is completely garbage. It's completely content free, there's nothing to it.

  In the new paper, instead of gauge invariance being useless, there's a conjecture that locality and unitarity, instead of being fundamental principles, follow from gauge invariance.

  There's a long tradition in the philosophy of physics literature of arguing over whether gauge symmetry is a fundamental idea or a useless redundancy. I'm on "fundamental idea" side, but of course exactly what the role of gauge symmetry is in fundamental physics is something that we have yet to fully comprehend.

Comments

1. **Ben**
   December 15, 2016

   What are you thoughts on the likelihood of a multiverse? Will take a link if you have already discussed it.

2. **Peter Woit**
   December 15, 2016

   Ben,
   That's a meaningless question, the multiverse is pseudo-science. I've written endlessly about this on the blog, see

http://www.math.columbia.edu/~woit/wordpress/?cat=10
and some of the questions in the blog FAQ.

One thing to notice about the many multiverse promotional efforts like this is that they never include multiverse critics (and I think being critical of the multiverse as not science is a majority point of view among physicists). Their only discussion of criticism of the multiverse as pseudo-science is to counter straw-man arguments.

That said, the last thing I want is another discussion here of exactly the same arguments as always. If you have something new, please comment, otherwise please restrain yourself, I'm just going to delete attempts to carry on old arguments.

3. **David**
December 15, 2016

"One thing to notice about the many multiverse promotional efforts like this is that they never include multiverse critics " – this is actually proof that multiverse theories are wrong. If they were true, there would be many promotional efforts that focussed on the negative aspects. (sorry if the joke falls flat)

4. **Bee**
December 16, 2016

Thanks for the link 🙂

Gauge symmetry can both be useful and be redundant, I don't see why these are two exclusive categories. One could say that thermodynamics is redundant, to pick a not-quite random example, but that doesn't make it useless.

5. **Manfred Requardt**
December 16, 2016

Dear Peter, I too think that gauge theory is a fundamental building block of quantum nature and is not an indication of some redundancy. Frequently what appears to be reduntant from the point of view of classical physics has a deep meaning in quantum reality. A nice discussion of this phenomenon can e.g. be found in the second volume of Richard Feynman about electrodynamics concerning the vector potential.

6. **neil**
December 16, 2016

Interesting article by Wolchover. I am interested in learning more on the relationship of proton decay to SUSY. As I understand it, there are SUSY and non-SUSY GUTs. I suppose the LHC results make SUSY GUTs a whole lot less interesting, but what about non-SUSY GUTs like minimal SO(10)? I am surprised Glashow threw in the towel on GUTs just because his SU(5) was ruled out. Are there other problems with these higher symmetry non-SUSY GUTs?

7. **Peter Woit**
December 16, 2016

neil,

Minimal non-SUSY SO(10) is also already ruled out, I doubt the (not very large since they're both rank 4) difference between SO(10) and SU(5) models was that significant to Glashow.

Nanopoulos explains well the general problem of why, even if you can make a more complicated model than the SU(5) or SO(10) ones, specially designed to evade conflict with experiment, you might not want to:

> "People can construct models with higher symmetries and stand on their nose and try to avoid proton decay," Nanopoulos said. "OK, you can do it, but … you cannot show it to your mother with a straight face.""

8. **Chris Austin**
December 16, 2016

SO(10) is D_5, and is rank 5. SU(5) is A_4, and is rank 4.

9. **paddy**
December 16, 2016

I think Glashow threw in the towel ~ 30 years ago. He (in my way of thinking) has been faithful to principle. The beauty/simplicity/falsifiability of Georgi and his GUTS model was minimal SU(5). Perhaps I misremember, but I think he walked away back when proton decay contradicted this model . He didn't introduce additional degrees of freedom to clutter the model in order to tune it in order to save it from being falsified–i.e., make it no longer predictive.

10. **Peter Woit**
December 16, 2016

Chris Austin,
Thanks, that's right, my mistake about the ranks, I was thinking of something else (SU(5) is the subgroup of SO(10) that preserves a complex structure).

11. **Frank**
December 17, 2016

Peter,

it might be less well known that various people who worked on the the standard model – several of them with Swedish prizes – do think that the search for a unique gauge group is misguided. After all, the electroweak model is not a real unification, as it still requires two independent coupling constants. And in the standard model, SU(3) has a third, independent constant. Both experiment and theory show that it is not possible to describe nature with SU(5) or SO(10) or another single group with only one coupling constant. Nature has three gauge forces, not one.

But there is an important reason to cling to grand unification: it is predicted, or at least suggested, by string theory. So we are again in the difficult situation that experiment is against grand unification, whereas string theory is in favor of it. (The situation is similar to supersymmetry.) It seems that theory will make progress only once all the people believing in GUT and SUSY are gone.

12. **Shantanu**

December 17, 2016

Peter, I agree with Glashow. looking for proton decay is looking for El Dorado.
That said I know several grad students who continue to be lured into doing thesis on proton decay.

13. **piscator**
December 17, 2016

nothing wrong with experimental theses on proton decay – always good to push any measurement to a higher level of sensitivity, almost independent of theoretical motivation.

(and proton decay experiments have already won one Nobel Prize…..)

14. **Peter Woit**
December 17, 2016

Frank,
The basic problem with GUTs and SUSY is similar: you postulate a more unified theory using a larger symmetry group (or supergroup), but then have to somehow break the symmetry to explain why we don't see representations of this larger symmetry group. The ad hoc symmetry breaking sector makes the whole idea much less compelling and predictive. These ideas were born 40 years ago around the same time, back then everyone thought they would either lead somewhere in a few years or get abandoned. It's remarkable that instead they entered the textbooks and became institutionalized as a seemingly permanent part of the subject.

Shantanu,
Just because finding proton decay is less likely doesn't mean one shouldn't do such experiments. I'm no expert, but my impression was that many such detectors are now configured to do double-duty as neutrino experiments.

15. **neil**
December 17, 2016

You are right Peter. Proton decay was the primary purpose of Super-K, but with the Kajita Nobel prize much of the research there is on neutrino oscillations. And the DUNE neutrino observatory has a proton decay experiment.

Proton decay seems less and less likely for the reasons stated but, wow, baryon number violation would be a huge discovery.

16. **Louis**
December 17, 2016

The 'wife showing up late' comment is interesting, but is missing a major aspect. The prior probability of your wife's continued existence and intent to return home should be much higher than the prior probability that your favourite theory which isn't known to be inconsistent with experiment is an accurate extension of current models. At least for most marriages. Its more like you're attending a dinner event in the city your crush lives in and you're judging the probability that you'll to run into them.

Or maybe I'm just asking for a bit too much from analogies.

17. **Peter Woit**
December 17, 2016

Louis,
You're right, it's a strange analogy. Until you realize that the particle theory community has been living with GUT/SUSY speculation for so long that it is like a close family member, one whose death (due to a conclusive experimental result) would be unexpected and heart-breaking. Better to do anything to keep it alive and not face that.

18. **serious question here**
December 17, 2016

how do these new experimental limits on proton decay + LHC results affect supersymmetry GUT such as SUSY GUT SU(5) or SO(10)?

it's my understanding adding SUSY to GUT increases proton lifetime enough to evade these bounds.

19. **Frank**
December 18, 2016

Bee writes:

In lack of experimental guidance, what we need in the foundations of physics is conceptual clarity. We need rigorous math, not claims to experience, intuition, and aesthetic appeal. Don't be afraid, but we need more math.

Allow me to partly disagree. Conceptual clarity is needed. But it is *not* achieved with math. Math cannot help to decide whether the Planck scale has a fundamental importance or not. Math cannot decide whether GUT or SUSY are correct. Math cannot decide whether strings are correct. Math cannot tell which symmetry is correct. Math cannot tell how many dimensions nature has. If math would help to get conceptual clarity, we would have found the TOE already years ago.

Conceptual clarity is not achieved with math, it is achieved by checks with experimental data. GUT is mathematically sound, but wrong. So is SUSY. So are strings.

Math helps to draw correct conclusions. But it does not help in finding the foundations. Math leads to conceptual consistency. Math does not lead to conceptual clarity. And in the history of physics, it never did.

Take the issue of symmetry. If you know that a flower has fivefold symmetry, you still do not know the shape of a petal. You just know how the other four look like if you have only one. Math (in this case symmetry) helps; but it does not provide the full information. Experiment does. We have the same issue with nature.

20. **Peter Woit**
December 18, 2016

Frank,
I think what Bee has in mind is the situation in her field of quantum gravity. There many of the research topics (ER=EPR, firewall paradox, Verlinde's entropic gravity, etc, etc) suffer from the problem she identifies: people are manipulating very vague, ill-defined speculative ideas, claiming "intuitive", "physical" understanding, but you can't

pin down exactly what these ideas are. Before you can confront your theories with experiment, you first need to have a well-defined theory, and it is mathematics that can provide you with this.

21. **Peter Woit**
December 18, 2016

serious question here,

There's a graphic in the Quanta article that addresses this, showing in particular most of the range for supersymmetric SO(10) already ruled out. One problem though is that these theories have a lot of undetermined parameters, so claims about their "predictions" tend to have a bunch of built-in assumptions. If you look at the history of these "predictions", my impression is that they have tended to creep up as experimental bounds move up. For an example of the calculations involved, see https://arxiv.org/abs/hep-ph/0007213

22. **Apostolos Syropoulos**
December 18, 2016

"Why String Theory?" is Physics World's book of 2016:

http://physicsworld.com/cws/article/news/2016/dec/14/robust-defence-of-string-theory-wins-physics-world-2016-book-of-the-year

23. **Shantanu**
December 19, 2016

Peter/others:
I am not objecting to building/operating such detectors. My own thesis was on such a one. I am surprised that gullible students continue to work on analysis of proton decay.

24. **Pavel**
December 21, 2016

Dear Peter,

I recommend your readers to read a new review

https://arxiv.org/pdf/1501.01886.pdf

Minimal non-SU(5) was ruled out by the wrong relation between the down quark and charged leptons masses. Even before you compute the lifetime of the proton the model is ruled out. Now, once you write down a consistent model for fermion masses it is possible to achieve unification without supersymmetry in a simple SU(5) theory, see for example for a recent paper:

https://arxiv.org/pdf/1604.03377.pdf

Best,
Pavel

25. **John Baez**
December 27, 2016

Peter wrote:

> You're right, it's a strange analogy. Better to do anything to keep it alive and not face that.

It's less strange if you remember why people actually like the SO(10) grand unified theory. In this theory, each generation of fermions and antifermions fits neatly into a single family of particles, the spinor representation of SO(10) (or really Spin(10)). This theory "explains" why quarks have charges 2/3 and -1/3 while leptons have integer charge, and much more. All sorts of facts that otherwise seem strange and random suddenly fit together in a beautiful way.

However, there's a lot that it *doesn't* explain, like the masses of particles, and one must invoke extra Higgs bosons to break the symmetry from Spin(10) down to SU(3) x SU(2) x U(1).

So, it's absolutely heart-breaking that this theory seems to be wrong, but we can hope that there's something right about the underlying algebraic patterns that make it tick.

Unfortunately we may not live to see the next really interesting development in this mystery. So, unless one has a really promising new idea, it's better to think about something else.

26. **Peter Woit**
December 27, 2016

John,
I agree that the fact that a generation fits into the spinor rep of SO(10) is something very appealing, an indication of something right about the idea (and less right about the original SU(5). The problem with GUTs has always been that the unification is a bit of a fake, since you don't have a compelling idea about why it breaks (introducing a special set of new Higgs fields isn't very pretty…)

My guess is that the hint here is that there is some sense (one we don't understand) in which there are five fundamental degrees of freedom, with a generation the exterior algebra on these five degrees of freedom. The relation to the spinor rep is that you can construct the spinor rep of Spin(2n) using the complex exterior algebra on n-dimensional complex space (i.e. as the state space of five fermionic oscillators, see discussion in my book).

27. **Yatima**
December 30, 2016

Maybe of some interest:

A question that appeared on Stackexchange: [Which were some major mathematical breakthroughs 2016?]()

28. **Sebastian Thaler**
    January 1, 2017

    Peter,

    FYI, the responses to the 2017 Edge.org annual question have been posted. This year's question was, "What scientific term or concept ought to be more widely known?" Martin Rees suggested "multiverse": https://www.edge.org/response-detail/27129

29. **Jim Given**
    January 8, 2017

    Vedic Science a la John Hagelin and the Maharishi University makes lousy science, but good art! I was in the MIT Physics Dept. circa 1986, and a particle theorist had a large multi-color poster showing how an incarnation of SU(5) accorded with purported Hindu constructs. But the craziness was mostly in the margin. Most of it recalled the lovely illustrations of the Eightfold Way etc. from 1960's Scientific American. Can I get one of these?

What Graduate School in Theoretical Physics is Really Like

December 29, 2016
Categories: Uncategorized

I'm about to head off for a short New Year's vacation in West Texas, but wanted to recommend a wonderful article that just appeared at Nautilus. It's a memoir by Bob Henderson (who I met when he wrote about me, see here), appearing under the title What Does Any of This Have To Do with Physics? (although the title of the web-page, *What Graduate School in Theoretical Physics is Really Like*, is more descriptive).

Henderson was a graduate student at Rochester in theoretical physics, working with S.G. Rajeev. He later went to work on Wall Street, and more recently in journalism. His Nautilus piece is the best explanation I've ever seen of what it's like to start working in this field as a graduate student, should certainly be required reading for anyone thinking of going into the subject. It's also somewhat of a profile of Rajeev, who has worked on a wide variety of topics in theoretical physics.

One of the main themes of the piece is Henderson's thinking about how and why he left theoretical physics, why he "quit". Something to keep in mind is that this kind of decision is what most people who get Ph.Ds in the subject end up facing. There are 5-10 times more people getting Ph.Ds in this field than there are permanent positions doing research in it, so the career path starts out with a game of musical chairs that you are highly likely to lose. Different people make the choice to quit the game and do something else at different points and in different ways.

Henderson does an excellent job also of explaining what the real problem is with doing this kind of research: that of figuring out what the right thing to calculate is. For everyone, but especially for those at the beginning of a career, the subject is a huge collections of topics one doesn't understand. One has to somehow choose a direction to pursue, and it most likely won't go anywhere:

> Writers talk of the terror of facing a blank page, but it's no different for theorists like Rajeev trying to choose which path to take. There are an infinite number to choose from, and most go nowhere or back from where you came. The clock is always ticking and you spend so much time in the dark that it can make you not only question your path, but your own self worth. It can make you feel stupid.

Sticking with this and making a career of it involve some combination of good luck (being in the right place at the right time), ability, self-confidence, not having a family to support, and a host of other factors. As Rajeev explains to him:

> Without naming names, he ticked through a catalog of his contemporaries who'd succeeded in theoretical physics even without having the towering mathematical intellect that I was sure it took and that Rajeev surely has. They'd made it, Rajeev explained, by focusing on problems that played to their strengths, or by taking advantage of computers, or by collaborating with peers who had complementary skills. Some socially gifted but not so mathematically talented types had gone quite far this way, earned a lot of renown.

Anyway, the whole piece is well-worth reading. Another recently published Nautilus piece that I learned about from a link on this one is The Universes of a Woman in Science. It's by Kate Marvel, who shares with Henderson (and hundreds if not thousands of others…) the experience of getting a theoretical physics Ph. D. (string cosmology in her case), and then leaving the subject for another field (in her case, climate science, which she blogs about here).

Comments

1. **Tim May**
   December 30, 2016

   Two poignant stories.

   Things were bad when I was in physics in the 70s, but seem much worse now. I cannot imagine that Ph.D. students think they will become career professors.

   Myself, I once cooked steaks for Feynman in Isla Vista in 1973. We sat around in our typically dingy student apartment and Feynman opined, with great humor, about his adventures. More seriously, he said the "easy days" of discoveries and major new theories were just about over.

   We asked him where he thought the new excitement, or revolutionary spirit, might be.

   He said "computers."

   A year later I opted to delay going to grad school for a while and joined a then-small company, Intel Corporation. I learned it was heavily based on some good physics and I was constantly challenged. Physicists were not too common (EEs and ChemEs were more common), so I did some good stuff. In 1977 I discovered that a single bit error problem which was a problem in dynamic RAMS was caused mostly by alpha particles from low levels of uranium and thorium in packages. And to a much lesser extent, then, by cosmic rays.

   Just three years after sitting down on cushions in our apartment with Richard Feynman. What an inspiration he was.

   Oh, and I also got to work at Intel with Gordon Moore, Andy Grove, Craig Barrett, and Bob Noyce. A stellar group. I was fortunate to work for Craig Barrett who worked for Andy Grove who worked for Gordon Moore. My results and summaries went right up to the top every day…like working on the Manhattan Project. Heady days.

   And now, merging black holes. Personally, the failure of SUSY is not that big a deal. Something else will come along.

   Happy New Year!

2. **Chris Oakley**
   December 30, 2016

   Interesting article, although it should be pointed out that you do not need relativity to get nonsensical, infinite answers in quantum field theory. Second-quantised non-relativistic QM does this perfectly well. Also I, too would get angry or suicidal if required to work 15-hour days on quantum gravity in one dimension.

3. **Low Math, Meekly Interacting**
   December 30, 2016

   Surely one of the more foolish questions you're likely to get, but what the Hell: Why is all this labor needed in theory? My background is purely experimental, and I've mixed with experimentalist grad students in the areas of biology, chemistry and physical chemistry. In these disciplines, it was quite obvious what grad students were for: slave labor in the laboratory. The more the better. Cheaper even than technicians and so terrified half the time they'd do any dirty job they were asked to just to avoid being forgotten entirely. And there's no end of dirty jobs to do. But, aside from grading and other pedagogical grunt work, why have so many unneeded theory grad students? What else do they do for the institution?

4. **AcademicLurker**
   December 30, 2016

   LMMI:

   I've heard it said that really experienced physicists often guess the answer to their problem/question using heuristic arguments, and then do the math to make sure their guess was correct. Maybe that's the role of theory students, at least before they start an independent project. "I think the answer is X. Go check it out."

5. **cgh**
   December 30, 2016

   In 1999 I started work on my PhD. It was in physics. I had some grant money and was simultaneously publishing. The work on my thesis wasn't going as fast as it could of, probably because of this, but I felt productive. I was meeting regularly with a mathematician who was not my advisor but was working independently with me on related ideas. He is / was well known in the NY area for RH and some analysis work. One day, I suppose in retrospect, I was complaining. The gist of my complaint was about what I was going to do after I finished. He responded that if I did this to be employed I didn't get it and was in for a rude awakening. To him, it wasn't about employment, it was about math, and solving problems. He was an established mathematician with tenure, then, now emeritus. He didn't have to take endless strings of adjunct positions in the boondocks. When he was working on his PhD in the 60's if you thought hard and did good work things came to you. One didn't need to think, at least as much, about food, of family, or being near family. He spent his entire career between 3 NY universities, 2 in Manhattan within 20 miles of where he grew up and raised his family, without giving it much thought. So in 2001 I went to Wall Street. I shared an office with a Caltech postdoc that came from the control and dyn systems group. I exchanged the hype of strings for, then, fast PDE solvers and, today, the hype of AI, deep and machine learning.

   December 30, 2016

   I started my PhD in 1986, in math. Back then, anyone in math with a doctorate from a good school got an academic job. I finished in 92, the year the job market collapsed. But even that year, most people ended up with academic jobs, just not at the level they expected. I have tenure, I get to do some research, it's not the research 1 place I expected (my thesis was published in Mathematische Annalen, in a normal year I probably would have gotten a much better offer) but I'm happy. It's much worse now, even in math. We're hiring this year, we put our ad in really late, 2 weeks ago, and we're already close to 200 applications. Very qualified people, including people with doctorates from places like Berkeley and Oxford, with publications in good journals. cgh is right about the old days, all my professors basically got their jobs when their advisors called someone to tell them to hire them. I have a funny feeling I might know the person he's talking about, since I got my doctorate in the city…

7. **X**
   December 31, 2016

   Interesting article by Henderson, with things that all of us who have gone through the PhD experience can relate to. But what I found even more interesting was the insight it gave into the working life of his advisor Rajeev. He seems to have been extraordinarily generous with the time and effort he put into his students to bring them along on his research path. And his 'rewards' for that seem to have been pretty mixed. Imagine what it must have been like for him when, after all that time and effort, Henderson started hating him (which Rajeev and any advisor in that situation would definitely pick up on), rejected his research path and went off to try find his own.

   I'm not blaming Henderson for that, since it was a difficult situation for him and understandable that he wanted to find/generate sufficient output to justify the input and hardship from his perspective. Relations between PhD students and their advisors are often difficult and complex, since both are investing so much and the outputs they seek are not always aligned. But this illustrates a reality of the working life of faculty which can be pretty draining.

   So I think those considering doing a PhD in this field should not only look at Henderson's experience as a student but also the close-up description of Rajeev's working life as a prof, assuming finding a faculty job is the person's ultimate plan/hope when embarking on this path.
   In a comment above, cgh recounts how a maths prof told him that "it wasn't about employment, it was about math, and solving problems." That's true for the motivation of people who go down this deprived and often dead-end path, but it's a far from accurate description of what the job really is for those "lucky" enough to land a faculty position.

   The reality is that it is first and foremost an educator job. Teaching classes, guiding graduate students, supervising undergraduate student projects, doing outreach activities in high schools, etc…(plus various administrative things). Research is something you basically do in your spare time, e.g. waking up at 3am to have a bit of spare time for it as Rajeev did in the story. (And this is at research universities such as Rochester; at liberal arts colleges getting research done is even more challenging.)

   Young people aspiring to a faculty job in this field because they "want to do research", and think that "doing a bit of teaching is bearable and a fair trade-off for the freedom to do research" have misunderstood the nature of the job. It is an education industry job rather than research job. They should ask themselves if they really want to spend their working life in the education industry rather than, e.g., doing graphics software design for Apple, working on automated car driving for Tesla, or the myriad of other interesting and intellectually challenging things that smart and hardworking young people can aspire to do. If doing research is really so important you can always go work on Wall Street, retire rich at 50, and spend the rest of your life doing research without constraints or other commitments.
   (I'm speaking from experience here as someone who reached the "holy grail" of a faculty position at a research university and discovered that the job was not quite what I imagined it would be…)

   It was very refreshing how Rajeev acknowledged that "Some socially gifted but not so mathematically talented types had gone quite far this way, earned a lot of renown." For quite a few people (myself included), one of the motivations for going down this path was the expectation that our lack of interest and talent for "sucking up" wouldn't matter so much compared to careers in the business world or elsewhere. This is a myth though – it is no different than other walks of life in this regard.

   Re. LMMI's question above about the need for PhD student "labor" in fields like theoretical particle physics: No it is generally not needed for the research, in fact it is often a time and effort-consuming burden on the prof to drag the students along his/her research path, as Henderson's story illustrates. One explanation for why it happens anyway (perhaps the main one at many institutions) is that the number of PhDs produced is a metric on which individual faculty and departments as a whole are evaluated. I remember one faculty meeting where the dean excitedly told us about a new opportunity for PhD funding, and urged us to "go and grab this opportunity" – presumably by finding students to lure into the PhD path. There was no discussion of whether there was a need for more PhDs or what their future career prospects would be…

8. **A reader**
   December 31, 2016

   It is a beautiful and soulful article/essay.
   The key message for me is "Control your emotions." It takes time. Sometimes it is too late.
   Between "Pursuing the Holy Grail" and "Shutting up and calculate," is it not possible to find some middle ground?
   Like … "Be part of an epic human endeavour (we are primates), enjoy trying to understand/solve a problem, be ready to move on when it is over?"

   That said, from afar, and even though he obviously can write very well, I really wish that Bob Henderson gets a chance to go back to working on that he evidently loves:

Physics.

9. **Jeff M**
December 31, 2016

X

I think what you describe, professors as educators, research a sideline, is sometimes true, and sometimes not. It is certainly true for anyone who teaches somewhere like I do, though even here it's possible to do it differently. One of my colleagues, who just retired, used to only ever teach all sections of the easiest course he could get, and paid as little attention to teaching as he could. You don't need to do much prep to teach what is really high school level math. And from what I've been told, there are plenty of people at research 1 schools like Rochester who are nothing like Rajeev, and who don't even really care much about their advisees, much less the undergrads. As to retiring early and doing research on your own, it's a thought I had when I didn't think I would get an academic job. Decided I would sign a contract with myself that when I had x dollars in the bank I had to retire. Sometimes I look back and think it might have worked out OK, now that I'm stuck teaching summers to pay my kids school tuition. I could be relaxing in my Tribeca loft, sipping single malt, and thinking about math. Actually, back when I was finishing grad school, my wife and I lived in a giant loft in Williamsburg, but boy was the city different then.

10. **vmarko**
December 31, 2016

I have to say that I am not as fascinated by the Henderson article as many here are. To me it sounded like a story of a person having a naive, romanticized point of view on research in theoretical physics, only to be faced with a down-to-earth reality that has very little in common with his romanticized view. Einstein looked at a building through a window, and figured out general relativity — yeah, right. Everyone who thinks research can be done like that is certainly going to be very disappointed. And Rajeev was very very right at the end — Henderson's issue was not lack of ability, lack of open faculty positions, lack of quality or lack of effort. His issue was precisely that he decided to quit. Research was not what he naively imagined it to be, and he caved when he got under some pressure. It was lack of dedication.

In order to survive in a highly competitive research area such as hep-th, a person needs (aside from some luck, math abilities, good mentor, etc.) one crucial character trait not mentioned in the article — stubbornness. One simply needs to be more hardheaded, and not get too distracted by the reality being different from what one imagined.

Regarding mentoring and collaborating with a supervisor, Rajeev seems to be a good mentor, judging from what Henderson wrote in the article. In order to teach a student enough to do research (in hep-th at least), a supervisor needs to dedicate to each student at least one afternoon of uninterrupted discussion in front of a blackboard every week or two. My supervisors did it with me, I try to do it with my students. Those mentors that don't do that are plain and simply irresponsible, IMO. And it usually shows, in the number of years their students take to reach PhD's, and their research performance afterwards.

As for teaching vs. research, my anecdotal evidence is quite the opposite of what X is describing — I am in a research-only institute, doing quantum gravity, and I have literally no teaching duties (and never had any during my career, except when I substitute for a colleague). Moreover, recently I actually asked to get involved in teaching, at the graduate level. The reason is that I need more fresh PhD students as collaborators, to share the workload of my research. In a research-only institution I don't have any contact with PhD students, so it's hard to recruit them.

So anecdotal evidence can vary greatly, it all depends where you are. I've heard some people dreading research-only institutions like IAS, Princeton. No contact with students is a terrible handicap when doing research, they claim, as there are no fresh ideas and excitement that young motivated people bring along. And I tend to agree — one needs to find some sweet spot between teaching and research, since each of the two extremes will have some drawbacks.

Best, 🙂
Marko

11. **Low Math, Meekly Interacting**
December 31, 2016

Re. X: Ah, I see. They're adornments. I know enough about academia that should have been obvious. Thanks.

12. **Why**
January 1, 2017

It is really confusing when you think about it. On one hand, the need for specialising in one of the so many new disciplines in theoretical physics seems to increasingly recquire new PhDs and post docs and on the other hand the increase of the population seems to require more tenured professors to be hired to teach.
So why all this crisis in theoretical physics job market?

13. **X**
January 1, 2017

Jeff M,

"there are plenty of people at research 1 schools like Rochester who are nothing like Rajeev, and who don't even really care much about their advisees, much less the undergrads"

That's no doubt true, but it's difficult to get away with as a tenure-track faculty, and probably getting harder for tenured faculty too. With rising tuition costs students are being regarded more and more as paying customers, and making them satisfied seems to be becoming a higher priority for universities.

At the university I was at (ranked in the top 100 in the world in several rankings), teaching performance was important and given equal weight with research performance in our annual evaluations. There were people who were denied tenure despite having done well in research because their teaching sucked according to the student evaluations. And I'm pretty sure that if someone got tenure and then proceeded to be a terrible teacher thereafter, the powers-that-be would still find a way to push him/her out… (In fact there was a tenured prof who the powers-that-be didn't like for some reason, and they made his position in the dept so uncomfortable that he "voluntarily" left…)
In any case, I felt morally obliged to at least try to be a good and conscientious teacher/lecturer.

As for the actual time and effort that the teaching side requires, it depends enormously on the details of the teaching assignments as you mentioned. There were some people who taught the same couple of courses every year, requiring zero preparation time and allowing them to get high student evaluation scores after fine-tuning the courses for so long. Those tended to be people who were favored by the powers-that-be for whatever reason… There were also assignments that required preparing course materials from scratch (including powerpoint lecture slides, handout notes, tutorial question & solution sets, online quizzes etc) for a new course or because the previously used course materials were disastrously bad. Less favored faculty such as myself tended to get those assignments…

So unless the person is very favored and fortunate with his/her teaching assignments (and has great PhD students who don't require much time or cause much stress), or doesn't care about being a good teacher and is able to get away with not caring about it, I think the reality of the job even at most research universities is being first and foremost an educator, with research as a sideline.

On the topic of gaining financial freedom as a path to being free to do research in future, Wall Street is not the only route. Marrying a successful businesswoman with her own company is another way, one that I was fortunate to follow (more by accident than plan…) These days I'm free to do whatever I want once the housework is done. 🙂

14. **colorado**
January 1, 2017

For a person coming from condensed matter theory, it is amazing that professors in HEP theory still do actual calculations and not rely on their students and postdocs to enlarge their publication list. In my field, a PhD advisor would not give an open problem to a student or postdoc without hoping to get a coauthorship. In fact, if you discuss more than an hour about what you are doing with a senior person, he or she would expect his/her name on the paper.

15. **future**
January 1, 2017

what is sad and ominous for the future of "physics" is that several people want to co-opt "theoretical physics" to mean high-energy theory / particle theory or at the very least, something quantum.

many of the best theoretical physicists i know (having spent my time exclusively at the most "famous" institutions around the country) don't work on quantum problems at all – and certainly not high energy physics. They work on condensed matter problems – quantum and classical, soft matter and increasingly, biology.

The real test for physics departments is whether they quickly redefine physics to be these exciting areas with actual deep ideas – or restrict "theoretical physics" to mean rehashing of 40 year old high-energy ideas.

The exciting new theoretical physics in biology, classical non-linear physics and condensed matter will thrive for sure.. but it may end up in biology and engineering departments in 50 years from now and "physics departments" will become the Nokia to their Apple.

16. **X**
January 2, 2017

colorado,

Faculty in HEP theory definitely rely on postdocs to generate publications (and PhD students too, to the extent that they are able). In fact it is a main way they keep up a 'respectable' rate of research output, considering that their own time for doing research is often very limited. Research projects are farmed out to postdocs and students who do most of the actual research work, while the prof's role is mainly 'research manager'. I guess this is the standard model throughout academic sciences. At any rate, the people who were productive and successful in research where I was all followed this model to some degree. (Personally I consider it a horrible model and refused to play that game…)

17. **Why**
January 2, 2017

To those thinking that it is a good idea to work in business until retirement and then start doing research: can you give me one single example from the history of physics where somebody made a significant contribution to physics after retiring?

18. **Another Anon**
January 2, 2017

That's a great piece of writing by Bob Henderson. I think it answers his question of where it all went wrong: his talents lay in being a writer, not being a physicist.

19. **Thomas Larsson**
January 2, 2017

Why,

Although not exactly physics, an example would be Leopold Kronecker, who retired from the family business to pursue a career in mathematics. Of course, most of us cannot afford to retire at the age of 32.

20. **Jeff M**
January 2, 2017

The whole "research manager" thing I find amazing. I appreciate it's very common in the sciences, but in math from my experience it's very different. A postdoc working with a senior researcher would only put the senior persons name on a paper if they wrote it together. It wouldn't happen if the senior person suggested a topic, and then made some suggestions while the postdoc was working on it. The senior person would get thanked, sure, but not writing credit. When I started work on my thesis, my advisor suggested something, which I went off and worked on. After a few months, I realized I could show that what my advisor thought was true wasn't true, but I had an idea what should be, and that it was interesting. But I had no clue how to prove it. Neither did my advisor. So he asked around, and a friend suggested an idea he had once had for a related problem, which he never ended up working out, since he figured out an easier way to do what he wanted. So I worked it out, all the details, and proved what I wanted. I thanked the (very famous) guy who suggested the basic technique, but he certainly didn't get writing credit, and in fact the technical lemma is known as "M***'s lemma" in the field. I did do all the hard work on it….

21. **Oldster**
January 2, 2017

Why: Does Copernicus count? I think I recall from Arthur Koestler's book, "The Sleepwalkers", that he was actually on his deathbed before he saw the first printed copy of his book. He'd been somewhat known as an advocate for the Heliocentric Theory prior to that, at least locally. And maybe that doesn't count as "retirement", even though he was dying …

22. **Why**
January 2, 2017

Thomas Larsson,
Thank you for your answer. But that was an exception that confirms the "rule": one generally does not produce anything significant after age 60. I am not well aware about teaching in the U.S. but why somebody like Henderson does not teach at high school after getting a PhD and have plenty of time for independent research instead of

waiting until age 50 or 60 to retire before starting research? Besides, I guess one does not need a PhD to teach in a high school, so why all this pressure on physicists who really love to teach and do physics?

23. **Jeff M**
January 2, 2017

Why,

Teaching high school is hard. Doesn't leave any time for research. And leaves no time for things like going to talks and conferences and such, except over the summer. The high school teachers I know are some of the hardest working people around.

24. **vmarko**
January 2, 2017

Why,

Teaching at a university and teaching in high school are two completely different things. In high school, the course material is very easy, but you typically have several classes per day with 20-30 pupils in each class. You need to give classes basically every day and every week, which means no time to attend meetings, workshops, conferences etc (as Jeff said). In addition, you need to provide exams to all those pupils, and grade them, which takes a huge amount of time. In other words, its intellectually easy, but the workload is enormous.

In contrast, at a university, the course material requires some preparation, but you typically have one or two courses per semester, which amounts to giving lectures twice a week, to 20-30 students in total. You have the ability to skip or reschedule the lectures to make room for travel, and you have a teaching assistant who does all the grunt work of working the students through the problem books and grading their exams. So it's intellectually less trivial, but the workload is nowhere near the amount of high school.

Best, 🙂
Marko

25. **A reader**
January 2, 2017

Why, your question is interesting. I don't know whether it is OT or not, but … IMO, it is not very useful to repeat/promote that myth(?), that somebody can do research working all alone. Is there any modern example (say after 1946) of a theoretical physicist or a mathematician who has been able to do proper research without being part of/interacting with a community of peers? See for example 3. How is mathematical understanding communicated? in that essay of William Thurston, On proof and progress in mathematics, which Peter Woit mentioned a long time ago: http://www.ams.org/journals/bull/1994-30-02/S0273-0979-1994-00502-6/S0273-0979-1994-00502-6.pdf (arxiv.org/pdf/math/9404236v1.pdf)

26. **Peter Woit**
January 2, 2017

A Reader,
Perelman came up with his proof of the Poincare Conjecture while not having an academic job (I don't know how he was supporting himself, certainly not by working at another job).

27. **Dragster**
January 3, 2017

Why,
And, out of curiosity, what percentage of tenured professors do you feel have made a 'significant contribution to physics'?
Seems retired amateurs aren't necessarily lagging so far behind if you want to use that metric. Perhaps they just feel less compunction to publish mediocre papers.

28. **Why**
January 3, 2017

Thank you all for your comments and answers.

29. **Petite Kabylie**
January 3, 2017

Through Why's question and others replys and comments I understand now better why unifying the laws of Nature is not the holy grail for a theoretical physicist as is a tenured professorship!

Thank you!

30. **A reader**
January 3, 2017

Peter, thank you!

31. **srp**
January 3, 2017

Great article and informative thread here. Thanks.

32. **Pavel Krapivsky**
January 3, 2017

Perelman quit his job at Steklov Institute at the end of 2005, long after he submitted his proof to arXiv. I watched a Russian documentary about Perelman where some of his colleagues were guessing that his mother pension plus support from his sister were crucial. The wiki article about Perelman refers to articles in Russian press claiming that from 2014 Perelman is working, perhaps part time, in Sweden. His sister apparently works in Stockholm, so hopefully Perelman is surrounding by family and happy.

33. **Yi-Zen Chu**
January 4, 2017

Jeff M's comments above (January 2, 2017 at 9:54 am) reinforces why I hold mathematicians with higher intellectual regard than I do theoretical physicists.

Jeff M: How do mathematicians maintain this high level of intellectual and scientific integrity — i.e., where only the ones who did the actual work get on the paper? Is this unspoken culture, or are there concrete incentives in place that support and encourage such behavior? As the job market/funding withers and competition increases, is there any discussion regarding how the math community can continue to maintain such high standards?

I have been wondering for a while now, why major journals in physics (Physical Review, JHEP, JCAP, etc.) do not, at the minimum, require authors to enumerate their individual contributions in some detail. This would level the playing field at least a tiny bit for people who do not wish to play the game of riding on other people's hard work, or be exploited by others. (Much more, of course, can be said regarding the credit structure of theoretical physics.)

Lest Peter boots me for being off-topic, let me mention this is highly relevant to the experience of being a graduate student in theoretical physics. It is indeed true that the (rarely challenged) cultural norm of theoretical physics is that, if the adviser came up with the idea, he/she would most definitely show up on the paper — regardless of how much work he/she had put into the actual implementation. It's almost as if the details aren't important; when we know. in science, this is untrue. Furthermore, the student often ends up being mentored by postdocs and other grad students, especially if the adviser is very senior. When the project succeeds, the adviser gets to put it on his/her CV, which will be viewed by funding agencies and colleagues as yet another contribution to his/her field. With the money obtained, the adviser is able to pay his/her summer salary, his/her standing with school administration advances further — and quite importantly, he/she gets to travel around to interact with distant colleagues; build his/her network; write yet more papers simply by "chatting" with others; etc. What the graduate student may not realize at first, is that many "ideas," "insights," or "open questions" in theoretical physics are bounced around among the people in the know/loop; and so while the student may wonder in awe how the heck his/her adviser came up with these research directions, the basic framework/questions are often quite well known to researchers who have been in the field for a while. On the other hand, when the project progresses very slowly because of genuine technical/scientific issues or even fails completely, the burden of the ensuing consequences — say, the lack of postdoc opportunities because of the low rate of publication — oftentimes falls squarely on the lower ranking members, particularly the graduate student. How this is an ethical reward structure, especially given the dire job situation of our times and given we are supposed to be "scientists," is something that has boggled me for many years. (I also believe these issues are intimately tied to the reliability of the theoretical physics research literature.)

34. **chethan krishnan**
January 4, 2017

I am sure there are plenty of senior guys who piggy-back on the blood, sweat and tears of grad students and postdocs, but that doesn't mean that there is no value to the leadership, intuition and experience that a senior person brings to the table.

The skill of asking the key questions and having the key ideas that solve problems requires maturity. Together with a bit of (delusional?) confidence, a sense of direction, and an ability to not panic while fumbling in the dark. This last bit is what happened to Henderson as he beautifully narrates in his piece.

In Jeff M's example, think the senior person deserved some credit. He had a key input in solving the problem. He didn't want the credit, but that doesn't change that fact. It is also a tribute to Jeff M's integrity that he is open about it.

For the purpose of full disclosure, I have a permanent job. But I eat my greens and I calculate, dammit! 🙂

35. **piscator**
January 4, 2017

Some comments on this.

1. In the big picture of science in terms of authorship, theoretical physics is pretty close to maths. Go look at any lab subject to see papers where the senior author *really* has no intellectual contribution to the subject (conventionally the last name).

2. A lot of the comments here miss the fact that a paper by a graduate student on an OK-but-not-revolutionary topic gets *more* impact with a senior person's name on it than if by themselves – this helps the student not hinders them, and senior folks' reputation in theoretical physics is not normally based on being senior author on OK papers done primarily by graduate students.

3. Problems given to graduate students are often of the 'I know how to do it if not the precise result, these are the broad methods that will work, this is the broad structure of the result.' The 'idea' is a large part of the work, and normally the advisor will also be writing parts of the paper as well (relating the work to the wider context of the subject etc).

4. Probably the single biggest failing of graduate students is to have an overly-narrow focus on the precise technical details of their own calculations, at the expense of understanding *why* something is important (and therefore focus on calculating *things that matter*).

5. Scientific contributions are on a logarithmic scale. Most advisor/student papers are as much training projects as they are advances in science. Reputations are based on big results – and important, open and easily doable problems don't get assigned to graduate students, they get done as quickly as possible by anyone who encounters them.

36. **Bernd**
January 4, 2017

piscator,

at least in some areas, #1 is not true anymore. In some groups, it is normal for pure theory papers to have about a dozen of authors. This is crazy of course. However, people involved in this game receive much higher citation statistics so they have an easier life on the job market, perpetuating this practice.

While #2 might be true for the impact of the particular paper, it is not helpful to the individual student. If you have a single author paper, it will look much better on your CV than if all your papers are together with your PhD advisor.

37. **piscator**
January 4, 2017

Bernd:

My more detailed statement would be that the optimal positioning for a student on the job market is to have one or two papers that are by themselves or with other students, and the rest coauthored with senior people. So I broadly agree with you here, ideally a student in TP will neither have all papers by themselves or all papers with their advisor.

38. **Richard**
January 4, 2017

An interesting, enlightening — and ultimately * depressing * thread: as I made my way through it (N.B. I read the Henderson piece in its entirety before doing so.), I could not shake the increasingly intense feeling that the garment — to the weaving of which such a thread best lends itself — is a shroud….

39. **Jeff M**
January 4, 2017

Some general comments. First, there aren't really any incentives in math in relation to giving author credit, it's just the way it is. I think the fact that there is much less money in math is part of it. It's also maybe that it's hard to imagine a math paper with 15 authors if you've ever written a math paper. It's pretty hard to imagine a paper with 4 authors, although I know a few (they tend to be from conferences, where some people got together over lunch and wrote something). As far as the senior person who helped me on my thesis, he of course did get credit, just not author credit. I thanked him, something like "I would like to thank so and so for suggesting this technique, from an unpublished manuscript." In the published version and the in house thesis both. Very common in math papers.

40. **colorado**
January 4, 2017

I do agree that collecting data or calculating numbers is not doing science. Figuring out which quantity to measure or calculate, coming up with the way to do such measurement/calculation, and analyzing the data/numbers is the real part of the science in action. In my experience, many students and postdocs do most of these things, while the "PI" just tells his/her minions to work on a particular area. If the PI is paying the students and postdocs, then it's alright that they are expected to work together with the PI. My gripe is that the PI's are never working, and they expect their work to be done by the students and postdocs.

41. **Radioactive**
January 5, 2017

I don't know if there was really a problem with Henderson or his advisor here¸ more that the inspirational material he read didn't describe the reality of doing theoretical physics. Kind of like watching the Olympics and assuming that you'd be standing on the podium without realising most of your life would be training, and that the vast majority of people who try, fail.

Who doesn't want to solve the mysteries of the universe? That's simply not enough.

42. **Justin**
January 5, 2017

How difficult is it for a particle physics graduate to switch into mathematics where I think the employment prospects are much better? At my undergraduate institution (only a top 70 school) the phd math graduates had decent employment rates at very small unknown four year colleges. Maybe this isn't what one would consider glamorous, but if the physics grads can't find any physics jobs, isn't the switch to math an option they could consider?

43. **Jeff M**
January 6, 2017

Justin,

I can tell you my school we wouldn't hire someone with a physics PhD, we have way to many math PhD applicants to consider it. I'm a state U (second level) I tend to think liberal arts schools are the same. Even in math people have trouble getting an academic job, though if you are willing to teach anywhere and have good teaching refs you can often get something. We're hiring this year, we got our ad in late (state budget issues), it only got posted about christmas, and I just checked, we already have 218 applicants. Plenty of them with degrees from top 20 schools.

January 6, 2017

The problem is neither theoretical physics nor capricious advisers, but rather the mind-numbing, interminably gray weather of Rochester. I relapse to seasonal affective disorder just thinking of my 15 years there. It is no surprise that in the third paragraph Henderson has his epiphany under the first blue sky *in the wake of one of Rochester, New York's typically brutal winters*.

January 8, 2017

Chethan Krishnan (January 4, 2017 at 5:12 am): Senior scientists most certainly possess the potential to contribute intellectually to the papers their names appear on — from the ideas on and guidance towards the important questions; to providing invaluable insights and problem solving approaches along the course of research; to suggesting the appropriate checks that ought to be performed after an arduous calculation; etc. I personally view these as a vital part of the mentor-ship a senior scientist should be providing to his/her students and postdocs. My main point is, given the contrast between the reward structure faced by established scientists and those by the students/postdocs — as well as the dearth of jobs/over population of students and postdocs — how frequently does this mentor-ship scenario actually play out? (Expecting senior physicists to perform their own independent calculations is largely out of the question these days; this is why those who still write papers on their own certainly command my respect.)

On the other hand, I should have clarified that my observations are somewhat US-centric, having spent graduate school and postdoc years here. In particular, I have little sense of how the Indian academic/theoretical physics system works. Finally, please do not view my comments as a reckless attack against all senior theorists. They are, instead, based on a genuine desire to uphold high standards of scientific honesty. (It is because I take these issue serious, that is why I do not post these comments anonymously — as you probably can recognize, as a lowly postdoc, my comments do carry some level of personal risk if they are misconstrued.) Mature scientists should be able to look to other scientific communities — in my case at hand, mathematicians — to adopt whatever good practices they have, so as to help safeguard the integrity of one's own scientific community.

piscator (January 4, 2017 at 5:25 am): Your #2 — that getting senior people on papers benefits the junior ones — is, strictly speaking, a political statement and not a scientific one. Now, I am just as guilty as the next person for clicking on an arXiv paper because it has a famous name on it. But isn't this precisely why it is an issue of integrity that we should be sensitive to? In addition to the intellectual discipline we should exercise, to judge a paper by its merits and not by who wrote it — should we not question who actually did the work and implemented the ideas involved? (This is why I suggested all journals should, at the minimum, require authors to enumerate in some detail their individual contributions.) Why are we unfairly rewarding people who have infinite job security while watering down the credit of those who likely have to quit some time down the road? I would also point out, the more everyone buys into this mode of operation, the more the incentives are stacked in favor of established people and against the students/postdocs.

Do you recognize your #4 describing the failure of the adviser involved too? In other words, when a student "fails" to sift out the important physics from the complicated technicalities, is it not the adviser's job to steer him/her back on course? I believe the cultural norms and ethical standards of theoretical physics oftentimes place unfair and unrealistic expectations on graduate students. While academia pays lip-service to the notion of "diversity" — and from what I can tell many physicists do claim to subscribe to liberal and/or progressive values — the reality on the ground is really quite different. How can we claim to truly value a diverse range of viewpoints if we do not seriously invest the effort to nurture and support budding scientists, i.e., the graduate students/postdocs?

Jeff M (January 4, 2017 at 3:44 pm): Incentives need not be very explicit "if you do X you will receive Y," although the money/funding you mentioned likely serves as a significant driver of behavior among more senior theoretical physicists. Given we are social animals, cultural norms exert powerful pressures on us all — sometimes for the good. If, for instance, mathematicians "grow up" watching their advisers being extremely scrupulous about giving proper credit and finding multiple ways to check their work for errors — these practices will likely be passed on to the next generation. On the other hand, if questions such as "Can we take limits to check if this messy answer makes physical sense?" come up rather infrequently; while students/postdocs witness it is the people who publish O(10-15 papers) per year that ultimately get hired — then these are rather concrete disincentives against upholding basic standards of carefulness/thoroughness. In theoretical physics, "bend-over-backwards" attitudes are essentially extinct; while fashion-chasing and publication-rate-amplification is high on most people's agenda. As I've alluded to before, given the current climate, I worry about how reliable the literature is. (The sloppy nature of peer review does not help either — but here, I am wary about straying too far off-topic…)

46. **anon**
January 14, 2017

It seems utterly depressing that the best minds of the last two generations (at least) have been guided by circumstances and a changing culture into squandering their talents on toys (e.g. social media) and predatory finance.

New Year's Multiverse

January 7, 2017
Categories: Multiverse Mania

I see little to be hopeful about the new year, but had a glimmer of a hope that we'll see a reduction in Multiverse Mania. Surely people will sooner or later get tired of stale pseudo-science. Just got back to work from vacation and it seems that so far this is not working out at all, quite the opposite.

At the yearly Edge question site, Martin Rees's answer to the question "What scientific term or concept ought to be more widely known?" is The Multiverse, and he starts out with the usual sort of breathless hype:

> An astonishing concept has entered mainstream cosmological thought…

Critics of the multiverse are described as having two arguments:

- "Some claim that unobservable entities aren't part of science."
- "Some physicists don't like the multiverse: they'd be disappointed if some of the key numbers they are trying to explain turn out to be mere environmental contingencies governing our local space-time patch—no more truly "fundamental" than the parameters of the Earth's orbit round the Sun."

The first of these is the usual straw man argument, painting multiverse critics as too ignorant to realize that much of science is based upon indirect evidence, not direct observation. The actual argument of this sort against the multiverse is not that we can't get direct evidence for it, but that there is no evidence of any kind for it, direct or indirect, and no plausible prospects of getting any. This case has been made ad nauseam here on this blog.

The second of these arguments is treated in much more detail in a new article at Nautilus by string theorist Tasneem Zehra Husain with the title Even Physicists Find the Multiverse Faintly Disturbing. Husain treats in detail the question of how physicists "feel" about the multiverse, and like Rees, makes the point that what physicists don't "like" about the multiverse is that it removes hopes of being able to do things like understand the nature and strengths of fundamental forces, or calculate the masses of elementary particles.

Rees tells us that physicists are wrong to feel this way, that instead they should be awed by "the revelation that physical reality was grander and richer than hitherto envisioned" and that "If we're in a multiverse, it would imply a fourth and grandest Copernican revolution." Husain in the end seems to agree, quoting Gian Giudice:

> Perhaps we need to let go of something we're holding onto too tightly. Maybe we need to think bigger, refocus, regroup, reframe our questions to nature. The multiverse, he says, could open up "extremely satisfying, gratifying, and mind-opening possibilities."
>
> Of all the pro-multiverse arguments I heard, this is the one that appeals to me the most. In every scenario, for every physical system, we can pose infinitely many questions. We try to strip a problem back to the essentials and ask the most basic questions, but our intuition is built upon what came before, and it is entirely possible that we are drawing upon paradigms that are no longer relevant for the new realms we are trying to probe.
>
> The multiverse is less like a closed door and more like a key. To me, the word is now tinged with promise and fraught with possibility. It seems no more wasteful than a bower full of roses.

Rees and Husain do a good job of showing that if science is about feelings, then Multiverse fans have a fine argument against critics arguing based on their negative feelings. The problem of course is that science is not about feelings but about evidence. The argument by critics that needs to be addressed is that there is no evidence at all for current multiverse scenarios, and no plausible way of getting any by scientific methods.

Nautilus has another multiverse-related piece just out, We Have Pushed Physics Too Far, by Marcelo Gleiser. My reading of the piece is that Gleiser agrees that the Multiverse is not successful science ("Parallel universes are a non-answer"), and I believe most physicists also agree. Unfortunately the lessons he draws from this (as I'm afraid many others are doing) is that the problem not a particular research program that failed (string theory, by ending up with the string landscape and the multiverse), but the whole idea of pursuing mathematical ideas about further unification:

> We can call this the ultimate Platonic dream, the quest for a single simple and broad-ranging theory of physics. Indeed, during the past four decades, the search for such a theory has inspired many of the brightest physicists in the world. But today we are seeing the limits of this Platonic thrust to mathematize nature, due to a lack of experimental validation and several theoretical obstacles—including the possibility of multiple universes and the troubling questions they pose.

Gleiser sees successful physics as "an expression of intellectual humility", with our current problem that of Icarus, trying to fly too close to the sun. I strongly disagree with him about this, seeing some of the best of physics as an expression of intellectual arrogance, not humility. It is intellectual arrogance that has gotten our understanding of nature as far as it has gone, and it will require intellectual arrogance to go farther. The current problem of theoretical physics is due not the sin of arrogance, but to a somewhat different one, that of refusing to admit error. Multiverse mania is largely about the refusal to admit that string theory unification is a failed idea. Yes, arrogance is one reason for this refusal, and admitting failure takes some humility. But then moving on to find different, more successful ideas will require a lot of both mathematics and intellectual arrogance.

Update: One more article at Nautilus about the multiverse. At least this one is explicitly theology, it explains:

> a section of liturgy recited whenever we take the Torah out of the ark, and it's related to a prayer that many Jews know, "Adon Olam." The phrase is usually translated as "Sovereign of the Universe," where the word olam can mean both "the universe" and "eternity," expressing tremendous expanses of both space and time. But in this particular section of the Torah service, God is called "Adon Olamim," where the suffix -im makes the word plural. This means that God is "Sovereign of the Universes," as in, "more than one universe." God doesn't need to be a designer who had a specific plan in mind that led to the creation of humanity. God is, in fact, the Sovereign over all the universes, including the ones that don't have life in them.

Update: Yet more explicit theological coverage of the Multiverse at science magazine Nautilus, with an article from Mary-Jane Rubinstein, a professor of religion, who is interested in multiverse versions of pantheism and explains:

> As a professor of religious studies, I am particularly drawn to the places where religion and science seem antagonistic, but turn out to be entwined. The multiverse, I would argue, is one of those places.

My only disagreement here would be whether being a place where science and religion are intertwined is a good or bad thing…

Update: Yet more in the Nautilus series on the Multiverse: more theology, and now teleology.

Update: In case you were worried that Multiverse pseudo-science was incompatible with the Quran, have no fear.

Update: 2017 is well on its way to a bumper crop of Multiverse Mania. Today it's New Scientist's turn.

Update: This crap is just endless, more every day. Today it's at Astronomy Magazine, about this nonsense, debunked long ago by Jennifer Ouellette.

Comments

1. **reader**
   January 7, 2017

   This is a tired topic, but I find your point of view quite odd. The global structure of the universe is either essentially homogeneous or it is of the multiverse type. We don't know which version is true, so it seems quite reasonable to consider both options. What exactly is your stance: that the multiverse picture is ruled out in some way, or that the whole question is pointless? To me, the homogeneous versus the multiverse structure are roughly equally likely a priori. It doesn't seem so far fetched that the two options will leave different observable imprints of some sort. Whether this is indeed the case is a difficult question that requires serious thought and analysis, yet you call this pseudo-science. Speaking for myself, there are few questions more grand than that of the global structure of the universe, and we should do everything we can to look for experimental signature before declaring that the search is futile. Your negativity on this matter is puzzling.

2. **S. P. Nova**
   January 7, 2017

   Perhaps confidence would be a better term for what you mean, rather than arrogance, which has never served anybody well. Quite the contrary. Confidence and humility can co-exist. Arrogance and humility cannot.

3. **Jeff M**
   January 7, 2017

   I don't see why unification is mathematization. All physics is mathematization. The four forces are mathematized if they have nothing to do with each other. The fact that a mathematical structure exists which seems to show some relation between three of them is no more mathematical than their individual structures, it's just different math. And I would agree with SP Nova about confidence, though I have known plenty of arrogant physicists….

4. **neil**
   January 7, 2017

   "Multiverse mania is largely about the refusal to admit that string theory unification is a failed idea. "

   I agree that the string theory multiverse is a failed idea for the reasons you state, but what about the eternal inflation multiverse, or for that matter the MWI? In these cases the appeal seems more about the anthropic principle or interpreting QFT than the multiple compactifications of string theory. Do you find these ideas any more appealing than string theory unification?

5. **Laurence B Lurio**
   January 7, 2017

   There is an article by Steven Weinberg in the most recent New York Review of Books where he says he is looking for a modification to quantum mechanics in order to avoid the multiverse issues. See http://www.nybooks.com/articles/2017/01/19/trouble-with-quantum-mechanics/#fn-3

6. **Peter Woit**
   January 7, 2017

   S.P. Nova,
   I was specifying "intellectual" arrogance as opposed to other kinds, and by that I meant just the opposite of Gleiser's "intellectual humility", which to me means having a low opinion of one's ability to solve difficult problems. Having an unreasonably high (and thus "arrogant") opinion of one's ability to solve an intellectual problem is generally a prerequisite for making a serious attempt at solving the most difficult unsolved problems.

   As for the more general sort of arrogance, there's a lot of that too among successful theoretical physicists, and the part of that characteristic that leads one to refuse to admit something doesn't work is generally very much not helpful.

   "Intellectual humility" says that the puny human brain is incapable of understanding how the world works at the deepest level. Unlike Gleiser, I see the practice of fundamental theoretical physics as a rejection of this idea and the pursuit of its opposite.

7. **Peter Woit**
   January 7, 2017

   neil/Laurence B. Lurio,

   The multiple worlds interpretation of quantum mechanics has nothing to do with the multiverse discussed in these articles, one where laws of physics are different in different universes. Bringing completely unrelated things together, making it impossible to know what one is actually talking about, is part of multiverse mania. I don't want to discuss MWI here.

   I read the Weinberg piece, didn't see anything at all new there, and it's off-topic here.

8. **Peter Woit**
   January 7, 2017

   reader,
   My claim is that the question is pointless in the sense that it's not now science. Maybe someday someone will come up with a multiverse theory that explains something and can be (indirectly) tested. At the moment the "theories" being put forth that have different physics in different universes don't explain anything, all they are is elaborate excuses for failure.

9. **S. P. Nova**
   January 7, 2017

   Perhaps "reader" confuses the general concept of inhomogeneous cosmological models, of which there are many, with the specific concept of a string theory multiverse of 10^500 universes with different constants and physics in each.

10. **Peter Woit**

January 8, 2017

S.P. Nova,

Yes, that's the essential point. That the Big Bang was just one of many such events, with lots of other universes out there with the same physics as ours is a plausible idea, and you can even claim it follows from your favorite inflationary model. Personally I'm not very interested since it explains nothing about unanswered questions of fundamental theory, and I doubt it has testable implications. A claim that there are lots more universes out there like ours, but disconnected from us, may be thrilling to some but it tells us nothing about ours.

Unless you have a model you can calculate things in (unlike the string theory landscape) a multiverse with different physics in different universes also tells us nothing about our universe, all it adds is an excuse for why we can never calculate certain things (they depend on which universe one is in). Maybe this excuse is true, maybe not, but lacking any way to calculate things and make testable predictions, all it is is an excuse, and pseudo-science rather than science.

11. **reader**
January 8, 2017

I would like to stress that whether or not you like the multiverse or find it interesting has no bearing on whether or not is a true fact of our world. Everyone agrees that it would be lovely if, for example, SU(3)xSU(2)xU(1) was the unique outcome of some deep new principle yet to be discovered. But the world might not be like that — it might just be a more or less random fact about our local vacuum. It's a challenging situation, since it's hard to think of ways to distinguish the two possibilities. What is pseudoscience is to pretend that this issue does not exist.

12. **Thomas**
January 8, 2017

reader,

it might be that SU(3)xSU(2)xU(1) is due to the sequence octonions, quaternions, complex, real; it might be that SU(3)xSU(2)xU(1) is due to the three Reidemeister moves; it might be that SU(3)xSU(2)xU(1) is due to some other principle. But SU(3)xSU(2)xU(1) cannot be due to the multiverse, because that term makes no sense: multi-everything is a contradiction.

13. **a1**
January 8, 2017

Re arrogance vs. humility I would say that humility is to admit that we still do not know everything knowable. But pushing humility too far would destroy science, it would amount to say that we will never know. Saying 'never' is of course arrogance. Multiverse theory is arrogant as it assumes that we already know everything relevant: obviously this is not enough to explain some features of physics, so a multiverse has to be hypothesized. But the real point is that it obliterates our lack of relevant knowledge.

14. **Bee**
January 8, 2017

"In every scenario, for every physical system, we can pose infinitely many questions."

The multiverse is great because it means they can write papers about fictional universes until eternity.

15. **Peter Woit**
January 8, 2017

reader,
Yes, the string landscape explanation may be true, it also may be true that SU(3)xSU(2)xU(1) was chosen by the Jolly Green Giant for reasons we can never understand. The problem is that neither explanation is a scientific one.

16. **reader**
January 8, 2017

Thomas,

You left out the possibility that SU(3)xSU(2)xU(1) might not be "due" to anything. Of course the danger lies in jumping to that conclusion prematurely, which is why it seems best not to "believe" in the multi-verse, but rather to accept it as a possibility and remain vigilant for signs of its (non)existence.

Here is the kind of questionable logic one reads on this blog and elsewhere: string theory predicts the multiverse, the multiverse in inherently unpredictive, therefore "string theory unification doesn't work". This logic would only make sense if there were some alternative theory that had a monoverse and that made some successful prediction beyond what string theory can do. But in the absence of that, if you assign a priori 50-50 odds for multiverse or monoverse, you can't possibly use the "string theory predicts multiverse" line to argue that string theory is "wrong" or "doesn't work" — that makes no logical sense.

17. **Jeff M**
January 8, 2017

I think Bee hit the nail on the head 🙂

18. **Peter Morgan**
January 8, 2017

"Multiverse mania is largely about the refusal to admit that string theory unification is a failed idea." I'll pick up on this for a different reason than that given by neil.

I find string theory/Multiverse ideas too unsupported by evidence, but to say that it's all a "failed idea" seems too much. Someone could come up with a big new idea tomorrow that changes all that. I can expend a lot of hot air on how unlikely I think that is, but that's just feelings. Nonetheless, it's always too soon to declare an idea "failed". I think far too many resources are being given to string theory, but the alternatives seem in about the same shape, of needing a new idea to make it really attractive enough as a possibility for many people to move to it. Note that I don't think of this as the common "we should all work on string theory because there's no alternative" argument, because there are plenty of slight possibilities that might deserve a decade of someone's time, or even mine, but research most always gives the desperate feeling of having made bad choices, except for the occasional, fleeting moments when everything feels kinda right.

19. **Peter Woit**

January 8, 2017

reader,
The logic is: the string theory unification hypothesis leads to a scenario that predicts nothing (or, anything, the same thing…) and thus cannot ever be tested. This means the hypothesis is scientifically empty, on a par with the Jolly Green Giant theory and many others. You can decide to believe it if you want, and devote your life to arguing that your untestable explanation is the best one around, but you're not doing science.

Peter Morgan,

I think it best to call a spade a spade.

20. **tt**
January 8, 2017

"you assign a priori 50-50 odds for multiverse or monoverse,"

Occams razor would not agree with that prior

21. **reader**
January 8, 2017

Peter,

If we knew for certain that the multiverse hypothesis cannot ever be tested then I would basically agree. But this conclusion seems rather premature, although I admittedly can't provide you with a clear path towards testing the theory.

What odds do you assign to the multiverse being a true description of nature? I start with something like a 50% prior belief. Weinberg's argument for the cosmological constant, combined with the complete failure over several decades to uncover any deeper structure behind the Standard Model, pushes the probability to perhaps 60% for the multiverse. I think that anyone whose ultimate goal is to understand the laws of nature should do this exercise, and I encourage all readers of this blog to think about this in a serious way.

22. **RandomAnonymous**
January 8, 2017

reader:
What "exercise" – you simply pull numbers out of the air. You cannot possibly expect anyone to take a starting point of 50/50 seriously.

"this conclusion seems rather premature, although I admittedly can't provide you with a clear path towards testing the theory."
If someone comes up with a testable theory then we can discuss it. Until then, the multiverse is empty metaphysics. Predict something or go home.

23. **Peter Woit**
January 8, 2017

reader,

I expressed an opinion about this question here:
http://www.math.columbia.edu/~woit/wordpress/?p=8587

24. **Roofus McLoofus**
January 8, 2017

"[…]is due not the sin of arrogance, but to a somewhat different one, that of refusing to admit error. […] Yes, arrogance is one reason for this refusal, and admitting failure takes some humility. But then moving on to find different, more successful ideas will require a lot of both mathematics and intellectual arrogance."

I will align these statements with that of Dr. Richard Hamming: "…the difference between being 'strong-willed' and 'stubborn'…I've seen people abandon a good idea too soon, and I've seen people cling to a bad idea too long. They're both difficult problems."

25. **reader**
January 8, 2017

Random anonymous writes: "What "exercise" – you simply pull numbers out of the air. You cannot possibly expect anyone to take a starting point of 50/50 seriously."
Yes, to you this probably seems like it's pulled out of thin air. But some of us have spent a lot of time thinking about the early universe and the kinds of behavior that can occur. A Lagrangian with lots of different fields and a complicated potential doesn't seem terribly unlikely given what we know, and this sort of theory seems to lead to a multiverse. Sorry if you find that uncomfortable.

Peter: thanks for the link, although it seems that you are avoiding the question. It's incredibly important to separate which observed facts about our world have a deeper explanation and which are just essentially random variables. The decades long search for deeper mathematical structure underlying the SM has so far had zero success in terms of contact with experiment. This doesn't mean we should stop trying, but intellectual honesty requires that we consider the possibility that the task is misguided.

26. **RandomAnonymous**
January 8, 2017

You spent a lot of time thinking and postulating Lagrangians, and what you got in return was a guess of exactly 50/50? I'm truly sorry.
I don't find the idea uncomfortable, I find it unscientific, there is a difference. What exactly is it that we know which points to a Lagrangian with a huge number of fields and a complicated potential?

27. **reader**
January 8, 2017

RandomAnonymous: answering your question here would take up too much space and get off topic. But I will say this: it's not "unscientific", quite the opposite. If you are a scientist thinking about fundamental theory this sort of judgement call about what might be calculable literally affects how you spend your time every single day. You have to decide: "should I attempt to come up with an explanation as to why the dark energy density / CC is what it is, or should I just view it as a random number with no explanation.". Actual scientists, as opposed to blog readers, can't avoid confronting this issue.

28. **Peter Woit**
January 8, 2017

reader,
I should note that RandomAnonymous seems no more unlikely to me to be a serious scientist than you are. You'd be surprised who comments here anonymously. The ad hominem argument isn't a good one.

The problem with your argument about how scientists work is that
1. attempting to calculate X
2. deciding that X is a random number with no explanation
are not the only two possibilities. If you don't have an idea for how to attack 1, a much more sensible attitude than 2. would be
3. I don't know what explains X, will keep this open question in the back of my mind, maybe someday I or someone else will get an idea about this.

This is the serious problem here: instead of just admitting that string theory unification doesn't work, and we don't understand where some things come from, multiverse maniacs claim that string theory shows that no testable explanation is possible. There's a big difference between telling people "I don't know how to solve this problem" and "This problem can't be solved". Here I guess I'm with Gleiser that some humility is in order. Just because you have failed to solve a problem doesn't imply that the problem is insoluble.

29. **reader**
January 8, 2017

Peter,

option (3) is of course what most people do in practice. But when you get a glimmer of an idea, you have to decide: am I going to pursue this with full vigor, pushing my other projects aside, or am I just going to let this thought flow in and out of my brain. Taking the example of the cosmological constant, which option you choose is heavily influenced by your belief as to whether a deeper explanation exists. This sounds abstract, but it is in fact how people operate. My comment about "blog readers" was not meant as an ad hominem attack, it was to emphasize that when you are at home sitting on your couch reading a blog you can dismiss these issues, but you can't when sit in your office and get to work.
.
Saying "string theory unification doesn't work," is a gross simplification of a complex issue, and does little to advance understanding. But I agree that more humility is in order.

30. **RandomAnonymous**
January 8, 2017

Here we are both readers, in real life we are both scientists. It is clear that you are a hep-th theorist, so for fairness I'll state that I'm a hep-ex experimentalist.
I stand by my "unscientific" claim. A scientific idea may yet arise by pursuing this direction, but until then the multiverse is empty. At times we all have to decide which speculative direction to pursue, and this by necessity must be done without proper evidence, and based only on half-formed ideas / priors / guesses / etc. For this purpose the kind of reasoning you present above is ok – but absolutely not as a serious explanatory statement about nature. This is currently a big problem with your community – that the speculative ideas currently regarded as most promising get presented far too much as accepted fact.
"Saying "string theory unification doesn't work," is a gross simplification of a complex issue, and does little to advance understanding."
As things stand, it is impossible to argue that string theory unification has worked. Wasn't it originally meant to be a theory of QCD before that? A breakthrough could change all of this and the program could turn into a spectacular success of course. Until then, I repeat the statement from my first post – predict something, or go home.

31. **vmarko**
January 9, 2017

reader:

"But the world might not be like that — it might just be a more or less random fact about our local vacuum. It's a challenging situation, since it's hard to think of ways to distinguish the two possibilities."

The way to distinguish between universal laws of nature and random contingencies is well-known: given a statement about the physical system, if all instances of the physical system obey the statement, it's a law. If only a few instances obey it, it's a contingency.

Maybe the most vivid example of this at work was the Titius-Bode law, which was considered to be a true law of nature, even used (successfully!) to make predictions, until people discovered Neptune, and later on other solar systems different from our own. At that point the "law" was demoted to the contingency of the initial conditions for the formation of the Solar system.

The problem with interpreting physical constants as a contingency of the multiverse is therefore obvious — until you find experimental evidence that in some part of spacetime the constants are different, I have no reason to say that they are a contingency. In contrast, there is overwhelming evidence that the constants are the same throughout observable spacetime, making a 50/50 prior very unrealistic.

And if you try to claim that the patches of spacetime where constants are different are necessarily beyond the observable horizon, then you are leaving the realm of science, and talking metaphysics. I can equally claim that there are unicorns beyond our observable horizon, and assign to it a 50/50 prior. That just isn't science anymore.

Best, 🙂
Marko

32. **Dan Winslow**
January 9, 2017

Well, science has to end somewhere, right? The idea that we can find every explanation for everything seems like it would have to result in a circularity or infinitely receding stack at some point.
I guess the question ultimately is : can Science contain itself? Since we are using chains of causality in our thinking, don't we ultimately have to wind up at a first cause, an outermost explanation? If we get to any explanation, isn't there then by definition the need for an explanation for that?
I am not talking about anything to do with a diety at all.I just mean that I don't think we can arrive at an explanation for everything. It's got to end somewhere, even if it's just our own ability to understand. Have we reached that spot? I have no idea, but we might be getting close. The way that current thought about physics seems to be fracturing and wandering off into theology and wishful thinking may be an indication of that.

33. **Peter Woit**
January 9, 2017

Dan Winslow,

Yes, there's a real danger that we're getting to the limits of what we can understand. What concerns me is that instead of having a situation where the open problems we don't understand are clear and people can keep trying if they wish to make progress, we'll end up instead with an entrenched influential ideology saying that the string landscape is our best understanding, and that shows that no progress is possible, no point in trying. This would be convenient for a generation of theorists who invested heavily in string theory: they can avoid admitting failure, and might figure that there's little hope of progress anyway during the rest of their careers. It would not be a good thing for physics, or for science and its public perception in general.

34. **Anonyrat**
January 9, 2017

Gravity was an elaboration on Newton for centuries, until Einstein. Particle physics might have a similar centuries-long detailing of the Standard Model before the next step. There is no reason yet to succumb to the multiverse because one or two generations of physicists haven't made the next breakthrough.

35. **Arnaud**
January 9, 2017

reader :
I think the multiverse hype is the failure of string as a theory for the following reason where I use in parallel the example of gauge theory.
A postulate of string theory is a 4+D dimensions space where the D dimensions as to be compactified to describe our universe. A postulate in gauge theory is that it exists a gauge group G describing fundamental interactions.
In string theory nobody knows how to compactify the D dimensions to get our observed physics and there is 10^(…) possibilities. In gauge theory we have a priori an infinite number of group but we know G = SU(3)xSU(2)xU(1) works very well (may be it has to be extended somehow but at least now, it does the job).
Last step, some string theorists unable to find the correct compactification for our universe postulate a multiverse. This is where the science fails. It would be like postulating that since gauge theory works here then there is another type of "gauge multiverse" where all different gauge group are realized. It is useless to understand physics in our universe to postulate that it exists other universe with other gauge groups. It is bad science to hide the fact that no known compactification describes our universe (at the precision of current experiments) by postulating a multiverse.

36. **DoZen**
January 9, 2017

Peter,

(Sorry for my ignorance, I'm not a physicist).
If string theory is not intrinsically incompatible with other approaches (representation theory, QFT, quantum gravity, twistors,….???) then all the other approaches also allow for nearly infinite mathematical possibilities. If, on the other hand, they are incompatible, that is Big News. Or does the question even make sense?

As to string theory per se: if you are stuck, why can't it be left on the back burner while other approaches are tried?

As a mathematician, it's hard to understand the struggle physicists are having. We work on things we think are interesting, and the main (only, for many of us) guide is interest and beauty. There's fairly wide acceptance of what fits these criteria. If I do something good, colleagues will be interested. So I never need have the feeling I am wasting my time, that it was all for naught! So there is no need to be defensive, or to write self-congratulatory expository articles. The reward is in the struggle, in the insight, in the doing.

I think some people confuse mathematical possibilities with physical possibilities.
Somebody could study gravitational orbits with a law different from inverse-square,
but that doesn't mean it "exists" someplace else, and it certainly doesn't mean it's
worth spending time on. If some grad student wants to do that as an exercise, well and good, but I wouldn't wake up in the morning excited to think about it- at least not yet. If I do some day, good for me; that would make me happy! But I hope I won't run around claiming this is an alternate "reality".

There are very real limits to what we can know and understand. Zen Buddhists have
understood this for a long time; their explanations are completely compatible with science. The experience of zen "knowing" by not knowing (perhaps called "just this") is quite useful and refreshing for scientists, as a lesson in humility and wonder. If you don't have to know it all, and yet "can" in a different way, you can relax a bit and have fun. The stress is less, and the delight remains. It all fits together, and it is all remarkable and amazing. The only part that causes a misfit is due to
our own egos, arrogance and jealousy. Anyone who gets to spend some time thinking about math, physics and all this is supremely lucky, can make real contributions, and could brag a little less while feeling a little more of gratitude. At least in this part of the multiverse!

37. **EThomas**
January 9, 2017

Peter,

Is it reasonable to expect all of reality to be accessible via empirical scientific methods? Is it even reasonable to expect all of reality to be conducive to mathematical modeling?

If not, where do we go from there?

(Disclaimer: I am not a fan of String Theory, or the Multiverse theories, mostly for some of the same reasons you state)

38. **Peter Woit**
January 9, 2017

Ethomas,
We have no way of knowing in advance how much further we can go, with experiment or mathematics. The only thing that's clear though is that if we convince ourselves it's not worth trying, we definitely won't go any further. So, for that I'd like to see a solid argument, not the bogus ones that prop up the string theory landscape.

As to where to go from here, personally it seems to me that there is still a huge amount we don't understand about quantum field theory, which has been our best tool for understanding fundamental physics. I don't see any serious argument for why we can't understand quantum field theory better, and hope to make progress that way.

39. **Chris Kennedy**
January 9, 2017

To put the Jolly Green Giant in the same category as the Multiverse is an insult to the Jolly Green Giant. At least there is a 55 foot statue of the JGG in Blue Earth Minnesota. There is no statue of the Multiverse (at least not in this Universe).
Personally, I think there are a lot of branches of science who are missing out on a wonderful opportunity currently monopolized by the theoretical physics community. For example: Multiverse Meteorologists could forecast for planets in the multiverse and predict the high/low temps, precipitation, etc. without fear of ever being incorrect. They might even be able to convince viewers that their forecast accuracy rate for worlds in the multiverse is 90%. Of course, once you multiply that 0.90 by "reader's" 50/50 chances of the planets being there to begin with, the more realistic figure drops to around 45%.

40. **Peter Woit**
January 9, 2017

Chris Kennedy,
I don't know about a sculpture, but there is this
http://www.crawickmultiverse.co.uk/

41. **Petite Kabylie**
January 10, 2017

Peter,

What if in 20 or 30 years a new theory, completely different from string theory, and based on sound and strong first principles, comes along and reveals the same landscape of the laws of physics as well as universes for ever disconnected from ours. Would you endorse the multiverse concept?
Thank you!

42. **Petite Kabylie**
January 10, 2017

N.B: Assume this theory has made tested predictions for phenomena in our universe.
Thank you!

43. **chris**
January 10, 2017

reader,

I am genuinely curious how you come up with a 50/50 prior for the existence of a multiverse. The arguments you gave (brooding over Lagrangeans etc.) seem purely sociological to me and i at least try to disregard such items as background noise when thinking about laws of nature.

Subtracting all the jargon, the statement "i give a 50/50 prior to the multiverse" for me is just the plain statement:
"The existence of things we can never detect is equally likely than not."
I guess this is something i would expect from an agnostic or maybe a philosopher – but what is the scientific content of such a statement?

44. **martibal**
January 10, 2017

Thanks Anonymat for your comment 🙂 I find quite arrogant the idea that "we may be at the end of what physics can explain". Why on Earth should the fact that the so-called "best minds" of the last (or two last) generations did not reach a breakthrough mean that we are reaching a limit of what could be explained ? It sounds as meaningless as "the end of history" of Fukuyama (after the end of communism, the world will leave in a the war-free happiness of free market).

Also, regarding the repetitive argument that multiverse deserves all the hype it gets because there is northing more convincing on the market, it is a bit tiring to repeat that there are others approaches which try to understand – with quite success – the structure of the standard model (e.g. noncommutative geometry). Not that these other approaches should be much more hyped, but at least they could make the the multiversemaniacs understand that it would be very, very, nice for everybody if they calm down a little bit.

45. **Peter Woit**
January 10, 2017

Petite Kabylie,
If there were a convincing fundamental theory that made confirmed testable predictions, and also predicted a multiverse with different parameters for particle masses etc, making them environmentally determined, I would be a believer in this multiverse (in the sense of assigning it a high probability and acting accordingly).

46. **reader**
January 10, 2017

Chris,

50/50 is really meant as shorthand for the middle third of three options: very unlikely, somewhat likely, very likely. I don't think that "brooding over Lagrangians" is "purely sociological", as the space of Lagrangians is our best way of thinking about the space of physical laws. And once you start thinking about this you realize how incredibly easy it is to get a multiverse picture: you basically just need a large number of fields and this is generically what you will find. The Standard Model seems to me to be intermediate between being very simple and very complicated. It's clearly a bit of a mess, but not nearly as messy as it could be. Extrapolating this lesson to higher energies where eternal inflation would take place, it seems to me fairly plausible that the Lagrangian at this scale is of the needed complexity to support a landscape and eternal inflation.

Anti-multiversalists hold on to the hope that the Standard Model is actually much simpler because there is some deep structure there that we haven't yet uncovered. Could be, but decades of effort devoted to finding this deep structure have so far yielded zilch.

47. **BR**
January 10, 2017

Reading some of the posts one could arrive at the conclusion that the multiverse is a dominant theme in hep-th, which is far from true in my opinion.
My impression is that outside the community it is discussed much more than inside. Perhaps that a few but influential scientists push for the idea,
either because for some reason they got convinced or because they simply started running out of steam and have a hard time to swallow the fact
may have some truth in it, however whatever they have to say I think has most of its impact on the general public and I suspect in fact that they are fine with that.
Historians of physics could perhaps look for some other situation in the past where a concrete subgroup of legitimate physicists declared the problems that
could not solve as (essentially) unsolvable or pointless. I would bet that this is not the first time, but I do not know.
And if those problems where eventually understood and solved or they indeed turned out to be unsolvable.
Also, more generally, I have the feeling that this is not the first period in time where the boundary region between fundamental science and philosophy is
a bit more fuzzy than usual.
On the other hand I would not be so sure that string theory and the multiverse are in one to one correspondence, at least not until
we understand its dynamics more deeply, including supersymmetry breaking and (related) non-perturbative effects.
Now wether the scientific relevance of string theory has been connected by its development too tightly to sociological and personal arrogance issues I think
is an unpleasant but fair discussion because these things are then connected to positions, grants, future research directions, education etc.
But the system can and does eventually regulate itself, one needs some patience and accept the fact that the time scale of such processes may be larger than O(30) years…

48. **vmarko**
January 10, 2017

EThomas,

"Is it reasonable to expect all of reality to be accessible via empirical scientific methods? Is it even reasonable to expect all of reality to be conducive to mathematical modeling?"

I just noticed that nobody addressed these two questions of yours. 🙂 Regarding the first question, the answer is — it depends. Regarding the second, the answer is — no.

The idea that all of reality can be understood by empirical scientific methods is a metaphysical position one may or may not endorse. People who believe in reductionism of everything that exists to (ultimately) elementary particles ("more is not different") tend to endorse that idea, and believe that everything can be reduced to (ultimately) fundamental physics. On the other hand, people who do not believe in reductionism ("more is different") are usually more open-minded to the possibility of non-scientific access to knowledge about reality, complementing the scientific one. So the answer to your first question depends on who you are talking to, and their prejudices and opinions about reality.

Regarding the second question — already in physics there are systems which resist being properly mathematically modeled. Examples include high-Tc superconductivity, mass gap in Yang-Mills theories, etc. Beyond physics (your question was about the whole reality), I think that systems which are complicated enough (things studied by biology, psychology, sociology, ecology, meteorology, etc.) will always be out-of-reach of mathematical models, despite our best efforts. This is basically a property of all strongly interacting physical systems, which cannot be studied by cutting the system into pieces and analyzing it piece by piece. The latter, so-called "analytic" technique is effective only if the interaction between the pieces is reasonably low and reasonably local, which is not the case for a huge class of systems (say, a human brain). The highly-interacting systems need to be studied using "synthetic" (also called "holistic") techniques, which study the system as an undivided whole — and most such systems are utterly awfully hard to describe mathematically. So no, it is not reasonable to expect that all of reality can be described using mathematical models.

Best, 🙂
Marko

49. **Peter Shor**
January 11, 2017

Chris: you say

> decades of effort devoted to finding this deep structure have so far yielded zilch.

These decades of effort were nearly all devoted to finding this deep structure using string theory. How do you know that the reason for the failure isn't due to string theory rather than a multiverse?

50. **Peter Shor**
January 11, 2017

Oops: that last comment should have been directed to "reader" rather than "Chris".

51. **AcademicLurker**
January 11, 2017

vmarko,

I'm not sure that "more is different" is in conflict with understanding phenomena through empirical scientific methods. After all, in P.W. Anderson's famous article, he was talking about things like states of (bulk) matter, phase transitions, & etc. I'd say we understand a lot of those things pretty well.

52. **Douglas Natelson**
January 11, 2017

To echo AcademicLurker, vmarko makes it sound like condensed matter physicists are believers in the supernatural. I don't think there's anything at all contradictory between ideas of emergence (large-scale properties that are highly nonobvious can emerge from the collective response of comparatively simple underlying degrees of freedom interacting via simple rules) and scientific empiricism. It is sometimes a lament (see RB Laughlin's first book) that emergent properties can make it difficult to access the underlying degrees of freedom, but that doesn't mean giving up on experiment and observation.

53. **Low Math, Meekly Interacting**
January 11, 2017

Hopefully I'm not offending our host with off-topic nonsense…

I love that Anderson article, but something about it makes me a bit queasy. He seems to be suggesting there's a unifying law or laws governing emergent phenomena that make them amenable to some sort of generalized system of mathematical modeling, i.e. broadly predictable using maths that are substantially less complex than the phenomena being studied.

I'm quite inclined to believe the notion that "more" is insurmountably "different", in a way that will always make the laws of fundamental physics rather useless for describing many real-world phenomena. But I see no real-world evidence anywhere that would make me believe there's some unifying mathematical law of emergence that will make disparate complex phenomena easier to comprehend, describe, or predict. Probably turbulence, high temp. superconductivity, and neurocognition have absolutely nothing to do with one another beyond involving aggregations of matter. I wouldn't think it a good idea to advise someone looking to answer a big, fundamental question, to walk down a road that tries to "unify" these things.

That's not to say infusions of greater quantitative talent aren't desperately needed in, for instance, the study of neurophysiology and consciousness. I just don't think those disciplines will ever appeal to someone attracted finding deep, unifying mathematical laws that accurately describe reality. At least, they won't appeal in anything remotely like the same way.

54. **Peter Woit**
January 11, 2017

Sorry, but enough about "more is different". This is an interesting topic, but really has nothing at all to do with the topic of this posting.

55. **reader**
January 11, 2017

Peter Shor,

These decades of effort were nearly all devoted to finding this deep structure using string theory. How do you know that the reason for the failure isn't due to string theory rather than a multiverse?

I disagree with "nearly all", or what is more relevant, even if you take away all work on string theory that still leaves a vast number of physicist years devoted to this problem. Fortunately, working on a topic like quantum field theory has its own rich rewards even if it has not so far shed much light on why the seemingly arbitrary features of the Standard Model are as they are. I certainly don't advocate ceasing to work on non-string related approaches to this issue, just pointing out that many have gone down this path before without success.

56. **AcademicLurker**
January 11, 2017

Peter,

Apologies for the derail!

More on-topic, since you've stated several times that trying to gain a deeper understanding of QFT would be a good place for more theorists to put their time and effort, here's a question. When was the last period where you would say that fundamental advances in our understanding of QFT (as opposed to the standard model in particular) were taking place at a reasonable pace? Were the 70s that last golden era?

57. **Peter Woit**
January 11, 2017

Academic Lurker,

There have been people working on QFT problems and making progress all the time, the problem has more been that the faddish nature of the field means that only a small number of possible directions are pursued by a significant number of people. In the late 80s to early 90s Witten's discoveries about topological quantum field theories were a major advance, and work on those continues to this day. The AdS/CFT business starting in the late 90s and continuing to now also led to progress on understanding some QFTs. More recently, the work on the amplitudes has led to progress.

I should stop going on about this and discourage others. This really is off-topic and deserves its own serious discussion in a better context.

58. **M Mahin**
January 11, 2017

See my post below on Husain's post, entitled "Pretzel Logic of the Multiverse Fantasists."

http://futureandcosmos.blogspot.com/2017/01/pretzel-logic-of-multiverse-fantasists.html

I discuss her strangest statement: "Logically speaking, an infinity of universes is simpler than a single universe would be—there is less to explain."

59. **Maximillian G. Tresmond, Esq.**
January 11, 2017

Dr. Woit,

As a non-physicist who regularly follows your site with interest, I have to ask: Why do credentialed scientists continue to to promote the multiverse "hypothesis" to the public when they know that the concept falls well outside the realm of legitimate science? The harm they are doing to the public understanding of science is likely to have a spillover effect to other branches which in turn could have a detrimental impact on public policy.

60. **Peter Woit**
January 11, 2017

Maximillian G. Tresmond, Esq.,

One thing to keep in mind is that the physicists doing this are a small minority of the community. Another question to ask is why more physicists aren't complaining publicly about what is going on.

As for why certain physicists do this, I'm sure that they believe that there is something to multiverse explanations and that they are legitimate science (they do argue that this is legitimate science, although I disagree with their arguments). A less obvious reason is that the multiverse is a topic that easily lends itself to a popular exposition: there's no significant difficult math or physics to explain, and people eat this up since it appears to be deep and mind-blowing, and they can kind of understand it. A physicist is a lot more likely to be asked to write a popular article or give a public talk about the multiverse than about ideas on, say, what the right variables are for computing scattering amplitudes (somehow Arkani-Hamed manages both, but he's a singular point…).

Finally, for some deeply devoted to string theory, they are torn between the multiverse being pseudo-science, and its providing them an explanation for the lack of predictivity of string theory. From them, one often hears "I don't like the idea of the multiverse, but it may be true".

61. **Tim Nguyen**
January 11, 2017

"But then moving on to find different, more successful ideas will require a lot of both mathematics and intellectual arrogance."

In my experience, another key problem is the lack of a fundamental symbiosis between math and fundamental physics. Sure, mathematicians will work on random math problems that physicists want to know the answer to (various knot/geometric invariants, etc.), but e.g. there isn't a single math department to my knowledge that has a lattice gauge theorist (despite Yang-Mills being a Millennium problem). This gap just keeps getting worse since physics moves very fast with its loose standards of rigor, leaving mathematicians, who are grounded and systematic in the dark about what's going on. On top of that, you have cultural issues – mathematicians who work on fundamental physics either aren't "doing real math" (in the conservative eyes of mathematicians) or "doing what's already well understood" (by the loose standards of physicists).

Unfortunately, I don't see a solution to this dilemma in the near future, which seems to be a prerequisite for needing more mathematical ideas (related to physics). There aren't even enough mathematicians thinking about QFT, much less string theory or multi-versey things.

62. **Cosmonut**
January 11, 2017

Another remarkable aspect about multiverse mania is that this nonsense wouldn't be tolerated in any other field.

So suppose I claim I have an economic model which will exactly predict the price of potatoes tomorrow.
Then I give a printout of a few million numbers and say:
"Look one of these is the correct price, I just have no idea which one. And by the way, the other numbers are ALL correct as well – those are just the price of potatoes tomorrow in various parallel worlds somewhere."
I can't see any circumstance where people will say "Hmm, he's got a point" instead of dismissing my potato-price model as crackpottery.
In fact, I will only make things worse for myself by getting all aggressive with "You can't prove that my numbers are wrong, so I must be right !", which is what string theory/multiverse champs seem to be doing.

I suspect a part of the story is that popular books and media have convinced people that modern physics is all about "weird and wonderful" stuff. So, if you say something sufficiently weird, it must be wonderful as well. :/

63. **srp**
January 11, 2017

Very interesting point by Tim:

"On top of that, you have cultural issues – mathematicians who work on fundamental physics either aren't "doing real math" (in the conservative eyes of mathematicians) or "doing what's already well understood" (by the loose standards of physicists)."

In the past, private science funders (e.g. Rockefeller Foundation with Morgan and Pauling on biochemistry and molecular biology), targeted these kinds of gaps by giving money to people working the particular interdisciplinary gap they had identified. Maybe that's where some of today's big players (Templeton, Breakthrough) could funnel some resources.

64. **Peter Woit**
January 11, 2017

srp,

The Simons Center at Stony Brook is doing exactly this.

Again though, the math/physics interface is a topic of endless interest to me, but has nothing to do with the multiverse, so discussion of it best left to another posting.

65. **Tim Nguyen**
January 11, 2017

"The Simons Center at Stony Brook is doing exactly this."

I was one of the research assistant professors there and it was a great experience. However, proximity of mathematicians and physicists should not be confused with overcoming the cultural barriers mentioned above. And at the end of the day, one research center alone can't change an entire cultural divide.

66. **chris**
January 12, 2017

reader,

thanks a lot for the insight. I do not agree with your proability assignment, but I think I at least understand a bit how it comes about.

Tim Nguyen,

there are math departments that have lattice gauge theorists, especially in UK/ireland for historical reasons. There also are lattice people working on the millenium problem, but they are preciously few.

I think the problem there is the same as almost everywhere: it's not bread and butter physics that you can easily sell to your funding agencies. In our research environment, who is willing and able to work on a hard problem with small chances of success and who is going to finance it?

67. **Tim Nguyen**

January 12, 2017

Chris,

That's nice to know! I imagine you might be referring to places like DAMTP? I'd be really surprised though to find an ordinary pure math department with a lattice gauge theorist. Of course, the way in which science is currently funded (a whole other topic of discussion) only exacerbates cultural differences and only encourages people to do what's normative and trendy in their field. If you don't even have enough people working on/caring about pure Yang-Mills (which is just a tiny part of the Standard Model), you can't really expect there to be any breakthrough mathematics in high energy physics. There was a time when mathematicians like Hilbert, von Neumann, and Weyl were doing math that was in tandem with deep and fundamental physics. Now mathematicians occur as citations and occasionally coauthors for physicists, rather than as leading figures.

68. **Jesper**
January 12, 2017

@ reader

you write "Anti-multiversalists hold on to the hope that the Standard Model is actually much simpler because there is some deep structure there that we haven't yet uncovered. Could be, but decades of effort devoted to finding this deep structure have so far yielded zilch."

Well, Connes and Chamseddine's work/noncommutative geometry.

69. **anon**
January 14, 2017

I miss the days when science popularization meant Carl Sagan. I don't even want to tell lay people I am a physicist anymore, since I am then invariably forced to discuss multiverses.

70. **Alan**
January 15, 2017

Thanks for the link to Professor Halvorsen's piece you gave under "more theology" above. As he says, he is religious, so can anyone give me (degree level physics) any clues how this can fit into physics? I mean, where do we go with this, where do we start?

71. **Peter Woit**
January 15, 2017

Alan,
Personally I don't think theology has anything to do with physics. There's an interesting sociological question of why some physicists have started engaging in theology, but I don't think there's a scientific question there.

72. **Alan**
January 15, 2017

Peter,
Thanks for reply, but isn't this (with respect) just the default position? Is there at least a way out of the problem he covers, as Halvorson sees this, by some input of philosophy at least. I mean, he sees a real problem. And I don't mean to go on endlessly about this (!). His point is framed by his question … "why is it the case that it's unlikely for an arbitrary universe to be conducive to life?"

73. **Peter Woit**
January 15, 2017

Alan,
The problem is that this isn't physics unless you have a testable scientific theory for what "an arbitrary universe" means. I'd claim there is currently no such thing.

Various and Sundry

Categories: Uncategorized

A few links for your weekend reading:

- If you just can't get enough of the Multiverse, Inference has commentary on Max Tegmark from Daniel Kleitman and Sheldon Glashow.
- Coverage of the important topic of blackboards is to be found here. To those ill-informed sorts who think that blackboards are the past, whiteboards or some other technology the future, I'll point out the following. When I came to Columbia back in 1989, there was a recently installed modest-sized whiteboard in the math department common room. Everyone hated it, and after many years it was replaced by a similar-sized blackboard. Last year, in a renovation of the lounge, that blackboard was replaced by a better one, and one whole wall of the room was replaced by a floor-to-ceiling blackboard. A year or so ago, a newly renovated Theory Center was unveiled here in the Physics department: floor-to-ceiling, wall-to-wall blackboards. That's the future, the whiteboard is the past.
- The latest CERN Courier has a long article by Hermann Nicolai, mostly about quantum gravity. Nicolai makes the following interesting comments about supersymmetry and unification:

  > To the great disappointment of many, experimental searches at the LHC so far have found no evidence for the superpartners predicted by N = 1 supersymmetry. However, there is no reason to give up on the idea of supersymmetry as such, since the refutation of low-energy supersymmetry would only mean that the most simple-minded way of implementing this idea does not work. Indeed, the initial excitement about supersymmetry in the 1970s had nothing to do with the hierarchy problem, but rather because it offered a way to circumvent the so-called Coleman–Mandula no-go theorem – a beautiful possibility that is precisely not realised by the models currently being tested at the LHC.
  >
  > In fact, the reduplication of internal quantum numbers predicted by N = 1 supersymmetry is avoided in theories with extended (N > 1) supersymmetry. Among all supersymmetric theories, maximal N = 8 supergravity stands out as the most symmetric. Its status with regard to perturbative finiteness is still unclear, although recent work has revealed amazing and unexpected cancellations. However, there is one very strange agreement between this theory and observation, first emphasised by Gell-Mann: the number of spin-1/2 fermions remaining after complete breaking of supersymmetry is $48 = 3 \times 16$, equal to the number of quarks and leptons (including right-handed neutrinos) in three generations (see "The many lives of supergravity"). To go beyond the partial matching of quantum numbers achieved so far will, however, require some completely new insights, especially concerning the emergence of chiral gauge interactions.

  I think this is an interesting perspective on the main problem with supersymmetry, which I'd summarize as follows. In N=1 SUSY you can get a chiral theory like the SM, but if you get the SM this way, you predict for every SM particle a new particle with the exact same charges (behavior under internal symmetry transformation), but spin differing by 1/2. This is in radical disagreement with experiment. What you'd really like is to use SUSY to say something about internal symmetry, and this is what you can do in principle with higher values of N. The problem is that you don't really know how to get a chiral theory this way. That may be a much more fruitful problem to focus on than the supposed hierarchy problem.

- Progress in geometric Langlands marches on, with a new paper yesterday from Aganagic, Frenkel and Okounkov on the Quantum q-Langlands Correspondence, a two-parameter generalization of geometric Langlands. Among many other things, they formulate (Conjecture 6.3) a conjecture generalizing the characterization (using BRST methods) of affine Lie algebra representations at the critical level that from the beginning of the subject described a major aspect of how geometric Langlands works locally (for details on this, see Frenkel's book Langlands Correspndence for Loop Groups).

   January 13, 2017

   The end of the blackboard article, where they say that chemists have moved beyond blackboards, is not correct — at least not universally so. At my university a new "Science Teaching and Learning Center" just opened up, as a renovation of the "Old Chem" building which had been abandoned since the late 1980's (due to safety concerns for earthquakes, I believe). The Chemistry department was adamant that the lecture rooms in this new building must have blackboards. The request was denied, but nobody told them until the building was unveiled last month and it was noticed that there were whiteboards everywhere. Some baloney was offered about high-tech markers and space-age "erasers" that are crap.

   The Chemistry faculty were livid, offering multiple reasons why they absolutely prefer blackboards to whiteboards for teaching purposes. They were very pleased that Math is standing alongside them in this matter. So now Chemistry and Math have jointly protested, and hopefully by the summer the whiteboards will be swapped out for blackboards. Then I can move on to undo the damage in the History dept. from last summer when workmen came in unannounced one day and swapped out all blackboards for whiteboards…

   January 13, 2017

   How many boxes of Hagoromo chalk did you buy, BCnrd? I've heard it was a lot…

3. **Peter Woit**
   January 13, 2017

   For the Hagoromo chalk story, see
   http://gizmodo.com/why-mathematicians-are-hoarding-this-special-type-of-ja-1711008881
   In that story, a "15 year supply" for BCnrd is specified.

4. **BCnrd**
   January 13, 2017

   David, after that Japanese film crew visited here to make the US portion of their Hagaromo documentary, I decided to stock up some more for the apocalypse (not realizing that the company would come back into existence in South Korea some months later). I contacted my supplier in Oakland and she made some final drop-offs on campus with her dwindling goods from the back of her van. The campus police walked by during the transaction but had no idea what was inside the packed boxes. I now have what I estimate to be a 20-year supply in my office. It fits snugly inside some cabinets.

5. **Jeff M**
   January 13, 2017

   I hate whiteboards. At my university, the reason given for switching to whiteboards has been that chalk dust is bad for computers, which is just BS. I seriously hope we go back soon. Last semester I was lucky enough to have both classes in a blackboard room 🙂

6. **J.J. Green**
January 13, 2017

With reference to blackboards in toilets, they can be found in the Newton Institute in Cambridge.

7. **Magnema**
January 13, 2017

Worse than either chalkboards OR whiteboards is having both in the same room. Yes, I have seen this. Chalkboard at the front, whiteboard on the side, and another chalkboard in the back. At teacher's request, in that room, the back and side were swapped, approximately mid-semester.

8. **anon**
January 14, 2017

I often worry that I am being poisoned by the whiteboard marker fumes I am forced to breathe (and probably absorb through the skin) at my institution. I have a macular degeneration condition whose symptoms are always worse after teaching.

9. **David Roberts**
January 14, 2017

There were blackboards in the toilets at the Erwin Schrödinger Institute when I was there in 2006.

10. **srp**
January 14, 2017

OK, troglodytes, stick to your blackboards, which are indeed wonderful for the first strokes but completely suck once you start erasing and rewriting. In the U.S. I suspect this may be an East Coast (blackboards) versus West Coast (whiteboards) thing, with the ivy-covered traditionalists stubbornly sticking to the dirty, less-readable, fewer-colored, chalk-breaking and squeaking blackboard.

11. **Jon Awbrey**
January 14, 2017

Techtonic Shift — it was the subduction of disk drives that caused the upthrust of chalk and slate.

12. **Jeff M**
January 14, 2017

@Jon Awbrey

Yes indeed, now that everything is solid state, the excuse for whiteboards is dead. Still have to convince the IT people. As for @srp, sorry, whiteboards never erase properly. The markers dry out, often several times in the same lecture. How many times have you gotten to a room with 15 whiteboard markers, none of which work? The markers smell. No comparison. As to East versus West, interesting thought. First time I remember being stuck at a whiteboard was a conference at the University of Washington, in '93. So maybe….

13. **Radioactive**
January 14, 2017

While Max Tegmark's ideas maybe wrong, I have much more sympathy for them than for Inference – a magazine which seems to consist completely of cranky letters from retired professors.

14. **paddy**
January 14, 2017

On chalk: On my first day of crumbly chalk teaching in West Africa in the late 70's, I walked into the staff room covered head-to-foot with white dust after class. The head master smiled at me and said something to the effect that this was a sign of a hard working teacher. Thereafter I could never do wrong in his eyes.

On the Tegmark reviews (and multiverse): As a lowly experimentalist with no philosophical training my main issue has always been whether probability arguments are being used where probability arguably does not apply–i.e., where one does not have clearcut arguments that the idea of an ensemble pertains. Moreover in some twists (multiverses) it would seem that positing the applicability of probability begs the question.

15. **Urs Schreiber**
January 14, 2017

> What you'd really like is to use SUSY to say something about internal symmetry, and this is what you can do in principle with higher values of N. The problem is that you don't really know how to get a chiral theory this way.

There is a program dealing with this: first uplift the extended SuGra theory back to d=11 (that's how N=8 d=4 was constructed in the first place) then compactify on ADE-singularities. This goes back to around [Acharya-Witten 01](). This program is called "M-theory phenomenology".

16. **Chris Kennedy**
January 14, 2017

A third thing: I had a great freshman chem professor who used an overhead projector. Sure he was motionless, less animated but he was able cover more material per hour and allowed us to realize our potential since less time and energy was wasted on kinetic motion.

17. **Peter Woit**
January 14, 2017

Urs,
I'm sure Nicolai is well aware of that idea, didn't mention it because he was suggesting not pursuing complicated old ideas that don't work, and instead look for something new that does.

18. **C. Denson Hill**
January 14, 2017

The reason(s) mathematicians very strongly prefer blackboards:
1. Ever try to write a complicated formula, with many indices upstairs and downstairs, with indices on the indices, perhaps with double summations up in an exponential under some integral signs, with complicated limits of integration? It is virtually impossible with (dried up) markers…and because of the chisel tip on (even a wet) marker, the width of the line you get depends on the direction of motion. And the coefficient of friction prevents good penmanship. Result with markers is sloppy and virtually unreadable.
2. The speed at which you can write a legible statement of hypotheses and conclusions of a theorem or lemma is perfectly suited to the speed of comprehension in the audience. Unlike slides, projectors, or god forbid reading bullit points, which is like chloroform.
3. Marker dust is far more toxic than chalk dust.
The only people who like white boards are those whose lectures require very little writing during the lecture. At my university, a certain provost decided to replace all blackboards by white boards…for no good reason…and we mathematicians rose up and got him fired. You should all do that!

19. **Jonas**
January 14, 2017

Interesting to see so many claim that mathematicians prefer blackboards. It is certainly not true to the degree that some here seem to think.

In my own department, a rather large marh one, the overwhelming majority prefer whiteboard and that is why we have now gotten rid of all but one of the blackboards in our building. The only one left has been kept for a few years extra but we'll soon get rid of that too.
The only ones in the department who preferred blackboards when we changed boards were some in the then 60+ age range, but they have all retired by now. None among the younger have asked for the blackboards back, and we do give proper lectures with lots of writing, and we never use projectors and slides in teaching.

I've never had a "dry" marker in years. Put the cork back on, remember to put the empty ones in the recycling bin, and you have no such problems.

20. **Bill**
January 14, 2017

One can tell a good math department from a bad one by a number of people who prefer blackboards to whiteboards.

21. **srp**
January 14, 2017

The dried-up marker issue is easily dealt with in the same manner that chalk users do–bring your own chalk (the chalk lying around is usually broken or stubby) = bring your own markers. (There will often be some duds left for you by others in the room, but also usually some that work fine.) It is easy to control a dry-erase market to write at any size–I have no idea what CDH above is talking about. As for the erasing ability of the two, a whiteboard marker is much, much easier to completely erase than a chalk mark, especially if you use the green marker.

I wonder if my West Coast hypothesis holds for Jonas.

22. **Jeff M**
January 14, 2017

srp

White boards never completely erase. Ever. Blackboards do build up dust, but a quick wipe with a wet anything fixes that. And I always bring my own markers but feel ridiculous going through 100 markers a semester, especially when I know every single other person is too. I would bet you that the average time a white board marker lasts is less than one lecture, even for people who are good at putting caps on. White board markers are much less precise than chalk. There is less feedback. Just one more way the east coast rules 🙂

23. **Peter Shor**
January 14, 2017

In my experience, good-quality whiteboards actually work well … you can erase them completely, and they stay erasable for a number of years.

However, most whiteboards you actually run into are inferior-quality whiteboards, which are much worse than the average blackboard. I don't know what the price difference between the good whiteboards and the bad whiteboards is, but I suspect it is substantial. I also don't know which brands or surfaces are good.

24. **Jeff M**
January 14, 2017

Peter Shor,

I totally believe that good quality whiteboards can be reasonable. But even you say "stay erasable for a number of years." A good blackboard is erasable for 50 years. Maybe longer.

25. **Giotis**
January 14, 2017

Regarding the Langland's paper by Frenkel et al.

Its outcome means that (as suspected) stringy degrees of freedom (i.e. 6d (2,0) Little String Theory which is just a limit of type II ST) are needed for the physical counterpart of the quantum deformed Langland's correspondence and thus the correspondence doesn't stop at 6d (2,0) SCFT.

Remember that the little strings of (2,0) LST are not the tensionless solitonic strings of (2,0) SCFT coming from D3 branes wrapping 2-cycles, they are fundamental strings of type II when we take the string coupling to zero limit.

By all accounts this was anticipated from string theory point of view, since the (2,0) LST is the high energy limit of (2,0) SCFT, but not from field theory point of view since (2,0) SCFT is perfect on its own.

Thus string theory is required instead of being a redundant description of a deep mathematical correspondence which implies the N=4 SYM S-duality i.e. of the YM Montone-Olive duality conjecture which is an extrapolation of the electromagnetic duality.

The implications are indeed profound; Nature via mathematics (and vice versa) requires Strings.

26. **Richard Séguin**
January 15, 2017

Chalk dust is probably not good for your lungs, and the solvent in markers is undoubtedly toxic. It would be instructive to survey users and look for increased COPD in chalk users, and increased cancers in white board marker users. Personally, I find the solvent smell from markers to be much more repulsive than chalk dust.

27. **theoreticalminimum**
January 15, 2017

What about using a Windows-operated convertible laptop with Windows Journal (much like what Nima Arkani-Hamed does with a convertible Lenovo Thinkpad) connected to a projector to lecture classes? I have been doing this for a few years now. It very simply solves all of the above-mentioned toxicity issues, and there are many obvious added advantages.

28. **chiz**
January 15, 2017

Types of whiteboard:

> Enameled whiteboards, also referred to as porcelain, and sometimes glass boards, have the advantage that markings can be erased completely; other materials tend to become stained over time. Enameled boards are more expensive and less used in commercial environments, but in more demanding environments with heavier use, such as educational establishments, porcelain boards are considered superior.

The solvent for marker pens is ethanol (safe) and isopropanol (not so safe).

29. **Petite Kabylie**
January 15, 2017

I am using usual power-point slides and they work fine. I think as long as one puts in all the steps in one’s derivations and synchronises one’s rate of changing slides with the flow of ideas in one’s lecture neither blackboards nor whiteboards compare.

30. **G. S.**
January 15, 2017

If Hollywood has taught me anything, it’s that true groundbreaking work is done not on blackboards or whiteboards, but on clear glass dormitory windows.

31. **Peter Woit**
January 15, 2017

Giotis,
Yes, one can look at a complicated and interesting story about mathematics and just get out of it “string theory rules!”, which is both stupid and boring. Enough.

32. **BCnrd**
January 15, 2017

@srp:

I am at Stanford, and I know from experience here and at the math departments at UCLA, Caltech, and Berkeley as well as at MSRI there is no evidence in favor of your “East vs. West” hypothesis. Even at CCR West, the room set up for seminar talks by visiting mathematicians has blackboards. On the other hand, the West Coast is a veritable “multiverse” of colleges and universities, so perhaps somewhere out there is evidence in favor of any hypothesis. 🙂

33. **Maximillian G. Tresmond, Esq.**
January 15, 2017

Whiteboards could be the bane of a law school student’s existence. The fumes given off by some of those chisel tips leave you wondering if they should be on a DEA schedule.

34. **Jim Clarage**
January 15, 2017

Another subtle problem with dry-erase involves color. Not all humans perceive color the same, either physiologically or psychologically. Some eyes (like mine, mildly color-blind) perceive no contast of green markers on white boards, yet I know professors who prefer to write in green (or use it since all the “other colors” are dried up on that day). Some students have told me they can see black-marker best, others say blue is most visible, while others say green (about 40-40-20 in my surveys). On the psychological side, many professors (or students called up to the board) will use red-marker, which to many eyes just screams error-error-panic.

p.s. I’d like to know what markers Jonas orders which never go dry. And what recycling service he has which actually can handle the rigid plastic in e.g., Expo markers. (only certain plastics can actually be recycled once they get to the plant, many just end up being burned, like the inner casing inside the old marker surely is).

35. **srp**
January 15, 2017

BCnrd: Interesting. There definitely seems to be such a coastal distinction in econ departments.

36. **milkshaken**
January 15, 2017

re solvents in erasable markers: it is not true isopropyl alcohol is unsafe, it is one of the least toxic solvents: you can actually ingest it in non-denatured form (up to a spoonful, not more) even if the taste is unpleasant. But xylenes are worse, and you can definitely smell those in some erasable markers we use – it smells like petrol and paint thinners.

37. **Tim**
January 16, 2017

Yup, I'm not sure why people who dislike whiteboards want to go overboard with false claims about health risks … the number of cancers due to white board markers is probably less than the number of verified predictions of string theory.

If you like chalk and blackboards, that's fine, but don't make up "facts" to support your position. There's far too much of that going around these days.

38. **Tim May**
January 16, 2017

I was at Intel (the company, not the intelligence agencies!) from 1974 to 1986.

Whiteboards and dry-erase markers were all we ever had. A big change from the blackboards and chalk we had in college

The whiteboards always caused me to feel "light-headed." I never learned why this may've happened. I tried directly "smelling" one around 1978 or so and nearly passed out. I had to use them, given my job, but avoided them as best I could.

(I still don't know. But I avoid whiteboards and dry erase markers like the plague.)

39. **Jeff M**
January 16, 2017

I think some people are sensitive to whiteboard markers. I certainly am, I'm sensitive to latex paint too. And my wife is an artist, we had a loft for years in Brooklyn and I had to live with paint smells constantly 🙂 On another note, and I assume Peter will take this down, I don't understand why I can't mention my shock that a famous physicist like Tegmark doesn't understand infinity, when Peter himself posted two reviews which say exactly that.

40. **Perpetual Student**
January 16, 2017

@Jeff M
I can report that the U.Washington physics dept these days has plenty of blackboards, having cursed the glare that can make some of the chalk writing all but invisible.

41. **John**
January 16, 2017

Are all the SUSY bets based on N=1 or is this a way around resolving those bets?

42. **Peter Woit**
January 16, 2017

John,
All SUSY bets and discussion of SUSY at the LHC is based on N=1, since higher N theories as conventionally understood are incompatible with what we know already about the Standard Model (chiral gauge couplings). As Nicolai comments, to use higher N in the way he suggests requires "some completely new insights", something we don't now understand.

43. **Frog Leg**
January 16, 2017

Sensitivity goes both ways. I have to wear gloves if I have write on a chalkboard; the feel of a chalkboard against my hand is very painful (as is the sound). The smell of dry erase markers does not bother me at all.

44. **serious question here**
January 16, 2017

is string/m theory based on susy N=1, or higher N?

is 11D SUGRA that is the low-energy limit of M-theory N=1 or higher N?

regards

45. **DoZen**
January 17, 2017

I'm very glad to hear Columbia is setting the pace for a blackboard renaissance.

The squeak problem of chalk seems to depend partly on the quality of the chalk,
but mostly on the experience of the writer- it never squeaks on me.

Memories: when I visited Yale, a regular diversion in seminars was Serge Lang yelling "break the chalk"! at the speaker, then watching the befuddled speaker trying to figure out what they'd done wrong (Lang's theory being that breaking the chalk destroys the resonances necessary for squeaking- but I prefer long chalk and never have that problem).

Power point and its cousins predictably put the audience to sleep, for multiple obvious reasons:
-the light is low so dozing off is encouraged;
-too often the lazy prof is reading from their own slides prepared days or months ahead while having forgotten how the proof actually goes, and arrogantly and wrongly thinking they can think while trying to read and decipher what is there above and beyond them;
-the definitions or key formulas are scattered on previous pages, making it impossible to follow the logic…
Result: I have seen maybe 2 effective PP presentations in years of conferences.

By contrast, in a board talk the presenter is forced to make the material come alive, as their brain is actively engaged in re-creating the math. They are more likely to look

at the audience for feedback, rather than at their own slides. That is more fun for all concerned. Since one is not locked in to an order, a good speaker can change the order, emphasis, content completely in response to questions and the flow of the talk.
(I have often realized while walking to the lecture -whether a course or a seminar- that it would be much better to totally invert the order- or even to change the subject!)
A whiteboard talk is in-between. I agree with all criticisms voiced here. Chalkboard is best for both the presenter and audience, with absolute best being real slate with good-quality chalk. This is not just true for letters, but also for diagrams and illustrations- try drawing a sphere with chalk versus with a slidy stinky marker.

A related new problem is that kids in school may not be learning good pensmanship,
and lately even may not learn to write (or read) cursive at all. This is a developing disaster. At a board, having to print letters slows one down too much, and is much more tiring on the arm and hand. But those who never learned how to write properly will never know the difference. As the products of such misguided educational "reform" filter up to faculty level, we'll likely see -and sleep through- more and more PP talks.

46. **bob sykes**
January 17, 2017

In 1970, I began my career at Union College, Schenectady, NY. The old Carnegie Bldg then had polished, black slate blackboards. In the whole 37 years of my career, using every kind of writing surface invented, nothing ever came even close to the perfect of those blackboards.

47. **Cormac O Rafferty**
January 17, 2017

I thought that article on blackboards was quite poor. The author never addressed the basic question – why do many mathematicians, more than other scientists, prefer blackboards?
The answer has to be that the blackboard suits mathematics better than other subjects. Which suggests that the blackboard is very suitable for writing equations, since math lectures tends to contain more equations than other areas of science. And the reason for this last is not hard to fathom – the friction of chalk and board creates a pace that is just about right for talking and explaining math. QED

48. **Cormac O Rafferty**
January 17, 2017

P.S. I discovered a while ago that writing on a blackboard used by Einstein during a lecture at Oxford in 1931 contains a numerical error, an error that casts useful light on a puzzling mistake in a cosmology paper he published that year. (Einstein's 'Oxford blackboard' is quite well known, but no one noticed the error). If whiteboards existed in 1931, I doubt Einstein's mistake would still be visible!

49. **Jeff M**
January 17, 2017

Cormac

I just looked up Einsteins blackboard at wikipedia, thanks for making my day 🙂 I can't believe I never heard of it before, I've even been to Oxford. Of course, our tour guide was a friend of a friend who took us all over, but he had been a student of politics so we didn't make it to the museum of science. Did make it to several wonderful 500 year old pubs though.

50. **C Denson Hill**
January 17, 2017

1.Probably many of you are too young to have ever experienced the sublime pleasure and satisfaction of lecturing on a real slate blackboard with good quality chalk. The lines are crisp and clear, the coefficient of friction is perfect to create a Palmer-like script, which is beautiful and easily read, and erasure is clean. You and the students leave class in a good mood.
2. But then I have noticed that many people in physics are unable to write (script), and can only print…which usually makes the precise statement of any theorem too slow.
3. Finally, if you think a canned lecture, prepared in advance, via some sort of laptop presentation is the way to go, then I suggest you just email the pdf file to the students, and they (and you) do not have to go to class…all spontaneity is lost…just have them buy the book, and you can dispense with classes and lecturing altogether.

51. **Jeff M**
January 17, 2017

I'm fine with using slides (LaTeX please, not PP) for conference presentations, since I assume my audience has a pretty good idea of what I'm talking about. For classes, they're terrible. I got stuck once teaching upper level analysis from slides, and it was really really hard to keep it interesting. I felt very detached from the material, and it was impossible to improvise when I thought of something interesting not in the slides. When I'm teaching something low level, like calculus, I don't even like to use notes since that makes it too canned.

52. **paddy**
January 17, 2017

Wendell Furry used "view foils" c. '74-'75 for his EMT class. But this due to his infirmity at the time. He did wander to the blackboard though on occasion to digress. I loved his digressions.

53. **Jonny iTouch**
January 18, 2017

For almost 15 years, Hermann Nicolai's (of Nicolai map fame!) has been publishing on the program of subsuming the 48 spin 1/2 fermions as unfaithful representations of K(E10) arose from M-theory at space-like singularities (see e.g. https://arxiv.org/pdf/1504.01586v2.pdf, https://arxiv.org/pdf/1602.04116v1.pdf, …, http://journals.aps.org/prl/pdf/10.1103/PhysRevLett.89.221601). His discussion in the article seemed, to me, to be alluding to those same publications, yet comments here seem to suggest that Nicolai's decided the M theory was just along for the ride and has some other scenario for that E10? Can someone point to some references about that, because that would surely be an interesting read?

54. **chris**
January 18, 2017

I love blackboards because they don't get in the way. No thinking about capping your pens or when they will run out. with good chalk the stroke is clear and perfectly readable down to the last inch. and you can rearrange blackboards! (why this has not been impelented with whiteboards totally eludes me).

literally, with a blackboard i can arrange my thought process in a spatial manner and concentrate on that, forgetting chalk and board, while a whiteboard (like all higher tech) is constantly competing for your attention.

and don't get me started on "smart boards". oh yes they are cool – which is another way of saying they grab your attention. more than half the brain will be dedicated to the presentation medium rather than the topic.

maybe this will change for future generations that grow up with these things. i doubt though that the naturalness with which humans can handle simple physical objects (like chalk and moving boards) will ever be reached with more sophisticated tools and their potential for distraction will always be larger.

55. **Peter Woit**
January 18, 2017

Jonny iTouch,
The fact that Nicolai doesn't mention M-theory seems like pretty good evidence that that's not what he sees as the solution. Note that he's explicitly talking about the implications of non-observation of superpartners at the LHC. If he wanted to argue that this is some sort of argument for M-theory, that would be an argument I've never heard before and I doubt he would be making it while not mentioning M-theory.

56. **Jon Orloff**
January 18, 2017

Couldn't agree more about blackboards. I had to use slides once when I had an injury and couldn't walk. I didn't like it because I couldn't write addenda. Whiteboards are awful – the ink stains and it smells like it isn't good for you. Love blackboards. I'm also retired (U. Maryland) and probably considered to be a crank on the subject.

57. **Cormac O Rafferty**
January 18, 2017

Chris:
I don't understand it either. The Oxford blackboard is not as well known as it should be; I was very lucky to come across it online before I submitted our paper on Einstein's cosmological model of 1931.
The most likely explanation is that the historians who were aware of the blackboard (as a museum exhibit) didn't realise that the writing on the board represented a model of the universe – this is the problem with historians of science who may not have a background in science

58. **Artie Prendergast-Smith**
January 19, 2017

I agree with Cormac O Rafferty that the article on blackboard preference was pretty weak stuff.

Responses here have repeatedly highlighted some of the main reasons for blackboard-boosting: tactile quality, good visibility, and (crucially for mathematicians) the natural pacing induced by blackboards.

By contrast, the reasons offered in that article — the sound discouraging interruptions, the impossibility of total erasure — read to me like fatuous just-so stories.

59. **Alejandro Rivero**
February 3, 2017

For reference. Gell-Mann article cited by Nicolai is scanned in Santa Fe:

http://tuvalu.santafe.edu/~mgm/Site/Publications_files/MGM%2094.pdf

Fake Physics

January 20, 2017
Categories: Fake Physics, Favorite Old Posts, Multiverse Mania

2016 so far wins my lifetime award for most depressing and disturbing year ever (on the front of the larger world one reads about in the newspaper and elsewhere, personally things are fine, thanks). Perhaps the most disturbing thing has been seeing the way in which people's access to information about the larger world has become more and more dominated by what has become known as "Fake News": stuff which is not true, but which someone with an agenda successfully gets others to believe. This is a problem that goes far beyond obvious nonsense fed to rubes on Facebook, to the point of including what a lot of my well-educated colleagues believe because they read it on the front page of the New York Times.

I have no idea what to do about this larger problem and no intention of further discussing it here. I've started to come to the conclusion though that the most disturbing trend in theoretical physics of recent years may best be understood as a related phenomenon: "Fake Physics". The first few weeks of 2017 are seeing a flood of examples of what I have in mind, including for instance:

- Fake Physics I
- Fake Physics II
- Fake Physics III
- Fake Physics IV
- Fake Physics V
- Fake Physics VI
- Fake Physics VII
- Fake Physics VIII (forthcoming)

Note that the above examples are just ones written by physicists or reporting claims of physicists, there are also philosophers, theologians and others putting out similar articles, although without the claims to scientific authority coming from the physicists.

Fake Physics VII just appeared and is rather bizarre. It essentially argues that the idea of assuming a Multiverse and using it to make statistical predictions doesn't work. But instead of drawing the obvious conclusion (this was a scientifically worthless idea, as seemed likely to most everyone else), the argument is that we need a "revolution in our understanding of physics" that will make the idea work.

Fake Physics shares several characteristics with Fake News:

- *It's clickbait*. While getting anyone to pay attention to the solution of a difficult technical problem in quantum field theory is likely to be nearly impossible, topics like "What happened before the Big Bang?" and "Did you know that there's someone exactly identical to you somewhere else in the multiverse, and they're dating Scarlet Johansson?" are sure crowd-pleasers. This motivates some physicists, and even more journalists, with the latter having the much better excuse that their livelihood depends on getting people to click on their stories.
- *It's a propaganda tactic designed to mask failure*. The main reason for the current mania for the Multiverse is the failure of the string theory unification program. Some who have invested their lives in this program have decided to use this sort of Fake Physics as an excuse to avoid admitting failure.
- *The group driving this is small but determined, ideology-driven and well-funded by rich people with an ax to grind. The majority of the community is unwilling to take on the unpleasant and unrewarding task of challenging them*. While Multiverse Fake Physics plays a large role in media coverage of fundamental physics, partially because of funding from the Templeton Foundation, there are very few actual papers on the subject and "research" in this area is a small fraction of what theorists are doing. Most physicists just hope that if they ignore this it will go away.

Unfortunately Fake Physics is not going away, but becoming ever more widespread. While I don't know what to do about Fake News, I think there still is a chance to successfully fight Fake Physics and hope others will help with this.

Update: There's more

- Fake Physics IX explains that the Many Worlds multiverse and the cosmological multiverse are one and the same. Sean Carroll is featured.
- Fake Physics X includes the following from Carroll:

> David Chalmers does a wonderful job at making an important point: "A virtual world is just as real as a physical world."… what's real to one person might be virtual to someone else.

People at Hacker News are discussing this. There I'm accused of "misleading people" by making them think the cosmological multiverse is the same thing as the Many Worlds interpretation. Oy.

Update: Thanks to a commenter for pointing out Fake Physics XI, courtesy of Science Friday. As usual, the same vigorous ideologues promoting Fake Physics, the same dearth of voices pointing out the problems with it.

Comments

   January 20, 2017

   Peter,

   I'm assuming it's the site, but if you click on any of the Nautilus links they take over your browser, you lose your history for the tab your in, every page is a Nautilus page. Not that it matters much probably, but might be worth warning everyone.

2. **zzz**
   January 20, 2017

   yeah, its like a multiverse of webpages over there

3. **Peter Woit**
   January 20, 2017

   Jeff M/zzz,

I hadn't noticed that "feature" of Nautilus until recently. Maybe they funded its development with this recent grant: https://www.templeton.org/what-we-fund/grants/nautilus-magazine

Upon further investigation looks like this inability to get back happens to those (like me) who set their browser not to save history. Best if people who want to pursue this do so with the Nautilus people.

4. **a1**
January 20, 2017

just remember the etymology of 'evangelism' – good news, not true news

5. **Mitchell Porter**
January 20, 2017

This dizziness about ever-larger realities happened before, when the stars were revealed to be suns, and people were confronted with the idea of spatial infinity. Given sufficient time, the human race should be able to sort out the multiverse question: what exactly are the options; are they true, false, or unknowable; and can they be empirically judged, or is logic the only guide.

6. **Carl**
January 20, 2017

It's not all doom and gloom. I just got done reading Penrose's "Fashion, Faith and Fantasy". And I realized that his takedown of multiverse theory works equally well as a critique of the proposal that our universe is a simulation, a piece of alleged philosophy that actually annoys me even more than multiverses.

7. **Richard J. Gaylord**
January 21, 2017

i guess your too politic to name the culprits who bear the main responsibility for your mood: Trump and Tegmark.

8. **Marty Tysanner**
January 21, 2017

While I'm not a fan of multiverse physics, I think some people may paint it with an overly broad brush by saying "It's Not Science!" without properly qualifying their claim. There is some subtlety to whether a multiverse from eternal inflation has scientific content or not.

Some of my research in grad school related to eternal inflation, and thus a multiverse. More specifically: How likely is it we could observe CMB signatures of collisions between bubble universes that "nucleate" sufficiently close together in an eternally inflating (de Sitter space) background? (My advisor had already been working with others on whether bubble collisions might have observable consequences, and the topic was interesting to me.) In such scenarios the multiverse of "bubble universes" grows exponentially in time as new universes continually nucleate — the available volume for nucleation grows exponentially in time while the rate per unit volume stays constant — so each time a new bubble occurs one expects a finite probability it has nucleated close enough to an existing bubble to collide with it; a collision would be very energetic and have a predictable symmetry.

The scenarios we considered were agnostic about whether the fundamental physics inside the different bubbles (e.g., electron charge, spectrum of particle masses) were different. Freivogel, on the other hand, suggested in your "Fake Physics VII" article that different constants of Nature should exist in different bubble universes. In general that is neither implied nor required — different physics is only "required" by string theorists in the sense that eternal inflation can't do the job of populating the huge set of string theory vacua unless each bubble nucleation can (randomly) realize any one string vacuum. Coincidentally, Freivogel at that time was also actively involved in looking at whether CMB signatures of bubble collisions might plausibly be observed.

Alas, our conclusion was that CMB signatures of bubble collisions were likely to be unobservably small because in general they would occupy a tiny angle in the sky. Observable signatures weren't ruled out; they were just very unlikely. At that point I lost interest in researching eternal inflation — without a plausible way to observationally test it, "multiverse physics" seems like an empty dead end to me. Nonetheless, I think those who continue to look for observational evidence of past bubble collisions are doing real science even if I personally don't see it being ultimately successful.

Given these qualifications and subtleties, I too have a problem with what Peter calls "multiverse mania." I frankly don't understand why there is enduring interest in the idea among cosmologists, given the lack of a plausible way to confront it with observations, even though almost all models of inflation imply eternal inflation, and eternal inflation in turn implies a multiverse (but not necessarily one with different physics/constants/geometry in different bubble universes). True, we can say that if inflation is a correct idea then there is a multiverse, but so what? We learn nothing new about the Universe we know and love — all we get from the deal is a "just so" story that lets us make believe we understand something we don't. And for those who find it appealing, we also get an excuse for avoiding hard physics questions that have eluded quantitative answers for many decades, but I wonder how satisfying such thin gruel is to someone who entered "fundamental" theoretical physics with dreams of deeply understanding why Nature is as it is.

10. **Another Anon**
January 21, 2017

Oops, I see you already noted that one.

11. **Petite Kabylie**
January 21, 2017

Peter,
All the "Fake Physics" links you put out belong to the multiverse mania category. It would have been nice and more complete for the reader, though, if you put out also some links (if there are any this year), of "Fake Physics" that belong to the realm of particle physics or the "universe as a simulation" mania category.
Thanks for those anyway.

12. **Peter Woit**
January 21, 2017

Richard J. Gaylord,

I don't think the "Fake Physics" problem is due to anyone in particular, and if I had to choose a short list of those who have had the most damaging effect here, it wouldn't include Tegmark. It's a systemic problem with how certain sorts of theoretical physics research are evaluated and communicated.

I'd also like to make clear that on any scale, "Fake Physics" and the unhealthy things it has led to in the physics community are negligibly small potatoes compared to what "Fake News" has brought us and the future it promises human society.

13. **Peter Woit**
January 21, 2017

Marty,
I pretty much agree, and have always tried to make clear that the argument about whether the Multiverse is science is a non-trivial one that requires actually looking at and evaluating the details of attempts to make science out of it.

Sure, in principle you could have a theory that implies a multiverse and makes non-trivial testable predictions by statistical argument. But you don't, as looking at any of the attempts to do this (and Freivogel's piece) makes clear. In principle you could observe effects of another universe colliding with ours and sure, people should look for this. But there's no evidence of this so far, and no theory that predicts an effect invisible until now, but visible with a plausible further effort. At some point efforts to see evidence of another universe by doing analysis X of the data become just wishful thinking, not science. People can do this and hope for the best if they want, but they shouldn't be making misleading claims about what they are doing to the public.

14. **Peter Woit**
January 21, 2017

Petite Kabylie,
Just as it's worth distinguishing which sorts of "Fake News" is really a problem, among the many kinds of "Fake Physics" at the moment it's the Multiverse Mania that's what's really a problem. Silly discussions of empty ideas like the "simulation argument" have always been with us and always will be, but I don't think they're a real danger to physics research. HEP "Fake Physics" doesn't seem to be as big a problem now as it has been: you pretty much never hear anymore about how the LHC is going to produce black holes and discover extra dimensions, and misguided claims about supersymmetry are finally running into trouble with the reality principle.

15. **Mike Klymkowsky**
January 21, 2017

There seems to be an accelerating erosion of accountability and candor when making claims (and staking positions), much like the current political discourse where the mottos: "Never apologize," he told Mr. Trump. "Facts are white noise" and "emotions rule" seems to prevail.

Perhaps multiversers should consider a communal apology, or at least an "oops". http://blogs.plos.org/scied/2016/11/30/the-pernicious-effects-of-disrespecting-the-constraints-of-science/

16. **JohnB**
January 21, 2017

I don't know a lot about the physics community (mainly what I read here), but maybe it'd be worth extending the attitude of skepticism towards the physics community, to one of cynicism – and to follow the money, and see in general what kind of incentives people may have to deliberately misdirect resources in the physics community.

If someone has a neverending research project, like the string-theory/multiverse stuff, that can't ever be proven/disproven, then that sounds like the ultimate gravy-train to me, if that part of the community can gain enough political power and money for marketing, to convince people that this is still 'science', so that they can keep the funding rolling in.

As the Upton Sinclair quote goes "It is difficult to get a man to understand something, when his salary depends upon his not understanding it" – the reasons for that can include self-interested malice, rather than just ignorance.

Maybe something that some muckraking investigative journalists, with lots of harsh/bad publicity, would do a better job of researching/fixing this – rather than waiting for the physics community to sort itself out (the latter being the "science advances one funeral at a time" approach).

17. **Peter Woit**
January 21, 2017

All,
Please stick to "Fake Physics". Unfortunately I don't see anything useful to come out of me trying to host and moderate a discussion of the much more serious problem of "Fake News" and where it has led us. Besides, I have no time for that, I have a demonstration to get to…

18. **S. P. Nova**
January 21, 2017

Jim Baggott's books, like "Farewell To Reality", are sort of relevant to what JohnB suggests.

Unfortunately, the voice of reason is largely drowned out in the cacophony of today's information overload, laden as it is with misdirection and outright mendacity.

19. **lars**
January 21, 2017

"Virtual Reality"

If multiverse is real
Then universe is not
Cuz virtual appeal
In multiverse is hot

See Paul Davies' "fake universe" hypothesis

20. **Anonymous mathematician**
January 21, 2017

It seems to me that “fake physics” goes beyond multiverse mania and universe as simulation, to things like ER=EPR, which seems to contradict established physics in so many ways that it cannot possibly be correct.

Yet physicists are, if not jumping on the bandwagon, at least not debating it. Is silence consent?

21. **Marty Tysanner**
January 21, 2017

Peter,

Yes, you have distinguished in the past between efforts to detect bubble collisions, which is “real” science, and unscientific, unsupported claims and breathless hype about the multiverse on the the other hand. I wasn’t thinking of you when cautioning against painting “multiverse physics” with an overly broad brush.

JohnB,

I’m sure you can find various instances where researchers work to misdirect resources to enhance their own career prospects. After all, researchers are human too (most of them anyway!), and there seems to be no shortage of people who are more interested in enhancing their own position than working toward the greater good.

On the other hand, it is a long, arduous and often discouraging path to get through grad school, and then post docs after that, in order to secure a faculty position at a research university. Research physicists tend to be quite smart and most could easily command better pay (and probably have better career advancement prospects) in industry compared to being a faculty member or researcher in a national lab. On the other hand, working for a company means adopting that company’s R&D goals, which may be very different from pursuing one’s own passion — that’s the trade-off as I see it, and there is no shortage of people who are willing to give up better pay so they can work toward something they believe in.

What I’m getting at is that working in a university or national lab is not a good path to riches for the great majority of theoretical physicists, so the “follow the money” idea doesn’t apply to institutional research the way it does to industry and politics. I believe most theoretical physicists seek grant money and promote their research program because they honestly believe in it, and not because they cynically think that excessively hyping their program means more riches for them and a bigger empire of grad students and postdocs for them to manage. There simply are other, easier ways for them to gain riches and power than doing theoretical physics.

22. **Death By Hiccups**
January 21, 2017

Fake Physics: I think you’re right with some aspects of this picture despite generating large size influence and feedback entirely or mostly on their on own steam, are nevertheless of a secondary or non-fundamental order or else simplistic in and of, the being of that. The media and the majority of the interested public like the multiverse for essentially the same reason as the scientists: It’s the easy road. It doesn’t take much immersion (any, necessarily) before the far-reaching insights to burble in the region of the stomach, the excitement and euphoric emotion that in the end is about a revived hope-that-we-can-believe-in for transcendental survival of the tragedy of old age and death. Easy to make a documentary with all the same feelings and accolades of our colleagues. Easy to absorb a popular book and feel all the things that promise what we most want if we cannot be the best;our equivalence, as a personal potential, in a different life. There’s no such thing as a counter-factual in a multiverse.
The easy way is the rational way, that’s always been the truth. Why go the hard way if there is an easy way. It takes a lot of up front richness to see it different. Science was the jewel in the crown of doing things the hard way. It’s immensely inefficient at the level of a single life. But over the centuries it supplanted all else and created a new world. Those amazing insights that are so addictive particularly to the scientist who otherwise will be lucky to get half as much for a whole lifetimes work. The hard path has no answer for that.

23. **Peter Woit**
January 21, 2017

JohnB/Marty,

In general I agree with Marty: the motivation for physicists here is mostly not about money. There is one sense though in which people really should follow the money. If you trace back where a lot of these Fake Physics stories come from, you find that they’re funded by the Templeton Foundation. This foundation is the largest funder of Fake Physics, and a big part of the problem. They have an ideological commitment to bringing together religion and physics, and put a lot of money behind it, money going both to journalists and to physicists.

24. **srp**
January 21, 2017

Press release: Peter Woit says that in another universe you are dating Scarlett Johansen! Click here for the details of your relationship!

25. **Peter Woit**
January 21, 2017

Anonymous mathematician,
Personally I’ve never been able to figure out what ER=EPR is supposed to mean. Straightforwardly interpreted, it’s obvious nonsense, clearly it is supposed to be interpreted as some sort of speculative statement about some class of speculative theories of quantum gravity. Presumably experts on the subject can give more of a characterization of what this class of theories is and what kind of statement is being proposed, but personally every time I’ve tried to look into this I’ve ended up deciding that other projects looked like more promising ways to spend my time.

26. **dirk bruere**
January 22, 2017

I really don’t see why you are so against multiverse theories. As you say, little research is being done in that field, so they are hardly subtracting from the successes of String Theorists (ie none at all when it comes to proof). For the general public, they are fun. As they are for philosophers. Anyway, good luck with the ongoing failure of fundamental physics – I’m sure a new generation of String workers sucking the life out of all other possible routes to the mythical TOE will bring rich rewards.

27. **Alan**
January 22, 2017

There was one piece from Nautil.us (not given above) titled The Not-So-Fine Tuning of the Universe by Prof. Fred Adams which doesn’t look like Fake Physics. So he says that the universe isn’t so fine-tuned. Just wondering if first, how true is this and second, if anyone can enlighten me whether this goes against the multiverse concept. So, more wriggle room for the fundamental constants.

28. **Konstantinos**
January 22, 2017

I see how some of the links mentioned are just garbage (especially the *cough* Templeton's *cough* purely philosophical ones), but the article written on the site of the Astronomy magazine shouldn't be among them. Actually it goes against the popsci wave and notes that the most important part of a physics (or in general, scientific) hypothesis is to be falsifiable. Something that most (or every?) multiverse (as well as other "revolutionary") hypotheses lack.

29. **Shantanu**
January 22, 2017

Peter, something OT. David Gross giving a public talk at Spenta Wadia fest

30. **Doug McDonald**
January 22, 2017

Its not just fake physics. Its fakechemistry, biology, indeed any hard science.

The correct term, which Peter used, is "Clickbait Physics". My chemistry colleagues … even the best … absolutely insist that it is necessary. The University management just loves it. When I confront them all but one .. the best one … insist it isn't "wrong" , "its just hype, and its necessary as clickbait". I specifically offer any piece hyping the great future we face (Yes! the future will be better than the past — we'll all live longer and better lives") due to research in any field beginning with "nano". One was so farfetched I literally ROTFL in my secretaries' office when I looked at the poster.

When I was a grad student we would have said "this will make missiles obsolete … photon torpedoes based on it will travel at the speed of light, and even push through fog". (That one, of course, except for the "obsolete" part, is now reality.) My career suffered because I am simply unable to conjure up hype that excites folks used to "journalisticly correct hype."

31. **Peter Woit**
January 22, 2017

Alan,
Yes, that's one problem the "fine-tuning" argument, and that piece does a good job of explaining it.

In general I've found that the Nautilus people generally put out high-quality articles. The large number of dubious multiverse ones, including a lot of theology, which is not normally their thing, I found surprising.

Konstantinos,

Just as few Fake News pieces acknowledge not caring about whether they are true or not, most Fake Physics doesn't acknowledge that it is giving up on science, instead claims that what they are talking about is testable. As with Fake News, you have to look into it to see if it really is what it is claimed to be. I think if you look into the claims about evidence of other universes described in the Astronomy article, you'll find they don't stand up to serious examination (At the time they appeared in 2015, Jennifer Ouellette wrote a piece debunking them).

Doug McDonald,
The hype problem is much more widespread than the Fake Physics problem, of which hype is only a part of the story.

32. **Anonymous**
January 22, 2017

(disclaimer: I am not a physicist, nor do I play one on TV)

Science reporting has been in shambles for a very long time, and with the rise of facebook and the ad economy, I have seen headlines like "You too could live forever like this one strange organism!" that, when you trace back the interpretation of an article that summarizes a summary of an abstract, the actual paper being reported on is about anhydrobiosis not previously seen in a particular variety of nematode.

This sort of reporting is written by those with neither a desire to spread knowledge nor an understanding of the subject matter. It is there to make money, and the patronizing "wow, your mind is blown!" language of the writing drips with this cynicism.

Joining them are those that wish to build a religion on paradigm-shaking beliefs. Again, a cynical cash grab based not on the potential merits of a hypothesis, but based on mysticizing the observable and testable universe.

33. **Peter Woit**
January 22, 2017

Anonymous,

On the whole, I don't think the Fake Physics problem is coming from journalists, but from physicists. There's some bad science journalism out there, but if you avoid the obviously low quality journalism sources, what you find are journalists on the whole doing a pretty good job of explaining claims being made by serious physicists. Yes, many journalists can't resist covering Multiverse Fake Physics, but they're doing it because well-known physicists are pushing it.

34. **serious question here**
January 22, 2017

is it fake physics news if the news media report claims from respected physicists in papers, one example of which is Verlinde's recent paper on gravity which tries to explain away dark matter?

Verlinde published a paper in entropic gravity in 2016 that does away with the need for dark matter, and the news media called him the next Einstein.

fake physics news or genuine physics news?

if genuine physics news, since it is based on an actual physics research paper by an actual physicist, Erik Verlinde, there are of course research papers written by string theorists on the multiverse.

35. **Peter Woit**
January 22, 2017

serious question here,

I'm not talking about fake physics news, but about Fake Physics, a concept that I don't think really applies to preliminary speculative work like Verlinde's. He has an idea the validity or usefulness of which is unclear, he's discussing it in a paper, and that's getting reported in the news. This is perfectly normal scientific activity and its normal press coverage.

If after a lot of investigation, it turns out that "entropic gravity" is a useless untestable idea that tells us nothing, but Verlinde keeps working on it and promoting it, with serious financial backing, lots of press articles appearing, and his colleagues unwilling to stand up and tell people it's an idea that doesn't work, then we'll be in the realm of Fake Physics.

36. **Maximillian G. Tresmond, Esq.**
January 22, 2017

Why is the Templeton Foundation pushing the multiverse idea?

37. **Peter Woit**
January 23, 2017

Maximillian,

The Templeton Foundation's mission is to bring science and religion together, it was set up for this purpose by the late Sir John Templeton. They have been funding and pushing Multiverse research for a long time, since it fits very well with their mission, blurring the boundary of science and religion. The recent Nautilus multiverse articles fit well with their point of view, getting both theologians and scientists to discuss the topic.

38. **Balazs**
January 23, 2017

I'm an engineer, not a physicist, so I'm not familiar with the mathematical fundamentals of the inflation filed, but it seems to me that the concept of multiverse is based on the assumption that the inflation field (if it exists) is going through random fluctuations, so at any point in space it has equal chance of producing a new bubble universe with random properties. So my question is, why do physicist assume (without having any observational evidence) that the inflation field is random? It's basically a scalar function that (if exists) we don't know anything about, so why can't it have any particular shape. Why can't it have a characteristic feature localized somewhere that will produce just one universe and that's it… Of course in that case we would need to explain why it looks like that, but complete randomness also needs explanation.
I'm looking for an answer that is not than it's because of the Heisenberg uncertainty principle, because we don't know if that applies to a hypothetical inflation field.

39. **Peter Woit**
January 23, 2017

Balazs,

The conjectured inflaton (not "inflation") field is supposed to be a quantum field, not a classical field. It has energy and couples to gravity, you certainly can make models like this, with probabilistic behavior implied by quantum mechanics. These come with a huge freedom even for a single inflaton field since you can choose the self-interaction potential.

One problem for even a single inflaton field is getting any signficant testable predictions out of this. Much more seriously, the actual theories being promoted (string landscape) are vastly more complicated, involving hundreds of inflaton-like fields and all sorts of other structures, with no well-defined theory that governs them. So far, this is a completely empty idea since it predicts nothing (or everything, which is the same thing…)

40. **George S Williams**
January 23, 2017

Actually. it's no longer Fake Physics, it's now Alternative Physics.

41. **Darrell Burgan**
January 23, 2017

I'm not disagreeing with the POV expressed here, just genuinely curious: what qualifies an idea as "real" physics? Is it merely falsifiability or is there more to it than that?

As a non-physicist outsider, maybe I'm oversimplifying, but it seems to me the real problem is that the line between science and fun speculation seems to be eroding, not that speculation is in and of itself wrong.

42. **Zach D.**
January 24, 2017

I'd like to see you back up your comment about fake news appearng in the NY Times with evidence. (Of course all news outlets make mistakes at times, and all will occasionally have an employee who doesn't play by the rules. But if you're going to point the finger at that news outlet, I assume you feel that fake news is not the exception for them.)

43. **NoGo**
January 24, 2017

Are there other scientists, blogs, or publications that systematically push back against fake physics like you do?
I know that Sabine Hossenfelder occasionally does, but that's the only other one I am aware of…

44. **John**
January 24, 2017

So what does fake physics and fakes news have in common? It's that fake stuff can be pushed by anyone with an agenda and you can no longer rely on credentials or the previous standards of the publishing site. It really comes down to "reader beware".

At the end of the day we can no longer accept as fact anything that is published. And that is a sad state of affairs.

45. **Zack Yezek**
January 24, 2017

This all seems to me to stem from a simple but unpleasant reality- most of fundamental physics has been stagnating due to a lack of new information from experiments.

Is it really so surprising that many theorists have been spinning their wheels or going off into la-la land for the last 40 years? The many null results and experimental falsifications of various GUT theories, flavors of SuperSymmetry, etc. are non-trivial and useful data in their own right, but only in a negative sense. My own guess is that real progress will originate in the neutrino sector, the first place the Standard Model finally made a flat-out wrong prediction and the one place we already have experiments probing new physics. Because unification has stalled out for the time being due to insufficient data, and won't really go anywhere until we get some more.

46. **Peter Woit**
January 24, 2017

John,
Unfortunately I think the problem is not just that of lower standards at publishing sites. On the physics side, physics journals have always published a certain amount of nonsense and popular science publications have covered this. The Multiverse fake physics campaign is something new I don't think we've ever seen: a concerted ideological campaign by a group of people with the best credentials at our best institutions, with multi-million dollar funding behind them, funding not subject to review by their peers. The problem isn't that popular science publications have lowered their standards to report this, it has always been their job to report claims made by scientists with these credentials.

I don't want to moderate a discussion of the disturbing story of US democracy and Fake News here, and will delete further comments about this, but since it's my blog, my thoughts about this are the following:

Besides the well-known, well-funded right wing Fake News machine that has come to dominate the political reporting scene in recent years, the rot goes deeper. Even the most reliable of our news sources (e.g. the New York Times) have been infected with this, and show no signs of having any idea how to counter Fake News. As far as I can tell, they seem to have often decided that vigorously fighting Fake News would make them appear to be partisans, so at time have joined in the Fake News business hoping it will make them look less partisan and thus more credible.

What I have in mind in particular (responding to Zach D.) is the behavior of the New York Times toward Hillary Clinton, their campaign of Fake News attacking her character. This has a long history, going back to the first Clinton administration (Travelgate, Whitewater), and continuing through the past year (email server, Clinton Foundation). Some of their writers (e.g. Maureen Dowd) have now written literally hundreds of pieces attacking Clinton's character. I didn't understand why they were doing that in the 1990s, even less so this past year. I suspect their editors thought that there was no way she could lose this election, so using her as a punching bag was harmless sport.

At least with their last disastrous promotion of Fake News (publishing Judith Miller on Iraq), they seem to have realized they made a mistake. They show no evidence now of understanding what significance of what they did during the Clinton-Trump campaign. Their Public Editor is an idiot. After defending the most egregiously awful things they have done, this weekend she announced that she has found something they did wrong: not reporting absurd accusations about some computer server belonging to an obscure part of the Trump organization, see
https://www.nytimes.com/2017/01/20/public-editor/trump-russia-fbi-liz-spayd-public-editor.html
This level of stupidity at an organization of this importance is scary.

If I had any idea what to do about Fake News I'd open comments here and try to do something. I do see what needs to be done though about Fake Physics: people in the physics community need to step up and take some responsibility. The problem is not going away.

NoGo,
Besides Sabine I'm having trouble of thinking of anyone. Lubos on some days will rant about the Multiverse, but having him on your side tends not to be helpful, as string theorists have discovered.

47. **Michael**
January 24, 2017

I think you should reinvestigate "Fake Physics VI" (the one from astronomy.com) as it doesn't exactly fit your bill of fake physics. While the title is certainly clickbait-y, the article takes the point of view that physical theories need be testable and discusses a cosmological multiverse where interactions at the boundaries of the universes could be relevant in interpreting anomalies in the CMB. They are quick to acknowledge that this is just a suggested theory, and there are other possible explanations for their data which require further investigation.

48. **Peter Woit**
January 24, 2017

Michael,
Sorry, but I disagree. One feature of Fake News is that the writer often goes on about what a problem Fake News is, that luckily for the reader, what they are reading is from someone aware of the problem, and willing to help them get the real stuff.

Same with Fake Physics: bogus claims to have real testable science are often framed by a discussion of what a problem it is that others have been making untestable claims.

49. **Patrick Harris**
January 24, 2017

Hello Dr. Woit,

Did you want "Fake News IX" and "Fake News X" to read "Fake Physics" IX & X? Or are was the distinction deliberate? Just curious…

Thanks for the great discussion!

50. **Peter Woit**
January 24, 2017

Patrick Harris,

That was a mistake, fixed. Thanks for pointing it out!

51. **Another Anon**
January 25, 2017

In defence of Nautilus, this is a great article:

http://cosmos.nautil.us/short/90/we-have-pushed-physics-too-far

52. **Peter Woit**
January 25, 2017

Another Anon,
I'm afraid I disagree, wrote about why here
http://www.math.columbia.edu/~woit/wordpress/?p=9027

That piece is not fake physics, but it's a point of view (very crudely put, physicists should become humble and give up on hopes for certain kinds of progress in fundamental physics) that is a side-effect of the nihilistic Fake Physics campaign. It's also a point of view that fits very well with the Templeton Foundation one: mankind should be humble before the glory of God (again, this is a crude caricature).

This kind of thing is analogous to one tactical goal of the ideologues behind Fake News: use it to discourage your opposition, even when they realize it's not true.

53. **Another Anon**
January 25, 2017

Yeah, now I read what you said about it earlier, you might have a point.

54. **NoGo**
January 27, 2017

What I still don't quite understand is how Templeton's money can be at work with regard to Fake Physics: I presume (and you say, if I am not mistaken) that the physicists involved actually believe in their theories, and anyway it's hard to imagine prominent scientists taking money to misrepresent their work. It is easier to imagine such money influencing the media to "amplify" already existing "signal", but again it's hard to imagine reputable journalists and publications taking money directly, so it must be somewhat subtle… Can you elaborate on this a little bit?

55. **Thomas Lee Elifritz**
January 27, 2017

Science Friday this week has an article that appears to be the epitome of 'woo woo'.

http://www.sciencefriday.com/articles/why-the-multiverse-isnt-just-madness/

Science Friday is supported by listener contributions, member stations, and by: Anonymous; Alfred P. Sloan Foundation; Del Mar Global Trust; The Dirk and Charlene Kabcenell Foundation; Macmillan Education; Mellam Family Foundation; Michael J. Connell Foundation; Sedgwick Family Fund at the Cleveland Foundation; Swig Foundation; The Winston Foundation

56. **Peter Woit**
January 27, 2017

NoGo,

I don't think there's anything subtle about $10 million targeted at producing this particular journalism, see:

https://www.templeton.org/what-we-fund/grant-search/results/nautilus

$15 million in grant money to physicists isn't subtle either:

https://www.templeton.org/what-we-fund/grant-search/results/fqxi

It has a significant effect on what sort of research physicists decide to engage in, as well as how they choose to communicate it to the public.

Thomas Lee Elfritz,

The flood of these things is really depressing, I'll add that one as Fake News XI. Another depressing thing is that all of these stories quote the same list of proponents of the multiverse, portray them as fighting for a new idea against the conservative scientific establishment, but almost never manage to talk to anyone willing to make an argument against what is going on. The lone exception is Paul Steinhardt. Good for him, but I don't understand why the rest of the physics community is staying quiet.

57. **Louis Wilbur**
January 29, 2017

Thanks Peter for raising this issue; you are right to be concerned that very speculative ideas are being given a level of coverage and credence that they don't deserve. The question is how to address it and understand why the scientific mainstream has not pushed back against such speculative ideas. Perhaps it is because they view it sort of like philosophy; it is something they simply don't want to spend time responding to. But both the popular and scientific press could do some pushback by simply correcting the sensationalism that typically appears in such articles. For example, in her blog on 12/19/15 Sabine Hossenfelder wrote "But the longer the chain of inference, and the less trust you have in the theories used for inference, the less real objects become. In this layered reality the multiverse is currently at the outer fringes. It's as unreal as something can be without being plain fantasy". She also wrote in a different blog that the multiverse is something that researchers within the scientific community spend almost no time on.

This means that the multiverse has not "gone mainstream" and there has not been "a great change in attitude" as some of the stories in your fake news links claim. I think the basic idea that the very early cosmos was dominated by some type of vacuum energy is plausible but the physics of it is completely mysterious. It is grossly premature to say that the mechanisms postulated in traditional inflationary theory are even approximately correct explanations of that vacuum energy. Something like cosmic inflation may have been caused by some completely unknown process, perhaps some kind of quantum black hole foam or some type of QCD-like fluid. For these reasons and others there is no basis at all to claim that such "inflation" is eternal. Another sensational claim is that non-eternal types of inflation are contrived and unrealistic. Actually they are not. For example, Wikipedia writes "In hybrid inflation, one scalar field is responsible for most of the energy density (thus determining the rate of expansion), while another is responsible for the slow roll (thus determining the period of inflation and its termination). Thus fluctuations in the former inflaton would not affect inflation termination, while fluctuations in the latter would not affect the rate of expansion. Therefore, hybrid inflation is not eternal. When the second (slow-rolling) inflaton reaches the bottom of its potential, it changes the location of the minimum of the first inflaton's potential, which leads to a fast roll of the inflaton down its potential, leading to termination of inflation". The February 2017 Scientific American article "Cosmic Inflation Theory Faces Challenges" By Anna Ijjas, Paul J. Steinhardt and Abraham Loeb explains some of the problems with traditional inflationary mechanisms.

So cosmologist who study inflationary theory are guilty of group think and this is the reason why other types of mechanisms underlying an "inflationary" expansion are not being pursued. It also explains why bounce scenarios are not given the greater attention and study that they should be. Such alternative ideas should be pursued since semi-classical gravity and effective field theory are probably inapplicable in the very early universe and a full inventory of nature's quantum fields and how they are coupled together is lacking. Also lacking is the correct quantized version of General Relativity, how it is united to nature's quantum fields, and the implications of all of this for the very early universe. There is a lot to vacuum energy that is not understood: the various hierarchy problems, dark energy, and the cosmological constant for example. There should be pushback to the traditional ways of thinking about inflationary mechanisms and pushback to the whole idea of multiverses. Everett's many worlds multiverse is nonsense and I am baffled as to how and why it manages to get the coverage that it does. For instance, no explanation is given as to where the energy comes from to make all of the split-off universes and no explanation is given as to how a split occurs outside the light cone of a state reduced event. Thank you Peter for the post.

58. **Samuel Keays**
January 30, 2017

https://www.youtube.com/watch?v=Q8ccXzM3x8A

This was posted today. Kind of interested on what you think about the idea that it is primarily a controversy only in the eyes of the general public, not among the scientific consensus.

59. **Peter Woit**
January 30, 2017

Samuel Keays,

That's off-topic, little to do with the multiverse. From a quick skim, it's garden variety ancient string theory propaganda, pretty much exactly what I wrote my book 15 years ago to counter. The one thing that has changed since then is that string theory is significantly less popular in physics departments (as well as to the general public).

Fascism and the Current National Emergency

January 28, 2017
Categories: Uncategorized

After the election it seemed to me that it would be a good idea to ignore what Trump tweeted or said, and wait to see what he and the people he surrounded himself with would actually do. We've been finding this out over the past few days, and today the nature of the problem we face is now clear. The actions ordered today that are now being carried out by US officials around the world are the product of a deranged and dangerous personality who has surrounded himself with similar others. This is a national emergency with no parallel in our history.

While the US has never seen the likes of this situation, Europe has, with Trump following a playbook familiar from the history of the 1930s. At this point the US may be one terrorist attack away from full-blown Fascism, this time with nuclear weapons. This needs to be stopped, now.

The Constitution does provide two ways to deal with something like this: either the impeachment process or removal under the Twenty-Fifth Amendment as "unable to discharge the powers and duties of his office." Many of Trump's recent statements are clearly the product of delusional mind that is incapable of dealing with reality, and these delusions are now reflected in his actions.

Removing Trump and those he has surrounded himself with will require the cooperation of a significant number of Republican legislators. Anyone who cares about US democracy should be trying to figure out how to get this to happen. Those of us in the US desperately need some good ideas about how to do this. Those in other countries should be pressing their governments and institutions to fight back against the US, as well as doing what they can to keep their own societies from following the US down this path.

I'm moderating comments here and will only post one kind of comment: positive ideas about what to do about this emergency situation. At this point I think what's needed are ideas way beyond suggestions of a "scientist's march" to promote rationality. We need to figure out how to fight a new form of Fascism that has just come to power and is starting to rule by decree.

Update: With the Republican Congress so far deciding to sit back and let Donald Trump, Steve Bannon and Stephen Miller rule by decree, all hopes for now are with the Judiciary. Last night a judge issued an emergency stay on parts of the executive order, this was followed by a statement from Miller on behalf of the White House that the order "remains in full, complete and total effect." The suggestion to donate to the ACLU is a good one, they are on the front lines here.

The President of my institution, Columbia University, at 1 am sent an email to the University community denouncing this executive order and involving the University in this in an unprecedented way:

> As I have said on many occasions, it is critically important that the University, as such, not take stands on ideological or political issues. Yet it is also true that the University, as an institution in the society, must step forward to object when policies and state action conflict with its fundamental values, and especially when they bespeak purposes and a mentality that are at odds with our basic mission. This is such a case.

There is a petition being signed by academics here, which likely will have no effect, but I signed it anyway, and you may want to too.

Update: A small glimmer of hope: a joint statement criticizing the executive order by Republican senators McCain and Graham, and a Twitter response from Trump identifying any opposition from them as "looking to start World War III". World War III between Trump and Republican senators is what we all need to root for.

Worth watching: news reports that the Trump administration is defying court orders requiring access to lawyers by detainees at Dulles airport. A decision by Trump and his people to defy court orders would provide grounds for impeachment.

Update: Just wrote the following to a correspondent, thought I might as well also post it here.

My advice would be to consider focusing on the following, and not getting distracted by the blizzard of appalling things one might reasonably find concerning about the current situation:

- It was unclear who would actually be running things in a Trump administration (since Trump himself clearly neither knows nor cares about anything other than getting attention) until the past couple days. The answer now seems to be that it's Steve Bannon of Breitbart. Bannon is a self-described "Leninist", see for instance.

  His self-described goal is to tear the country apart: "to destroy the state… destroy all of today's establishment." This means he's not just our enemy, but is also the enemy of much of the Republican Party, including for example John McCain and Lindsey Graham. He's also not about to let himself be thwarted by the courts. I think we're already seeing defiance of court orders, with a lot more of that to come.

- There's always the possibility of something like a military coup, but the only constitutional way out of this is impeachment or the 25th amendment route. This requires convincing a sizable number of Republican legislators that they have to abandon Trump and support his removal. To me, the big question here is what can be done to make that happen. How does one get the Republican establishment (legislators and/or Fox News, Wall Street Journal, etc.) to turn on Trump? My guess is that where they are now is that they know they have a problem on their hands, but are deathly afraid of Trump's supporters, of ending up with their heads on a pike.
- There's not much time here. Looking at history, what happens next in this kind of situation is some episode of violence gets used to rally the country to the leader and justify his assumption of emergency power to rule by decree. We're one episode of some enraged person shooting a lot of people away from that happening, in a country full of heavily armed angry people.
- The best, most successful thing to hope for here is something I and maybe many of you find a depressing prospect: President Pence. But, there we are.

Hoping I'm wrong about all of this…

Update: Thanks to commenter Fred P. for the link to this. For something sensible from a conservative, see this by Eliot A. Cohen, which includes:

> For the community of conservative thinkers and experts, and more importantly, conservative politicians, this is a testing time. Either you stand up for your principles and for what you know is decent behavior, or you go down, if not now, then years from now, as a coward or opportunist. Your reputation will never recover, nor should it.

Update: There was an incident last night (in Quebec City) of an enraged person shooting a lot of innocent people, killing 6 and wounding 8 others. Since the shooter was an Islamophobe and the victims were Muslims praying at a mosque, so this was of no use to Trump/Bannon, this has gotten just about zero attention.

Update: The Quebec City shooter was a Trump fan radicalized by Marine Le Pen.

Update: Terry Tao has a blog entry about this, emphasizing the damage to the math community.

Update: Leonard Susskind has also decided to issue a statement warning about Fascism and the Trump administration, using his YouTube channel.

Update: For commentary from historians of the rise of fascism in Germany on analogies with the current situation in the US, see Ron Rosenbaum and Isabel Virgina Hull.

Comments

1. **Robert Gauthier**
   January 28, 2017

   Anyone that thinks this is going to end peacefully is naïve. Don't forget there was a constituency that voted him into power that will see his removal as an attack on them as a class. They are armed, and think they have nothing to lose. This is a recipe for civil war.

2. **Vadim Zeitlin**
   January 28, 2017

   Civic disobedience is the only non-catastrophic way out of this situation that I see. Right now, there must be at least some immigration officials able to put their moral principles above the principle of subordination and they should be encouraged by everyone who values American democracy to do just this. And this, unfortunately, probably won't stay limited to just the immigration officials, so even if you don't know of those, it's still worth trying to disseminate the idea that illegal and immoral orders must not be followed as widely as possible.

3. **Heinz Lackner**
   January 28, 2017

   Flipping 4 Senate and 24 House seats would be the cleanest road to impeachment. That is unfortunately 21 month away. In the meantime, we have to speak up, unite and remind a handful of Republican Senators that they can stop this nonsense by showing that Country comes before Party and their own reelection.

4. **Kevin S. Van Horn**
   January 28, 2017

   Trump has enormous power because his predecessors — especially Bush and Obama — usurped powers for the presidency that were never authorized by the Constitution. These include the power to take the country to war, the power to rewrite bills passed by Congress, the power to unilaterally create new laws via executive orders, the power to summarily execute (via drone) whomever the president decides is dangerous, etc. It's time to roll back the imperial presidency. This is a project in which Constitutionalist conservatives would gladly cooperate with Democrats.

   Here's a good start:
   http://foreignpolicy.com/2017/01/24/senator-and-congressman-introduce-restricting-first-use-of-nuclear-weapons-act-trump/

6. **Robert Gauthier**
   January 28, 2017

   As far as impeachment goes, does anyone think Pence will be much of an improvement? He may well be worse given he knows how the system works and just how far it can be pushed before it breaks.

7. **neil**
   January 29, 2017

   Write or phone your congressional representative right now and express your outrage and disgust with this order. Encourage everyone you know to do the same. PLEASE.

8. **Bee**
   January 29, 2017

   It'll not help in the present situation, but in the long run I think the US voting system should be overhauled by the constitutional court. In Germany the voting system is basically constantly ruled unconstitutional and being fixed in one way or the other because it doesn't appropriately guarantee a good representation of the people's will. It's beyond me why the same isn't happening in the US.

   Something else that comes to mind. In Germany, the president (not the chancellor) can call for new elections. Is there a similar arrangement in the US? Circumstances that can require a new election?

   I find it not without irony that we owe much of our democratic system to Americans, but they failed to update their own system.

10. **AS**
    January 29, 2017

    Bien étonné de se trouver ensemble… While (unfortunately) I cannot give any suggestions on how to act, indeed one of the most serious threats to democracy is that it is very fragile by its very nature and that it can easily be destroyed from within, I can suggest a book with scary parallels and which convincingly shows how fast things could deteriorate. Perhaps better than "1984", one should (re)read Philip Roth's "Plot Against America".

11. **S**

January 29, 2017

Pence is very right-wing; he is not mentally unstable. Failure to distinguish those things at this time, while perhaps painful for the left, will be very dangerous to the country.

I don't think Trump can be impeached yet. Not only is it not that clear that his actions so far constitute "high crimes and misdemeanors," but even if it were (and arguably, of course, it is), I do not think it is possible yet that sufficient political will exists at this time (see Robert Gauthier's comment above). What I do think is worth pursuing is working to get conservatives in important positions to *privately* swing against Trump. Then, given the excuse, they can impeach him and hopefully will.

To this end, I think two things are important. First, the left, which is the primary (but not only) source of dissent right now, must *religiously* distinguish between "policies we really hate that are nevertheless mainstream conservative goals for decades," and "unhinged, fascist policies." This is difficult given the high-rhetoric times in which we live, but it is key. Few conservatives are going to be genuinely upset about reduced abortion funding, for example. Plenty can be talked into being upset about building a wall, instituting tariffs by executive action, closing down immigration or keeping out permanent residents. Rhetoric such as the above — "is Pence really better than Trump?" — is exactly the opposite of what I am proposing. Pence is very conservative, but if you genuinely can't distinguish him from a maybe-Hitler, then any attempt to convince Republicans to work with you on this is going to be futile.

And next, having chosen to focus on those overreaches that, genuinely, any sane American of goodwill, of any political persuasion, must find abominable, the left should reach out to actively join with the few conservative voices that have been saying the same thing. This will involve, once again, pain: allying with a George Will, a David French, even a Matt Walsh will be horribly distasteful to those who believe those men's opinions represent bigotry. But that, I think, is the hard step that leading voices on the left and in academia must take if they want to have any hope of getting the attention, and changing the behavior, of Republican Congressmen to the extent that they impeach their own President.

12. **Shecky R**
January 29, 2017

Given the intransigence and simplemindedness of Trump supporters I fear there are only bad solutions to get through this crisis. I'll stand in jaw-dropping awe of our Founding Fathers if we do somehow emerge peacefully from this grievous situation.

13. **Low Math, Meekly Interacting**
January 29, 2017

The Republican Congress has more or less fallen in line, unwilling to even acknowledge earlier congressional statutes (e.g. the Immigration and Nationality Act). The Democrats' political incompetence has left them neutered. I see little hope outside of Federal courts, assuming legal challenges to Trump's orders don't make appeals all the way to the Supreme Court, which soon will be the the last branch of the Federal Govt. to fall. Donate to the ACLU, I guess. They're going to be very, very busy these next four years.

14. **sdf**
January 29, 2017

It was pointed out by lawyers associated with the former Bush administration that Trump was open to impeachment as soon as he is inaugurated because he had stated that he would not (and has not) placed executive control of his various business interests in an independent trust (actually there seems to some who interpret the relevant laws as meaning that he would have to sell his business interests). It was reported that such legal proceeding are already under way. Just yesterday Democracy Now! had an interview with Prof. Richard Painter, who is professor of corporate law at U of Minnesota and was in Bush administration regarding same (also he is one of the complainants in lawsuit), the transcript of that interview is here

https://www.democracynow.org/2016/12/28/george_w_bushs_ethics_lawyer_trump

15. **AR**
January 29, 2017

We are not that far from full-blown fascism here in Europe, either. Just a few (hackable ?) elections and (false-flag ?) terrorists attacks away. In my opinion, we really are witnessing textbook fascism, advancing all over the world. My advice, and what I am going to do: Try your utmost to preserve your integrity and credibility, at any price (it won't be easy). Try your utmost to be compassionate, to build bridges between people. Try your utmost to understand why many chose to vote for Trump, why many are going to vote for Le Pen, why many for two decades have voted for Berlusconi. Try not to despise them unnecessarily, but try to understand them, their daily struggles, the extreme precariousness of their lives, their despised and dying communities (all of which does not justify their choices, but try to understand those choices), because otherwise it is may be going to degenerate into a civil war and it will play into these fascists' hands. Remember Orwell's 1984: War is Peace.
Again: Try your utmost to preserve your integrity and credibility, at any price (it won't be easy). I am a primary-school teacher, and that is going to be my ground (my task). I'll give it my best.

16. **Nate**
January 29, 2017

Heinz Lapman: It requires a 2/3 vote in the Senate to remove a President, so flipping 4 Senators is not enough.

Bee: no court in the US has the authority to change or eliminate the Electoral College. That could only be done by ammending the Constitution, which would require 2/3 majority in Congress and ratification by 3/4 of the States. (Necessarily including many small states that have disproportionate power now. In fact an ammendment to reduce one state's representation in the Senate must be approved specifically by that State.) So changes seem very unlikely. And no, there is no mechanism for calling for a new electricion.

17. **Anonyrat**
January 29, 2017

Note that Congress is crucial to holding the UnPresident in check or even removing him.

1. Attend your representative's town hall meetings and ask questions.
2. Call your representative's office in Washington DC and talk to the staff who take the call.

These are the two most effective methods for individual voters with no significant money to donate to a political campaign, to influence their representatives.

To do better than this, you will need to work in concert with others, i.e., through organization.

18. **Felipe Pait**
January 29, 2017

At this point the only thing we can do – have to do! – is cede no ground. The main instrument of defense are the courts. We have to hope that with a tireless defense of our liberties and of good government, cracks will appear in the administration – they are altogether not competent at the business of running things and will make mistakes.

How we prevent them from continuing the unconstitutional power grab they are executing depends on the nature of the illicit activities that are uncovered. The situation is not ready for immediate impeachment, but we don't have the luxury of waiting 2 years until the midterm election. In the meantime, special attention must be paid to vote suppression – the repeated lies about nonexistent fraud have to be understood as a declaration of intent to commit electoral fraud, and in that they will have support from the Republican party.

19. **Low Math, Meekly Interacting**
    January 29, 2017

    Anyone who thinks Trump is going to be impeached over emoluments is, I'm terribly sorry, smoking crack. Impeachment is a vote. It requires those casting the votes to have a moral compass and a spine. There isn't enough of either to get to a supermajority in the legislative branch, my friends, so dream on. Trump could eat a baby on live TV and Paul Ryan and Mitch McConnell would choke down the leftovers if they thought that would play well to Trump's base. They've as much as demonstrated it. And the Democrats…well, most of the midterm flipping will be happening in Trump Country, so don't expect them to be casting themselves on any pyres.

    The very sad truth is we progressives have very few, if any, levers of Federal power to push on, and the quislings in charge on both sides of the aisle can be expected to try to ride the populist wave so as to keep their careers afloat. Kirsten Gillibrand (of all people) can't do it alone, folks. And aside from a few grey-hairs like Sanders, she may as well be.

    We're facing a very long game here, and the damage to be undone is so extensive it's hard to fight off a sense of total despair. The Democratic party, already gasping for life prior to 2016, has been so badly pummeled that it's risking total and permanent irrelevance beyond its safe urban coastal enclaves.Republicans top Democrats in state legislative seats by at least 1000 (i.e. Republicans are about 3/5 in control, with 17 states having veto-proof majorities). It's worse at the executive level, with 33 GOP governors to the Dem's 16. The opposition, such as it was, has been routed.

    We have no choice but to suck it up or get involved at the local level. That's going to be a very uncomfortable position for many people. My sense is collectively we're not the types who spoiling for a fight with our neighbors, and don't much relish the idea of bricks through our windows, or worse. But that's the reality that left-wing collusion and complacency has wrought. There's not going to be a quick fix, and some of whatever damage is coming may be irreparable. That's the reality. We either leave, take it, or fight at the grass-roots level by running for office, which I'm guessing the vast majority of us have little time or stomach for. But I see no other long-term alternative, and the short term is grim enough.

20. **Tyrkky**
    January 29, 2017

    Almost 50% did not bother to vote at all. I don't think many of them would had voted for Trump – more likely they were discouraged because Dems did not offer anything to them. You need to get them understand that sometimes one has to vote for the lesser evil. Keep making noise and maybe enough will wake up to make a difference next time.

21. **anon**
    January 29, 2017

    "And no, there is no mechanism for calling for a new electricion."

    … well, in that case I guess the last one out of the country had better switch off the lights.

22. **johndoe_fr**
    January 29, 2017

    Sympathies from this French reader to the all the US citizens harmed directly or symbolically by these executive orders. The only two pieces of advice I can think of are:
    (a) plan his next possible moves and take judiciary counter-measures early to make it that bit harder for him and his team (among his next moves is that trade war with China for instance) ;
    (b) since people voted for him mainly for jobs and anti-immigrant policies, the only way to turn his base away from him is to provide jobs to those people before he does (e.g. collectively fund small businesses in the Rust Belt, buy their stuff, and make sure the folks know their wages or income is from well-meaning democratic-leaning folks), as well as show that the anti-immigrant policies weaken the economy. Clearly a job of many years, the aim being that he's not re-elected.

23. **Abby yorker**
    January 29, 2017

    I am one of the few to vote twice against mr trump…in the general and also in the Texas primary, where I pretended to be a republican.

    But I agree with others that impeachment is not in the cards at this early stage and I would not personally support it given the current information. I look forward to the congressional elections…if there is not a reversal of the majority, then I think we have to live with trump for the whole 4 or 8 years.

    Yes, American democracy is a little risky. They had an interesting episode on that in that series, "west wing".

    My recommendation is along the lines of ACLU support. But pick your own recipient, the cause you feel is most pressing. I myself am contributing to Planned Parenthood, which appears to be losing federal funding. Perhaps billionaires could donate significant sums to completely replace federal funding in key areas.

    Thinking a little more about my previous comment. I would like to see a web site that shows all federal funding recipients together with cuts imposed by the trump administration. There would be a running count of imbalances not covered by current contributions, assuming that the recipients would be willing provide this information. User would use the information to decide on the best use of their donations.

    I think that obvious issues with this scheme (e.g. accuracy of donations quoted by recipients) could be worked out.

    This "How to effectively talk to your member of congress" advice from a former congressional staffer got some press after the election:
    https://storify.com/editoremilye/i-worked-for-congress-for-six-years

    In addition to emphasizing that phone calls are more effective than letters, she argues that it's more effective to contact the local (district) office rather than the DC office.

It’s also possible to arrange to visit the local office and speak with staff in person. I did that with an anti-war group in ’02 or ’03.

My favorite comment about online petitions comes from former Rep. Barney Frank (D-MA): “Signing an online petition is like scratching your nose. Nobody in Congress is impressed because you pushed a button on an online petition. What matters is individual communication.”

That said, I’m not optimistic about much of substance coming out of Congress for the foreseeable future. In the meantime I would like to see the “moral responsibility to disobey unjust laws” (and executive orders) gain more prominence in popular consciousness and discussion, since I anticipate many more unjust orders from this administration. I’m quoting the phrase from King’s Letter from a Birmingham Jail, and of course the idea has a long history. Here’s a short article about it (that I’m sharing in part because Larry Rockwood is an acquaintance of mine):

Speaking from outside USA, was hoping you guys would remove your ‘leader’ from the world stage by investigating his tax affairs as you eventually removed Al Copone from organised crime.

I think many are missing the point. Trump is not alone. Hitler was not alone. So it is not a matter of getting rid of a crackpot. It is a matter of civil disobedience, patience and resolve…

To be blunt, we are either confronted with 1) an incompetent administration fueled by a reality TV sensibility; or 2) we are experiencing the early stages of a coup. I assume 2) for a variety of reasons, including a) Bannon is ex-Navy and worked at a high-level in the Pentagon; b) Flynn is an experienced hand in the Intel community; c) Giuliani is a crank with actual experience in governance and law. Trump has an immense talent w.r.t. media manipulation along with obvious personality characteristics that would be disqualifying in most other pursuits than national politics and TV.

So what is the remedy? As others have pointed out civil disobedience is number one on the list of actions and needs to be taken early and relentlessly until this administration is ended. It’s not just the Immigration EO but also Standing Rock, the assault on EPA and so on.

Another action is to ensure that all government databases across the board are cloned outside the control of the U.S. government. For example, the ncbi.nlm.nih.gov is over 9 Pb and is in part replicated via bio-mirror.net around the planet but not in its entirety. Those with the resources to help preserve decades of quality U.S. Federal collected data in all areas of study should help to create resilient distributed collections that can be referred to in the event of suppression by the current anti-science, anti-elite administration.

(echoing previous comments)

Focus single-mindedly on the marginal Trump effect, i.e. policies or actions that are unique to Trump and are not standard Republican policies. To be more than simply party politics, a case has to be made that a Trump presidency is qualitatively different (and qualitatively less preferable) than e.g. a Mike Pence presidency 0r a Ted Cruz presidency.
