Introduction

March 17, 2004
Categories: Uncategorized

This is an experimental new weblog. Let's see if I can find anything of interest to put on here, and how long it takes for someone else to find out it exists.

Comments

1. **Peter**
   March 21, 2004

   Hi Pyracantha,
   I enjoyed seeing your weblog, the posting about "Science Porn" was pretty funny and very much on target. I hadn't seen 't Hooft's page on how to become a theoretical physicist before. Interesting, but you don't need to know absolutely ALL of that stuff!

2. **Pyracantha**
   March 19, 2004

   Dear Dr. Woit:

   At the risk of putting myself forward I write this comment. I found your blog through Sean Carroll's "Preposterous Universe" which I read daily. I am a beginning math/physics student – in my middle age. I have NO crackpot "theory of everything" to promote nor will I ever have one. I am an artist who was inspired to begin studying math/physics by a trip to Fermilab in 2000. I have my own blog, "Electron Blue," which is my journal about this process. It's available on the Website whose URL I have posted above. I will be reading your blog and understanding as much as I can. I hope I will understand more as time goes on.

   Yours, Pyracantha

3. **Peter**
   March 19, 2004

   Thanks! This encourages me to try and write something more here, also I hope to find time to finish writing up the last few representation theory notes and get to work writing up the notes for my QFT class.

4. **Santo D'Agostino**
   March 18, 2004

   Your course notes for Lie groups and representations are very good, and your criticisms of string theory are interesting.

   And yes, someone out here now knows that your blog exists.

   Best wishes,
   Santo

Talk by David Gross

March 19, 2004
Categories: Uncategorized

Last Friday I went to hear a talk by David Gross at the CUNY Graduate Center on "The Coming Revolutions in Fundamental Physics". This was more or less Gross's standard advertisement for string theory that he has been giving for nearly 20 years now. He explicitly started off with the claim:

"Fundamental Physics = String Theory"

His first PowerPoint slide was a quote from "Hannibal" by Thomas Harris, a sequel to the novel "Silence of the Lambs". Evidently late in this novel the main character is depicted manipulating the "symbols of string theory", with "equations that begin brilliantly and end in wishful thinking". It sounds like Harris really has got the right idea about string theory, but Gross said his talk was designed to argue that string theory was not wishful thinking.

He then went on to claim that in 3-4 years there will be a headline in the New York Times about the discovery of supersymmetry at the LHC. From what I can tell, the LHC should have first beams in 2007, but even if everything goes according to plan, it won't be until 2008 that the experiments there will have accumulated a non-trivial amount of data and analyzed it. Experience with colliders generally has been that getting them running at a useful luminosity can take quite awhile after they are first turned on. So 3 years from now is definitely out, 4 years is optimistic. This is now getting close enough that Gross and others seem intent on ignoring the failures of string theory, desperately hoping that superpartners will pop out of the LHC, thereby providing at least some vindication of the train of reasoning that lead to string theory. What will be interesting to see will be what Gross et. al. do when this doesn't happen. Will they drop string theory? Quite possibly the LHC will revolutionize physics by showing us what is really causing the spontaneous breaking of the electroweak gauge symmetry. If this happens, everyone will abandon string theory and start working on this, 1984-2008 then becoming a period in the history of physics that particle theorists try and not think about.

Gross's talk contained the usual tendentious pro-string theory points, here's a few of them with commentary:

1. " String theory is in a period like that of 1913-1925, it's like the Bohr model, we're waiting for the analog of Heisenberg's or Schrodinger's breakthroughs"

The problem with this is that the Bohr model was actually predictive, for instance it predicted a lot about atomic spectra that could be experimentally checked. There clearly was something right about the Bohr model, there is no good evidence there is something right about string theory.

2. "String theory is better than QFT, because QFT Feynman diagrams have these interaction vertices you can assign any interaction strength you want to"

This is not true of gauge theories, the different vertices are related by gauge symmetry. True you have to pick over-all gauge groups and representations, and the Higgs sector is problematic, but the claim that there is just one string theory is just wishful thinking.

3. "String theory is better than QFT because interactions are not at points, so short distance behavior is better"

Gross should be well aware that asymptotically free gauge theories are extremely well-behaved at short distances despite having point-like interactions, since he discovered this. It is also true that string theory perturbation theory is only known to be well-behaved up to two loops. My colleague Phong claims that higher loops remain very much not understood.

4. "String theory is a consistent, finite quantum theory of gravity"

Simply not true. Peturbative string theory is a divergent expansion, non-perturbative definitions don't work for four large flat dimensions, rest small.

5. "String theory inspired brane-world scenarios, although I don't really believe these"

Why would you think that an argument in a theory's favor was that it inspired some clearly wrong models that you don't believe and that don't predict anything?

While Gross mentioned the "discretium", he didn't really explain exactly how disastrous this is for string theory, since it makes it essentiallly vacuous. He made a big deal of string theory implying that our notions of space and time need to be changed, but made it clear that no one really has a viable idea about how to change them. He puts his hopes in the fact that we still don't understand what string theory is. This seems to me to be exactly the sort of wishful thinking that he claimed at the beginning was not what string theorists were doing.

His talk went on for more than an hour and a half. Several questions from the audience were taken, including one from Michio Kaku who claimed that dark energy was evidence of supersymmetry and asked about theories with two times. Gross didn't seem interested in saying much about such theories. I noticed that two string theory postdocs I know were in the audience. They've both told me that they think the subject is at a point of crisis and they are thinking of quitting. I don't think anything Gross said was likely to encourage them to continue.

   Epicycles, aether, string theory?

2. **Peter**
   March 27, 2004

   I don't believe at all that it would be a "stunning triumph" to find a consistent version of string theory that is compatible with any QFT. Quite the opposite: it would be a stunning failure. It would mean that, as a theory of particle physics, string theory was completely and utterly vacuous. There's no reason other than wishful thinking to believe that such a theory would predict anything (if your theory fundamentally has nothing to say about matter, there's no reason to believe it's going to be able to precisely predict anything about any physical process).

   Gross doesn't believe this nonsense. He's known to start quoting Churchill, shouting "Never, never, never, never give up!" when people like Susskind (or Srednicki) start talking about how great it would be to have a theory that is compatible with anything. At his CUNY talk and elsewhere he emphasized that it is the role of particle theorists to find a theory that explains the things about particle physics that the standard model doesn't, not to congratulate themselves for having found a theory that is consistent with anything.

   Gross now stakes his hopes on the idea that the presently known version of string theory is inconsistent and that when a consistent theory is found it will have better uniqueness properties. I (and many others, including Susskind) think this is wishful thinking. I also think he should ditch his powerpoint slide that says that string theory is a finite and consistent theory of quantum gravity, when later in his talk he is pinning his hopes on its inconsistency.

3. **Matt**
March 27, 2004

I think Mark's point is this: it would be a "stunning triumph" to find a candidate for a UV completion of the Standard Model including gravity. Surely this would make new predictions. Granted, there is the issue that perturbative string theory is not provably finite. But, this does not mean the string theory would not let us calculate things we could not otherwise do.

Of course, this won't lead us immediately to the "theory of everything," whatever that might mean. But it could be an important step. We could try to test, for instance, whether the real world looks like some intersecting brane scenario.

4. **Peter**
March 26, 2004

We really do strongly disagree here.

First of all, even if you believe in finiteness of higher loops in string perturbation theory, perturbative string theory is not a finite theory. All evidence is that the expansion in the string coupling constant is a divergent series. What you've got is presumably an asymptotic expansion. This may give a useful approximation if the string coupling constant is very small, a useless one if it isn't. Saying that perturbative string theory is a "finite, consistent theory of quantum gravity" is simply not true. You can't sum the series to get something finite, and if you cut it off at a finite order your theory is inconsistent (not unitary).

So if you can get any QFT + gravity out of perturbative string theory + a choice of background, what have you actually got? You've got an exceedingly complex theory that predicts absolutely not a single thing about anything and is inconsistent to boot. Would this be a "stunning triumph"?

If you want to engage in extreme wishful thinking and believe that string theorists will come up with a finite, non-perturbative string theory that could have any QFT as its low energy limit, calling such a thing a "stunning triumph" would still be complete hype. It would predict nothing about anything. Theorists should save terms like "stunning triumph" for the day they actually manage to make a single solid prediction that in anyway goes beyond the standard model.

5. **Mark Srednicki**
March 26, 2004

"While Gross mentioned the "discretuum", he didn't really explain exactly how disastrous this is for string theory, since it makes it essentiallly vacuous."

I strongly disagree with this. The extreme case of the discretuum is that *every* QFT is realizable as the low-energy limit of string theory. This probably isn't right, but suppose it is. Then we could take *any* QFT (with some exceptions: no Landau poles below the Planck scale, for example), include gravity, and have a finite quantum theory (assuming string finiteness holds up, which it may not). This should be considered a stunning triumph!

Furthermore, probably not *every* QFT is realizable in this way. Some are, some aren't. Which class is the Standard Model in? It seems to me that this is a very important (though also very hard) question.

The great dream was that there would be only *one* QFT realizable as the low energy limit of string theory, and that it would turn out to be the Standard Model. It would've been great, but right now it doesn't seem likely. That certainly doesn't mean that string theory is vacuous.

6. **Peter**
March 24, 2004

Hi Fred!

The interesting thing about Gross's talk was that he was kind of going out on a limb on the issue of supersymmetry at the LHC. I'm more and more convinced that he and a lot of others are getting discouraged about string theory and no supersymmetry at the LHC will be the final straw.

The worst possible thing for particle theory would be if the standard model Higgs shows up, behaving like a standard elementary scalar field with a certain mass. Then we would still be in the situation of having no idea where the Higgs potential or couplings come from, and no prospects for doing experiments in our lifetime to find out.

I'm also hoping the LHC doesn't find a standard Higgs field, but evidence for some more interesting way of breaking electroweak gauge symmetry, one that we haven't thought of yet.

7. **Fred**
March 24, 2004

Hi Peter..

If they don't find any SUSY at LHC, I doubt it will be the death knell of String Theory. Alas, there is enough degrees of freedom there to just argue that it breaks at a higher scale, no big deal!

The nasty thing of course is that it just adds more fine tuning to minimal SUSY, and much of the original point would be lost.

I'm more interested though, in the (seemingly absurd) case that the LHC doesn't discover the Higgs! AFAICS, all reasonable models put it firmly in reach of the LHC.. If we don't find it, well, something drastic has got to give. I don't see many people talking about that, so entrenched is the SM gospel in our minds. What a strange higgs sector that would imply.

8. **Peter**
March 21, 2004

Hi Matt,

Have you decided where to go to grad school yet?

Today I've put up somewhat more positive posts, and in general hope to mix the positive and negative. Unfortunately even the positive posts will probably be so speculative as to be "Not Even Wrong". When I figure out a unification idea that really works I'll dump the blog and start instead enjoying the fruits of fame and fortune that accrue to super-star physicists.

Your idea of pursuing applications of string theory to better understand strongly interacting gauge theories is quite reasonable. I don't have any problem with that part of the string theory program. My problem very specifically is with the continual hyping of the failed idea of unifying the standard model and gravity in a 10/11d supersymmetric string/M-theory.

I'm not so convinced that new information about strongly interacting gauge theories coming from string theory duals will solve the problem of spontaneous gauge symmetry breaking. The technicolor idea is quite beautiful, but all implementations of it seem to involve adding a huge amount of new structure to one's theory, while not being able to actually calculate anything one wants to calculate. On the other hand, maybe one can use string duals to
find a way of calculating things, and if this is the way the world works, there should be real evidence for it a few years from now.

9. **Peter**
March 21, 2004

Hi Sean, thanks for the advice about graphics, I'll give that some thought. I'm still trying to see exactly how this thing works, so not sure how to comment on your comment in some way that news of this gets back to you. If you're lacking topics to write about in your own blog, I've put up an entry here today with some questions for cosmologists.

10. **Matt Reece**
March 19, 2004

Interesting to see that you have a blog. I've followed some of your s.p.r posts in the past with interest.

I'm an undergrad now, but I'll be going into particle theory as a grad student next year. I have some skepticism about the virtue of a lot of research in string theory, but I can't share your extreme skepticism.

I notice you divide your links into "non-string theory" and "string theory," and title your blog "Not Even Wrong." Does this indicate you intend to focus on anti-string theory polemics? Personally I would find some more positive posts interesting.

I was much more skeptical of string theory until the past year or so. Curiosity about various models of "large extra dimensions" led me to read papers of Hall and Nomura on orbifold GUTs, which then led to Nomura's papers on warped geometry and "Higgsless" models. These led me to all sorts of other phenomenological articles, and at some point it became clear that the AdS/CFT correspondence is quite important in the phenomenology of Randall-Sundrum models and their variations.

Although it's certainly not proven (but then, little in field theory is), I think the indications of dualities of field and string theories are too compelling to ignore. You bring up that asymptotically free gauge theories are well behaved. One interesting possible for electroweak symmetry breaking, as I'm sure you know, is the possibility that the Standard Model is embedded in a strongly interacting gauge theory at higher energies. The simplest technicolor scenarios aren't feasible, and harder ones are tough to construct. Thus the discovery that certain such models might be dual to stringy models in higher dimensions seems to me a compelling reason to learn about string theory. These dualities might provide calculational tools that are lacking in field theory. Effective field theory, lattice gauge theory, and string theory, I think, should all be viewed as powerful tools for elucidating the behavior of physical theories we otherwise can't understand.

I'm rather more skeptical of claims that string theory, on its own, will give us a theory of fundamental physics. Certainly we need further experimental input to progress much farther. The apparent existence of a "string theory landscape" that doesn't uniquely predict a vacuum is disappointing. But, as they say, let's not throw the baby out with the bathwater.

11. **Sean**
March 19, 2004

Peter, welcome to the blogosphere. I found your blog in the usual way — your link to mine. I suspect I will disagree with many things you say (I'm a fan of string theory, although not a string theorist myself), but that's all part of the fun.

By the way, if you want to get a lot of hits, I've found it helps to stick up a pretty picture from the Hubble Space Telescope. Posts with words in them don't seem to draw as well, for some reason.

The Holy Grail of Physics

March 21, 2004
Categories: Uncategorized

It's pretty common these days for people to refer to successfully quantizing general relativity as "the Holy Grail of Physics", but it seems to me that there is a different problem that better deserves this name:

"Why does the vacuum state break electroweak gauge symmetry?"

If we could answer this question, we'd probably understand where masses of particles come from, as well as just about all of the undetermined parameters of the standard model (except for a couple ratios of the strengths of the gauge interactions). The exciting thing about this problem is that we have good reason to expect experiments to give us some new clues about it in 2008 when data from the LHC begins to come in.

The standard unification paradigm these days explains this in terms of the potential for a Higgs field, with various grand and super-unification schemes allowing an appropriate Higgs field but somehow never being able to predict anything at all about it. Even worse, such schemes not only don't explain anything about this field, but also require the addition of extra Higgs fields beyond the single one required by the standard model.

An idea I've always found appealing is that this spontaneous gauge symmetry breaking is somehow related to the other mysterious aspect of electroweak gauge symmetry: its chiral nature. SU(2) gauge fields couple only to left-handed spinors, not right-handed ones. In the standard view of the symmetries of nature, this is very weird. The SU(2) gauge symmetry is supposed to be a purely internal symmetry, having nothing to do with space-time symmetries, but left and right-handed spinors are distinguished purely by their behavior under a space-time symmetry, Lorentz symmetry. So SU(2) gauge symmetry is not only spontaneously broken, but also somehow knows about the subtle spin geometry of space-time. Surely there's a connection here…

This idea has motivated various people, including Roman Jackiw, who has several papers about chiral gauge theories that are very much worth reading. The problem you quickly get into is that the gauge symmetry of chiral gauge theories is generally anomalous. People mostly believe that theories with an anomalous gauge symmetry make no sense, but it is perhaps more accurate to say that no one has yet found a unitary, Lorentz-invariant, renormalizable way of quantizing them. In the standard model, the contributions to the anomaly from different particles cancel, so you can at least make sense of the standard perturbation expansion. Outside of perturbation theory, chiral gauge theories remain quite mysterious, even when the overall anomaly cancels.

So, this is my candidate for the Holy Grail of Physics, together with a guess as to which direction to go looking for it. There is even a possible connection to the other Holy Grail, I'll probably get around to writing about that some other time.

Comments

1. **Jacques Distler**
   April 3, 2004

   > Jacques means it is good for string theory if there are few realistic KKLT sorts of vacua because the alternative is a huge problem. If, as some people believe, there are 10^500 or so relatively realistic looking vacua, string theory is utterly useless for ever predicting anything.

   You will kindly *refrain* from putting words in my mouth, especially when they are incorrect ones.

   If there were, indeed, a plenitude of "realistic looking vacua", then string theory would be reduced to the level of quantum field theory, where the particle content, gauge groups, and coupling constants are *input parameters*, not calculable from some underlying principle.

   This would not be a *disaster* for string theory, but it certainly would be a disappointment. I, for one, would hope that at least *some* of these seemingly arbitrary parameters (say, the electron-muon mass ratio, or the ratio of the QCD scale to the Planck Mass, or the values of the KM mixing angles) would be *calculable* in a fundamental theory.

   It could turn out that they are just as arbitrary in string theory as they are in field theory. Disappointing? You bet! A disaster? Not exactly.

   But, then, for a variety of technical reasons, I don't think that's the way things work in string theory.

2. **Peter**
   April 1, 2004

   Jacques means it is good for string theory if there are few realistic KKLT sorts of vacua because the alternative is a huge problem. If, as some people believe, there are 10^500 or so relatively realistic looking vacua, string theory is utterly useless for ever predicting anything. In this case, those who take string theory on faith will keep trumpeting how wonderful it is, while anyone who believes in the scientific method will stop paying attention to it.

   His preferred situation is that either

   1. Just a small number of the vacua now under study are realistic, and one of them is an approximation to the real world.

   2. Some new non-perturbative insight will explain why the vacua now under study are not true vacua, at the same time identifying the true vacua, one of which we live in.

   Needless to say, there is no evidence for either 1. or 2. other than wishful thinking.

3. **Fred**
   April 1, 2004

   " Vacua of this sort which look even vaguely like the real world: acceptably small rate of proton-decay, suppression of flavour-changing neutral currents, etc, etc, are very rare indeed — if they exist at all."

   What, why is this good for String theory? You better hope they exist, or else you have a close to falsified theory on your hands.

   I think I agree however, it would be nice if the vacua that describes are world would look like an isolated point. It makes it in principle, easier to single out sometime in the future if we ever get a realistic mechanism that picks out vacua.

4. **Jacques Distler**
   March 29, 2004

> I'd be genuinely interested to hear what you mean by this.

In short, I believe that de Sitter vacua with small cosmological constant exist, but are not as dirt-common as KKLT would have you believe. Vacua of this sort which look even *vaguely* like the real world: acceptably small rate of proton-decay, suppression of flavour-changing neutral currents, etc, etc, are *very* rare indeed — if they exist at all.

To say more would require equations and stuff. Perhaps I will post something on my own blog.

> Note that I never said that it would be a disaster if KKLT can be made to work. I don't agree with that claim. If deS can be extracted from string theory, even in a lame way, that would be major progress…

You didn't. Peter did. Maybe, in the meantime, the two of you could settle between yourselves whether KKLT being right/wrong would be a triumph/disaster for string theory.

5. **serenus zeitblom**
March 29, 2004

Jacques Distler wrote:
My personal opinion, contra KKLT, is that it is hard to find appropriate (meta)stable de Sitter vacua. And I view that difficulty as a good thing.

I'd be genuinely interested to hear what you mean by this. Note that I never said that it would be a disaster if KKLT can be made to work. I don't agree with that claim. If deS can be extracted from string theory, even in a lame way, that would be major progress, provided of course that everyone admits that it is indeed lame….. The *worst* thing that can happen is for everyone to run off and hope that the cosmological constant will somehow go away while they work on something else.

6. **Peter**
March 28, 2004

It certainly seems to me that if KKLT is right, it's a bad thing for string theory, if it's wrong it's a good thing but just in the sense that a bad thing didn't happen.

If I understood what a Rutgers post-doc was trying to explain to me on the shuttle bus there a few weeks ago, he and others had found that certain conditions needed to make KKLT work were not so easy to achieve, although they did have some solutions for these conditions. So, my impression was that they thought there were fewer viable solutions than the vast numbers that were initially expected (no idea whether "fewer" means 10 or 10^50). Caveat: no, I'm no expert on this and I'm just recounting what I understood of a conversation on a short bus ride. Maybe I've got this wrong somehow..

7. **Jacques Distler**
March 28, 2004

> But
> the persistent failure to get de Sitter out of
> string theory—that *is* a crisis.

I see. So, if KKLT are right, it's a disaster for string theory. If KKLT are wrong, it's also a disaster for string theory.

Poor bastards, they're doomed either way!

My personal opinion, contra KKLT, is that it is hard to find *appropriate* (meta)stable de Sitter vacua. And I view that difficulty as a *good* thing.

8. **serenus zeitblom**
March 28, 2004

"The rate of progress in any field is far from uniform. I'd be the first to agree that the rate of progress in string theory recently is slower than we have been accustomed to. But to call that a "crisis" is seriously overblown."

I agree that *that* is no sign of crisis. But
the persistent failure to get de Sitter out of
string theory—that *is* a crisis. I am reliably
informed that the Rutgers gang has been trying
hard to get the KKLT proposal — and it is no
more than that — actually to work. And they
are getting badly discouraged. But Lubos Motl
isn't, of course — he just claims, apparently
with a straight face after that nasty tic is
modded out, that it is "premature"
to worry about this! Well, the latest data
show that the Big Crunch is at least 40 gyr
away, so we still have time to get string
cosmology to work.

9. **Peter**
March 27, 2004

You really can't help yourself…

"Just because SU(3)xU(1) is nonchiral doesn't mean it is well-understood nonperturbatively."

Did I say anywhere that SU(3)xU(1) gauge theory with fermions is well-understood?

"If you turn off SU(3)xU(1), you obtain an SU(2) gauge theory that is *nonchiral*."

Did I say anything about turning off SU(3)xU(1)?

"Your repeated dismissal of the twistor stuff as insignificant"

Did I ever refer to Witten's work on this as "insignificant"?

I don't think so, since that's not what I've ever thought about it. I have repeatedly, here and elsewhere, said I don't really understand its significance, hoping to get explanations of its significance from others more knowledgeable than myself. The comment explaining to me its significance for calculating tree-level, multi-gluon amplitudes was the first response I've gotten to the question from someone knowledgable. The only other responses I'd gotten were incoherent rantings from Lubos Motl.

No, I'm not going to tell you who the postdocs and more senior theorists were that I was referring to, and they are unlikely to speak publicly. Besides the obvious reasons, they are unlikely to want to get publicly attacked as incompetent fools by various fanatics

10. **Jacques Distler**
March 27, 2004

> Glad to see that you're following my weblog so closely. If you keep doing this I'm sure you'll find many more opportunities…

I doubt it. Uninformed anti-string rants get real old, real fast. You'll have to come up with something more interesting if you want to hold my attention.

> To try and say things in a way that will be less easy for you to misconstrue, all I was saying was the following. If you turn off the weak interactions, you have a SU(3)xU(1) non-chiral gauge theory. Turn on the weak interactions and you have something much trickier and less-well understood non-perturbatively: a chiral gauge theory with spontaneously broken gauge theory.

Just because SU(3)xU(1) is nonchiral doesn't mean it is well-understood nonperturbatively. The U(1) does not exist nonperturbatively. You identified the SU(2) gauge theory as the part that is chiral (and hence hard to understand nonperturbatively). This is *incorrect*. If you turn off SU(3)xU(1), you obtain an SU(2) gauge theory that is *nonchiral*. It is very hard to come up with an interpretation of your post, and of your responses to Mark that does not involve your asserting the contrary. Take, for instance:

> An idea I've always found appealing is that this spontaneous gauge symmetry breaking is somehow related to the other mysterious aspect of electroweak gauge symmetry: its chiral nature. SU(2) gauge fields couple only to left-handed spinors, not right-handed ones…

> All I was saying was that if you think of SU(2) gauge theory as a purely internal symmetry, it is in some sense surprising that it is chiral…

> The chirality of the SU(2) couplings in this case may be a clue…

> The SU(2) gauge symmetry knows the difference between right and left-handed spinors…

There are other misapprehensions in your post. Most importantly, as Mark says, the generic quantum field theory is chiral, so "chirality" is hardly a puzzle to explain. But it's hard to discuss the big picture when you persist in misapprehensions about the basics.

> 1. Multiple string theory postdocs who have recently told me they find the field in crisis, very depressing, no new ideas, to the extent that they are thinking of quitting.

> 2. Multiple senior theorists, string theorists and others, who have told me that there are no interesting new ideas in the subject (with the possible exception of Witten's twistor stuff).

There are dozens of recent papers I find as interesting, or more interesting than the developments in twistor theory.

The rate of progress in any field is far from uniform. I'd be the first to agree that the rate of progress in string theory recently is slower than we have been accustomed to. But to call that a "crisis" is seriously overblown.

> 3. Attending talks about string theory, looking at recent talks on the web, scanning the new papers on the arxiv. No, I don't understand everything I read or hear this way, but do understand enough of it to note that the experts I talk to seem to be right.

Your repeated dismissal of the twistor stuff as insignificant (a dismissal you've made repeatedly, both in this venue and elsewhere) is, I think, indicative of the general fact that you haven't the *context* necessary to evaluate the significance of the talks you've heard and the eprints you've tried to read.

I might take seriously the opinions of the unnamed "senior theorists" and "string theory postdocs" if you'd care to tell us who they were, and exactly what they said.

Or, better yet, they can speak for themselves.

11. **Peter**
March 27, 2004

Hi Jacques,

Glad to see that you're following my weblog so closely. If you keep doing this I'm sure you'll find many more opportunities to take something imprecise that I write, make up an interpretation of it that is incorrect, then use this to demonstrate my ignorance of basic facts. In the future when you do this, if you're more careful, your correction might even be correct. You're quite right that "this is getting really embarassing", but I think we probably disagree for whom.

To try and say things in a way that will be less easy for you to misconstrue, all I was saying was the following. If you turn off the weak interactions, you have a SU(3)xU(1) non-chiral gauge theory. Turn on the weak interactions and you have something much trickier and less-well understood non-perturbatively: a chiral gauge theory with spontaneously broken gauge theory.

No, I wasn't the guy who "had no clue as to why anyone would want to calculate multigluon perturbative Yang-Mills amplitudes", that guy lives only in your over-worked imagination. I was the guy who knew very well that multigluon perturbative YM amplitudes were important things to calculate in collider physics, but would have guessed that the calculations were pretty straight-forward for tree amplitudes, only really difficult when you put in loops. I was very pleased to learn something new from the comment posted here.

As for whether there is any progress being made in the last few years in string theory, I base my judgment on the following evidence:

1. Multiple string theory postdocs who have recently told me they find the field in crisis, very depressing, no new ideas, to the extent that they are thinking of quitting.

2. Multiple senior theorists, string theorists and others, who have told me that there are no interesting new ideas in the subject (with the possible exception of Witten's twistor stuff).

3. Attending talks about string theory, looking at recent talks on the web, scanning the new papers on the arxiv. No, I don't understand everything I read or hear this way, but do understand enough of it to note that the experts I talk to seem to be right.

So, let's get this straight: the students I mentioned are "fools", I'm an embarassing, incompetent fool and the post-docs and senior faculty who think string theory is in crisis are also probably fools. The only people in the world who aren't fools are you and perhaps some of the few other string theorists out there who spend their time hyping a theory which has utterly failed to provide its promised new insights into unification of physics. Have I got this right?

12. **Field Theorist**
    March 26, 2004

    Make that "real," not "pseudoreal."

13. **Field Theorist**
    March 26, 2004

    > It's surprising if you think geometrically and take the standard view that internal and space-time symmetries have nothing to do with each other. The U(1) and SU(3) gauge symmetries are not chiral and are truly independent of the space-time geometry. The SU(2) gauge symmetry knows the difference between right and left-handed spinors so in a subtle way it knows something about space-time geometry. More precisely, it knows about the spinor geometry.

    This is getting really embarassing.

    For the last time. The left-handed fermions of the standard model form a *real* representation of SU(3)xU(1), and they form a *pseudoreal* representation of SU(2). It's only when you look at the *full* SU(3)xSU(2)xU(1), that you find that they form a complex (ie, chiral) representation of the gauge group.

    > Sure, I think the NSF and DOE should stop funding theorists who send in grant proposals that say "String theory has made huge progress in the last few years, we intend to keep doing the same thing". The fact of the matter is that string theory hasn't been making any progress and this needs to be honestly addressed.

    Weren't you the guy who, until yesterday, had no *clue* as to why anyone would want to calculate multigluon perturbative Yang-Mills amplitude, much less how the recent work on twistors represents a *revolution* in our ability to do so?

    What makes you *competent* to decide whether progress is being made?

    > I personally know quite a few really good young students who have left physics because they saw no way to make a career for themselves in the field other than by working on string theory, which they didn't believe in.

    Then they are fools. The job market, at the moment, for good young phenomenologist is considerably better than that for young string theorists. (Not that the latter is bad, just that good young phenomenologists are much sought-after nowadays.)

14. **Peter**
    March 26, 2004

    About chirality again:
    It's surprising if you think geometrically and take the standard view that internal and space-time symmetries have nothing to do with each other. The U(1) and SU(3) gauge symmetries are not chiral and are truly independent of the space-time geometry. The SU(2) gauge symmetry knows the difference between right and left-handed spinors so in a subtle way it knows something about space-time geometry. More precisely, it knows about the spinor geometry.

    Is it a coincidence that the piece of the standard model gauge symmetry that is chiral is also the piece that is spontaneously broken? Maybe, or maybe there's GUT lore about this I'm not thinking about. Is it a coincidence that, besides having its gauge symmetry spontaneously broken, the SU(2) chiral gauge theory is also really hard to understand non-perturbatively? Maybe.

    I've never, anywhere, denigrated string theorists as "dilettantes and poseurs". That's not what I think about them. Some of my best friends are string theorists, and most people doing string theory are very smart and harder-working than I am. On any metric for how smart and hard-working someone is, Ed Witten is off the scale.

    About funding:
    Sure, I think the NSF and DOE should stop funding theorists who send in grant proposals that say "String theory has made huge progress in the last few years, we intend to keep doing the same thing". The fact of the matter is that string theory hasn't been making any progress and this needs to be honestly addressed. The panels that allocate very scarce funding for theoretical physics are the place this is supposed to happen.

    The over-hyping of string theory is doing more damage to theoretical physics than any cut in government funding ever could. I personally know quite a few really good young students who have left physics because they saw no way to make a career for themselves in the field other than by working on string theory, which they didn't believe in.

15. **Mark Srednicki**
    March 25, 2004

    "As far as I can tell your point is essentially just the obvious one that since we know how to write down chirally asymmetric theories, a generic theory is going to be chiral."

    If this point is obvious, why did you say that it is "in some sense surprising" that the QFT that describes the real world is chiral?

    As for anomalous gauge theories, if you (or Roman Jackiw or anyone else) can construct them, great! I'd be very interested. But I think there are very good reasons why it can't be done, reasons that are as close as we ever get to a proof in QFT. I don't agree that it's "more accurate" to say that these theories just haven't been quantized yet.

    As for arrogance, when you denigrate a whole group of dedicated, hard working scientists as dilettantes and poseurs because you don't share their taste in interesting problems, it's hard to want to be polite. Change the name of this blog from "Not Even Wrong", a famous insult in physics, to something more neutral, and I'll be a lot more polite in the future.

    You say that you're "not in the business of telling people what they should work on and there is no danger they would pay much attention to me if I was". But there is. You are seeking publicity in the larger public arena, via your article in American Scientist and this blog. You denigrate a lot of hard honest work done by brilliant people. There is a small but significant chance that this denigration could ultimately have a detrimental impact on science funding.

    You think that it is a terrible crime that string theory has been overhyped. But if science was better funded, more young people would have more of a chance to make an impact, however they choose to try to do it, before irrevocable decisions have to be made about their futures.

    That's why I took the time and effort to respond in the first place.

16. **Peter**

March 25, 2004

We probably did overlap somewhere back in the 80's, I was a grad student at Princeton 1979-84. Unfortunately one aspect of middle age for me involves the inability to remember exactly people I was glancingly acquainted with back then.

Your latest post starts with the generic argument for string theory in terms of quantum gravity. Responding to that seriously would take a while and someday I'll get around to it on the weblog.

The other comments you make about the sociology of why people do string theory are interesting and worth responding to. Again, I'll try and do so at length at some point soon, but a couple quick comments: No, I don't think it's a conspiracy and I'm sure most of them do so because they think it is the best bet for making some kind of progress (this is less true of those poor bastards trying to get a permanent job). On the other hand I don't agree with you at all that the community is now open to new ideas.

I'm not in the business of telling people what they should work on and there is no danger they would pay much attention to me if I was. My interest here is in trying to do two things:

1. Explain exactly what the present state of string theory is, minus the hype. You and others are welcome to argue with me when I do this. It's a complicated subject and probably I'll get some things wrong.

2. Explain some highly speculative ideas of my own. These are also "Not Even Wrong" at this point and will be clearly labeled as such.

17. **Peter**
March 25, 2004

About chirality:
As far as I can tell your point is essentially just the obvious one that since we know how to write down chirally asymmetric theories, a generic theory is going to be chiral. If you are a believer in Susskind's landscape then maybe our world is governed by a generic theory and of course it is not surprising it is chiral. I may be wrong, but my point of view is to try and find something special about SU(3)xSU(2)xU(1) and the standard model representations that would explain where this symmetry comes from. The chirality of the SU(2) couplings in this case may be a clue. You may think this kind of speculation is pointless, a waste of time, has all been done before, whatever. But it's clearly labeled as speculation, it's just as "Not Even Wrong" as string theory. If you think my speculative ramblings are wrong-headed, don't read them.

Anomalous gauge theories:
You seem really exercised that someone would even implicitly question conventional wisdom. Clearly we're not going to get along here. At most points in the history of science spending one's time figuring out the implications of new ideas is a more fruitful thing to do than questioning conventional wisdom. I think this point is different: there are no new good ideas and we need to question how we got to this point. Certainly something goes wrong with our standard understanding of gauge theory when you try and quantize an anomalous theory. I happen to think it's worthwhile to think about this and try and better understand exactly what happens. One of my reasons is that in 2d there is some really beautiful and new mathematics that makes its appearance. Maybe this is irrelevant to 4d, maybe not.

My "tone about poor benighted theorists":
Well, for 20 years the smartest people in the business have been to a large extent off thinking about quantizing gravity instead of electroweak symmetry breaking. Right now when I talk to them they are bitching and moaning that in string theory there are no new ideas, everything that anyone has tried either has failed or can't be pushed further. Under the circumstances I do think it would be healthier if more of them would stop doing this and would start instead bitching and moaning about how hard it is to come up with a new idea about electroweak symmetry breaking.

About arrogance:
First of all your initial post was simply rude and insulting. Today also brought an even more juvenile string of insults from a Junior Fellow at Harvard, Lubos Motl. What is with you people? Grow Up! Do your parents know you behave like this? You don't know me and seem to think it's all right to start insulting someone you don't know on the basis of your interpretation of a couple vague sentences they write about complex issues in QFT. What about posting a comment saying you disagree with something I wrote, explaining why and asking me to justify what I wrote? Then when I can't justify it, you're welcome to start accusing me of ignorance.

While I was about to finish this, another post from you came through. I'll stop this one, continue with another after reading your latest.

18. **Mark Srednicki**
March 25, 2004

Looking at your credentials, I see that we must have overlapped at Princeton in the early '80s. I confess that I thought you were a mathematician who was dabbling in physics.

As for string theory being "not even wrong", the title of your blog, it is QFT that deserves this description.

Pick up a book. Hold it at arm's length. Let go. Did it fall? You just disproved the Standard Model, which does not incorporate gravity.

The only known way to deal with gravity in QFT is to put in an ad hoc cutoff at the Planck scale. Then you lose either Lorentz invariance or unitarity or both. We could perhaps live with violations of Lorentz symmetry, but before giving up on it, perhaps we should search for a more clever cutoff.

And that's exactly what string theory provides. It *may* be that it doesn't work in the end; that's still an open question. But *this* is why string theory is exciting: it's an extension of quantum field theory that (1) incorporates gravity in a natural way and (2) provides the *possibility* of a finite theory that does not require an ad hoc cutoff.

The tradeoff is that it's *much* harder to find specific quantum field theories as the low energy limit of string theory. There's been a huge amount of work on this, work that continues at a feverish pace. A QFT that looks like the Standard Model has not been found yet. Whether or not one exists is an open question.

Senior string theorists work on string theory because they think it's the best bet for a more fundamental theory than QFT with an ad hoc cutoff. That's all there is to it. No vast conspiracy. People with tenure who want to work on other things, do. People without tenure have to hedge their bets on what to work on. One can certainly criticize the fairness of the tenure system in general, but there is nothing unique or special about string theory in this regard.

Indeed, my experience is that the particle theory community is about as open to new ideas as a group of human beings can possibly be. Let's not forget that 20 years ago, the string community was pretty much down to Green, Schwarz, and Brink. It's grown enormously since then because people were genuinely interested and excited about it, not because they were forced to work on it.

I am *extremely* skeptical of *any* claim that scientists in general are working on the "wrong thing" and should be told to work on something else. I trust the community at large far more than the judgement of any one person.

19. **Mark Srednicki**
March 25, 2004

"The arrogance of people in the particle theory community never ceases to amaze me. Assuming that anyone who dares to criticize what is going on in the subject must be ignorant is all too common behavior."

I did not *assume* you were ignorant because you criticized what is going on (though your understanding of what is going on is mistaken, in my view). I *concluded* that you were ignorant because you made several statements that indicated misunderstandings of various issues in quantum field theory and particle physics.

20. **Mark Srednicki**
March 25, 2004

"All I was saying was that if you think of SU(2) gauge theory as a purely internal symmetry, it is in some sense surprising that it is chiral, since chirality is an aspect of behavior under Lorentz symmetry, which is a space-time symmetry."

This betrays a profound misunderstanding of the nature of chiral symmetry. One more time: if you start with three or more fermion fields, and one or more scalar fields, and include all couplings allowed by renormalizability, your theory will automatically be chiral, unless you choose special values for some of the couplings. Thus chirality in nature is no surprise; it's a generic prediction of quantum field theory.

"I was just making the uncontroversial comment that if you take a classical chiral gauge theory such that quantizing the fermions produces an anomaly in the gauge symmetry, no one knows how to quantize such a theory."

The conventional wisdom is that such theories DO NOT EXIST, not that we haven't figured out how to quantize them. Your original comment questioned this belief. No one can prove anything either way. But the arguments against the existence of these theories are about as strong as any arguments in QFT.

All bets are off in two dimensions, where lots of special things happen.

"Maybe an elementary scalar field is what is causing electroweak symmetry breaking, and one has to ultimately understand this field and its couplings as coming from fluxes in a Calabi-Yau or who knows what. But theorists should not be so arrogant."

Arrogance has nothing to do with it. Theorists have thoroughly explored all the alternatives they could think of (with some, like large extra dimensions, still under active investigation). Most died because they made predictions in immediate or eventual conflict with experiment. Theorists would be *thrilled* if something unexpected turned up at the LHC. The whole tone of your original comment was that poor benighted theorists are off thinking about quantizing gravity instead of electroweak symmetry breaking. This is wrong!

21. **Peter**
March 25, 2004

The arrogance of people in the particle theory community never ceases to amaze me. Assuming that anyone who dares to criticize what is going on in the subject must be ignorant is all too common behavior.

I won't recite my qualifications extensively here, other than to note that the places where I first learned QFT included Weinberg's course on the subject at Harvard that lead to part of the books Srednicki mentions. I also took Coleman's QFT course there, as well as Gross's course at Princeton where I got my Ph.D in particle theory in 1984 (Curt Callan was my advisor there).

It's hard to extract from the torrent of personal abuse what Srednicki's criticisms are. The weird thing is he doesn't deal with my views on string theory, which are controversial, but here gets very worked up about what are accurate and not at all controversial statements.

"Wrong, Wrong, Wrong" number one. Hard to tell what he is getting worked up about here. All I was saying was that if you think of SU(2) gauge theory as a purely internal symmetry, it is in some sense surprising that it is chiral, since chirality is an aspect of behavior under Lorentz symmetry, which is a space-time symmetry. Chiral gauge theory is tricky, as Srednicki should know well, since he started out his career, like I did, doing lattice gauge theory. If you try and put spinors on a lattice and couple them chirally to gauge fields, it's surprising how much trouble you run into.

"Wrong, wrong, wrong" number two. I can't see what he's upset about here either. I was just making the uncontroversial comment that if you take a classical chiral gauge theory such that quantizing the fermions produces an anomaly in the gauge symmetry, no one knows how to quantize such a theory of coupled gauge fields and spinors in such a way that you end up with a unitary, Lorentz-invariant, renormalizable QFT. I didn't say anything about the gauge invariance of such a QFT or claim that I have any idea how to do this.
Jackiw does claim to be able to do this (for the chiral Schwinger model) in 1+1d, maybe Srednicki should send him an e-mail about how ignorant about QFT he is.

"Sigh" Again, I can't figure out what he is getting so excited about, since what he quotes is completely uncontroversial. I'm well aware that there is by now a long history of unsuccessful attempts by theorists to find a good alternative to using an elementary scalar field to break electroweak symmetry. Maybe an elementary scalar field is what is causing electroweak symmetry breaking, and one has to ultimately understand this field and its couplings as coming from fluxes in a Calabi-Yau or who knows what. But theorists should not be so arrogant. There's a long history of experiments coming up with results that theorists had good reason to believe were not possible. In the late sixties theorists would have claimed that the strong interactions were such that scaling in deep inelastic scattering was impossible at high energies. And yet, that's what was found, leading Gross et. al. to the discovery of asymptotic freedom. Let's wait and see what the experimental results have to say about the dynamics of the Higgs sector before being so sure that all possibilities for what it can be are well-known.

22. **Mark Srednicki**
March 25, 2004

I came to your web site because I was told that you are a critic of string theory, and I wanted to see what you had to say about it. What I find is appalling ignorance. You really ought to spend some time learning some physics before you attack it. I recommend starting with Weinberg's three-volume text on quantum field theory.

I don't have the time or the energy to explain *all* the errors on this web site, or even all the ones in this single comment. But I'll tackle a few of them.

"The SU(2) gauge symmetry is supposed to be a purely internal symmetry, having nothing to do with space-time symmetries, but left and right-handed spinors are distinguished purely by their behavior under a space-time symmetry, Lorentz symmetry."

Wrong, wrong, wrong! RH spinors are hermitian conjugates of LH spinors; you can't have one without the other (in 3+1 dimensions; things are different in different numbers of dimensions). Parity swaps the LH and RH spinors (as does hermitian conjugation). The question is, in a particular theory, can we assign parity transformation rules to the scalar and vector fields (if any) so that parity is a symmetry of the action? If there are more than 3 LH spinors, and at least one scalar, then the answer is generically "no", even if there are no gauge fields at all. (By "generically", I mean you include all couplings allowed by gauge symmetries and renormalizability.) If there is some gauge symmetry, then the answer is also "no" if the LH spinors form a complex representation of the gauge group (with or without scalars). In no case is there any need for some mysterious intertwining of Lorentz and gauge symmetry.

"People mostly believe that theories with an anomalous gauge symmetry make no sense, but it perhaps more accurate to say that no one has yet found a unitrary, Lorentz-invariant, renormalizable way of quantizing them."

Wrong, wrong, wrong! In the case of anomalous violation of a global symmetry, we know from experiment that the symmetry does not hold: this is proven by the decay rate of the neutral pion (for electromagnetic anomalies) and by the nonexistence of a ninth light pseudoscalar (for chromodynamic anomalies). Coupling a vector field to a non-conserved current violates gauge invariance. Of course, since *no* quantum field theory (in more than two dimensions) has been proven to exist (and gee, isn't this one of the mighty criticisms you aim at string theory?), you are free to believe that something could be constructed that could be interpreted as an anomalous gauge theory. But it wouldn't actually have any gauge symmetry.

"Why does the vacuum state break electroweak gauge symmetry?
If we could answer this question, we'd probably understand where masses of particles come from, as well as just about all of the undetermined parameters of the standard model (except for a couple ratios of the strengths of the gauge interactions). The exciting thing about this problem is that we have good reason to expect experiments to give us some new clues about it in 2008 when data from the LHC begins to come in."

Sigh. Now we come to appalling ignorance of the history of ideas in particle physics. This sounds like it was written in 1979. A *huge* amount of effort went into exploring alternatives to the standard Higgs field in the 1980s. All these models died at the hands of the experimentalists, because they all kept predicting things that were not observed. We are left believing that the Higgs field is a fundamental scalar because there is no alternative that agrees with experiment, not because we are muddle-headed idiots who can't think of the obvious.

I'm horrified that the ideas of someone as ignorant as you can be so widely circulated without serious rebuttal. You haven't gotten serious rebuttal because the serious people have better things to do with their time. If you want to learn some physics first, fine. Unless and until you do, please stop trying to tell funding agencies (all staffed with people far more knowledgable than you are) how to best use their meager sums.

Questions for Cosmologists

March 21, 2004
Categories: Uncategorized

I was pleased to get a comment from cosmologist Sean Carroll frighteningly soon after starting this thing up. Here's some questions about cosmology that have been on my mind recently, maybe he or someone else will be able to answer them:

Witten has argued to me that "results about CMB fluctuations which are suggestive of inflation at the GUT scale" provide evidence that "grand unification is on the right track". What exactly does the CMB data say about inflation? Can one extract the GUT scale from either the current CMB data or any conceivable better future CMB data?

More generally, while I've heard a lot about attempts to extract information about Planck-scale physics from CMB data, what about all the scales in between where accelerators stop (hundreds of Gev) and the Planck scale? Can one find out anything about electroweak symmetry breaking? Could this have anything to do with inflation?

There's another question that often bothers me: "How can you have a field called 'String Cosmology' when string theory isn't really a theory and can't be used to predict anything?", but I'll be good for now and leave that rant for another time.

Comments

1. **Gary**
   March 29, 2004

   Who can really know for a certainty where future CMB research will lead (if but to answer the aforementioned question regarding the extraction of the GUT scale from CMB data.) We will just have to wait and see. But I will tell you this much, that when we do hopefully we'll be smart enough to recognize a designer involved in the greater scheme of creation, and not the theories themselves.

2. **Alexander Crawford**
   March 25, 2004

   However interesting the statistical/mathematical models may or may not be, the actual difficulties aren't addressed very seriously in terms of experimental problems or circuit design methods (errrr… the standard deviation measure of step rise times from step response to impulse response doesn't suggest "extra-dimensionality" in a physical sense).

   It'd probably be very interesting for most theoretical physicists to look into the wire spring relay developed by Western Electric and current in the mid-1960's, especially for those interested in String Theory. It might be as interesting as the M-M interferometer design as that relates to other somewhat older cosmological models. The magnetic field model is available at MIT and a couple of other sites (view source option-read comments) for a curious take on m-m data.

   Regarding the questions specifics…

   Here's a link to the NIST page for phase noise and metrology:

   http://www.boulder.nist.gov/timefreq/phase/

   Here's the optical frequency measurement group links

   http://www.boulder.nist.gov/timefreq/ofm/index.html

   useful glossary:

   http://www.boulder.nist.gov/timefreq/general/glossary.htm

   (The USNO has a very comprehensive library of technical papers for the serious.)

3. **Sean**
   March 21, 2004

   These are very good questions, so much so that I started a multi-part answer over at my blog. Basically, the energy scale of inflation is roughly equal to the Planck scale times the square root of the perturbation amplitude; this works out to be the GUT scale. It's nicely consistent, but by no means direct evidence; Witten was right to say that it's "suggestive," but not more than that. If we were able to measure gravitational-wave modes, that would give a direct measurement of the energy scale.

   This is only in the simplest models, of course. If you get more baroque you can do whatever you like, including inflation at the electroweak scale. But you have to work at it. Likewise with getting information about Planck-scale effects; it's unlikely, but worth thinking about.

   We should talk about string cosmology another time. String theory is not a completely well understood theory, but it's not vacuous, either. But string cosmology is in its infancy, to say the least.

Various Stuff on the Web

March 23, 2004
Categories: Uncategorized

One can keep track of what is going on in theoretical physics now by taking a look at conference websites. Often after the conference they put up speaker's transparencies or even audio or video of the talk. Some very recent examples:

[Strings and Cosmology]

a conference last week at Texas A and M, and

[Spring School on Superstring Theory and Related Topics]

at the ICTP in Trieste. Among the Trieste lectures, Marcos Marino's notes give a nice discussion of some things you can do with topological strings. Brandenberger's notes on "Challenges in String Cosmology" include the peculiar statement that "String cosmology does not exist because non-perturbative string theory is not yet known". That was my impression too, but this doesn't really explain why he is lecturing on a subject that doesn't exist or why people devote many conferences to it.

Among the new papers appearing at the arXiv is Witten's latest:
[Parity Invariance for Strings in Twistor Space]

I'm still kind of not seeing why Witten and others are so interested in this. Using strings as a dual to QCD to understand its strong coupling behavior is obviously interesting, but why is reformulating something you understand well (perturbative Yang-Mills) in terms of strings in a super-version of twistor space so interesting? The interesting thing about twistors always seemed to me that they were naturally parity asymmetric, one chirality of spinors is tautologically defined. Witten's latest paper seems to just be showing how to get rid of this natural chiral asymmetry in this case.

Another new paper is:

[The Emergence of Anticommuting Coordinates and the Dirac-Ramond-Kostant operators]

by Lars Brink. The Kostant version of the Dirac operator is pretty amazing and too little known, both among mathematicians and physicists. I'm not so sure what Brink is trying to do with it leads anywhere, but there are other applications of it I'll try and write about some day.

Comments

1. **Matt**
   March 27, 2004

   I think the problem with computing gauge theory at weak coupling is that, even though one can easily write down Feynman diagrams, the number of diagrams grows more or less factorially with the order in perturbation theory. Computers can be fast but they can't handle calculations at high order when the number of graphs grows so quickly. Any technique that lets you get away with fewer diagrams will lead to better predictions.

   There may be issues aside from the computational one, but this strikes me as a major advantage.

2. **Peter**
   March 26, 2004

   We'll have to see how far this can be pushed. But the thing that has bothered me about it from the beginning is that, unless Witten has something up his sleeve he isn't telling us, the most optimistic thing he seems to be hoping for is to get a reformulation of perturbative YM in terms of a string theory on twistor space. The string theory on twistor space is a topological one that seems to have nothing to do with the string theory that is supposed to unify gravity and the standard model. So this doesn't help at all with the idea of quantizing gravity via the string. It would be kind of like AdS/CFT, where a string theory helps you understand a gauge theory. But even so, it is helping you understand not the mysterious aspect of gauge theory (strong coupling), but the weak coupling aspect, which I had thought was well understood. It was very interesting to see the comment that, in terms of computability, weak coupling gauge theory is not as well understood as I thought.

3. **serenus zeitblom**
   March 26, 2004

   It's pretty amazing that the twistor stuff is actually "useful". But the techniques of the CSW paper look "string-motivated" to me, not really stringy. If this "useful twistor" stuff pans out, to what extent can that be interpreted as a plus point for string theory per se?

4. **Peter**
   March 25, 2004

   Hi Mark,

   Thanks for writing this, that's very interesting to hear. I didn't know that tree-level perturbative YM amplitudes could be that hard to compute, so didn't realize that Witten's results would be so useful. The fact that abstract theory involving strings and twistors is leading to phenomenologically important calculational techniques is pretty amazing. Will be interesting to see what happens with loops, presumably there are a lot of people working on that now!

5. **Marcus Spradlin**
   March 25, 2004

   Hi,

   I am replying to Peter's comment that

"It wasn't clear whether the twistor ideas really help do any calculations these people [at the Tevatron and LHC] care about."

Here at the KITP we've had a workshop on collider physics for the past two months, and all of the experts in exactly this field have been at hand. It's hard for me to overstate the excitement, in particular of Zvi Bern (workshop organizer and undoubtedly one of the leading experts on perturbative QCD calculations). Calling the paper hep-th/0403047 a "home run", Zvi said that this is exactly the technology they've wanted for more than a decade. For more, see Zvi's colloquium at
http://online.itp.ucsb.edu/online/colloq/bern1/

To give an example, consider the 8-gluon amplitude with helicities ++++—-. As recently as March 2, 2004, one could have invested many, many months of effort into calculating this and written a lengthy paper on it (7-gluon amplitudes appear in a 40-page paper in 1990). After March 3, I (and independently David Kosower and I think Zvi as well), spent part of a lazy afternoon writing this amplitude down "just for fun". It's only 44 CSW diagrams, versus 34,300 Feynman diagrams.

People who write Monte Carlo programs for the Tevatron and LHC need to know these (and other) amplitudes in order to get a better handle on experimental backgrounds. Zvi said that these programs would all have to be rewritten now to use the fantastic new CSW technology. So, quoting from the mouth of an expert: Yes, people care!

Of course, so far Witten's new technology has been only applied at tree level. The REAL (practical) payoff from twistors will come from finding some way to apply this technology to loops, where the perturbative QCD calculations start getting VERY hard.

I inserted the word practical above to emphasize that there are other, more theoretical payoffs from Witten's work (such as some interesting new ideas on S-duality for topological strings, as well as other ideas surely to be discovered), but I specifically wanted to limit my reply to your question in the context of the usefulness of twistors for QCD calculations.

Mark

March 25, 2004

Oh no! Now I'm going to have to start reading Jacques Distler's postings about how to keep cranks from spamming the comment sections of one's weblog. Maybe Jacques can explain how to filter out just physicists from Harvard with Junior Fellowships.

As usual, Lubos is devoting his efforts to insulting others while avoiding the issue under discussion. He's still not answering the question I asked him when Witten's paper first came out: "What good is this new connection between perturbative YM and strings on super-twistor space?"

The claim that "twistors used to be nearly as popular as string theory is nowadays" is pretty weird. One could check this out with the SPIRES database, but I'd guess that in any of the last 20 years there have been 10-100 times more papers about string theory than the number written about twistor theory in the year of its peak popularity, whenever that was. Given Witten's paper and the complete lack of any other ideas for string theorists to work on, maybe 2004 will be the year of the peak number of twistor theory papers.

7. **Lubo? Motl**
March 25, 2004

Amazing, Peter! If I did not see this, I would not be able to believe that you are able to establish your own blog. I wonder whether you will erase this comment from your page, even though the people who don't know yet can learn that you are a bitter and intellectually limited person.

Recall that you were saying on sci.physics.research that this twistor stuff is beautiful, as soon as Witten started, and it's great that the people in the field would have to follow Witten. Your comments about physics are not not obsolete, silly, and annoying, but as we see now and again, they are also internally inconsistent.

Twistors used to be nearly as popular as string theory is nowadays, and Penrose himself believed that it was important to investigate this unusual description of the Minkowski spacetime because it might teach us something about quantum gravity.

His dreams have not been realized because their research was always very primitive. In the best case, it allowed them to calculate various things in a new way – for example the moduli space of instantons (ADHM) was first obtained using these methods. The twistors are now studied seriously, i.e. by string theorists, and all the potentially good and useful ideas and notions (such as D-brane instantons etc.) can be applied.

Twistors make the left-right parity symmetry very obscure, and therefore an explicit proof of this symmetry was (and is) very desirable. Witten's proof of this fact (and our earlier proof in Berkovits+Motl, as well as the proof in the paper by Volovich et al. a day later) is perhaps not a new revolution in physics, but it is certainly an interesting result – definitely more interesting than anything that you have done during the last 12 years, and therefore I would expect a little bit of respect from you, especially if you are – please accept my apologies for being straightforward – such a loser.

8. **Peter**
March 23, 2004

I saw that Witten gave a talk about this stuff to the workshop at the KITP where some people are doing perturbative QCD calculations necessary to understand backgrounds at the Tevatron and the LHC.

It wasn't clear whether the twistor ideas really help do any calculations these people care about, and they are the only ones I can think of who might be able to use better ways of doing perturbative YM computations. I'd guess Witten mainly hopes to get new insight into the relation of string theory and gauge theory out of all this, but I don't see anything that promising here yet.

9. **Matt**
March 23, 2004

Brief comment on the twistor stuff, but I don't know very much: I was visiting Harvard yesterday (as I might go there for grad school) and Nima Arkani-Hamed explained a bit about this to me. Apparently scattering amplitudes in Yang-Mills theory turn out to have much nicer forms than one sees in doing the perturbative calculation. My impression is that you might hope to calculate things more easily this way — you don't have to sum as many graphs — and also maybe certain analytic properties are easier to understand. But, I've only heard this briefly explained, so I'm not too sure of what the advantages are. People do seem convinced that this is useful.

My (Not So) Brilliant Career

March 26, 2004
Categories: Favorite Old Posts, Uncategorized

One of the weirder things that happened yesterday was that I noticed there was a long thread in a discussion group about my academic qualifications. You can find this at [Physics Forums]

My academic career has been a bit unusual, and the current position I have at Columbia is kind of confusing, so for those who want to carefully examine my qualifications before deciding whether to take anything I write seriously, here's a short outline:

1979: B.A. and M.A. in physics, Harvard University. As an undergraduate spent one summer working on a particle physics experiment at SLAC.

1984: Ph. D. in theoretical physics, Princeton University, advisor Curtis Callan, thesis title "Topological Charge in Lattice Gauge Theory".

In my thesis I developed a workable way of calculating the topological charge of lattice gauge fields and did Monte-Carlo calculations using it. This led to joint work with collaborators including N. Seiberg at the Institute in Princeton and about seven published papers on the subject in the mid to late-eighties.

1984-87 Postdoc at the Stony Brook ITP
Got interested in spinor geometry,TQFT and representation theory, started talking to a lot of the mathematicians at Stony Brook

In 1987 it became clear to me that someone who didn't believe in string theory but wanted to apply mathematics to QFT didn't have much of a future in physics depts in the US. I spent 1987-88 as an unpaid visitor at the Harvard physics dept., earning a living teaching calculus in the Tufts math department.

1988-89 Postdoctoral fellowship at MSRI in Berkeley. Published a couple papers on spinor geometry and the standard model, TQFT and representation theory.

1989-1993 Assistant professor, math department, Columbia.

This wasn't a tenure-track position, so at this point I needed to find a new one and my current job became available in the math department. It is an unusual, "off-ladder" untenured but permanent position with the title "Director of Instruction". Its responsibilities include administering the dept computer system, teaching a course each semester, and participating in research activities of the department. I've held this position for ten years.

It should be made perfectly clear that I'm not a regular, tenured professor at Columbia and have never claimed to be. On the other hand, I've spent a lot of time learning mathematics, often by teaching it. I've taught many of our undergraduate courses and some of our graduate courses, including Representation theory and QFT for mathematicians.

So that's my weird academic background and status. make of it what you will.

Personally I feel rather lucky at how this has turned out. It all started with having relatively well-off parents who could afford to send me to Harvard, I then enjoyed about the best education in particle theory possible, and now I have a permanent job surrounded by very talented people that I like, one that gives me a fair amount of time to think about what I choose. Anyone who thinks I'm an embittered soul doesn't know me very well. While I've seen a lot of talented people be badly treated by universities and by the atrociously bad job situation in many fields, I don't have anything to complain about.

One problem with this is I don't know what career advice to give young people interested in particle theory. They'd be fools to do what I did, but if they follow the standard path they'll probably get screwed. It seems to me that a very big question the particle theory community needs to be addressing is how to provide a career path for really smart students that gives them encouragement to strike out in new directions, with a viable chance at making a permanent career of it. Right now many of the young people in the field I talk to are very discouraged, feeling that their choice is to either try and make a name for themselves by working on a not very promising but trendy string theory topic, or to commit academic suicide by trying something different that probably won't work out. This situation is extremely unhealthy.

   March 28, 2004

   Hi Pyracantha,

   It's hard to talk about physics in general, different subfields have different things happening in them. As far as particle physics goes, progress has undeniably slowed in the past 25 years (people will disagree about how much…) for two overriding reasons:

   1. The standard model is just too good, making the field a victim of its own success. It was in place by the mid-seventies and all experiments agree with it (or to be precise, with a slight extension of it to include neutrino masses). It's vastly harder to come up with good new ideas about physics when you don't have experimental results that conflict with theory and point you in the right direction to improve the theory.

   2. Available accelerator technology is reaching its limits: there are diminishing returns and going to higher energies is more and more difficult and expensive. There will finally be a big new jump in energy at the LHC in a few years, but both political and financial problems have caused this jump to be a long time coming.

2. **Peter**
   March 28, 2004

   Hi Erin,

   I spend most of my time among mathematicians, so I'm very aware what they think of QFT and string theory. With few exceptions, they're pretty confused about the distinctions between QFT, string theory, supersymmetric QFT, etc. They generally see all of these as one uniform, mysterious set of methods that undeniably has lead to some fantastic mathematics. This isn't really surprising: these are complicated ideas, with complex relations between each of them and between them and more standard mathematics.

   So, they're often surprised to hear me criticizing string theory, saying "but it has lead to so much great math!". To a large extent this is right: string theory has lead to some great math and in many ways its influence on math has been very positive. Unfortunately many mathematicians believe that everything that has come out of physics came out of string theory, believing for instance that the work that Witten got the Fields medal for was string theory. It's hard to explain to them that many things like this came out of QFT, not string theory. It gets even more confusing since some of the most interesting math has come out of conformal field theory, which is both 2d QFT and a crucial part of perturbative string theory.

Personally I'm pretty convinced that, while good mathematics will continue to come out of string theory, QFT will ultimately have an even bigger impact on math. QFT involves mathematical structures that are infinite-dimensional examples of structures that are well-known to mathematicians in the finite dimensional case. Mathematicians often hadn't thought too hard about how to generalize to infinite dimensions, because typically there are many ways to do this and, until QFT came along, it wasn't clear which if any ways lead to something interesting. Even after getting guidance from QFT about which way to go, it is still very difficult to rigorously deal with these infinite dimensional things, so mathematical progress is frustratingly slow. If the study of QFT in physics was in a healthier state, there might be even more fruitful interchange between math and physics than there is at the moment.

3. **Pyracantha**
March 28, 2004

Is there a sense of "diminishing returns" in current physics research – more studies and more theorizing, but fewer results and less ability to verify by experiment?

Pyracantha

4. **erinj**
March 27, 2004

"Hype" indeed. String theory thrives upon hype and media attention in my opinion; for example, Greene's `The Theory of Everything' TV series recently shown here [known as `The Elegant Universe' in the U.S.]. Topics like the Standard Model just aren't the sort of thing people wish to popularize into TV series.

I recently read a mathematician refer to string theory as a particular quantum field theory (but perhaps he meant string field theory instead of string theory…?), and seeing any success – past, present or future – in string theory is difficult. Yes, I too hope things will change for the better. Surely the study of QFT is far from over, and is really only just beginning, for both physicists and mathematicians.

Incidentally, I thought Carlo Rovelli's `A dialog on quantum gravity' provided an excellent catalogue of many of the things string theory keeps on not doing and highlights many misconceptions surrounding the alleged successes of string theory. I especially liked the way Rovelli included a debunking of the claim that the Veneziano amplitude is `correct' (not something many string theory papers discuss these days, I suppose).

Erin

P.S. I would leave a valid e-mail address, but one never knows who's reading this (anyway, I'm not actively involved in academic research).

5. **Peter**
March 26, 2004

Hi Erin,

It seems to me that situation in the US is polarized in exactly the same way as in the UK. To an increasing extent, this seems to be the case around the world. Globalization also applies to particle theory, I guess.

The standard story you'll get from string theorists is that QFT is essentially a closed book, and that everything interesting about it is known. From their point of view, someone wanting to work on field theory is either too much of a wimp to do string theory, or just too ignorant to realize that everything of interest about field theory has already been done.

This point of view makes sense if you believe the hype that string theory is a successful extension of QFT that explains all the things QFT can't. When and if people realize that string theory actually doesn't live up to its hype, maybe things will change.

I think the situation now is very analogous to what happened in the late 60s, early 70s. Most of the leaders in particle theory had abandoned QFT and were doing S-matrix theory (and later, string theory). The few people like Veltman still doing QFT weren't taken very seriously, I'm sure many people explained to him why he was a fool to work on quantizing and renormalizing non-abelian gauge theory. This all changed with the advent of the standard model, one can hope that a similar shift will happen again in our lifetimes.

6. **erinj**
March 26, 2004

Hello Peter,

Ever since `String Theory: An Evaluation', I've made sure I read your articles and papers, and only a few days ago I discovered that you had begun a weblog: it's marvellous and fascinating, and I certainly agree with your views on string theory.

I myself am a British, disgruntled former particle theory postdoc, and I can relate to your comments on young people entering – or attempting to enter – the field of particle theory research. My PhD research was concerned with field theory, and I wished to continue with field theory research, but found that the opportunities for that in the U.K. were far more limited than I had expected. Increasingly left out in the cold, and struggling to do something which might earn me another postdoc in field theory (which no one seemed interested in), I was dropped and now consider myself a failure. I do wish I could have continued.

To me, there seems to be a stark choice those interested in particle theory research have to make: do phenomenology, or do string theory. This is the message I received during my time in research. Perhaps if I had chosen one of these, instead of being interested in field theory, I might still be a postdoc.

It would seem that if you choose to do research in field theory or mathematical physics – or indeed anything other than phenomenology or string theory – one has to be prepared to work towards either string theory or phenomenology, for doing anything else seems to offer no stable, long-term employment or any career development prospects in particle theory research. Why is it that present (U.K.) research in particle theory seems to be so polarized? Is it the same situation in the U.S., or even worldwide?

Incidentally, during my PhD, my field theorist supervisor was just beginning to turn into a string theorist, and now the transformation is complete. It was a rather discouraging thing to see. I do wonder if he felt pressure to migrate to string theory in order to remain in academia.

Atiyah and Singer Share Abel Prize

March 26, 2004
Categories: Uncategorized

The Abel prize is a new yearly prize in mathematics, intended to function somewhat like a Nobel Prize for mathematics. The first one was awarded last year to Jean-Pierre Serre and this year's has gone to Sir Michael Atiyah and Isadore Singer, specifically for their development of the Atiyah-Singer index theorem.

Atiyah and Singer are great heroes of mine, especially Atiyah. They have both taken a great interest in the relation of mathematics and quantum field theory and are responsible for much of the fruitful exchange of ideas between the two subjects over the last 25 years. I consider much of my mathematical education to have come from a lot of time spent reading through Atiyah's five-volume collected works. His interests have ranged over a wide swath of modern mathematics and his writing is always a model of clarity. A good case could be made that Atiyah has been the most important figure in mathematics during the second half of the twentieth century.

The Atiyah-Singer index theorem is perhaps the single most important theorem of the last half century. It links together analysis, topology, geometry and representation theory in a fundamental and surprising way, one that is dear to any physicist since it involves the Dirac operator. Very roughly, what Atiyah and Singer discovered was that the dimension of the space of solutions of certain PDEs on compact manifolds was a topological invariant, one that they could explicitly compute in terms of more well-understood topological invariants: the cohomology classes of the manifold.

They did this by noticing that the general case could be reduced to the case of the Dirac operator, twisted by the various possible vector bundles on the manifold. They actually rediscovered the Dirac operator for themselves in the course of their research. The natural abstract framework for these new topological invariants is K-theory, where classes are represented by vector bundles, much as cohomology classes are represented by differential forms.

Things get even more interesting if there is a symmetry group acting on the whole set-up. Then the space of solutions carries not just an integer, the dimension, but is a representation of the group. You can actually use the Atiyah-Singer index theorem to classify and construct geometrically the representations of many classes of Lie groups, or going the other way, use representation theory to get more powerful topological invariants. The explicit cohomological formulas you get in these cases often have versions which localize to fixed points of the group action; so you can find your answer just by locating the fixed points and looking at what happens in a neighborhood about them.

I hope Atiyah and Singer enjoy their shared $875,000!

Comments

1. **Danny Ross Lunsford**
   March 31, 2004

   Hi Peter,

   Could you elaborate on Grothendieck's new ideas of "space"? Do you mean change of element (e.g. Pluecker) or something totally new?

   I can hardly believe I'd never heard of this person!

   -danny

2. **Danny Ross Lunsford**
   March 31, 2004

   Hi Erin,

   I can't make any definite statements about LQG because I don't know enough about it. My understanding is – it makes more physical sense than strings but there are fewer "results". Neither is finished in the sense of having a definite schemata and methods. IMO string theory is ab initio preposterous, while LQG is excessively formal. Having some detailed knowledge of the history of physics, progress just does not come that way.

   I don't want to spam Peter's blog with details, but if you are interested in what I did I'd be happy to explain it elsewhere. In contrast to LQG or strings, it's a complete scheme with sensible elements and very little arbitrariness, and does not purport to be quantum gravity up front (although I am quite confident that strict locality in this theory makes it a much better candidate for quantization than GR). It is a shame to have to work in isolation because I could really use input from field theorists with physical grounding at this point. This after all is why collaborative environments in universities were invented.

3. **Peter**
   March 30, 2004

   Grothendieck's work and life are truly amazing. Someone should write a biography and make a movie; it would make John Nash's story ("A Beautiful Mind") look pretty prosaic.

   I had looked at that web-site last year, but there is a lot more material there now. It has a pdf of "Recoltes et Semailles" the ravings of Grothendieck's later years, scanned by a student here at Columbia (Max Lipyansky) from a copy I had in my office. For physicists, I recommend reading the article by Pierre Cartier about Grothendieck's work, subtitled "The evolution of concepts of space and symmetry". Grothendieck's mathematical concerns were far from physics, but he developed fantastic new ideas about how to think about a "space". Since physicists are now so sure that the standard geometrical concepts of space and time need to be generalized, they might get some inspiration from Grothendieck's ideas.

4. **erinj**
   March 30, 2004

   Hi Peter,

   Yes, it would be very interesting if the Abel Prize were to be awarded to – or attempted to be awarded to – Grothendieck. I believe he also refused to travel to Moscow in 1966 to collect his Fields Medal. Have you ever seen the following website? I recommend it:

   http://www.grothendieck-circle.org

   Grothendieck is/was a fascinating mathematician! His work is astonishing, in my opinion. (I'm a bit of a fan of his, even if most of his major works remain untranslated into English.)

5. **Peter**
March 30, 2004

Hi Erin,

I think the whole idea of setting up the Abel prize was to have something more or less equivalent to a Nobel prize in mathematics. One reason for this certainly is to raise the public profile of mathematics. We'll see if it works.

The Fields medal until now has been the most well-known prize in mathematics (although there are some others, including the Wolf prize). It is somewhat different in that it is given only once every four years (to 2-4 people), is restricted to mathematicians under the age of forty, and carries little or no money with it. So there are relatively few Fields medalists compared to, say Physics Nobelists, and quite a few very good mathematicians don't have one since either they didn't do their best work or it wasn't recognized before they were 40. An example is Andrew Wiles, who was a bit over 40 by the time he found a proof of Fermat's last theorem.

It's kind of a strange situation, to start up a new prize like this. One has all the best living mathematicians to choose from; many of them have Fields medals, some don't. There was some speculation the Abel prize committee might decide to first award prizes to those who didn't get a Fields medal (e.g. Wiles), but that isn't what they are doing. I'd guess a lot of mathematicians would list as the top three living mathematicians of the last half century Serre, Atiyah and Grothendieck. It will be interesting to see what the Abel committee does about Grothendieck. He's still alive, but stopped doing mathematics and hid himself away in the mountains in France. The last time someone tried to give him a prize (the Crafoord Prize), he very publicly rejected it. I'd assume he'd do the same thing if the Abel committee tries to award him the prize.

6. **erinj**
March 30, 2004

Hi Peter,

It's wonderful to see great mathematicians of our era such as these recognized and honoured like this. (I realize I should have posted these comments earlier, but I'll do so anyway now, disconnected as they are from the preceding posts.)

I've often wondered if the existence of a Nobel Prize in Mathematics would have improved the global public perception of mathematics, and especially made mathematics be considered on a par with the other sciences for which Nobel Prizes exist (which surely it is, isn't it?). Perhaps more people would study mathematics if they knew there were Nobel Prizes awarded for it. I myself think Nobel did mathematics a bit of diservice by excluding it.

So if the Fields Medal is the `equivalent' of the Nobel Prize in mathematics (despite being awarded only every four years, restricted to those younger then 40 years of age and having a smaller prize fund), then where does that leave the Abel Prize? Doesn't the Abel Prize perhaps go some way to being the Nobel Prize in mathematics (awarded annually, Scandanavian, large prize fund, likely to be awarded to those over 40 years of age… perhaps always awarded to fewer than three people?)?

Another thing: both Serre and Atiyah already have Fields Medals, but Singer does not. How many other future Abel Prize winners will also be Fields Medallists or have worked with one?

Erin

P.S. Danny: isn't the theory of loop quantum gravity equivalent to background-independent – presumably synonymous with "background-free" – Yang-Mills gauge theory? If it is, then there are already at least some physicists working on this theory.

7. **Peter**
March 30, 2004

Hi Chris,

I've seen the academic system (at least its US version) at work from closeup in two different fields, particle physics and math, and the differences are interesting. There are problems with how it works in math that are somewhat the same as those in physics: it is tough for young people who want to try to do something really ambitious, and the safest bet for one's career is to work on a not too ambitious topic in a hot area. But things are very different in math for several reasons:

1. The ratio of good young people to jobs is nowhere near as bad as in particle theory. Very roughly I'd guess the situation in math is that there are perhaps twice as many people getting Ph.D.s in math as there are permanent teaching jobs that might allow you time to do research. In particle theory the situation is closer to ten times as many people as permanent jobs. The game of musical chairs for young people in particle theory is a lot more brutal than in math.

2. Particle theory has always been a much trendier subject than math, partly for the good reason that , historically, as unexpected new experimental results became available, the smart thing to do was generally to be thinking about what they meant. The lack of any unexpected experimental results for nearly 30 years has been hugely problematic for particle theory.

So, while we agree that the particle theory academic system is quite unhealthy these days, I don't think that moving the power base to the young would help much (besides being extremely unlikely to happen; the old do not give up power so easily!). If older people as well as younger ones were all in the same situation of way too few jobs, with the only way to survive to be working on the latest trend, things might not be any better.

My own general ideas about how to make particle theory a healthier business are something like the following:

1. First of all, the hype has to be brought under control. As long as ideas that don't work are being sold as huge successes, the field is going to be really unhealthy no matter how it is organized.

2. Bring the ratio of good young people to jobs under control, either by finding a way to fund more positions (this may happen to some extent naturally as the rate of retirements picks up) or by limiting the size and number of particle theory Ph.D. programs.

3. Find ways of encouraging people to work on less trendy things. This would require a real change in the whole sociology of how particle theory is organized. There are a lot of ways you could imagine encouraging such a change.

I must admit though, that prospects for any such changes look pretty dismal.

8. **Chris Oakley**
March 30, 2004

Hi Danny,

Nice to hear an assenting voice. Or any voice at all, for that matter. My beliefs on QFT [anti-renormalization] and academic research in general [anti-gerontocracy] have thus far provoked a deafening silence. Maybe there are too many vested interests. If Dirac had lived 50 years later, I might have survived better. I particularly liked his quote, when talking about QED: “Just because a theory agrees with experiment, it does not mean that it is correct.” Thank-you, Paul. As usual concise and to the point.

I have to say, though, that in many ways I believe that I am only stating the obvious. In the first case it is the obvious fact that you can get any answer you want by subtracting infinity from infinity and in the second case, I, like everyone else, was more creative and mentally agile at the age of 22 than I am now at 44. One should accept these things, and it is grossly unfair that someone my age now who has an academic post can put obstacles in the way of a young researcher with new ideas just because they are not *my* ideas.

I am not answering your question … I am *sort of* still working on QFT in my spare time, but on a kind of QFT text book (sans renormalization, obviously) rather than research. I will post it on my site in the not-too-distant future.

In the meantime, in particular as regards the komissar, do not forget the old adage:

Non Illegitemi Carborundum

9. **Danny Ross Lunsford**
   March 30, 2004

   You just have to stick to the ideas and hope the world gets better. At least you are still working.

   I remember your work, it was interesting. Are you still at it?

   If it’s any consolation, I actually managed to solve Einstein’s problem and get it published, only to be blacklisted from the archive by its komissar. No one in the entire world seems to be interested in background-free electrodynamics (and coming soon, background-free Yang-Mills!) This to me is the deepest mystery of all.

   Keep at it, all you can do is – all you can do.

   -danny

10. **Chris Oakley**
    March 30, 2004

    This is neither an ad for sexual-performance-enhancing chemicals or an assessment of whether or not Michael Atiyah deserved $437,500 for his index theorem, being rather some general observations about academic research which have already been made on my web site, but will be expanded on when I can be bothered. It follows on from Peter’s post “My (Not So) Brilliant Career”.

    As far as I can tell, the research situation now is much the same as it was when I was a graduate student/research fellow (1982-1987). The basic fact is that an institution (pure academic research) that has no clearly-defined objective will by definition lack a self-correction mechanism. This is not the case in financial software, which is what I work in now, as measures of success and failure are often brutally apparent, even to those who have never written a line of code in their lives.

    If the academic system worked as it should, every graduate student entering the field would be told something along the lines of the following: “You are where you are because have exceptional ability in mathematics and science. It may well be, although it does not necessarily follow, that you have valuable contributions to make to your subject. It does not necessarily follow because what you are now embarked upon is essentially different to what you have done up till now. Instead of jumping through hoops that others have set up, you will now be deciding the nature and shape of the hoops themselves. If the task of passing exams were to be likened to being an accountant, the task of doing research is like being an entrepreneur. Read and absorb everything you can get your hands on. Do not rely on others to tell you what is important as these assessments have to come from within yourself. If having done this, you decide that, in all honesty, all you can hope to contribute is a few dotted i’s and crossed t’s then get out and do something useful instead. You will almost certainly be better paid if you do.”

    No-one said this to me in 1981. What it was about was not doing what you thought was right, but getting noticed. You had to attach yourself to some research project, however little you believed in it, and then hope that the “big shots” in this field liked you enough to offer you employment. Fine if you believed in it, but if there was *nothing* that they were doing that you believed in, and you wanted to start your own line of enquiry, then there was nowhere to go except out. The herding tendency was embarrassing. “Safety in numbers” was and is the principle, and I am amazed at the extent to which researchers were and are prepared to sacrifice integrity, enjoyment and quality of life for the sake of the distant prospect of a poorly-paid tenured academic job. If the situation in particle physics was bad 20 years ago, then it is ten times worse today.

    The model of researchers as inquisitive children rather than flocks of sheep would work much better for me. How might one get there? The obvious step would be to move the power base to younger people, by (a) only granting research posts on a rolling 5-year basis, i.e. NO permanent posts and (b) giving equal votes in hiring, etc. to ALL involved in research, including graduate students. These steps would perhaps not solve *all* the problems, but they would at least make academic research more interesting.

Various Hype

March 29, 2004
Categories: This Week's Hype, Uncategorized

A recent new experimental result from Brookhaven has lead to some news stories like:

Theory of matter in for a “sensational” revision

which sounds pretty exciting. If you look into this more carefully, you’ll find that it’s based on a report from the E949 experiment at Brookhaven of the observation of a single event of a decay

K+ to pi+,nu, nubar

The preprint is at
hep-ex/0403036
From reading it, as far as I can tell the bottom line is that this is the third candidate event for such a decay ever observed, the two previous ones were from Brookhaven E747 in 1997 and 2002. The standard model prediction is for about 1.5 events for the combined data from both experiments, with expected background of about .5 events. So, all together, the expected number of events is two, they have seen three. Where does the “sensational” come from?

At Slashdot, there’s some more string-theory related hype:

Testing Relativity

about a proposed experiment for the International Space Station that would “test general relativity to a precision within the bounds of superstring (and other) theories to predict deviation.” This article links to a NASA webpage

Evicting Einstein

which goes on about string theory and extra dimensions in the usual way, then describes the proposed “Laser Astrometric Test of Relativity” (LATOR) experiment, which would precisely measure the effects of general relativity on solar system scales. If you read the NASA page closely you’ll see that its author was careful to just say

1. String theory, etc. predict deviations from GR

2. LATOR will test GR precisely

and not to mention that 2 has nothing to do with 1, since the deviations that LATOR could see aren’t the deviations you expect to see from string theory (although since string theory can be used to “predict” just about anything, perhaps you could claim that it “predicts” some unobserved nearly massless field whose effects LATOR would see).

String Theorists Finally Admit Defeat

April 1, 2004
Categories: Uncategorized

The news that next week's "Science Times" will run an article by NYT reporter James Glanz in which several leading string theorists say that they are giving up on the idea is rapidly spreading throughout the particle theory community. Evidently Glanz recently went down to Princeton to interview Edward Witten, who took the opportunity to announce that he has changed his mind about whether string theory will ever be a "Theory of Everything". When Glanz contacted other string theorists and read to them what Witten had said, almost all of them told him that they too had been having their doubts about the theory.

Glanz quotes Witten as follows:

"One night a few weeks ago I was sitting at my kitchen table trying to make sense of Douglas's latest work on the KKLT proposal and all of a sudden it really hit me that this is a completely lost cause. If perturbative string theory has any relation to Planck scale physics, then KKLT or something like it should work and string theory is vacuous since it can never predict anything. If perturbative string theory isn't useful then we really don't have anything since we've never been able to come up with a non-perturbative version that makes sense. Twenty years of this is enough. It's time to give up."

When Glanz asked him what he intends to do now, Witten responded:

"I don't really know. There are still promising ideas about using string theory to solve QCD, and I could keep working on those. Maybe I should take up something completely different, like biology. I'm starting to worry that John Horgan was right about the 'End of Science'. Right now I just definitely need a long vacation."

When Glanz read Witten's statement over the phone to David Gross, Frederick W. Gluck Professor of Physics at UCSB and Director of the Fred Kavli Institute for Theoretical Physics, Gross thought for a moment and then told him "Yeah, despite my quote last year from Churchill, I've also been thinking of giving up. Not sure though how I'm going to break this to the two Freds."

The news of Glanz's article has had dramatic effects at many universities and research institutes. At MIT yesterday, Prof. Barton Zwiebach shocked students in his Physics 8.251 "String Theory for Undergraduates" class by announcing that he wasn't going to collect the homework due that day and was canceling his lectures for the rest of the semester. He also asked Cambridge University Press to halt publication of his new undergraduate textbook called "A First Course in String Theory", the release of which had been planned for next month.

Search committees at several institutions that hadn't finished their hiring yet this season held new meetings to decide how to react to the news. A prominent theorist at a UC campus told me in an e-mail that "our chair had the phone in his hand and had already dialed the number of a string theory graduate student from Princeton we were going to offer a post-doc to. I ran into his office as soon as I heard the news and stopped him just in time. Last week we were sure that string theorists were the smartest guys around and considered only them for jobs, but now there's no way we're going to hire any more, ever!".

At the Institute in Princeton this year's "Summer Program for Graduate Students in String Theory" scheduled for July has been canceled, with one of its organizers remarking "what graduate student would now be crazy enough to show up for a program like this?" Next week's conference on "The Status of M-theory" at the Michigan Center for Theoretical Physics has also been canceled on very short notice. The director there, Michael Duff, commented "We had to do this because the status of M-theory is all too clear. It's passed on! This theory is no more! It has ceased to be! It's expired and gone to meet its maker! … This is an ex-theory!"

   April 5, 2004

   Hi Urs,

   There are non-perturbative string theory calculations out there, but they have no known relation to the real world, so can't be used to predict anything.

   I'm not sure what Douglas and Vafa work you are referring to. One guess would be toy d=2 string models and topological strings. Neither of these has any understood connection to 4d physics. Similarly with matrix models. There simply is no such thing as a non-perturbative formulation of string theory that allows one to calculate anything in the situation one cares about of four large dimensions.

   Even worse, you not only don't have a theory you can calculate with, you don't even know the energy scale of the mythical theory you want to believe in. Is it the Planck scale, is it 1 Tev? It could be anything as long as it's not too small since then it would be ruled out by experiment.

   So, not only is there no prediction of an infinite tower of new states, there is no prediction of how many new states to expect from the theory, what their properties will be, or even at what energy scale they will occur.

2. **nnyhav**
   April 5, 2004

   Seems a shame the parrot sketch will only share space with the Holy Grail for a bit longer … but BBC4 chimed in on the latter …

3. **Urs Schreiber**
   April 4, 2004

   Hi –

   true, the full tower of massive states would only be observable for vanishing coupling. At finite coupling string self-interactions lead to a collapse of highly excited states as computed in papers concerned with string/black hole correspondence, e.g.

   Thibault Damour & Gabriele Veneziano, Self-gravitating fundamental strings and black-holes (1999)

   This effect leads to the creation of '*string balls*':

   Kingman Cheung, Black hole, string ball, and p-brane production at hadronic supercolliders (2002)

(I recall that we had a very similar discussion before.)

Yes, the above paper mentiones large extra dimensions such that the string scale would come into reach of next-generation colliders. If the string scale is further away, this means that these experiments will be possible only at higher energies. But it is possible in principle.

Regarding the general criticism that only perturbative effects are known: Recent results by Douglas on D-branes and by Vafa and others are all concerned with non-perturbative effects. But I don't understand these very technical paper well enough to say much more about them.

Regarding the fact that Gross and Witten say that a full non-perturbative formulation is still not known:

Sure. Robert Helling for instance (together with Nicolai and others) has shown that BFSS can only apply to a certain 'sector' of M-theory. But there it is a fully non-perturbative formulation. Helling tells me that the advent of the AdS/CFT 'bandwagon' has caused many people to reduce research in BFSS and concentrate on Maldacena's conjecture. Hence counting number of people and papers in these fields doesn't say much about the field itself.

4. **Peter**
April 2, 2004

Hi Urs,

A few comments:

About non-perturbative string theory: I did quickly look at the matrix model references you gave and saw no real evidence there of any hope of extracting realistic, 4d physics out of them. Maybe you or someone else can make progress on this, but it looks to me like a very unpromising idea to pursue. The statement that there is no known consistent non-perturbative formulation of string theory that gives realistic physics (only four large dimensions, recognizable particle spectrum) is not controversial. Gross and Witten for years have made clear in all of their general talks about string theory that they feel they don't have a good idea about what non-perturbative string theory is.

About Distler's comments: He says that string theory "promises you" universal behavior of quantum gravitational effects at high energies. The problem is that this is still a promise, not reality, and will continue to be only a promise until either someone shows that perturbative string theory is a consistent approximation to something or finds a true non-perturbative theory.

About the string theory "prediction" of an infinite tower of states:

This is a "prediction" of perturbative string theory. Why should one believe that perturbation theory gets the properties of the higher mass states right but not the vacuum state? Isn't this just because one can experimentally check whether a prediction of the vacuum state is right, but you can't check "predictions" of higher energy states so you are free to claim them? Non-perturbatively you are going to have all sorts of things happening with these higher energy states. Won't you start producing not just perturbative excitations of the string, but black holes, branes, and who knows what else? The high energy spectrum could be just about anything.

"Just wondering–and no disrespect meant–is this an April Fools Day joke?"

Ummmm, yes. Some people think it was rather too subtle, some not.

"I heard from Harvard yesterday that Lubos Motl has decided to take up professional wrestling now that his job there is being cancelled."

I had thought about including news about Lubos, but he is pretty hard to parody.

6. **Urs Schreiber**
April 2, 2004

Hi Thomas Larsson –

I think it is a reasonable standpoint to say, as you implicitly do in your last comment, that quantum gravity as such is a problematic enterprise because it is not clear yet if and how the theory can be experimentally tested *in practice*.

If anyone feels that this is reason enough for him or her not to be interested in quantum gravity then that's fine with me. Similar comments probably apply to research for instance in theoretical quantum computing as well as some aspects of (classical) cosmology.

7. **Thomas Larsson**
April 2, 2004

>
It's not very subtle. String theory predicts for instance a tower of infinitely many massive particles.

At the moment we cannot check this, just as we cannot check if the core of Pluto isn't made of green cheese.
>

Hence this prediction is not falsifyable within a reasonable amount of time. Or is there any experiment that can produce this tower of infinitely massive particles?

This is probably the most disturbing aspect of string theory. It may make predictions in principle, like LQG predicts quantization of area and volume, but no experiment will ever be able to disprove these predictions, so they are not falsifyable. As Dan Friedan points out, only large-distance physics is really science.

I find it very disturbing that most string theorists simply don't seem to understand that a theory is not testable unless there is some experiment that can test it, and falsify it, within a reasonable amount of time.

8. **raj**
April 2, 2004

Just wondering–and no disrespect meant–is this an April Fools Day joke?

>
I can't help but feel that the 'doesn't predict anything' mantra is of the same quality as the 'will give us particle masses in two months' missaprehension was.
>

Please, Urs! Do you really claim that string theory makes hard predictions, that can be conclusively tested, and possibly falsified, within our lifetime or indeed within the present millenium? Would you then please tell us exactly which experimental result that would conclusively prove string theory wrong? No light Higgs at the Tevatron? No sparticles or extradimensions at LHC? No proton decay at SuperK? A positive cosmological constant?

Unless you can give us an example of a falsifyable string theory prediction that can be tested within a reasonable amount of time, I think you should stop insinuating that there is.

I agree with you that LQG cannot make such predictions neither, and that it has other problems as well, but at least Ashtekar and Rovelli don't go around and claim that LQG is more predictive than QFT.

11. **Urs Schreiber**
April 2, 2004

Peter insinuated that string theorist's have

> never been able to come up with a non-perturbative version that makes sense

Last time that I tried to discuss this with you I didn't hear back from you, unfortunately.

I believe this could be a rewarding discussion for both sides, when done with care and focusing on the technical aspects. Over at the Coffee Table there are Robert and Lubos who have both worked on Matrix Models and Arvind is an expert on AdS/CFT. So if there really is any desire to discuss the status of non-perturbative formulations it should be possible. I'd enjoy it.

Young String Theorist Did OK On His Final

April 5, 2004
Categories: Uncategorized

A while back when looking for theoretical physics related weblogs I ran across

The Search For A Theory of Myself: The Struggle Against String Theory

which at first sounded right up my alley. It turns out to be the weblog of a grad student at UCSB who is taking a course in string theory there from Polchinski. He's working quite hard at doing well in the course, and seemed very worried about his final on March 15. After the final postings stopped, so I was kind of worried about what had happened to him. Yesterday he finally posted again. He got an 88 % and seems to be all right.

KKLT Smackdown

April 7, 2004
Categories: Favorite Old Posts, Multiverse Mania

I was dubious of the value of a new “sci.physics.strings” newsgroup when it was first proposed, but now must admit it seems to have been a great idea It started up a week or two ago, and quickly someone asked the seemingly innocuous question of how many different possible vacuum states were expected in string theory. This is a hugely controversial issue among string theorists, largely because recent evidence is that the number is definitely astronomically large, and this makes it very unlikely that current ideas about string theory can ever be used to predict anything about the real world.

A lot of the discussion revolves around the “KKLT” proposal for constructing a large number of these vacuum states. The acronym is the initials of the authors, three of whom are at Stanford: Shamit Kachru, Renata Kallosh and Andrei Linde. Also at Stanford is Lenny Susskind, who has been spending the last year or so going around giving talks on the “Landscape of String Theory”. It’s hard to believe this, but Susskind’s claim is essentially that the lack of predictivity of string theory is a good thing, since it allows so many possibilities that anything can happen. One can then invoke the “Anthropic Principle” to explain why the world is the way it is. It seems that Susskind is even writing a book about this wonderful “discovery”.

Amazingly enough, the thread about this on sci.physics.strings, entitled “Conceptual question”, has brought a public attack on the “Stanford propaganda machine” by a well-known European string theorist (Wolfgang Lerche), a detailed defense of his ideas by one of the KKLT authors (Kachru), contributions from the inimitable Lubos Motl from Harvard, and, while I was writing this, a defense of the anthropic principle from Joe Polchinski just appeared, which attacks the “cult of monovacuism” embodied by David Gross and Ed Witten.

Thanks are due to the creators of this newsgroup. Pass the popcorn!

   Hi String Theorist,

   The argument that maybe the things we don’t understand about the standard model are artifacts of history and not something a more fundamental theory can predict deserves a longer response than I have time for right now. It’s an important issue and I’ll try and write up some thoughts about it soon.

   You’re not answering the question I’ve been trying to get an answer to from string theorists: what exactly do you expect string theory to be able to ever predict?

2. **D R Lunsford**
   April 13, 2004

   Comments to comments by Anonymous Stringer:

   “Just because string theory is a “theory of everything” does not mean it can be used to calculate everything! Let me explain by analogy.”

   This is like absurdist fiction. No other comment required. One invokes the “prima facie preposterous idea” argument with success.

   “Do you think that Newton’s theory of gravity is vacuous because it cannot predict the number of planets in the solar system, or calculate their distances from the sun (0.39, 0.72, 1.00, 1.52, etc A.U.)?”

   This is an absurd analogy. What Newtonian gravity comprehensively succeeds at is explaining orbital motion and dynamics, and that is all that is required. The proper analogy would be a version of string theory that, given a proper limiting argument, showed that weak interactions did not conserve parity, explained the tiny mass of the neutrino, gave a theoretical justification for the phenomenology of the Higgs mechanism etc.

   “One of the hallmarks of scientific progress is that frequently, what we had thought were interesting scientific questions turn out to not be scientific questions at all.”

   This is more absurdist fiction. The same questions – what is motion, what is the structure of matter, etc. – are as self-evident and vital today as they were in the time of Democritus. There are no real questions of science that later turn out to be misguided – what DOES exist is a clear history of trying to explain away the uncomfortable facts, as in mechanical models of the ether.

   “Nowadays, of course, we understand that there is no reason to require physics to be able to calculate the number of planets, or their orbital periods or sizes. They are what they are.”

   This is sheer sophistry and an embarrasing confusion of phenomenology with theory.

   “This is why I asked you what you thought string theory should be able to calculate. And, as I expected, the things you mentioned are all things to be observed, not things to be calculated.”

   What can be calculated can only be determined after a theoretical model is in place. There is no real model in string theory other than the on-the-face-of-it preposterous idea of fibrills in an umpteen-dimensional wonderland without any bearing on history or reality.

   In fact the goal of any subsuming theory should be to explain the previous one by a limiting argument that not only shows why the last one failed, but how the new one points to new phenomena to be expected. All the previous successes in physics are like this.

   “It is no more “necessary” for the gauge group of the universe to be SU(3)xSU(2)xU(1) than it is “necessary” for there to be four gas giant planets in our solar system.”

   This is totally wrong-headed. Particle physics is phenomenology that will one day be explained theoretically when the excresences of this generation are forgotten. The gauge group of the Standard Model is simply the encoding of the phenomenology – this is not a criticism, rather praise for experimentalists and field theorists to get at least part of it unmistakably correct. There is more truth in one generator of this “arbitrary” group than in all the decades of windmill-tilting of stringers.

   “Similarly, when you say “Calculate for me the fermion mass matrix” it sounds the same to me as “Calculate the masses of the planets.”

   More absurdist fiction. A real encompassing theory, such as the one that explains the relation of electricity to magnetism, always includes dynamical explanations of previously phenomenological inputs. The masses of the Fermions are the LEAST things to expect from a good theory. And in fact, there already exists a good theory of

Fermion masses based on analysis of Clifford algebras – so clearly this is not going to be the hardest problem.

"There are still plenty of people clinging to the modern day equivalent of Bode's Law or Kepler's solids, believing that there might be a unique consistent quantum field theory which therefore is necessarily the one describing our universe. But I think this point of view will soon be widely seen as outdated."

Who are they? The only physicists who seem manifestly Dadaist to me, are you people. If you only knew how foolish are the things you claim, you would desist and try something else.

3. **String Theorist**
April 12, 2004

Hi,

I think it is very important to discuss the issue of what kinds of things we should and should not expect to be able to calculate within string theory. Just because string theory is a "theory of everything" does not mean it can be used to calculate everything! Let me explain by analogy.

You seem to think that string theory is vacuous because (among other things) it cannot predict the gauge group, or calculate the fermion mass matrix.

Do you think that Newton's theory of gravity is vacuous because it cannot predict the number of planets in the solar system, or calculate their distances from the sun (0.39, 0.72, 1.00, 1.52, etc A.U.)?

This is a fair analogy: Newton's gravity is a theory of everything relevant to the dynamics of non-relativistic gravitationally interacting bodies (such as planets), while string theory is a theory of everything relevant to the dynamics of elementary particles (such as gauge particles and fermions).

One of the hallmarks of scientific progress is that frequently, what we had thought were interesting scientific questions turn out to not be scientific questions at all.

For example, the ancients thought there were five planets, and spent a great deal of intellectual effort theorizing why there HAD to be precisely five planets. Once it was realized that the Earth also orbits the sun, Johannes Kepler tried to explain the existence of precisely six planets (and to explain the sizes of their orbits!) by inscribing the five Platonic perfect solids between the orbits of successive planets.

The discovery of Uranus in 1781 relegated the Platonic solid idea to the history books. Now the best theory was Bode's law, originally pointed out in 1766 by Johann Titius, which predicted the location of Uranus almost spot-on! Unfortunately, Neptune didn't fit into the picture very well.

Nowadays, of course, we understand that there is no reason to require physics to be able to calculate the number of planets, or their orbital periods or sizes. They are what they are.

This is why I asked you what you thought string theory should be able to calculate. And, as I expected, the things you mentioned are all things to be observed, not things to be calculated.

It is no more "necessary" for the gauge group of the universe to be SU(3)xSU(2)xU(1) than it is "necessary" for there to be four gas giant planets in our solar system.

Similarly, when you say "Calculate for me the fermion mass matrix" it sounds the same to me as "Calculate the masses of the planets."

There are still plenty of people clinging to the modern day equivalent of Bode's Law or Kepler's solids, believing that there might be a unique consistent quantum field theory which therefore is necessarily the one describing our universe. But I think this point of view will soon be widely seen as outdated.

String Theorist

4. **Peter**
April 12, 2004

The list of things an improvement on the standard model should be able to predict is well-known: choice of gauge groups and representations in the SM, gauge couplings, Higgs sector parameters (including fermion mass matrix), Newton's constant (for instance as ratio of Planck/GUT scale), cosmological constant. Presumably the standard model breaks down at some energy scale; one should be able to say what that is and predict what new phenomena occur above that scale. Especially impressive would be a prediction of one of the still unmeasured SM parameters (the Higgs or neutrino masses).

The closest thing I know of to a framework that can do any of this is the supersymmetric GUT framework, where one can get a prediction of one gauge coupling in terms of the two others that works at the 10% level. Unfortunately this comes with a lot of baggage, including another hundred or so undetermined parameters of the supersymmetric extension of the standard model. If one is pursuing this idea about unification, these are on the list to be predicted.

I'm curious how string theorists look at this. What are the prospects now for using string theory to make any predictions of the sort listed above?

5. **String Theorist**
April 11, 2004

Hi Peter,

OK, I'll bite. You wrote:

Last year as a joke I was telling people that the way things would end up is that string theorists would simply declare victory, announcing that string theory was the final TOE even though it was inherently incapable of calculating anything.

What exactly would you most like to see us (try to) calculate? Maybe you could give us a 10 most wanted list?

String Theorist

6. **Peter**
April 11, 2004

Hi Thomas,

I did notice that Lerche was on the "multivac" side of the discussion; that he was just annoyed that others were claiming credit for it.

On the sci.physics.strings newsgroup only Motl seems willing to defend the "univac" side (presumably Gross and Witten still haven't given up, but are unlikely to take to posting on a newsgroup).

Last year as a joke I was telling people that the way things would end up is that string theorists would simply declare victory, announcing that string theory was the final TOE even though it was inherently incapable of calculating anything. This year this doesn't seem to be a joke.

7. **Thomas Larsson**
   April 9, 2004

   It seems that Wolfgang Lerche does not object to the AP per se. Rather, he complains that people who proposed the AP back in 1986/87 (himself??) did not get credit for it.

A Hole in Texas

April 12, 2004
Categories: Book Reviews

A short book review.

This past weekend my scientific activities included reading Herman Wouk's new novel "A Hole in Texas". The plot revolves around the story of the cancellation of the SSC and a supposed discovery of the Higgs Boson by a group of Chinese physicists. Wouk clearly did a lot of careful research and/or had some very competent advice since the technical and historical parts of the story are reasonably accurate.

Wouk has the US Congress and media getting tremendously excited over the Chinese Higgs discovery, leading to massive new funding for high energy physics, a charming but unlikely idea. In general the book is somewhat of a romance/wish fulfillment novel for older particle physics experimentalists. The protagonist, an experimentalist formerly involved with the SSC project, gets huge media attention, a lot of money and the use of a private jet, an old romance revived, a new romance with a beautiful Congresswoman who loves to listen to him explain physics, and funding for his current project.

Comments

1. **Chris Oakley**
   April 13, 2004

   Peter & Danny –

   I am very keen on theories which have a unique vacuum defined simply as the zero-particle state. As yet, I have seen no reason why I should abandon this requirement. Whether there is some value in doing mathematical tricks with Lagrangians that lead one to temporarily abandon this notion, I am not sure, but certainly the Higgs mechanism as it stands does not pass the test since, apart from anything else, the relevant manipulations only make sense for classical fields. However, I cannot help noticing that neither of you believe any more than I do that there are spin zero particles with mass tantalising out of reach of current experiments, just waiting to be discovered by the next generation of colliders. If, on the other hand, the required particles *are* found, then my personal view (note – not shared by anyone in the field that I know of who is prepared to be counted, anyway) is that it will set the subject back in that it will give all that dirty mathematics that led us there a new lease of life.

   By way of comparison, consider the W/Z boson discoveries in the eighties – a wealth of indirect evidence led us there. Unlike the Higgs particles now, even if one did not fully buy into the Glashow-Weinberg-Salam model, it would have been very surprising if the particles had *not* been found.

2. **Peter**
   April 13, 2004

   Hi Pyracantha,

   Actually the congresswoman was not just "beautiful", but an ex-Hollywood starlet. Wouk spends a lot of time describing how attractive the female protagonists of the book are; this is after all the fantasy of a 90 year old guy who grew up in the 1930s.

   On the other hand, the leader of the Chinese team that supposedly discovers the Higgs is also a woman, depicted both as extremely competent and of course as "beautiful".

3. **D R Lunsford**
   April 13, 2004

   Chris –

   In addition to Peter's explanation the following analogy may be helpful. If you want to calculate the motion of a ball bearing on a surface, you can either do it in three dimensions with a complicated constraint that forces the ball bearing to remain on the surface, or you can introduce a "surface force field" via Lagrange multipliers – in the Lagrangian for the problem the constraint appears like a effective force of undetermined origin. If we didn't know about the surface, we might be impelled to introduce just such a force to phenomenologically explain the motion of the ball bearing. Then we might discover the surface and say "aha! That phenomenology term is just the constraint in action!"

   Afsar Abbas showed that the Higgs can have arbitrary isospin and hypercharge and the SM still holds unchanged of experimental content. This is exactly the same state as with the above analogy – the normal force on the ball bearing is exactly what it needs to be to maintain the constraint – so the Higgs represents a sort of vacuum in itself, the referent to which the other elements must resort to have a meaning.

   http://arxiv.org/abs/hep-ph/9912243

   Peter's explanation in terms of Cooper pairs is perfect and right on – in the London theory there was simply the issue of a suddenly massive photon – in the BCS theory we now have a theoretical explanation of the pairing process that shows up as the apparent gain of photon mass. If the "real" theory of particles retains the Higgs and basis in Yang-Mills ideas, then it is very likely that the gauge invariances will be exact and the Higgs mechanism will have an encompassing explanation as with Cooper pairs. It could be said that this IS the real goal (or should be), of research in field theory.

   April 12, 2004

   yeah, women in book reviews and blurbs are always "beautiful." In fact, in this kind of writing, "beautiful" is code language for "female." Just like in real life.

   Beautifully,

   Pyracantha

5. **Peter**
   April 12, 2004

   Hi Chris,

One way to convince yourself there might be something to the Higgs mechanism is to study a non-relativistic analog: the Meissner effect in a superconductor. You can think about superconductivity as something that occurs when electrons can lower their energy by pairing together into “Cooper pairs”. Then one says that electrons have “condensed” in the lowest energy state, and low-energy excitations about this state are given by these pairs. There’s an effective complex scalar field theory describing how these excitations behave. In this theory the complex scalar field has a non-zero expectation value in the vacuum and so the U(1) symmetry of phase transformations of this field is spontaneously broken. If you now couple this theory to EM, i.e make it a U(1) gauge theory, you find that the photon field acquires a mass term.

All of this can be made sense of in a nonrelativistic QFT setting where infinities are completely under control, and describes real-world aspects of superconductivity that you can check experimentally. The relativistic, non-abelian, version of this used in the standard model is much trickier and one can argue about whether it makes sense rigorously. It also is bad news in that it introduces most of the undetermined parameters into the standard model. There are two well-known philosophies about this:

1. The standard model Higgs field is just an effective field for some kind of more basic fermion fields that pair together something like Cooper pairs. “Technicolor” is one implementation of this idea. There are various problems with it.

2. The standard model Higgs field is a superpartner of some fermionic field in a supersymmetric QFT. Supersymmetry helps with some of the divergences of pure scalar field theory, but this idea also has its problems.

Quite possibly a new idea about this is needed, maybe the LHC will give us a clue. But the success of the standard model means that something is causing spontaneous symmetry breaking of the electroweak gauge symmetry, we just don’t know exactly what it is yet.

6. **Chris Oakley**
April 12, 2004

Excuse me: missing the words “universe” and “a”. See if you can guess where.

7. **Chris Oakley**
April 12, 2004

Although neither beautiful nor a congresswoman, I would not mind someone explaining the Higgs mechanism to me, especially if they feel confident of persuading me that it is not the one of most contrived arguments that anyone has ever taken seriously (other than, of course, the notion that the is 10 or 11 dimensional entity composed of tiny vibrating strings).

Are Fermion Masses Like Planetary Orbits?

April 14, 2004
Categories: Uncategorized

A more and more common argument one hears from string theorists these days (for one version see a recent anonymous comment posted here) goes more or less like this:

"A fundamental theory shouldn't be expected to predict things like fermion masses or the standard model gauge group anymore than it should be able to predict the physical properties of the planets. Anyone who expects this is making the same mistake as Kepler, who tried to relate Platonic solids to planet orbits."

The idea here is that many or even all of the things we don't understand about the standard model are not fundamental aspects of the theory we should expect to be able to predict. Perhaps they are determined by the details of the history of how we ended up in this particular time and place, just as the properties of the planets were determined by the detailed history of the formation of the solar system.

As far as we can tell, the properties of the standard model hold uniformly throughout the observable universe, so to adopt this point of view one needs to postulate the existence of an unobservable "multiverse" of which we see only one small part. The so-called "landscape" of an unimaginably large number of possible vacuum solutions for string theory provides one realization of such a multiverse.

What are the problems with this idea? First of all, it is not so easy to dismiss out of hand. One can certainly imagine the possibility of the existence of an M-theory (maybe now the "M" is for "Multiverse") with a local vacuum state that corresponds to our universe, and some dynamics that allows evolution from one universe to another. Perhaps tomorrow night a preprint will appear on arxiv.org containing a simple equation expressing a dynamics such that the possibility of a universe exactly like ours does arise as some part of a solution. Should we believe in such a new theory, whatever it is?

There seem to me to be two possible cases in which such a theory would be compelling. The first would be if the theory made experimentally testable predictions. Perhaps it would have only one solution that agreed completely with current experimental observations. Then the properties of this solution could be used to predict the results of experiments not yet done. If these predictions were accurate, the theory would have strong evidence in its favor.

Even if the theory had so many solutions that one couldn't readily use it to make predictions, one still might find it compelling due to its "beauty" or "elegance". If it were based on a very simple equation or idea, the fact that the relatively complex structure of the standard model could be made to fall out of a much simpler equation would again be strong evidence for such a theory. Just how compelling this would be would depend on how much simpler it was than the standard model. If the new equation was more or less as complicated as the equations which determine the standard model, it wouldn't be compelling at all.

The current state of affairs in particle theory is that many people believe that they are on the road to finding such a compelling theory, but all the evidence is that this is nothing but wishful thinking on their part. There is no viable proposal for an M-theory based on a simple set of equations with a solution corresponding to the real world. This simply does not exist. An easy way to embarass a string theorist who is going on about the beauty of the theory is to ask them to write down a simple set of equations that characterize this beautiful theory. They can't do it now and I don't see any reason to believe they ever will be able to in the future.

What string theorists have now is not a single, consistent theory, but a set of several inconsistent fragmentary theories that they hope can be turned into a consistent whole. This circle of ideas is significantly more complicated than the standard model that it is trying to explain.

Even this complex of ideas might be compelling if it could be used to explain one or more not yet understood aspects of the standard model, or if it made new experimental predictions that could be checked. All the evidence of recent years is that this is impossible. If the whole framework makes any sense at all, it appears to predict nothing and explain nothing about the standard model. Not a single one of the parameters of the standard model can be calculated, not a single experimental prediction, at any energy scale, can be made. It is becoming increasingly clear that the circle of ideas known as "M-theory" is completely vacuous.

Strong evidence that this is the case comes from the fact that string theorists have no idea what, if anything, M-theory is supposed to be able to predict. Polchinski and others feel they have demonstrated that M-theory can't predict the cosmological constant, but can't come up with anything else it can predict and, increasingly, seem happy to live with the idea of promoting a theory that can't predict anything. This wholesale abandonment of the scientific method upsets some physicists such as David Gross quite a bit, but more and more people seem to have no problem with this. Frankly I find this all bizarre, disturbing, and becoming ever more so all the time.

   April 27, 2004

   Er… empirical Bode's law fits the planetery orbits, isn't it. And I have heard some good attacks to try to derive the orbits from chaotical dynamics, particularly at the moment of condensation of the planets.

2. **Peter**
   April 19, 2004

   I'm afraid I'm really the wrong person to ask the questions you're asking, since these aren't the kinds of alternative ideas I've ever tried to pursue. They are close enough to string/M-theory that you are more likely to get good answers from a string/M-theorist.

   I don't think any of these things have rigorous no-go theorems. The closest may be the higher-spin problems, where I think what happens is if you look at the structure of the poles of the propagator, you can see that there's a problem with finding a prescription for dealing with them in a way that maintains locality and causality. I've never looked at this carefully, but if this is the heart of the problem, there may be a rigorous argument possible.

   For dealing with the conformal factor, a lot of people have worked on this, often in the context of trying to get strings to work in 4d. You really need to find an expert on this, not me.

   Similarly with theories of quantized membranes. A lot of people have tried hard to do this and they are the ones who would know what the fundamental problems are.

3. **gut**
   April 19, 2004

   For the cases of massless spin > 2 particles in interacting quantum theories, is there a rigorous theorem that says these theories don't exist? Or is it mostly "circumstantial evidence" of repeated failures in attempts to construct these particular interacting theories? (ie. we don't know what to do, so we just ignore the problem?)

   Can the same be said about d > 11 brane theories with respect to (conformal) anomaly cancellations?

(ie. “rigorous theorem” vs. “we don’t know what to do, so we just ignore the problem”?)

Has anyone ever produced a quantized membrane or p-brane theory that at least has a perturbative Feynman diagram type of expansion (with or without renormalization)?

4. **Peter**
   April 19, 2004

   Superstring theory is in d=10 because that’s the dimension in which the conformal anomaly cancels. For higher d, you’ll need to figure out some way of dealing with the conformal degree of freedom. M-theory conjecturally handles this in 11d, I don’t think anyone knows what to do for d>11. The dimension of your branes is limited by the space-time dimension.

   Interacting QFTs with spin >2 have problems with unitarity and causality that no one knows how to resolve. This limits the number of supersymmetries you can have.

   Nothing sensible I can say about the other questions.

5. **gut**
   April 19, 2004

   I have a question.

   Why stop at 11 dimensional M-theory or 10 dimensional superstring theory?

   Why don’t we have interacting quantum theories with massless particles with spin 3, spin 4, spin 66, spin 500, spin 9678900, spin aleph_0, and higher?

   Why don’t we have quantum theories of 30-branes, 32-branes, or for that matter 100-branes, 210-branes, 10024-branes, and higher?

   Why don’t we have field theories with N=43, N=200, N=1000, N=12345 supersymmetries, and higher?

   Why don’t lie algebras with 3-grading, 5-grading, 1001-grading, 665543-grading, and higher show up as a more “general supersymmetry”?

   Why do we only count dimensions by positive integers? Why don’t we have a non-integer number “dimensions”, such as 0.4444 dimensions, log(500) dimensions, pi^300 dimensions, -34 dimensions, -log(35353522) dimensions, etc …?

   Why don’t we have aleph_1, aleph_4, aleph_700, aleph_34588345, etc … being used in the number of dimensions, number of supersymmetries, lie algebra grading, or aleph_34 branes, massless spin aleph_2 particles, etc …?

   Why would a “unified field theory” reject such objects mentioned above?

6. **Peter**
   April 19, 2004

   Note that I didn’t say this was what string theorists as a whole think, I said it was an argument one hears from string theorists more and more often. For other examples of this, search the last year or so of sci.physics.research to find Robert Helling arguing that expecting string theory to predict standard model parameters is like expecting a fundamental theory to predict the properties of screws. I also recall Urs Schreiber making the analogy with predicting his phone number. Here’s a quote from Lenny Susskind:

   “Physicists always wanted to believe that the answer was unique. Somehow there was something very special about the answer, but the myth of uniqueness is one that I think is a fool’s errand. That is, some believe that there is some very fundamental, powerful, simple theory which, when you understand it and solve its equations, will uniquely determine what the electron mass is, what the proton mass is, and what all the constants of nature are…. On the other hand you could have a theory which permitted many different environments, and a theory which permitted many different environments would be one in which you would expect that it would vary from place to place. What we’ve discovered in the last several years is that string theory has an incredible diversity?a tremendous number of solutions?and allows different kinds of environments. A lot of the practitioners of this kind of mathematical theory have been in a state of denial about it. They didn’t want to recognize it. They want to believe the universe is an elegant universe?and it’s not so elegant. It’s different over here. It’s that over here. It’s a Rube Goldberg machine over here. And this has created a sort of sense of denial about the facts about the theory. The theory is going to win, and physicists who are trying to deny what’s going on are going to lose.”

   As for consistency and beauty, all the things you mention either are completely inconsistent with reality (four large dimensions and the standard model)

   N=1 supergravity in 11 dimensions, known facts about matrix theory, N=2 and N=4 supersymmetric vacua

   or completely ill-defined

   M-theory, conjectural matrix theories with better properties

   N=1 supergravity in 11d may or may not be beautiful, but it doesn’t look at all like the real world.

   I never said that there aren’t people who think that “low-energy N=1 supersymmetry might be a prediction of string theory”. But even though many if not most string theorists wish this were a prediction of string theory, it isn’t. It’s a nonsensical abuse of language to say that something “might” be a prediction. To make a prediction is to claim that something “will” be true, not that it “might” be true.

   String theory has failed utterly as a unification idea. It has no consistent version that can give 4d and the standard model and it makes absolutely no predictions whatsoever. If most of the energy of the particle theory community hadn’t gone into string theory for the past 20 years, we might have some good alternatives now.

7. **Thomas Dent**
   April 19, 2004

   An anonymous comment is good evidence for what string theorists as a whole think? At least, try to find someone speaking ‘on the record’. Otherwise we will be at the level of letters that begin “As a lifelong Democrat…”.

   Please tell us how string theory (or theories) is or are “inconsistent” as you claim. On the contrary, it is believed that many perturbative N=4 and N=2 supersymmetric vacua are theoretically perfectly consistent. I don’t think you have any counterargument to this. Perhaps you mean that more recent developments are inconsistent. But in what way?

   Some people (in Santa Cruz, Michigan and other places) think that low-energy N=1 supersymmetry might be a prediction of string theory. You could at least acknowledge that such people exist.

Do you not think that N=1 supergravity in 11 dimensions is a beautiful theory? And this is what M-theory is in some limit. There are lots of other beautiful things about, for example matrix theory. Of course, they take a little time to explain.

What is the alternative to string theory? Because nothing else could possibly “predict” the Standard Model parameters either, in the strong sense that you want.

In QFT we have GUT’s and other symmetric constructions, that build on our prejudice for simplicity and unification, but strictly, field theory has no predictions, since there might be a field theory that is not unified but has values of the SM parameters very close to GUT values: there is a continuous infinity of equally consistent QFT’s in flat space.

But, of course, no field theory is completely consistent as a description of the world. If we are not to do string theory, what can we do to make QFT work with gravity? After all, people didn’t go into string theory for no reason at all.

8. **gut**
   April 18, 2004

   A few very telling lines on page 87 of the postscript version, or on the web version

   http://relativity.livingreviews.org/Articles/lrr-2004-2/articlesu15.html

   Another confession of Pauli?s went to Paul Ehrenfest:

   ?By the way, I now no longer believe in one syllable of teleparallelism; Einstein seems to have been abandoned by the dear Lord.? 195 (Pauli to Ehrenfest 29 September 1929; [250], p. 524)

   Pauli?s remark shows the importance of ideology in this field: As long as no empirical basis exists, beliefs, hopes, expectations, and rationally guided guesses abound.

9. **D R Lunsford**
   April 18, 2004

   gut (?) –

   Seems like a very fine review, and the list of references is comprehensive, but oddly misses the main point for modern work, namely:

   The unification of Kaluza is non-dynamical. This is most easily seen by dimensional analysis. Mathematically, the “leftovers” in bottom corner of the extended metric must be constrained in an artificial, purely formal way that forces the n5.. components in the metric to mimic the required behavior. The vacuum problem of string theory is the price paid. That this is the death blow to Kaluza’s ansatz was already known by Pauli ages ago. I can’t see how anything has changed since then. The “cylinder condition” is never really lifted, only explained as projective differential geometry in a particular representation. The lack of a cogent variational principle without essential arbitrariness is further evidence for the ad-hoc nature of the ideas.

   Given the leading role of string theory, I find it strange that so little is said about the basic nature of the Kaluza ansatz. It would be interesting to understand how Kaluza’s theory became popular again after having so completely failed as physics and for so simple a reason. I have no idea how this happened. One should emphasise the marked contrast to Weyl’s ansatz, which is dynamical from the outset, because of the fundamental role of Am in the geometry. The persistent hints that masses are associated with conformal scaling should inspire more interest in this idea, but in spite of all efforts this seems unlikely to happen.

   In the newsgroup the issue of a theory of trivectors (three-forms) came up. I’ve actually worked this out and, as an illustration of the non-essential nature of the Kaluza ansatz, can exhibit it in “unified” form with the 4-d metric. The potential is a bivector and one need only form symmetric objects from it – these are easy to find (think of the energy tensor for electrodynamics). There is a gauge invariance that gets mimicked under the cylinder condition in exactly the same way the gauge invariance of the vector potential does in the original. Is it a UFT? Of course not. The metric is what it is, and the gauge potentials are what they are. The “twain may meet”, but only in a more comprehensive geometry than Riemann’s. Attempting to make the gauge potentials part of the metric itself is physical folly.

   I was pleased to see the work of V.A. Fock acknowledged – he was the first person to take seriously the role of the Dirac gammas as geometrical objects (frame basis). I once owned a galley proof of the paper “L’Equation d’Onde de Dirac et la Geometrie de Riemann” autographed by Born, from his own personal effects (a friend at Maryland had found it on rummaging through some discards of the Physics dept.) It got lost in a move and could not be recovered 🙁 IMO this work is still interesting in the context of Weyl’s ideas because gamma_5 suddenly acquires an essentially dynamical role.

10. **gut**
    April 16, 2004

    Are you referring to this article:

    http://relativity.livingreviews.org/Articles/lrr-2004-2/index.html

    “On the History of Unified Field Theories”
    by Hubert F.M. Goenner

    ????

11. **D R Lunsford**
    April 16, 2004

    Peter –

    The situation is very reminiscent of the deluge of “unified field theories” from 1930-50 from Einstein, Schroedinger, and Eddington. Unlike Weyl’s theory which has a simple, cogent principle at base (“pure infinitesimal geometry”), none of these others – “fernparallismus”, asymmetric metric, asymmetric connection, “lambda” invariance – had anything other than a purely formal standing and they are all reducible (no unique vacuum). Because the times were ripe for experimentalists, these theories were rightly forgotten or held up as examples of what not to do.

    Included among these theoretical husks was of course the Kaluza theory, including Klein’s modifications – because like the others, it was based on a purely formal principle without any direct connection to physics.

    That an already rejected, dead theory would be taken so seriously is a sign of either theoretical desperation, or a semi-conscious effort to prop up a publication and funding bonanza.

12. **Peter**

April 15, 2004

I'm actually agnostic on the "univac" vs. "multivac" issue, since my best guess is that the whole set-up in which this discussion is taking place isn't such that one can get well-defined answers to questions like this.

What I was writing about was something different. I'd always assumed that all serious theorists would agree that if the "multivac" scenario is correct and there really are so many vacua that you can't use string/M theory to predict any of the parameters of the standard model, then you would have to abandon the theory as being useless and not explaining anything. David Gross clearly recognizes what a disaster for string theory the "multivac" scenario is, and I assumed his was the majority view these days. I seem to have annoyed Jacques Distler by thinking he was in Gross's camp. Now I have no idea whether he is "univac" or "multivac" and don't want to get in trouble by speculating about this.

It has amazed me recently to see how many string theorists are willing to argue the case that even if the theory can't explain anything about the standard model, this is not a disaster. They seem to intend to continue believing in string/M-theory unification, even when convinced that there is no way to use it to make predictions or explain any known aspects of the universe. As far as I can tell they are willing to abandon the scientific method in order to keep defending string theory.

Perhaps I'm misrepresenting people's views, but my evidence for this includes the following:

1. The anonymous string theorist here who argued that the standard model parameters and gauge groups are no more likely to be predictable from fundamental theory than planetary orbits. You can find the same argument made in many places these days by many people.

2. Srednicki's claim here that even if string theory could not explain anything about the standard model, if it were consistent it would be a "striking success".

3. Polchinski, Kachru and others uniformly refuse to answer a question I keep trying to put to them: in the "multivac" scenario, name something that you expect to be able to predict. The fact that they don't answer this question seems to me strong evidence that the answer is that they retain the wishful thinking that something, someday may be predictable, but have no idea what it may be.

13. **serenus zeitblom**
April 15, 2004

Peter, you should look at http://arxiv.org/abs/hep-th/0404075
It's clear that the claim that string
theory can produce "anything" just isn't
true. In particular, it is very far from
clear that it can produce a deSitter
background. The KKLT proposal essentially
suggested that you could get dS out of string
theory if you were willing to tolerate extremely
contrived models involving known gadgets such
as fluxes. Now it seems likely that even
this is not true. NOTE that I am not saying
that it can't be done — nobody knows this
yet. What we do know now is that getting dS
out of string theory is going to be very hard.
In view of this, it seems rather odd that people
are worrying about a vast landscape when, as
Vijay B reminds us, we do not have even *one* credible dS background for string theory! Perhaps *this*
is *what* Jacques *Distler* was *going* to
explain, no *doubt* with a *superfluity* of
italics, in his *blog*, which *unfortunately*
is *mainly* about *itself* these *days*……

It seems that the second most important web-site in the particle theory community (the first is obviously the arXiv) has been shut down by the University of Washington. The Theoretical Particle Physics Jobs Rumor Mill has for years been a comprehensive source of information about who's hot, who's not, the hiring plans of all the theoretical particle physics groups in the United States and Canada, and the career moves of more established theorists. I hope a new home for the site can be found at a less fearful institution. I'd consider putting it up here, but I've got enough particle theorists annoyed at me already…

Comments

1. **Peter**
   April 19, 2004

   At least in the US, academic freedom traditionally does mean that academic staff have the freedom to use the university resources normally made available to them to disseminate information they choose about their scholarly field.

   That said, I suppose one could argue that the sort of information being disseminated there was not the sort that traditionally is protected by guarantees of academic freedom. I have no idea who at UW was running this web-site or why the department there insisted that it be closed down.

2. **Thomas Dent**
   April 19, 2004

   Actually, the person responsible for the Rumor Mill page is perfectly free to pay for his own private website hosting and display the exact same information in his free time.

   I don't know exactly why U-W physics no longer wanted that webpage to be hosted on its server, but it might have something to do with a contract between the faculty member and the university concerning proper use of the physics department webspace.

   Freedom of speech doesn't mean freedom to put your speech on a website paid for by another person or institution.

HEPAP

April 22, 2004
Categories: Uncategorized

HEPAP is the Department of Energy's "High Energy Physics Advisory Panel", which holds meetings 3-4 times a year. At these meetings, people from the DOE and NSF report on the latest news about US government funding for particle physcs, and physicists from the universities and national labs report on how their experiments are going.

The latest HEPAP meeting was held this past weekend in Washington, and some of the presentations there have already been made available online. These include a detailed report on the progress of the LHC and the two experiments (CMS and Atlas) that will do physics there. The LHC construction is 90% complete, with magnets beginning to be installed in the tunnel. Things seem to be on track for turning on the machine in the spring of 2007. Optimistically, this would mean the first physics results should be available sometime in 2008.

Another presentation gave an overview of the DOE's support of university-based particle physics. This includes the largest source of support in the US for theoretical particle physics. In FY 2003 the DOE spent \$23.3 million supporting theory research at 68 universities, funding 215 faculty, 116 postdocs and 114 graduate students. The other main source of US funding for particle theory is the NSF, which spends about half as much as the DOE (\$12 million in FY 2003).

HEPAP also adopted a new report on the "Quantum Universe". This follows the trend of recent years of trying to justify particle physics research by emphasizing its relation to the very healthy and sexy field of cosmology. The acid test of this over the next few years will be to see if it helps with the difficult problem of getting funding for the Linear Collider.

Rumors Available Again

April 23, 2004
Categories: Uncategorized

The Theoretical Particle Physics Jobs Rumor Mill has a new home. It's no longer at the University of Washington, now it's at the College of William and Mary Physics department.

Now that it's available again, the Rumor Mill has the striking news that Harvard has chosen for a faculty position one of its postdocs: Lubos Motl. Lubos is well-known as undoubtedly the most rabidly fanatic string theorist around, always willing to heap abuse and scorn on anyone who questions the idea that string theory is the language in which God wrote the world. Unlike many string theorists though, he actually knows what is going on in the field and is someone who can give you an accurate view of exactly what the state of the theory is (all you have to do is strip out his ravings about how string theory is unique and the source of all good ideas in physics and mathematics). He's also not foolish enough to swallow the "Anthropic" nonsense that is becoming ever more prevalent among string theorists, and it's a been a bit scary recently to see him acting as the voice of reason in the subject.

Comments

   April 28, 2004

   I think you may already be better informed about this than I am. I took a course from Georgi when he was still a junior faculty member (and sharing an office with Witten) and remember when he got tenure. Coleman had already been tenured for quite awhile when I got there and I didn't know he had started on the tenure-track. The others you mention got tenure after I shifted over into mathematics and wasn't paying much attention to exactly what was going on in the Harvard or Princeton physics departments.

2. **gut**
   April 28, 2004

   Besides Maldacena, were Vafa, Georgi, and Coleman the only particle theory folks (in recent times) who started off their careers as junior faculty at Harvard and eventually got tenure? Was Klebanov the only recent particle guy at Princeton who started off as a junior faculty at Princeton and eventually got tenure?

3. **Peter**
   April 28, 2004

   Since Harvard and Princeton generally feel that they can hire just about anyone they want directly at the senior level, they mostly don't tenure their junior people who are nominally on the tenure track. So, for those people the reason to take the job is not so much that you are likely to get tenure there, but you'll be in a very good place for quite a few years and in a good position to jump to a tenured job elsewhere. I remember that one of my fellow Princeton grad students, Jon Bagger, did this, going from a tenure-track position at Harvard to a tenured one at Johns Hopkins where he is now. It also is not unheard of for these places to end up promoting one of their junior people. But, while at many less august places the idea is that if tenure-track people do reasonably well, they can expect to get tenure, this isn't the case at Harvard or Princeton.

   April 28, 2004

   Is there any truth to the folklore stories that assistant professor jobs at places like Harvard, Princeton, etc … aren't much more than the functional equivalent of an "extended postdoc" that lasts for 6 or 7 years? On the surface, Harvard doesn't seem to give tenure very often to folks who start off their careers there as an assistant professor.

5. **D R Lunsford**
   April 26, 2004

   Chris –

   The antropic principle has many forms. Here's one

   F = ma

   Why?

   Because I said so!

   Then there's the Dirac equation with "anthropic coupling" in psiberspace

   (ym dm + im ok you're ok) psi approx = 0

   Note that this eqn includes an explanation of "Me" generations.

   Of course there is a background-free version

   R_mu_nu_and_Tyler_2 = NULL;

   This one is easy to simulate on the computer.

   -drl

6. **Chris Oakley**
   April 26, 2004

   Am I to assume that the "Anthropic Principle" means that we postulate that "we are lucky winners of a Monte Carlo simulation in which every choice was tried and one survived?" [NB: borrowed words]. I would not mind clarification here.

7. **Thomas Larsson**
   April 25, 2004

   John Horgan wrote somewhere that Ed Witten was “the most naive ironic scientist I ever met”.
   He hadn’t met Lubos Motl.

   It is sad, really. Motl is undoubtedly very hard-working and technically skilled, perhaps even a genius. In another time, he could have used his brilliance to advance physics rather than to do the opposite.

8. **D R Lunsford**
   April 24, 2004

   Peter,

   You’re no fun 🙂

   I always imagined a place like Princeton would be just intellectual paradise. But, I’ve had friends who took PhDs at MIT, Princeton, etc. and they all seem glad to be away. I suppose in retrospect the situation at Ga. Tech in fact *was* a sort of paradise, with an unlimited copier budget and open stack library with complete series of all the major and minor journals back to inception – and a nice college bar/pizza joint about 2 blocks away and the beautiful city of Atlanta before it got too big.

9. **Peter**
   April 24, 2004

   I don’t have a lot of contact with the physics department here, although I know quite a few people over there and talk to them every so often. My knowledge of the short list for their latest job comes from the Rumor Mill. Their latest theory hire is not a string theorist.

   I first met Brian around the time he got his Ph.D. more than fifteen years ago, and interact with him regularly since he joined the department here nearly eight years ago. When he first heard about my anti-string activities a few years ago he offered me 10% of any bump he saw in sales of “The Elegant Universe”. I haven’t seen any cash.

   Math department faculty meetings are pretty boring, as well-run faculty meetings should be.

   Hmm, whoever you are, your IP number is very local. You should probably be stopping by Math 421 sometime to say hello so I can tell you the real dirt that could never be discussed in public.

10. **Tim**
    April 23, 2004

    Do you have any contact with the Columbia physics department? Regardless, has their hiring been exclusively string theorists?

    Also, what is your interaction with Brian Greene? Any interesting Math department faculty meetings?

The Good Old Days

April 26, 2004
Categories: Uncategorized

Alvaro de Rujula has posted on the arXiv under the title "Fifty years of Yang-Mills Theories: a phenomenological point of view" some of his recollections from the mid-seventies. These bring back my own memories of taking a course on particle theory from him at Harvard around 1977-78. One amusing aspect of the course was that when introducing a concept carrying someone's name, de Rujula would always say something like "this is the so-called Weinberg angle, which of course was discovered by Glashow". In one lecture he did something a bit different, saying something like "this is the Cabibbo angle, which, strangely enough, I think actually may have been discovered by Cabibbo". de Rujula's paper contains one of his famous drawings from the period and an amusing picture of Georgi and Glashow arguing. His asides are entertaining, but some so obscure I confess to not knowing exactly what he is referring to.

Today's arXiv postings also contain a review talk on the state of string theory. It discusses the "landscape" with the comment "However, with such large numbers of vacua involved, one must wonder whether the scheme is at all testable, even in principle." Normally string theory reviews start by describing the theory as the "only known" or "best candidate" or "most promising" approach to unification. This one replaces those phrases by "dominant framework", and one certainly can't argue with that.

Comments

1. **D R Lunsford**
   April 27, 2004

   Peter –

   Well the story is very interesting, and if we ever meet I'll relate it.

   IMO Zweig deserves a great deal of credit – for one thing he wasn't just thinking about symmetry, but suppressed reactions being explained by new conservation laws. "Aces" implies 4 things, so his idea foreshadowed charm before anyone had heard of strangeness. There is more to the story as told to me, which I would not feel comfortable relating here.

   There is the well-known story that Zweig didn't publish his ideas because that would have meant putting it in a CERN report instead of Physical Review. This recalls Stueckelberg's diagrams, which he also did not publish, based on the same idea as Feynman's (backward-in-time -E electron = positron).

   Of course there are many such "accidents" in the history of science.

   -drl

2. **Peter**
   April 27, 2004

   I've read various versions of the story of Zweig and his "aces", but don't know what story you are referring to.

   This is something though where I think Gell-Mann deserves the lion's credit. He (and independently Yuval Ne'eman) was the one to realize strongly interacting particles could be organized using SU(3) representations and got the prediction of the Omega-minus and its mass. I've heard that several people claim to have recognized that since you can construct all SU(3) reps out of tensor products of the fundamental 3-dim one, the existence of a fundamental triplet was a natural conjecture. The problem was that you quickly found the charges to be non-integral, disagreeing with experiment. So I think SU(3) was worth a Nobel prize, but after that postulating the existence of the triplet was not such a big deal.

   Gell-Mann was involved in another similar story, the V-A theory of weak interactions, where you'll find a whole bunch of people claiming credit for the idea around the same time.

3. **D R Lunsford**
   April 27, 2004

   In school one of my professors who was present at Caltech told me a certain story about Gell-Mann and Zweig and the issue of credit. Anyone heard it? I won't repeat it here.

   I am happy to see that these days, Zweig gets shared credit.

   -drl

4. **Peter**
   April 27, 2004

   Actually according to de Rujula, Gell-Mann claims to have discovered the Cabibbo angle, in an obscure footnote. Thus his reference to it as the "funny angle" instead of "Cabibbo angle". I also remember from long ago Howard Georgi being very amused by a Harvard secretary's typo in one of his papers. The Cabibbo "angle" had become the Cabibbo "angel".

   "The Second Creation" by Crease and Mann is by far the best book I know of about the standard model and its history, and I recommend it enthusiastically to anyone learning about particle physics.

5. **Thomas Larsson**
   April 27, 2004

   Re Cabibbo angle. I must confess that I bought Veltman's book mainly because of the last paragraph – as you can see at the Amazon.com review, he also uses the phrase "not even wrong" about string theory. However, the book contains a lot of amusing stuff. Apparently Gell-Mann insisted on calling it "that funny angle", so at one conference Cabibbo wrote "Funny Cabibbo" on his name-tag.

6. **Alejandro Rivero**
   April 27, 2004

Alvaro is a sort of “show bussiness” by himself. I remember him to actually explain the popular “turtles all way down” joke, in a speech to undergraduate/secondary school teachers, adscribing it to himself.

As for Cabibbo angle, a pesky Spanish nuclear physics teacher, recently deceased, is said to have tried to claim discovery. I do not know if Rujula was aware of it, but it could be.

7. **Chris Oakley**
   April 27, 2004

   The story of the J/Psi and charm is well told in “The Second Creation” by Robert Crease & Charles Mann. Their account is accessible to non-specialists and is as gripping as a good novel.

8. **Peter**
   April 27, 2004

   I’m sure just about all theorists are very disappointed that there hasn’t been much of an active interchange between theorists and experimentalists since the 70s. de Rujula himself has pretty much left particle physics and is doing astronomy.

   The underlying problems are that the standard model is just too good and progress on getting higher energy accelerators has been slow. If the SSC had been constructed, maybe we would already be well into a new period of exciting experimental results.

9. **D R Lunsford**
   April 26, 2004

   Peter –

   That’s a wonderful read. What exciting times! I was just learning calculus “ex curriculis” in those days – I remember some NOVA programs on the Standard Model, and the interviews with Feynman in particular. I can’t remember how I first learned about all this stuff in detail, but I know it was much later – I was really busy working through Sommerfeld’s lectures and deliberately avoided new results that I would not understand yet. In retrospect, the early to mid 80s was a great time in physics history to be in school – funny it didn’t seem that way at the time…

   The whole paper is about what got calculated and why. From this day’s perspective – how quaint 🙂

   Is there any disappointment that the theory is still in the post-phenomenology phase? Are people surprised that not a great deal more progress has been made since W/Z?

   -drl

The Fundamental Lemma

April 27, 2004
Categories: Uncategorized

For quite a few years now, when I ask my colleague Herve Jacquet about what is going on in his field, he tells me something like: "Maybe someone will soon be able to prove the Fundamental Lemma". This is a bit of a joke since the terminology "lemma" is supposed to refer to an easy to prove, simple technical result needed on the way to proving a real theorem. In this case the name "Fundamental Lemma" has ended up getting attached to a crucial conjecture that is part of the so-called "Langlands Program", and this conjecture has resisted all attempts to prove it for more than twenty years.

A few weeks ago Jacquet told me that he had heard that two French mathematicians, Gerard Laumon and Bao Chau Ngo, finally had a proof and today a manuscript has appeared on the arXiv. The techniques it uses are way beyond me (and even Jacquet claims he doesn't understand them), but are related to those used in the so-called "Geometric Langlands Program" that has interesting relations to conformal field theory.

I won't embarrass myself by trying to explain in any detail the little that I know about this kind of mathematics, but in extremely vague terms the Langlands Program relates representations of the Galois group (which tell one about the number of solutions of arithmetic problems) to representations of algebraic groups like the general linear group. One example of this kind of thing is the Taniyama-Shimura-Weil conjecture that was proved by Wiles and implies Fermat's Last Theorem. One way of approaching the Langlands program uses generalizations of the Selberg trace formula, and the lack of a proof of the fundamental lemma has evidently been the main obstruction to getting all that one would like out of the trace formula methods. Maybe someday I'll understand some of this enough to try and write something more, but that will probably take quite a while. In the meantime, one of the few expository papers I've found about the fundamental lemma is here.

Comments

1. **Peter**
   April 27, 2004

   Right now Fermat already is just a corollary of Taniyama-Shimura-Weil (as proved by Wiles-Taylor). It is quite possible that at some point Taniyama-Shimura-Weil will be a corollary of a very general theorem coming out of the Langlands program. However, this seems very far off at this point.

2. **Dick Thompson**
   April 27, 2004

   Would this mean the Fermat theorem would be reduced to a minor corollary? That's my uniform expectation about all these famous problems; they are just special cases in temporary lack of an enveloping general theory.

What Is Thought?

April 30, 2004
Categories: Book Reviews

Eric Baum was a fellow physics student both at Harvard and Princeton, completing his Ph.D. in the early 1980s on a topic in quantum gravity. During his years as a physics postdoc he came up with an argument for why the cosmological constant is so small that is sometimes referred to as the "Hawking-Baum" argument. He finally left physics, joining NEC Research in Princeton to work in cognitive science.

Eric has a new book out from MIT Press called "What Is Thought", and you can read a review by Witten on the Amazon web-site. There's also a web-site for the book.

His point of view on cognitive science is very much that of a physicist, emphasizing the way the brain encodes a very compact understanding of how the world works that has been made possible by the huge amount of computation and experiment that has taken place during the evolution of the human organism. One thing that most impressed me about the book is the underlying theme that he refers to as his version of Occam's razor and summarizes as follows:

"mind is a complex but still compact program that captures and exploits the underlying compact structure of the world."

To understand something about the world is to capture its features in a compact subroutine that allows one to effectively interact with it. This is clearly related to what theoretical physicists mean when they discuss the "beauty" or "elegance" of the fundamental equations and concepts that they are exploiting. So, if you have an interest in cognitive science, and enough interest in physics to be reading this weblog, I recommend heartily that you find yourself a copy of Eric's book.

Comments

1. **Peter**
   May 8, 2004

   My comment involved a different kind of "compactness", not the compactness of the supposed extra dimensions. A description of nature is a "compact" one if it can be expressed simply in terms of a small number of fundamental objects or ideas. A small number of simple equations, if you like. String theory is a very complex business and its proponents hope that it can be reduced to some simple principle or equation, but there is no evidence that this is the case.

2. **sol**
   May 8, 2004

   Peter,

   http://www.tech.port.ac.uk/staffweb/seahras/images/compact.jpg

   "The are several different ways in which one can "roll-up" a non compact manifold, like the one on the left, into a compact space, like the other surfaces"

   http://www.tech.port.ac.uk/staffweb/seahras/neat_physics/extra_dimensions/fifth.htm

   I looked at number 2 of your response here and what you thought of string theory as not having this compaction principle?

   What is your response to the above?

3. **Peter**
   May 5, 2004

   I guess I think of the mathematical formalisms of theoretical physics as more powerful extensions of the sort of understanding of the world built into our minds that Eric is writing about. As we try and improve them, the criteria should be:
   1. Do they agree with the real world, as our minds have managed to understand it?
   2. Are they compact, since to understand something new seems to mean to find a compact representation of it.?

   For the three theories you mention, there's still no compact form of them that agrees with the world. String theory is in the middle of desperately trying to get agreement with the world by abandoning the requirement of compactness, and adopting a huge, nearly infinitely complex theory.

4. **Sol**
   May 5, 2004

   "To understand something about the world is to capture its features in a compact subroutine that allows one to effectively interact with it. This is clearly related to what theoretical physicists mean when they discuss the "beauty" or "elegance" of the fundamental equations and concepts that they are exploiting. So, if you have an interest in cognitive science, and enough interest in physics to be reading this weblog, I recommend heartily that you find yourself a copy of Eric's book."

   As I mentioned on another site, I find the need here to understand how such mathematical discriptions are born in mind to demonstrate the natural expressions that emerge from describing that nature.

   This has been the quest as far as I understood it, from a student perspective. If one looks to Penrose or Smolin, there is always this need to explain the world from a basis of logical undertanding. So it first startsfrom a philospohcal discussion and then moves from this basis of logic, into the forms and requirments of the new math?

   Examples here would have been Twistor Theory, Loop Quantum Gravity, or String Theory.

   What are your thoughts here?

The Kostant Dirac Operator

May 8, 2004
Categories: Uncategorized

Quantum mechanics and representation theory are very closely linked subjects since the Hilbert space of a quantum system with symmetry group G carries a unitary representation of G. To the extent that one has a way of quantizing a classical Hamiltonian system with G-symmetry, one has a way of constructing representations of G out of symplectic manifolds with G-action. This "geometric quantization" approach to constructing representations has been a very fruitful one.

For the case of G compact, connected, with maximal torus T (the crucial example to keep in mind is G=SU(2), T=U(1)), the "flag manifold" G/T (the 2-sphere for G=SU(2)) is a symplectic manifold (actually Kahler) and can be thought of as a classical phase space with G-symmetry. Choosing a representation of T (a "weight") allows one to construct a line bundle over G/T, which turns out to be holomorphic. The Borel-Weil theorem says that irreducible G-representations are given by holomorphic sections of this line bundle, for "dominant" weights.

For weights that are not dominant, one gets not holomorphic sections, but elements in higher cohomology groups. These can be expressed either in terms of the sheaf cohomology of G/T with coefficients in the sheaf of holomorphic sections of the line bundle, or in terms of Lie algebra cohomology. This is known as the Borel-Weil-Bott theorem, which first appeared in:

Bott, R., Homogeneous Vector Bundles, Ann. of Math. 66 (1967) 203.

the Lie algebra version was further developed by Kostant in

Kostant, B., Lie Algebra Cohomology and the Generalized Borel-Weil Theorem, Ann. of Math. 74 (1961) 329.

Instead of using complex manifold methods and the Dolbeaut operator to construct cohomology classes, one can use spinors and the Dirac operator, with the representation appearing as the kernel of the Dirac operator (or, more accurately, its index). For this point of view, which fits in beautifully with equivariant K-theory and the index theorem, see:

Bott, R., The Index Theorem for Homogeneous Differential Operators, in: Differential and Combinatorial Topology: A Symposium in honor of Marston Morse, Princeton (1964) 71.

The Dirac operator approach to representation theory has been extended to some cases of G non-compact by various authors. In the last few years, Kostant has come up with a new version of the Dirac operator in this context which has quite interesting properties. He likes to work algebraically, so his Dirac operator on G is given as an element of U(Lie G)XCliff(Lie G), where U(g) is the universal enveloping algebra of the Lie algebra Lie G and Cliff(Lie G) is the Clifford algebra of Lie G. The Kostant Dirac operator is the standard one you would expect, with the addition of an extra cubic term. For the details of all this, see Kostant's paper:

Kostant, B. , A Cubic Dirac Operator and the Emergence of Euler Number Multiplets of Representations for Equal Rank Subgroups, Duke Math. J. 100 (1999) 447.

Things get interesting when you consider the case of H a subgroup of G of the same rank (one example is H=T, another important one is G=S0(2n+1), H=SO(2n), where G/H is an even-dimensional sphere). Taking the difference of Kostant Dirac operators for G and H gives something that corresponds to a Dirac operator on G/H, which acts on the product of a G rep with the spinors associated to Cliff (Lie G/Lie H). For H=T, one gets back the old Bott-Kostant construction of representations, but with the Lie algebra cohomology replace by the index of a Dirac operator.

Part of this story is that one finds that, starting with an irreducible G-representation, the kernel of Kostant's Dirac operator consists of a "multiplet" of H representations of size given by the Euler characteristic of G/H. The existence of these multipliets was first noticed by Ramond for the case H=SO(9), where SO(9) is the massless little group in 11 dimensions and the multiplets appear in the massless spectrum of N=1 11d-supergravity (the low energy limit of a conjectural M-theory). These SO(9) multiplets come about because SO(9) is an equal rank subgroup of the exceptional group F4, so for each irreducible F4 representation one gets a multiplet of SO(9) representations.

The first paper about this was by Gross, Kostant, Ramond and Sternberg, for more about this from a geometrical point of view, see a paper by Greg Landweber. For a discussion of the relation of this to supersymmetric models in physics, look up recent preprints by Pierre Ramond, one of which is by Brink and Ramond.

Greg Landweber has applied these ideas to loop groups, getting a beautiful interpretation in terms of loop group representation theory of certain N=2 superconformal models first studied by Kazama and Suzuki in 1989. This paper also contains a detailed exposition of the story both for finite dimensional groups and loop groups.

More recently, Freed, Hopkins and Teleman have used a modified version of the Kostant Dirac operator to give a proof of their theorem relating the Verlinde algebra and twisted K-theory. Their construction is quite beautiful and gives a new point of view on the whole story of the relation of geometric methods of quantization to K-theory and the index of Dirac operators. I'll try and write something about this at some later date.

   May 18, 2004

   JC,

   It's been a while since I looked at fundamental aspects of supersymmetry, and my own copies of the Coleman-Mandula and HLS papers are boxed away, but I could offer an answer to your question. (Though the last time I wrote about SUSY involving these papers was in my thesis, which I also boxed away, and I'm no longer an academic.)

   I believe – possibly incorrectly – that the answer is no, there have been no other ways to circumvent the Coleman-Mandula `No-Go Theorem'. I believe this is the case because:

   (a) I myself once pondered this question and either asked someone once or read up on it to provide an answer for myself, and

   (b) Doesn't the paper by HLS, or a follow-up paper by HLS, actually contain a proof that, on physical grounds (e.g. positive energy), there is no other way to circumvent the Coleman-Mandula theorem other than SUSY. That is, SUSY is the unique and only way to circumvent the constraints imposed on the S-Matrix by the Coleman-Mandula theorem?

   Please correct me if I am wrong, as I think my SUSY has become very rusty from lack of use.

   Erin

2. **JC**
May 14, 2004

Has anyone ever found any other loopholes around the Coleman-Mandula theorem, besides the Z_2 grading SUSY case covered by the Haag-Lopuszansky-Sohnius theorem?

Such as:

A*A*A ~= vector, where A is like a "one third vector"

or

B*B*B*B ~= vector, where B is like a "one quarter vector"

or in general,

Q^n ~= vector, where Q is like a fractional "one n'th vector"

3. **Peter**
May 13, 2004

I'd never heard of the "half vector" terminology, but it sounds plausible. People often say that spinors are "square roots" of vectors. More generally, given a vector space, the space of antisymmetric tensors can be identified with the spinor space times its dual.

I don't know of any way in which there would be more general fractional powers or fractions of vectors.

4. **JC**
May 13, 2004

Did Landau refer to a spinor as a "half vector"?

Is there any mathematical objects that could possibly be described as a "one third" or "one quarter" vector? Or for that matter any non-integer fractional vector?

5. **Peter**
May 12, 2004

I'm afraid the lack of much response to this post is due to it being rather obscure. I've been thinking about the Kostant Dirac operator, so wanted to write something about it, but to write something readable by a significant number of people would require giving a lot more detail. Maybe I'll try and do that at some later point.

The geometry of spinors is truly amazing, and all evidence is that it is more fundamental than the geometry of vectors and tensors. The Dirac operator is a fascinating thing, and Kostant's recent version of it is something that deserves to be better known. I hope at least some people will be inspired to look into some of this, I especially recommend the Landweber paper as being pretty readable.

6. **erinj**
May 12, 2004

Isn't it startling, Peter, how much attention a squabble over comments made in a string theory forum attracts, whereas your post on a fascinating and intriguing area of mathematics and mathematical physics seems to receive much less?

Admittedly your post is a rather technical one, but nonetheless it is illuminating. I myself find the applications and historical development of the Dirac operator continually amazing. Is there no end to its uses? No bound to its development?

Spinors and Dirac's operator seem to keep surfacing in surprising places, and always seem to simplify things when they do – as in the representation theory in your post, and in other examples such as Witten's proof (using spinors) of the positive mass theorem in General Relativity. I couldn't resist recalling Hermann Weyl's remark about spinors (and the orthogonal group) whilst reading your post:

"Only with spinors do we strike that level in the theory of representations on which Euclid himself, flourishing ruler and compass, so deftly moves in the realm of geometric figures."

It's wonderful, inspirational mathematics and mathematical physics! Now I certainly appreciate Konstant's work, which beforehand I was only very vaguely aware of, after reading your post.

The only downside, for me, upon reading your post, is not being able to access some of the papers you refer to in it, now that I have left academia :\

The Landscape at Davis

May 15, 2004
Categories: Uncategorized

I'm in Nothern California this week, and have been attending some of the talks at the conference at UC Davis celebrating Albert Schwarz's 70th birthday. The landscape at Davis is exceedingly flat, but this morning Lenny Susskind gave a remarkable talk with the title "Exploring the Landscape".

It was a pretty strange talk for a mathematical physics conference since it contained zero mathematics (and it's arguable whether there was any physics…). Susskind blamed Iz Singer for this, claiming that Singer told him he should talk about the landscape stuff since it was leading to a new mathematical field of "statistical topology". He began by holding up a copy of Steven Weinberg's "Dreams of a Final Theory" and reading a quote from it about the cosmological constant. He liked this so much he read the same quote a second time a little while later.

He then discussed some of the recent history of string theory, noting that for a long time string theorists were hoping for a mathematical silver bullet that would provide a more or less unique solution to the theory that looked like the real world. He announced that now the probability of this is less than 1 in 10^500.

Susskind then explained a bit about KKLT vacua, saying that his main reason for discussing them was to show how silly and inelegant they are. He compared them to a Rube Goldberg machine and called Shamit Kachru the "master Rube Goldberg architect".

The most dramatic part of Susskind's talk was something new: an attack on the idea of low-energy supersymmetry. He explained the standard fine-tuning argument for supersymmetry, but then indicated that he thought an anthropic argument made more sense. The reason the Higgs mass is so much smaller than the Planck mass is not supersymmetry, but instead because that small size is necessary for our existence. He said that the question of low-energy supersymmetry is something that Douglas's statistical analysis of vacua should address (Douglas will talk tomorrow), but his view is that low-energy supersymmetry will be very unlikely.

In the question session, John Schwarz challenged him about this, claiming that there were other reasons to believe in low-energy supersymmetry, including the unification of coupling constants and the idea that dark matter is the lowest mass superpartner. Susskind's response was that even though there were a couple reasons like those, there were many more that indicated problems with the idea of low-energy supersymmetry, including problems with too fast proton decay.

It was pretty amazing to see someone challenging the supersymmetry orthodoxy. On the other hand, the whole program Susskind and others are pursuing is completely loony. String theory predicts absolutely nothing, and instead of drawing the obvious conclusion that it is a useless idea, Susskind is trying to turn this failure into some perverse sort of virtue.

Update: In Michael Douglas's talk today he said that his calculations show no reason for a low-energy supersymmetry breaking scale to be especially likely. So he expects that supersymmetry will only be broken at a high energy. Maybe somebody should tell the people working on the LHC experiments that the whole supersymmetry thing is now off, they should find something else to look for.

He began by holding up a copy of Steven Weinberg's "Dreams of a Final Theory" and reading a quote from it about the cosmological constant. He liked this so much he read the same quote a second time a little while later.

   He then discussed some of the recent history of string theory, noting that for a long time string theorists were hoping for a mathematical silver bullet that would provide a more or less unique solution to the theory that looked like the real world. He announced that now the probability of this is less than 1 in 10^500.

   Susskind then explained a bit about KKLT vacua, saying that his main reason for discussing them was to show how silly and inelegant they are. He compared them to a Rube Goldberg machine and called Shamit Kachru the "master Rube Goldberg architect".

   The most dramatic part of Susskind's talk was something new: an attack on the idea of low-energy supersymmetry. He explained the standard fine-tuning argument for supersymmetry, but then indicated that he thought an anthropic argument made more sense. The reason the Higgs mass is so much smaller than the Planck mass is not supersymmetry, but instead because that small size is necessary for our existence. He said that the question of low-energy supersymmetry is something that Douglas's statistical analysis of vacua should address (Douglas will talk tomorrow), but his view is that low-energy supersymmetry will be very unlikely."

   [Sarfatti Commentary: According to Lenny's world hologram idea, the effective Planck scale Lp* should be increasing as the universe expands with scale factor R(t) in units of length as

   Lp*(t) = Lp^2/3R(t)^1/3

   This means that time's arrow is tied to the expansion of the universe with the Hawking hologram entropy of the universe S(t) obeying

   S(t)/k ~ R(t)^2/Lp*^2 ~ R(t)^4/3

   On the other hand, the effective G* from

   Lp*^2 = hG*/c^3

   cannot operate on the large scale where we know G is Newton's.

   Note that Lp*(now) ~ 1 fermi

   This is very curious, making G* ~ 10^40G, which we can posit to act only on the scale of Lp*.

Note also that Lp** = Lp^2/3(c/Ho)^1/3 is also ~ 1 fermi

Einstein's cosmological constant is /\ ~ (Ho/c)^2

where

/\ = (Lp*)^-2[(Lp*^3|Vacuum Coherence|^2 – 1]

H = R(t)^-1dR(t)/dt

Lp* ~ R(t)^1/3

So we seem to get a differential equation in this model. However, Vacuum Coherence also has a dynamics. It has a covariant Landau-Ginzburg eq with a Mexican Hat Potential for spontaneous broken vacuum symmetry.

So the idea is still not coherent in my mind, but it seems to be pointing to something important.]

"In the question session, John Schwarz challenged him about this, claiming that there were other reasons to believe in low-energy supersymmetry, including the unification of coupling constants and the idea that dark matter is the lowest mass superpartner."

[Sarfatti Commentary: This is a wrong idea. Dark matter is exotic vacuum with positive zero point pressure. Dark matter detectors will never click in principle with the "Right Stuff" to explain Omega(DM) ~ 0.23. So far observation is on my side in this hard exact prediction. The Italian claims to contrary have proved wrong. So far, so good.]

"Susskind's response was that even though there were a couple reasons like those, there were many more that indicated problems with the idea of low-energy supersymmetry, including problems with too fast proton decay."

[Sarfatti Commentary: Susskind is on right track here.]

"It was pretty amazing to see someone challenging the supersymmetry orthodoxy. On the other hand, the whole program Susskind and others are pursuing is completely loony."

[Sarfatti Commentary: But is it loony enough to be true?]

"String theory predicts absolutely nothing, and instead of drawing the obvious conclusion that it is a useless idea, Susskind is trying to turn this failure into some perverse sort of virtue."

[Sarfatti Commentary: Indeed string theory has much less observational support than

1. Flying saucers

2. Parapsychology

3. Cold Fusion

It probably has as much observational support as does Ashtekar's non-perturbative background independent quantum gravity?

I do think however that all of the above have some interesting ideas and factual support that will survive – even sting theory, oh pardon me, I meant even string theory. ;-)]

Isn't Brian Greene a member of Professor Woit's Department? You mean the landscape is not elegant? Kidding aside, I think Lenny's work is not as bad as it is made out to be below. "Sting Theory" may be a more appropriate name after all? 🙂

Lenny's holographic universe idea may turn out to be true. It is certainly very interesting.

The generalized uncertainty relation is also interesting

uncertainty in position ~ h/(uncertainty in momentum) + (quantum of area)(uncertainty in momentum)/h

is a good idea coming from black hole formation when too much energy is concentrated into too small a volume.

On Jun 19, 2004, at 9:58 AM, Doc Savage wrote:

More Landscape Stream of Consciousness

It looks like particle theory has now degenerated to the point where its leading figures can't think of anything better to do than to write rambling articles with virtually no equations that reach no real conclusions. Last week was Lenny Susskind, tonight there's a new article by Michael Douglas.

His conclusion, such as it is, goes like this:

"If I had to bet at the moment, I would still bet that string theory favors the low scale, for the reasons outlined above, but it is not at all obvious that this is what will come out in the end.… We should keep in mind that 'favoring' one type of vacuum or mechanism over another is not a strong result, if both types of vacuums exist…"

So, maybe string theory "favors" a low supersymmetry-breaking scale, maybe not. As usual, not only can't it predict anything, it can't even predict the scale at which it can't predict anything. I really cannot understand why anyone thinks this kind of thing is science."

http://www.math.columbia.edu/~woit/blog/archives/000031.html

The stupendous Landscape of sting theory vacua

"At an early stage in the Los Alamos preprint archive it was split up into hep-th (for more formal or speculative work not directly relevant to experiment) and hep-ph (for "phenomenological" papers directly related to experiment). Susskind has just come out with his latest and now seems to feel that his ideas about the "Landscape" are directly of interest to experimenters and so belong in hep-ph.

The preprint is riddled with typos, for instance the third paragraph starts like this:

"During the last couple of years an entirely new paradigm has emerged from the ashes of a more traditional view of string theory. The basis of the new paradigm is the stupendous Landscape of sting [sic] theory vacua — especially the non-supersymmetric vacua. These vacua appear to be so numerous that the word Discrtuum [sic] is used to describe the spectrum of possible values of the cosmological constant….."

You get the idea.

Some high points of the article:

1. "low energy supersymmetry – an ugly solution" to the naturalness problem. Now he tells us. From what I remember the "beauty of supersymmetry" has always been one argument made in its favor.

2. "the ashes of a more traditional view of string theory". It seems that the picture of the world according to string theory that has been heavily sold for the last twenty years has burned down to the ground.

3. The argument in his last paper, such as it was, was wrong. Now he's got a new one with a similar conclusion.

4. "… a prediction that supersymmetry will not be seen at the TEV scale seems warranted". OK, string theory is finally making a prediction.

5. "If it turns out that low energy supersymmetry is a feature of TEV physics, then we will have to conclude that other considerations outweigh the counting of vacua on the Landscape". So, even though string theory predicts no low energy supersymmetry, if it is found it doesn't mean string theory is wrong. Got it?"

4. **Peter**
May 18, 2004

I've tried to get some action on the Kaku/Horgan bet from string theorists, with no success. They don't seem to be willing to put their money where their mouth is (actually they increasingly seem unwilling to put their mouth there either: Horgan had trouble finding someone to bet against him and most string theorists are now unwilling to make any guess as to when string theory will ever predict anything).

Rube Goldberg was a cartoonist who drew cartoons of absurd complicated devices that accomplished something very simple. He seems to have fallen out of favor, these things were well-known (at least in the US) during the 60s. For an example, see

http://www.rube-goldberg.com/html/pencil_sharpener.htm

No, Susskind didn't discover branes, that's generally attributed to Polchinski. Susskind was one of the co-discoverers of string theory: he and a couple others realized that the Veneziano amplitude could be derived from quantizing a string.

Susskind isn't necessarily giving up on supersymmetry, just the idea that it will appear at accessible energies. One argument for supersymmetry at LHC energies has always been that you could then explain why the electroweak breaking scale was so much lower than the Planck mass without "fine-tuning". Susskind's argument is that one shouldn't worry about fine-tuning, just figure out what parameter ranges are consistent with human existence, and if there is a uniform distribution of string vacua with those scales, then any one is as good as any other. If so, it is very unlikely that supersymmetry breaking will happen at LHC energies, more likely it will be at very high energies near the Planck or string scale.

5. **erinj**
May 18, 2004

Well, if Lenny's right about that probability – and I hope he is – then Michio Kaku's bet on LongBets.org is almost certainly scuppered! Loser!

I mention Kaku's bet as I first mistook your report of Susskind's remark about Kachru as being one about Kaku, who I then remembered has made a long bet involving string theory at LongBets.org… ever tempted to place a bet there, Peter? Increasingly, the reports in your April 1st post look like they may yet come true!

But back to your post: I once saw a talk by Susskind and I was amazed that so many field theorists came out of his talk seemingly convinced of the validity of string theory. Like the talk you saw, I found his equally repetitive and with minimal mathematical (and physical) content.

Wasn't Susskind the guy who introduced (or, less likely, `discovered') branes? If so, I think him guilty of prolonging the atrocious waste of effort and time that string theory has and had already inflicted upon theoretical high energy physics.

Just what is all this anthropic nonsense, too? String theory is correct because we are here, and because we have `discovered' string theory? Loony all right.

I agree that to see a proponent of superstring theory, and not just string theory (as don't string theorists dislike working on plain old string theory, given how many extra dimensions and other complications string theory without supersymmetry brings with it?), loosing faith in supersymmetry is suprising. Where would matter fields in string theory be without the simplifying axiom of supersymmetry? As far as I know, all those elaborate intersecting brane theories in which the Standard Model supposedly appears depend upon SUSY at higher energies neatly tying things together.

Also, shouldn't string theorist's listen to the experimentalists? (Not more, but in the first place, I mean 🙂

About two years ago I saw a talk by an experimentalist working on some DESY experiment involving a search for `low-energy SUSY', and he stated that their results permitted them to categorically rule out the lightest possible SUSY superpartner, the higgsino, at the present highest energies attainable (though perhaps a heavy Higgs or something might rescue this). So even back then low-energy SUSY looked unlikely, according to the people who actually go out there and look for these things. I certainly came out of that talk with much less belief in SUSY.

By the way, who or what is "Rube Goldberg"?

More From Davis

May 17, 2004
Categories: Uncategorized

The last two talks at the Davis conference were quite interesting. Alexandre Givental gave one entitled "Twisted Loop Groups and Gromov-Witten Theory", which went by way too fast. He has an interpretation of the generating functional for Gromov-Witten invariants that uses a loop group. Some infinite dimensional symplectic geometry involving this group gives a conjectural explanation of the properties of these invariants. The talk covered a lot of material so, while intriguing, was quite hard to follow.

Witten gave the last talk, and his philosophy was the opposite of Givental's. He covered only a little material, at a level that was easy to follow. The nominal topic of his talk was his recent work on the relation of strings in twistor space to gauge theory scattering amplitudes, but he didn't really get to this. He began by saying that there were at least a couple different possible talks he could give about the background to his recent work. One was the one he gave a couple weeks ago at a conference at NYU which covered gauge theory scattering amplitudes. Luckily for me since I had heard that one, he decided to give a different one at Davis, mostly covering some of the ideas about twistors used in his work. He discussed the twistor theory construction of an SU(2,2) representation using the massless single particle solutions of a fixed helicity. This is related to a non-compact version of the Borel-Weil-Bott theorem, constructing a representation on a higher cohomology space. Presumably one could also do this using the Kostant Dirac operator techniques I mentioned recently.

Comments

1. **Peter**
   May 21, 2004

   SU(n,n) means special unitary transformations that preserve a metric of signature (n,n) (i.e. 2n-dimensional complex space with metric with n + signs and n – signs). For supergroups people write them with a bar, like SU(n|n) for a group with n bosonic and n fermionic generators.

   Part of the twistor story is that SU(2,2) is the group of conformal transformations in 4d.

   There are a lot of different ways of thinking about twistors, but they are pretty natural objects if you are thinking about the geometry of spinors in 4d in a way that makes explicit the conformal symmetry.

   I'm also mystified about why Witten remains such a believer in string theory. I think one reason he keeps working on it is that there continue to be interesting relations between string theory and gauge theory, so even if it doesn't work as a unification idea, string theory can still lead to interesting new ways of thinking about gauge theories (e.g. AdS/CFT).

   His recent work has certainly lead to interesting results about perturbative gauge theory amplitudes, although the relation to string theory seems somewhat tenuous to me even though it is clearly a big part of his motivation.

2. **erinj**
   May 21, 2004

   I saw Witten's paper and thought that this was another attempt to concretely link string theory with gauge theory, or to indicate that gauge theory is contained within string theory in a convoluted manner and therefor subsumes it – thus demonstrating the correctness or superiority of string theory. This has been attempted before, hasn't it, with things like AdS/CFT, dualities, etc. Surely if this strategy was correct, they would have found much simpler and more obvious connections between string theory and gauge theory than all this stuff about bulks and boundaries, SUSY, AdS, SUGRA and twistors.

   It seems to me as if the string theorists are grasping at straws with this approach – that is, try and dig up gauge theory quantities out of string theory in peculiar situations. They just keep re-hashing the same old arguments and try and squeeze gauge theory out of strings all the time. I'm a fan of Witten's marvellous non-string theory work (e.g. SUSY QM & Morse theory, TQFT & knot theory, bosonization, Seiberg-Witten/Donaldson theory, QFT & elliptic genera, etc.), and I thought his Fields Medal was a crowning achievement, but why he keeps on spending so much cerebral energy on string theory mystifies me.

   Also, it would seem preferable, and surely much simpler, to build representations on higher cohomology spaces using the Kostant Dirac operator and spinors than with twistors, which appear to be far less intuitive objects and are harder to work with.

   Incidentally, Peter, I've always had some confusion over the notation SU(n,n) – isn't the (n,n) notation something to do with the signs of the metric components? And isn't SU(n,n) a `supergroup', meaning that it's Lie algebra is modified to include anti-commutators (as with the super-Poincare group)? I ask as I've never been able to find a proper definition for this notation or a reference which defines it clearly.

3. **Pyracantha**
   May 17, 2004

   I am looking forward with a kind of eschatological eagerness to the time when I will be able to recognize and understand what you are talking about in this entry, and what the speakers at that conference are talking about. However, by the time I get that far in my physics and math self-education project, all of that will probably be very obsolete.

More Crackpots

May 19, 2004
Categories: Uncategorized

Slate this morning has an article by Jim Holt about an interview with Andrei Linde. In the interview, Linde speculates that universes like ours could be created in a lab, that maybe we live in such a universe, and that the creator of such a universe could communicate with his/her creations by tuning the parameters of its "Landscape".

Comments

1. **Peter**
   May 21, 2004

   I heard Linde talk about inflation and the landscape at Davis, and his talk was no more crackpot than others. Still I don't understand why he thinks it is a good idea to sit around promoting the idea that maybe we live in a universe created by an intelligent being who may try and communicate with us through the fundamental parameters of physics. That's definitely over the line into serious crackpot territory.

2. May 21, 2004

   As far as I know Linde's idea is not new. It is his version of inflationary scenario, called chaotic inflation. The only new component in the story is its connection to string landscape.

3. **erinj**
   May 19, 2004

   This idea has already appeared before in science fiction (Gregory Benford's `Cosm') and is not science. So I agree, Peter, I'm awaiting the arrival of the `SuperCosmos' bandwagon, hope to leap on it, publish trillions of papers on it (say, at one a month) and become an eminent physicist with permanent tenure and a big office.

   If an `eminent' physicist like Linde can borrow such ideas and promote them as science, what is the scientific world coming to?

   Perhaps the book store clerk who placed that copy of F. David Peat's `Superstrings' book I once found in the science fiction section was doing the right thing after all…

   (Incidentally, I've just seen a book titled `Superstrings and Other Things: A Guide to Physics', by Carlos Calle, and it's a British product… as if superstrings are established physics! The shame of it – using string theory's hype and media presence to sell a book about physics!)

   Given that the vague term "landscape" keeps cropping up in association with strings, perhaps somebody should write up a glossary of string theory buzz-words/phrases or `flavours of the month' for easy later reference, which would also help chart the mess the `theory' has gotten itself into.

4. **Simplex**
   May 19, 2004

   Peter, great blog!
   I have to admit Linde's interview (in which I detected humor and irony) could be gravely misconstrued and abused by a religious Told-you-so.

   But the journalist warned his readers about Linde's irony before getting into it:

   "Linde, it should be said, is famous for his mock-gloomy manner, and these words were laced with irony. But he insisted that this genesis-in-a-lab scenario was feasible, at least in principle…"

   and he included this rather irreverent quote from Linde:

   '"You might take this all as a joke," he said, "but perhaps it is not entirely absurd. It may be the explanation for why the world we live in is so weird. On the evidence, our universe was created not by a divine being, but by a physicist hacker."'

   I suspect there is nothing new here, just Linde's usual schtick. And it sounded as if Linde's imagined Hacker was communicating to us mainly, if at all, by chosing basic dimensionless constants like the ratio of proton to electron mass
   1836.152…
   if a nut wanted to decode those digits and discover the ten commandments then he could have already started working on the number pi.

   "But then Linde thought of another channel of communication between creator and creation?the only one possible, as far as he could tell. The creator, by manipulating the cosmic seed in the right way, has the power to ordain certain physical parameters of the universe he ushers into being. So says the theory. He can determine, for example, what the numerical ratio of the electron's mass to the proton's will be. Such ratios, called constants of nature, look like arbitrary numbers to us: There is no obvious reason they should take one value rather than another…But the creator, by fixing certain values for these dozens of constants, could write a subtle message into the very structure of the universe…"

   I guess I want to say I wasn't as shocked as you and Linde seems less goofy than Sarfatti to me—and more entertaining.

5. **Chris Oakley**
   May 19, 2004

   Personally, I subscribe to the views of the Jatravartid People of Viltvodle Six. They firmly believe that the entire universe was sneezed out of the nose of a being called The Great Green Arkleseizure. They live in perpetual fear of the time they call The Coming Of The Great White Handkerchief.

   But seriously … however wacky people may think Linde or other's ideas about Cosmology, it is hard to prove them wrong. Why? Because (in my humble opinion, obviously) Cosmology is not a science, and probably never will be. Maybe it would help if people concentrated on ideas that *can* be proved wrong.

Attack on the Main Argument for Supersymmetry

May 19, 2004
Categories: Uncategorized

The hundreds of expository articles about supersymmetry written over the last twenty years or more tend to begin by giving one of two arguments to motivate the idea of supersymmetry in particle physics. The first of these goes something like "supersymmetry unifies bosons and fermions, isn't that great?" This argument doesn't really make a whole lot of sense since none of the observed bosons or fermions can be related to each other by supersymmetry (basically because there are no observed boson-fermion pairs with the same internal quantum numbers). So supersymmetry relates observed bosons and fermions to unobserved, conjectural fermions and bosons for which there is no experimental evidence.

Smarter people avoid this first argument since it is clearly kind of silly, and use a second one: the "fine-tuning" argument first forcefully put forward by Witten in lectures about supersymmetry at Erice in 1981. This argument says that in a grand unified theory extension of the standard model, there is no symmetry that can explain why the Higgs mass (or electroweak symmetry breaking scale) is so much smaller than the grand unification scale. The fact that the ratio of these two scales is so small is "unnatural" in a technical sense, and its small size must be "fine-tuned" into the theory.

This argument has had a huge impact over the last twenty years or so. Most surveys of supersymmetry begin with it and it justifies the belief that supersymmetric particles with masses accessible at the LHC must exist. Much of the experimental program at the Tevatron and the LHC revolve around looking for such particles. If you believe the fine-tuning argument, the energy scale of supersymmetry breaking can't be too much larger than the electroweak symmetry breaking scale, i.e. it should be in the range of 100s of Gev- 1 Tev or so. Experiments at LEP and the Tevatron have ruled out much of the energy range in which one expects to see something and the fine-tuning argument is already at the point of starting to be in conflict with experiment, for more about this, see a recent posting by Jacques Distler.

Last week at Davis I was suprised to hear Lenny Susskind attacking the fine-tuning argument, claiming that the distribution of possible supersymmetry breaking scales in the landscape was probably pretty uniform, so there was no reason to expect it to be small. He believes that the anthropic explanation of the cosmological constant shows that the "naturalness" paradigm that particle theorists have been invoking is misguided, so there is no valid argument for the supersymmetry breaking scale to be low.

I had thought this point of view was just Susskind being provocative, but today a new preprint appeared by Nima Arkani-Hamed and Savas Dimopoulos entitled "Supersymmetric Unification Without Low Energy Supersymmetry and Signatures for Fine-Tuning at the LHC". In this article the authors go over all the problems with the standard picture of supersymmetry and describe the last twenty-five years or so of attempts to address them as "epicyclic model-building". They claim that all these problems can be solved by adopting the anthopic principle (which they rename the "structure" or "galactic" or "atomic" principle to try and throw off those who think the "anthropic" principle is not science) to explain the electroweak breaking scale, and assuming the supersymmetry breaking scale is very large.

It's not suprising you can solve all the well-known problems of supersymmetric extensions of the standard model by claiming that all effects of supersymmetry only occur at unobservably large energy scales, so all we ever will see is the non-supersymmetric standard model. By itself this idea is as silly as it sounds, but they do have one twist on it. They claim that even if the supersymmetry breaking scale is very high, one can find models where chiral symmetries keep the masses of the fermionic superpartners small, perhaps at observably low energies. They also claim that in this case the standard calculation of running coupling constants still more or less works.

The main experimental argument for supersymmetry has always been that the running of the three gauge coupling constants is such that they meet more or less at a point corresponding to a unification energy not too much below the Planck scale, in a way that works much better with than without supersymmetry. It turns out that this calculation works very well at one-loop, but is a lot less impressive when you go to two-loops. Read as a prediction of the strong coupling constant in terms of the two others, it comes out 10-15% different than the observed value.

I don't think the argument for the light fermionic superpartners is particularly compelling and the bottom line here is that two of the most prominent particle theorists around have abandoned the main argument for supersymmetry. Without the pillar of this argument, the case for supersymmetry is exceedingly weak and my guess is that the whole idea of the supersymmetric extension of the standard model is now on its way out.

One other thing of note: in the abstract the authors refer to "Weinberg's successful prediction of the cosmological constant". The standard definition of what a prediction of a physical theory is has now been redefined down to include "predictions" one makes by announcing that one has no idea what is causing the phenomenon under study.

Comments

1. **Aaron**
   May 23, 2004

   To various people, I'm sorry, but I really don't have to time to answer questions on QFT in a comments thread. You might want to consider posting to sci.physics.research. Anyways, various theories of SUSY breaking do have hidden sectors in which the breaking occurs and is then transmitted in some way to the visible sector. Finally, it's a theorem that particles statistics are governed by one dimensional representations of the fundamental group of the configuration space of n points in *space*. For d>2, that's the symmetric group and the only reps are the trivial and the antisymmetric one. In two dimensions, it's the braid group which has all sorts of fun one dimensional representations. This gives what are called anyons.

   To Peter, I continually wonder what physicists you hang out with. None of this stuff is secret. I was at a department wide talk which brought this stuff up in the past few months. Again, I'm rather curious what else you would have us tell the experimentalists to look for.

2. **Peter**
   May 23, 2004

   Hi Aaron,

   I wasn't under the impression that the degree of fine-tuning needed if the bound on the Higgs goes up by 5-10 Gev was such that it would cause people to give up on supersymmetry. If so, one might not even need to wait for the LHC if the luminosity at the Tevatron improves sufficiently.

   There are at least two reasons why a lot more honesty about the failings of low-energy supersymmetry would be a healthy thing (and I don't see a downside since I don't think there's any danger the experimentalists at the LHC won't look for superpartners).

   1. Experimentalists deserve an honest appraisal of how likely various possibilities are so they can make intelligent allocations of their resources.

   2. The dishonesy and over-hyping of supersymmetry is part of a larger problem in particle theory. The amount of this in superstring theory/M-theory is vastly greater, and no experiments are likely to save us from this there. Theorists should start behaving a lot more like scientists, with a lot less hype and a lot more healthy skepticism about ideas that don't work.

3. **Peter**
May 23, 2004

Hi Chris,

Sure, you can add other gauge groups, but if the particles we see have charges with respect to them, they'll experience a new force and will behave differently, so there are all sorts of bounds on such a thing.

If you assume that the particles we know about are all uncharged with respect to the new gauge group, then it is a "hidden sector", and its effects will be hard to observe (perhaps only through gravity).

4. **Peter**
May 23, 2004

Hi JC,

The "Planck Scale" is only the scale of quantum gravity if you assume that however you calculate the effective Newton's constant, you get dimensionless numbers of order unity and dimensionful ones coming from the scale. If the calculation of the effective Newton's constant contains an exponentially small dimensionless number, the scale could be quite different.

I don't see any reason to try and get the standard model forces as induced from some other theory, but people have speculated that quantum gravity is induced from the other gauge forces. One intriguing fact about 2d WZW models is that they can be formulated as theories with a gauge (or loop group) symmetry, but the Sugawara construction shows they automatically also are non-trivial reps of the diffeomorphism group, so in some sense one is getting for free a theory of gravity from a theory with just a gauge symmetry.

5. **JC**
May 23, 2004

On a different note, how do we know that the known elementary particles ONLY obey bose and fermi statistics? How do we know that they are NOT obeying more general parabose and parafermi statistics, or for that matter some other generalized permutation symmetry groups?

6. **Chris Oakley**
May 23, 2004

There is a point raised by JC that I have never heard discussed, but I feel ought to be taken seriously. If there was a "new" kind of force that conserved all the quantum numbers of (say) the Strong interaction, but was much weaker, how would we ever know about it? What is to stop me claiming that SU(3)xSU(3)xSU(2)xU(1) is the "real" theory of the world with my weak-strong interaction as the other SU(3)?

7. **Aaron**
May 22, 2004

That should be

G = <T>

the expectation value of the stress energy tensor.

8. **Aaron**
May 22, 2004

Just by dimensional analysis, the Planck scale is the scale where gravity becomes relevant. On the other hand, the Planck scale might not actually be what we think it is. Some theories with extra dimensions have the Planck scale and the weak scale coinciding.

The problem with keeping gravity classical is that you have to couple it to quantum stress energy. The obvious way to do that

G =

has problems. I'm open for suggestions on other ways to do it. Sakharov's induced gravity gets things off by orders of magnitude as I remember it, but I don't remember it very well.

Epicycles are completely irrelevant here. When you add epicycles, it means you're adding parameters to your theory to account for the fact that the theory doesn't fit the data. The standard model fits the data amazingly well.

There are theories where gravity unifies at the same point as the other forces. GUTs are going to have massive gauge bosons at the scale of the breaking. You can break large gauge groups in stages E8 -> E6 -> SO(10) …, for example. There's all sorts of stuff that can happen, really.

The almost convergences of the couplings was not imposed in any form. It follows directly from the formulae.

Finally, I doubt the electroweak forces and QED are "induced" in any way (I'm not sure what that would mean, really.) The theories that we have for them now work just fine.

9. **JC**
May 22, 2004

Aaron,

I never quite understood exactly why the scale for a quantum theory of gravity has to be taken at the Planck scale specifically. Are there any rigorous and/or mathematical arguments which shows that this always has to be the case? Why can't the quantum gravity scale be at something like several million or billion TeV's, or for that matter several billion or trillion times larger than the Planck scale itself? Is the Planck scale for quantum gravity just accepted on faith or by fiat decree?

Is there a possiblity that gravity is just strictly a classical force with no quantum counterpart? Are there any experiments that have confirmed any quantum gravity phenomena, such as the Unruh effect? (Would the Unruh effect even be a good candidate to search for in a tabletop experiment?) Is this belief in quantum gravity just an extrapolation of the three other forces being quantized? Could gravity just be nothing more than a "residual force" produced by higher order quantum effects, in the style of Sakhrov's induced gravity?

On the surface, adding in more particles, symmetries, and other "junk" into the standard model feels a lot like adding in more "epicycles" and free parameters into an already grotesque looking theory. (Well, maybe not completely "grotesque" looking.) Could the electroweak and qcd forces be an "induced" force of some sort, in the spirit of Sakharov?

With the idea of three coupling constants merging at one point at some high energy scale, why doesn't gravity also converge too to that exact same point as the other three coupling constants? Or for that matter if there's a 5th or 6th force that we aren't aware of yet, would their coupling constants also converge to this exact same point too? Is this convergence point just something that was noticed by running the coupling constants to higher energy scales, or was it imposed a priori by fiat decree?

10. **Aaron**
May 22, 2004

There are a few answers to your question about the standard model. The most obvious is that it doesn't incorporate gravity and we've got pretty good evidence that gravity exists, so any theory really ought to include it. One can ask at what energy scales does a quantum theory have to take gravity into account. The answer to that is approximately the Planck scale. That's why it's important.

The other answers are a bit more technical. One is that, as has been discussed a bit here, the standard model isn't natural. There are two types of naturalness, actually. What it really comes down to, however, is that the scale of the electroweak interaction is much, much smaller than the Planck scale. We don't know why this is true. This is dissatisfying.

There's also technical naturalness which says that the Higgs mass is naturally at the Planck scale because of loop effects. Supersymmetry stops this from happening. So, why it doesn't explain why the weak scale is so much smaller than the Planck scale, it does stabilize the Higgs mass.

A third reason to believe that there might be something beyond the standard model is that if you were to draw three random lines on a piece of paper, there's little chance they'll intersect at a simply point. Nonetheless, if you look at the runnings of the coupling in the standard model, you get three lines to come reasonably close to intersecting. This is a coincidence that is not explained by the standard model. It could just be random, of course, but it could also be a clue.

As for why finding just the Higgs would be depressing, where would we go, then? Building a larger accelerator is unlikely. It means that this dataless purgatory we currently inhabit is likely to last for the foreseeable future. That would suck.

11. **Aaron**
May 22, 2004

If you don't like fine tuning, then, as I understand it, there's just not much more room for the Higgs left. Another 5 or 10 GeV and you've got issues. Are you telling me that other considerations give you the same bounds?

"I just think that if one is honest one sees that the GUT and low-energy supersymmetry ideas are failures. If you don't acknowledge failure and keep promoting failed theories you're not doing science anymore."

Such pessimism. You can't wait five more years for them to turn on the damn machine before you make these sweeping pronouncements? Even if you want to argue that, in your sense of the word, SUSY makes no predictions, I assume you agree that there are plenty of things that would strongly support SUSY if discovered at the LHC? Are we now not only theorizing without the aid of experiment, but also pronouncing theories abject failures before even attempting to test them?

Let the experimenters do their work. If they just see a Higgs, we all go home. If they see SUSY, then, presumably you admit it wasn't a completely false direction to purse, and we start measuring the weak SUSY breaking parameters. If we see something else entirely unlike SUSY, we all go out and study that.

That's the joy of experiment.

12. **JC**
May 22, 2004

Are there any empirical reasons why the standard model is NOT the final answer to particle physics?
Or is it mainly ideological or philosophical reasons why people think the standard model is not the final answer?

Why would finding the Higgs particle be a depressing event? Could there be a 4th or 5th family of quarks/leptons heavier than the mass of the Higgs?

Why should we take the notion of a "Planck scale" energy seriously? Could it be possible that the "Planck energy" is just a product of several known physical constants which produces a "number" that has no physical relevance in the real world? Is there any empirical and/or fundamental reason why Newton's gravitational constant is important at higher energy scales?

13. **Aaron**
May 22, 2004

There are unitarity arguments that tell us something has to happen really soon. There are Higgsless models of EWSB. The ones I've heard about use boundary conditions in extra dimensions, but there could be others. I don't want to say too much because I really don't know much about them, but I'm pretty sure they predict something happening at LHC.

People might find this paper interesting as an outlook on what might come:

hep-ph/0312096

If you ask any particle physicist what lives in their nightmares about the next few years, the answer is this: that the LHC discovers a Higgs, and that's it. Everything is completely described by the standard model. If that happens, we might just all have to go home.

14. **Peter**
May 22, 2004

The proliferation of undetermined parameters in supersymmetric GUTs comes not just from the supersymmetry breaking, but also from the GUT symmetry breaking (via the Higgs mechanism or whatever). In principle one can hope that some compelling model for supersymmetry breaking exists that predicts the 100 or so parameters, but the fact of the matter is that all pheonomenologically viable methods of supersymmetry breaking are complicated, contrived, and don't do much in the way of fixing those parameters.

I really wish people would reserve the term "prediction" for its standard usage: one has a well-defined model in which something is calculable and you calculate it. In the standard supersymmetry picture, you don't know what causes supersymmetry breaking or even what its scale is, and the mass of the Higgs is constrained only by the very vague "naturalness" principle (just how much fine-tuning is too much?).

Essentially all low-energy supersymmetry and naturalness are telling you is that the Higgs can't be too heavy. But there are other reasons for that (Higgs sector becomes strongly coupled if the Higgs mass is too high), so it isn't really telling you anything new.

If I had a successful extension of the standard model I'd be preparing my speech for Stockholm. I just think that if one is honest one sees that the GUT and low-energy supersymmetry ideas are failures. If you don't acknowledge failure and keep promoting failed theories you're not doing science anymore.

15.
May 22, 2004

How would the picture of the standard model change if no Higgs particle is discovered for several hundred thousands of TeV above 1 TeV? What viable mechanisms could replace the Higgs in this case?

16. **Aaron**
May 22, 2004

SO(10) also nicely accommodates neutrino masses. The dark matter candidate is also more robust than you indicate, I think. If you just write down general Lagrangian, it's easy to find Flavor Changing Neutral Currents (FCNCs) from SUSY. One way to eliminate them is by imposing a symmetry called R-parity by fiat. This then necessitates a Lightest Supersymmetric Partner (LSP) that fits all the cosmological requirements for a WIMP.

The 100 or so parameters you refer to are in the weak SUSY breaking lagrangian. They really parametrize our ignorance. One expects that when the mechanism of SUSY breaking is understood (assuming low energy SUSY really exists), there will be tons of relations among the parameters of that lagrangian. It would probably work the other way around. We'd measure the parameters in the weak SUSY breaking lagrangian, discover relations and use that to better understand the mechanism of SUSY breaking. Regardless, the idea that there really are 100 (or whatever) free parameters isn't really true.

I already gave you a prediction of SUSY: the light Higgs. That it hasn't been seen is one reason, I think, that people are getting a bit more skeptical. Also, one would hope to see all sorts of fun stuff at the LHC.

No one's claiming SUSY is perfect. But, before you knock it too much, what other extensions of the standard model do you propose people study? Because, believe me, people are always interested in something new.

17. **Peter**
May 22, 2004

Hi Aaron,

At some point soon I'll try and write up a more detailed discussion of the pros and cons of supersymmetry. The issues have been around now for more than two decades and the only interesting change I've seen recently is that Witten is concerned enough about this to have given several talks in the past year or two discussing the problems with supersymmetry. Also,now Susskind, Arkami-Hamed and Dimopoulos seem willing to argue that the problems of low-energy supersymmetry are such that perhaps the idea should be abandoned.

The standard ideology is that the idea of low-energy supersymmetry combined with grand unification is, as you say, "very compelling". I've always disagreed with this and continue to do so strongly. I think the only statement that can be defended is that the idea has aspects that are "suggestive". The two best arguments for this ideology are:

1. The fact that the particles in one generation fit rather naturally into the SO(10) spinor representation.

2. The coupling constant unification, which is off by 10-15%, an amount one could hope to ascribe to threshold effects.

(A third standard argument, that in this framework there is a candidate particle that could be dark mattter, seems to me such a weak argument that I don't think it is worth taking very seriously)

I don't think either of these is "very compelling", partly because they come at a huge cost. A supersymmetric GUT is a vastly more complex theory than the standard model with at least 10 times more undetermined parameters. In return for this huge increase in the complexity of the theory, one gets the measly return of the two points mentioned above and a huge number of problems one has to find some way of arguing away (too much baryon number violation, FCNC, CP violation, etc.)

The huge number of undetermined parameters and lack of any idea of what the supersymmetry breaking scale is mean that it is extremely hard to get a real prediction out of this framework. The closest thing to one would be that of proton decay, but even here a prediction is possible only in a very tenuous sense. For a generic choice of the undetermined parameters one gets proton decay faster than experimentally observed. One can choose parameters that make the rate much smaller, although there is a point at which you run into trouble doing this. So supersymmetric GUTs are consistent with a huge range of possible proton decay rates, which is not exactly much in the way of a prediction.

18. **Aaron**
May 22, 2004

There's no trial going on. As I'm sure you know, the standard model works depressingly well. SUSY extends it in useful ways. In addition to what I've mentioned it also provides a useful candidate for a WIMP. The fact that it does this, betters coupling unification and sort-of-solves the naturalness problem seems like pretty good reasons to look at it.

With the Higgs not found yet, that's a strike against it, sure. But, why the opprobrium? It's a very nice idea that may or may not be correct.

As for doing QFT rigorously, none of the directions that I've seen out there interested me all that much. I'm glad people out there are working on it, and I'm glad they aren't me. In the meantime, QFT works pretty damn well as we use it, so I'm not too constrained.

19. **Chris Oakley**
May 22, 2004

Aaron –

One difference between a civil and a criminal case in English law is that the verdict is based on the "balance of probabilities" in a civil case, whereas "proof beyond reasonable doubt" is required in a criminal case. With SUSY in the dock, I would deliver the former verdict against it, but not the latter. To put it another way, I do not think that SUSY is leading anywhere good (and I am not sure that I ever did). Feel free to prove me wrong, though.

As for the Millenium Prize, the fact that it exists at all is proof enough of failure on all of our parts. We should not be relying on someone to provide a silver bullet to cure the elementary problems of QFT. More people should be working on solving these problems: not just a handful of German mathematicians. I did what I could – what did *you* do?

20. **Aaron**
May 21, 2004

There are plenty of QFTs without Lagrangian descriptions. Look up minimal models in CFT, for example.

Also, of course SUSY has guided experimental searches. You have to trigger on something, and SUSY has been the most viable extension of the standard model for quite a while. I don't think anyone would argue that it's not worthwhile to look for. Experimentalists trigger on all sorts of other things however.

SUSY favors a light Higgs, by the way. (The tree level prediction is around the Z-mass, I think, which is what's being referring to. Loop effects push it up.) In fact, the nondiscovery of the Higgs below 115 GeV or so has begun to push SUSY into the realm of fine tuning. Push it up too much more and the model loses a lot of its appeal.

The equation of string theory and SUSY is not a good idea. There are plenty of reasons to believe SUSY completely irrespective of strings. As you allude to, the two major ones are that it seems to protect the hierarchy of the weak scale versus the Planck scale (although I think this gets a bit iffy when you actually break the thing). The second is that, in the standard model, if you run the couplings up a ways, they almost unify, but not quite. If you add in SUSY, this agreement gets a lot better. If you believe that it's too much a coincidence for the coupling to almost unify, then the fact that SUSY gets them closer is a big deal. Unfortunately, apparently, the two loop calculations spoil this a bit. Nonetheless, it's still better than the standard model.

I'm rather surprised by the statement "The GUT and supersymmetry ideas have been intensively investigated, but don't lead to any convincing predictions or compelling picture." This is certainly false. The pictures are very compelling. The unification of the couplings points towards GUTs. The SO(10) GUT has a number of nice properties. GUTs also make predictions, the most important being proton decay. For this reason, the nonsupersymmetric SU(5) GUT is pretty much dead. IIRC, the supersymmetric SU(5) GUT isn't doing so well, either, though there may be more room for fudging on that.

SUSY also makes predictions like the light Higgs and presents a very compelling picture. If you think that the only reason people work on supersymmetry is because string theorists need it, trust me when I tell you that the idea is laughable.

The fact is that if you can come up with an interesting extension of the standard model, people would be very interested in. Precision electroweak measurements strongly constrain what you can do. For example, I always thought technicolor was a very pretty way to resolve the hierarchy problem and get rid of the Higgs kludge. Unfortunately, it has also been almost completely killed by experiment.

I also want to note that I don't think anyone has a problem with the infinities in individual diagrams in QFT. There are prescriptions which avoid this, but the regularization procedure both works and is understood. This is not to say that we understand QFT. I don't think we do. I'd love to replace it with something better defined. There's a million bucks waiting for you if you manage to do it, so good luck.

Lastly, I'm sort of astounded how you manage to draw such sweeping conclusions from such minor issues. You want to believe that the field is much more dogmatic than it really is. Nobody's abandoned much of anything, much less "the main argument for supersymmetry". In fact, what is being done is that people are exploring new directions. I would think that you would think that this is a good thing. For a long time, people thought that naturalness was a useful criterion for model building. If some version of the anthropic principle turns out to be correct, then we can abandon naturalness for certain (but *not all*) parameters. This opens up the possibility of new, possibly, interesting models to explore. That's what Nima and Savas are doing.

I like exploration. Don't you?

21. **Steve**
May 21, 2004

It looks increasingly likely that supersymmetry (and supergravity) has had its day and it is probably not a true symmetry of nature, even in broken form. Nature (or god if you prefer) is not obliged to follow the aesthetic ideals of mathematicians/physicists and might not even care about mathematical beauty/elegance as much as we do. If anything, this universe is looking more and more messy, inelegant and confusing! Personally though, I always found the idea of pairing off known bosons and fermions with superpartners like "squarks" artificial and I would bet money that none of
these "sparticles" are ever going to show up in any upcoming experiments. This is especially serious for string theory and "M-theory", where supersymmetry is required of course in order to wield any analytical control (and to get the dimensions down to a mere 10.) It was the Green-Schwarz superstring that started the whole string craze back in 1984 after all. Before that nobody simply cared. Even if superparticles did turn up in future experiments it does'nt prove string theory but does make it more likely; but without supersymmetry somehow existing in nature the work of the past 20 years all crumbles–back to the much maligned old bosonic/tachyonic string in 26 dimensions. In effect string theory sinks like a lead hippopotamus without supersymmetry. Of course string theorists will conveniently take refuge in arguments that supersymmetry is manifest only at immense energies
just like they are now taking refuge in cop-out anthropic arguments. Supersymmetry and the consequent superstrings were indeed powerful and promising mathematical ideas and were worth pursuing, but are wearing a bit thin now after 20 years.

22. **JC**
May 21, 2004

Is there a possibility that the only reason why quantum field theory and renormalization is "accepted" these days, is that nobody else has found a better theoretical framework which does NOT produce garbage calculations? It seems like any framework that increases the amount of calculational labor involved, just to get the same results as quantum field theory, largely gets ignored for the most part after awhile. Why bother with these "alternative" frameworks when they reproduce the same results (with many more times the labor involved) as ordinary quantum field theory?

If quantum theory is more "fundamental" than classical physics, why do we still use the framework of Lagrangian dynamics as a "stepping stone" to eventually do quantum field theory? Is this just another case of "nobody has found a better way to do things"? Are there any "intrinsic quantum" frameworks which do NOT involve the intermediate step of using Lagrangian dynamics with an "ad-hoc" quantization prescription?

Are there any better quantum entities to calculate, besides the S-matrix?

Should we even believe that quantum theory retains it's present form, when we go to higher and higher energy scales?

23. **Peter**
May 21, 2004

One thing I've wondered about is how heavily the search for supersymmetry is biasing the data analysis or even experimental design of detectors. In the worst case it might affect the design of the triggers. Presumably experimentalists have a healthy enough skepticism about theory that they are likely to not believe in the supersymmetry picture too strongly.

Still, maybe they should be made aware of exactly how tenuous the argument for supersymmetry really is.

24. **Alejandro Rivero**
May 21, 2004

A recent worry I have got is to wonder if SUSY was even biasing the results of experiments. Some years ago, a small signal was detected for a charged Higgs at L3 in CERN in a quark channel. Regretly it was 69 GeV thus too low for MSSM. Fast, it was averaged with measurements in *lepton* channels so the effect went down from 3.5 to less than 2 sigmas; and then the next edition of the pdg claimed a 95%confidence level above 75 GeV… I am thinking that all this "manoeuvre" was justified only if the faith in SUSY was (is) so strong as to be sure that H+ runs well above the Z0 mass.

25. **Chris Oakley**
May 21, 2004

Hello Matthew,

We are digressing from the main topic, so when I have had a chance to collect my thoughts, I will answer you by e-mail.

One last thought in regard to the main topic: if we are marking the demise of supersymmetry, then I personally do not mourn its passing as like Twistor theory or Strings it is an interesting mathematical idea that never had much of a connection with physics. Superfields & superspace were interesting to study, but at the end of the day one ends up doing much the same things as before, only with less of a prospect of explaining reality.

As for mass hierarchies, this never bothered me anyway. Worrying about this problem, if it is a problem, is premature.

26. **Matthew Nobes**
May 21, 2004

Hi Chris

Your points about QFT seem wrong to me… I'll grant that there is no mathmatically rigorous construction, but each of the points you make don't impact on that.

"1. It is only a theory of scattering. The
much-vaunted calculation of the anomalous
magnetic moment of leptons takes the Compton
scattering of a single photon as representing
the interaction of the lepton with an external
magnetic field without satisfactory
justification."

Well the first justification is that it agrees to many decimal places 🙂 But more to the point, you can consider the scattering off of a heavy Dirac lepton (say the muon) and take the limit as the mass of the heavy lepton goes to infinity. As far as I know, there's nothing wrong with that.

"2. No theory of bound states exists, so how can
one claim the prediction of the Lamb shift in a
single-electron atom as a success?"

This is simply untrue. One can extract energy levels, for example, using lattice field theory. There is an algorithmic way to extract bound state properties from the path integral, we just need big enough computers.

As for the Lamb shift, IIRC you start with Hydrogenic wave functions and consider perturbations to them, rather than the "textbook" plane wave states. Again, since the system is essentially non-relativistic this is justified.

"3. If, as seems to me to be likely, we need to
look beyond local field equations to cure the
infinities, then I would much rather not do it
with this framework. It is too messy,
complicated and self-contradictory."

It's unclear which infinities you're worried about. The diagrammatic infinities are cured by renormalization. Thanks to Wilson (and others) we actually understand this fairly well.

27. **Peter**
May 21, 2004

Hi Erin,

Unfortunately I think the present situation is that we don't have any good ideas about how to extend the symmetries of the standard model. The GUT and supersymmetry ideas have been intensively investigated, but don't lead to any convincing predictions or compelling picture. Some new ideas are desperately needed.

28. **Peter**
May 21, 2004

Hi JC,

My own best guess about what will ultimately happen with QFT is that it will turn out that a certain class of them, including the one describing the real world, can be interpreted as a formalism for dealing with representations of certain infinite dimensional symmetry groups, including the gauge and diffeomorphism groups. The idea is that there is some fundamental geometric structure, it has an infinite dimensional symmetry group with a distinguished representation, and this is the underlying mathematical structure that the standard model QFT is related to.

I posted a preprint about this a year or two ago, which hasn't attracted any interest, partly for the quite good reason that the ideas I discuss are too vague and ill-formed. I'm working on a much more specific version of all this that I think I more or less understand now in 1+1 d, hope to have something written about it this summer.

29. **erinj**
May 21, 2004

Hi Matthew,

Thanks for pointing out Bondi's name – to be honest, I wasn't sure if he was still alive or not (I always think of him being stuck in the era when Fred Hoyle was around), so I thought this was another Bondi, not the Bondi.

I'd forgotten about CMBR when I made my comment. Isn't this evidence all a bit vague still?

After I read up on MOND (Modified Newtonian Dynamics), I became much more skeptical about dark matter. MOND certainly seems a viable alternative, and seems to be at a nascent stage where an empirical rule makes predictions which appear to agree in most cases with observed galactic rotation curves, although the physical origin of this law is presently unknown (but hey, we've been here before, with things like Balmer's formula, etc., which do work and ultimately are consequences of a physically meaningful theory).

Aside from this, if supersymmetry is soon to be abandoned as you suggest, Peter, then what other ideas are there that might unify the coupling constants at high energy? I'm not aware of any, and without SUSY or other symmetry principles, how else does one extend the Standard Model?

30. **Chris Oakley**
May 21, 2004

Peter –

My own investigations do not contradict what you just said. But good old Feynman-Dyson perturbation theory is IMHO an obstacle to further progress. As well as the reasons given by me at (boring) length elsewhere, let me add –

1. It is only a theory of scattering. The much-vaunted calculation of the anomalous magnetic moment of leptons takes the Compton scattering of a single photon as representing the interaction of the lepton with an external magnetic field without satisfactory justification.

2. No theory of bound states exists, so how can one claim the prediction of the Lamb shift in a single-electron atom as a success?

3. If, as seems to me to be likely, we need to look beyond local field equations to cure the infinities, then I would much rather not do it with this framework. It is too messy, complicated and self-contradictory.

I do not think that quantum field theory is wrong *per se*, but higher standards of mathematical consistency need to be demanded.

31. **JC**
May 21, 2004

Are there any promising candidates at the present time that could possibly replace the quantum field theory framework?

It appears ideas like SUSY, string theory, supergravity, Schwinger's source theory, analytic S-Matrix theory, stochastic quantization, geometric quantization, Epstein-Glaser construction of the S-Matrix, Wightman's axiomatic quantum field theory, Haag's algebraic/local quantum field theory, loop quantum gravity, Isham's category theory approach to quantum theory, Penrose's twistor theory program, etc … all appear to be "stalled by potholes" of various sorts and are either going out of style and/or they only have a handful of supporters that nobody really pays attention to them outside of their circles.

It seems like anything that isn't constrained by experimental data, becomes governed by trendiness and ideology. Perhaps Freeman Dyson's quote is really telling:

"Physics is littered with the corpses of dead unified field theories."

32. **Peter**
May 20, 2004

I don't think we've reached a final understanding of what QFT exactly is, especially in 4d. But there is so much physics that the present QFT formalism correctly predicts and there is so much beautiful mathematics related to it, that I think there is something very right about the formalism. Whatever replaces it in the long term is likely to be so close to it that it will still be called QFT. So I think it is kind of a different situation than things like supersymmetry and string theory, where the whole concept will likely have to be thrown out.

33. **Chris Oakley**
May 20, 2004

I notice that QFT is on your list of "well-tested" theories.

What is well-tested is not quantum field theory. It is a calculational recipe centred around Feynman graphs, to which mathematically meaningless infinite subtractions are applied when pathological divergences show up.

"Quantum field theory" is too grandiose a name for this arbitrary and unattractive setup, and I when I hear mathematicians condoning it, I wonder whether we'll ever progress beyond it.

34. **Peter**
May 20, 2004

I'm no expert on cosmology, but from everything I've seen the evidence for the standard picture of cosmology is a lot stronger than the authors of this statement are willing to concede. It seemed to me that the WMAP data was in close agreement with what was expected, and there was no reason for this to be true if the standard picture is completely wrong.

One problem is that it is unclear what is meant by the "Big-Bang model". If you include all the conjectural stuff about inflation and dark matter, it probably is true that it hasn't been convincingly tested, but the idea of an expanding universe does seem to have passed quite a few tests.

From my experience with string/supersymmetry, I'm inclined to be sympathetic to claims that there are problems with certain orthodoxies in physics. But I've also seen that there are quite a few people who reject not just the more speculative parts of physics, but large parts of well-tested theories also (e.g. rejecting not just string theory, but the standard model, QFT, even quantum mechanics). This statement sounds to me suspiciously like something that may be along those lines.

35. **Matthew Nobes**
May 20, 2004

Well, I don't know about that cosmology statment. There are some names of respected people I recognize on there (Bondi, for example). There are also a few crackpots though (Arp, Marmet and Lerner) who have been throughly debunked in the past.

The statement seems rather strong as well. Certianly the Big Bang theory has had lots of quantitative sucesses. The microwave background was a predicition, as was the abundence of light elements. I don't think those have been seriously challenged (though I'm by no means up to date on the field).

As for dark matter, there are a few different observations which point to it. If I recall correctily they're even roughly consistent. That is, if you determine the dark matter density by looking at galactic rotations and by cosmological observations they come out roughly the same.

36. **erinj**
May 20, 2004

I realize that this isn't (perhaps) directly related to the topic under discussion here, but I've just come across this suprising open letter on big bang theory, at

http://www.cosmologystatement.org

and the first sentence of it made me think about string theory and supersymmetry, as theoretical proposals which may never yield observable or measurable predictions. I quote:

"The big bang today relies on a growing number of hypothetical entities, things that we have never observed– inflation, dark matter and dark energy are the most prominent examples,"

and

"What is more, the big bang theory can boast of no quantitative predictions that have subsequently been validated by observation."

Are the signatories of this letter doing the right thing? (I myself only recognized the names Woodward and Narlikar amongst them.) Might there be similar statements in the future for supersymmetry and string theory?

37. **Peter**
May 20, 2004

Perhaps one supposedly finite theory would be N=4 super Yang-Mills, where the beta-function is zero, so there is no coupling constant renormalization. The superconformal invariance of the theory may eliminate the usual sources of infinities. I believe there are also similar examples with N=2 supersymmetry.

The other "finiteness" has to do with finiteness of Feynman diagrams at 1, 2, etc. loops. For a while people believed that N=8 supergravity might have all terms in its Feynman diagram expansion finite, but now the belief seems to be that at high enough order one gets infinities.

38. **Chris Oakley**
May 20, 2004

Your post prompted me to dig out my Supersymmetry notes from about 1982. One of the promises made by Peter West at the time was that Supersymmetric theories were "finite". That would in itself be a reason for studying it, but the two pages I have on "Perturbation theory in Superspace" looks depressingly like the familar infinity-plagued Feynman-Dyson perturbation theory. I am wondering therefore whether this finiteness is mere wishful thinking. Do you or anyone else who might be reading this know more about this?

For many years now the SPIRES database at SLAC has been used to produce a list of the most frequently cited papers during each year. Since 1997 Michael Peskin has been doing this, while at the same time writing up a description of what is in the 40 or so most popular papers, together with comments on what this data shows about trends in particle physics. The 2003 edition of Peskin's review has recently appeared.

Peskin notes that SPIRES has begun indexing more astrophysical papers during the last two years, and many particle physicists have turned their attention to cosmology. He has expanded the number of top papers he reviews from 40 to 50 to take into account the greater coverage of the database.

The most frequently cited article, this year and every year, is the Particle Data Group's "Review of Particle Physics" compilation of experimental particle physics data. It is conventional for experimental papers to often refer to this instead of to the original papers. This year the number two and three positions are held by papers from the WMAP experiment, with number four the original results on high redshift supernovae that indicated a non-zero cosmological constant.

The first particle theory paper is the Randall-Sundrum one at number five, and Maldacena's AdS/CFT paper is at number seven. For many years the top part of this list was heavily dominated by relatively new string theory papers, but the situation is now dramatically different. The highest-ranked post-1999 paper is one about PP-waves at number 18, the next is one at number 37 by Ashoke Sen about time-dependent backgrounds. The only other post-1999 paper in the top 50 is the Dijkgraaf-Vafa paper about supersymmetric gauge theories, which is at number 39.

This list provides pretty conclusive evidence that the field of particle theory more or less flat-lined about 5 years ago, with only a small number of minor blips of brain activity since then.

There's also a cumulative list of the most highly cited papers of all time. Here the dramatic movement one can watch is the speed with which Maldacena's paper accumulates citations. At the end of last year it was at number 6 on the list of all-time most frequently cited papers; it has now moved to number 5 and soon will overtake number 4. Within a couple of years it should be at number three, only outranked by the Review of Particle Properties and Weinberg's original paper on the Weinberg-Salam model.

   May 24, 2004

   The SPIRES numbers are probably quite accurate for the last ten years or so (and thus for the Maldacena paper), since just about all particle papers are at the arXiv. Their coverage is less good for older papers.

   In any case, people sooner or later stop referring to older papers as they become part of the common lore of the field. I'm suprised that so many people continue to refer to Weinberg's paper, since the standard model is now so well-entrenched.

2. **JC**
   May 23, 2004

   Is there a possible "undercounting" of older papers that have become "common knowledge", such as Weinberg's 1967 lepton paper? It seems like once something becomes common knowledge or "textbook material", people seem to cite it less and less. These days how many people still cite the old Schrodinger and Dirac papers from the 1920's on their respective equations?

   How many citations of these older papers would be missed in the spires database? It would be interesting to see how many citations show up for them in the citation indicies, coming from papers which do not show up on spires (ie. long forgotten papers and/or papers published in obscure journals that nobody cares about).

   Would it be a safe bet to say that the citations on the Maldacena AdS/CFT paper on spires, has had a reasonable and accurate tracking of it? It would seem that almost every paper that would have cited it, would have been submitted to the arxiv preprint server. Perhaps even crackpot papers (that slipped through the cracks onto arxiv) which cited it, would have also been tracked too.

Not Even Not Even Wrong

   May 28, 2004

   My view is that the "anthropic principle" is a way to camouflage experimental input as if it were theoretical input. Surely most of the papers can be driven to a more standard format, separating really theoretical restrictions from just empirical restrictions. If they prefer this way, it is perhaps because the theoretical restrictions are not, say, very spectacular by themselves.

   I could write a paper claiming that atoms of, well, 82 protons, are necessary for human beings, and that the perturbative stability of this kind of atoms ask for a fine structure constant smaller than 1/82. But nobody should mistake such paper with a theoretical work.

2. **Thomas Larsson**
   May 26, 2004

   Maybe you can argue that human life requires that the aether wind be neglible, which would explain the Michelson-Morley experiment.

3. **JC**
   May 25, 2004

   Did anyone ever try to cook up an "anthropic" explanation for something like the Balmer spectra of hydrogen, before the Bohr model ever existed?

   It would be interesting to see what sort of phenomena had "anthropic" explanations more than century ago, which today have relatively well established theories and experiments.

   It seems like "anthropic" explanations are not much more convincing that saying something happens because of "God's will" or that "it's the work of Satan" type of stupidity.

4. **Peter**
   May 25, 2004

   Weinberg's argument is just that the cosmological constant can't be too large, or else galaxies won't form. So he is telling you that even if you have no idea what causes the cosmological constant, there is an allowed range it can be in. People are calling this a "successful prediction" because the observed value is (by some measure) in the middle part of that range. I don't think this deserves to be a called a scientific prediction because:

   1. It is not based on understanding anything about the phenomenon at issue, it is based on claiming utter ignorance about it.

   2. It can never be made precise, because you really are not actually understanding anything.

   The idea that one can make "predictions" by looking at all vacuum states and saying we should be in a generic one, could in principle be falsifiable, if you had a good understanding of what all the vacuum states are. The problem is that you don't really know what string theory is well enough for this to be a well-defined problem. Susskind can thus go and do silly things like claim that if you stack enough branes on the KKLT construction you can evade falsification.

   There's a pretty standard human behavior of "group-think", where each member of a group of people starts doing something stupid because others around them are doing it. This has a lot to do with the whole string theory phenomenon, now an even more bizarre version of it seems to be going on at Stanford. Susskind devotes a lot of his time to proselytizing for this nonsense, evidently he's even writing a popular book to promote these ideas more widely.

5. **erinj**
   May 25, 2004

   Isn't astronomy the only physical science where quantitative predictions within "a couple of orders of magnitude" are thought of as being "successful"? Are such predictions acceptable in cosmology?

   Surely the "anthropic principle" is a misnomer, as even if it is falsifiable, it hasn't been established as a scientific principle – so I certainly agree, Peter, that it isn't science. OK, it's nonsense. It reads even worse if you call it, as Dimopoulos does, "habitability criteria". Now that's just silly!

   Isn't there a pattern here as well? Susskind is at Stanford. So is Dimopoulos, Kachru and Kallosh. Andre Linde is there too. So we have KKLT, the `anthropic virus', Susskind's "landscape" and Linde's `universes in the lab' all emanating out of Stanford. Are all these things the result of infighting and petty competition between these Stanford guys? Are they trying to out-do each other? Something in whatever they drink there?

6. **D R Lunsford**
   May 25, 2004

   What is Weinberg's 1987 paper like?

7. **serenus zeitblom**
   May 25, 2004

   Well, the desperation revealed there at least shows that the anthropic principle *is* science. Clearly LS is worried that the AP can be falsified. The only catch is that it *has* been falsified by the longevity of the proton.
   Actually this longevity-of-the-proton argument has been around for a long time, and it is the reason I never took anthropism seriously. I thought that this was well-known, and I am very puzzled that it is being bandied about now as if it were some sensational new discovery….anyway the point is that anthropism is clearly wrong, and LS's paper has the virtue of advertizing this obvious fact!

Other People's Stuff

It's always a little worrying when this happens, but sometimes I find myself very much agreeing with at least parts of what Lubos Motl has to say. For example see this recent posting to sci.physics.strings. In it Motl argues that

"I think it is premature to try to construct this major framework that would explain the character of vacuum selection and very early cosmology in string theory"

and

"So my belief is that we will have to understand the nonperturbative structure of the stringy arena using some new universal definition of string theory – a definition that is both non-perturbative (reaches the strongly coupled regions) as well as background-universal (reaches the geometries and non-geometries that are different from the starting one), and only afterwards, we will be able to start answering the stringy cosmological questions in a better context. Without this new tool, everything is just vague guesswork.

In my opinion, the research of string cosmology; stringy inflation; de Sitter space in string theory; scattering in backgrounds with non-standard causal diagrams; and all similar things that have essentially be started by the observation of accelerating Universe back in 1998 – has led to a very small number of intriguing results. There is almost nothing non-trivial and mathematically intriguing going on here; there is as much output as much input we insert. It remains a combination of phenomenology and speculations where conjectures can rarely be clearly ruled out."

I've never really understood why there are fields of "string phenomenology" and "string cosmology" when the theory is still in a state that it can't reliably calculate anything. While I think it is wishful thinking to believe that if you understood string theory better it would reproduce the real world, at least Motl's is a consistent scientific position.

Motl is also a fierce opponent of the "anthropic" arguments that have become popular among string theorists. For the latest example of anthropic argumentation, see this posting at Jacques Distler's weblog.

   How depressing!

   I found my info on the web a couple of months ago, but was evidently outdated.

2. **Peter**
   May 29, 2004

   Hi Thomas,

   I was going by a famous graph I've seen in many places, e.g. here, which I read as saying that discovery of a 115 Gev Higgs requires

   1. Almost 2 fb^-1 for 95% confidence level

   2. About 5 fb^-1 for 3 sigma

   3. Nearly 20 fb^-1 for 5 sigma

   The most optimistic Tevatron Run II projections now seem to be that 2 fb^-1 would be available by 2006, 5 fb^-1 by the time the LHC turns on (late 2007), and it's unlikely they'll ever get 20 fb^-1 since they're not likely to run the machine for too many years after the LHC is up and running.

3. **Thomas Larsson**
   May 29, 2004

   Peter:

   I think you are overly pessimistic. I have also seen that 2fb^-1 is required for a 5-sigma discovery of the Higgs (whether combined or for each individual experiment is unclear to me), but surely you can get hints with less than that. People have been excited about 2.5 sigma signals before. It also takes a lot less statistics to rule out a light Higgs; a 5-sigma discovery will take until 2009, but it will be possible to rule out a light Higgs at 95% CL already in 2006. Now that is only two years away, which suggests to me that if the LEP signal is real, some kind of bump should be visible at 115 GeV very soon, if not already.

4. **Simplex**
   May 28, 2004

   "So my belief is that we will have to understand the nonperturbative structure of the stringy arena using some new universal definition of string theory – a definition that is both non-perturbative (reaches the strongly coupled regions) as well as background-universal (reaches the geometries and non-geometries that are different from the starting one), and only afterwards,…"

   Background-universality reads for practical purposes like a euphemism for background independence! Holy Smolin, Lubos, could this be a nod in the Loop Gravity direction?

5. **Alejandro Rivero**
   May 28, 2004

   Thomas,

   That one got a lot less of press coverage. It was hinted, preliminary, in hep-ex/0105057 and then dismissed progressively via statistical methods. See also plots in hep-ex/9909044 and hep-ex/0009010. The statistic dismissal was based, it seems, on adding other dissintegration channels where signal was not seen. Pretty much the same history than 115 Gev.

Probably a motivation to forget about this event is that a low Higgs+ it is not compatible with the minimal supersymmetric standard model. I had also forgotten it, until recently a model forced my neurons to expel these papers from my deep repressed memories 🙂

6. **Peter**
May 28, 2004

Grants generally aren't given on a year-to-year basis, more typically people are part of a group that has a grant that may have to be renewed every five years. So, if you have a permanent job, you don't need to worry about this each and every year, but every few years you very much need to worry about whether you've been publishing enough articles.

Postdocs and junior faculty are under a lot more pressure. Their jobs may be as short as one-year appointments, and they definitely need to be producing as many publications as possible as quickly as possible if they want to continue to eat.

There certainly are a lot of very routine, resume-padding articles appearing, but this is not specific to string theory or high-energy theory. Pretty much every academic field, even very healthy ones, have this phenomenon. What's scary about particle theory in recent years is not how many routine papers there are, but how few there are with any sort of interesting new idea at all.

7. **Peter**
May 28, 2004

With only 200 pb^-1 in Run II, the Tevatron can't see much that they couldn't see in Run I, where they had around 100 pb^-1. To start pushing up the mass limit on the Higgs above that from LEP, they need 2000 pb^-1 or so. They hope to get that over the next few years before the LHC gets going.

8. **Thomas Larsson**
May 28, 2004

What is the 68 GeV particle? I evidently missed it.

Yesterday there was a status report from the Tevatron on the arxiv. CDF and D0 now have an integrated luminosity ~200$ pb**-1 (per experiment), but evidently they don't see any deviations from the standard model. Does anyone know if this is significant?

9. **Alejandro Rivero**
May 28, 2004

No, I am pretty sure that the inertia of stringthings is independent of funding gravy. It is just that when people is trained with a weak mechanism of choosing goals, the herd effects happen (stock market jargon; no pun intended).

Perhaps experimentalists are more sensible to funding phenomena. I am still astonished about the 115 and 68 GeV particles in LEP2; they were so in hurry to finish the experiment that they did not got time to take more measurements there.

10. **JC**
May 28, 2004

Perhaps from an ulterior motive, it's a way of folks attempting to justify the government grant funding gravy train to string theory or particle theory in general?

Regardless of whether string theory is a legitimate or illegitimate field of research, is there any truth to the folklore stories that if you don't publish anything during a year you'll end up losing most, if not all, of your grant money for the next year?

Many papers that show up every day on the arxiv preprint server look like they aren't much more than the equivalent of "resume padding" for a researcher's CV. Perhaps it's not so surprising if it's papers produced by some 2nd or 3rd rate researchers at some 3rd or 4th rate universities, hoping to get tenure. Or for that matter, postdocs hoping to get an assistant professor job.

Slides from Davis Conference

Slides used by many of the lecturers at the recent Davis mathematical physics conference in honor of Albert Schwarz are now online.

Comments

1. **Peter**
   May 30, 2004

   I'm just getting this from Lawson-Michelson, Spin Geometry, Theorem 8.4, Chapter I, where they also get the cover correct.

2. **D R Lunsford**
   May 30, 2004

   Hmm I thought the double (actually 4-fold) cover for SO(p,q) was Spin(p,q)…how did you pull out SL(4,R)?

   The Clifford algebra Cl(3,3) does have a "Weyl"-like representation

   Bmu = [[0, gamma_mu],[gamma_mu, 0]]

   B5 = [[0, -gamma_5],[-gamma_5, 0]]

   B6 = [[0, i],[-i, 0]]

   and since the gammas have a purely imaginary (Majorana) representation (for spacetime = —+) I can see SL4R coming in…

3. **Peter**
   May 29, 2004

   I don't really know anything about SO(3,3). It's not the conformal symmetry group of Minkowski space. Its spin double cover is not SU(2,2), but SL(4,R). The tricks Witten is talking about that get representations of SU(2,2) by "quantizing" C^4 and using the action of SU(2,2) on C^4 won't work for SO(3,3).

4. **D R Lunsford**
   May 29, 2004

   How does the whole argument change if we start with SO(3,3)?

5. **Peter**
   May 29, 2004

   He never really got to talking strings. In the last part of his talk he was just explaining his formula for gauge theory scattering amplitudes as integrals over 2d-subspaces D (actually algebraic curves of genus zero) in CP^3. You can try and interpret these curves as world-sheets of strings, but he didn't get into that in this talk.

6. **D R Lunsford**
   May 29, 2004

   3/4s of Witten's talk was fun (I think it's just a rehash of Penrose) but he lost me when he started talking strings. What was his point?

Anti-Big Bang Open Letter

May 30, 2004
Categories: Uncategorized

Sean Carroll has some comments about the anti-big bang petition. He also points to Ned Wright's explanation of what is wrong with various proposed alternatives to the big bang scenario. In particular this explains in detail what the problems with Irving Segal's "Chronometric Cosmology" are, something I'd always wondered about.

Segal was a very good mathematician, who did serious work on quantum field theory in the 50s and 60s. He's the "Segal" in what is sometimes called the "Segal-Shale-Weil" representation. Segal is a counter-example to Carroll's observation that, for the most part, opponents of the big bang are not very smart. Unfortunately, it seems that quite smart and otherwise reasonable people can have unshakable faith in ideas that don't work. Segal's student John Baez wrote up some of his memories of his advisor and his cosmological research.

1. **Jack Sarfatti**
   July 4, 2004

   On Jul 3, 2004, at 8:33 PM, Paul Zielinski wrote:

   Everyone agrees that the laws of GR are formally covariant under
   general coordinate transformations — or under the group Diff(4)
   of point set diffeomorphisms on a 4-dim pseudo-Riemannian manifold
   (which is subtly different).

   But this is not enough to give us *actual physical relativity*
   with respect to accelerated motion.

   The reversible tetrad map LNIF(P) LIF(P) does that

   i.e.

   guv(LNIF at P) = Eu^a(P)(Minkowski)ab(LIF)Ev^b(P)

   After all, in classical mechanics Newton's second law F = ma also
   holds *formally* in non-inertial frames; but this cannot amount to
   true relativity with respect to such frames, since the observed
   forces are regarded as "fictitious" — i.e., only apparent, a
   kinematical artifact.

   Bad use of language since we feel and measure fictitious forces same as gravity!

   So whether we do or do not have physical relativity depends not only
   on the formal symmetries of the theory, but also on the *physical
   interpretation* of the covariant laws.

   Einstein's original approach was to interpret such "fictitious"
   forces as real, based on his concept of the unified gravito-inertial
   field, described by the transformable/deformable metric tensor g_uv.
   This was at the core of his original concept of general relativity, as
   I have previously argued.

   Still true today.

   Einstein himself explained this very clearly in his earlier papers
   and in several books on relativity. I have all the quotes.

   If Einstein's math is interpreted differently — as some have
   proposed — then we lose physical general relativity, even while the
   formal general covariant character of the laws is left undisturbed.

   Again I do not think these gyrations of the informal language that leave the formal equations alone and do not change any operational procedures and gedankenexperiments are important scientifically – at best a matter of psychology and cognitive style.

   So general covariance is not the same as Einsteinian "general relativity".

   Never said it was. It is necessary not sufficient. Puthoff seems to say in PV it is NOT necessary – an error.

   As I understand it, the current consensus in gravitational physics is
   indeed in favor of a NON-"general relativistic" interpretation of the
   formal theory.

   Show me with exact quotes.

   If I am confused on this, then so are most contemporary gravitational
   physicists. Even Wheeler writes that "'general relativity' is the name
   Einstein gave to his theory of gravitation". Weinberg and Feynman,
   to name just two others, thought that Einstein equivalence is a red
   herring — a mere heuristic tool that happened to lead to the current
   theory, but not now part of the correct interpretation of that theory.

I have not read Weinberg on this. I do not read Feynman that way. Cite specifics.

If there is no "general relativity", then there is in reality no physical relativity, except in some weak phenomenological sense (which latter, ironically, was Einstein's original 1905 view of SR as a: theory of principle").

The "beef" of GR is the TENSOR eq (under Diff(4) globally and O(3,1) locally)

Guv + /\zpfguv = – (8piG/c^4)Tuv("matter")

Therefore, I simply do not understand what you are saying.

Einstein pretty much implied all this himself: he viewed his proposed extended relativity principle as a natural development of his special relativity principle to encompass accelerated motion.

Right. That's the way I understand it.

If you only include observers in uniform relative motion and assume invariance of c under that limited group of transformations including global translations as well as all 6 space-time rotations you get 1905 SR. SR means do NOT locally gauge the Poincare group! It means do not locally gauge any space-time symmetry group under the constraint that the speed of light in vacuum is an absolute invariant. That c is an absolute invariant does NOT imply it is an upper speed limit to anything. To get that, one must make something like an Arrow of Time additional postulate that future causes of past effects is impossible. That is an entirely different story beyond relativity as simply a symmetry theory of space-time.

If you include COINCIDENT observers at SAME event P (i.e. in tiny ball centered at P) in arbitrary relative motion then you get GR(1916) relative to that choice of connection field that comes from ONLY locally gauging the 4-parameter translation sub-group T4 of the 10-parameter Poincare group.

Now, Einstein did NOT historically derive GR that way because the modern understanding of the organizing idea of "local gauge invariance" did not exist until after he died.

If further, you locally gauge the 6-parameter Lorentz group O(1,3) you get an additional torsion field piece to the connection field for parallel transport of tensors (and spinors using Penrose-Newman) along vector fields in the base space. You now have a larger local symmetry group than GR's 1916 Diff(4)xO(1,3). If you go even further and locally gauge the full 15-parameter conformal group, or even the 16-parameter GL(4,R) you will get even a bigger connection field with new physical consequences to be explored.

But it now looks like this aspect of his program was not successful.

I think it has been extraordinarily successful.

Of course, the term "general relativity" has in the meantime been quietly redefined to mean something quite different: the reciprocal influence of gravitating matter on the vacuum, and vice versa.

I thought Einstein always thought of it that way – I mean from at least ~ 1916 on? I am not up on the detailed history of how his thought evolved. What he may have said between 1905 – 1916 is not really relevant.

Even Einstein abandoned "Mach's principle" (really a hypothesis) by 1920, since it clearly entails instantaneous action at a distance in order to explain inertial phenomena — which of course leads us to a very different view of inertia as arising locally from a matter-vacuum interaction.

Agreed, Mach's principle is not a necessary part of GR even though it heuristically motivated Einstein. Also the recent discovery that 96% of the stuff of the universe is not "matter" as Mach and Einstein thought of it means that the whole idea of Mach's Principle rests on very shaky ground and must be re-evaluated in the light of new surprising observations.

The ghost of the departed Lorentzian ether. Quite a different kettle of fish.

Paul

"Ether" is back in, although not the old Galilean group version. "Ether" like "tensor", "spinor", "connection" are all relative terms defined relative to a choice of symmetry group G.

P.S. I have been revisiting SR, and I think I now may have a bulletproof version of the clock paradox that I'd like you and Hal to take a look at.

Would you be willing to do that?

Depends what you mean by "clock paradox" – time dilation is a proven fact in many experiments.

I know this must sound like a crank perpetual motion thesis — but I'm serious.

Jack Sarfatti wrote:

General coordinate transformations handle all – so I do not understand what you mean.
I think you are confused here.
True, given any symmetry group G you can make the laws covariant under G.
GR deals with a special choice G = Diff(4).
Diff(4) handles LNIF –> LNIF'

Also it includes EEP tetrads LNIF LIF

On Jul 3, 2004, at 1:28 AM, Paul Zielinski wrote:

I meant physical relativity of all motion, including accelerated motion.

The general principle of relativity was initially supposed by Einstein to be modeled on the special principle and was supposed to be an extension of it.

That's not the way it turned out — or at least that's what I understand to be the current view of the matter.

On Jul 3, 2004, at 9:07 PM, Paul Zielinski wrote:

Jack Sarfatti wrote:

The general principle includes the special principle.

Only if the special principle is re-interpreted *ad hoc* to bring it in line with the general principle as currently interpreted.

OK – what's wrong with that?

Jack, here you are disagreeing not just with me, but with most contemporary authors.

This is all explained in Ohanian & Ruffini, "Spacetime and Gravitation", which I believe you have.

What pages specifically?

Who now actually believes with Einstein 1907-1916 that physical gravitation is simply a form of variable frame acceleration controlled by the distribution of matter?

I do if you change "simply" to "essentially" and if you change "matter" to "matter and exotic vacua."

Do you?

Of course.

When curvature is zero everywhere when special relativity works globally, i.e. there exist global inertial frames GIF

OK.

When there is curvature the special principle works locally subject to the 2 restrictions I mentioned previously.

In general, only at a spacetime point.

More precisely in a neighborhood of space-time point P of scale L small compared to scale of local radii of curvature. Since the latter at surface of Earth is ~ 1AU that is not much of a restriction on L for terrestrial measurements.

Also L >> Lp* which is usually taken as 10^-33 cm though it may be larger.

What this means is that the predictions of SR in an LIF are *empirically compatible* with those of GR when the LIF is contracted to a point.

No to a "ball" and here at Earth it can be a pretty big ball. You need to put this "point" thing into proper perspective with numbers.

Where there is non-zero Riemann curvature (i.e. gravity) in any finite volume of spacetime, they are only approximately compatible.

As explained in detail in MTW for example. Obviously the 4th rank curvature tensor is NOT generally zero and that includes LIFs as well as LNIFs – but its practical effects on surface of Earth are very tiny and for a majority of practical purposes are ignorable.

Of course this does not mean that even in such a contracted LIF the predictions of SR *match* those of SR — they are only a subset. For example, SR makes no predictions regarding tidal forces, even if we extend SR to handle accelerated frames. Yet according to modern GR, tidal effects may be empirically detectable everywhere in an LIF.

What's your point? It is trivial that SR is a sub-theory of GR and that SR needs GR corrections if one does precise enough measurements. All covering theories transcend the theories they cover. All this confusion about "aether" for example is because people try to use SR outside of its proper domain of validity. Our universe has a Hubble flow in which absolute velocity and absolute global cosmic time are practically and usefully defined in terms of the cosmic black body radiation isotropy and temperature respectively. This is no different from fact that non-spherically symmetric ferromagnets exist even though their Hamiltonians are spherically symmetric. The particular solutions do not share the symmetries of the dynamics! Not all atomic electron states of hydrogen are S states! In particular, when the ground state of a complex system does not share all the symmetries of its dynamical action we say the symmetry is spontaneously broken. This same thing happens with the cosmology of our universe! This is common indeed ubiquitous! Read PW Anderson's "More is different" and other papers in his "A Career in Theoretical Physics" (World Scientific) – worth buying.

Note let a,b be LIF indices and u,v be LNIF indices both in small neighborhood of same local event P

Ruvwl(P) = Eu^a(P)Ev^b(P)Ew^c(P)El^d(P)Rabcd(P)

Curvature is a local field measurable in principle in the LIF.

OK.

E's are the tetrad components, i.e. local fields

In globally flat space-time the E's are Kronecker deltas &au^a, distinction between a's and u's disappears – degenerate limit e'u(P) = Eu^a(P)ea

[e0, e1,e2,e3] is basis for a LIF at P

[e'0,e'1,e'2,e'3] is basis for a "coincident" LNIF at P

OK.

INTRINSICALLY

e'u(P) = ea&u^a + Lp*^2(Macro-Quantum Coherent Vacuum Phase),u (NEW to my theory

,u is ordinary partial derivative

guv(P) = nuv(Minkowski) + (1/2)[e'u,v(P) + e'v,u(P)] = Eu^a(P)nab(Minkowski)Ev^b(P)

So far all this is for usual torsion-free connection.

So your "curvature field" is directly determined by the coordinate derivatives of the macroquantum
phase of your virtual BEC?

Yes, of course. I have been saying this over and over and it's in my two books from late 2002.
This is the elastic analog to Bohm's hydrodynamic constraint of IT by quBIT in

velocity of IT particle = (hbar/m)Gradient of phase of quBIT pilot waved)

I replace the quantum of circulation (AKA vorticity flux) hbar/m in 3D by the "Quantum of Area" in the 4D elastic world crystal lattice picture of Hagen Kleinert from Free University of Berlin.

The LIF ea with zero partial derivatives have dimensions of length in above formulae and guv is dimensionless.

If so, this looks like a flat-background quantum field model with a correspondence bridge to
"curved" Einstein g_uv.

Only FORMALLY not PHYSICALLY – important you make that distinction!

That is, there is no assumption of perturbation theory here.

In

guv(P) = nuv(Minkowski) + (1/2)[e'u,v(P) + e'v,u(P)]

In no sense do I assume

nuv(Minkowski) >> (1/2)[e'u,v(P) + e'v,u(P)]

The way Feynman does in his Lectures on Gravity using spin 2 quantum field on Poincare symmetry group background vacuum.

I am not doing that at all! Also these are SMOOTH MACRO-QUANTUM ODLRO functions. There will be a micro-quantum normal fluid spin 2 tensor quantum field on this smooth curved space-time background of course along with all the spin 1/2 and spin 1 quantum fields ALL together contribute to /\zpf!
But my theory is automatically BACKGROUND-INDEPENDENT and NON-PERTURBATIVE since guv(P) is a dynamical field from the beginning determined globally self-consistently in a self-organizing manner!

I'm curious: What in your model causes mechanical inertia? And what in your model explains, or
at least might explain, the exact proportionality of inertial and gravitational mass?

Exactly same as John Wheeler explains "Mass without mass" in his classic book "Geometrodynamics" with new feature Lp* ~ 10^20Lp on scale of 1 fermi to make the spatially-extended quasi Kerr-Newman micro-geons of the lepto-quarks out of exotic vacuum with "charges" as quantized vortex trapped flux fields not only U(1) but also SU(2) and SU(3).

The lepto-quark masses m ~ Vacuum Coherence consistent with Higgs mechanism – not Haisch's & Puthoff's random EM ZPF friction.

~ 1 Mev for first generation that dominates Omega(Matter) ~ 0.04 where total Omega = 1 the remaining 0.96 is ALL w = -1 ZPF exotic vacuum! Hence dark matter detectors silent in principle sans false positives.

Then use QCD Lite bag model (Frank Wilczek) to get hadronic masses M ~ 1Gev from lepto-quarks glued together again by /\zpf in a cascade process.

I have not proved consistency as yet. This is all heuristics based on my physical picture.

OK.

Z.

On Jul 3, 2004, at 1:28 AM, Paul Zielinski wrote:

I meant physical relativity of all motion, including accelerated motion.

The general principle of relativity was initially supposed by Einstein to
be modeled on the special principle and was supposed to be an extension
of it.

That's not the way it turned out — or at least that's what I understand
to be the current view of the matter.

Jack Sarfatti wrote:

I think the cutoff is much larger than Planck distance at scale 1 fermi in fact it is 1 fermi on scale of 1 fermi

i.e. Lp* = 10^20Lp on scale of 1 fermi to stabilize electron as an extended micro-geon.

On Jul 2, 2004, at 12:19 AM, Paul Zielinski wrote:

I was under the impression that there is a class of v^3 ZPE
density distributions that are Lorentz invariant?

Yes, that's what I am alluding to below. However, that does not have a finite cut-off in it, which is the problem.

The nitpicking point I first raised here is really not relevant to the main issue,
which is what happens to LI when the emptically confirmed v^3 ZPE spectrum
(which I suppose is actually a v^2 density distribution) is truncated at the Planck
scale.

Everyone here (except perhaps TS) says that this would destroy exact LI.

Puthoff seems to be saying that such a cutoff would nevertheless not have currently
observable consequences, while Ibison is not so sure.

What do you think?

Z.

I say it will have observable consequences that should be looked for in angular correlations in Lambshift radiation for example.

   Guys:

   You can debate theory up your yin-yang.

   Check out reality at http://www.proton21.com.ua

   If anyone wants to whine about the lack of detail

   on making "coherent electron bunches", just try reading ALL of Adamenko's papers.

   It's not really that mysterious.

   Here's the point: If you can MODEL stellar processes with an actual EXPERIMENT…then you can begin to understand them.

   Forget all this "zero point energy" stuff, let's start with SHN's and see where we get from there.
   (We may get to ZPE, and to large amounts of antimatter…cheaply.)

   bcc

   Memorandum for the historical record on the emergence of metric engineering concepts.

   Dear Marc

   Mine is the only one of your proposals coming in which has even a ghost of a chance of working as practical metric engineering because:

   It only uses battle-tested mainstream physics, i.e. Einstein's GR, quantum theory, condensed matter physics of macro-quantum coherent order parameters described by P.W. Anderson as "More is different" that includes Andrei Sakharov's "metric elasticity" 1967 for emergent gravity as "generalized phase rigidity" of the local macro-quantum vacuum coherence order parameter. Also, unlike ALL of your proposals coming in, mine has a seamless connection with the major problems in physics today e.g. the dark energy/cosmological constant problem, the renormalization problem in quantum field theory (e.g. stability of electron under its self-charge), stability of galaxy, universal Regge slope of hadronic resonances, Ken Shoulders' "charge clusters." Dare I also mention the heretical 3 letter word "UFO"? No, I guess not. 🙂

   Hal Puthoff's competing program to mine, i.e. the "PV" dielectric analogy approach to GR is much further out of the mainstream and so far his published results disagree with actual empirical data. Hal tries to avoid standard tensor calculus with metrics, consequently he has yet to publish a model with a rotating source, and he has yet to show how his theory based on a special action principle can give a warp drive in the sense of Alcubierre and the recent paper by Visser et-al
   http://www.arxiv.org/PS_cache/gr-qc/pdf/0406/0406083.pdf
   Also Hal has yet to show how an applied electromagnetic Fuv field can change his vacuum K function by a large enough amount to make a practical difference for actual metric engineering. He cannot do it using orthodox QED, the effect is too small.

   Note that Visser and Lobo also make reference to dark energy in the context of a warp drive – probably first in a mainstream paper, but my two books from end of 2002 already have that idea clearly spelled out. Visser also bends over backwards to caution the reader not to get too enthusiastic about imminent technological applications since the "fact" of UFOs is denied otherwise he could not publish his paper – quite obviously.

   One important technical point on Visser's latest paper on warp drive

   He uses only

Guv = (8piG/c^4)Tuv

Not the equation I use which is

Guv + /\zpfguv = (8piG/c^4)Tuv

That I approximate as the pure exotic vacuum equation

Guv + /\zpfguv ~ 0

assuming G/c^4 ~ 10^-33 cm/10^19Gev

so that, with my subsidiary vacuum coherence equations

/\zpfguv >> (8piG/c^4)Tuv

Is the "metric engineering regime" of practical interest with

/\zpf controlled by an electromagnetic Au potential in a Bohm-Aharonov- Josephson gauge covariant "weak link" in the relative phase between a control macro-quantum coherent field and the vacuum coherence of virtual electron-positron pairs.

Ken Shoulders EVO data http://qedcorp.com/destiny/ExotcVacuumObjects.pdf seem to confirm this basic idea, as well as the absence of dark matter particles after 14 years of trying with only false alarms.

On Jun 21, 2004, at 9:34 AM, michael ibison a signer to the anti-Big Bang letter wrote:

"That I don't embrace BB is an accurate description. I do not hold a strong view on whether or not the currently accepted view is correct. That makes me a radical. Not because I say it is wrong, but because I am an agnostic.

Cheers,

Michael"

That's only because you have not kept up with advances in the field. I agree that prior to say end of 2002 the position held in that May 22, 2004 New Scientist Letter was slightly plausible and defensible as a long shot – but no longer. Without applying a double standard, the Baysean probability that the standard model with chaotic inflation, dark energy/matter is essentially correct is very close to 100% and getting closer all the time as new data comes in. What we have here is a debate on how to weigh the new data that you admit you are not very up on. I have been to 2 APS meetings on this topic in 2003 and listened closely to Mike Turner and Saul Perlmutter – the experimental work is beautiful – some of the best in the history of physics. This is a real turning point. It also explains the saucers, the emergence of Einstein's gravity from the cohering of random noise ZPF not from its friction, the stability of electrically charged elementary particles as spatially extended structures that shrink when hit hard, the stability of the galaxy, the universal Regge slope, Ken Shoulder's charge clusters, the Arrow of Time and even the emergence of consciousness in the many worlds. What more do you want? This is grand!

Strong prediction that can falsify my idea: Dark matter detectors cannot click, in principle, with the right stuff to explain Omega(DM) ~ 0.23 any more than the motion of the Earth through the Galilean ether can be detected with a Michelson-Morley interferometer in the domain of validity of special relativity where the scale of the relative phase measurements are small compared to the radius of curvature that the Sun makes at the position of the Earth in its orbit.

PS How do Marshall Trevor/Haisch, Puthoff, Rueda, Cole et-al explain observed sub-Poisson statistics of photon anti-bunching in laser light which requires negative probability if you use SED?

WHAT IS THE UNIVERSE MADE OF?
The emergence of gravity and dark energy/matter from the cohering of zero point energy.

JACK SARFATTI
ISEP
1714 Stockton Street
Suite 100
San Francisco, CA 94133

Abstract

Ordinary matter made from real on-mass-shell lepto-quark fermions and gauge force bosons only accounts for approximately 4% of all the large-scale stuff of our universe, which may be one of a infinity of parallel universes in hyperspace that we call ?Super Cosmos.? I propose that the remaining 96% of our universe consists of two forms of partially coherent exotic vacuum dominated by a condensate of bound virtual electron-positron pairs. Einstein?s gravity emerges from the variations in the macro-quantum coherent phase field of the condensate. This condensate is the inflation field in the large-scale cosmological limit. Both dark energy and dark matter are

simply residual total zero point energy densities that emerge from the vacuum condensate?s intensity variations. Approximately 73% is anti-gravitating zero point ?dark energy? density with equal and opposite negative pressure that is causing our universe to accelerate in its expansion rate. The remaining gravitating 23%, called ?dark matter,? is also zero point energy density with equal and opposite positive pressure found concentrated in large-scale structures like the galactic halo that prevents our solar system from escaping into inter-galactic space. Astrophysical scale geon structures of w = -1 dark matter simulate w = 0 CDM in terms of their gravity lensing. The electron, as a Bohm ?hidden variable? on the micro-scale for example, is a spatially extended structure whose self-electric charge repulsion, Casimir force and repulsive spin rotation are balanced by the strong short-range zero point energy induced gravity from its exotic vacuum core. The electron, and the quarks, shrink in size, up to a certain minimum, when hit with large momentum scattering transfers from strong space warping that makes their surface areas small compared to what they would be in flat space for a given radial distance. An experimental appendix by Ken Shoulders on “exotic vacuum objects” or “EVO” charged geons made from large numbers of electrons glued together by zero point energy is included. The zero point force holding as many as one hundred billion electrons together is not the QED Casimir force, which may even be repulsive, but is the entirely different strong short-range gravity force induced by the zero point energy by the entirely different process of Einstein’s general relativity omitted from the flat space-time QED calculations. These EVOs show anomalous motions and energies that seem to be examples of Alcubierre’s “warp drive” and “cold fusion” respectively.

A preliminary copy of the Ken Shoulders EVO experiments is at
http://qedcorp.com/destiny/ExoticVacuumObjects.pdf

Ken worked for years in USG Intelligence as a gadgeteer for James Bond types. He holds patents on tiny electronic devices and is a microwave expert. Some of his devices were crucial to the microchip revolution by Intel et-al.

June 16, 2004

Both Ibison and Soares are signers of the New Scientist letter. I am defending mainstream precision cosmology against this letter’s position. Herman Bondi from Cambridge, who also signed the letter, got very upset with me last night because of this.

I support intelligent debate on this topic of course. However, having attended two major APS meetings on the topic with Mike Turner, Saul Perlmutter talking at both, and I will also be at GR17 in Dublin, it is clear to me that you are fighting a hopeless rear guard action. In the course of doing so, you will be led to change your mind. Resistance is futile. I think Sean Carroll’s attitude is the objective optimum one – the best Bayesean estimate. 😉

Note best fit in latest Physics Today is a Big Rip Phantom Energy w ~ -1.31 (if I recall correctly) but it is ~ 1 standard deviation away from my hard prediction of w = -1 as an exact result. So we will see how new data affects this. Also recall my other hard prediction, no dark matter detectors will click with the right stuff that explains Omega(DM) ~ 0.23. That would be like Michelson-Morley showing the speed through aether – I mean once we remove curvature corrections from general relativity. There is some small discrepancy there as I recall, but it is my impression that it can be explained by GR?

On Jun 16, 2004, at 10:23 AM, michael ibison wrote:

Thank you for your note Domingos.

“I appreciate your comments and am interested in what you have to say.
Sean Carroll (according to Jack) cites the following alleged PREDICTIONS
made by BB:

‘How about acoustic peaks in the power spectrum of temperature fluctuations in the cosmic microwave background? And the polarization signal, and its spectrum? And the baryon density as deduced from light-element abundances agreeing with that deduced from the CMB? And baryon fluctuations in the power spectrum of large-scale structure? And the transition from acceleration to deceleration in the Hubble diagram of high-redshift supernovae? And the relativistic time delay in supernova light curves?’

I think I can contest the allegedly predictive role of BB for some of these, but would appreciate a view from someone more qualified. Would you be good enough to offer a short comment on each of them?

Best wishes,

Michael”

On Jun 16, 2004, at 5:23 AM, Domingos Savio de Lima Soares wrote:

16jun04

“Hello Jack,

Thanks for your message — enthusiastic message, I should say — defending the inflationary Big Bang model. I, and my students as well, have now material for much discussion. Thanks, indeed. Ned Wright’s web page is present in my own personal page for a long time now, I would like to mention. And I always recommend it for those interested
in cosmology. In any case, I added, after receiving your note on the “Errors” section, a special link for this particular section of Ned’s page. What you, Sean Carroll, Mike Turner and followers, need to explain is

1- Why the “dark cake”, Fig. 10 of Freedman and Turner (astro-ph/0308418), has only 0.5% that is actually observed? Remember, from the 4% of baryons,there are some 3.5% still dark, i.e., invisible, that is to say, we can’t see, measure, whatever. Do they exist or perhaps should we wait a bit more?”

I do not claim to be an expert in data analysis. That’s Turner’s et-al’s job. I seem to recall Turner saying that was mostly cold hydrogen gas? What is important however is the 96%!

“2- Take w=-1.”

That’s what my theory says it must be – both dark energy and dark matter. However globs of w = -1 dark matter will look like w = 0 CDM from far away in terms of gravity lensing. This is a crucial test of my theory BTW. No dark matter particles! We, I mean Ken Shoulders, seem to be seeing this phenomena on lab scale!
http://qedcorp.com/destiny/ExoticVacuumObjects.pdf

“What do you do with the so-called ‘cosmological constantproblem’?”

I have solved it! Vacuum coherence explains it. The dominant contribution to Vacuum Coherence is a condensate of virtual electron-positron pairs bound together by virtual photons all occupying the same center of mass bound pair state. The phase variations in this macro-quantum occupied single particle state give Einstein's metric guv field.

The incoherent estimate of Einstein's cosmological constant /\ is ~ 1/Lp^2

My theory says that the coherent value of the cosmological constant is

/\ = Lp^-2[Lp^3|Vacuum Coherence|^2 – 1]

The "equilibrium" is at /\ = 0 where the Vacuum Coherence is the Planck density.

Vacuum Coherence obeys a covariant Landau Ginzburg eq. that must be solved self-consistently with Einstein's eq

Guv + /\guv = (8piG/c^4)Tuv

"You know, the value implied by the inflationary BB model makes our universe 10 to the minus 10 second old and 3 cm large, which is definitely, and frankly, not observed."

Again this is no longer a problem – it is solved conceptually.

"3- Why not make science with a character, I mean, following strictly "scientific method" and listening to what Nature presents and we can see?"

This is polemics – not a valid objection. It is obvious to my mind, that the preponderance of evidence is on the side of mainstream precision cosmology with dark energy now that I have explained the cosmological constant paradox as a simple vacuum coherence effect analogous to the two-fluid model of superfluids. Einstein's gravity emerges as a simple ODLRO effect with general coordinate transformations as derivative from local phase transformations on the vacuum coherence field. Curvature and torsion are simply local compensating gauge fields from stringy "vortex" singular lines in the phase of the vacuum coherence where the intensity of the vacuum coherent scalar field(s) drop to zero. Space-time physics is local because of the locality of the ODLRO vacuum coherence.

"Of course, you may turn out to be right in the end, BUT — sorry fot the capitals — you are not with all that just now. So, it is perfectly normal that others have their chance also. That's the point.

Cheers, explain that,

Domingos"

Let's keep the censorship issue distinct from the physics content. I completely support your complaint of censorship and black listing of physicists. Censorship prevents the kind of debate we are having here. I personally agree with Sean Carroll that funding of the kind of alternative you profess is a bad bet. Up until ~ 2003 you may have had a valid case there, but no longer. The kind of cosmology you profess is dead in the water and will lose support rapidly with all the new data coming in. It's time to move on. The same is true for the two eccentric theories Hal Puthoff has been promoting in the media i.e. PV theory of gravity and random EM ZPF origin of inertia of lepto-quarks, which BTW cannot explain the rest mass of the neutrinos. Both gravity and inertia are like Siamese Twins. They BOTH come from vacuum coherence (e.g. Higgs mechanism). You cannot have real matter Omega ~ 0.04 without vacuum coherence. All you have then is pre-inflation false globally flat vacuum. Vacuum coherence is also the inflation scalar field(s).

7. **Jack Sarfatti**
June 16, 2004

The local pure gravity stress-energy density tensor is simply

tuv(Gravity) = (c^4/8piG)Guv

where Guv = Ruv – (1/2)Rguv

For ordinary vacuum

tuv(Gravity) = 0

But for exotic vacuum

tuv(Gravity) = (c^4/8piG)/\zpfguv

where /\zpf is a local scalar field

/\zpf = (Quantum of Area)^-1[(Quantum of Area)^3/2|Vacuum Coherence|^2 – 1]

8. **Jack Sarfatti**
June 16, 2004

Some wag quipped that mathematical physicists are mathematicians who cannot do first-class pure math and that theoretical physicists are physicists who cannot do experimental physics. John Baez is a mathematician pretending to be a theoretical physicist. Indeed, most of modern theoretical physics has been taken over by mathematicians in theoretical physicist's clothing. In this context, both string theory and loop quantum gravity are what Richard Feynman would call "Cargo Cult Pseudoscience" and what Wolfgang Pauli would call "not even wrong." Are string theory and spin foams et-al interesting as conceptual art? Most certainly, but they are not yet real physics and it is intellectually dishonest for Brian Greene to misrepresent them as important physics on NOVA.

On Jun 15, 2004, at 10:32 AM, michael ibison wrote:

I haven't read the Freedman paper http://arxiv.org/abs/astro-ph/0308418 If Domingos has, perhaps he would be good enough to offer comments on it.

Jack Sarfatti wrote: The point here is that there is a preponderance of evidence from independent sources for the basic picture that essentially all the stuff of the universe is, at its core, exotic vacuum zero point energy density including Omega (atoms, radiation etc) ~ 0.04. Mundane explanations for anomalous dimming of Type 1a supernovae have been clearly eliminated observationally by the evidence. There will be more evidence. The ideas in the May 22, 2004 are not contenders to the objective mind without an ax to grind or a hobby horse to ride – assuming one can find such a mind? 😉

Not only that, but this large-scale picture solves unsolved basic problems of the particle physics,

I. Is the electron (lepto-quark) a point particle? NO.

Hence no more need for infinite renormalizations and no more need perhaps for using distributions and the need for regularization that plays such a big role in say Ashtekar's program of spin foams and weaves to make smooth space-time.

II. What stabilizes the spatially extended electron (perhaps with "tight atomic states" J.P. Vigier)? Zero point energy pressure. These are the Lorentz-Abraham-Becker stresses.

III. Why does the electron (and the quark) appear to shrink from 10^-11 cm at low energy imaging to ~ 10^-17 cm at high energy imaging? Strong space-warp from the exotic vacuum zero point energy core.

IV. Why Regge universal slope for hadronic resonances? Kerr-Newman "micro-geon" (e.g. A. Burinskii) solution in strong short-range gravity induced in the zero point exotic vacuum core.

Which interpretation of quantum theory is needed? Bohm's.

Does the quantum wave describe individual particles or only statistical ensembles? Individual particles.

Why does our solar system not escape into inter-galactic space? For the same reason that the electric charge on a single electron does not explode! i.e. the pressure from w = -1 zero point energy cores.

Note that the present "best fit" for dark energy is not w = -1, however, I say that more data will show w = -1. I also say that dark matter detectors will never "click" with The Right Stuff. These are two crucial tests that will falsify my theory.

Finally, look to the skies. Heads up. What do you see "Out There" Michael? How do they fly? Dark energy that's how.

Therefore, I have a clear story to tell that most people can understand compared to the alternatives. Also my story is clearly falsifiable in Karl Popper's sense.

Michael Ibison: Personally, I have no strong opinion on the matter of dark matter, but if you feel there is 'REAL SCIENTIFIC EVIDENCE', perhaps you could share what you think that is – i.e. what specific data do you find so persuasive?

Sarfatti replied to Michael who is one of the signers of the New Scientist letter:
http://arxiv.org/abs/astro-ph/0308418 Here is the evidence. It is more than satisfactory to my mind. Not only that, it explains what Hal Puthoff has been attempting to explain for at least 30 years.

BTW you need to distinguish "dark energy" from "dark matter" though I think they are essentially the same, i.e. net zero point energy density of negative and positive pressure respectively modulated by variable partial vacuum coherence, I am alone in that opinion. All of The Pundits think dark matter consists of real on-mass-shell particles whizzing around in space. I say that is a mistake. Dark matter, like dark energy, is a form of exotic quantum vacuum that is essentially 100% of all the stuff of the Universe. Even ordinary matter made from spatially-extended lepto-quarks (Bohm's hidden variables) is exotic vacuum quantum pressure gluing together shells of charge as I show in a recent paper with Ken Shoulders on "charge clusters" http://qedcorp.com/destiny/ExoticVacuumObjects.pdf still under construction. Note that Ken worked with Hal on this same problem for many years and has now obviously voted with his feet! The point here is that Hal has never written down the correct zero point energy/gravity relationship, which in the simplest Newtonian limit of Einstein's GR is the static Poisson equation, sans factors of pi

Laplacian of Gravity Potential Energy Per Unit Test Mass of Exotic Vacuum ~ c^2/\zpf

/\zpf = (Quantum of Area)^-1[(Quantum of Area)^3/2|Vacuum Coherence|^2 – 1]

Vacuum Coherence obeys a generally covariant Landau-Ginzburg equation with a Mexican Hat Potential.

15. **YHS taking a Break**
May 31, 2004

Quoth D R Lunsford :

The CMBR is not predicted by BB, it is an assumed and tunable side-effect of nucleosynthesis and atom-building and subsequent thermalization of radiation, and also depends on a strict separation of EM and gravity. The WMAP data is open to any number of interpretations (I've seen some that go against BBw/I). Compared to this, the large scale "walling" and enormous filamentary structures actually *seen* are heavy counter-evidence.

As a custom it must be by now, this website

http://background.uchicago.edu/~whu/physics/tour.html

reading must be required before one open the mouth to speaketh about the Big Bang and CMBR.

(Ok, that's an unsuccessful attempt at Old English Yodaspeaketh.)

16. **D R Lunsford**
May 31, 2004

"The Big Bang model is also well confirmed, the CMBR, for one. And the elemental abundances. Plus, the clear peak in the WMAP data is a generic prediciton of inflationary models."

The CMBR is not predicted by BB, it is an assumed and tunable side-effect of nucleosynthesis and atom-building and subsequent thermalization of radiation, and also depends on a strict separation of EM and gravity. The WMAP data is open to any number of interpretations (I've seen some that go against BBw/I). Compared to this, the large scale "walling" and enormous filamentary structures actually *seen* are heavy counter-evidence.

If somehow the long-range forces *are* related on some level then everything is in thrown into a cocked hat. Cosmology as it stands, even without the ad-hockery of inflation etc. is simply too much extrapolation from too little data, IMO. Mind you I am not a steady-stater – I'm just against religiosity in science.

17. **Matthew**
May 31, 2004

"GR, although well-tested in the (very) weak field case provided by the vacuum neighborhood of the Sun, is simply assumed to hold under all conditions, and is made the cornerstone for building the entire universe"

I'm not really sure that's true. There's at least one "strong field" prediction of GR that's been confirmed, the behaviour of the Husle-Taylor binary plusar.

There are other weak field predicitons that seem to hold as well. Lensing, for example. And, as I understand it, the dark matter density inferred from lensing (a GR effect) is consistent with that inferred from rotation curves (essentially a Newtonian effect).

The Big Bang model is also well confirmed, the CMBR, for one. And the elemental abundances. Plus, the clear peak in the WMAP data is a generic prediciton of inflationary models.

GR and the big bang model may have issues, and it's appropriate to point them out. But, to pretend that the observational support for them is limited to extrapolations of solar system tests is just wrong.

18. **D R Lunsford**
May 31, 2004

I can assure you Lerner understands GR. I think he believes that it is incomplete, and the energy problem is a symptom of that, and that it is not the only operative factor in the large scale structure of the universe.

I find it difficult to construct the right sentences to express the heterodox opinion. GR, although well-tested in the (very) weak field case provided by the vacuum neighborhood of the Sun, is simply assumed to hold under all conditions, and is made the cornerstone for building the entire universe. Something in the soul of the the skeptic just cannot accept this extreme extrapolation, the moreso since large-scale effects of electromagnetism seem to be deliberately ignored, in spite of the existence of enormous filamentary structures which are well-explained as plasma phenomena. The skeptics do not trust the objectivity of the orthodoxoi, and adduce Markarian 205 etc. and the ostracism of Halton Arp as examples. See for example

http://www.angelfire.com/id/jsredshift/review.htm

A scientific community that embraces string theory and anthropomorphism in particle physics, is fully capable of equal excrescence in other fields. So, it is not GR as such that is being questioned – it is the entire attitude of the scientific community that Lerner et. al are fighting against, IMO with great courage.

I would also point out that the energy problem is resolved in Weyl's approach, but it is nearly impossible to get anyone to pay attention to this remarkable fact.

19. **Chris W**
May 30, 2004

Here is another reminiscence about a talk given by Segal, written by a former research associate of his, Ray Streater.

20. **Simplex**
May 30, 2004

I dont quite understand your objection to Carroll's criticism of Lerner. It seems to me that Lerner raised the issue of energy non-conservation. So your remark–that it is meaningless to even bring energy up–actually applies more to Lerner than to Carroll. Here is a quote (in which Carroll quotes Lerner):

" Consider this quote by Eric Lerner, petition signatory and author of The Big Bang Never Happened:

[i]'No Conservation of Energy
The hypothetical dark energy field violates one of the best-tested laws of physics–the conservation of energy and matter, since the field produces energy at a titanic rate out of nothingness. To toss aside this basic conservation law in order to preserve the Big Bang theory is something that would never be acceptable in any other field of physics.'[/i]

Actually, there is a field of physics in which energy is not conserved: it's called general relativity. In an expanding universe, as we have known for many decades, the total energy is not conserved. Nothing fancy to do with dark energy — the same thing is true for ordinary radiation. Every photon loses energy by redshifting as the universe expands, while the total number of photons remains conserved, so the total energy decreases. An effect which has, of course, been observed."

Maybe you can straighten me out, but though I dont always like Carroll's style or tone of voice this seem legit on his part.

21. **D R Lunsford**
May 30, 2004

The argument against Lerner is specious – in fact the main problem with GR is that of defining energy – so when he says "energy is not conserved" it's wrong both technically and philosophically. Technically, energy is not even local, so of course it's not "conserved" as that term is usually understood – philosophically, insofar as GR is a theory of tensors, and there is no tensor for the gravitational energy, it's meaningless in a real sense to even bring it up. This kind of dismissive comment is what annoys many people who see Bangers as a priesthood with a recevied wisdom to fall on.

More Landscape Stream of Consciousness

May 31, 2004
Categories: Multiverse Mania

It looks like particle theory has now degenerated to the point where its leading figures can't think of anything better to do than to write rambling articles with virtually no equations that reach no real conclusions. Last week was Lenny Susskind, tonight there's a new article by Michael Douglas.

His conclusion, such as it is, goes like this:

"If I had to bet at the moment, I would still bet that string theory favors the low scale, for the reasons outlined above, but it is not at all obvious that this is what will come out in the end…. We should keep in mind that 'favoring' one type of vacuum or mechanism over another is not a strong result, if both types of vacuums exist…"

So, maybe string theory "favors" a low supersymmetry-breaking scale, maybe not. As usual, not only can't it predict anything, it can't even predict the scale at which it can't predict anything. I really cannot understand why anyone thinks this kind of thing is science.

   An addendum about Nomura.

   I had forgotten it, but time ago I had quoted W.T. Shaw in the first page of my essay physics/0001033.

   "if we are getting discrete data from the market, how can we claim that the derivative is not zero? Should we say that our derivative is *almost non zero*? What control do we have over the inversion process?"

2. **Alejandro Rivero**
   June 5, 2004

   Hi Chris, :DDD

   I am still happily surprised that some minor, unpolished, works (the "Lecture on Divergences" between them) get random attention even if unpublished. In this case, I took care to blame Gabay, the librarian, by indirectly drawing my attention towards such pathologial matters. I know I am setting a bad example for future archeologists (I doubt it will be a younger generation of physicists), but at least now I understand why our elders were not afraid of divergences (btw, baez did some nice postings recently on borel transforms etc). As for the problem of renormalization itself, I am optimistic that it can be tamed, and it will show to be a problem in the concept of derivative. Long long time ago I heard a Field medallist to say that, of course, trivialy, blah blah, the derivative is just the simplest example of controlled substraction of infinities.

   Let me to do a bit of propaganda for Nomura: hi guys, write Oakley! Imagine, you will be able to pay a flat in Newton street (pretty smail address), to buy your ve/getables at Holborn market, and even to walk straigthly to the work, no need of tube, no need of car!

   Around the end of 1999 I visited some of these financial industries in London City -I can not say if Nomura itself, but Chris could look in the CV database- and I found them to be very nice places to work. There exist some meetings on econophysics, so you can still train your research sword if you want and meet interesting people around.

   On other hand, the financial research is interesting because it is a purely artificial system, so it helps you to understand what facts come from physics and which ones come from mathematics.

3. **JC**
   June 5, 2004

   Alejandro,

   After when I left academia, initially I thought of doing some independent research on my own. It turned out after a year or so I found myself pursuing numerous "dead ends" and drifting around aimlessly, bouncing around from idea to idea and making very little progress. Despite keeping in contact with old colleagues via email, I still found it was difficult to settle down and work on calculations. Whether it's my own lack of self discipline or laziness, I know now from experience that pursuing independent research outside of academia to be a long hard "road less travelled".

   Despite having long periods of time devoted to thinking and contemplating about math and physics, in between job searches and sleeping, I still found it relatively hard to bring many of my research ideas to fruition while working alone in a solitary manner. At times I wonder how folks like Julian Barbour, Grigori Perelman, or Andrew Wiles worked during their "self imposed exiles" away from mainstream research communities.

4. **Chris Oakley**
   June 5, 2004

   Hi JC,

   My detailed knowledge of string theory comes from Peter Woit – the most unbiased source – so I am unable to shed light on issues you raise. I would suggest an e-mail to William – he's busy, but I am sure that he would be happy to discuss these matters.

   I'm similarly useless on path integrals. I never liked them and they never liked me. I have always suspected sleight of hand here, but have never been able to prove it. A bit like having a dishonest cleaning lady. It just seemed to me that the good old operator-commutator methods were stronger tools, and that if something went wrong that it would be more difficult to weasel out. This way one gets a clearer picture of what is going on.

5. **JC**
   June 5, 2004

   Chris,

   I took a look at William Shaw's www page at Oxford and noticed he had a pdf file of his recent presentation in finding an anomaly free way of doing string theory in 4 dimensions via twistors.

Over the years I've always wondered if there's any compelling loopholes in "quantizing" string theory which bypasses the anomalies that locks the number of spacetime dimensions at 10 (superstring) or 26 (bosonic string). Some paper a few months ago by Thiemann hep-th/0401172 attempted to "quantize" the bosonic string by loop quantum gravity methods which appears on the surface to bypass the usual string anomaly. From what I could figure out of Thiemann's paper and in the various discussions about it on the string coffee table (at Distler's site) and physicsforums.com (in the string section), it appears on the surface to be a "quantization" which seems to lack a path integral formulation and looks almost "vacuous". So far I haven't seen anybody attempting to do a tree level amplitude type of calculation to see what the classical limit produces. (ie. Do we get back anything that looks like a Veneziano type of formula?)

It seems like the anomalies in the conventional quantizations (ie. canonical and path integral) of string theory are very well entrenched in standard treatments of string theory, with so much effort expended over the last 20 years on dealing with the "extra dimensions" compactified on Calabi-Yau manifolds. If there is indeed an "alternative quantization" method which bypasses the anomalies in string theory which lock the number of spacetime dimensions to 10 or 26, it may possibly put into question all that volume of work done on Calabi-Yau compactifications. From a self-serving perspective, I would probably find it difficult to give up on all that compactification stuff in string theory if I was still doing particle/string research today. Less "resume padding" type of papers to work on in string theory, if all that Calabi-Yau stuff turns out to be irrelevent in the end.

Sometimes I wonder if the path integral is really the most general way of thinking about quantization. At this point I would be somewhat reluctant to throw it away into history's trash bin, considering how effective it's been in understanding Yang-Mills theory and the Standard Model. Arguably many folks would be hard pressed to think of something else that could possibly replace the path integral.

6. **Chris Oakley**
   June 4, 2004

   Hi Alejandro,

   No hires have as yet resulted from that permanent job ad on my CV on my web site, partly because the CVs I have been sent as a result have never quite fitted the vacancies at the time. The most prominent physicist at Nomura – although he is really more a mathematician – was William Shaw, who now runs the Mathematical Finance course at Oxford. We still see him from time to time. He has written a book on solving mathematical finance problems with Mathematica, and has a book on Complex Analysis in preparation. He started out doing Twistors, and still works on this from time to time. He gave a talk recently to the String theorists at Cambridge, showing how one could do Strings in four dimensions without anomalies using Twistors. This talk, he says, "went down like a lead balloon". I guess that they don't want to be deprived of the exciting challenge of explaining what happened to the six they have spare in *their* formulation.

   By the way, as for your 2002 "Short Lecture on Divergences" – wash your mouth out! You should be apologising for pathological divergences, not justifying them. What kind of example is this setting to the younger generation?

7. **Alejandro Rivero**
   June 4, 2004

   As for research outside academia, I find that it is very hard to do calculations when one is alone. But forming a research team of "exiles" sharing a common seems not easy; I do not know any.

   One could mention solitary snippers, as for instance Barbour, but the research then is very exotic by itself (not to mention, ahem, mine).

8. **Alejandro Rivero**
   June 4, 2004

   Chris, how many years does a physicist hang in nomura? I am amazed you keep needing people all the time.

9. **Peter**
   June 4, 2004

   Hi JC,

   I don't know much about Steklov, but I think the IAS is pretty different. It has only a small number of permanent people, and those jobs are among the hardest to get in the world, so they are held by absolutely the most highly respected physicists around. It's true they have no formal duties, and some end up doing nothing, but in general the level of the people and their activity there is very high.

   The theory groups at the national labs might be a bit more similar, but again these have only small numbers of permanent people, and I assume there is some sort of evaluation process they are subject to. I don't think the US has ever had anything analogous, i.e. a large institute with a lot of people hired on the old communist system of "we don't really pay them, and they don't really work".

10. **Peter**
    June 4, 2004

    Hi Chris,

    Job advertisements for mathematicians and physicists are encouraged. A huge improvement over the penis enlargement ads that spam the comment section and have to be periodically deleted!

11. **Chris Oakley**
    June 4, 2004

    I'm embarrassed to put a job ad in a physics discussion forum, but we did briefly discuss jobs in Finance …

    It so happens that we are looking for a numerate C++ programmer with UNIX experience here at Nomura (in the City of London). The job is mostly programming, but expect to do maths as well. Salary ?50K + benefits. If interested, send me a CV (chris.oakley@uk.nomura.com)

12. **JC**
    June 4, 2004

    Peter,

    Do you think the IAS resembles the research institutes that were common in Soviet Russia, such as the various Steklov Institutes? Several old Russian friends and colleagues mentioned that in some of those research institutes, there was virtually no teaching duties nor was anyone required to publish anything. Almost everybody was paid something like $200 per month salary, regardless whether they did anything or just sat around doing nothing for the whole time. After the communist Soviet system fell apart, some of the better researchers as well as many younger folks left Russia and took up faculty or postdoc jobs at American universities.

Or would these Russian research institute jobs more closely resemble tenured jobs at places like Los Alamos, Argonne, Brookhaven, etc …?

13. **Peter**
June 3, 2004

Hi Erin,

While I think it's really hard to do great research outside of academia, you're right that at this point it's also very hard in some subjects like particle theory to do it inside academia also.

Two of the greatest achievements in math during the last decade both took about 7-8 years of sustained, very independent work. One was Wiles's proof of Fermat's Last Theorem, he did this from a permanent academic position. The other was Perelman's proof of the Poincare conjecture, which he seems to have done from outside academia. So both are possible, but both required somebody at the height of their powers who was able to devote most of their intellectual energy for 7-8 years to the project. This certainly is not the kind of thing a postdoc is in any position to do, since they need to get a new job every 2-3 years, and no one is going to give them one based on being in the middle of a difficult ambitious project that may not work out.

14. **Peter**
June 3, 2004

Hi JC,
There certainly are examples of people who never did very much after getting permanent positions at the institute. Hard to tell if it would have been different if they were somewhere else. I always found the atmosphere there a bit weird, the isolation may not be a good thing for many people.

It will be interesting to see what happens with Seiberg and Maldacena. I think Witten spends a lot of his time traveling and interacting with people who come to Princeton, so he hasn't become as isolated as some others there in the past. The one thing that he may be missing is the experience of regularly teaching graduate-level courses, something that forces one to regularly rethink one's understanding of the basics of one's subject.

15. **JC**
June 3, 2004

Chris,

Seems like some Nobel laureates went beyond the deep end and never climbed out of the abyss, such as Brian Josephson working on psychic/voodoo type of phenomenon, or Julian Schwinger working on cold fusion in the last years of his life. The only Fields medalist I can think of offhand who turned into an oddball, was Grothendieck disappearing in 1991 without a trace.

Anybody know of other oddball cases of Nobel laureates or Fields medalists?

16. **Chris Oakley**
June 3, 2004

Hello erinj,

You raise some interesting points.

The stories about Einstein and Newton do not surprise me. Anyone who has done real research (as opposed to just CV padding) will be well aware of just how chaotic and haphazard the process is. The organising of the chaos that the academic research establishment tries to do is somewhat reminiscent of Hollywood, where production companies try to turn the successful one-off, off-the-wall idea into a steady revenue stream, forgetting that the very reason why the idea succeeded was *because* it was different and crazy.

It seems to me that the amount of "craziness" (for want of a better word) that is tolerated depends on your status. For Nobel laureates and Fields medallists, any amount of craziness is tolerated – not only that, but many will follow one into the abyss. For tenured academics, ditto, but probably few will follow. For graduate students or post-docs, on the other hand, deviation from the party line is not tolerated at all. Given that in the last century almost every significant idea in theoretical physics was from someone in their 20's, it would seem to me that something is very wrong here.

17. **erinj**
June 3, 2004

I agree with your comments, Peter, on independent research, but surely there are examples of successful independent research which has taken place outside of academia, although some degree of intellectual stimulation may have been present? An obvious example would be Einstein, working as a patent clerk in Berne and having meetings with others as part of the `Olympia Academy'. Einstein must have had, or found, the time to dedicate to his three 1905 papers. Newton's `miracle year' (1665/6?) was one were he was, as far as I've read, isolated on his mother's farm, Cambridge having closed due to the plague. Also, people like Hawking and John Nash appear to have drifted through their PhDs, waiting until the last year or months before finally focussing on a problem (and then solving it). Hey, and didn't Louis de Broglie, wealthy aristocrat that he was, do physics research for fun?

Having been a postdoc, I often wonder whether the time and freedom (and possibly lack of pressure) necessary for `great', or major, works, is more likely to be found outside of academia, and perhaps the really big problems of the past, present and future do require a proportionately large amount of time and thought to solve. No publish or perish rule, no scrabbling or begging for funding – perhaps a menial job in the background to earn enough to live on whilst one concentrates on the `real' work. I admit that this reads as an exceptionally difficult route to acheivement, but perhaps in such conditions the `survival instinct' takes over and intellectual challenges become all-consuming instead of being part of the potentially droll `day job'.

This seems to be the approach that many – if not all – major, award-winning and famous novelists, dramatists and poets take, as they are even less likely to be paid to produce work in these areas than scientists. The sheer difficulty of their circumstances perhaps drives them to brilliance and creative heights, but I suppose this requires immense resilience and dedication, perhaps to the detriment of family, friends, health, etc. In fact, the parallel goes further, as I read that Einstein essentially slept for two weeks, exhausted and ill, after arriving at his final formulation of special relativity. Didn't Newton's hair gradually turn white after his `miracle year', as well? Maybe the cliche `no pain, no gain' really does hold.

I personally don't believe there is sufficient freedom for risk-taking and novel research in academia as funding bodies and research leaders are very cautious, which is probably to be expected (their jobs being on the line as well, if things go badly…). Then again, string theory research seems to have garnered a very large part of global particle theory research funding over the past ten years or more. I myself believe string theorists gain funding because of links to particle theory rather than any claims about string theory being the "best candidate" for a quantum theory of gravitation. Quantum gravity is a problem that I believe is not going to be readily solved inside academia, unless funding for loop QG and other `alternatives' to string theory QG receive more funding so that they can be explored more fully. The really big and difficult problems just don't receive the funding necessary to resolve them, inside academia: the risk is just too great, and in consequence I wouldn't be surprised that a lot of research becomes "resume padding". Surely we need more of Feynman's "leaps into the wild blue yonder" (I do hope that quotation is correct).

18. **JC**
June 3, 2004

Peter,

Do you think the IAS was a cause or symptom for folks like Einstein, Goedel, Oppenheimer, etc … in producing nothing of significance for the rest of their lives, and/or producing garbage research bordering on crackpottery?

I remember reading something in a short biography of Kurt Goedel, where his wife thought that the IAS wasn't much more than the equivalent of a "retirement home" for famous academics who are long past their prime.

19. **Peter**
June 3, 2004

It's pretty unusual for people to be able to do much research outside of the standard academic system these days. Perelman is an interesting special case, I actually don't know to what extent he really was cut off from the math community in Russia while he was doing his research, or whether he did have colleagues to talk to. One funny thing about him is that he's in line for a million dollars from the Clay foundation, but seems to have no interest in the money. Definitely an unusual character, very devoted to a pure approach to abstract research.

One problem with being outside academia is getting the necessary blocks of time to devote to thinking about research. It also is much harder to make progress on one's work if one doesn't have people to talk to about it, or continuing stimulation of new ideas to think about. I've always thought the Institute in Princeton wasn't such a great idea, because by isolating people from having to teach classes and deal with students, it can keep them from having to think about anything other than the one approach to their research they are pursuing. It can be quite helpful to be forced to think about different topics, and may give one ideas about new ways to think about one's research.

20. **JC**
June 3, 2004

Peter,

How common is it for math or physics folks to take up independent research outside of the formal academic system, such as Grigori Perelman working on a proof of the Thurston geometrization conjecture in relative isolation for many years in St. Petersburg?

Arguably there's no pressure to publish any "resume padding" type of papers, or for that matter publishing anything, when one isn't a part of the formal academia system.

At times I wonder how many folks would be working independently (ie. outside of the formal academic system) on things like SUSY and/or string theory, if there were no tenured faculty nor any untenured faculty or postdocs working on it. I always wondered if John Schwarz would have worked on string theory during 1970's and early 1980's if Murray Gell-Mann had never kept him around as a "permanent postdoc" when string was in hibernation, and possibly would have had to take a day job in the private sector outside of academia.

21. **Peter**
June 2, 2004

I mainly know what happens these days with grad-students and young faculty in math. Very few grad students leave without getting a degree. When they graduate, some don't even try and get an academic job, instead going directly into finance jobs, computer jobs, or maybe doing something like working for the NSA.

Of those who get a first academic job, many leave academia after a couple of years or so.

For both categories of people, the situation is similar. Getting a postdoc at a good place is hard, and getting a tenure-track job at a good institution that will support your research is harder. So people find that the jobs they can get are either in places they really don't want to live, or at primarily teaching institutions. Many people find they really don't enjoy not being paid very well to do a lot of very low-level teaching. A well-paid job in New York doing financial math looks a lot more attractive in many ways.

Once people get to the point of having a tenure-track job in math and do it long enough to know they want to stick with it, most end up getting tenure, either at the place they start or somewhere else.

The job situation is particle theory is much worse than in math, but I haven't been following the careers of more than a few young grad students and postdocs in it, so don't have much data about what is happening to them right now.

22. **JC**
June 2, 2004

Peter,

What reasons do math/physics people have for leaving grad school or academia these days?

The main reasons I've heard of over the years from old friends and colleagues (excluding political or gross misconduct reasons), were involuntary ones like

– a grad student couldn't get a postdoc
– a postdoc couldn't get another postdoc and/or couldn't get an assistant professor job
– an untenured faculty member was denied tenure or couldn't get a tenured faculty job
– an untenured faculty member lost most of their grant funding (especially in the case of an experimentalist)

while voluntary reasons were ones like

– a grad student didn't like graduate school and didn't feel like it was worth the effort to finish their PhD research work
– a grad student got bored or sick of their field and quit after getting their PhD
– an untenured person got sick and tired of their field, and had a hard time getting any funding when they tried changing into another field (in some cases not even getting any funding at all in their new field)
– a postdoc felt they had no chance in hell of getting a faculty job, and subsequently quit
– a postdoc got bored or sick and tired of their field, and subsequently quit

– a tenured faculty member got sick and tired of cranking out meaningless “resume padding” type of papers just to maintain their research grant money; ended up quitting to find more greener pastures outside of academia
– a postdoc got sick and tired of cranking out tons of meaningless “resume padding” type of papers, with no end in sight (ie. the “permanent postdoc” types who are on their 4th, 5th, or higher postdoc); ended up quitting out of discouragement

23. **Peter**
June 2, 2004

Since the bubble burst I don’t know anyone who has gone into the computer industry. All the people I can think of who have left academia recently have gone into finance. Part of this may just be because I’m in New York, where there are lots of finance jobs and few computer ones. Maybe the experience of people on the West Coast is different.

24. **JC**
June 2, 2004

Peter,

How common is it for math or physics PhDs to go into computers ever since the dotcom bubble bursted a few years ago?

Almost everybody I know who still has a paying job in computer/hi-tech and even the defense sectors are paranoid of being laid off, especially with many jobs being “outsourced” to places like India or China. This seems to be almost universal from the folks who do data entry all the way up to PhDs who do the cutting edge research & development work, who are not in upper management. On the surface it sounds “suicidal” for a company to be firing many of their research and development folks just to save a few bucks in costs, or “outsourcing” their research and development work to countries which don’t have much in terms of intellectual property laws and enforcement.

25. **Chris Oakley**
June 2, 2004

I’m keeping out of the Cosmology discussion (although, if pressed, am prepared to vociferously defend my beliefs about the Great Green Arkleseizure) …

My comment is on Peter’s remark below:

Unfortunately the thing that seems to me the most sensible idea in the present circumstance, that of going back and trying to really understand the things one doesn’t understand about gauge theories and the standard model, doesn’t seem to have any takers. People have convinced themselves that there’s nothing new to be found that way.

There are a handful of takers, but, being focused on irrelevancies, they never got anywhere.

26. **D R Lunsford**
June 1, 2004

One thing that is true of anti-bangers (and perhaps bangers) – one makes up his mind early, and tends to stick to that decision. e.g. I have always found the BB hateful, even before inflation which only made it much worse. There is too much “play” in GR for comfort, so the extrapolation to cosmic time scales is very suspect, the moreso since the entire idea of energy is on shaky ground – and so also time. Time is all balled up in GR no matter how you cut it. The following thought experiment illustrates – you can never “watch a movie” of the formation of a black hole – since you can’t see anything beyond the horizon, that stuff can never have been “out here”, from my perspective, and therefore a black hole cannot form in finite local time, and must have always existed, from my perspective. Now the problem here is not the horizon, but time itself – and it’s just the other side of the energy problem. I cannot think of any counter-argument that allows a Big Bang. Time is more than duration, it’s “persistence”. GR is only complete when the substance – persistence – comes automatically out of the basic idea of curvature. That is, by its nature GR is a vacuum theory, and in fact the only part of it that is well-tested is $R_{mn} = 0$.

27. **Peter**
June 1, 2004

I don’t have a lot of information about what is happening to current particle theory PhDs, but a large fraction of the ones from my era (early-mid 80s) ended up working in the computer or finance industries (about equal numbers in each).

Over the last ten-fifteen years I’ve seen a lot of young math grad students and faculty leave academia, mostly for finance. Ten years ago the academic job market was terrible and it wasn’t so hard to get a finance job. More recently the academic job market has improved, but finance jobs seem to take a lot more effort for people to get. One reason is that there are now a lot of financial math master’s degree programs (we have a very successful one here in our department). So there are a lot of students coming out with some training and good credentials in financial math. It is harder for straight math PhDs without any experience in finance to compete with them.

28. **Chris Oakley**
June 1, 2004

Hello erinj,

If there is less tolerance now for quants who don’t program in the City, then I accept part of the blame. I have always argued that they should. The problem is that if bringing the model into production means involving a team of programmers to turn the model into something that can work in a production environment then the process will take too long, and as I probably do not need to tell you, traders are not patient people. The system we have at Nomura just involves deriving a (C++/COM) class from one called “Trade” and overriding some virtual functions. That way our quants can have a new trade type in the system on the same day (there is a bit more to it than that, but that is the basic idea).

We are now getting way off topic. Drop me an e-mail with your CV to chris.oakley@uk.nomura.com and I will see if I can come up with some suggestions.

29. **erinj**
June 1, 2004

Hello Chris,

I made two serious attempts to gain employment in the City (of London, banking and finance sector), about two years apart, and came up against a brick wall on both occasions – once as a new theoretical physics PhD, and once as a recent high energy physics post-doc. Despite advice to the contrary, I found it impossible to gain work as a junior `quant’ (quantitative analyst).

I contacted many banks and finance firms, got advice from an economics university lecturer who was a former `quant’ team member, and read up on as much financial mathematics and economics as I could. I couldn't even secure an interview! My CV was listed on quite a few specialist finance employment agencies, and I could get nothing. I was, and still am, baffled by the lack of interest my skills, which I assumed were valued by the finance sector, brought me.

After asking for feedback about this, I was told by employment agencies – who relayed what quant team leaders told me about my applications – that the reasons I was never shortlisted were: lack of experience in the financial world, too many other PhDs applications, and that my programming skills were not as extensive as other applicants. Well, if they wanted computer programmers, why did they give the impression that they wanted theoretical physicists – people who can work with and solve mathematical and modelling problems?

I think that there are, and have been, too many applicants for finance sector jobs who don't have enough programming skills, like myself, and who have also been misled about how much computer programming is required in these jobs. The aforementioned former quant told me that it would be about 75% of the time – is this true in your experience, Chris?

My impression (and I've seen job ads asking for candidates in this direction) is that, in the post-9/11 era, combined with the economic down-turn, economics and financial mathematics PhDs are the candidates more likely to be successful, as well as graduates who have worked as part of summer programmes with banks (internships/work experience), and even computer science PhDs.

So now I'll never get to see the `front office' or the trader's floors, nor be paid the fabled big salaries and bonuses of the City.

June 1, 2004

Chris,

Perhaps it was the folks I was speaking with over the years. These old colleagues in particular ended up quitting Wall St. after 6 or 7 years, after getting sick and tired of trading or writing computer code that priced derivatives securities. I never asked them specifically what they defined as "burnout" in their line of work. My trading friends were always complaining about their work related stress, such as their telephone ringing every 30 seconds and having to keep track of information simultaneously on 5 or 6 computer screens all day. The friends who did the computer derivatives calculations stuff had less complaints, other than many of them finding their work boring and/or not very interesting after awhile. In some ways I got the sense they felt their work started to become "routine" or a "chore" to them, and the initial "excitement" was gone for the most part.

Whether these folks chose the "wrong" profession to go into, I don't know for sure. Some thought the money would keep them happy, but in the longer term it didn't. Others I suspect saw the money as a "means to an end", where they were able to make a large enough fortune to "retire" and do whatever they wanted afterwards with the rest of their life.

Certainly none of them had any complaints about the money they were making. Every one of them were able to pay off all their student loan debts, as well as a large portion of their mortgages if they lived outside of Manhattan.

I have not kept contact with any of these old friends and colleagues over the last few years. So I don't know what they're thinking these days, or if they changed their minds about what they regard as "burnout". A few folks I'm aware of went back to writing particle and/or string papers while others literally "disappeared" without a trace.

31. **Chris Oakley**
June 1, 2004

Speaking as one who "sold out" and left particle physics to to work in Wall Street (the City of London, actually) – I feel it my duty to correct the bleak picture painted earlier of this career path. First off, if you choose to go into trading as did former string theorists Kelly Kirklin and Paul Miron then you can make *a lot* of money. I don't know the exact score with these two, but my guess is that they both have enough to retire. Kelly is now a post-doc at Cambridge. Whether he is paying for himself, or denying some much more deserving youngster by holding this post I do not know, but the point is that with plenty of money in the bank, he is now able to do what he wants, which is physics – a bit like the "gentleman scientists" of old, like Lord Rayleigh. Personally, I never went into trading, mainly because I find software far more interesting, but having said that, although I have not done nearly as well as these two, I nonetheless was able to pay off my mortgage about two years ago.

Some basic points that all physicists thinking of making this transition ought to be aware of:

= There is a lot of interesting mathematical work to be done in the Finance world.

= The route from science PhD to quantitative analyst in an investment bank is well-trodden & you will not have to explain or justify yourself. Mathematical skills *are* valued.

32. **D R Lunsford**
June 1, 2004

Weinberg in astrophysics – how nice.

I heard a talk a UMd on early string theory (the 26-dim weaving of it) by Gell-Mann. He opened his talk with a comment about the "half-asstrophysicists" in the audience. I wanted to punch him out. Instead I asked him an impromptu group theory question he could not answer extemporare, which was almost better.

33. **JC**
June 1, 2004

How popular is it for physics or math folks to go to Wall St. these days?

I knew many particle theory and some string folks that went the Wall St. route through the 1990's. Main drawback I've heard from old friends and colleagues is that there's a very high burnout rate on Wall St. with a half-life of around 6-7 years for many physics and math types.

Only other major "competitive" route I was aware of that many math and physics folks went to, was management consulting. Last I heard from friends and colleagues that went into consulting, many consulting firms (ie. Accenture, McKinsey, etc …) were laying off folks like crazy in periodic "purges" over the last few years.

34. **Peter**
June 1, 2004

A lot of people are already abandoning particle theory for astrophysics, Steven Weinberg would be one prominent example. Many string theorists have moved into cosmology, often hoping there is something to be done there with string theory, my colleague Brian Greene is an example.

I hear my advisor (Curt Callan at Princeton) is mostly doing biology these days. A few people have moved into mathematics.

Presumably John Schwarz would be one of the last to give up on string theory. Witten certainly seems to continue to believe in string theory, something which mystifies me. He hasn't gone in for the anthropic nonsense, or for "string cosmology" or "string phenomenology". I'd bet he's well aware that the present state of string theory is such that progress can't be made in those areas.

I suspect the SUSY people will hang in there until data from the LHC comes in. If something interesting that isn't SUSY turns up there, they'll all jump on it.

Unfortunately the thing that seems to me the most sensible idea in the present circumstance, that of going back and trying to really understand the things one doesn't understand about gauge theories and the standard model, doesn't seem to have any takers. People have convinced themselves that there's nothing new to be found that way.

35. **JC**
May 31, 2004

Any bets on what string theory folks will be working on, if string theory falls out of favor and into hibernation like it did in the late 70's and early 80's? Any bets that somebody like Edward Witten would abdicate from string theory, and/or John Schwarz would continue slogging on with string theory to the day he dies?

Any bets on what the SUSY crowd will be working on, if SUSY falls out of favor too?

Apart from my very limited knowledge of particle physics history, I don't even have any clue as to what I could be working on if I was still doing particle theory, outside of SUSY and/or string theory. If I was a young naive grad student today, I would be tempted to go into something like astroparticle theory or possibly do an MBA or law school instead.

Witten on Electroweak Symmetry Breaking

June 3, 2004
Categories: Uncategorized

Witten has contributed an essay to the latest issue of Nature about electroweak symmetry breaking. He describes the main conventional ideas about this, ending with the latest anthropic ones. Here are his comments about those:

"One approach is the anthropic principle, according to which the dark energy and the Higgs particle mass take different values in different parts of the Universe, and we inevitably live in a region in which they are small enough to make life possible. If so, many other properties of the Universe that we usually consider fundamental ? such as the mass and charge of the electron ? are probably also environmental accidents. Although I hope that this line of thought is not correct, it will inevitably become more popular if experiment shows that electroweak-symmetry breaking is governed by the textbook standard model with a Higgs particle and nothing else."

He ends with the eminently reasonable summary:

"As yet, none of these theoretical proposals about electroweak-symmetry breaking are entirely satisfying. Hopefully, by the end of this decade, experimental findings at the Tevatron and the LHC will set us on the right track. But the diversity and scope of ideas on electroweak-symmetry breaking suggests that the solution to this riddle will determine the future direction of particle physics."

Comments

1. **Peter**
   June 4, 2004

   Witten certainly didn't need me to point out to him the importance of this problem. But maybe the reason he just said that current proposals are not "entirely satisfying" but didn't offer any speculation about alternatives is that he didn't want Srednicki and Distler telling him he was an incompetent moron for thinking there might be alternatives.

2. **Simplex**
   June 4, 2004

   Too bad the Nature article is online to subscribers only. This
   2003 talk by Witten on a similar theme might be useful for comparison.
   http://conferences.fnal.gov/lp2003/program/papers/witten.pdf

   The title is "Supersymmetry and Other Scenarios". The talk
   was given at a conference at Fermilab and there was some discussion afterwards, which is included at the end.

3. **Thomas Larsson**
   June 4, 2004

   Unfortunetely the link is for Nature subscribers only and I don't have a subscription. However, I distinctively recall that somebody else recently emphasized that EW symmetry breaking may be the key problem. So it looks like Witten is following Woit's suggestion. One may wonder if the connection is causal or merely temporal. 🙂

Dartmouth Talk

June 4, 2004
Categories: Uncategorized

I was visiting the math department at Dartmouth the past couple days, and gave a colloquium talk there. It's now available online.

Comments

1. **Peter**
   June 9, 2004

   I'm using the term "weight" in the precise sense it is used in representation theory, the label for a representation of T. More generally it can label reps of some Abelian subgroup, e.g. multiplicative groups. If the group is the real numbers, the weights are given by arbitrary numbers, not necessarily integers like in the U(1) case.

2. **D R Lunsford**
   June 8, 2004

   Why specifically is the word "weight" used? Weyl was very precise with language so by weight he would have meant the exponent on a multiplicative factor, in whatever sense (in the talk, the context is projective representations of spin groups).

   In the sense of Weyl geometry, the weight of the Dirac spinor field is imaginary, ie. The weight of a Yang-Mills field should be something like iek Tk as a kind of dyadic.

3. **Peter**
   June 8, 2004

   Hi Danny,
   The "weights" I'm talking about are for compact Lie groups G and come about as follows:

   1. For G of rank r, this means there is a subgroup T of r copies of U(1). For any representation of G, you can restrict attention to T and think of it as a representation of T. If you start with an irreducible representation of G, it will break up as several irreducible representations of T (all one-dimensional since T is Abelian). These representations of T are the "weights" of the original G representation.

   2. More explicitly, an irreducible representation of U(1) is labeled by an integer n, and e^{i\theta} acts by multiplication by e^{in\theta}. An irreducible representation of T is labeled by r integers.

   Things are different and much more complicated for non-compact groups (like the conformal group), then you typically have copies of R (the real numbers) in the maximal Abelian subgroup. Representations of R are labeled not by integers but by real numbers.

4. **D R Lunsford**
   June 7, 2004

   RE Peter-Weyl and Borel-Weil theorems –

   One thing I have been thinking about is extending the idea of conformal weight in an attempt to understand the relation of the covariant derivative

   (d/dm + ie Tk Akm)

   in field theory, to

   (d/dm + N Am)

   in Weyl conformal geometry – where N is the Weyl conformal weight. Am I right in saying that the "weights" mentioned in your talk are some kind of generalized phase which will turn out to correspond in gauge theory to charges?

5. **Peter**
   June 5, 2004

   I used the latex macro package called "prosper". For now the latex source file is at
   http://www.math.columbia.edu/~woit/dartmouth.tex

6. **D R Lunsford**
   June 5, 2004

   I love the interview with Dirac – that's priceless!

   Once a friend drove Dirac from the airport to the hotel in New Orleans. It had recently rained a great deal and snakes had emerged from the swamp, which Dirac noticed with a short comment like "snakes are interesting". My friend was on the organizing committee for the conference, and part of his job was to deliver Dirac and find something entertaining for him to do in New Orleans. So, he picks the zoo and the herpatarium in particular and asks Dirac if he'd like to see it "since you like snakes". Dirac said "I did not say I liked snakes. I said they were interesting."

   I felt really good about both Dirac and Weyl after reading that story. On his part, Weyl was the first person to really understand the significance of the Dirac equation. Weyl was very generous with praise when it was deserved.

7. **D R Lunsford**
   June 5, 2004

   Aside, what tools did you use to create this?

Bogdanovs Redux

June 5, 2004
Categories: Uncategorized

A couple years ago two French brothers, Igor and Grichka Bogdanov, managed to get Ph.Ds in France and publish several nonsensical papers about quantum gravity in refereed physics journals, several of them rather well-known and prestigious ones. John Baez has a useful web-page about this story.

This whole thing seemed to me strong evidence of how in recent years there has been a collapse of any real intellectual standards in this part of theoretical physics, and I ended up being quoted about this in various places. The "Affaire Bogdanov" died down fairly quickly, and the scandal doesn't seem to have lead to much in the way of higher standards.

I recently heard from Fabien Besnard, who wrote to tell me that the Bogdanovs have a new book out, called "Avant le Big-bang" (Before the Big Bang), in which they quote me as endorsing their work. Besnard has a web-page (in French) on the latest developments in the L'affaire Bogdanoff.

The Bogdanovs wrote me last year, here's a copy of their e-mail. I made the mistake of thinking "maybe these guys aren't so bad, just overly-enthusiastic sorts who could use a little helpful advice", and wrote this back to them. In their book they use part of my e-mail, mis-translating:

"It's certainly possible that you have some new worthwhile results on quantum groups.." (I was being too polite here; while possible, it is unlikely)

as

"Il est tout a fait certain que vous avez obtenu des resultats nouveaux et utiles dans les groupe quantiques" (It is completely certain that you have obtained new worthwhile results on quantum groups).

One lesson from this is not to write back to crackpots. Another strange part of this story: late last year I received an e-mail purporting to be from a "Prof. L. Yang" at the "International Institute of Mathematical Physics" at Hong Kong University. It appeared to come from

th-phys.edu.hk

a domain name that is registered with the Hong Kong DNS, supposedly by the Hong Kong University of Science and Technology. I connected to the web-site at this address, which at the time contained an official-looking web-page for this Insitute. It now contains just a listing of directories, one of which is full of .pdf files of the papers of Arkadiusz Jadczyk.

This web-site is hosted by a US web-hosting company "Everyone's Internet, Inc." If you look carefully at the header for this e-mail you see that while it purports to be from

"liu-yang.imp@th-phys.edu.hk"

it really comes from

th-phys.edu.hk (ATuileries-117-1-27-138.w193-253.abo.wanadoo.fr)

which appears to be a machine connecting to the internet from Paris, set to claim to be "th-phys.edu.hk".

It's looking more and more like the original idea that the Bogdanovs were hoaxers, putting on the physics community, was closer to the truth than the idea that they are serious, just not very good, researchers.

Update: The comment section received a message from a supposed mathematician named "Roland Schwartz" defending the Bogdanov's work on quantum groups. The source of the comment was
IP number 217.128.255.129. The DNS shows

nslookup 217.128.255.129

Name: ATuileries-117-1-29-129.w217-128.abo.wanadoo.fr
Address: 217.128.255.129

Funny, this seems to be a very close neighbor in Paris of Prof. L. Yang…..

I also just noticed that Jacques Distler has posted an account of his experiences with "Prof. L. Yang" et. al.

Comments

1. **Jack Sarfatti**
   June 20, 2004

   What is a "crackpot."?

   John Baez has a definition, which, if used without a double standard, implies that his own thesis advisor Irving Segal at MIT was/is a crackpot. Baez's criteria are perhaps too strong. A distinction must be made between amateurs who clearly have no idea what they are talking about and those with serious credentials in the field they are writing about who are expressing deviant, unpopular, strange (because they are so far ahead of the pack perhaps like Feynman was with his diagrams, or Bohm was with his quantum potential) or perhaps they are wrong, and even "not even wrong" on some particular hobby horse. In any case "crackpot" is a "smear" word like Joe McCarthy's use of "Red" etc, which should be avoided. By all means correct technical errors but best to avoid charged personal terms. Is Lenny Susskind, for example, a "crackpot."? By Baez's criterion he would have to be. I don't think he is. I worked with Lenny at Cornell in 1963-64.

2. **the-real-yang!**
   June 13, 2004

   Schwarz-petitot-bogdanoff said :
   "A few days ago a debate of this kind was organized and it showed that Bogdanoffs were very convincing as far as their domain of research is concerned."

   Where and when ? I can't remember it!

3. **Bogdanoff**

Comments: Bogdanov Thesis Reports

Good morning,

We would like to react to Peter Woit comment on our thesis and reports.

Woit wrote : "I wouldn't be surprised if some reports were missing."

IGB : There are no reports missing. These are the "official reports" that everyone has the possibility to check with University of Bourgogne. This makes a total of 15 reports (which is quite unusual in itself since normally a thesis only requires 2 reports). This answers clearly the question : there is no "hidden report".

Woit wrote : "I've always had some sympathy for the people who ended up on the Bogdanov's thesis committees. It's a difficult position to be in when you have to decide what to do with students who seem to be enthusiastic and have worked hard, but are very weak and have completed not very good theses.

IGB : How do you know that we have completed not very thesis? We are mathematicians, you are physicist. In a sympathetic letter, you wrote us that you do not know quantum groups theory ; "A large part of your work has to do with quantum groups and I'm not an expert in this field."

Question : why don't you trust Majid when he says "Bogdanov's ideas about signature fluctuations are to my mind about the more original and interesting that I have come across?"

Why do you refuse to admit that we have build a bicrossproduct "of a type not seen before" (theorem 3.3.2) The basic theme is tomix algebraic structures associated to the Euclidean and the Lorentzian signatures intosingle algebraic constructions. Bogdanov identifies this as constructing certain cocycle Hopf algebras ot a type not seen before : " These cocycle bicrossproduct results, in section3.3, from a body of original work which could certainly be the basis of a published researchpaper. "

We have spent many, many years working with Majid. He knows our ideas from A to Z. Do you think that he would have allowed the work to contain "some mistakes" or nonsensical parts?

The answer is NO.

Woit wrote : " A not unreasonable thing to do under the circumstances is to do one's best to find something of value in their work, "

IGB Yes. That would be a good thing to do.

Woit wrote : But the Bogdanov theses, especially Igor's, were so full of egregious nonsense, in particular with respect to topological quantum field theory, that they should have been beyond the pale.

IGB : It is rather bizarre that you insist so much on the "nonsense" of our work. After all you wrote that you are not an expert in quantum groups. This theory is the mathematical basis of our signature fluctuations model. If you do not understand quantum groups, you do not understand our model. Nothing wrong about it. But then, stop saying "it's nonsense".

Woit wrote : While some of these reviewers were string theorists, others weren't, so the whole mess can't be blamed on string theory.

IGB : Do you seriously think that a scientist of the magnitude of Jackiw signed his report without filtering every idea, sentence, proposition, of the thesis? We worked extensively before he would agree with the quality of the work. Jackiw would never have approved "nonsensical" work just because he found us "enthousiastic" (by the way, we never met him before he wrote his report : all the work was based on reading the thesis and exchanging informations or arguments by mail).

We can accept that you disagree, as a physicist, with our signature fluctuations model. But again we are mathematicians. And we developped our work on mathematical basis. Therefore the only thing that matters is : is our major theorem (a cocycle bicrossproduct of new type) valid or not?

The answer given by experts is YES, without any doubt.

If you disagree with this yoy know will have to prove it.

Thank you for your attention,

Igor Boganoff Grichka Bogdanoff
Posted by Bogdanoff at June 12, 2004 09:42 AM

I have always felt that the American system, where you kick out weak students after two years if they don?t pass their qualifying exams, is better for everybody than the European system, where the only real checkpoint is the dissertation, and people can linger forever. It is not really fair to let people work for a decade and then deny them a Ph. D.

I am not sure how consistently the American system is implemented in the US, however. It is probably not so easy to keep people out if they don't require funding.

I did not have any opinion untill now. But after my reading of all the reports, I must admit that I was very interested and also surprised. After all, it seems that B&B have really done something.

5. **JC**
June 11, 2004

Peter,

Speaking of the parallels between postmodernism and string theory becoming dominant, one can see a similar parallel in the "neoconservatives" becoming dominant in conservative thinking which first started in academia and eventually made it's way into official political policy in the Dubya administration.

Many of the ideas which eventually came to fruition in the Bush administration's policy in pre-emptive wars in invading and taking over Iraq, were ideas cooked up by folks like political philosopher Leo Strauss and eventually taken up by guys in Dubya's administration like Paul Wolfowitz, Richard Perle, etc … who started to spread their ideas of pre-emptive wars and an American empire all the way back to the days when they were in the Reagan administration. With the present disaster in Iraq with oil pipelines being blown up every few weeks, American soldiers being killed every other day by insurgents, etc … despite Saddam being caputured and out of the picture, the "neoconservatives" have been slowly falling out of favor and being blamed for everything that is going wrong in Iraq.

It seems like the easiest way "unpopular" and/or "unrealistic" ideas can become dominant is attributed to Nazi propaganda minister Joseph Goebbels, (paraphrased as) "If you tell a big lie and keep on repeating it often enough, people will eventually perceive it as the truth."

It would be interesting to see if the popularity of ideas such as postmodernism, string theory, neoconservativism, etc … came about by hype and propaganda being repeated over and over again for many years.

On the surface it appears things that are "propped up" mainly by propaganda and hype, seem to follow speculative "bubble" type of patterns in their rise and downfalls. During the upward rise of the bubble, many people are willing to "suspend disbelief" in the promises made. Eventually a "bubble" bursts when the hype can no longer fool anyone and "reality" starts to set in. After the point of the bubble bursting, it seems to be only the diehard fanatics who still believe in the hype and propaganda while everybody else has moved on.
In the end, making too many unrealistic promises and repeatedly proclaiming triumphalism in an idea, seems to doom it when the promises are unfulfilled and "reality" takes over.

6. **P.Rozinski**
June 11, 2004

I wish to add the following comment about these reports. My opinion is that most of them (probably because of the public personality of Bogdanoffs) go far beyond a simple formal or academic expertise : everyone can feel that people like Kounnas or Jackiw have done a real work on Bogdanoffs thesis. Moreover all the reports following the defense are (in essence) not academic and only aiming at a technical evaluation of the manuscrit. All this shed a new light on Bogdanoffs work which (contrarely to the image created by the rumor) suddenly appears as quite original and serious.

7. **P.Rozinski**
June 11, 2004

I have read all the reports about the two thesis of Bogdanoff brothers : I must admit that it is not only "supportive", it is also very impressive. Mainly because one can obviously see that experts like Majid did invest a lot of time and work on the content of the quantum groups part of Bogdanoff thesis. His 3 different reports are extremely precise and there is no doubt that his conclusions regarding the importance of Bogdanoff theorem are deeply based on his own expertise of the field and a serious knowledge of Bogdanoffs work. His report is a real example of what a good and sound report of expert should be.

8. **Alejandro Rivero**
June 11, 2004

I do not know why they have preferred to register them as CERN-OPEN instead of CERN-EXTernal. I supposse it is because of the involvement of some CERN researchers.

The report of Majid is certainly supportive. It is perhaps on his nature. It should be remarked we are speaking of a couple of PhD thesis, no less but no more. As Majid says, it is the *basis* for future work.

9. **J.Devers**
June 11, 2004

BOGDANOFF THESIS REPORTS

Note that for the first time since the beginning of this affair in 2002, all the 15 reports concerning the thesis of Bogdanoffs are available on the CERN document server :

http://cdsweb.cern.ch/search.py?recid=740747&ln=en

10. **petitot**
June 10, 2004

Dear Grantot,

1) Prof. Yang = Roland Schwartz = J.Petitot = the Bogdanovs.

True. It's a perfect equivalence.

The only way I see out of this mess would be a public grilling of the brothers (on TV, in front of the public, since they want the public to take part) by experts on quantum groups and topological field theory, who would ask them basic questions and then more involved specific stuff.

The bogdanoffs would be delighted to debate with any expert in the fields. A few days ago a debate of this kind was organized and it showed that Bogdanoffs were very convincing as far as their domain of research is concerned. So yes : let's organize this "grill session" as soon as possible.

11. **Grantot**
June 10, 2004

For those who lost the plot:

1) Prof. Yang = Roland Schwartz = J.Petitot = the Bogdanovs. [You can easily recognize them, at least until now, by the way they quote messages, and the way they are aware of absolutely everything about the brothers.]

2) crankbuster = Grantot = somebody who is fed up with this story, in particular to see that they distorted what Schreiber and Woit said and published it in a book now being read by thousands of french people… Under crankbuster I showed that Roland Schwartz talks nonsense. The brothers realized that and then appeared as J.Petitot. I posted again under crankbuster and then Grantot to reply to the messages by J.Petitot. [The name Grantot is a joke: since Petitot could be translated as Small-oh in english, I went for Grantot, which is Big-oh.]

3) Moyentot = somebody else, who has a better sense of humor than me ;-). I think I recognise him from fsm. [Moyentot, as you've guessed, means Medium-oh.]

4) If the brothers can come back to this affair anyway it is also, apart from the aformentioned new distortions, because some of the members of their PhD jurys spoke out in favour of them 3 years ago. That left the door open. We know that Robert Oeckl or Alain Connes said they work on quantum groups was weak, but Majid has been apparently a little more sympathetic. This is on what they are entirely relying, as can be seen when they write (under Petitot) "Regarding my other remarks (Oekl) you did not answer any of my observations : does that mean that you agree that Majid is a more reliable source regarding the quality of Bogdanoffs work than Oeckl?. As far as I am concerrned, I follow his conclusions: Bogdanoffs theorem in quantum groups is original and important."

The only way I see out of this mess would be a public grilling of the brothers (on TV, in front of the public, since they want the public to take part) by experts on quantum groups and topological field theory, who would ask them basic questions and then more involved specific stuff.

12. **petitot**
June 9, 2004

Dear polytot,

Here are some quick reactions to your last message :

You wrote : "since you have published precisely 4 papers and only 4 papers, indeed, a fixed number of 4 papers,

How do you know that I published 4 papers?

Therefore, dear Moyentot, may I kindly ask you to explain to me how it works to make bunches of people seriously discuss a paper that is based on the observation that when setting T=0 in the expression beta=1/T things look really weird?

There is nothing mysterious here : beta is only the inverse of temperature. Come on : you know quite well that T = 0 can be seen as a topological limit of any field theory. And in this case (on this limit) beta goes to infinite (as usual). There are tons of references on this particular point.

Ah, you mean it suffices to mention the term 'quantum groups' in the process, because it will intimidate everybody to such an extend that he forgets to laugh?

Be serious for a minute, please. Would be much more interesting four our readers.

13. **Peter**
June 9, 2004

Hi JC,

The Postmodernism article generator is great. Perhaps someone should write a string-theory version, surely this is possible.

The whole history of string theory and how it took over the major physics departments in the US is very similar to the experience many humanities departments had with Postmodern "theory". The parallels between these two stories are remarkable.

14. **Moyentot**
June 9, 2004

Dear Moyentot –

since you have published precisely 4 papers and only 4 papers, indeed, a fixed number of 4 papers, I am willing to trust your opinion precisely 4/3 the amount that I trust Besnard, who has published 3, no more no less, precisely 3, and 3 only.

(Since I cannot tell right from wrong myself and cannot explain to anyone the mysterious relation between Foucault pundulums and FRW cosmologies, I spend my time counting the number (and precisely the number, the fixed and invariant number) of publications of some people.)

Therefore, dear Moyentot, may I kindly ask you to explain to me how it works to make bunches of people seriously discuss a paper that is based on the observation that when setting T=0 in the expression beta=1/T things look really weird?

Ah, you mean it suffices to mention the term 'quantum groups' in the process, because it will intimidate everybody to such an extend that he forgets to laugh?

My, dear Moyentot, this was a very helpful answer indeed.

Sincerely,
Moyentot.

15. **grantot**
June 9, 2004

Dear Grantot,

you wrote : " The very fact that you ignore what this is (Mathscinet) says it all."

I ignore where you found that I do not know mathscinet. In fact, in my post dated June 8, I wrote : "I have read the article in reference and contrarely to what you say it is obvious that Oeckl is *forced* to recognize the value of Bogdanoff Theorem : he simply cannot deny their result."

A simple contextual reading shows that I wrote having read the paper in Mathscinet. I know this database for years (this is not exceptional, no?).

(By the way, the only J.Petitot in Mathscinet is an epistemologist from Ecole Polytechnique, who never published anything on quantum groups.)

So what?

You wrote : "Now I found this, also published in 2001:

F. Besnard: Number Operator Algebras, Mathematical Physics Electronic Journal Vol 7, paper 4, 59pp, 2001.

OK. I must admit that this electronic publication did not attract my attention beyond the arXiv version. Nevertheless the total number of publications is invariant : 3 and only 3. Even if the quality of a research is not based on the number of published papers, it is a "sign" : Besnard should not give any lessons to anyone, simply because he is not a reference. He failed to meet bogdanoffs proposal regarding a detailed scientific report on their quantum groups theorem. Instead he developped a "dark rumor" on his site and sent all sorts of emails to different people, hoping that he would create a new "affair" (see his site). Do you really think Besnard reacted honestly and objectively? I do not think so and I maintain that his attitude is definitly not scientific.

16. **JC**
June 9, 2004

This thread is reading more and more like an episode of Beavis and Butthead (B&B). Perhaps a better name for B&B (Bogdanov & Bogdanov) would be "Beavis & Bogdanov" and their never ending misadventures in physics hoaxes.

At times I wonder whether the previous posts by Grantot, Petitot, Roland Schwartz, crankbuster, etc … are really just B&B "talking" to themselves in an attempt to produce an "illusion" of dialog. Astroturfing or generating hype deliberately to get even more attention for themselves.

What would be amusing is if somebody rewrote the code to the Dada Postmodernism random essay generator at

http://www.elsewhere.org/cgi-bin/postmodern/

and

http://dev.null.org/dadaengine/

such that it randomly generated legitimate looking "theoretical physics" papers in the style of Beavis & Bogdanov (B&B).

17. **Grantot**
June 9, 2004

Dear Petitot,

you wrote: "the reference does not appear in any database, even not arXiv where the paper is "due to be published in lmp"

but you've just been told that they appear in Mathscinet! The very fact that you ignore what this is says it all. (By the way, the only J.Petitot in Mathscinet is an epistemologist from Ecole Polytechnique, who never published anything on quantum groups.)

You also wrote: "Nevertheless, all in all (and this time I am sure) Besnard had only 1 paper published in 2001."

Now I found this, also published in 2001:

F. Besnard: Number Operator Algebras, Mathematical Physics Electronic Journal Vol 7, paper 4, 59pp, 2001.

18. **Alejandro Rivero**
June 9, 2004

Noticing the relationship between this new surge and the B&B new book, Urs has suggested to go to the amazon.fr website and similar selling points and upload the criticisms there.

19. **petitot**
June 9, 2004

This is a reply to Crackbuster.

You are quite right regarding the publication in L.M.P. : I had not seen that Besnard had indeed one paper published in this journal (the reference does not appear in any database, even not arXiv where the paper is "due to be published in lmp). So yes, I admit I was wrong.

Nevertheless, all in all (and this time I am sure) Besnard had only 1 paper published in 2001. He never published anything since then. Nothing wrong with that. But he should not pretend (as he does on his site) that he is the mighty scientific Judge of Bogdanoffs case. They have published 6 papers, Besnard only one (and still, in LMP : do you know that this journal was created by M.Flato, the first director of thesis of…Bogdanoff? and do you also know that LMP is managed today by D. Sternheimer, the second director of thesis of Bogdanoff?)

Regarding my other remarks (Oekl) you did not answer any of my observations : does that mean that you agree that Majid is a more reliable source regarding the quality of Bogdanoffs work than Oeckl?). As far as I am concerrned, I follow his conclusions: Bogdanoffs theorem in quantum groups is original and important.

20. **crankbuster**
June 9, 2004

An now a reply to Petitot (and I'll stop there):

3. anybody can go to the website of Letters in Mathematical Physics and see that Besnard indeed published there the following:

F.Besnard, Number Operator Algebras and Deformations of ε-Poisson Algebras, Letters in Mathematical Physics, 55 (2): 113-125, February 2001.

So now who is lying ?

21. **Petitot**
June 8, 2004

This is a message to "crankbuster" in reply to certain elements of his post that appears not to be correct.

Contrarely to him, I am an expert but (not for the same reasons) things also look dodgy to me. Here are my answers :

1. Do you know that there is a review of one of the B&B papers by R.Oeckl (who did his PhD with Majid apparently) in Mathscinet, see the review MR1894907 (2003f:81231) at . In it Oeckl says:

"even if they had shown the existence of the bicrossproduct this is completely at odds with the sentence following the "proof": "Clearly, Proposition 4.1 proves the possible `unification' between the q-Lorentzian and the q-Euclidean Hopf algebras at the Planck scale."

This is not a valid example. I have read the article in reference and contrarely to what you say it is obvious that Oeckl is *forced* to recognize the value of Bogdanoff Theorem : he simply cannot deny their result. Majid himself recognized this original result in his report dated Jan.2000 : "The (Bogdanoff work) contains useful algebraic constructions of cocycle Hopf algebras of various kinds motivated from physics.The basic theme is to mix algebraic structures associated to the Euclidean and the Lorentzian signatures into single algebraic constructions. Bogdanov identifies this as constructing certain cocycle Hopf algebras ot a type not seen before. These cocycle bicrossproduct results, in section 3.3, from a body of original work which could certainly be the basis of a published research paper.

So you have a specialist in quantum groups (the thesis director of Oeckl himself) who writes that Bogdanoff results are original and could certainly be the basis of published research paper."

Question : Who shoul we beleive? you (and your vague quotation of Oeckl) or Majid himself?

3. This is wrong: Mathscinet says F.Besnard published 3 papers.

Sorry : this is a typical distortion of the truth. Besnard has never published any paper in a refereed journal : the 3 papers that appear in the database are only published in the archive (and not in a journal). Besnard has never published in a journal based on experts committee.

7. It is not the first part of the sentence which is biased but the second part. I agree with your traduction of the first part as: "As the physicist Peter Woit said to us with some despite, these new instruments (quantum groups) are not well known by physicists:".

But the traduction of the remaining french text is ": it is absolutely clear that you have obtained new and useful results about quantum groups, but to understand what you wrote and how it relates to what is already known requires an expertise that only a handful of people in the world possess." So I confirm what P.Woit wrote in the first message in this thread: they seriously distorted what he meant.

No. Because when you read the whole sentence in french it does not sound at all like a supportive text. You see, the important thing is the "global content" of a phrase, not a framgment of it. The first part of Woit's sentence (where Bogdanoff insists on Woit's dispite) relates to the rest of the phrase and, in a way, disqualifies any support. This was recognized by anyone around me.

In conclusion, here, the "twisters" are Besnard and Woit. Not the Bogdanoff.

22. **crankbuster**
June 8, 2004

This is a reply to the post by R.Schwartz. I'm not an expert but even on the surface things look dodgy to me. Numbers refer to his post:

1. Do you know that there is a review of one of the B&B papers by R.Oeckl (who did his PhD with Majid apparently) in Mathscinet, see the review MR1894907 (2003f:81231) at . In it Oeckl says:

"even if they had shown the existence of the bicrossproduct this is completely at odds with the sentence following the "proof": "Clearly, Proposition 4.1 proves the possible `unification' between the q-Lorentzian and the q-Euclidean Hopf algebras at the Planck scale." " So here you have a specialist in quantum groups who disagrees.

3. This is wrong: Mathscinet says F.Besnard published 3 papers.

7. It is not the first part of the sentence which is biased but the second part. I agree with your traduction of the first part as: "As the physicist Peter Woit said to us with some despite, these new instruments (quantum groups) are not well known by physicists:".

But the traduction of the remaining french text is ": it is absolutely clear that you have obtained new and useful results about quantum groups, but to understand what you wrote and how it relates to what is already known requires an expertise that only a handful of people in the world possess." So I confirm what P.Woit wrote in the first message in this thread: they seriously distorted what he meant.

23. **Thomas Larsson**
June 7, 2004

The book "An guide to quantum groups" by V Chari and A Pressley has a 60-page biography with references to just about anybody that has ever written anything remotely connected to quantum groups, including an obscure reference to myself. Oddly enough, this huge biography does not mention neither to R Schwartz nor to L Yang…

24. **Urs Schreiber**
June 7, 2004

It is not true that it is hard to understand what Bogdanov & Bogdanov are saying. It is easy.

To see if I got them right I once wrote a little summary of their ideas. They told me that this summary is 'very accurate' and that I am among the few who understands what they are aiming at. But what I had summarized of their ideas was a list of nonsense! (See here for more details)

Luckily, they even quote my summary in their new book. They removed the phrases that were obviously critical and made it sound like I am supporting them, but neverthelesse fortunately now everybody can read these couple of lines containing very simple reasoning, understandable to everyone who knows what a partition sum and what a topological field theory is. And what they write is obviously nonsense.

It is the familiar kind of nonsensical speculations that some students make when being confronted and while learning new theories and techniques. The only difference is that the usual student realizes that he was on the wrong track and moves on. B&B wrote a book about it. Apparently their only concern is being in the media as often as possible.

25. **Roland Schwartz**
June 6, 2004

Let me first introduce myself : I am a mathematician and I think I know quantum groups theory well enough to clearly make up my mind about Bogdanoff's work. Following an article that was written by a certain Fabien Besnard against the Bogdanioffs, I decided to post my answer on fr.sciences physics newsgroup. My remarks were as follows :
1. The quantum groups work made by Bogdanoffs is sound and original. They have constructed a bicrossproduct of a new type between lorentzian and euclidean forms.

This construction gave a sound theorem. The value of this theorem has been accepted as such by experts of quantum groups theory (Majid, Gurevich, Oeckl, etc. By the way, Oeckl is nos a supporter of Bogdanoffs but he had to admit their results – see SPR).
2. Fabien Besnard criticized the Bogdanoffs without having the expertise to do so. He does not know quantum groups and therefore is not even able to read Bogdanoff's work.
3. Fabien Besnard never published any paper. He can hardly be considered as an expert in any field.
4. In a private mail to Bogdanoffs (see ref on this page) Peter Woit recognized that he cannot understand any of their work in quantum groups.
5. Nevertheless, he claims that Bogdanoffs work is nonsensical.
6. My conclusion is that (based on his own words) the opinion of Peter Woit on the particular point regarding the value of Bogdanoffs work is therefore totally nonsensical.
7. I have read and compared the translation made by Bogdanoffs in their book regarding the comment of Peter Woit. Contrarely to what claims Fabien Besnard, this (very short) phrase reported by Bogdanoffs does not give at all the feeling that Woit is supporting them : "Ces nouveaux instruments (groupes quantiques) sont tr?s peu connus des physiciens comme nous l'a confi? avec une pointe d'amertume le physicien Peter Woit : Il est tout ? fait certain que vous avez obtenu des r?sultats nouveaux et utiles dans les groupes quantiques, mais comprendre rapidement la signification de ce que vous avez ?crit et comment cela se raccorde ? ce qui est d?j? connu requiert une expertise que seule une poign?e de gens poss?de dans le monde." This phrase translates as : "As the physicist Peter Woit said to us with some despite, these new instruments (quantum groups) are not well known by physicists..;" etc. In french language the work "amertume" has a negative connotation and it is quite clear that Woit does not appear in the book as a supporter of Bogdanoffs work. This prooves that Mr Besnard twists the reality and appears as a dishonest and unrelyable agent in this artificial polemique. Once again, there is no phrase, nowhere in the book, indicating that Woit is a supporter of Bogdanoffs work. From our own view, following a serious expertise of their construction in quantum groups, we maintain that it is sound, original and very interesting. If Fabien Besnaard or Peter Woit think the countrary, then they have to demonstrate it.

26. **D R Lunsford**
June 5, 2004

Well that's a good point. It's OK to be a crackpot if you know what you are talking about 🙂 It's not OK to be just wrong.

27. **Steve**
June 5, 2004

A quick web search shows that the "International Institute of Mathematical Sciences" does actually exist in Hong Kong, with a Prof Yau as director(same as in Calibi-Yau fame I think). However, nothing can be found on a "Prof. Liu Yang" except for the same pro-bogdanov email posted to an obscure web forum/discussion group. See http://www.matthewyglesias.com/archives/
002028.html
and scroll down.
This was not posted by "Prof. Yang" himself but by "one of his colleagues" lol. Says "something also about "we are mathematicians and not showmen like John Baez". It seems that this "Prof Yang" and "his colleagues" not only have the time, expertise and desire to fully study, comprehend and appreciate the depth, originality and potential of the Bogdanov papers in detail, but also have additional time to trawl the web and participate in any obscure forums where the Bogdanovs are criticised in any way, and thus come to their defence with "expert opinions". Sounds highly suspect and highly unlikely in the extreme. And like you mentioned, the internet connection seems to be coming out of France. Still you have to give these dudes an "E" for effort lol.

28. **Alejandro Rivero**
June 5, 2004

Well, I write back to crackpots sometimes, simply suggesting readings or points to work out; if/when then show they are not interested in physics but in "his theory", I hang the line.

On the other side, I have become sort of crackpot myself. The whole history is not to be told yet, but the result is that my last work seems very crackpotty if read from some standpoints. As a byproduct I have had the opportunity to see the rejection mechanism completely at work. I didn't know, for instance, that the barrier was not in the referee side but in the editors. A double edged sword, because when a referee receives a work, he could already to assume that the filter has been passed, thus no further checks against "bogdanoff maladie" are done.

de Branges and the Riemann Hypothesis

June 10, 2004
Categories: Uncategorized

Louis de Branges is a mathematician at Purdue who has had a long history of claiming proofs of the Riemann hypothesis. His latest claim has lead to a press release from Purdue. The press release points to what seems to be an older manuscript by de Branges outlining some of the history of the Riemann hypothesis and his work on it. This also includes some history of his ancestors, and de Branges has taken to calling himself “Louis de Branges de Bourcia”. He more or less promises that if he wins the Clay million dollar prize for solution of this problem he would use it to restore the ruined chateau de Bourcia for use as a mathematical research institute.

The actual purported proof is here. One mystifying thing about it is that in the abstract and introductory paragraph it repeatedly refers to relations to quantum mechanics, but there seems to be nothing about this in the body of the paper. Weyl’s book on quantum mechanics and group theory appears in the references, but nothing in the text seems to refer to this.

de Branges has a checkered history as a mathematician, with several of his claimed proofs of the Riemann hypothesis and other problems turning out to be incorrect. On the other hand, he did produce a correct proof of one well-known problem, the Bieberbach Conjecture. In that case his initial manuscript was pretty impenetrable, but after he explained his ideas to a group of Russian mathematicians, they gave a more understandable version of the proof and it became clear that de Branges really did have a proof. It looks like this one may also take some major effort to see what he really has.

For more about de Branges and the Riemann hypothesis, see the recent popular book “The Riemann Hypothesis: the Greatest Unsolved Problem of Mathematics” by Karl Sabbagh. A review of this book has some interesting comments about de Branges and his NSF funding.

A couple weeks ago a preprint appeared on the arXiv by R. A. Arenstorf, a mathematician at Vanderbilt University, claiming a proof of the twin prime conjecture. I asked one of my colleagues who is an expert on the subject about it and he said he didn’t believe it and would bet $100 it was wrong. Today I see that Arenstorf has withdrawn the preprint, saying that a serious error has been found.

   June 10, 2004

   “One mystifying thing about it is that in the abstract and introductory paragraph it repeatedly refers to relations to quantum mechanics, but there seems to be nothing about this in the body of the paper.”

   It was Connes who, some years ago, stressed the relationship between quantum mechanics and some methods to attack Riemann hypothesis. As Alain had part in the Clay formulation of the problems, I guess that the remark is just implicit hommage.

Bogdanov Thesis Reports

June 11, 2004
Categories: Uncategorized

From one of the comments here I see that the Bogdanovs have put the [reports]() on their theses on the CERN document server. One should perhaps take these with a grain of salt given their source. For instance, I wouldn't be surprised if some reports were missing.

I've always had some sympathy for the people who ended up on the Bogdanov's thesis committees. It's a difficult position to be in when you have to decide what to do with students who seem to be enthusiastic and have worked hard, but are very weak and have completed not very good theses. A not unreasonable thing to do under the circumstances is to do one's best to find something of value in their work, and leave the job of keeping nonsense out of the literature to journal referees.

But the Bogdanov theses, especially Igor's, were so full of egregious nonsense, in particular with respect to topological quantum field theory, that they should have been beyond the pale. While some of these reviewers were string theorists, others weren't, so the whole mess can't be blamed on string theory.

Comments

1. **Bogdanoffez**
   June 12, 2004

   Well, dear Peter, you see that one of the consequences of your constant position to deny any value to our work gives reactions like : "It would be interesting to see if University of Bourgogne starts to get fed up with all the bad press coverage about the Bogdanovs, that it starts an investigation of their own into their PhD theses work and eventually revokes their PhD degrees."

   It really goes beyond our mind to realize that it seems to be impossible de discuss what we did on "normal" basis. As it seems impossible to everyone to recognize, honestly, that we did serious work. What is going on in your mind? Do we criticize your work? do we say that you produced "nonsense" in all your articles? You perfectly know that we could say so very easily. So please respect our work and we will respect yours.

2. **Peter**
   June 12, 2004

   This is pretty different than an experimentalist faking data. If universities start investigating every theoretical physics thesis that doesn't make sense, this could become a very large project….

3. **JC**
   June 12, 2004

   Just noticed these articles today about Jan Hendrik Schoen (the guy who was discovered to have pulled off a huge data falsification job at Bell Labs in 2002), being revoked of his PhD by University of Constance

   http://www.lasvegassun.com/sunbin/stories/tech/2004/jun/11/061107856.html

   and

   http://science.slashdot.org/science/04/06/11/2142223.shtml?tid=134&tid=146&tid=99

   It would be interesting to see if University of Bourgogne starts to get fed up with all the bad press coverage about the Bogdanovs, that it starts an investigation of their own into their PhD theses work and eventually revokes their PhD degrees.

4. **Peter**
   June 12, 2004

   While I'm not an expert on quantum groups, I know a lot about topological quantum field theories, and I am not relying on anyone else's judgement but my own when I say that those parts of your theses involving TQFT are nonsense. Why this is true has been explained to you in several places by several people. The fact that you have managed to get some physicists to write reports saying something positive about what I know to be nonsense doesn't give me any confidence that the positive reports about the quantum groups stuff are any better founded.

5. **Bogdanoff**
   June 12, 2004

   Good morning,

   We would like to react to Peter Woit comment on our thesis and reports.

   Woit wrote : "I wouldn't be surprised if some reports were missing."

   IGB : There are no reports missing. These are the "official reports" that everyone has the possibility to check with University of Bourgogne. This makes a total of 15 reports (which is quite unusual in itself since normally a thesis only requires 2 reports). This answers clearly the question : there is no "hidden report".

   Woit wrote : "I've always had some sympathy for the people who ended up on the Bogdanov's thesis committees. It's a difficult position to be in when you have to decide what to do with students who seem to be enthusiastic and have worked hard, but are very weak and have completed not very good theses.

   IGB : How do you know that we have completed not very thesis? We are mathematicians, you are physicist. In a sympathetic letter, you wrote us that you do not know quantum groups theory ; "A large part of your work has to do with quantum groups and I'm not an expert in this field."

   Question : why don't you trust Majid when he says "Bogdanov's ideas about signature fluctuations are to my mind about the more original and interesting that I have come across?"

   Why do you refuse to admit that we have build a bicrossproduct "of a type not seen before" (theorem 3.3.2) The basic theme is tomix algebraic structures associated to the Euclidean and the Lorentzian signatures intosingle algebraic constructions. Bogdanov identifies this as constructing certain cocycle Hopf algebras ot a type not seen before : " These cocycle bicrossproduct results, in section3.3, from a body of original work which could certainly be the basis of a published researchpaper. "

We have spent many, many years working with Majid. He knows our ideas from A to Z. Do you think that he would have allowed the work to contain “some mistakes” or nonsensical parts?

The answer is NO.

Woit wrote : ” A not unreasonable thing to do under the circumstances is to do one’s best to find something of value in their work, ”

IGB Yes. That would be a good thing to do.

Woit wrote : But the Bogdanov theses, especially Igor’s, were so full of egregious nonsense, in particular with respect to topological quantum field theory, that they should have been beyond the pale.

IGB : It is rather bizarre that you insist so much on the “nonsense” of our work. After all you wrote that you are not an expert in quantum groups. This theory is the mathematical basis of our signature fluctuations model. If you do not understand quantum groups, you do not understand our model. Nothing wrong about it. But then, stop saying “it’s nonsense”.

Woit wrote : While some of these reviewers were string theorists, others weren’t, so the whole mess can’t be blamed on string theory.

IGB : Do you seriously think that a scientist of the magnitude of Jackiw signed his report without filtering every idea, sentence, proposition, of the thesis? We worked extensively before he would agree with the quality of the work. Jackiw would never have approved “nonsensical” work just because he found us “enthousiastic” (by the way, we never met him before he wrote his report : all the work was based on reading the thesis and exchanging informations or arguments by mail).

We can accept that you disagree, as a physicist, with our signature fluctuations model. But again we are mathematicians. And we developped our work on mathematical basis. Therefore the only thing that matters is : is our major theorem (a cocycle bicrossproduct of new type) valid or not?

The answer given by experts is YES, without any doubt.

If you disagree with this yoy know will have to prove it.

Thank you for your attention,

Igor Boganoff Grichka Bogdanoff

6. **Thomas Larsson**
   June 12, 2004

   I have always felt that the American system, where you kick out weak students after two years if they don?t pass their qualifying exams, is better for everybody than the European system, where the only real checkpoint is the dissertation, and people can linger forever. It is not really fair to let people work for a decade and then deny them a Ph. D.

   I am not sure how consistently the American system is implemented in the US, however. It is probably not so easy to keep people out if they don’t require funding.

Cosmic String Hype

June 12, 2004
Categories: Uncategorized

According to a press release from UCSB, three theoretical physicists have proposed “the most viable test to date for determining whether string theory is on the right track”. This is based on a paper about cosmic strings where the authors manage to cook up a highly unlikely scenario where large strings exist and produce gravitational radiation observable by LIGO in the next couple of years.

Normally in the English language, calling something a “test” of a scientific theory would indicate that if it doesn’t work the theory is wrong. When LIGO doesn’t see this effect in the next two years I kind of doubt that there will be wholesale abandonment of string theory.

Comments

   June 17, 2004

   Hi JC,

   That’s an interesting looking article, and the older article by Feynman they reference is probably worth reading. I don’t know much about this stuff, but have often seen how tricky gauge theories are exactly because there is no simple set of gauge-invariant variables to work with.

2. **JC**
   June 17, 2004

   Just noticed this paper this morning which reviews the variational principle in nonperturbative qcd:

   “Variational techniques in non-perturbative QCD”
   by Kovner and Milhano, hep-ph/0406165

   Progress appears to be relatively slow over the years in finding a reliable variational setup, when taking account of gauge invariance issues.

3. **Peter**
   June 17, 2004

   Hi Urs,

   That’s fine. If I put something on the weblog, it’s for public consumption and you quoted me accurately and fully. I just wanted to explain why I wasn’t even trying to answer your further question, and to reiterate that I’m no expert on this and definitely not speaking for d’Hoker or Phong.

4. **Urs**
   June 17, 2004

   Re: superstring finiteness

   Peter, I apologize if you don’t like to see your summary on sps. I thought that since you made it publically available here at your weblog you are content with its public distribution. I took care to fully indicate your qualifications that you just reported, possibly incompletely, the opinion of third person(s). I hope nobody is harmed by the fact that Phong and D’Hoker see a subtlety in Berkovits’ approach.

5. **Peter**
   June 17, 2004

   Since I’m not an expert, I really don’t want to get involved in a discussion of the details of this issue. If Berkovits, D’Hoker and Phong want to discuss this issue in a public forum that would be great, but I’ve already perhaps gone too far in reporting a perhaps garbled version of private conversations.

   As far as I can tell though, everyone involved agrees that there is no proof of higher-loop finiteness, with one difficulty being understanding what Berkovits calls the “unphysical divergences” in moduli space.

6. **Urs Schreiber**
   June 17, 2004

   Re: superstring finiteness

   Peter paraphrased Phong and D’Hoker as saying:

   > To make them [the picture changing operators] well-defined in a way that is gauge invariant requires understanding some global terms.

   Many thanks for this information about your discussion with Phong and D’Hoker. I have taken the liberty to quote your comment over at sci.physics.strings. Maybe we get the chance to see Nathan Berkovits’ opinion on this issue.

   For instance, is D’Hoker&Phong’s criticism dealt with by the remarks on p. 14 of Berkovits’ hep-th/0406055?

7. **JC**
   June 16, 2004

   Peter,

   Has anyone ever successfully applied the variational technique in examining “nonperturbative” or strong coupling phenomena in any quantum field theories? The variational technique at getting approximate solutions seems to be in almost every quantum mechanics textbook, while it seems to be a rarity in most quantum field theory books.

If I didn't know any better, the only "trial functional" that appears to be easily integrable is something that resembles a gaussian. I can't think of any other obvious "trial functional" that could be easily dealt with analytically in the variational setup.

8. **Peter**
June 16, 2004

You can't claim to have a proof based on an unproven assumption.

I don't want to speak for D'Hoker and Phong, but this is my probably somewhat garbled understanding from having discussed this with both of them:

Berkovits's claim of finiteness explicitly assumes "there are no unphysical divergences in the interior of moduli space". This assumption (that these divergences cancel) is exactly what is hard to prove in the two-loop case and no one knows how to do for higher loops. In conformal gauge Berkovits argues that "there are no obvious potential sources for these unphysical divergences in the interior of moduli space since the amplitudes are independent (up to surface terms) of the locations of picture-changing operators." D'Hoker and Phong have found that the correct definition of picture-changing operators is quite subtle here. These are operator products at a point and their definition is ambiguous. To make them well-defined in a way that is gauge invariant requires understanding some global terms. Unless you do this you don't have well-defined picture-changing operators and can get whatever answer you want.

Again, I'm obviously not an expert at this, but that is my understanding of what the experts told me. While I don't want to speak for them, from what they told me I am under the strong impression that these experts don't believe that Berkovits has a proof.

9. **Urs Schreiber**
June 16, 2004

Concerning the higher-loop finiteness of string theory:

A couple of days agao Nathan Berkovits claimed to have a proof for the finiteness of the superstring at every order.

See his message on s.p.s.: apparently one unproven assumption enters the proof, which is argued to be true in covariant contexts at least.

10. **JC**
June 16, 2004

Thomas,

I was thinking of something outside of the various lattice models, such as a Thirring or Sine-Gordon type of model beyond 2 dimensions.

Lately I've been reading Kleinert's book on path integrals, where he presents a path integral way of doing many of the traditional quantum mechanics problems like the hydrogen atom, infinite square well, etc …. and other interesting looking cases I've never seen before. I was thinking more along the lines of whether somebody has ever come up with an exact analytical expression for the path integral of an "interacting" quantum field theory in 3 or more dimensions, without resorting to any approximations.

On a slightly different track, awhile ago I was reading some book (don't recall the author's name offhand) about various "quasi-exact" solutions to the Schrodinger equation for various potentials with terms like x^4 and/or x^6 with particular coefficients that makes it easier to get an analytical solution of some sort. (On the surface, it appears to be a very sophisticated way of doing a WKB approximation). Though still an approximation, I wondered whether the same "quasi-exact" tricks can be applied to some interacting quantum field theories to get a non-trivial path integral, which doesn't use perturbation theory. The upshot of the "quasi-exact" method seems to be finding coefficients for the x^4, x^6, etc … terms such that the expression under the square root sign inside the WKB integral takes on a "nice" form. Usually this "nice" form looks like a factorization of the expression under the square root sign, for the less horrible cases.

Naively I tried to see whether it can be applied directly to something like phi^4 or QED, but so far I've been stumped. I went searching through the literature for path integral treatments of 'quasi-exact' type of problems in quantum mechanics, but so far they haven't led to much further insight. After awhile I just dropped the problem and moved on to something else.

If "quasi-exact" types of solutions can be found for something like phi^4 theory, it would be interesting to see what a semiclassical calculation around these "quasi-exact" solutions would produce.

11. **Thomas Larsson**
June 16, 2004

"Has anyone ever found any exact analytical solutions to any "interacting" quantum field theories in 3 or more dimensions, without using any approximations at all?"

JC,

Would exact solutions to integrable lattice models count? In 2D, a sufficient (and in practice necessary) condition is that one has a solution to the Yang-Baxter equation,

R_12 R_13 R_23 = R_23 R_13 R_12,

where R_12 acts one the tensor product of three spaces, trivially on the last. At criticality, such a lattice model is described by a conformal field theory.

There is an analogous condition in 3D, known as the tetrahedron equation,

R_123 R_145 R_246 R_356 = R_356 R_246 R_145 R_123,

which acts on the tensor product of six spaces. A solution to this equation can be translated into a solution of some 3D lattice model, which would be described by a field theory at criticality.

Unfortunately, I am not aware of any good solutions to the tetrahedron equation. Zamolodchikov found one solution in 1981 (and introduced the tetrahedron equation in the same paper), but his model lack unitarity; Baxter later translated his work into a lattice model and showed that some of the Boltzmann weights are negative. Nevertheless, the Zamolodchikov model is believed to be at a critical point and should therefore be a field theory.

12. **JC**
June 15, 2004

Has anyone ever found any exact analytical solutions to any "interacting" quantum field theories in 3 or more dimensions, without using any approximations at all?

13. **Peter**
June 15, 2004

In the context of string theory, where the perturbation expansion is the only thing that is well-defined, "non-perturbative" is to some degree a synonym for "things we don't understand but would like to exist"

In many quantum field theories, the theory is well-defined outside of a perturbation expansion and there can be lots of different ways of trying to do "non-perturbative calculations", e.g.

1. lattice Monte-Carlo

2. 1/N expansion

3. semi-classical methods: take a non-zero solution to the equations of motion and do your perturbation theory about that instead of about the zero field. This is where instantons, solitons, etc. come in.

14. **JC**
June 15, 2004

I get the sense folks like to throw around the word "nonperturbative" as if it was a "fudge factor" that solves all the "diseases" and problems in their theories.

I see that the popular choices of nonperturbative things that many folks like to invoke, seem to be objects like monopoles, instantons, or some other "soliton" type of object. Are there other "nonperturbative" effects and/or objects than these ones, which are not too horrible to deal with analytically and algebraically?

Over the years whenever I saw the word "nonperturbative" in many papers, I started to become very skeptical. Many seem to be mostly "hot air" and hype, than anything concrete. Though one case that looked impressive on the surface was the Seiberg-Witten stuff from a decade ago, in calculating "nonperturbative" instanton corrections to N=2 SUSY Yang-Mills. To a lesser extent in the early 1990's, the mirror symmetry stuff in doing instanton calculations in string theory also looked impressive on the surface at the time.

15. **Peter**
June 15, 2004

You can set up the perturbation series for any choice of Calabi-Yau, with any choice of moduli parameters fixing its size and shape. If the series is only asymptotic you can hope that unknown non-perturbative effects choose the Calabi-Yau and fix the moduli. If the series is finite, you have a consistent theory for each Calabi-Yau and each value of the moduli.

16. **JC**
June 15, 2004

Peter,

What's the argument behind point 3, where there would be an infinity of consistent string theories if the full perturbative series is finite?

17. **Peter**
June 15, 2004

I was thinking of writing a blog entry related to this sometime, but here are the facts:

1. One-loop and two-loops are finite, the latter is a recent result of Phong and D'Hoker.

2. Higher than two loops are conjectured to be finite, but this has not been shown.

3. The full series is conjectured to be asymptotic. No reason to believe it is finite (and if it were there would be an infinity of consistent string theories).

18. **JC**
June 15, 2004

Has anyone ever shown that the perturbative expansion of superstring theory is renormalizable or finite, to all orders in perturbation theory? Is it even a convergent series, or at best only a asymptotic series? Can this even be done at all in a rigorous manner without much "hand waving"?

19. **Peter**
June 15, 2004

No, I'm not happy. You still don't seem to understand the difference between having a well-defined theory and not having one. QCD has a precise and simple non-perturbative definition (lattice QCD) and well-understood calculational methods that give controlled approximations to the exact theory. For some physical variables (the low-lying spectrum) you can do reasonably accurate calculations with control of the errors and, within the errors, you get results that agree with experiment. For others (S-matrix elements), you have a well-defined theory, but no good calculational methods. If string theory is ever going to be useful it probably would be in attacking this problem, rather than as a TOE.

People can do calculations in 11d supergravity and, when asked about the divergences, can say "oh, I'm really doing M-theory, the magical, mystical ultraviolet completion of supergravity" if they want. But they should be a lot more honest about what is wishful thinking and what is real science. You're welcome to tell us that supergravity is just an "effective theory", but normally when people work with an effective theory it is one that can be compared to experiment. In QCD the sigma-model is an effective theory for pions; you can calculate things about pions and compare them to experimental results. The "effective theory" you are working with predicts absolutely nothing, it is a complicated setup for making excuses for not being able to predict anything, not real physics.

20. **Thomas Dent**
June 15, 2004

For QCD, read "QCD at strong coupling". Happy now? Then perhaps you would give the reference of the paper which predicts the proton-proton scattering cross-section at low energies from the QCD action. Maybe the lattice people will get round to it about the same time as they do matrix theory.

Supergravity is an *effective theory*. Just like the theory of pions at low energies. It works if corrections to it are sufficiently small, which is true in the small curvature and low energy regimes.

Or it can be thought of as like electromagnetism. You don't need to know the short-distance structure of an electron to use Maxwell's equations. However, the fact that Maxwell's equations admit a solution with a pointlike charged object is a strong indication that a more complete theory should include something that looks like such an object at long distances. In supergravity (mutatis mutandis) this is a p-brane.

Polchinski showed that the supergravity calculation of the force between two p-branes and the perturbative string theory calculation of the force between two D-branes exactly corresponded. This calculation, and the fact that the electric and magnetic charges behave correctly, is regarded as a "good enough" reason to admit branes as objects in string theory. They have not led to any fatal internal contradiction so far.

Indeed string theorists are very commonly doing calculations of a similar sort, finding correspondences between different theories that lead many people to believe that (unless there is some stupendous conspiracy of coincidences) the objects of apparently different string theories can be translated from one into another, and into the objects of 11d supergravity including solitonic (magnetic) and singular (electric) charged solutions.

Some people call this "M-theory": of course this is just a name. If you want to attack string theorists for saying the words "M-theory", you are free to do so, but it is not a strong scientific argument. Such an argument would begin to focus on specific claims about specific theories, e.g. whether 11d supergravity on R^10 X S^1 does really correspond to the IIA superstring.

21. **Peter**
June 14, 2004

Actually many of the "M-theory" things I see are just classical supergravity. There's often no quantum theory, much less higher loops. As far as I can tell, absolutely no one has the slightest clue about how to make progress on finding the new magical theory that will do what they want. The existence of this now ossified ideology of the magical eleven-dimensional theory is part of what is killing off the field. Everyone runs around repeating to each other the same misguided wishful thinking, and people end up spending their whole careers wrapped up in trying to make sense of an idea which just doesn't work.

22. **JC**
June 14, 2004

When folks are doing calculations of supergravity and/or Yang-Mills theory in 4 or more dimensions, what exactly are they trying to find if the theory is nonrenormalizable at higher loops? Are they searching for some "miracle" that will cancel out the nonrenormalizable stuff? I remember a number of older supergravity papers from the 1980's which attempted to find "miracles" in higher order loop calculations. In the end many papers had a conclusion of the sort "there are no miracles in field theory".

Every time I came across papers which attempted to deal with nonrenormalizable theories via "nonperturbative" means, I always got the impression many of these papers were mostly "hot air" and hype than anything concrete. Many of the "nonperturbative" calculations done weren't entirely convincing.

23. **Peter**
June 14, 2004

The only thing at all like even a conjectural definition of M-theory is certain versions of Matrix theory, which only work on special backgrounds (e.g. flat 11d). With seven compactified dimensions, there isn't even a conjecture of what might work, just wishful thinking that something will. Whatever M-theory is, it is supposed to reduce to 11d supergravity at low energies while somehow getting around the non-renormalizability problems at high energies. In practice when people say they are calculating something in "M-theory", they almost always mean they are doing an 11d supergravity calculation.

24. **JC**
June 14, 2004

Has anyone ever come up with a better "definition" of M-theory, besides just saying that it has a low energy limit of 11 dimensional supergravity and/or it reproduces the other string theories as some limit in 10 dimensions? Everybody I've asked this question to, almost always gave those two limits as a "definition". A few folks stated "M-theory" as being the limit of some matrix theory like BFSS a number of years ago, which doesn't seem to be as popular these days. I haven't heard of any better "definitions", which does NOT use the statement "in the limit of …*blah blah blah*".

At times I wonder whether this is just pure wishful thinking on the part of string folks, by being purposely vague about what M-theory is really all about.

25. **Peter**
June 14, 2004

So, if the conjecture that there is an underlying M-theory is just wrong, and no such theory exists, string theorists will never, ever give up?

Comparing a theory that doesn't exist (M-theory) to QCD is really just silly. There are two huge differences:

1. QCD is a beautiful, well-defined theory with no free parameters (1 if you count the theta angle), which makes an infinite number of detailed, specific predictions. The reason a mathematics foundation has a prize for its solution is that it's a well-defined problem to rigorously prove things about QCD. Many things can be reliably calculated to fairly high precision, using perturbation theory or lattice methods.

2. Not only does the theory make predictions, but they all work. To within the accuracy that one can calculate, you get complete agreement with experiment. These predictions cover a huge range of particle physics phenomena: e+ e- annihilation, deep inelastic scattering, phenomena at hadron colliders, properties of charm and bottom bound states, etc. The theory has been tested and tested and tested again and has passed every test. For an example, see the first figure in Wilczek's hep-ph/0212128.

Compare this to M-theory, where there is no theory at all, just a bunch of people's wishful thinking that a theory might exist with properties that they would like. This non-existent theory makes zero physical predictions, so it can never be tested, allowing some people to spend twenty years going on about how wonderful their "theory" is and now doing really silly things like claim that its status is similar to that of QCD.

26. **Thomas Dent**
June 14, 2004

Susskind's baby technicolor was very popular at one point, until it was realized that one can't really calculate much in it, due to strong coupling, and that so far as one could calculate the electroweak loop corrections probably went in the wrong way compared to data.

Nowadays strongly coupled gauge theory is understood slightly better – thanks mainly to SUSY and string theory! – but it's still difficult to get technicolor off the ground in the sense of agreeing with LEP precision data. It's a very elegant idea, more so even than SUSY, but somehow Nature doesn't appear to be sold a bunch on it.

As to what would cause string theory to be abandoned: if a real underlying M-theory were formulated and solved and none of the solutions were anything like the real world.

In other words, the theory isn't sufficiently well understood that it can be discarded.

As for renormalizable gauge theories providing precise testable predictions, this hasn't really happened with QCD. It's taken several decades of lattice computations to come up with a reasonable (to within a few percent) baryon and meson spectrum. Chiral fermions were only recently latticized. And this hypertrophy of computation, although impressive, is about as far from a simple and elegant explanation of observed facts as can be. The million dollar prize for explaining confinement in QCD goes unclaimed.

For decades, QCD has also satisfied the description "not sufficiently well understood that it can be discarded"…

27. **JC**
June 14, 2004

Peter,

The cases of physics folks being denied tenure I'm familiar with, usually fit into one of two categories:

1 – folks who changed from a trendy hot area of research to another field that wasn't as trendy or hot

2 – folks who change from one trendy hot area of research to another field that was also trendy and hot

The first category of folks were frequently denied tenure already at the department level. Their papers were not getting many citations, if any citations at all, besides citing their own papers. These particular cases seemed to be pretty clear cut as to why they were denied tenure.

The second category of folks weren't quite as clear cut. They were commonly cranking out average to below-average papers which resembled "resume padding" stuff in their new field, compared to their papers in their previous field which got more citations and were somewhat better than "average". Perhaps their tenure committees used the "decline" of the quality of their papers, as an excuse to deny them tenure? A few cases even used teaching evaluations as an excuse to deny tenure, just to get rid of a person who they didn't like.

The exceptional cases of folks changing fields who eventually got tenure, usually were producing better papers in their new field and were able to attract many more citations. To top it off, some were even invited to lecture at summer schools such as TASI or Les Houches. Being denied tenure would have been surprising for these particular exceptional cases, unless it had to do with nonresearch reasons like politics or misconduct.

28. **Peter**
June 14, 2004

It's pretty premature to speculate about what will happen if SUSY and string theory are no longer perceived as promising things to work on. But many people in this business are very used to shifting gears and if something else replaces SUSY/string theory they'll jump on that pretty quickly.

29. **JC**
June 14, 2004

Peter,

What do you think will happen to all those grad students, postdocs, and assistant professors up for tenure review, who invested many years on SUSY and/or string theory if both SUSY and string theory die and become "illegitimate" fields of physics research? (ie. "illegitimate" in the sense of folks still doing research on something like bootstrap analytic S-matrix theory after the wholesale abandonment of it, for example). Arguably for folks who already have tenure, their careers could die away like Geoff Chew's career (ie. a painful decline into irrelevance), if they don't change into another field

I suppose the grad students and early postdocs (ie. folks on their first postdoc) could always change fields more easily. I wonder if the later postdocs and assistant professors (without tenure or on tenure track) can easily change fields without much "career disruption". Without mentioning any names, I knew of a number of cases of assistant professors in physics who attempted to changed fields about a year or two after getting their faculty jobs. By the time they were up for tenure review, almost every single one of them were denied tenure regardless of how many citations their papers were getting, except in a few very exceptional cases where the person in question became a "superstar" overnight.

30. **Peter**
June 13, 2004

Yes, in the technicolor idea the Higgs would be something like a Cooper pair.

The vague idea about chiral gauge theories is more something like this: when there's an anomaly one way of thinking about what happens is that the gauge degrees of freedom acquire non-trivial dynamics. Then there are problems with non-renormalizability and/or unitarity, which is why people think the such theories are inconsistent. In the standard model, the quarks and leptons each separately have an anomaly, but they cancel against each other. Perhaps there's more to this story than one sees in perturbation theory, and it might have something to do with the Higgs.

31. **D R Lunsford**
June 13, 2004

That is very nice, I've been thinking a lot about directional time as well 🙂

You need a natural idea of orthogonality in time.

So the technicolor theory is basically Cooper pairs for the Higgs?

As for "non-perturbative quantization of chiral gauge theories", do you mean something like the Dirac monopole argument? It always seems that gamma_5 is the center of the mystery.

32. **Peter**
June 13, 2004

The standard speculation is some new strong dynamics for which the Higgs is a bound state (technicolor).

Two completely ill-defined speculations I've always found attractive, but have no idea how to turn into anything real are:

1. The non-perturbative quantization of chiral gauge theories is more subtle than we think and if we understood it better we'd find that the Higgs appeared naturally.

2. Despite appearances, we really live in Euclidean 4-space, with group of frame rotations Spin(4)=SU(2)xSU(2). One of the SU(2)s is spatial rotations, the other is the electroweak gauge group. A choice of time direction is what breaks the electroweak SU(2).

You really shouldn't take any of the above seriously unless I can someday figure out how to turn them into a well-defined proposal of a new theory.

33. **D R Lunsford**
June 13, 2004

Peter said

"something more interesting than a scalar Higgs"

Care to speculate? 🙂

34. **Peter**
June 13, 2004

I think it was Max Planck who commented that the way science progresses is by people dying, not by them changing their minds. There will be plenty of supersymmetry die-hards, but I get the impression that Witten and others are already starting to get used to the idea that the whole low-energy supersymmetry scenario might be wrong.

Optimistically, what will happen in 2008 is that the LHC will find evidence for what is really causing electroweak symmetry breaking and it will be something more interesting than an elementary scalar Higgs. If so, most people will drop low energy supersymmetry immediately, pretending the whole thing never happened.

35. **JC**
June 13, 2004

Any bets on whether string theory will die if a light Higgs is NOT found at LHC? If I didn't know any better, I would think many string folks will just keep on pushing up the SUSY breaking scale and attempt to justify SUSY only as a symmetry at higher and higher energies such as at the GUT or Planck scales. It seems like a neverending game of "suspending disbelief" where the masses of SUSY particles keep on getting heavier and heavier with time.

Perhaps it will take another generation or so for SUSY and/or string theory to completely disappear from the thinking of physicists, if LHC rules out SUSY at the low energy scales.

It would be interesting to look back into physics history more than a century ago, and examine how long it took to shake off the idea of an "ether" in many physicists' thinking. I wouldn't be surprised if many physicists of the generation directly preceding Einstein, were still "true believers" in an "ether" to the day they died (ie. Lorenz, etc …).

36. **Peter**
June 13, 2004

Hi JC,

Actually at this point the only thing I can think of that would cause a wholesale abandonment of string theory is Witten publicly giving up on the idea. And I don't think that's going to happen until 2008. He and others who are completely invested in the idea will hang on until results from the LHC come out, hoping that superpartners will appear, thus validating part of the whole scenario.

37. **Steve**
June 12, 2004

Typical string-theoretic hype aimed again at convincing the public–one thing the theory has been very highly successful at. Well at least they are trying to connect with experiment and real observations of the universe. However, I would agree that a theory is supposed to be discarded once its experimental predictions simply don't happen. That is the central crux of what science is about, but this won't ever happen in string theory, and that is my main problem with it and the people who do it (not so much the theory itself). There is more chance of a ufo landing in your back yard and Elvis getting out of it than there is of this cosmic string scenario and its predictions actually coming about. I would confidently bet money (a fair bit) that these signals will never appear. Such is the current state of theoretical physics–these guys are tied up in cosmic strings, anthropic Lenny S is lost and wandering in the "Landscape", Ed has exhumed twistors, and the Brothers Bogdanov are again obsessing over their fluctuating metric signature and quantum groups! No disrespect to any of these guys actually (and none intended) but my point is the field is getting crazier each year and people are really in danger of getting lost in/obsessed with their own mathematical fantasy scenarios. The line between crackpotdom and science is now very blurred indeed. Also, some seem so totally convinced they are right that they feel obliged to bring out popular books:the Bogdanovs have one out now and I hear LS is putting one out on the "Landscape". I don't know what the way forward is and maybe (hopefully) things will be much clearer near the end of the decade. But in the meantime, some of these guys could check themselves into the "Rest Home for Deranged Scientists" as was featured in the Thomas Dolby video of the 80s hit "She Blinded me With Science". Not that I can talk–this jacket is too tight, forcing me to type one letter at a time with a pencil in my mouth, and they won't give me a sharpener for my crayons…

38. **Chris Oakley**
June 12, 2004

JC,

There must be something in what you say, as Lubos Motl, the most in-your-face String theorist around, is also an Astrologer.

39. **JC**
June 12, 2004

Peter,

What exactly do you think will cause a wholesale abandonment of string theory?

It seems like having no viable physical predictions isn't going to stop people from being true believers in string theory. Historically, was the first demise of string theory and Geoff Chew's analytic S-matrix theory in the 1970's caused by renormalizable gauge theories producing precise physical predictions that were testable in accelerator experiments, while string theory hardly produced anything other than Regge trajectories at the time?

Offhand I can't think of any obvious compelling reasons that would cause a wholesale abandonment of string theory as if it was like a sinking ship. Even Geoff Chew was still cranking out papers on the bootstrap principle well into the 80's, despite everybody else moving on to gauge theories many years before.

Only naive reason I can think of for a wholesale abandonment of string theory, is if somebody ever found an easy way around the Sagnotti nonrenormalizable 2-loop divergence result in 4 dimensional pure quantum gravity and where additional divergences can be renormalized when fermions, gauge bosons, etc … are added in. This naive scenario would probably require a HUGE miracle to be pulled off, and I'm not particular optimistic about it happening.

At times I wonder if areas like string theory, loop quantum gravity, SUSY, twistor theory, etc … are resembling how economics research is done. Various schools of economics don't appear to be much more than "normative" prescriptions imposed by decree, especially when it agrees with a particular brand of political ideology. Some schools of economics seem to have diehard "true believers" regardless of any empirical data, such as the "supply siders" behind Reaganomics, the Keynesians which managed the economy in the 1970's to 20% inflation in America (or worse, such as 300% inflation in Israel in the early 1980's), the Monetarists which ran the monetary policy in America, Germany, England, etc … in the 70's and 80's by managing monetary aggregates, etc ….. There's some folks who don't even believe in "supply and demand".

It's amusing about a year ago or so, the economics Nobel laureate Milton Friedman finally admitted that his "monetarist" theories of managing monetary aggregates were a total failure in the end, despite being popular policies in government central banks over the last 30+ years. It took millions of lives and decades of economic mismanagement for economists to finally figure out that Marxist/communist, Nazi/fascist, and other totalitarian types of policies run in these sorts of regimes were total economic basketcases and failures in the end.

Perhaps there's a lot of truth in what economist John Kenneth Galbraith said:

"The only function of economic forecasting is to make astrology look respectable."

Can the same be said about the various schools of "quantum gravity" type of research?

The Top Quark Mass

June 13, 2004
Categories: Uncategorized

Recently I've been reading a new book, The Evidence for the Top Quark, by a philosopher of science named Kent Staley. It's a combination of a history of the CDF collaboration's work leading up to their claim to have discovered the top quark, together with an extensive discussion of issues in the philosophy of science raised by the different methods used to analyze the data. The book is very topical since last week the D0 collaboration published an article in Nature claiming a new, more accurate, mass for the top quark based upon a re-analysis of their data from Run I of the Tevatron, which lasted from around 1992-96. The old analysis of the D0 data gave a top mass of 172.0 +/- 7.1 Gev, the new analysis gives 179.0 +/- 5.1 Gev. Combining the D0 data with the CDF data, the old analysis gave 174.3 +/- 5.1 Gev, the new 178.0 +/- 4.3 Gev.

Measuring the top quark mass is quite tricky since there are not a lot of events to work with and one needs to precisely measure the energies of jets. If a linear collider ever gets built, it would allow much more precise measurements. Knowing the top quark mass accurately is very important for the following reasons:

1. In the standard model one can try and use precision measurements of the electroweak parameters to observe the effects of higher loops including the Higgs and get a prediction for the mass of the Higgs. This crucially involves the top quark mass, since that is the strength of the top-Higgs coupling and the top quark couples far more strongly to the Higgs than any of the other fermions. With the latest D0 value for the top quark mass, one now expects (95% confidence level) that the mass of the Higgs is less than 237 Gev. For more details see websites at CERN and Fermilab.

2. In the minimal supersymmetric extension of the standard model there is an upper bound on the mass of the lightest neutral Higgs, a bound that depends strongly on the top mass. There's an explanation of this on Jacques Distler's weblog. With the newest value for the top quark mass one expects that the Higgs mass should be below 140 Gev in the supersymmetric case.

There are a few funny things about this report from D0:

1. It was published in Nature rather than the more conventional Physical Review Letters. Nature is not where high energy experiments normally announce their results and this appears to be an attempt to get wider publicity than is usual for such a result. For some comments on this, see David Harris's weblog.

2. The new method of analysis is similar to one discussed extensively by Staley in his book: the "dynamical likelihood method" due to Kuni Kondo. Ten years ago the CDF collaboration was rather skeptical of this method and decided not to use it, basically seeing it as too complex to be reliable. Have they changed their minds? Will CDF re-analyze its Run I data using this technique too?

3. Much is made in the paper and the associated Fermilab press release that this result changes the "best estimate" of the Higgs mass from 96 Gev (which is excluded by LEP results) to 117 Gev, which isn't. While this sounds impressive, it would be a lot less so if you do what you are taught in high-school physics and quote error bars with your numbers. As mentioned above, while it is true that the new result is that 117 Gev is "most likely", it is also true that a very wide range of values is almost equally likely. A more sensible but much less impressive way of saying things would be to just say that at 95% confidence level the Higgs mass has to be between about 50 and about 250 Gev.

Update: The D0 Nature article is now at the arXiv.

   July 1, 2004

   http://elasticity2.tripod.com/
   On above site I give formula for the field structures of particles and atoms. The particle formula is based on the mass of the electron as this is the most accurately known particle mass. This indicates that a mass of 174GeV is the correct figure for the top quark.

2. **D R Lunsford**
   June 20, 2004

   Peter, the reason your b-log is so well received is very simple – the topic is physics as it once was practiced, with excursions into math for variety. You seem to me to be close to unique in having a mathematician's sensibility and depth combined with a physicist's common sense. It really shows in all your writing.

3. **Peter**
   June 17, 2004

   Glad to hear you enjoy the weblog and thanks for the encouraging words. I've been surprised how much attention it has gotten.

   The string theory situation is a rather weird one and the public discussion of the theory has been almost all coming from its promoters. I hope I'm redressing that situation a bit, and that people will look at both sides of the story and make up their own minds.

4. **raj**
   June 16, 2004

   FWIW, I am not a physicist by profession (although I did undergrad and graduate work in physics many years ago, and continue to follow some of the literature), I wanted to let you know that I enjoy your blog very much. I am particularly interested in your criticisms of string theory. It has gotten such hype in the popular press, but I have yet to see anything that appears to make sense about it. I read Brian Greene's book and, although I found it interesting (particularly the first quarter, relating to quantum mechanics and general relativity), I hate to say it but it did seem more than a bit unpersuasive.

   Regardless, I do enjoy the blog, and I would encourage you to keep it up.

5. **Peter**
   June 14, 2004

   Hi Thomas,

   A good recent reference for all this is chapter 5 of some lectures by Sally Dawson, hep-ph/0303191.

   In the SM there is no tree-level restriction on the Higgs mass. However, increasing the Higgs mass requires increasing the quartic Higgs coupling, and perturbation theory breaks down if this gets too large. For perturbation theory to be valid the Higgs mass can't be more than a few hundred Gev.

In the MSSM you have to introduce a second Higgs field (otherwise the anomaly from the superpartners of the first one are uncanceled). You can show that, at tree level, the lightest neutral Higgs should have mass less than that of the Z. Taking into account one-loop effects the upper bound goes up. It depends on the extra parameters in the theory (e.g. tan \beta, the ratio of vacuum expectation values of the two Higgs), but overall it has to be less than 140 Gev.

6. **Thomas Larsson**
June 14, 2004

   Is a light Higgs compatible with the ordinary standard model?

   I have seen somewhere that the tree-level prediction from the SM for the Higgs mass is m_H = m_Z = 91 GeV; that's the same with or without SUSY. The big difference is that the uncertainty in the radiative corrections is much smaller with SUSY, so the upper bound gets much tighter. So a light Higgs wouldn't really be a proof for SUSY, but the absense would be a proof against it.

   OTOH, I have seen an argument by Frank Wilczek that a light Higgs would be problematic for the ordinary SM, but I don't remember the details.

   The discovery of sparticles at the LHC would be a proof SUSY though, and would be a pretty strong indication that the string line of though is on the right track. But that doesn't seem to be too likely, does it?

7. **D R Lunsford**
June 13, 2004

   Tony Smith's analysis: http://www.innerx.net/personal/tsmith/TQvacua.html

   He gets these numbers as ratios of volumes within Shilov boundaries (as I understand it).

The stupendous Landscape of sting theory vacua

June 17, 2004
Categories: Uncategorized

At an early stage in the Los Alamos preprint archive it was split up into hep-th (for more formal or speculative work not directly relevant to experiment) and hep-ph (for "phenomenological" papers directly related to experiment). Susskind has just come out with his latest and now seems to feel that his ideas about the "Landscape" are directly of interest to experimenters and so belong in hep-ph.

The preprint is riddled with typos, for instance the third paragraph starts like this:

"During the last couple of years an entirely new paradigm has emerged from the ashes of a more traditional view of string theory. The basis of the new paradigm is the stupendous Landscape of sting theory vacua — especially the non-supersymmetric vacua. These vacua appear to be so numerous that the word *Discrtuum* is used to describe the spectrum of possible values of the cosmological constant….."

You get the idea.

Some high points of the article:

1. "low energy supersymmetry – an ugly solution" to the naturalness problem. Now he tells us. From what I remember the "beauty of supersymmetry" has always been one argument made in its favor.

2. "the ashes of a more traditional view of string theory". It seems that the picture of the world according to string theory that has been heavily sold for the last twenty years has burned down to the ground.

3. The argument in his last paper, such as it was, was wrong. Now he's got a new one with a similar conclusion.

4. "… a prediction that supersymmetry will not be seen at the TEV scale seems warranted". OK, string theory is finally making a prediction.

5. "If it turns out that low energy supersymmetry is a feature of TEV physics, then we will have to conclude that other considerations outweigh the counting of vacua on the Landscape". So, even though string theory predicts no low energy supersymmetry, if it is found it doesn't mean string theory is wrong. Got it?

   "I wonder what made Susskind withdraw his paper today, that was the original subject of this thread?"

   Look carefully at the final part of

   http://arxiv.org/abs/hep-th/0405279

   [version 4]

2. **JC**
   June 30, 2004

   I wonder what made Susskind withdraw his paper today, that was the original subject of this thread?

   Any good guesses on this?

3. **JC**
   June 22, 2004

   Perhaps it's not so surprising in seeing some folks pursue weird or crackpot ideas, the closer they are to retirement and/or the less they have to answer to anybody for approval or money (either as a salary, a grant, or a pension)?

   If it's the case of a tenured professor towards the end of their career, some may very well fall into a "lame duck" phase of their careers and just do whatever they want, with very little to no pressure to publish anything or get research grant money. Some folks may view that they have nothing to lose in pursuing weird or crackpot ideas, while counting down to the day when they can start collecting their pensions and social security checks.

   In the case of Stephen Wolfram, it appears he's independently wealthy from his company selling Mathematica over the years. Considering Wolfram hasn't published extensively since he left academia, his case appears on the surface to be almost like a "vanity" (ie. self indulgent and/or self aggrandizement) type of research project which cumulated into his 2002 book "A New Kind of Science". Some stuff in his book looked interesting, though some parts seemed too outlandish to be readily believable. At times I wonder if his book would have even been published if he didn't publish it through his own publishing company. (In principle anybody can publish anything through their own publishing company or journal, if they have all the money in the world to squander on it and convince enough bookstores to sell it). Perhaps this project isn't much more than an ego trip for Wolfram?

   These days any "crackpot" can just set up their own web site and "publish" whatever they want.

   If string theory and/or loop quantum gravity ever fell out of favor to the point where even journals like Nucl. Phys. B or JHEP, started to refuse to publish any string and/or loop gravity papers, I wouldn't be surprised if the "fanatical" string and/or loop gravity folks will just "publish" their papers on their own web site or even start their own dedicated string and/or loop gravity journals, while giving the "middle finger" to the older journals which won't publish any of their papers.

   Second try: 't Hooft, Gerard

5. **Alejandro Rivero**

June 21, 2004

‘t Hooft holds a webpage, so perhaps his powerpoint presentations are available. Usually funnier than the papers.

I would put appart Stephen Wolfram’s. He left physics very early to go to computer science. I was very surprised when his articles on one dimensional cellular automata were published in Physical Review. Now the book is a separate, personal quest. If to someone, he could be alike to Julien Barbour.

As for Julian Schwinger and cold fusion, google suggest a pair of links:

http://www.infinite-energy.com/iemagazine/issue1/colfusthe.html
http://arxiv.org/pdf/physics/0303078

From it I wonder if he overreacted mainly to counter the general tendence, specially phys rev letters as he mentions. The old fathers as Schwinger are surely more humble about the success of modern quantum theory, they can have more perspective.

6. **Thomas Larsson**
June 21, 2004

‘t Hooft has a bunch of papers in the arxiv on Planck scale determinism, e.g.

http://www.arxiv.org/abs/hep-th/0104219

(An Essay in honour of John S. Bell!). However, ‘t Hooft undoubtedly knows a lot more about Bell’s theorem and its possible loopholes than I do, so I am certainly not in the position to judge. Determinism gives me bad vibrations, though.

7. **Urs Schreiber**
June 21, 2004

Re: t’Hooft on hidden variables

I have heard about that, but no details. Does anyone know what precisely t’Hooft is thinking about in detail with respect to hidden variables?

8. **Thomas Larsson**
June 21, 2004

Coming back to the issue of famous people that have done strange things. Here are some more recent examples that made my eyebrows rise a bit: Julian Schwinger’s support for cold fusion, ‘t Hooft’s work on hidden variables (or something very similar, and Stephen Wolfram’s New Kind of Science. I wouldn’t go so far as calling any of this crankish, however, and I observe that cold fusion apparently is starting to get some funding again. The stuff that Brian Josephson does is really weird, though.

9. **Alejandro Rivero**
June 20, 2004

Steve, yep, I concede that it is too many pages for just an artistic parody; It seems you are right, he is serious about this.

On other hand, the high quality of the graphics and the insistent sexual metaphor, sometimes almost Dali-nian, seem to point to an artistically inclined mind. The insistence on using physics vocabulary reminders me of another famous internet crackpot, Archimedes Plutonium, but in this case the ego is not so inflated, more the contrary.

Have you seen the “about” page and the crico.com website? Some years ago, all Spain was invaded by these puzzles. Guess he can pay the $ of the homepage, if he has been able to collect the royalties.

10. **D R Lunsford**
June 20, 2004

I find it somewhat astonishing that Dyson feels free to make such statements about Dirac, given his own lack of any definitive creative act in physics. I don’t consider mathematical technique to be creativity in physics. If blame needs to be assigned (it doesn’t) for the lack of success in fundamental theories, then put it at the door of chez Bourbaki and the formalists.

11. **JC**
June 20, 2004

Thomas,

The Dyson review of Greene’s book is at at:

http://www.nybooks.com/articles/17094

It’s interesting how Dyson asserts that revolutionaries and conservatives in physics come and go in an almost cyclic sinusoidal manner (with a phase shift of pi between the revolutionary and conservative curves of “popularity”). I wonder if Dyson’s assertion is true going back further in time, to the time periods before Newton or Kepler or Copernicus.

In the Dyson article, it sounds like the pioneers of quantum mechanics like Heisenberg, Dirac, Schrodinger, etc … were attempting to create an “encore” performance after their first “standing ovation” performance of creating quantum mechanics. Possibly at that time period in the 1900’s to 1920’s, the deviation between experiment and classical theory became so great that many radical theories were proposed and tried out? It would be interesting to go back and find old journal papers of theories which were competitors to quantum mechanics in the 1920’s, but which are now long gone and forgotten.

Perhaps there is a time and place for radical new ideas and theories in physics when the deviations between experiment and theory become really big, and where the old theories don’t seem to work anymore regardless of how many “epicycles” are added into the old theories. These days there doesn’t seem to be enough empirical data yet to reveal a huge deviation between classical and quantum gravity phenomena. It would be interesting to see in the near future how much new astro data will come in, and whether there’s a really compelling case that reveals a significant deviation from classical general relativity.

In today’s cases of string theory, loop quantum gravity, etc … and other forms of “quantum gravity” research, it appears to fit very much into Dyson’s category of “revolutionaries” attempting to build “castles in the sky”. Perhaps it can be argued that today’s “quantum gravity” folks are really just “pseudo revolutionaries” masquerading in a “revolutionary’s drag”, in the sense of folks attempting to create a “revolution” when there’s very little to nothing there to be “revolutionary” about in the first place? An analogy would be the difference between the “real revolutionaries” like the Bolsheviks, the Irgun, the solidarity movement in Poland, etc … compared to the “pseudo revolutionaries” like the american hippies from the 1960’s, or the British punk rockers from the late 1970’s and early 1980’s. Certainly the pioneers of quantum theory like Dirac, Schrodinger, Heisenberg, etc … would fit into the “real revolutionaries” category when they were creating quantum mechanics in the 1920’s, but they gradually turned into “pseudo revolutionaries” when they got older and were advocating their radical “crackpot” ideas that had very little to no experimental support.

In many ways, “pseudo revolutionaries” are probably common throughout history and will continue to be that way well into the future. Perhaps the only big difference between the “pseudo revolutionaries” and the “real revolutionaries”, is that the “real revolutionaries” just happened to be in the right place at the right time by coincidence. In another time and place, these “real revolutionaries” would have been written off as “pseudo revolutionaries” or “crackpots”, and eventually would have faded away into obscurity and largely forgotten, like what happened eventually to the American hippies and British punk rockers. In another place and time, somebody like Adolf Hitler would have been an insignificant 4th rate artist, homeless street bum, or even a Paris or Vienna coffee house intellectual, instead of the destructive Fuehrer of Nazi Germany.

Perhaps the differentiating factor between “revolutionaries” (whether pseudo or real) and “conservatives”, has a lot more to do with a person’s personality? I wouldn’t be surprised if during “revolutionary” time periods, the “conservatives” would just be plodding along into obscurity with their old theories/paradigms and become largely forgotten by history in the end, while during “conservative” time periods, the “revolutionaries” would just be making fools of themselves and also become largely forgotten by history in the end too. If string theory dies and fades away into the dustbins of physics history, will physics history remember who Witten, John Schwarz, or Maldacena are in a hundred years? (I think Witten would be definitely remembered in the math history books, as a Fields medalist winner). For somebody like Geoff Chew, he seems to have already faded away into obscurity and into the dustbins of physics history, other than as a footnote reference to the analytic S-Matrix theory origins of string theory.

12. **Steve**
June 20, 2004

Actually, the guy who wrote this stuff, a Dirk Lauryssens seems deadly serious (or else pretends to be). Although it does look like a parody of string theory and the buzzwords/jargon used. He is either a genuine crackpot or just pretending to be one to wind people up (presumably physicists/real string theorists). Don’t understand why he is getting space on a Hollywood info website though–would’nt that cost him $?–but the net is full of strange stuff. I noticed this site a while back when someone pointed it out to me but it has grown quite a bit now since he seems to have gotton very inspired by Brian Greene’s PBS series on string theory. I also notice on his “conclusion” page he quotes an abstract of S. Majid to support his claims! Poor old Majid. First the Bogdanovs now this guy lol. Don’t what he has done to deserve it.

13. **D R Lunsford**
June 20, 2004

Recall that the list of crackpots at one time included Clifford, Kaluza, Bolyai, Grassmann, etc. etc. Pauli himself blasted Dirac’s idea of “holes” then later, perforce, retracted. Boltzmann committed suicide in despair, followed by Ehrenfest. All really new ideas generaate enmity it would seem.

Yes, some of the later work of people like Einstein and Dirac seems futile in retrospect – but even a hopeless idea like “lambda invariance” is more interesting than brainless triumphalism. And it’s entertaining! I had great *fun* reading Dirac’s papers on the superconducting vacuum. There’s more to life than eternal verities.

14. **Alejandro Rivero**
June 20, 2004

Steve, it is just elaborate irony with a lot of sexual clues. Note for instance as the “Mama brane” is drawn milking her particles.

15. **Steve**
June 20, 2004

Check out this bunk.
http://www.hollywood.org
and scroll down to “Breaking Science News.Cosmology”. This is not just an obscure crackpot page…this page must get major hits. String theory unfortunately seems to be giving credibility to this sort of thing and I worry if real rigorous science can ultimately survive. You could use the email link and complain but sadly the author(s) would probably relish the attention.

16. **Thomas Larsson**
June 20, 2004

“It would be interesting to go back and find some weird or crackpot unpublished papers that were written by folks like Dirac, Einstein, Fermi, Schwinger, Heisenberg, Eddington, etc …. ”

Dyson recently wrote a review of Brian Greene’s latest book (I lost the reference, but it appeared on this blog so maybe somebody else can fill it in). In particular, he remembered that when he was young in 1950, old heroes like Einstein, Heisenberg, Born, Dirac each had their own wacky idea, which they thought should to start another revolution like the quantum one. Since I am a big fan of PAM, it disturbed me that Dirac’s idea seemed the weirdest; it had something to do with probabilities ranging between +2 and -2.

Dyson remarks that seeing these old men making fools of themselves turned his generation, with Schwinger, Feynmann and others, into conservatives. I would not be surprised if today’s excesses by the aging string theorists will have a similar effect on the next generation.

However, Dyson is too conservative even for my taste, since he seems happy with gravity being described by a classical theory.

17.
June 19, 2004

Well, I have a recent paper that got into a real journal (Feb this year, IJTP) but is banned from the archives! I feel a perverse pride in this 🙂

18. **JC**
June 19, 2004

Tim,

So far none of Susskind’s anthropic preprints appear to have been published in any real journals which require peer review. Maybe at this point he doesn’t even care if they end up in a journal or not? His first anthropic paper (hep-th/0302219) seems to be getting many citations already.

It would be interesting to go back and find some weird or crackpot unpublished papers that were written by folks like Dirac, Einstein, Fermi, Schwinger, Heisenberg, Eddington, etc …. that would be good candidates for a “physics hall of shame”. Maybe old age and/or senility are the root causes of some folks starting to work on weird or crackpot research ideas? I can’t think of any good reason for younger folks wanting to work on weird or crackpot ideas, other than perhaps simple brainwashing or just plain intellectual laziness.

19. **Tim**
    June 19, 2004

    Do any of these ridiculous Susskind preprints ever get published in journals?

20. **JC**
    June 19, 2004

    The only stuff I’ve ever came across that’s even more mindless and incoherent than Hegel or Derrida, would be the lyrics of most pop music songs especially in its more extreme forms like heavy metal or punk rock. Whether intentional or not, most pop song lyrics make very little to no sense and frequently appears to be just pure nonsense attempting to say something profound. Perhaps it only makes “sense” to a person who is high on drugs or really drunk?

    What I found amusing over the years, is how many pop songs frequently have the same underlying structures in musical chord progressions and rhythms such as

    intro – verse – chrous – verse – chorus – bridge/solo – chorus

    with the lyrics fitting into the same sort of rhythms of 4 or 8 syllables per line. It seems to be almost like a formula regardless of who the artist is, the year it was written, the particular style of pop music, or even what language or country it was written in.

    What would be amusing is if anyone has ever used that Dada Engine at

    http://dev.null.org/dadaengine/

    to “randomly” generate pop song lyrics, where it’s difficult to figure out if it’s a computer or person writing the lyrics.

    An even more sophisticated thing would be to get that Dada Engine to actually generate musical rhythms and melodies that sound typical of pop music. It seems like many pop songs are written in the same 4/4 time signature, with chord progressions fitting into the same sequences of musical notes and scales, usually some minor pentatonic scale (that’s frequently the first scale almost every musician learns when they picked up their first guitar or sat behind their first keyboard/piano).

    It would be even more amusing if this sophisticated “Dada Pop Music” generator actually produced pop music songs that are indistinguishable from the human written pop songs on MTV or the radio! Then they can rename this “Dada Pop Music” generator as the “Milli Vanilli” machine that fools everyone!

21. **Steve**
    June 19, 2004

    Brilliant and beautiful series the “Ascent of Man”. I have it on video. Bronowski was a truly unique intellectual figure and polymath discussing science and human cultural evolution with a warm poetic eloquence. In that episode “Knowledge and Certainty” I remember he describes Hagels as a philosopher he “specifically detests” and really knocks him down to size. That episode also ends with the famous powerful and moving scene at the pond at Auschwitz, which is the back sludge of the ashes of millions of people, including some of his family. He says, “when people believe they have absolute knowledge with no test in reality, this is how they behave. This is what men do when they aspire to the knowledge of gods”. If you can get the series on video or dvd at your university or local library then check it out. Well worth the time.

22. **D R Lunsford**
    June 19, 2004

    Jacob Bronowski in his series “Ascent of Man” bashed Hegel mercilessly by pointing out that, directly after publication of his Pythagero-philosophical proof that only 8 planets could exist, Ceres was discovered 🙂

    http://www.hegel.net/nature/ceres.htm

23. **JC**
    June 19, 2004

    Thomas,

    Judging from the hep-th abstracts, I’m sure what passes as “deconstruction” in string theory is a lot less sinister than Derrida’s notion of “deconstruction”.

    If you ever come across anything that’s written in a very “revisionist” manner, most likely the person is engaging in Derrida’s version of “deconstruction”. Some folks will say outright that they’re invoking Derrida, while other folks may be doing “deconstruction” without even being conscious of it!

    In the end, Derrida’s “deconstruction” isn’t much more than a person trying to rationalize their own self-denial. In many ways it’s sort of like Nazi propaganda minister Joseph Goebbels’ notion of “keep on repeating a lie, and in the long term it eventually becomes ‘true’ “. (It appears Bush, Cheney, Rumsfeld, etc … have all taken a cue from Goebbels and are actively applying it to everything they’re saying on television, hoping to eventually fool enough voters through election day in November).

    Perhaps all these string folks who are “true believers” in the anthropic stuff, are really unconsciously engaging in “deconstruction” without even knowing it! They’re all secret worshippers of Derrida. 😉

24. **Thomas Larsson**
    June 19, 2004

    JC,

    A hep-th search for eprints with the word “deconstruction” in the title during the past year gave 9 hits. Derrida rules!

25. **Peter**
    June 18, 2004

    A lot of string theory research can be compared to Derrida, Hegel, postmodernism, etc., in that a complex and difficult formalism is used to obscure some rather ill-thought out ideas. But Susskind is something different. It’s not hard at all to understand exactly what he is saying. He doesn’t hide behind a complicated set-up in the slightest and his mathematics is mostly what one learns in junior high school.

The weird thing about this is that someone can be taken seriously when they so obviously are not really doing science.

26. **Thomas Larsson**
June 18, 2004

4. "… a prediction that supersymmetry will not be seen at the TEV scale seems warranted".

I wonder how this affects Lubos Motl's experimental-SUSY-by-2006 bet.

27. **JC**
June 17, 2004

Hmmm …. Reading again over my description of Derrida several times, I just realized my statements make absolutely no sense.

I suspect this is the sort of twisted thinking many folks fall into when they are in denial about their own ignorance, whether philosophers, physicists, or anybody else. It's very easy to fall into.

28. **JC**
June 17, 2004

Blah. Forgot to put my name to the previous post.

29.
June 17, 2004

I never quite understood the "beauty of SUSY" arguments that were propagandized over the years.

Only thing I found SUSY useful for was in checking my Feynman diagram calculations by taking a SUSY limit, where if I did my calculaton properly it should reproduce the known SUSY results in the various SUSY limits. Other than using SUSY as a way of checking my calculations, I never quite bought into the "beauty" argument completely.

I think the only time I ever bought into the "beauty of SUSY" propaganda, was when I was a naive clueless undergrad with "stars in my eyes". I first heard about SUSY from some of my professors who did particle phenomenology, and just took their word for it without questioning it much. For the most part, it was somewhat "over my head" at the time. When I finally got around to learning SUSY in grad school, that's when I started to have second thoughts about it.

When I was still doing string stuff, I treated SUSY as if it was a Planck scale symmetry more or less by fiat decree.

On a different note, I wonder what Susskind's future book on the "Landscape" will look like. If it resembles the sort of papers he's been cranking out over the last year or so, will it start to read more like a philosophy book than a book about physics? What will be scary is if it ends up reading like "Tractatus Logico-Philosophicus" by Ludwig Wittgenstein, or worse, anything by Georg Wilhelm Friedrich Hegel or Jacques Derrida. If I didn't know any better, Hegel's work reads very much like nonsense masquerading as "legitimate discourse" in a manner similar to postmodernism stuff. Wittgenstein's work attempts to assert that all philosophical problems which are not scientific, are really ambiguities in our language. Derrida's "deconstruction" work seems to be searching for hidden or underlying meanings in something by "reading in between the lines", that are not so obvious on the surface. If I didn't know any better, I always got the sense "deconstruction" wasn't much more than a thinly veiled attempt at a "rorschach test" of a person's underlying biases and prejudices, when reading and critiquing something. It would be a sad day when physics starts to read a lot like Derrida, Hegel, or postmodernism.

Mazur and Basic Notions

June 17, 2004
Categories: Uncategorized

There's a quite remarkable article by Barry Mazur in the latest issue of the Bulletin of the AMS. It brings together ideas about elliptic curves and deformations of Galois representations that were used by Wiles to prove Fermat's last theorem, mirror symmetry, quantization, non-commutative geometry and much more. I'm not convinced it all hangs together, but it's a wonderful piece of expository writing.

Mazur claims to be inspired by a very interesting seminar held every week in the Harvard math department called the *Basic Notions Seminar*, parts of which have recently been put online. This issue of the Bulletin is dedicated to the great French mathematician Rene Thom, who died nearly two years ago. The articles by Michael Atiyah and Dennis Sullivan about Thom's work in topology are well worth reading.

   June 22, 2004

   I happened to see this article and the following comes to mind:

   a^p + b^p = c^p. If the p-norm, p of a metric space is not 2, then we have cyclotomic fields in a non-Hilbert space. Elliptic curves are just projections of SUSY spinors and are examples of cyclotomic fields. When p is 2, we can't have cyclotomic fields and can have only simple harmonic functions. The interesting thing is that a Riemann manifold requires just one spinor to fix it's position (like a rotating basketball), but when p>2, four spinors are needed and the space is quantized, by an integer ratio of a/c. Note that if 'a' is prime the field can't be cyclotomic.

   Wick ordering is a property of cyclotomic fields as well as NCG. My guess it that manifolds in non-Hilbert space are comprised of SUSY spinors and are exclusively solutions to non-linear PDEs. All non-Hilbert spaces are quantized — that's a shock and Banach space is not a linear or complete vector space — interesting.

   About the introduction of unstability in classical mechanics (page 22/328) I have from time to time redirecting people to Newton's Principia, proposition 1, Book I, to read how Newton himself decides explicitly to carry any quantum of angular momentum to zero. A lot of people mistakes this theorem as a trivial one of angular momentum preservation, didn't noticing that the continuum character of classical mechanics is defined there.

   By the way, I remember to have read a preprint where someone uses the unstability concept not only to get "h" out of classical mechanics, but also to get "c" out of galilean group. It speaks of stable and unstable theories or so.

Tevatron Run II Luminosity Record

June 21, 2004
Categories: Uncategorized

After an expensive upgrade to increase its luminosity, the Tevatron at Fermilab was turned back on in March 2001 to start "Run II", during which it was hoped that the machine would run with a dramatically higher luminosity than during "Run I" which ended in 1995. During Run I, about 140 inverse picobarns of collisions were generated, at the rate of about 3 inverse picobarns/week by the end of the run. The plan for Run II was for the new machine to get to a luminosity of about 17 inverse picobarns/week soon after the recomissioning, and ultimately to reach about 100 inverse picobarns/week.

This plan turned out to be wildly overoptimistic, as it took nearly a year and a half to get the machine operating even at the luminosity achieved during Run I. During FY02 the initial hope was to accumulate 320 inverse picobarns, rising to 830 in FY03 and 1300 in FY04. Instead 80 were produced in FY02 and 330 in FY03. While in FY02 the machine performed much worse than planned at the beginning of the year, in FY03 it did slightly better than planned.

As this fiscal year (FY04) is coming towards its end, the machine is doing significantly better than planned at the beginning of the year. The last few weeks have seen about 13 inverse picobarns/week being produced. Another measure, the luminosity at the beginning of a "store", reached a record value on Monday of 8.28×10^31 cm^2/sec. This is about five times higher than achieved at the end of Run I. You can follow the progress (as well as the trials and tribulations) of the Fermilab accelerator physicists through on-line daily reports and continually updated luminosity charts. For a collection of documents showing the history of the Run II problems and the most recent estimates of what will be achieved, see the proceedings of the latest review of the Tevatron luminosity, which took place last February.

About 2000 inverse picobarns of collisions will probably be needed before the Tevatron experiments can push up the current experimental limit on the Higgs mass (114 Gev) that comes from experiments at LEP. There now seems to be a good chance the Tevatron will get to this point before the LHC starts operating at much higher energy in FY 2008. If the LHC achieves anything like its design luminosity, it will quickly make the Tevatron obsolete. Then again, having seen how hard it was to get the upgraded Tevatron running, the job of commissioning the LHC may not be so easy…

String Theory by Press Release

June 22, 2004
Categories: Uncategorized

The KITP at Santa Barbara seems to be going all out to hype claims of observability by LIGO of effects of cosmic strings. The front page of the KITP website prominently features the story, and adds the personal phone numbers of the authors to encourage the press to contact them (something I've never seen theoretical physicists ever do before). Maybe these guys have already hired an agent.

Comments

   June 25, 2004

   I always felt a lot of that stuff which attempted to connect QCD with a string theory, looked kind of "ad hoc" and never really appeared to be all that convincing. When Maldacena's AdS-CFT stuff first came about it looked like a more sophisticated version of that "ad hoc" QCD string stuff, which initially I thought looked promising. After many years of folks working out the consequences of the AdS-CFT duality, I'm less convinced today of it's promises. Attempting to do string loop calculations on the AdS side seems to be a difficult problem, which so far hasn't produced many convincing results.

   In the end, that Maldacena AdS-CFT stuff may very well be just another "ad hoc" result in a long line of other "ad hoc" QCD string models.

2. **Alejandro Rivero**
   June 25, 2004

   JC,

   Search for "QCD String" in both hep-th and hep-ph. It started to be propagandised with the new century. I saw this campaign, then, as a way to drive people back into physics. Sort of leaving a scape gate.

3. **JC**
   June 25, 2004

   Speaking of weird string papers, just noticed this paper

   "Hadron pair photoproduction within the Veneziano model"
   hep-ph/0406267

   In 2004, I never would have thought anybody was still doing the string theory or dual resonance model stuff with respect to hadronic physics. The last time anybody took this stuff seriously, was when "California Dreamin" was still a top 40 hit song?

   A time warp back in time, to a more innocent and naive time period in physics history.

4. **Peter**
   June 24, 2004

   Thanks, I'm glad to hear that that you find the material here interesting, and I've been pleasantly surprised by how many people take and interest in it and make comments. But I'd rather not get involved in adding anything more elaborate to the site, mainly because I don't want to put any more time into it than I already do.

   That said, if you or anyone else wants to set something up and manage it themselves, I'll certainly set up links from here.

5.
   June 24, 2004

   OT request – would it be possible to implement a discussion section? Or desirable from your point?

   Some of us have a homemade board that runs on software written by one of our gurus (based on Zope and MySQL) that would be easy to implement for someone who knows Linux.

   I find this place more interesting than sci.physics.*.

6. **raj**
   June 23, 2004

   Maybe string theorists are adopting the techniques of the "creation science" crowd. And just when they caught the attention of US "public television." Witness Nova's series in the last year or two about string theory.

7. **JC**
   June 22, 2004

   Thomas,

   Some folks are willing to make all kinds of weird long term bets. Since they are not betting large amounts of money, if any money at all for that matter, they're simply not "putting their own money where their mouth is".

   If their bets end up being correct, they'll claim victory. If their bets end up being incorrect, they'll just "whitewash" it away by saying something like "I was young and stupid, but now I'm wiser", etc … or some other amusing excuse. There's no huge monetary losses on their part, regardless of whether they are right or wrong in the end.

   If they're wrong in the end, the most that will happen to them perhaps would be the depressing realization that they wasted a large portion of their working lives on something that was garbage in the end. It would be like "waking up" from a bad dream of being a member of a weird religious cult.

8. **Thomas Larsson**

June 22, 2004

For the last 20 years, Ed Witten has repeatedly stated that string theory makes one postdiction, gravity, and one prediction, supersymmetry. Alas, the natural signatures of supersymmetry have *already* been ruled out by experiments – this is what people mean when they say that supersymmetry requires finetuning at the percent level, isn't it? Thus, unless one gives up naturality (which was the only experimental motivation for SUSY in the first place), Witten's one string theory prediction has *already* been proven wrong. Pretty much bottom line.

9. **Peter**
June 22, 2004

The Fermilab story is about results of a fixed target experiment called SELEX, see hep-ex/0406045.
They stopped taking data in 1997, but recently went back to reanalyze their old data to look for to see if they could find evidence for the new states Babar was claiming.

They seem to have pretty good evidence for a new meson with a strange and charm quark, and supposedly much narrower than theoretical predictions. I really don't know how reliable the theory of the spectrum for such states is, so don't know how surprising this is.

Perhaps this is the kind of thing that could be confirmed and studied in more detail at SLAC or Cornell. Maybe there is something unexpected lurking in the physics of these mesons.

10. **JC**
June 22, 2004

The string theory advocates and "fanatics" over the years have sounded very similar in "spirit" to those folks who were ranting and raving about the "New Economy" during the 1990's dotcom bubble. After the dotcom bubble bursted in 2000, there were still many folks ranting about the "New Economy" for several years after, thinking that the Nasdaq "correction" was just temporary and that "prosperity" was just "around the corner". After about a year or so, the more level headed folks "woke up" and became more skeptical and less willing to "suspend disbelief". With time many of the advocates finally came to accept the notion that the "new economy" was just overblown hype, while the "fanatics" to this very day are still steadfast in their beliefs and refuse to capitulate. With time even some of the "fanatics" will eventually come to their "senses". For many folks, it would be very difficult emotionally to invest one's self in movements or ideas which don't work in the long term, especially when there's a huge investment of time, money, and ego involved.

A very similar sort of pattern happened the years before and after the 1929 stock market crash too.

Frequently movements or ideas that are built up by hype and overblown promises, end up following speculative "bubble" type behavior with the bubble frequently "bursting" after awhile when the hype deviates too much from reality to be sustainable in convincing many people to "suspend disbelief".

11. **D R Lunsford**
June 22, 2004

There is some kind of excitement at Fermilab:

http://www.theregister.co.uk/2004/06/18/meson_weirdness/

Any ideas?

12. **Peter**
June 22, 2004

The problem isn't that string theorists need encouragement to try and come up with an experimental prediction that can be tested. Most of them desperately would love to be able to do this. But the theory is so ill-defined it inherently can't predict anything.

The claims for "tests" of string theory are never-ending. I'd guess there's on average a new one once a month or so. A lot of science journalists are fooled by these claims, see for instance last year's article about string theory in Scientific American by George Musser that tells us that "in the mid-1990s the theory started to click together conceptually. It made some testable, if qualified, predictions."

Pretty much all the string theory "tests" are of the sort: "string theory predicts that X could happen" where X is something potentially observable. Note carefully the "could", they never say X "will" happen. In all these "predictions" string theory is compatible with some huge range of possible phenomena which include X (although X is exceedingly unlikely and there is no good reason to expect it to happen). These aren't real scientific predictions since when X isn't observed, this doesn't imply string theory is wrong. But it's amazing how many people are taken in by this stuff.

13. **Tim**
June 22, 2004

To JC,

Maybe this is a good thing. While their "test" may be dubious, if they get enough attention (and it seems like they have) it will encourage others to attempt to develop (and publicize, of course) other experimental string searches. Grounding theory in experiment is a good thing. Of course, if the theory is as poorly developed and vague as advertised here no possible experiment would be conclusive (not even wrong).

14. **Peter**
June 22, 2004

Hi Thomas,

This particular hype is different than the landscape hype and not inconsistent with the monovac philosophy, so no reason for Gross to suppress it. The truly sad day will be when the KITP starts issuing press releases about the stupendous Landscape.

15. **JC**
June 22, 2004

Perhaps this is the beginning of a series of "last gasps" of air for string theory?

When theoretical physicists are using the same hype and propaganda tricks that are common in political or marketing campaigns, one wonders if there's something really rotten underneath the surface that they're attempting to "whitewash" over. (ie. The anthropic stuff may be similar to maggots or termites slowly eating away into the string theory edifice of "legitimacy".)

It’s sort of like what they call the “cockroach effect” on the financial markets. Every time there’s “hints” of anything going wrong inside a company, everybody starts selling the company’s stock in a knee-jerk vote of “no confidence”. A sign of “bad news” (whether explicit or implicit) may very well be just “one cockroach” popping up at the surface, while underneath the surface is a whole colony of cockroaches and numerous deeper problems about the company in question.

16. **Thomas Larsson**
June 22, 2004

A long time ago, when Walter Kohn was director and the ITP didn’t have Kavli’s initial attached to it, I spent a year in grad school at UC Santa Barbara (a totally awesome place, fer sure). It saddens me that a place which meant a lot for my scientific worldview now is the center of such excesses. And what does the prophet of the cult of monovacuism in the office below Polchinski’s say about this?

Is that “Fau” for “Faux”?

June 25, 2004

Just got the following e-mail:

Date: Fri, 25 Jun 2004 19:40:58 +0200
From: fau.alex (fau.alex@wanadoo.fr)
To: woit@cpw.math.columbia.edu
Subject: Mr Woit

hi,
I am a french student and I will go in 1re(in France) the next year
and I want to speak with specialists because I want to work in science
when I will be adult … That’s why I write to you !
I want to know who are you ? What did you study, …
Thanks in advance for your answer
Best regards
Alexandre Faure

At first I thought “Oh yes, just another in the avalanche of fan-mail. Wonder if I should take the time to respond?” Then, looking more carefully at the HTML version of the e-mail, I found an embedded link at the bottom:

```
href="mailto:liu-yang.imp@th-phys.edu.hk"
```

That address looks awfully familiar.

Comments

1. **Phil**
   June 30, 2004

   It is already funny for a long time ago.
   How could you have met the prestigious professor Yang ? I have never met ghosts, maybe some ghost writers — those who write wrong mathematical sentences which are never re-read by the official writers of the book — but ghosts and imaginary creatures emerging from imaginary institute of “cosmomogy”, no, never. So Fabien you don’t have to answer to the common fallacies of these two people : almost nobody believe them. And by the way, thank you for your website.

2. **Fabien Besnard**
   June 30, 2004

   I can assure you I never met professor Yang ! (This is really getting funny !)

3. **Phil**
   June 29, 2004

   Dear Iogr and Grikcha Beudganov,

   (Learn how to write my nickname)

   I am sure that Mr “Yang”, from the famous Hong-Kong university devoted to your world-known works and thesis, would have been a perfect gentleman if I have had the honour to have met him. His very particular style showed it previously to me, but with most regrets I don’t even know his figure (with slavic features ?). No trace of your former posts about this so kind friend : could you remember me where they are, if you signed them ? By the way : I don’t know if you are only making juvenile provocation but I am not (and neither YBM is) Fabien Besnard : thanks to your delightful methods you have now several and distinct opponents.

   With most respect (ha ha ha),
   Phil Romnulphe

4. **Igor Grichka Bogdanoff**
   June 29, 2004

   Dear Phil Ronuphle,

   It is always a pleasure to read your kind messages. In fact (but there is nothing wrong with it) you did not read the posts where we spoke about the professor Yang. So please, go to our previous posts and read what we wrote about him. He is a charming and delighfull researcher, passionate with fundamental physics and complex maths problems. I am sure you would really like him (am I wrong? but I think that he already met Fabien Besnard some days ago).

   Kind regards

   IGB

5. **Phil**
   June 29, 2004

   So at last the Bogdanoffs do admit that they are in contact with the famous (and mysterious) Prof. Yang ? Could they talk more about him, for they forget to answer in the french newsgroups when he is on topic ? Is his famous Institute of “Cosmomogy” in Hong-Kong similar to the one in Riga ? As serious as it ? As we could say in French (forgive my “gallicisms”), ridicule un jour, ridicule toujours. Et j’ajoute : imposteurs d?masqu?s.

6. **Peter**
   June 28, 2004

The “Yang” address wasn’t in the header, it was embedded as a link in the HTML version of the message. Maybe young Faure is right and it appeared there because he was e-mailing “Yang”. It seems likely to me there’s more to this story than that, but I’m not wasting any time trying to figure it out.

7.
June 28, 2004

Dear Peter,

Our mutual friend “YBM” has alerted us about this “fau effect”, pretending that it was (another) Bogdanoffs pseudo. After checking we can assure you that Alexandre Fau has nothing to do with a) Yang, b) ourselves. You obviously got mistaken (somewhere) in the reading of the header of his email.
Nothing to really write home about.
Best regards

I/G

8. **Faur? Alexandre**
June 28, 2004

I just try to contact the Professor Yang ! That’s why this email is in this message …

9. **Peter**
June 28, 2004

I have no idea who you are, or what your relation to the Bogdanovs is, but I assure you that the e-mail address in question was embedded in your message to me.

10. **Faur? Alexandre**
June 28, 2004

Hi,

Contrary to that you said, or that you think, I am Alexandre Faure and I live in Toulouse.

First, I sent a message to you at :woit@math.columbia.edu

Secondly, read the real details of the message …

From: “fau.alex”

Summer Conferences

June 27, 2004
Categories: Uncategorized

Two of the year's largest particle theory conferences are taking place around now, with Lattice 2004 attracting 280 physicists to Batavia, Illinois this past week and Strings 2004 drawing almost 500 to Paris starting tomorrow. Normally I feel kind of sorry for string theorists since their field is in such bad shape, but this week I'm jealous since I would have loved to have an excuse to go to Paris this summer (I'm not jealous of the lattice gauge theorists who are getting to spend the week in Batavia).

Maybe I'm wrong about this, but the Paris string theory conference seems to me to be the largest gathering of particle theorists that I can remember ever having taken place. In recent years these things have been huge, with attendance around 400-450, but this one should be even larger. It is so over-subscribed that they haven't been taking on-line registrations for weeks.

Both conferences should have transparencies from the talks available soon on-line and the list of titles and speakers in Paris is now available. Some of the ones that look like they might be interesting are Robbert Dijkgraaf speaking about "Topological M-theory", Nikita Nekrasov on "Chasing M/F theory" and maybe Greg Moore, whose title is the mystifying "Anomalies, Gauss laws, and Page Charges in M-theory". One big theme of the conference looks like it will be N=4 super Yang-Mills theory. This is an interesting and well-defined quantum field theory, and one can study it whille claiming to be a string theorist because of the AdS/CFT conjecture and Witten's recent work reformulating it in terms of topological strings in twistor space.

Next Saturday in Paris there will be a whole day of talks devoted to the unrelenting hyping of string theory to the general public, something which is a standard feature of the "Strings XXXX" conferences, but not the "Lattice XXXX" ones. Somehow I suspect the speakers will neglect to emphasize the utter lack of any progress towards making any contact with reality during the past twenty years. In case the Paris conference is not enough, there are quite a few satellite conferences, including a pre-conference workshop at the IHES and post-conference workshops at CERN and Durham.

Update: It looks like Jacques Distler will be reporting direct from the conference.

Further Update: It seems that they have a WiFi connection at the Paris conference site. From my web server logs, it appears that one thing attendees at the conference are doing during the more boring talks is reading "Not Even Wrong" on the web. Hi Guys!

Comments

1. **JC**
   June 29, 2004

   Thomas,

   When I was a young naive undergraduate student, I took some smarter and older grad student's "advice" that the "best" place to learn field theory and string theory was Polyakov's "gauge fields and strings" book. At the time I didn't know any better, and was very much clueless about the field theory and string literature. I know now this smarter and older grad student was just joking around, and was trying to scare me away from theoretical physics in a "tongue and cheek" manner at the time. The last time I saw him, he joked about it and couldn't believe I took his "advice" as if it was a "gopel truth". Turns out that trying to learn introductory field and string theory from Polyakov's book, would be like trying to learn introductory quantum mechanics from Dirac's book. Both Polyakov and Dirac's books are really nice books to read once you know the subject well, but are difficult to learn from if you don't have any previous knowledge of the subjects.

   I ended up wasting a whole summer trying to figure out the calculations in Polyakov's book, where I spent most of my time in the library trying to figure out his papers that were referenced in his book. After that I still had a hard time figuring out Green, Schwarz, and Witten's books on superstring theory. Somehow I was able to reproduce most of the calculations in Polyakov and the Green, Schwarz, and Witten books, but I was still relatively clueless as to what the physical picture underneath all the mathematics was about. At the time I think took the Feynman idea of "shut up and calculate" mentality to the extreme. (I don't know if the quote was originally Feynman's, but over the years it seems to be attributed to him like an "urban legand".)

2. **Thomas Larsson**
   June 29, 2004

   Sasha Polyakov travels fast. Yesterday he was in Paris and gave a talk that Jacques Distler didn't like, and today he gave a talk at the 4ECM here in Stockholm. I haven't had any academic affiliation for a long time, but since P was one of the big heroes of my youth (for the BPZ work), I took the afternoon off and sneaked into the Aula Magna.

   The talk was intended for an audience of mathematicians and had the presumptious title "Physicist's view of mathematics". P started out with the thesis that math history has had three phases, characterized by the slogans

   "Things are numbers" (5th century BC)
   "Things are topological invariants" (20th century AD)
   "Things are words" (21st century AD)

   By topological invariants he means things which do not change at all under small deformations (I might have preferred the word "universal"), and gave three examples from physics:

   1. The quantum Hall effect, where conductivity is given by sigma_xy = n e^2/hbar, n integer.

   2. Instantons and their connection to the Atiyah-Singer index theorem and Donaldson's invariants.

   3. Critical exponents in the 2D Ising model and minimal models. With Schramm, Smirnov and Werner in the audience, I was somewhat surprised that he didn't make the very timely connection between CFT and SLE at this point.

   The "things are words" part turned out to be about his recent work on the connection between some 4D Yang-Mills theory in loop variables and some theory of random surfaces in 5D. This seems eminently plausible; if you take the intersection between a generic surface in 5D and a 4D hyperplane you'll end up with a loop in 4D, which may perhaps be a Wilson loop of some Y-M theory.

   Alas, the model stood by itself, without any reference to 10D or 26D or Calabi-Yau, even as a motivation. It seems like the smart string theorists are starting to pretend that those things never happened and go back to study 4D field theory again. It is difficult to be critical about using an extra dimension as a technical trick to study Y-M theory in 4D, although I got the impression that P's model isn't the physical Y-M theory of the standard model. Anyway, I missed the details because P didn't give any due to time limitations.

At this point one may wonder where the “things are words” slogan enters. The point, if there is any, is that correlation functions can be regarded as words, with elementary fields and their derivatives being letters. Natural enough, but surely people knew about OPEs before the 21st century…

In the question section it became clear that P didn’t think very highly of Wolfram’s New Kind of Science. But then again, who does?

3. **Steve**
June 28, 2004

Forget Lattice 2004 and Strings 2004–the best and most informative conference of 2004 has already taken place.

http://www.xs4all.nl/~rpronk/conference.htm

With the conference proceedings detailed here:

http://www.j-walk.com/other/conf/summary.htm

For those with a rightious sense of political correctness who don’t appreciate the humour of these links, that will quickly disappear if (like me) you have to delete 20-30 of these damn things virtually every day! At any rate, physicists could perhaps adopt the conference advice given on “uppercase letters” in order to make their preprints stand out in the hep archives:)

person: BOGDANOFF IGOR
address: none
phone: 33608250825
e-mail: igor.bogdanov@wanadoo.fr
nic-hdl: 23391-LUMII
source: LUMII

That address now hosts a web-site for the Mathematical Center of Riemannian Cosmology, which mysteriously seems devoted to the work of the Bogdanovs. The newsgroup fr.sci.physique has all sorts of threads devoted to the Bogdanovs. In one posting by the brothers, where they give their e-mail address as "igor.bogdanoff@phys-maths.edu.lv", they helpfully explain that the University of Riga set up the site for them and that's why it is in the Lithuanian DNS.

One problem: Riga is in Latvia, not Lithuania.

I take this kind of personally because, besides being an American citizen, I also have a Latvian passport (the Latvian version of my name is "Voits"). My father was born in Riga, and he and his parents became exiles at the time of the Soviet occupation starting during World War II. I've visited Riga several times (including a visit to the university), first soon after independence on a trip with my father while he was still alive. Riga is a beautiful city, with the downtown not much changed since before the war. In recent years the old city and much of the downtown have been elegantly renovated, and Riga is now once again a large, vibrant city with great restaurants, hotels, shops, etc. And now it has an International Institute of Mathematical Physics.

   July 1, 2004

   Dear Fabien,

   Just a precision. You write that our quantum group paper is in our book. But if you compare the "annexes" of Avant le Big Bang with the paper itself, you will have to admit that only a short fragment of it was published in the book. In fact, we published this extract (our theorem 3.3.2) much more as an example of a scientific paper (which may be of interest for a large audience). The objective was not to be understood by specialists of quantum groups theory (many readers said that they liked it the same way they like some creation of modern art.). But at the end, the only thing that matters is the "impression" left by a book. In the case Avant le Big Bang laks of precision or contains some mistakes, we hope that grace to you and others, we will be able to correct it.

   I/G

2. **Fabien Besnard**
   July 1, 2004

   The intersection is not the empty set since your quantum group paper IS in your "large audience" book ! When I say you do not follow the scientific method I include a lack of intellectual rigor which is a minimum requirement even in a large audience book.

3. **Bogdanoff**
   June 30, 2004

   Dear Fabien Besnard,

   Thank you for your response which has the advantage to be honest.
   But now : how can you compare a quantum group paper with a large audience book? From our view, the intersection between these two categories is really an empty set. A scientific paper is written for experts; by definition, it requires a high level of technicity and very few readers are able to grasp the real meaning of it. At the opposite, a book is not written for experts, even not for specialists of scientists : it is meant to be read and understood by a large audience. Before the Big Bang was written as a large audience book. Not as a scientific paper. Indeed you are right when you say that it does not follow the scientific method. Of course not. But it still reflects a certain "state of the Universe" by an other path. It may contain some mistakes, erros or misquotings (Woit, Schreiber); but at the end "something" good may remain; So we propose that instead of burning the whole, you make the effort to look after this tiny "something" that may be hidden somewhere between the pages.

   Thank you for your attention

   I/G

4. **Fabien Besnard**
   June 30, 2004

   To IGB : it is not the place to discuss about that, but since I have been attacked at several places on this weblog, I will made one last comment : I began to read your article but then I read your book, and there I found many evidences that you do not follow the scientific method (to say the least). So it was pointless to go on reading about bi-crossproducts. Another important thing is that I realized that if ever I turned out saying that just one line of calculation was right in your paper, you would go everywhere misquoting me, perhaps making me one of your supporters in your next book !

5. **Bogdanoff**
June 30, 2004

Tell us, dear Fabien Besnard, how you can follow such a line of de-reasoning? You see, since you wrote your article, you got involved in a matter that is obviously beyond your field of expertise. You even wrote us (May 20,2004) : " I had a glance on your "bicrossproduct article". Since I do not know this matter, I have to refer to Majid and it may take some time." You never got back to us. Following your own statement (since you admit in you letter that you do not understand our work in quantum groups) on what basis do you claim that this work should be "empty"?

Obviously, your reaction is neither "objective" nor scientific.

Thank you for your attention,

IGB

6. **serenus zeitblom**
June 30, 2004

By the way, I wonder how the people in the universities in Hong Kong feel about an address like http://th-phys.edu.hk/? Has anyone asked them?

7. **Fabien Besnard**
June 30, 2004

Tell me, dear Ark, how someone who "thinks" can still use such a line of reasoning as "A is a crank and go unnoticed, B has been caught, so I will defend B" ? I never heard of the people you speak of (Tiller et al) so they don't bother me. But now each morning I hear an advertisement for Bogdanov's book on my favourite radio station. This is enough for me not to turn my attention away from B&B at the moment…

8. **ark**
June 29, 2004

Nobody knows for sure why the world seems to be 4-dimensional. Anthropic principle is one pseudo-explanation. That I have five fingers on my hand, and one is evidently different than the other is another "explanation", as good as any other one, including one with four different kind of numbers.
Some people think, some don't. Some use their cerebral cortex, some don't. Some have souls, some, evidently, don't. That's normal.

Now, to just shift your (YBM (pseudo of Besnard))attention to a slightly different subject let me quote from a book by three American "scientists". In fact I invite all of you to visit my web page

http:/quantumfuture.net/cass/bogdanov3.htm

There you will find:

> "Conscious Acts of Creation: The emergence of new physics by William A. Tiller", PhD, Walter E. Dibble, Jr., PhD, and Michael J. Kochane, Ph. D. The Preface to the book is signed by Rustum Roy, Penn State, Wayne B. Jonas, USUHS and …. E.C. George Sudarshan, University of Texas, Austin.
>
> Are we ready to be bitten by monopoles? Here is a quotation:
>
> "Through the agency of a nine-dimensional coupling substance in the vacuum, called deltrons, the faster than light magnetic monopoles functioning in reciprocal space can interact with electric monopole substance functioning in direct space of physical matter. The vacuum phase transition mentioned above involves an ordered phase formation of magnetic monopole substance phase of R-space. These magnetic monopoles of R-space travel so fast that they 'write the waves,' thought to be de Broglie pilot waves, controlling the movement of particles in D-space. A symmetry principle, called the mirror principle is thought to operate between D-space substances and R- space substances so that the monopole charge singularities in one space produce dipole images through the mirror into the other space. Likewise, the monopole mass singularities in one space produce images through this mirror into the other space. Thus the negative negative monopole mass singularities of R-space are thought to be the origin of the 'dark matter' we currently detect with our instruments in D-space.(…)"
>
> If you think that these concepts are explained somewhere in the book – you may be surprised to find out that after you are through with the book, you will not have an idea of what the "theoretical part" is about.
>
> Now, let me mention that I wrote papers on magnetic monopoles and on "reciprocity" (including conformal symmetric spaces). Therefore, I suggest, that after we are done with KMS, signature fluctuactions, and topological field theory, there is a new field to be exploited in the space of hoaxes: D-spaces and R-spaces and monopoles that write the waves, thought to be de Broglie pilot waves…. All supported by PhDs.
>
> ark
>
> Conscious Acts of Creation is being madly promoted by the "alternative crowd" as "proof" that all their "you create your own reality" ideas are true.
> Conscious Acts of Creation, tells us:
> This book marks a sharp dividing line between old ways of scientific thought and old experimental protocols, wherein human qualities of consciousness, intention, emotion, mind and spirit cannot significantly affect physical reality, and a new paradigm wherein they can robustly do so! ?utilizing a unique experimental protocla on both inanimate and animate systems, that the human quality of focused intention can be made to act as a true thermodynamic potential and strongly influence experimental measurements for a variety of specific target experiments.
>
> After almost 400 pages of speculation and descriptions of experiments and very little math, we are told:
>
> Under some conditions, it is indeed possible to attach an aspect of human consciousness, a specific intention, to a simple electrical device and have that device, when activated, robustly influence an experiment conducted in its vicinity in complete accord with the attached intention. Thus, if they do it right, humans can influence their environment via specific, sustained intentions. [?] Some new field appears to be involved in the information passage that occurs between conditioned locales that are widely separated from each other in physical space. Even with transmitters and receivers located inside electrically grounded Faraday cages, highly correlated patterns of information appeared in the remotely located locales. [?] Although we don't fully understand them, we now have some new tools with which to probe the deeper structures of the universe and a new adventure is underway for humanity.
>
> It is important to note that the "intenders" of the experiments were long-time practitioners of Siddha Yoga and could thus be considered metaphysically "in tune" to some considerable extent. The question is: What did they accomplish? Based on the descriptions, it sounds pretty earth-shaking, right?

> Well, as noted, after almost 400 pages we find that the most significant result seems to have been changing the pH of a small sample of water.
>
> Yup. That's it.
>
> But we notice that nobody says a word about this sort of thing. At this point in time, the physics community hasn't said a discouraging word about Tom Bearden and his follower, Richard Hoagland – nor the interesting fact that Bearden is a former associate of Ira Einhorn, Andrija Puharich, the gang at Esalen and Penn State who flirted with the edges of the Secret Government experiments in mind control and the promotion of LSD to the young people of America. Nobody has cried "Hoax!"

Happy reading!

ark

9. **YBM**
June 29, 2004

? YBM (pseudo of Besnard) ?

The last line of defense : pretend that everyone and his brother questioning their work is in fact one person. It is so desperatly ridiculous (anyone familiar with fr.sci.* would know) that I wonder if I should deny.

BTW, Mr Woit, did you know that in their book they pretend (sqrt(5)+1)/2 is transcendental ? And that the Universe has four dimensions because there are four kind of number (integers, rationnals, reals and complexes) ? Therefore, in their spirit, I aprove the following statement :

if the golden ratio is not albebraic, then I am Fabien Besnard (and the Pope as well)

10. **Igor Grichka Bogdanoff**
June 29, 2004

Dear Peter,

We do not understand how someone (like you) who is very familiar with internet technics cannot make any basic difference between a post coming from us and a message coming from someone else. Instead of checking the situation with us you immediatly write an article on it, prentending that you got a message from us hidden behind a "double pseudo". Once for good : Alexandre Fau is NOT a pseudo of Bogdanoff! We do not know this person, we never met him, but we sent him an email yesterday. He must have sent you another email and we hope that you have a clearer view of the situation by now. If we want to write you, we do not need to hide ourselves behind anyone. We do it directly, as we wrote you this morning. Our advise is that you should not listen too much people like Besnard or YBM (pseudo of Besnard). There are much more serious things to do and other important problems to solve in the Universe.

Best regards

I/G

11. **ark**
June 29, 2004

Hi Peter,

I agree that misquoting was bad and you did the right thing pointing it out. As for problems "at the top levels" – well …. It all started long ago with the "publish and perish" ideology and research grants and money tied to politics. I decided to try to create an "alternative research institution". Whether it will fly or fall – we will see. For a couple of years I was a v-ce director of the Institute of Theoretical Physics in Uni Wroclaw, Poland. So I was witnessing how the level of the research deteriorates with the institution of plans and grants. It deteriorated to the extent that I decided to leave organized science completely. Ambitious and/or original projects have little chance to get support. In the US we have, in addition, the military complex that intercepts what is in their field of interests, which additionally severely restricts the freedom of research.

These are just few thoughts that are on my mind right now. I wish you success in your mission!

ark

12. **Peter**
June 28, 2004

Hi Ark,

Actually I'm not spending my time criticizing the scientific activities of the Bogdanovs. They're not much of a problem for the scientific community. Much more serious is the situation at the top levels of the US (and other country's) scientific establishment in particle theory, and it is that problem that I have been trying to do something about, despite warnings from many that it is unwise of me to challenge powerful interests.

On the other hand, if they are going to do things like publish books misquoting me and send me e-mail purporting to be from someone other than who it is really from, I'm going to use this forum to tell about this activity, and, yes, ridicule it.

13. **ark**
June 28, 2004

If only to amuse you (as apparently some of you guys has nothing better to do than follow Igor and Grichka, why don't you choose Thomas Bearden or Myron Evans, with connections to US DOD and DOE agencies?):

It does not matter when the server is – if it is convenient to have a server in Thailand – it will be in Thailand. The cheapest servers are certainly in US, but due to Bush Reich lies, some organizations do not like to have servers in US. While some do.

Notice that International Institute of Mathematical Physics has updated its web page at

http://th-phys.edu.hk/

(I did it) though it is still in status nascendi, so it will have its reasonable web site in due time. For the time it is just a "project", even though officially registered, yet it will take about a year to give it a shape.

If you wish to have me help you to find american targets for your attacks (because France has been already used), I will certainly be willing to help you. If you are really so moved by the idea that physics publications should all make sense, and all mistakes should be ridiculed – just try to read carefully, checking every formula and every sentence, all papers in arxiv.org. 80% of these papers will be nosnsensical, and can be easily ridiculed – if one is determined to do so, and has nothing better to do.

ark

14. **Mcrc**
June 28, 2004

There is nothing "mysterious" with the existence of this website : it has been legally registered and it is ruled from Paris. So what? Where is the problem? Why bother any further?

15. **YBM**
June 28, 2004

"Mathematical Center of Riemannian Cosmomogy"

"Cosmomogy" is the name ! Ridiculous and nonexistant : the place where you consider the consequences on the Universe of the hypothesis that the golden number is transcendant ?

16. **igor**
June 28, 2004

YBM wrote in message news:…
> Tiens, puisque vous ?tes r?veill?s, Peter Woit vient de mettre
> en ligne un r?sum? de votre pitoyable tentative d'inventer encore
> un Institut International de Math?matiques tout entier d?volu
> ? votre gloire :
>
> http://www.math.columbia.edu/~woit/blog/archives/000045.html
>
> Comment pouvez-vous ?tre si maladroits ?

Re bonjour,

A la suite d'une conf?rence faite ? Riga (2001), les responsables de l'informatique de l'Universit? nous ont propos? de cr?er un site. Comme il fallait bien lui donner un nom, nous avons pens? ? Mathematical Center of Riemannian Cosmomogy, qui refl?te exactement notre domaine de recherche.
Il y a environ un an, nous avons cr?? les quelques pages correspondant ? nos orientations de travail, papiers, etc. et le site a ?t? cr?? ? l'automne 2003. Comme tous les autres sites, il est administr? par l'institution suivante :

University of Latvia
Institute of Mathematics and Computer Science
Department of Network Solutions (DNS)
Rainis Boulevard 29
Riga LV-1459

Voil?. Depuis 2001, nous ne sommes plus jamais retourn?s ? Riga et n'entretenons aucun lien particulier avec ce pays. Notre seul lien tient au nom de domaine qui nous a ?t? attribu?s et que nous op?rons depuis la France.

Merci de ton attention,

Amicalement,

I/G

June 27, 2004

Oops that's Estonia. Guess I was thinking of Mikhail Tal? 🙂

18. **D R Lunsford**
June 27, 2004

Paul Keres!

19. **JC**
June 27, 2004

Also amusing is how some of the links on phys-maths.edu.lv to the Bogdanov's papers and *.gif picture files, all appear to be on an expired account at http://www.mydocsonline.com

These guys have been doing a piss poor job of even trying to perpetuate their own hoax. Probably even a high school computer whiz kid can do a better job!

20. **Peter**
June 27, 2004

Doing a "whois" search on the networksolutions.com website shows that the address is hosted by a web hosting company called "Ancient Media" at an IP address in South Carolina.

21. **JC**
June 27, 2004

It appears the machine hosting phys-maths.edu.lv is not even physically in Lithuania nor Latvia. A traceroute reading to phys-maths.edu.lv looks like it's hosted in north america. If you do a traceroute to machines located physically in Lithuania (.lt) or Latvia (.lv), you'll typically get longer delay times that are characteristic of transatlanic connection times to eastern europe or Russia. Even America -> England connections, shows the transatlanic delay.

The Tevatron as Earthquake Detector

June 29, 2004
Categories: Uncategorized

It seems that the Fermilab Tevatron is a quite sensitive detector for earthquakes. According to the Accelerator Update for yesterday, a small earthquake in Illinois caused the machine to lose its beam and a superconducting magnet to quench. A few hours later, a more significant earthquake in Alaska was quite visible to the Tevatron accelerator operators, and would have caused another quench, but they hadn't restored the beams yet.

Lattice 2004 Talks

June 30, 2004
Categories: Uncategorized

Some of the talks given at the Lattice 2004 conference are now available on-line. Particularly interesting is Kenneth Wilson's historical talk about his roles in the development of the renormalization group and of lattice gauge theory. He also refers to the website of the Dibner Institute.. One interesting thing there is a collection of materials relevant to the history of the renormalization group.

The Dibner Institute is at MIT, but during my high school days I recall visiting the library for the history of science that Bern Dibner had founded which was located close to where I lived, in Norwalk, Connecticut. The collection was moved up to Cambridge after Dibner's death in 1988.

Revising the Landscape

July 1, 2004
Categories: Uncategorized

One contributor to the comments here (JC) has pointed out that Susskind has withdrawn from the arXiv his recent paper on the stupendous Landscape of sting theory. This is pretty unusual, but often when it happens the author puts in the withdrawal statement some indication of why the paper was withdrawn, something Susskind didn't do in this case. Another contributor to the comments (Serenus Zeitblom) points out that one should look at recent changes to Douglas's paper on the arXiv, which is now up to its fourth version.

One feature of the arXiv is that all posted versions of papers are available, so one can compare them and see what changes the author made. The history of Douglas's paper is quite something. The original version was posted on May 30. Susskind's now withdrawn paper was posted on June 17, and in it he claims that Douglas's paper showed that Susskind's argument in an earlier (May 21) paper (which exists in three versions) was wrong. The latest version (4) of Douglas's paper now says that earlier versions of the paper are wrong. So, one reason Susskind withdrew his paper is presumably that its claims that his earlier paper was wrong were now wrong because they were based on Douglas's wrong paper. Got that? This all seems to me to be a new and original version of the "Not Even Wrong" phenomenon.

Some other high points of the changes in the four versions of Douglas's paper:

1. Going from version 1 (May 30) to version 2 (June 2), he changes

"If I had to bet at the moment, I would still bet that string theory favors the low scale, for the reasons outlined above, but it is not at all obvious that this is what will come out in the end."

to

"At this point, it is not at all obvious whether high or low scales will be preferred in the end."

2. Going from version 2 (June 2) to version 3 (June 22), he adds a reference to Susskind's June 17 paper, some criticism of it, and the sentence

"The correct assumptions could be determined from string/M theory considerations with more work, and we are optimistic that this can be done in time to make convincing predictions before LHC turns on in 2007."

3. Going from version 3 (June 22) to version 4 (June 29), he removes the sentence above (I guess he became less optimistic last week) and announces that the argument in the previous versions was wrong.

Comments

1. **sol**
   July 3, 2004

   I wanted to add this as well.

   "*Quantum gravity is the field devoted to finding the microstructure of spacetime. Is space continuous? Does spacetime geometry make sense near the initial singularity? Deep inside a black hole? These are the sort of questions a theory of quantum gravity is expected to answer. The root of our search for the theory is a exploration of the quantum foundations of spacetime. At the very least, quantum gravity ought to describe physics on the smallest possible scales – expected to be 10-35 meters. (Easy to find with dimensional analysis: Build a quantity with the dimensions of length using the speed of light, Planck's constant, and Newton's constant.) Whether quantum gravity will yield a revolutionary shift in quantum theory, general relativity, or both remains to be seen."*

   http://academics.hamilton.edu/physics/smajor/quantgrav.html

2. **sol**
   July 3, 2004

   JC,

   The Elegant Universe, by Brian Greene, pg 231 and Pg 232

   "But now, almost a century after Einstein's tour-de-force, string theory gives us a quantum-mechanical discription of gravity that, by necessity, modifies general relativity when distances involved become as short as the Planck length. Since Reinmannian geometry is the mathetical core of general relativity, this means that it too must be modified in order to reflect faithfully the new short distance physics of string theory. Whereas general relativity asserts that the curved properties of the universe are described by Reinmannian geometry, string theory asserts this is true only if we examine the fabric of the universe on large enough scales. On scales as small as planck length a new kind of geometry must emerge, one that aligns with the new physics of string theory. This new geometry is called, quantum geometry."

   You were right to point this out and from a common perspective, as a starting point .

   But these discription were not limited to string theory alone as we have come to witness from the participants of LQG or dynamical traingulations of quantum gravity(quantum geometry).

   Again you were right to point out the many facets of the attempts here, including Penrose and his twistors.

   I am trying to find a common bound between them all, as we all are?:) Some of my perspectives are being revealled on physicsforum, and the imput back to me, is pointing towards the usage of Glast as a possible discriptor of the metric.

   All speculation of course.

3. **JC**
   July 3, 2004

   sol,

   What is your definition of "quantum geometry"? Over the years I've noticed the term "quantum geometry" being used and abused for all kinds of things, depending on who you're speaking to.

I don't really have a good precise definition for the term "quantum geometry", other than perhaps (in a vague sense) looking at what happens to the geometry of classical general relativity when quantum corrections are added in. Since not many of the quantum gravity paradigms are particularly that successful, I don't feel there's really any easy way to even quote a universal definition of "quantum geometry" that everybody can agree upon. At this point in time, string theory has the furthest progress in terms of looking at a "quantum geometry".

In a non gravity context, perhaps "quantum geometry" could be defined as examining the "geometry" underlying quantum Yang-Mills theory.

Anyone else have a better or more precise definition of "quantum geometry"?

4. **Thomas Larsson**
July 3, 2004

Alejandro,

All I meant was that values of atomic masses are to some extent due to historical accident. The allowed ranges are of course too small to really affect the viability of human life.

5. **sol**
July 2, 2004

I was always fascinated by the relationship to the isometrical relationship orbitals presented in terms of self similarity. To cosmological situations the representations eem awfully uncannny.

Arivero, and from that standpoint, could we have indeed found a escoteric(has it been removed?) way to speak on the nature of quantum geometry?

6. **Alejandro Rivero**
July 2, 2004

Last week I was informally presenting to my elders my work on nuclear masses, and someone mentioned Rydberg but I was unaware of all the history. Thanks very much for bringing it here. Although I can not see how the isotope theory is anthropic-environmental (?). Well, of course, a sort of anthropicity principle could be to request the existence of Dalton's atoms. Plausibly this requires the proton mass to be well smaller than the ones in the higgs/electroweak sector, but this is too modern for Rydberg 🙂

Aside, I believe to remember that the original isotope proposal was linked somehow to esoterism.

7. **Thomas Larsson**
July 2, 2004

There is one obvious example successful of anthropic, or at least environmental, reasoning that I am surprised not to have seen mentioned: the isotope theory. 120 years ago, Janne Rydberg was probably Sweden's most famous physicist. Nowadays he is remembered for the series and the constant, but his main interest was to derive some deep explanation for atomic masses. When it eventually turned out that atomic mass is due to a rather random mixture of isotopes, he became so depressed that he had to seek professional help.

There are of course many differences, e.g. that we can successfully explain the masses of individual isotopes, at least in principle. But I don't see a problem if some numbers must be explained by historical accident, as long as the main predictions of your theory (extra-dimensions, SUSY, massless scalars, proton decay, huge and negative CC, etc.) agree with experiments.

8. **Alejandro Rivero**
July 2, 2004

JC, indeed it is easier and a lot more honest simply to point out the empirical data your theory needs. Newton does no predict the mass of the Earth nor Moon, and still it is a pretty theory.

The point here is that the "monovacuum" and "anthropic" folks actually share a common goal of defining a single theory having a single solution. But the second group has evolved towards a tricky, not very honest, methodology. The original anthropic principle, as I remembered it, claimed that we can not determine theoretically some fundamental constants because they could have any random value in some range, and we just happen to be in one of the possible ranges. The now-selling A.P. claims that the value of the fundamental constants is determined theoretically just because we are here.

The "monovacuum" folks follow a different argument. They are on the [very extended, but rarely explicit] oppinion that there is only a consistent way to describe spatial change (ie movement) in a mathematically consistent manner. In fact it is surprising how few methods do we have to describe dynamics, so it could be. In this view Classical Mechanics is logically incomplete or inconsistent (zero limits, incompatibility with electromagnetism) and the same happens with Classical Field Theory (self-energy of electromagnetism) and Quantum Field Theory (Renormalisation), while the fundamental yet to be string theory should be completely sound. The argument is antropic in a deeper sense than the antropic principle: it assumes that Reality must be exactly described my using [matematical] Words.

Hmm I feel I am not answering your comment but simply expanding or re-stating the previous of mine. Still, I wanted to go over it because of your mention of "compactness". A side of the "compactness" of a theory is related not to its mathematical complexity, but to its degree of uniqueness.

I supposse that at the end one can reduct this uniqueness to some counting of the axioms and postulates needed in the theory (while complexity could be a count of lemmas and theorems), and to count the external input too.

9. **JC**
July 1, 2004

Alejandro,

Many years ago I use to think of physical theories as a "compact" way of representing information about a particular phenomenon, in a vague sense. If a theory is so complicated and cumbersome, that it takes up more computer "storage space" to represent the mathematical formulas than it takes to represent the original experimental data, it would be easier just to quote the experimental data instead of the cumbersome "theory". (This is sort of an abuse of "Occam's Razor" without being too precise). The obvious case is that of Newton's laws representing many different phenomena like Kepler's laws, pendulum motion, free fall motion, etc … With quantum mechanics, the n-body Coulomb problem for the Schrodinger equation can account for the spectral lines of atoms, etc … The theories of Newton and Schrodinger are a very "compact" mathematical representation, compared to quoting all the experimental data for all the possible phenomena they represent. (I think it was Gregory Chaitlin who advocted this point of view over the years).

For really highly nonlinear systems that show up in fields like economics, biology, politics, psychology, etc … a lot of them are so mathematically cumbersome to the point that they are hopelessly complicated, where the most "compact" way of representing the phenomena is just to quote the original empirical data. A typical example of this is the empirical weather data, compared to the complicated nonlinear fluid dynamics systems which attempt to approximate the weather (in a less than satisfactory manner for the most part).

I'm being somewhat vague on purpose, since I don't have a precise definition for "compact" representation of a physical phenomenon. Over the years I have changed my views on some of these ideas. I may very well end up dropping the entire framework in the future if I can't find a way to resolve the issues that I have been deliberately vague about.

With respect to string theory, the "monovacuum" folks want a single unique vacuum solution which in a vague sense gives a "compact" representation for a quantum theory of gravity. With a proliferation of a zillion Calabi-Yau manifolds and many other solutions in the String Landscape, then string theory becomes one of those nasty cumbersome theories which becomes hopelessly complicated to deal with. It may very well be easier just to state the empirical data from the particle physics data books and the Standard Model, along with whatever empirical data is coming from the astrophysics folks (ie. cosmological constant, etc …) as the most "compact" representation of the phenomena that string theory originally was "advertised" to represent.

July 1, 2004

I had always though of it as a cosmologist/philosopher gadget. The Weak Anthopic Principle and all that.

A decent motivation for it can come from
"Things are words" (20, 21st century AD), as Larsson quotes Polyakov. But forget the explanation from P. I understand that the "things are words" principle can be used to tell us that any theory of Reality must be done with words, and thus all the physics we do is limited to this. A physicist can say "words, and more concretely mathematical words", and then look for a proof of existence and uniqueness of mathematical theories fitting the known data. This was the spirit of GUT and it is the spirit of string field theoretists, to use the "things are words" principle to get a single unique theory.

My understanding is that string is failing to get uniqueness, and then they perturb their own philosophical principle in order to say "things are words coming from empirical input", or something so. But then it loses all its appeal.

11. **JC**
July 1, 2004

Alejandro,

Do you have any insight as to why exactly some physics people end up believing in anthropic arguments and ideas?

If I didn't know any better, I get the sense that a person using the anthropic principle is attempting to justify a particular idea/theory (whether popular or unpopular) that they are not willing to give up on easily. In the days when I was still a true believer in string theory, I would have found it very difficult to give up on it as a solution to quantizing gravity. I probably would have been making every possible excuse and argument to rationalize my own personal biases and prejudices in favor of string theory. If the anthropic landscape ideas were around when I was still doing string theory, I certainly would have tried to use them as my own personal justification to continue to believe in string theory.

For some folks, it may possibly be an "ego" thing where they don't want to admit that they spent many years of their life, time, and energy on something that may very well be completely wrong in the end.

July 1, 2004

JC-

One thing that comes immediately to mind is Poincare and his wrestling with the metaphysics of F=ma (see "Science and Hypothesis" and "Science and Method"). If he had just forged ahead without worrying too much about how people are related to physics, he might have hit on relativity before Einstein.

-drl

13. **Alejandro Rivero**
July 1, 2004

I keep telling, suppose that we ask for sentient persons able to measure an earthly acceleration of 9.8 meters/second^2. Is this an anthropic requeriment? To me, it seems just experimental input. As people become aware that antropic=empirical input, the club will dissolve. I hope.

14. **JC**
July 1, 2004

It will be interesting to see how many "monovacuum" folks will still be left actively working on string theory, if the anthropic folks end up having the most influence on the string research agenda.

It would be interesting to go back into physics history and see which paradigms and research fields had a "kiss of death" once the experts were starting to use the anthropic principle in a "serious" manner.

Hawking Buzz

July 3, 2004
Categories: Uncategorized

The buzz is that Hawking has a new idea about how to resolve the “Black Hole Information Paradox”, the well known incompatibility between standard ideas about black holes and the unitary time evolution of the wave function that is fundamental to quantum mechanics. Evidently Hawking has asked to give a talk about this at GR17, a big conference on general relativity that will be held July 18-23 in Dublin.

The abstract for his talk goes like this:

“The Euclidean path integral over all topologically trivial metrics can be done by time slicing and so is unitary when analytically continued to the Lorentzian. On the other hand, the path integral over all topologically non-trivial metrics is asymptotically independent of the initial state. Thus the total path integral is unitary and information is not lost in the formation and evaporation of black holes. The way the information gets out seems to be that a true event horizon never forms, just an apparent horizon.”

I can’t tell exactly what that means either, so I guess we’ll have to wait for the talk. My own prejudice about quantum field theory is that the relation between the Euclidean and Minkowski space formulations of quantum field theory is actually much more interesting and subtle than people think. It’s not just a technical trick. So I’ll be interested to see what Hawking has to say about this.

Something else at the conference that may be interesting will be Sir Roger Penrose’s public talk entitled “Fashion, Faith and Fantasy in Modern Physical Theories”. Guess what he is referring to by “Fashion”.

   July 8, 2004

   Another subtlety about Minkowskian signatures is the embedding theorem. Not usually mentioned, but worth to have it at the back of some neuron.

2. **Urs Schreiber**
   July 8, 2004

   Wick rotation in QFT on a fixed background is certainly deep. But for quantum gravity it is for the obvious reason very problematic, as has been discussed at great length on s.p.r. for instance.

   Hawking has worked a lot on Euclidean path integrals for cosmology in the past, and he even goes as far as introducing his ‘Universe in a nutshell’ book with saying that our universe is essentially a Euclidean 4-sphere in a sense. (I think he should have mentioned that this is more of a personal view, a hunch, which is not necessarily shared by the community or even demonstrated by results, I’d think.) Maybe it is just due to my ignorance of the literature, but I am having trouble coming up with past results or even hints that the Euclidean path integral for gravity is the thing to look at. Now, maybe Hawking’s new idea about black hole information is just that hint which I am looking for, I don’t know. But currently I am a little sceptical.

3. **Godfrey Miller**
   July 6, 2004

   I saw Sir Roger when he gave the same talk(s) at Princeton on Oct. 17, 20, and 22. On that occasion, Fashion, Faith, and Fantasy were each the subject of one night’s talk.

   I thoroughly enjoyed what he had to say, but Princeton is a hub for string theory, and I got the distinct feeling that my position was in the minority.

   You can watch them at the following address:
   http://www.princeton.edu/WebMedia/lectures/

4. **D R Lunsford**
   July 5, 2004

   Peter,

   Could you give some information about it?

   To me the signature seems physical, and I don’t see how it is possible to alter it.

   Complex structures that arise naturally out of geometry are another matter. (Think for example of the circular points at infinity in plane projective geometry.)

5. **Alejandro Rivero**
   July 4, 2004

   The french girls did a good work to introduce the subtleties of path measuring, at the end of their geometry manual.

6. **Bogdanoff**
   July 3, 2004

   Quote : “My own prejudice about quantum field theory is that the relation between the Euclidean and Minkowski space formulations of quantum field theory is actually much more interesting and subtle than people think.”

   Well, it is exactly what we think. And by the way, certain questions raised by S.H. are developed in our “Topological field Theory of the Initial Singulariry of Space time” paper (CQG) that was extensively discussed but not really understood as a new formulation regarding the transition between lorentzian metric (real time, still valid et Planck scale) to euclidean metric imaginary time, only valid at 0 scale). In our model, this transition becomes effective between Planck scale and 0 scale and is characterized by quantum fluctuations of lorentzian and euclidean metrics (superposition (KMS) state of metrics). In this model, the “apparent horizon” evoked by Hawking could be the result of an “euclidean evolution” of events in the black hole whose final singularity does not exist in real (lorentzian time) but in imaginary (euclidean) time.

There They Go Again…

July 6, 2004
Categories: Uncategorized

Throughout the mid-to-late 80s, the NSF and other organizations would periodically issue alarmist reports about an impending dangerous shortage of scientists and engineers in the U.S. These projections for shortages turned out to be utter nonsense, as anyone who looked at the situation honestly could have foreseen. By the early 90s, instead of a shortage, the bottom dropped out of the employment market for scientists. In the math department here I saw a large number of very good graduate students and post-docs leave the field because there were no jobs for them.

Particle theory is a field in which the job market has been varying degrees of awful since about 1970. One might argue that while this is tough on young particle theorists, it means that the few who get jobs will be truly outstanding and the subject will flourish. The problem with this argument is that particle theory has seen extremely little progress since the mid-70s, about the time that one would expect the effects of the tight job market to be seen. The main reason for this is that the standard model is just too good, but one could plausibly argue that the evidence is that a very tight job market is bad for the field. Good people don't go into it; those that do and survive do so by not working on anything too ambitious, because it could easily fail and they'd be out on the street.

Mathematics is a much more normal job market than particle theory, but there still have always been a lot more Ph.D.s than jobs where they can use their talents. The job market in math was terrible in the early-to-mid nineties, got better in the late-nineties and is not so bad now. Our students seem to be doing relatively well at getting jobs. Budgets are tight, especially at state universities, but a lot of people hired during the 60s are finally starting to retire.

The NSF is now at it again, with its National Science Board issuing a glossy report entitled [An Emerging and Critical Problem of the Science and Engineering Labor Force](). A good [article]() in the Chronicle of Higher Education reports on this, but also has a lot of information debunking the report.

Why does the NSF repeatedly engage in this kind of alarmism and dishonesty? If you take a look at the membership of the National Science Board, you'll find no young scientists, but a lot of university and NSF administrators, corporate executives, and senior professors. All of these people have a large vested interest in flooding the scientific labor pool in the U.S. so that it will provide a lot of cheap labor. The NSF gets much of its funding from Congress by emphasizing its role in training scientists, so of course it wants to claim that more of this needs to be done. Universities and corporations want lots of new Ph.D.s so they can get the best ones to work for them for peanuts. Universities want lots of grad students to provide cheap labor as TAs. Senior professors, at least in the experimental sciences, want lots of grad students to staff their labs cheaply. These people all seem to firmly believe that a system that produces huge numbers of underemployed and badly paid young scientists is the best thing for science and for the U.S. as a whole. In fact, it is just the best thing for their personal interests.

   July 16, 2004

   wrong wrong wrong

   briefly:

   Just because our society doesn't 'value' science doesn't mean our society, the job market, the corporations, whatever, is right.

   The question is how to make the valuation of science match it's value.

   There's tons of incomplete scientific projects. Protenomics, diseases we didn't know we had, brain/computer research, nanotech, whatever… lots of valuable potential for hundreds of years. The fact that these are not getting the attention that they deserve, should be regarded as a fault of the system, not an affirmation of the system and it's correct working due to infallible economic 'laws'.

   People would benefit. If society structures (ie corporations, governments) don't "benefit", so much the worse for all. For what is it all for?

   An investment in science is an investment. If the current system can't see beyond the shortsighted next accounting period, so much the worse in my regard for the system.

   Wealth is result of science. Lawyers, MBAs don't create wealth, they just administer the moving of the wealth from pile to pile. (Even though they may be 'knowledge workers'.)

   If our society pays more for other jobs, encouraging our best to enter other fields, it's just evidence of being a badly organized society. It is not living up to what it COULD be. If planet Earth had to "compete" on a comparison basis with a similar planet Earth2 that had a much stronger scientific culture, which would be getting ahead? So why not make this world be that other world?

   The question, (as has been said,) is how to change it. (And if you don't recognize what quote I'm making an allusion too, well, so much the worst for us all.)

   Further weblog blatherings on this topic are available at
   http://science.slashdot.org/article.pl?sid=04/07/09/1941201&mode=thread&tid=134&tid=146&tid=99

   July 13, 2004

   My two pence on this: I also agree with Peter, and also JC and Steven. I too was appalled at how post-doc research actually was in reality (in the UK in my case), and I worked similar hours to you Steven. Increasingly I see my post-doc year as simply an experiment: I wanted to find out what it was like, and try to achieve something lasting, but looking back I am beginning to regret it, as it seems to have done little for me in terms of career prospects, it's value when applying for other occupations and my health.

   I could immediately relate to your comment about having "too many" degrees, JC: since finishing my post-doc, it has taken me months to find office-based temporary work, and I believe I only got the job because I omitted my PhD from my resume! For every other job I applied for, in which I included my PhD in my resume, I was either rejected or never contacted about the job.

   I never realized possessing a PhD would make things harder for me (especially when it comes to employment), but it definitely seems to have done so. People with PhD's are just not meant to find work easily!

July 13, 2004

Wish it were completely invaluable. I mean, that we had so huge quantity of reasoning minds that their monetary value were zero.

Actually I wish the same about production of commodities, but that is politics 🙂

4. **Ralph Lee**
   July 11, 2004

   appreciated the perspective, thanks.

5. **bob**
   July 10, 2004

   I'm so glad the academia is feeling the pain physical labour workers have known for a long time. Your work once it becomes commoditized is no longer valuable because of the surplus amount of workers competing for jobs you can exploit them for all they are worth for the benefit of the owners of the school or business in question.

6. **bob**
   July 10, 2004

   Welcome to the wonderful world of capitalism. Now you know why people like Albert einstein endorsed some form of socialist policy and regulation of capitalism, he didn't want to eliminate it totally he wanted to eliminate the exploitation that capitalism brings and the negative capitalistic traits. Capitalism is not about being competitive it's about making it to the top and making sure you and your family stay that way. Once you get a significant amount of money you can keep making more and more because the amount gives you the power to become an economic imperialist where you just buy out your competitors or sit on your nest egg and sell things below cost until your competitors go out of business and you have the monopoly of ownership once more.

   " I could really become a fat rat and get an MBA. There is no shortage of MBA's that have an actual clue about the technology. But the real question is this. Do I want to surround myself with assholes all day, or be in the technical trenches with my network administration team, discussing routing issues and solving congestion problems? Do I always want to have to rely on a geek like me to stay afloat in front of the board because I am clueless? Do I want to be in charge of a team that has no respect for me, aside from work authority and my witty personality? I am continuing my education in CS. Why? Because Im not a fucking moron that will dumb myself down for a bigger pool or lexus."

   Getting an MBA doesn't necessarily mean you have to work as an MBA.

   There's probably a good case to be made that, after getting a degree in science, getting an MBA would be a good way of making contacts with business people – either your professors, or your classmates.

   Knowing such people would make it easier to start up a company if you have an idea for a technical service or product. You'd do the science, they'd do the business.

   Or, if they know you have an advanced degree in science, they might turn to you if they need such a person as a partner in a new venture they are considering.

   It seems to me that one place where you do often find people with graduate science degrees is among the founders of startups or small companies. Getting an MBA and knowing MBAs are things that would help *you* be the founding partner with the graduate science degree.

   Come to think of it, maybe college science departments should start throwing meet & greet parties or dinners with the business department.

8. **Dennis Kipman**
   July 10, 2004

   Seven years ago I graduated from high school and went into the workforce building PC's. From building PC's at 7.50 an hour, I learned that a good way to make more money would be to learn how to build a network. So I did, reading $24.99 books at Barnes and Noble and taking advantage of any work opportunities (employers that didnt want to pay $$ for a college educated employee). I currently make $85k as a network analyst in IT after jumping a few jobs to increase my salary as I learned more topics over the years. Since my most recent job pays for school + all books, I couldn't pass up going to school and getting educated. Having gone through a BS in CS now, and about to embark on more schooling, I made a choice. I could really become a fat rat and get an MBA. There is no shortage of MBA's that have an actual clue about the technology. But the real question is this. Do I want to surround myself with assholes all day, or be in the technical trenches with my network administration team, discussing routing issues and solving congestion problems? Do I always want to have to rely on a geek like me to stay afloat in front of the board because I am clueless? Do I want to be in charge of a team that has no respect for me, aside from work authority and my witty personality? I am continuing my education in CS. Why? Because Im not a fucking moron that will dumb myself down for a bigger pool or lexus.

   Faraday a janitor? How do these legends get born? Is there an antilegend for every legend?

   Faraday was "Davy's greatest discovery". After Faraday presented him with a bound copy of his lectures on chemistry, Davy hired Faraday as a lab assistant.

   The info is only a google away.

   -drl

10. **Alejandro Rivero**
    July 8, 2004

    Michael Faraday was a janitor at the Royal Institution, wasn't it?

11. **JC**
    July 7, 2004

    Interesting www site about the "real deal" about science type jobs:

    http://scijobs.freeshell.org/

I don't know whether it's just "sour grapes" from the author, but a lot of the info at the site looks informative.

12. **Fabien Besnard**
July 7, 2004

Peter, I can't agree more with you !
In fact, what you have said fits really well with the situation here in France. What surprises me, is that I thought things were better in the States. We always consider the States to be a heaven for research, but it seems to have changed. However, the job market in France is certainly in a much poorer situation than in the USA, and this is the main reason for the huge protest of reaserchers that happened last year (it was the first time in the history of the country). We also have a report saying that there will be a shortage of scientists in the years to come, but this time it is true, because since about ten years, students leak away from science. There have been something around 30% loss of undergraduate students in ten years (the situation is especially critical in maths and physics).

13. **JC**
July 6, 2004

When I was in grad school, I was sort of a night owl type and was literally on a first name basis with the night shift janitors on my floor. Over the years I found out they were making around the same salary as many professors, and working a lot less hours.

One janitor I found out actually went to grad school for math in the 1970's but dropped out without finishing his thesis. He mentioned that it was difficult finding any science or engineering type jobs in the 70's, and he ended up doing various janitorial type jobs ever since. By the time more "jobs" opened up in the 80's, he was already a manager that dealt with overseeing janitorial duties for several large buildings on campus, and was being paid half decently for it. (He also had kids to support, which was a huge factor for him staying in the same job over the years).

A few other folks I knew over the years, who never pursued any post-secondary school education, ended up working at other menial or blue collar jobs, like garbage collection, post office, driving trucks, etc … Most of them are making more than many professors at the local universities nearby, and working a lot less hours.

At times I wonder what kids today are thinking, when word is already out that there's hardly any good paying jobs that require a PhD. In many workplaces, a degree isn't much more than an easy way to "weed out" job applicants. When HR has several hundred or thousands of resumes to sort through, it's easier on the first cut to just delete all the resumes which don't have any degrees or have "too many" degrees, so that they have a "managable" number of resumes to look at. Almost everybody I knew over the years who worked in HR at various corporations of all sizes, mentioned that most of their daily work is to "weed out" as many resumes as possible that are submitted over the internet or (less commonly) by postal mail.

I don't have a reference handy, but there's allegedly already huge declines in folks majoring in computer science and engineering over the last few years at places like MIT. Despite Bill Gates trying to advocate kids into majoring in fields like computer science, kids seem to be able to see through the farce and propaganda and aren't taking the bait so easily.

In the near future, will there be a day when going to college no longer makes any financial sense? At the present time the propaganda advocating college education seems to be things like low interest student loans, along with "dreams" of a better life and career after finishing college. In some cases it's family pressures. Many kids find out the hard way after graduation that their degrees are worth jack shit, and are hardly even worth the paper they're printed on.

At times I wonder if there will ever be another great "self-taught" mathematician and/or physicist that comes out of the blue, like a Ramanujan or Fermat. These days many of the "self-taught" physicists and/or mathematicians seem to be mostly crackpots, instead of serious scientists.

Historically before the 20th century, it seems to be an exception for mathematicians or physicists to be on faculty at a university. It appears that the expansion of university faculty jobs in America came after World War 2, with the GI Bill and Sputnik. With that huge surge in government money in the 1950's, it seems to have made many sciences a viable middle class career for a period of time afterwards.

14. **Steven**
July 6, 2004

Peter, you are spot on there. I got a phd in the 90s (from the UK, I am a Brit) and took up a postdoc in the US at a major university (an Ivy League one actually). This was in theoretical biophysics/biology although my background is in theoretical physics. I went with high ideals and enthusiasm but quickly became disillusioned and deflated to realise that the big postdoc pool there was badly paid and had virtually no status or respect. They were neither students or faculty and existed in a sort of limbo. I was under the illusion that the title "phd" at least carried some (a lot of) respect but in US universities even the secretaries consider themselves a cut above you. Most of them (postdocs) were from China and India, were paid very little, follow orders without question, and would work very long and hard for peanuts (including weekends/Saturdays and holidays). Any of them could easily be replaced. (I believe the Polish word is "Robotnic").

Basically they can have a pool of slave labour doing experiments and laboratory grunt work virtually 24/7. Very little academic freedom although being in theory was somewhat better. The campus (at postdoc level) felt like the intellectual equivalent of a slave plantation, far from the very niave ideal I once had of civilised minds working together to advance science and better humanity. Also NO American postdocs did I ever encounter and very few american graduate students. Most of them seem to have had wised up to the fact that science is no longer a viable middle-class career path.

The Darwinian misconception in all of the sciences at this level is that this system "weeds out" the weakest students/postdocs and that "the best" then survive. What actually happens is that it weeds out the people who don't want to destroy their lives working 60-70 hour weeks worrying about how ions affect protein folding dynamics and so on. It seems to get rid of the people who want balanced lives and other interests outside of science. Who want to go to art galleries, theatre/music concerts, restaurants, spend time with their families and have relationships etc–ie the sort of people who in the end actually make the best scientists!! The ones that make it to permanent positions often turn out to be (although not always) those that can withstand the most mindnumbing drudgery and who work the politics right, and who play safe, take no risks, and don't do anything that can actually advance science.

I published 4 papers in (good)journals but my supervisor did'nt consider it "useful or practical enough" and the funding eventually trickled away. Even if you do good work you can still be at the mercy of your superiors who might not like your style of doing things. Doing good work your superiors don't understand is also asking for trouble. One day I was in a diner, when it was not busy, listening to two waitresses at another table talking and filling in their tax stuff and I realised they had better money, hours and conditions than myself and any of my fellow postdocs! That was it for me really lol. I had had enough.

Later I tracked down some of the guys I graduated with (at degree and phd level) via internet and email to see how they were doing. One really brilliant guy I knew as an undergrad had done a years postdoc in particle theory and had also packed it in and left academia. So I am convinced academic science is losing a lot of good people (if not all the best people). I wish I could paint a brighter picture but I am sure very many other poeple have had virtually the same experience.

15. **JC**
July 6, 2004

Is it true that corporations really want PhDs in the first place? Over the years I got the impression the private sector aren't as interested in PhDs, compared to folks who only have a bachelor degrees. It seems like they will only hire PhDs when they really desperately "have to". In many ways, the overproduction of PhDs is the classic economic case of “supply WITHOUT demand”.

Getting the NSF to do the advocacy work for more PhDs with the government partially funding the programs which create more PhDs, in some ways is the ideal framework for many corporations. It’s an easy way of getting the taxpayers to pay most of the costs in educating more PhDs, while the private sector reaps all the rewards. With a huge flood of PhDs on the labor market, it acts like a damper on the salaries of white collar workers.

The only obvious cynical reason I can think of for corporations and universities advocating the production of more PhDs, is mainly to bring down the pay scales of white collar workers. If you have a huge flood of PhDs and other educated workers, the pay scales will be brought down eventually to the point where PhDs and other educated workers are a “dime a dozen”, or about the same salaries as blue collar workers.

Since slavery is illegal in most richer countries, the best they can do is to turn many skill sets and jobs into a “commodity”. It’s a lot easier to run a business when workers can be easily interchanged and/or replaced like a “commodity”, and where unions have very little to no power. All employers have to do these days is to threaten that they will move their operations overseas to places like India, China, etc … and it will stop most workers from asking too many hard or demanding questions.

Twisted K-theory

July 6, 2004
Categories: Uncategorized

Michael Atiyah and Graeme Segal have a new foundational paper out on twisted K-theory. It doesn't have too many examples or applications, but lays a rigorous foundation for a certain point of view on the subject. Section 5 is the one quantum field theorists should pay attention to, it explains the relation to the fermionic Fock space. For a more explicit construction relating QFT to twisted K-theory, besides the papers of Freed, Hopkins and Teleman, one can look at "Gerbes, (twisted) K-theory, and the supersymmetric WZW model" by Jouko Mickelsson.

   July 15, 2004

   Hi Peter –

   since you are an expert on loop space: Could you help me with the question that I ask here?

3. **Urs Schreiber**
   July 15, 2004

   > I was referring to my old problem of putting fermions on the lattice.There Kahler-Dirac fermions are basically Kogut-Susskind fermions, and disentangling a single spinor (an ideal in the Clifford algebra) is tricky.

   Ah, you are thinking of Dirac-Kähler on the lattice. This has problems even for a flat 'metric'. I have once thought about this a little together with Eric Forgy, when writing section 5.2 of our notes math-ph/0407005 on discrete differential geometry (where we used the loop space deformation techniques that describe superstring backgrounds and applied them to the point particle limit). Maybe Dirac-Hestenes spinors are the best choice for the lattice.

   What happens when lattice QFT is done with something that is not exactly a spinor in a single ideal? For small lattice spacing the undesireable mixing should disappear. Wouldn't that be sufficient? Or does a finite mixing survive the continuum limit?

   > Another way of getting spinors from forms is by picking a complex structure. Then spinors are (up to a twist by a square root of the top dim form) just the holomorphic exterior algebra, and this is preserved by the Levi-Civita connection when your metric is Kahler.

   Yes, when the metric is Kähler. Alternatively, if spinors are already modeled in left ideals on the exterior bundle, then a Kähler background allows one further split of degrees of freedom and admits to increase N=1 susy to N=2. When twisting one of these two susys one obtains the topological string and all kinds of major wonders begin to happen.

4. **Peter**
   July 14, 2004

   When I was quoting Witten I was referring to my old problem of putting fermions on the lattice.There Kahler-Dirac fermions are basically Kogut-Susskind fermions, and disentangling a single spinor (an ideal in the Clifford algebra) is tricky.

   In your case presumably what you say works. Another way of getting spinors from forms is by picking a complex structure. Then spinors are (up to a twist by a square root of the top dim form) just the holomorphic exterior algebra, and this is preserved by the Levi-Civita connection when your metric is Kahler.

5. **Urs Schreiber**
   July 14, 2004

   Hi Peter –

   you wrote:

   > As you might guess, I'm interested in this model as a 1+1 d QFT, not a string theory.

   That's fine with me. If one wants, for instance, to think of the WZW model as *not* describing a string in a group manifold, but as describing a group valued field on some low-dimensional spacetime, that doesn't change any of the results, of course.

   > I remember Witten pointing out to me "Yeah, but what you want are spinors, not the exterior algebra", which is the heart of the problem.

   Hm, now I am surprised. Of course it is true that we are interested in spinors and not in differential forms. But…

   The point is that the supercharges on the worldsheet simply *are* Dirac-Kähler operators. We are not choosing them to be such.

   So there is a puzzle, and it does have a resolution:

   The puzzle is: How can it be that the string has spinors in its spectrum, when the supercharge is really the Dirac-Kähler operator?

   As was noted already by Kähler himself, his equation models spinors on flat spacetime, but no longer on a curved spacetime. That's because the connection on the exterior bundle does not respect the spinor ideals, but mixes them. (I have once tried to give a hands-on physicist-like way to see how this works here.)

So how can it be that superstrings have spinors in their spectrum even on curved spacetime, if, as I claim, their supercharges are Dirac-Kähler operators?

Well, the reason is, for superstrings there are conditioons on the background fields. You cannot just arbitrarily curve the background. Something has to provide the energy-momentum density for this curvature and the background equations of motion have to be satisfied. These extra fields will enter into the Dirac-Kähler operator as additional connection-like terms, and these terms will *cancel* the problkematic mixing effect.

We know this has to be true in principle (it is essentially nothing but the chiral splitting on the worldsheet) but it is probably instructive to see how it works in specific examples. The best example I know is just the super WZW model. Here we have target space curvature (target space is a Lie group manifold with the standard Killing metric). But there is also a 2-form field on target space. This 2-form field induces a torsion term in the Dirac-Kähler operator. This is precisely the *parallelizing torsion* on the group manifold. But this means that it exactly *cancels* the Levi-Civita connection in the inavriant orthonormal basis. This way the mixing effect is removed and we have true spinors described by the WZW Dirac-Kähler operator! 🙂

I discuss this and all the details in section 2.1.4 of hep-th/0311064. (Unfortunately this paper is not very readably written, I have to admit.)

So the Dirac-Kähler operator is indeed at the heart of it, but there is no problem! 🙂

6. **Peter**
July 14, 2004

Yes, this is the worldsheet Hamiltonian. As you might guess, I'm interested in this model as a 1+1 d QFT, not a string theory.

The Dirac-Kahler stuff is very interesting, especially in its relation to TQFT, as in Witten's original Morse theory paper. I actually first got interested in this way back in grad school when I was thinking about fermions on lattices and Dirac-Kahler. I remember Witten pointing out to me "Yeah, but what you want are spinors, not the exterior algebra", which is the heart of the problem.

7. **Urs Schreiber**
July 14, 2004

Hi Peter –

I think that unless something weird happens looking at one chirality is fully sufficient, since both chirality sectors are decoupled and identical.

I would like to know what precisely you mean by the Hamiltonian picture. Probably and hopefully this refers to the worldsheet Hamiltonian, so that you are perhaps thinking of looking at the WZW QFT in the Schrödinger picture (operators do not depend on worldsheet time) instead of the usual Heisenberg picture of CFT (where they do)? That would be nice, because this is exactly the point of view which leads from superstrings to differential geometry on loop space.

Namely loop space is of course the configuration space of the string, which only makes an autonomous appearance in the Schrödinger picture. In other words, loop space is the *midi-superspace* (super in the sense of Wheeler, not in the sense of supersymmetry) of the worldsheet gravity theory.

My original motivation to look into strings at all was that I had found that all kinds of supersymmetric field theories, and in particular N=1, D=3+1 SUGRA, look like Dirac-Kähler systems (i.e. systems governed by (d + del)) when formulated in Schrödinger picture on their configuration space.

Since it is hard to make progress with this insight in 3+1 dimensional gravity, I applied it to 1+1 dimensional gravity and arrived at the string. Turns out that the Dirac-Kähler point of view here works wonders, in my opinion.

But it is also an unfamiliar point of view for physicists. It had been hinted at by Witten in his 'Morse theory' paper, but that's about it. I am hoping to convice some people that it is a fruitful point of view.

The comments you made suggest that this might in fact be easier in more mathematically inclined circles, where the notion of differential geometry on loop space is something that people can associate interesting results with.

So if you find the time to sketch some ideas by Mickelsson and others, you are guaranteed to have at least one interested reader.

8. **Peter**
July 14, 2004

I've always been somewhat confused by the relation between what Mickelsson does and supersymmetric WZW. For one thing, he's in a Hamiltonian picture, and only appears to be looking at one chirality.

At some point in the next few weeks I plan to get back to working on this and maybe the references you give will help me sort it out.

9. **Urs Schreiber**
July 14, 2004

So what is it Mickelsson is doing with the supersymmetric WZW model?

In the intro it says (and more I haven't read so far)

> We also discuss the construction of twisted K-theory classes by families of supercharges for the supersymmetric Wess-Zumino-Witten model.

The generic supercharges of the WZW model are just the left- and rightmoving worldsheet supercharges, which are (Kähler-)Dirac(-Ramond) operators on the loop group with respect to a connection which is Levi-Civita plus/minus the parallelizing torsion (as discussed for instance in hep-th/9310187 and hep-th/0311064). For certain groups there might be more supercharges (like when the group is complex Kähler – is that possible?).

So are these twisted K-theory classes constructed from Dirac operators, in general? Or how else are they related to supercharges?

Slate Article

July 7, 2004
Categories: Uncategorized

There a new article on Slate about string theory and my colleague Brian Greene. Also some commentary about it on David Appell's weblog Quark Soup.

Comments

1. **D R Lunsford**
   July 9, 2004

   Urs, your comment is that of the apologist.

   It's perfectly possible to give non-equation explanations that hang together of real physics. It can't be done for strings because there is nothing to really describe.

2. **Urs Schreiber**
   July 9, 2004

   Semiclassical elegance

   Popular descriptions of sciences which involve lots of math are always problematic. An infinity of analogies does not capture the content of an equation. It's indeed very much like talking about Beethoven's music without ever listening to it. You will never get the idea, no matter how many words you read about it.

   One thing is this common statement that 'all particles would be vibration modes of string'. While not fully wrong, this completely misses the point that the interesting thing about the superstring's spectrum is its *massless* part, where there is essentially no vibration at all!

   There is however sort of a 'supervibration' since the fermionic worldhseet modes are excited. The nature of the massless spectrum is in fact much better understood in terms of representation theory, very much as for point particles.

   I once tried to give a semi-popular description of how the superstring's spectrum really arises, trying to improve on the 'particles are violin string notes'-statement.

   If one is really interested in the pedagogy of string theory, i.e. in finding better ways to get this abstract formal entity into semi-laymen's brains, then I would rather recommend for instance the 'Geometric Algebra' approach, as a neat notational framework to fill all kinds of spinor constructions with life. For instance I claim that the world sheet spin fields that generate the Ramond-sector states of string, and hence the target space fermions, are nothing but slightly souped up 'rotors' that they are so very fond of in Hestenes' school of thinking about spin geometry.

   (As you all know and appreciate, every good idea is part of string theory – and rotors are a good idea. 😉

   By the way, in the slate article that Peter mentioned it says:

   > Greene plays fast and loose with terms like beauty and elegance, using them in a semiclassical, semiromantic sense

   Heh, I like that: 'Semiclassical elegance'! 🙂 If we could just fully quantize elegance Brian Greene might after all be able to prove that string theory is quantum-elegant. There might be quantum corrections to that, but I suspect most of the string's elegance is protected by supersymmetry or is dual to its romaticism.

Witten in Crete

July 8, 2004
Categories: Uncategorized

Witten is lecturing at a conference in Crete this week and some of his transparencies are already online. He is talking about perturbative gauge theory amplitudes and the idea of interpreting them in terms of strings in twistor space. He motivates this by noting that AdS/CFT is useful for understanding gauge theories at large g^2N, but at short distances asymptotic freedom implies g^2N is small and to understand gauge theory in terms of strings you need to do so for all g^2N. He warns "I can't promise that what I'll explain will turn out ot be useful in a string description of QCD, but at least I'll tell you interesting things about perturbative gauge theory!".

For something completely different, the latest on the Landscape is that, at least this week it predicts low energy supersymmetry, maybe.

1. **Urs Schreiber**
   July 14, 2004

   Hi Peter –

   yes, that's what I am talking about – in the abelian case. In the nonabelian case things are not as simple. There it does not make sense to simply intergrate over S^1, since that amounts to comparing elements in different fibers. So in the nonabelian case some parallel transport using a 1-form has to be there in order to relate the values of the 2-form at different points of the loop.

   Something along these lines was what Christiaan Hofman originally guessed, or proposed. I think the crucial point missing in Hofman's proposal is that there is parallel trasport back and forth, as in the equation at the very bottom of this MathML enabled entry. This also explains why you don't see the parallel transport in the abelian case.

2. **Peter**
   July 14, 2004

   Here's the way I know to construct a one-form on loop space from a 2-form on the space itself. Is your construction the same?

   There's a tautological gadget called the evaluation map

   ev: S^1 x Maps(S^1,M) \rightarrow M

   that just takes a point on the circle parametrizing the loop to the corresponding point on M given by the loop.

   Given an n-form on M, pull-back to S^1 x Maps(S^1,M) and integrate over S^1 to get an n-1 form on Maps(S^1,M)

3. **Urs Schreiber**
   July 14, 2004

   > what sort of geometry is a "connection 2-form" supposed to represent?

   Ah, I see. That's due to sloppy terminology on my part.

   The point is that a 2-form on target space lifts to a 1-form on loop space. What I derive in that paper is that a deformation of the worldsheet supercharges by something which should describe strings in nonabelian 2-form backgrounds indeed does produce a connection 1-form on loop space which is this 2-form lifted to loop space.

   This is – almost – what had been expected before, in hep-th/0207017 (see top of p. 7). But I derive a little correction to the formula given there and show that this correction is necessary for some crucial properties.

   An easy heuristic way to see why target-space 2-forms correspond to loop space 1-forms is the following physical picture:

   A point particle is charged under a 1-form and the 1-form is integrated over the worldline. A string is charged under a 2-form and the 2-form is integrated over the worldsheet. If you make an ADM split on the worldsheet, i.e. introduce a slicing of the 'tube' into 'circles', then you can see how 'each point' on these circles is similar to a point particle which is charged under the 1-form obtained by contracting B with the tangent to the circle.

   Now sum this up for all points in the 'circle' and you get the 1-form connection on loop space.

   At least this is the simple picture for the abelian case. In the nonabelian case you cannot just sum up the contributions from the different points, since you cannot compare elements of the bundle at different fibers. This is why Hofman expected the target space 1-form to play the role of parallel transporting the nonabelian 2-form values from each point of the string slice to some (arbitrary) origin on the circle. And indeed, this is what drops out from my deformation, which also demonstrates that there has to be parallel transport back and forth.

   In writing this, I am thinking of superstrings. Most of the work on higher gauge theory has been in broader contexts, mostly coming from a field theoretic or a purely mathematical point of view. But in any case a 2-form YM theory must somehow be about 'line particles', and then the above reasoning is relevant.

   Probably loop people like Baez, Girelli and Pfeiffer are thinking of parallel transport of spin network edges, instead. BTW, I think the text

   Girelli & Pfeiffer: Higher gauge theory – differential forms versus integral formulation (2004)

   is the most important one on 2-form gauge theory that I have seen. It clarifies an important open issue in John Baez' paper and very nicely elucidates the geometrical visualization. But it also seems to leave the authors puzzled: Namely they derive that the whole 2-form gauge theory businenss can only be consistent when the 2-form equals minus the field strength of the 1-form. This seems to drastically constrain the number of interesting higher gauge theory Lagrangians that one can write down.

   But from the string/loop space perpective this condition, as I show, is natural. It is equivalent to the 1-form connection on loop space to be flat, which again is the condition that closed strings don't couple to the nonabelian 2-form, and they should not, since they cannot carry Chan-Paton factors.

   I wasn't aware of Girreli & Pfeiffer until after I had derived this condition myself, but I think that my derivation still helps understanding 2-form gauge theory.

I'll look up the literature that you mentioned. Many thanks!

4. **Peter**
   July 13, 2004

   Hi Urs,

   I looked a little bit at your "higher gauge theory" stuff, but I'm afraid my initial reaction is that of a mathematician. What's the underlying geometrical gadget that this is supposed to be? A connection is an equivariant way of relating nearby fibers in a fiber bundle, and curvature is the holonomy about an infinitesimal loop in a bundle. I can make these ideas explicit using connection 1-forms and curvature 2-forms, but what sort of geometry is a "connection 2-form" supposed to represent?

   The kind of thing I'm doing with Dirac operators is essentially what is in a recent Freed-Hopkins-Teleman paper, the closest point of contact with string theory is probably some work of Greg Landweber's which is basically about N=2 superconformal coset models, see math.RT/0005057 on the arXiv.

5. **Urs Schreiber**
   July 13, 2004

   Peter wrote:

   > the Dirac operator on certain loop spaces is also a crucial part of what I've been thinking about

   Oh, interesting. I didn't know that you have been thinking along these lines. Maybe we can discuss some stuff.

   As you may have seen, I currently think that loop space differential geometry has something to say about what is called 'higher' gauge theory. The point is that many people have tried to more or less guess or use trial and error to find general properties of 2-form generalizations of Yang-Mills.

   In a kind of reversed fashion I tried to study 2-form Yang-Mills from the worldsheet point of view, seeing how the worldsheet theory determines the target space effective field theory.

   After some steps in the dark I think that I now understand what's going on. As soon as my draft passes my advisor's revision I'll put it on the arXiv. Since I have learned in the past that there is nothing like shameless self-advertisement, here is the link:

   Nonabelian 2-form connections from 2d BSCFT deformations

   I have had discussion about this with all kinds of people by now, but I am always happy to receive more comments.

   🙂

   July 13, 2004

   I don't know much about Dixon's work, but he gave a talk in Paris about how to use N=4 SYM to compute QCD amplitudes and how that leads to connections with all kinds of computations done in AdS/CFT.

7. **Peter**
   July 13, 2004

   Hi JC,

   Weird but true: I just checked the SPIRES HEPNames database trying to remember who Dixon's advisor was (Dixon and I overlapped as grad students for several years at Princeton). The example SPIRES gives for a search of this database is

   find name dixon and field hep-ph and not undergrad mit

   which leads precisely to Dixon's entry.

   Back when Dixon got his Ph.D.(1986), there wasn't a whole lot of choice in the matter, you pretty much absolutely had to be working on string theory if you wanted to get a job. I'd also be curious to know why he stopped working on string theory and what he thinks of it these days.

8. **JC**
   July 13, 2004

   Peter,

   I remember in early 90's when string theory was in sort of a slump. From what I remember, all that work on conformal field theories and string field theory didn't seem to make much new progress, while the mirror symmetry stuff eventually worked its course and subsequently "flatlined" shortly thereafter. (It was years before Seiberg-Witten theory and D-branes revived string theory).

   It seems like even back then, many string folks were finding many rationalizations and excuses to justify working on string theory. I remember some folks were even looking at "string inspired" stuff like Lance Dixon's work in the early 90's that found easier ways to calculate Yang-Mills amplitudes, as an "excuse" to justify doing string theory. (It's interesting that Witten's present work on twistors is attempting to explain the simple looking formulas that showed up in the papers of Dixon, Kosower, et al. from that era). I always wondered what made Dixon defect from string theory back in those days, considering many of his big papers from the 80's were all on string theory.

   It seems like the sociology behind string theory is very much like being sold the "dream" of the "holy grail" of a consistent theory of quantum gravity,

   In the 1970's, the sociological circumstances in the mid 70's which led to the mass abdication of string theory seemed to be 't Hooft's renormalization results and the subsequent "rebirth" of field theory. In this case, what led to string theory's first demise is pretty much how traditional science should work, when a better theory makes predictions that are subsequently confirmed by experimental results. Perhaps why there hasn't been a mass abdication yet in today's string theory, maybe has to do with the fact that the "dream" of the "holy grail" in a consistent theory of quantum gravity, is still very much alive and well in the spirits and minds of many string theory folks.

   For many "mass movements" in history, whether benevolent or malevolent, there's almost always a "dream" and/or "utopia" of some sort that is used to sustain the movement which keeps the "true believers" in line, as well as a way to get new recruits to their cause. Even once the "mass movement" becomes the "status quo", the "dream" and/or "utopia" is still repeated over and over as propaganda. (This is what happened in many communist countries, like Soviet Russia and China, after awhile).

The systems created by the "mass movements" usually start to crumble and eventually self-destruct when the propaganda of the "dream" and/or "utopia" can no longer sustain the spirits and minds of the people.

The only obvious scenario I can think of that could greatly destroy the "dream" of the "holy grail" of a consistent quantum gravity theory in the form of string theory, would be if Witten publicly abdicates and drops string theory for good.

9. **Peter**
July 13, 2004

Hi Urs,

Sure, one could attack any kind of speculative work as "wishful thinking", but I don't think I'm doing that. In 1984 when people were hopeful that their new speculation was about to lead to some real predictions, that was one thing. Twenty years later, after the accumulation of a lot of evidence that this idea doesn't work, that's something else.

My comment about sociology was meant to refer more to the question of why the more senior leaders of this field haven't given up and moved on to something else. The question of what a young theorist should do and what the sociological pressures are for them is a bit different. String theory is by now such a huge subject that there are plenty of things for someone starting out to try and do something with, and they're not the ones who should be expected to take leadership and change the direction of the whole field. Whether LQG or string theory or whatever, it's very hard to start a career in this business, and no one does it because it is the easy thing to do.

The fact that string theory includes so many different approaches allows you to find one that is at least mathematically interesting and may lead somewhere. While I'm not doing string theory, the Dirac operator on certain loop spaces is also a crucial part of what I've been thinking about, so if string theory leads you there, that's great.

July 13, 2004

Hi Sean Carroll –

since this blog does not support threaded comments my reply to Peter Woit's comment appeared as a reply to your comment.

Yes, I fully agree with what you say. 'Fortunate' and 'unfortunate' are inappropriate adjectives in this context, anyway, their only purpose being in casual conversation. There are facts and there is right and wrong, and we need to figure it out.

P.S. BTW, thanks for all the stuff that you make available online. I have learned GR from your notes (well, and some other reading, too, of course) and have tutored a GR class using them. Really nice. But I guess you have heard that before… 🙂

11. **Urs Schreiber**
July 13, 2004

Sure, it's wishful thinking. No matter which person starts to think about any physics beyond the standard model, he or she will tend to wish that there is a chance that this thinking actually leads in the correct direction. No matter which approach you favor over string theory, if its about beyond-the-standard-model then it is necessarily wishful thinking.

BTW, I am a good counterexample for the 'sociological reasons to go into string theory'. I found that it is pretty hard for someone like me to get 'into' the community. Experiences from talking to people indicated that it would have been much easier for me, as far as sociology is involved, to do some LQG, for instance.

Trust me or not, but I do find strings more interesting as such, and here is absolutely nobody in my vicinity who could have tried to talk me into believing that.

Maybe a curious side remark: One reason why I like strings (by no means the only or most important one, but still one reason) is due to the major role the Dirac operator plays in that theory.

But I didn't want to get into that kind of discussion again. Sorry. From now on only technical remarks/questions. Promised! 🙂

12. **Sean**
July 13, 2004

Urs, by "unfortunately for string theorists" (referring to the observed positive vacuum energy), I presume you mean "fortunately for string theorists." The AdS vacua we understand are all supersymmetric and not like the real world. It's hard to understand supersymmetry breaking, and it's hard to understand a positive vacuum energy, and it's hard to understand moduli stabilization. The hope has to be that these difficulties are somehow related to each other, which would help explain why easy-to-understand solutions to string theory don't look like the real world. I think that's a perfectly plausible scenario — no reason why a correct theory has to be easy for us mere mortals to immediately master, especially in the absence of detailed experimental input.

13. **Peter**
July 13, 2004

Hi Urs,

Thanks a lot for the detailed summary of the current point of view on the "landscape". I hope that helps Pyracantha, but if not here's a much over-simplified version:

String/M theory supposedly is a theory of strings and maybe other objects in an 11-dimensional space-time. We see 4 of the dimensions (3 space, 1 time), what about the other 7? The initial hope was that there would be a small number of possible consistent choices of these 7 dimensions, so there would be a small number of calculations you could do and see if one of them agreed with experiment.

Lately people have started to believe that there are an astronomically large number of possible consistent choices, and these are referred to as the "landscape". The reason for this terminology is that each such choice comes with an important number attached, the energy of the vacuum, and if one imagined mapping out all possible choices on a plane, one could imagine making a topographical map, with the energy the altitude. Zero energy choices would be at sea-level, and the whole thing would presumably have peaks and valleys, with our universe sitting at the bottom of some valley.

Anyway, that's very roughly the idea.

The standard ideology has always been that this large number of choices is just due to the fact that one only knows an approximation to the real string/M-theory, and that if one knew the real thing one would find that all or most of these choices were inconsistent. The other part of this ideology is that there is a unique real string/M-theory, for which all these choices are just possible lowest energy states. In this scenario, maybe they are only approximately at lowest energy and the true lowest energy state is something else, or maybe there really are an extremely large number of possible lowest energy states (this may include metastable states, not at lowest energy, but separated by an energy barrier from lower energy states).

My own point of view is that this standard ideology is just wishful thinking. My guess is that there isn't a simple unique 11-dimensional theory, but something rather complicated, involving a possibly infinite number of choices as to how to set it up. People are free to keep believing the standard ideology, since it's hard to prove a negative, to show that what they would like to exist doesn't.

The really strange thing that has happened in recent years is that a lot of string theorists, most prominently Susskind, have adopted the point of view that, whatever string theory is, it has an astronomically large "landscape" of equally good vacuum states, and thus equally good models of the universe. I would have thought that once someone had convinced themselves that, even if there was a unique real string theory, it would be consistent with an unimaginably large number of possible models of the universe and quite possibly be completely vacuous and unable to predict anything, they would give up on the whole idea. The idea Urs mentions, that maybe only a small number of these models is consistent with some simple facts one knows about the standard model, so you could use these to make predictions about other things, seems to me to be just more wishful thinking.

Given that you don't know the underlying theory, and what you do know leads to an essentially infinite number of possibilities, it's not clear that the kinds of arguments that Susskind et. al. are making are even science at all. Some of these papers are weird documents, with virtually no equations, just a lot of hand-waving arguments involving massive amounts of wishful thinking and no solid conclusions. My take on all this is that the time is long past at which a reasonable person should have given up on the whole idea and moved on to something more promising, but sociological reasons are keeping this from happening.

14. **Urs Schreiber**
July 13, 2004

Hi Pyracantha –

in so-called perturbative quantum theories one chooses a solutiuon of the classical equations of motion, the so-called 'background' and then studies quantum corrections to that background order by order.

For instance in ordinary quantum field theory the background might be flat Minkwoski spacetime and in that background we can imagine photons and electrons to propagate and interact in Feynman-diagram fashion. The 'vacuum' background together with all these particle whizzing around would then be a full perturbative state of the theory.

(One problem is that not all aspects of the full quantum theory are captured by such a perturbative procedure.)

Now, in string theory the idea is pretty much the same, only that here the particles are not pointlike but a have a small linear extension. This seemingly simple modification has drastic consequences. While in field theory there are many possible choices of fundamental particles, their interactions, and choices of background, the consistency of string interaction very much constrains all three of these. The big open question is: How much exactly?

When people talk about the 'string theory landscape' they are thinking of the abstract space in which each point is one consistent perturbative string theory background, i.e. one consistent choice of particle content, particle interaction and classical spacetime that they propagate in. In principle the number and position of points in this 'theory space' is determined by the background equations of motion of string theory (or equivalently, if you want to hear the technical terms, by the requirement that there is a supercfonformal field theory with central charge 15 on the worldsheet of the string).

There has been some recent progress in better understanding this space – but it is still immensely ill understood. Still, the progress that has been made has appeared significant enough to some people to base some more far reaching speculation on it. That's because a good understanding of which background solutions string theory admits is the key to be able to apply string theory to pheonomenological considerations. When a string theory background is found which is consistent with the observed particles of nature, then studying the stringy quantum corrections to it would allow to deduce what this background predicts as corrections to the currently known physics.

Peter Woit here has pointed out repeatedly that some of the speculations concerning the landscape that have been published are not at all based on results that have really been calculated.

On the other hand, the mere fact that a discussion of such a 'theory landscape' is possible (even though not easy) is important. It is not possible in field theory of point particles. There we also have some restrictions on the Lagrangians (i.e. the particle content and interaction) that we are allowed to consider as a consistent field theory, but they are far less severe than those found in string theory.

As has been pointed out very nicely by Jacques Distler in his weblog, the points in the landscape which are consistent with the experiments that we have made are probably very rare. In any case, none has been found so far. If there is none at all, then string theory is wrong as a theory of nature. If there is a single such point, then string theory, based on the currently known data, could make predictions about for instance new particles that could be found in future colliders. (These predictions could still be disporved by experiments, of course.). If however there are very many such points then predictions for new particles etc. would be very difficult. One might, in this case, still try to make some *statistical* predictions. Such statistics about properties of the 'landscape' are currently what some people are trying to do. But it seems fair to say that this is, while an intersting idea, quite premature.

Finally, there is the theoretical possibility that the world we live in cannot be understood as a small perturbation of some background. The success of perturbative field theory suggests otherwise, but nobody can know this for sure. So one possibility is that none of the points in the 'landscape' correspond to the world we live in, but some nonperturbative description of string theory is necessary to describe our world. Nonperturbative description of string theory tend to be described not by full classical backgrounds, but by *asymptotical* backgrounds, this means roughly that at spatial infinity the background is fixed, while 'in between' physics is described fully nonperturbatively. Nonperturbative discriptions of string theory are known for instance for universes which asymptotically have the geometry of what is called 'anti-deSitter Space'. This is, roughly, the shape of a universe with a negative cosmological constant.

Now, unfortunately for string theorists, recent very exciting measurements of various cosmological parameters have shown that instead we observe a cosmological constant which is *positive*. This means that the particular anti-deSitter non-perturbative deswcription of string theory appears not to be applicable to describe the universe that we live in.

This is probably the main reason for the current excitement about landscape discussions. Namely people are trying to find out if in the landscape admits universes which only temporarily have a positive cosmological constant, while *asymptotically* this constant goes negative. If this were the case then there would still be hope that the nonperturbative string theory description which involves asymptotically anti-deSitter space could be used to describe the world we observe.

So that's what all this landscape talk is about. Unfortunately, since there is so little known for sure about the 'landscape' (even though the landscape is a well defined mathematical object (space of all superconformal 2d theories with c=15) which can in principle be understood exactly), some of the discussion concerned with it recently has tended to be more philosophical than scientific.

15. **Pyracantha**
July 13, 2004

Pyracantha from "Electron Blue" here, the artist who is trying to learn math/physics in middle age. I read your site in the hope that someday I'll understand what you and your colleagues are talking about. But I have heard one phrase many times and it intrigues me. What is the "landscape?" Could you explain it in terms that a beginner like me could understand?

16. **Dick Thompson**
July 12, 2004

AR, Here are my notes on the article "Lovely as a Tree Amplitude" by Stephen K. Blau, in the Search and Discovery section of the July 2004 Physics Today. I urge you to read the original article whenever you can, it is well-written and has a lot more detail.

It reports on a three month long workshop on collider physics at the Kavli Institute in Santa Barbara. The workshop centered around the work of Witten and colleagues on a duality between string theory and perturbative QCD. Last December, Witten discovered this relationship between a certain string theory (B-theory) and the weak coupling domain of QCD [hep-th/0312171]. Witten, F. Cochazo, and P. Svrcek (CSW) used it to greatly simplify the expression for the leading perturbation terms in some QCD diagrams [hep-th0403047] .

In the covariant expression for an all-gluon Feynman diagram each gluon helicity is described by an overdetermined 4-vector. The extra symmetry doesn't affect the physics, but it makes the expression complicated. Following an alternative strategy of collecting particles by helicity, S. Park and T. Taylor in 1982 proposed a formula for maximal helicity violating (MHV) diagrams. The formula was proved later; it only handles massless particles. CSW show how to apply to off-shell MHV diagrams sewn together with propagators to to yield non-MHV amplitudes. The CSW construction has not been proved, but Zvi Bern at the workshop called it convincing. It satisfies certain powerful factorization properties.

Now, the twistors. A vector can be represented by two spinors. Witten considers tree-level amplitudes in spinor language, and asks how they behave under conformal transformations. To simplify expressions and symmetries, he fourier transforms into twistor space. Then when the momenta of nonvanishing MHV amplitudes are expressed in twistor space they lie in a straight line. Other helicity combinations lie on quadratics and cubics. A feature of the duality is the instanton string configurations reproduce QCD amplitudes and they wrap around structures in twistor space, giving a winding number.

R. Roiban, M. Spradin, and A. Volovich used the Witten duality conjecture to get 5-gluon amplitudes with two + helicities and three – helicities. [hep-th/0402016]

17. **Alejandro Rivero**
July 12, 2004

Lunsford, no, I was not thinking on Regge methods. I am not fluent enough on the trajectories, so I can no bet about how deep this methodology was. Was it related to the primitive string theory?

I mentioned *Runge* methods because Brouder pointed out that the systematics to classify them was the same than Connes-Kreimer for Feymann loops.

18. **Dick Thompson**
July 11, 2004

AR, about the article. I read it at the public library. I'll be going back there tomorrow (Monday July 12) and I'll take some notes.

19. **D R Lunsford**
July 9, 2004

AR, you mean Regge methods of course.

20. **Alejandro Rivero**
July 9, 2004

No surprise to know that there is hidden structure in Feynman diagrams. From Bogoliugov to Kreimer there has been deep insights on it (not to mention the strange connection with Runge Kutta methods, found by Brouder). But I am unsure about if the string framework is the most adequate to look into this.

A pity the Physics Today article is not open for general public. Can you tell more about?

21. **Dick Thompson**
July 8, 2004

There's a good article on this in the current Physics Today. Witten and coworkers can only do tree level, but others working in their wake have got plausible results for loops. The idea is to do better calculations on low energy (several TeV) soft scattering. When Witten plotted the maximum helicity violating states in twistor space, they fell on a straight line.

22. **Alejandro Rivero**
July 8, 2004

The icon in the upper left corner of the webpage is Phaistos disk, an undeciphered inscription that rivals string theory as a magnet for speculation.

Slides 1, 2, and 6 show that String theory is not more claiming to be a theory of elementary entities but a yet-weakly-foundamented area of mathematics. I could have told this to you already nine years ago. It is very much as the things topologists do to study spaces: To swept a manifold with a lower dimensional one, and to look for singularities in the evolution of the map.

This does not imply that they have lost hope on an elementary entities theory, as one can read between lines. But it is an aptitude change, and it goes back to take seriously Quantum Field Theory, no more a disposable effective theory.

23. **Thomas Larsson**
July 8, 2004

I am confused about the status of twistor-string theory. Berkovits and Witten seem to claim that the twistor string does not give you the right answer beyond tree level: "Those loop amplitudes will therefore not coincide with the loop amplitudes of pure super Yang-Mills theory. " Still, Witten keeps working on it. Does anyone understand what the goal is?

New Books

July 13, 2004
Categories: Uncategorized

Two new books from Cambridge that are now available:

A First Course in String Theory by Barton Zwiebach, based on a course on string theory for undergraduates taught at MIT. It's available for \$42 at Barnes and Noble, sales rank 565, for \$60 at Amazon, sales rank 13,559. The whole idea of trying to teach a very speculative theory that hasn't really worked and which is based on 2d quantum field theory to undergraduates seems to me to be utter lunacy. But maybe I'll even buy a copy.

Topology , Geometry and Quantum Field Theory, the proceedings of a symposium that I went to at Oxford in 2002 in honor of Graeme Segal's 60th birthday. This conference had some wonderful talks and I'm looking forward to reading many of the contributions. Supposedly it also contains Segal's manuscript "The Definition of Conformal Field Theory", which has been circulating in samizdat for years. My copy (which like many others contains the hand-written notation "Do Not Copy" on the front) is falling apart, yet another reason why I just ordered the book, even though it is \$90. The story I heard is that Segal didn't want his manuscript reproduced, but finally agreed on the condition that it not be re-typeset, but appear exactly as in the original, so that it would be clear that it was still something preliminary and tentative, with no corrections or improvements made since he wrote it.

Comments

1. **Peter**
   July 14, 2004

   Not anywhere I know of. I think what is on-line is what Segal had at the time (99), but don't know whether he has continued working on writing up these notes or how much progress he has made if so.

2. **D R Lunsford**
   July 14, 2004

   Thanks, I wonder where is lecture 4 (mainly CFT)?

3. **Peter**
   July 13, 2004

   Some of Segal's notes are on-line at

   http://www.cgtp.duke.edu/ITP99/segal

   His book "Loop Groups", is about the most amazing math book I know. Worth every penny. His conformal field theory notes are in some sense an extension of this book, although presumably he was never that happy with them, partly probably because soon afterwards Witten came out with his Chern-Simons stuff, which provides yet another perspective on CFT.

4. **D R Lunsford**
   July 13, 2004

   So where can we learn about Segal's real deal online?

Talks From Strings 2004

July 18, 2004
Categories: Strings 2XXX

Transparencies from the talks at Strings 2004 in Paris are starting to appear on-line. You can see a listing of what is available so far here. None of the ones I'd be most interested in seeing (Dijkgraaf, Nekrasov, Moore, Witten) have appeared yet.

On the hot topic of whether or not the landscape picture of string theory can predict whether supersymmetry will be seen at LHC energies, Douglas first gives an argument that there will be low-energy supersymmetry, then another that there won't. Recall that he kept adding and subtracting from his arXiv paper a sentence saying he thought there would be a solid argument by the time the LHC was operating in 2008. In Paris, he puts it this way:

"I *start to think* that *fairly* convincing predictions *could* come out of this approach in the next few years."

which contains enough qualifiers to cover any eventuality.

Of the talks for the public, Veneziano's was pretty much historical, with a couple comments about cosmology, Maldacena's was mostly about black holes, and John Schwarz's was remarkable mainly in that it completely ignored any developments of the last ten years. None of these three breathed a word about the landscape.

Comments

1. **serenus zeitblom**
   July 18, 2004

   I thought that Maldacena's public talk was excellent. He even drew the black hole singularity correctly, that is, as being spacelike, not a common thing in popularizations. Indeed, it is something beyond the comprehension of a lot of professional physicists, who *still* persist in drawing diagrams of black hole interiors which reveal the embarrassing fact that they think that the singularity is a point in space which has a timelike "worldline". With a heroic effort I resist the temptation to name names….the other nice thing about Maldacena's talk was that it was about something of genuine interest, which alas cannot be said about most of the talks in the conference proper. It is sad for example that there were almost no talks about cosmology, where all the action is nowadays….

Segal Conference Proceedings

July 18, 2004
Categories: Uncategorized

My copy of the proceedings of the conference in honor of Graeme Segal's 60th birthday finally arrived and I've been spending some enjoyable time reading parts of it. To me, the most interesting contributions were the ones by Ben-Zvi and Frenkel, Dijkgraaf, Moore, Stolz and Teichner, Teleman and Witten. Unfortunately, Dijkgraaf's beautiful paper about how matrix integrals give you Gromov-Witten invariants of Calabi-Yau manifolds doesn't seem to be available on-line. Neither is Witten's very interesting paper, which is about explaining the SL(2,Z) symmetry seen in N=4 SSYM in four dimensions in terms of the existence of a six-dimensional superconformal theory.

The Stolz and Teichner paper is quite interesting . They are pursuing the idea that conformal field theories provide geometrical representatives of elliptic cohomology classes. Segal and Mike Hopkins worked on this a bit in the late 80s, with no conclusive results. Recently Hopkins has reformulated the whole elliptic cohomology story in terms of a new cohomology theory he calls "topological modular forms". He gave a beautiful series of talks about this at the Segal Conference; this isn't written up in the proceedings, but was for the 2002 ICM. For a more expository version of the ideas of Stolz and Teichner, see Teichner's survey talk at a conference in Santa Barbara last summer.

Finally, the proceedings volume contains Segal's wonderful unfinished manuscript "The Definition of Conformal Field Theory", together with nine pages of very interesting comments about what he was trying to do then, what he would do differently now, and what had kept him from finishing the manuscript. The main problem seems to have been that he was unable by his methods to explicitly construct the "modular functor" that one should get out of WZW models, so for this reason the crucial chapter 11 on WZW models remains unwritten.

His comments begin with:

"The manuscript that follows was written fifteen years ago. On balance, though, conformal field theory has evolved less quickly than I expected, and to my mind the difficulties that kept me from finishing the paper are still not altogether elucidated."

Comments

1. **D R Lunsford**
July 18, 2004

   Re Witten's paper:

   Lie algebra of SO(3,3):

   Let indices go 1..4 (spacetime) with Pm=Jm5, Qm=Jm6, and M=J56.

   [Jmn, Jrs] = -i(gmr Jns – gms Jnr + gns Jmr – gnr Jms)

   [Jmn, Pr] = -i(gmr Pn – gnr Pm)

   [Jmn, Qr] = -i(gmr Qn – gnr Qm)

   [Pm, Pn] = [Qm, Qn] = -iJmn

   [Pm, Qn] = -[Qm, Pn] = -iM gmn

   [Pm, M] = iQm

   [Qm, M] = -iPm

   [Jmn, M] = 0

   Let Rm = Pm+iQm, Sm = Pm-iQm. Then Rm and Sm separately combined with Jmn, are Poincare algebras, implying finite translations (two are needed to get a real translation on spacetime). The appearence of algebraic translations is reminiscent of the appearence of translations as repeated supersymmetries.

   Is this related to what Witten is talking about?

   Note also that

   [Rm, M] = Rm

   [Sm, M] = -Sm

   [Rm, Sn] = -2(M gmn + iJmn)

   so the elementary translations are distinguished with respect to the ?mass? M=J56 and they don't commute. One can imagine this as a primitive distinction between matter and antimatter on the lowest level. (sorry in advance for sign errors).

Hawking in Dublin

July 21, 2004
Categories: Uncategorized

Hawking gave his widely anticpated talk in Dublin today and reports are on CNN and all sorts of other places in the media. Sean Carroll has managed to get ahold (via Dennis Overbye of the New York Times) of a transcript.

Here's the part where he summarizes his argument:

"I assume the evolution is given by a Euclidean path integral over metrics of all topologies. The integral over topologically trivial metrics, can be done by dividing the time interval into thin slices, and using a linear interpolation to the metric in each slice. The integral over each slice, will be unitary, and so the whole path integral will be unitary.

On the other hand, the path integral over topologically non trivial metrics, will lose information, and will be asymptotically independent of its initial conditions. Thus the total path integral will be unitary, and quantum mechanics is safe."

His argument is in Euclidean quantum gravity, which he describes as "the only sane way to do quantum gravity non-perturbatively", something which some might disagree with. What he seems to be arguing is that, while it is true you get information loss in the path integral over metrics on a fixed non-trivial black hole topology, you really need to sum over all topologies. When you do this you get unitary evolution from the trivial (no black hole) topology and the non-trivial topologies give contributions that are independent of the initial state and don't contribute to the initial-final state amplitude.

I guess what this means is that he is claiming that, sure, if you knew you really had a black hole, then there would be a problem with unitarity, but in quantum gravity you don't ever really know that you have a black hole, you also have to take into account the amplitude for not actually having one and when you properly do this the unitarity problem goes away.

He has some proposal for doing some kind of calculation that implements his proposal using the AdS/CFT correspondence.

Comments

1. **Peter**
   July 27, 2004

   I'm afraid I've never followed this whole black hole information paradox story very carefully. It always seemed to me that in the absence of a real theory of quantum gravity, you can't tell which if any of these proposals really makes sense. People seem to hope that by thinking about this they might make progress on understanding quantum gravity, but I haven't seen that happen. Spending some time thinking about the Hawking stuff has just reinforced this opinion. He has a vague plausible resolution of the paradox in Euclidean quantum gravity, so do other people in other frameworks. So it looks like the paradox is pretty much gone, which is bad since the hope of many was that solving it would help solve the quantum gravity problem.

   By the way, John Baez has a nice first-hand description of the scene in Dublin and a good explanation of Hawking's argument. See
   This week's finds in Mathematical Physics. Week 207

2. **Chris W.**
   July 26, 2004

   Peter,

   Have you discussed this issue with your Columbia colleague Maulik Parikh? He seems to have another take on the whole debate, the relative simplicity and clarity of which I find appealing. See:

   hep-th/0405160
   hep-th/0402166

   (..not that I know enough to render any kind of a judgment.)

3. **Stephen Lavelle**
   July 24, 2004

   I was there…he didn't really say that much about anything…i guess we just have to wait for the paper to come out (and even then…ah well, he's probably right)…Though they havn't finished up doing the general case (still not done for general geometries and topologies) yet according to his PhD student (i can't remember his name off hand…).

4. **Urs Schreiber**
   July 23, 2004

   It's hard to tell what really is Hawking's argument. One sees Maldacena here and a negative cosmological constant there – I don't know.

   Right at the beginning when he says

   > Since the conformal field theory is manifestly unitary, the argument is that supergravity must be information preserving. Any information that falls in a black hole in anti de Sitter space, must come out again. But it still wasn't clear, how information could get out of a black hole. It is this question, I will address.

   It sounds as if he is just going to clarify a detail of AdS/CFT.

   He does need a negative Lambda to make any sense of the Euclidean path integral, so that's where the need for AdS comes from. But if he really thinks about going to susystrings on AdS_5 times S5 I don't know. Before he could come to that he was busy talking about bets and encyclopedias.

   I don't know if one can do AdS/CFT on something else than AdS5 times S5. There are lots of CFT/gravity dualities mentioned in the literature, but I don't have a good overview. Since it's really sugra that is involved here, though, every lower dimensional thing must probably come from reducing the full 10d scenario.

   The funniest thing is that apparently Witten has done the calculations that are missing in Hawking's talk already six years ago, as recalled by Jacques Distler.

5. **Peter**
   July 23, 2004

   Well, at various points he is clearly arguing from the point of view of euclidean quantum gravity. I don't understand how he's bringing in AdS/CFT other than to show how his ideas are not in conflict with it, at least to the extent you interpret it as a relation between supergravity and a CFT.

   By the way, isn't AdS/CFT about 5d gravity? Can you really use AdS/CFT to study 4d gravity, i.e. is 4d quantum gravity dual to a 3d CFT, and if so which one?

6. **Urs Schreiber**
   July 23, 2004

   Well, Hawking seems to be relying on AdS/CFT. That tells you the evolution on the gravity side must be unitary. But it also tells you that you don't have just pure gravity – but susystrings and all that. This again means that it is most likely that the black holes described by AdS/CFT are not just the plain old black holes of Einstein-Hilbert, but have stringy degrees of freedom. It is not clear yet how these should look like. But Mathur has made some educated guesses.

   That's what I found most surprising about Hawking's talk: He just admitted that old AdS/CFT is the solution to it all and then tried to argue that his Euclidean semiclassical pet is not obviously in conflict with that.

   No wonder that this approach raises some eyebrows. Did you see what Susskind commented? 🙂

7. **Rahul Jain**
   July 22, 2004

   Decoherence would cause a non-unitary step in the evolution of the system, and a black hole will have to either be formed or not. This is irrespective of the fact that there may be an observer at infinity. The experiment with hot fullerene diffraction shows that a system can cause decoherence with itself if it emits a particle that contains enough information to betray a specific state of the source.

   However, the two particles that cause Hawking radiation may be entangled across the event horizon and the state of some particle within the event horizon may be teleported to the particle that escapes away from the horizon.

8. **Peter**
   July 22, 2004

   Somehow the idea seems to be that, asymptotically, the amplitudes for the black hole sector are just constants, don't depend on the initial state, so I guess they just change the normalization of the overall amplitude.

   Important disclaimer: I'm no expert on this stuff, and Hawking's transcript is so vague that you need a real expert to know what precise sense can be made of his statements. Hopefully he'll produce a real scientific paper with some details soon.

9. **Scott Aaronson**
   July 22, 2004

   I read the transcript, and I'm having a basic difficulty. It's *possible* that a black hole never formed, but the amplitude for that could be incredibly small, no? And yet that amplitude bears the whole burden of storing the information? So when the hole evaporates, you see nothing with probability 1-epsilon, and the information with probability epsilon? That isn't unitary. Maybe you can tell me if I'm missing something trivial.

Polyakov: String Theory is Crazy

July 26, 2004
Categories: Uncategorized

Alexander Polyakov is one of the most prominent figures in theoretical physics and one of the most well-known string theorists at Princeton. He has written a review of his career and of his efforts to understand the relation between gauge theory and string theory. His penultimate paragraph goes as follows:

"In my opinion, string theory in general may be too ambitious. We know too little about string dynamics to attack the fundamental questions of the 'right' vacua, hierarchies, to choose between anthropic and misanthropic principles, etc. The lack of control from the experiment makes going astray almost inevitable. I hope that gauge/string duality somewhat improves the situation. There we do have some control, both from experiment and from numerical simulations. Perhaps it will help to restore the mental health of string theory."

Seems to me he's saying that, while using string theory to understand gauge theory is sensible, those claiming that it provides a theory of everything have gone nuts. I wonder what his colleagues at Princeton think of this.

Comments

1. **Chris Oakley**
   July 31, 2004

   Excuse me for pointing out the obvious, but if Motl, Hawking, or any other "genius" out there can't back up speculations or half-baked science regarding black holes with a consistent quantum theory of gravity then I will continue to exercise my right to ignore them.

2. **serenus zeitblom**
   July 31, 2004

   I'm sad to have to report that my contribution to Lubos' education will not be shared with the readers of sci.physics.strings. Lubos replied that my contribution did not meet the high standards of his group [I wish you people wouldn't snicker like that–] and that anyway it should be obvious why nobody cares about the observations of black hole observers who are not infinitely far away from one. In the immortal words of Peter Woit: got that?
   Next question: whence this strange enthusiasm for Hawking's work on the part of LM?

3. **D R Lunsford**
   July 31, 2004

   Ah, the famous Schroedinger's soul problem!

4. **serenus zeitblom**
   July 30, 2004

   By the way, in case anyone doubts the literal truth of Peter's title for this section, you might like to have a look at Lubos Motl's latest writings on sci.physics.strings. His conclusion is that we shouldn't really worry about information loss since we are all gonna [sic] die anyway and *some* information will be lost in that way. Here is my response — it will be interesting to see how he behaves in his capacity as moderator:

   Lubos Motl wrote in
   >
   > Yes, no one has really resolved and defined the correct laws of physics as
   > seen by the infalling observers. Well, they're gonna die which
   > automatically means "some" loss of information from their point of view.
   [My reply]:
   Profound, truly profound. We're all gonna die and that will mean
   the loss of "some" information.

   Thank you. My doubts about unitarity in quantum gravity have
   all been answered.

   On second thoughts, what if we go to heaven? Or, in
   the case of some of us, to the Other Place? Will
   unitarity be preserved by supernatural tunneling?

5. **Urs Schreiber**
   July 28, 2004

   JC –

   I haven't looked at which calculations precisely Dixon does. But I am sure he said that he can relate QCD calculations of N=4 SYM and that hence any better understanding of the latter has an effect on the QCD calculations.

6. **JC**
   July 27, 2004

   Urs,

   Most of the stuff Dixon alludes to doesn't appear to use the AdS-CFT duality directly. The most that appears in his strings 2004 talk that alludes to AdS-CFT, doesn't look like it's much more than hand waving. I didn't see any explict AdS-CFT calculation results in his talk, nor in any of his previous papers. Where did you see Dixon's stuff on explict AdS-CFT type of calculations?

   In Dixon's earlier work on calculating QCD amplitudes, SUSY appears to be used as a calculational "tool" and not really as a fundamental symmetry. How he's able to this, I'm not entirely sure offhand. The only semi-plausible reason I can think of offhand is in the first quantization picture of gauge theories. There were a number of papers by Michael Schmidt (at Heidelberg, I think) from the 1990's which looked at QED in the first quantization picture. Turns out the Lagrangian for first quantized ordinary QED has an explicit “SUSY” symmetry, which doesn’t readily appear in the textbook version of 2nd quantizated QED. In some sense, the first quantized picture of ordinary QED gives you a “SUSY” symmetry literally for “free”. Where exactly this SUSY symmetry comes from in the first quantized ordinary QED, I don’t know offhand. There’s a section in Polyakov’s book which discusses the first quantization picture for ordinary QED.

It appears Schmidt, nor anybody else yet, has been able to generalize this result to the non-Abelian gauge group case. In principle, a first quantization picture of ordinary Yang-Mills theory coupled to fermions, should reproduce the results Dixon got in his earlier QCD calculation papers that used SUSY as a “tool”.

7. **Urs Schreiber**
July 27, 2004

Thomas –

there is string/gauge duality and it is best understood for cases which do not very much resemble the real world. N=4 SYM is best understood because of its high symmetry. That makes it easy. As Witten nicely explains in his intro to the Clay institute challenge on YM, the reasoning is as follows:

– we want to understand YM

– but YM is hard

– so as a first step move to a point in field theory space which is easier to handle

– this leads to the study of supersymmetric QFT and N=4 SYM in particular

– so let’s study this as a first approximation to what we are really interested in

– surprisingly it turns out that N=4 SYM is apparently equivalent to superstrings on AdS5 times S5 (this is a conjecture, true, which has been check to 2.5th order or something, pretty impressive already)

8. **Urs Schreiber**
July 27, 2004

JC –

at Strings04 in Paris Dixon gave a talk on how to compute QCD stuff by mapping it to N=4 SYM. For instance, if I recall correctly, he said that the tree level amplitudes are the same when you identify the SYM fermions appropriately, and that similarly higher loops can be mapped in a certain way to SYM.

But once you are doing anything with N=4 SYM you can equivalently compute on the dual string theory side. For instance the recent progress in computing anaomalous dimensions in N=4 SYM is all based on BMN, spin chains, semiclassical strings in AdS5 and so on.

9. **Thomas Larsson**
July 27, 2004

Urs,

I admit that I find the equivalence between N=4 SYM and gravity very confusing. However, this kind of correspondence only seems to work (if it does, Maldacena is still a conjecture, right?) for YM theories plagued by almost-falsified supersymmetry. I am positively sure that vanilla Yang-Mills, of the kind present in the standard model, does not contain gravity. The standard model is not a theory of gravity, is it?

I will come back to loop space gauge theories later.

10. **JC**
July 26, 2004

Urs,

Lance Dixon’s work doesn’t appear to be using the AdS-CFT duality stuff. Most of Dixon’s results look like they’re perturbative amplitude calculations in Yang-Mills theory, using string inspired methods such as in his lecture notes hep-ph/9601359

Looks like Dixon’s later work on calculating gravity amplitudes via Yang-Mills results, appears to be generalizing a result between open and closed strings in Kawai, Lewellen and Tye’s paper “a relation between tree amplitudes of closed and open strings” Nucl. Phys. B, 269 (1986), where Dixon et. al. takes the point particle limit. The net result he found appears to be writing perturbative gravity amplitudes as the “square” of some corresponding Yang-Mills amplitudes. On the surface it appears that it’s an easy way to get gravity amplitudes by just recycling old Yang-Mills amplitudes calculated previously. There’s a review paper by one of Dixon’s collaborators, Zvi Bern, that reviews all of these perturbative gravity calculations without having to calculate Feynman diagrams directly by brute force from first principles gr-qc/0206071

July 26, 2004

Hi Thomas –

I should definitely learn more about gauge theory in loop space formulation and maybe you can teach me something. (BTW, did you see my reply to your SCT comment.)

Concerning YM in 4D and gravity I don’t understand what you are saying. The big exciting fact is that N=4 SYM is equivalent to a theory of gravity. People like Dixon are even using this to investigate QCD amplitudes by using recent results on strings in AdS. If you like this or not or if you think the dual gravity can have any relation to the gravity that we observe, it is still there.

12. **Thomas Larsson**
July 26, 2004

Polyakov is probably my greatest living hero (Einstein and Dirac are unfortunately dead), so it makes me happy that he is ready to acknowledge problems in the string theory, despite his important contributions to that subject.

I don’t think that anybody has seriously questioned that gauge theories can be formulated in terms of stringy variables. This idea may go back to Faraday and his flux tubes, and it was completely clear with the introduction of Wilson lines in 1974. It is less clear to me how useful such a formulation is; the Migdal-Makeenko loop equations are now 30 years old and still defies any hope of solution. Loop space is really messy because it is so big.

However, Yang-Mills theory cannot be equivalent to string theory even if formulated in stringy terms, since it does not contain gravity and is consistent in 4D. There are of course close analogies between Yang-Mills and gravity, exploited e.g. in LQG, which is a loop space formulation of gravity in Ashtekar variables. But if you find gravity in Yang-Mills you must have done something more than a reformulation.

13. **Urs Schreiber**
July 26, 2004

This always leaves me puzzled: I may acknowledge that strings know about gauge theory but I may not be excited about them also knowing about gravity? 😉

14. **Alejandro Rivero**
July 26, 2004

The QCD strings, old or new ones, are the most promising silver bridge for trapped physicists -specially for younger ones- to escape from string theory. It is not rare, from time to time, to heard invitations to use it. In this way it does not seem that you have been years in the blue; instead you can claim a consistent career path and keep going.

Smolin on the Anthropic Principle

July 26, 2004
Categories: Uncategorized

Lee Smolin has a new preprint discussing the “anthropic principle”. He argues that one standard form of the anthropic principle that has been invoked by proponents of the “Landscape” is not falsifiable and he gives an eloquent explanation of the importance of falsifiability for a shared scientific enterprise. He also discusses the “prediction” of the rough magnitude of the cosmological constant that supposedly uses the anthropic principle and is due to Weinberg. He points out that this argument really isn’t an anthropic one, since it is independent of the existence of intelligent life. It just relies on showing that there is a relation between the cosmological constant and the existence of gravitationally bound structures. Then, since we see galaxies, we know something about the cosmological constant.

One of Smolin’s concerns is to show that his theory of “cosmological natural selection” (discussed in his book “The Life of the Cosmos”), while being a theory of a “multiverse” just like the string theory Landscape, is different in that it is potentially falsifiable, unlike some recent anthropic arguments.

He states well the predicament that theoretical physics finds itself in, with the tactic that worked so well throughout the 20th century, that of searching for unification by exploiting symmetry, no longer having much success. While I agree with most of what he has to say in this preprint, I’m more optimistic than him that future progress through new ideas about unification and the exploitation of symmetry is still possible. My point of view is more that the reason the last twenty years have seen no progress of this kind is that virtually all the field’s effort has gone into pursuing one very speculative and not very promising idea about unification, ignoring other possible lines of research.

   July 28, 2004

   Mathematically, exploitation of symmetry=representation theory. There are several techniques for constructing and studying representations that mathematicians have developed over the last 50 years, but physicists have never learned. In addition, for some of the groups that are experimentally known to be physically relevant (4d gauge and diffeomorphism groups), very little is known about their representations.

   Actually, the classical representation theory of these groups is well known – it is called *differential geometry*.

   This is pretty obvious once you think about it. Differential geometry is the theory of well-defined objects, which are precisely those that transform consistently under diffeomorphisms. Thus, tensor densities are (often irreducible) modules, the exterior derivative is an intertwining operator, a connection is a central extension of the module of (1,2) tensor fields, etc. Special geometries, like symplectic or contact geometry, can likewise be regarded as the representation theories of the appropriate subgroups of symplectomorphisms and contactomorphisms. To treat spinors, you need to consider groups of local frame rotations and vielbeine, etc.

   However, we know from conformal field theory that the Virasoro algebra has two qualitatively different kinds of reps: classical modules, which are called primary and secondary fields, and modules of lowest-weight type (Verma, Fock, vertex operator, coset, minimal models, etc.) which are relevant to quantum theory. Differential geometry only deals with the higher-dimensional analogues of the classical modules. This is easy to see, because all interesting (= non-trivial and unitary) quantum irreps always have a positive central charge.

   The Virasoro algebra is a central extension of the diffeomorphism algebra in 1D, so generalizing it to several dimensions would be a first step towards constructing quantum reps of the diffeomorphism group in several dimensions. At first sight this seems hopeless, since a no-go theorem tells us that the diff algebra has no central extension except in 1D. Nevertheless, a multi-dimensional Virasoro algebra does exist, although the extension is not central in higher dimensions. The first quantum reps were found in the seminal paper

   S.E. Rao and R.V. Moody,
   Vertex representations for N-toroidal Lie algebras and a generalization of the Virasoro algebra,
   Commun. Math. Phys. 159, 239-264 (1994)

   The underlying geometry was clarified in http://www.arxiv.org/abs/math-ph/9810003, which led to considerable generalization. We can now a construct quantum rep for each tensor density and each non-negative integer.

   Much remains to be done, of course. In particular, I don’t understand how to generalize the minimal models, which are needed to make physical predictions in CFT. One must expect that the full representation theory is much more complicated than for the Virasoro algebra. This is true already on the classical level, where the differential geometry of a circle is not very exciting. But the construction of a quantum analogue of differential geometry seems to me to be a quite interesting result in its own right. Anyway, I cannot imagine that I will ever discover anything as important again.

   So, it seems to me that the kind of new mathematics that is needed is clear and there are plenty of techniques to try and attack the problem with. But no physicists want to think about this, their reaction generally is “What does this have to do with M-theory?”

   Hear, hear! When I started to search for a multi-dimensional Virasoro algebra in 1987, one of my main motivations was that I wanted to apply it to quantum gravity. The fact that such an algebra exists and that it has good quantum representations (other anomalous algebras like Mickelsson-Faddeev apparently have not) is to me a strong indication that my physical motivation was not completely wrong.

   Whereupon I will disappear into a computer-free zone for a week.

2. **Peter**
   July 27, 2004

   Crackpots are much easier to deal with in mathematics since mathematicians insist that things be well defined and logically coherent before publishing them or taking them seriously. Coming up with math that hasn’t been done before that satisfies this criterion is hard, much too hard for the kind of crackpots that infest physics.

   Mathematically, exploitation of symmetry=representation theory. There are several techniques for constructing and studying representations that mathematicians have developed over the last 50 years, but physicists have never learned. In addition, for some of the groups that are experimentally known to be physically relevant (4d gauge and diffeomorphism groups), very little is known about their representations. So, it seems to me that the kind of new mathematics that is needed is clear and there are plenty of techniques to try and attack the problem with. But no physicists want to think about this, their reaction generally is “What does this have to do with M-theory?”

3. **JC**
   July 27, 2004

Peter,

If Smolin's scenario of symmetry principles becoming less and less useful in physics turns out to be true, what do you think physicists will do in place of exploiting symmetries?

Naively if I didn't know any better, I would be tempted to search through the math literature looking for mathematical structures that have not been used extensively in physics previously. Albeit, this would seem like a haphazard "brain dead" way of doing theoretical physics that could easily lead to numerous dead ends and wasted effort. This would definitely be an act of desperation, when everybody else has run out of brilliant ideas and are floundering around.

Only other thing I can think of offhand, would be to "invent" some new mathematics. Though inventing new mathematics out of "nothing" seems like it would be a lot harder than it looks. At times I wonder what the crackpot to non-crackpot ratio is these days in the area of "inventing" new mathematics.

Black Holes at the LHC

July 31, 2004
Categories: Uncategorized

Jacques Distler has something interesting about the prospects for [producing black holes at the LHC](). This has often been promoted as one of the most exciting possibilities for new physics from the LHC. Evidently it turns out that cosmic-ray experiments currently in progress also are sensitive to this kind of hypothetical black hole prediction. Depending on one's assumptions about the minimal mass of a black hole that can be cleanly distinguished, either all or almost all of the range of new fundamental gravity scales accessible to the LHC will have been covered by the cosmic-ray experiments. So, if there is a new unexpected gravity scale in the range of a few Tev, this is very likely to first be seen in cosmic-rays, not at the LHC.

These Tev-scale gravity models have gotten a lot of attention in recent years, much of it in the form of claims of string-theory "predictions" that could be tested at the LHC. A few days ago I was talking to one of my colleagues, who believed, based on hearing a talk by Nima Arkani-Hamed, that string theory made predictions about what would happen at the LHC. Of course this is nonsense. There are lots of models you can construct involving string theory and any gravity scale you want. Past experiments rule out the possibility of a gravity scale up to the range of 100's of Gev-1 Tev, but there is no reason other than wishful thinking and a desire to have something to say to people who point out that string theory makes no predictions, to believe that there is a gravity scale just a bit too high to have been seen at the Tevatron, but observable at the LHC. Such an assumption actually ruins what string theorists consider the major success of the whole string theory/supersymmetry picture, the fact that the 3 coupling constants in the standard model nearly come together at an energy somewhat below the Planck mass.

Personally I've always found the current "Large Extra Dimensions" Tev-scale gravity models to be just hideous and completely unmotivated. On the other hand, the one thing we know is that the electroweak-breaking scale is in this region, and since we don't yet know what is causing this breaking, it is not completely inconceivable that it has something to do with gravity. The argument that the scale of quantum gravity is the Planck scale is not water-tight. It is based on the assumption that whatever generates the Einstein-Hilbert action as the effective low-energy action for gravity produces it with a magnitude of order one. If instead it comes with an exponential factor, the underlying gravity scale could be quite different than the Planck scale.

Besides some enthusiasts whose talks give the impression that Tev-scale gravity is a prediction of string theory, most string theorists believe that this is something unlikely to occur (Distler is one of these). One of the weirder things I've encountered in arguing with prominent string theorists is that they like to say that the Tev-scale gravity models are one of the major achievements in string theory in recent years, while at the same time saying they don't believe in these models. What's up with claiming as a point in favor of your theory that it "predicts" something you don't believe?

Comments

   August 1, 2004

   For extra dimensions in general, I like the reinterpretation of Giorgi, Cohen and Arkani, going from 4D to higher dimensions by using a dinamical process and getting symmetry breaking from it.

   Also, to see mathematically the Higgs field as an extra dimension is already a well known theme.

Low Point in Hawking Coverage

July 31, 2004
Categories: Uncategorized

Gregg Easterbrook is a senior editor at the New Republic, and gives every indication of being a complete moron. His column about Hawking's recent talk on black hole information loss is a masterpiece of anti-intellectualism. He appears to believe that the problem with physics is that, in trying to understand the big bang, ideas have been invoked that "don't do especially well on the common-sense test".

Only someone with zero common-sense would think that common-sense is going to explain the state and dynamics of the universe billions of years ago when conditions were utterly unlike those in which humans evolved and continue to exist.

Comments

1. **Peter**
   August 1, 2004

   Hi Deane,

   Thanks for pointing out the earlier Easterbrook piece about string theory. I had seen it a while back but forgotten about it.

   Easterbrook seems interested not so much in criticizing string theory as in promoting religion. His older article is more of the same anti-intellectualism as in his Hawking piece, attacking physicists for trafficking in ideas that he doesn't understand. It shows clearly what I see as one of the main dangers of where string theory is leading physics. If a scientific field abandons the standard norms of what is science and what isn't, it will lose its credibility and people like Easterbrook will try and promote the idea that we can never understand much about the universe and try and replace science by theology. Wait till someone tells him about the recent "anthropic" nonsense….

2. **Chris W.**
   August 1, 2004

   I read the Beliefnet piece. Peter is right; he is a moron. He touts string theory's resemblance to theology, apparently in the hope of promoting the legitimacy of the latter (understood as a belief in an "unseen realm of the spirit").

3. **Deane**
   July 31, 2004

   But, Peter, he's on your side, when it comes to
   string theory! Check out

   http://www.beliefnet.com/story/96/story_9602_1.html

   And, if you think about it, his argument against
   string theory is remarkably similar to yours.

This is Powerful Stuff

   What would be amusing is if it said

   “String Theory: The so-called anthropic unified theory is indoctrinating young scientists into making fools of themselves”

More Landscape Looniness

August 1, 2004
Categories: Uncategorized

Susskind has posted a new preprint entitled "Cosmic Natural Selection". It's just two pages of various attacks on Lee Smolin's theory of cosmological (not cosmic) natural selection. Smolin's theory is described in detail in his book "The Life of the Cosmos", published seven years ago. As far as I know the terminology of "Landscape" entered physics in this book, where Smolin adopts the term "fitness landscape" from evolutionary biology.

Why is Susskind all of a sudden taking an interest in Smolin's old theory? Well, last Tuesday a preprint by Smolin appeared entitled "Scientific Alternatives to the Anthropic Principle" in which he gives a detailed criticism of the anthropic principle as unscientific. The next day Susskind tried to post a response to Smolin, consisting of a 3 page paper, half of which was just a quote from a summary of his argument that Smolin had sent to him. The one and a half pages that Susskind himself wrote were pretty much incoherent, and showed no sign that he had bothered to actually read Smolin's article.

This was such a bizarre document that someone responsible for the arXiv actually refused to accept it. I've heard of several non-mainstream physicists who have had problems getting their articles accepted, but this is the first time I've heard of this happening to a well-known mainstream physicist. Whoever did this was doing Susskind a huge favor, but he then immediately forwarded a copy of the paper via e-mail to a long distribution list.

So that's why Susskind's latest begins "In an unpublished note I criticized Smolin's theory of cosmological selection…" Note that he is not addressing any of Smolin's criticism of his own work as unscientific, instead he is attacking Smolin's own speculative ideas. I've personally experienced this kind of thing from more than one string theory fanatic. They don't respond to criticism of what they are doing (because they don't have much of a response), and instead forcefully and incoherently attack one for any speculative comments one may have made.

This just gets weirder and weirder all the time….

Comments

1. **Peter**
   August 15, 2004

   In his initial article submitted to the arXiv he states, concerning Smolin's article, "I took a quick look at the paper…", which I take as an explicit acknowledgement that he didn't read it. What he wrote showed no sign he had read it. Personally, this initial article seemed to me a disgraceful travesty of a scientific paper, for reasons I stated earlier. I don't know who at the arXiv rejected Susskind's article, but evidently they agree with me.

   To date Susskind has not publicly answered the detailed criticisms of his use of the anthropic principle contained in Smolin's article. If he has finally read the article and has an answer to Smolin's criticisms, scientifically his first priority should be to deal with this issue, not to attack Smolin's more speculative ideas. Doing what he has done gives the strong impression that he has no answer to Smolin's criticisms, and instead of confessing to this, has decided to go on the attack. Maybe "thuggery" was too strong a term, but I don't believe this has much to do with trying to get at scientific truth.

2. **Gil Steinberg**
   August 15, 2004

   Susskind must have read Smolin's work at some point, because the preprint "Cosmic Natural Selection" presents significant scientific criticisms of Smolin's theory, as detailed in my previous post. It is certainly appropriate that such criticisms be made public — this is how science works. I see nothing in Susskind's preprint that justifies your use of the highly charged terms `thuggery', `disgraceful', `beat up Smolin,' and `attack on Smolin.' I don't know what else appeared in the unpublished note, but according to your post it was a `defense of his [Susskind's] own work,' which again hardly seems to justify your strong language.

   By the way, Susskind is famous for not pulling punches, and he does not distinguish `string theorists' from non-`string theorists' when he thinks that someone is wrong. Have a look at his hep-th/9405103, `Comment on a Proposal by Strominger,' and also his contribution hep-th/0204027 to the Hawkingfest. Susskind's style is not for everyone, but I believe that it is his way of trying to get at the scientific truth, and I am sure that Smolin will take it in this way.

3. **Peter**
   August 15, 2004

   Hi, whoever you are at UCSB,

   Let me summarize again the facts about what Susskind did in response to Smolin's 40 page or so paper containing a detailed and serious critique of the anthropic principle and Susskind's use of it. Without even bothering to read it, within a day of its appearance he wrote a completely incoherent one and a half page defense of the anthropic principle and attack on Smolin, then tried to post it on the arXiv. This was such a ridiculous document that he was told he couldn't do this, something which is completely unheard of. A couple days later he stripped out the nonsensical defense of his own work, added a more detailed attack on Smolin, and managed to get this posted.

   I think this kind of behavior is disgraceful, and it has nothing to do with doing serious science. Susskind clearly just wanted to beat up Smolin for pointing out that what Susskind is doing is not science. I've seen all too much of this kind of thuggery, directed at anyone who dares criticize what string theorists are doing.

4. **Gil Steinberg**
   August 15, 2004

   Smolin's paper was explicitly about a scientific (that is, falsifiable) _alternative_ to the anthropic principle. So why are you criticizing Susskind for trying to falsify Smolin's alternative theory? Susskind's paper, although short, raises several very valid scientific objections to Smolin's theory. In particular, Smolin argues that production of new universes at a black hole singularity is on a firmer theoretical footing than production of new universes via bubble nucleation in an inflating universe (as in the landscape picture). Susskind argues that the reverse is true: bubble nucleation is observed in a wide variety of physical systems, and Einstein's equations imply that vacuum energy makes the universe expand (aside from the observational evidence that our universe has gone through two periods of vacuum-energy-driven expansion); it is hardly speculative to combine these two effects. The black hole bounce is on its face a more speculative thing, and as Susskind points out there are several problems here that have not been addressed: the effect of the Planckian energy densities at the singularity, and the relation to holography and the information problem. Moreover, even if the black hole bounce occurs, Susskind points out that inflation plus bubble nucleation is a vastly more efficient means to produce new universes than the black hole mechanism, so Smolin's theory is falsified. You are really putting string theorists in a no-win situation: thay are criticized for ignoring alternate theories, and then they are criticized for not ignoring them but instead subjecting them to the same level of theoretical self-consistency that they impose on string theory.

5. **Thomas Larsson**
   August 9, 2004

The Ginsparg-Glashow article to which I referred earlier is evidently available on the arxiv. Not much has changed since 1985, except perhaps that we now know that supersymmetry is close to being ruled out by experiments – it requires fine-tuning at the percent level.

6. **Peter**
August 4, 2004

Hi JC,

See my recent comments on "Black Holes at the LHC". I agree these models are basically silly, and most string theorists I've talked to say they don't believe them. The motivations for this kind of work are not just to get grants, but something more complicated. For one thing there is a desperation among string theorists to do something that can somehow count as an experimentally testable prediction, so the fact that you can cook up models of this kind that would have observable effects at the LHC is a huge motivation, even though the models are highly implausible and cooked up. A second motivation is that this stuff is technically very easy. You don't have to know any algebraic geometry, conformal field theory, etc. Much of this work just comes down to setting up and solving simple differential equations. It's a good subject for undergraduate projects.

7. **JC**
August 4, 2004

Peter,

Either I'm seeing things or asleep, but I recall seeing a comment on this thread about your view on those large TeV scale extra dimensions models.

When those models first appeared, I thought they weren't much more than somebody working out the consequences of some Kaluza-Klein theory, which didn't seem much more than a hypothetical exercise. After awhile when more and more folks were cranking out papers on this topic, I got the sense the subject was trying to making predictions that looked too silly to be true or even plausible. (ie. It didn't even pass the initial "laugh" test.)

After a few years of these large TeV scale extra dimensions models proliferating, I got the impression they seemed fit into the category of "let's propose these silly models that we know are too outlandish but are nevertheless 'trendy', just to get NSF or DOE funding". On the surface it sure smelled like an excuse for a grant funding grab. At times I wonder what sort of weird things people will propose, just to get grant money from the government, even if they know deep down in their hearts that the work is bogus from the start.

8. **Steven**
August 3, 2004

I read Smolin's article a few days back and have just finished the Susskind response. I generally think Smolin is a sober and level-headed physicist who usually puts forth interesting ideas and engaging and viable arguments.(Even if you don't agree with everything he says). I think he puts down a good case here for why the anthropic principle is simply unscientific.

The Susskind article however, does read like a blog/forum rant and not a carefuly thought out scientific article. He even admits he does'nt understand Smolin when he says" the detailed astrophysics that goes into Smolin's estimate is extremely complicated–too complicated for me–but the basic assumptions that go into the theory can be evaluated in the light of what string theory has taught us about the Landscape and black holes". How can he evaluate or respond to the article when he admits he doesnt understand the underlying astrophysical arguments?

Also, string theory has not really given any insights into real black holes or cosmology and is not in a sufficiently developed state to do so (many string theorists would actually agree). The Strominger-Vafa paper and other (admittedly interesting)papers in the 90s dealt with extremal black holes in string theory–not real astrophysical black holes. Similarly, string theory simply can't deal with deSitter space and a very small positive cosmological constant/accelerating universe despite the artifical constructions of the Stanford group.

Basically he seems only interested in promoting his own string-based agenda, even though it can't actually connect to anything in the observed universe, and any argument that does not conform to his dogma/agenda must be wrong in his eyes. I do find the whole thing somewhat strange. The pro-anthropic camp will have to really do a lot better if they are to maintain credibility. I really wish Susskind would produce one detailed cleary thought-out journal quality article carefully and rigorously promoting his ideas at least. (Papers he wrote years ago I found both interesting and informative, I just don't get this recent trend of his).

I think the arXiv is a double edged sword:one can instantly access the latest ideas/research in physics from anywhere but at the same time it is filling up with resume padding, career/grant maintaining, ego messaging stuff too. I try and stick to stuff in the Arxiv that at least has a journal acceptance/submission also. Peer review seems to have broken down in hep and string theory especially and I think it is going to be a problem for the field in the long run. I think it is fine for the people like Witten or Weinberg to just post their stuff but I think most others need the conventional journal route. String theorists should actually be the strongest critics of each others work rather than be a mutual admiration society (which is the impression I often get, whether that's right or wrong). Every other branch of science, engineeering, medicine has to go through the very rigorous "old fashioned" peer-review process via paper journals with subsequent online access. Although it is not perfect I think all scientists (whether students or established professors) still need the discipline/feedback provided by that or else the archive will end up like a ranting open physics forum. If the archive is going to be more rigorous in their acceptance criteria now then that could be a good thing.

9. **Peter**
August 3, 2004

I wasn't aware that the arXiv did any screening other than by author's affiliation, and wonder how often they reject papers from people with sponsors or with academic affiliations. Danny's story is a bit scary, I would have thought that some reason would have to be given to reject a paper, especially if it is sponsored.

But I think the right thing was done in rejecting Susskind's article. The arXiv shouldn't become like sci.physics.research, where people post comments of all sorts. It should remain a place where people post scientific articles of the sort that will ultimately appear in a peer-reviewed journal. I can't believe any such journal will ever publish the kind of thing Susskind has been putting out recently, so arguably others of his articles should also have been rejected. In any case this isn't an example of censorship of non-mainstream ideas, since Susskind is certainly part of the mainstream. His paper was rejected not because of his ideas, but because of its embarassingly incoherent and unscientific nature.

10. **D R Lunsford**

NEWS FLASH – Direct CP violation in B0 -> K+ pi- decay. Big news in real physics.

The gravity experiment (does antimatter fall up in the gravitational field of matter?) NEEDS to be done!

11. **D R Lunsford**
August 3, 2004

All I know is, I got a sponsor, the paper was submitted and a number assigned, it appeared in the archive and was then immediately removed. Never got an explanation, nor did the sponsor.

12. **Chris Oakley**
August 3, 2004

I was not aware that ArXiv was subject to any filtering at all other than the requirement that the sender should be at, or be sponsored by someone at a higher education establishment. If it is then that is a pity as instead of being a representative snapshot of the state of the art, it becomes a party political tool for whoever runs it.

The advent of the internet has enabled one to see what a physics discussion that is a complete free-for-all looks like. I am talking of course about the sci.physics forum. I like this newsgroup because of its entertainment value, but the serially-spamming crackpots and the immune reaction that they engender (headed by "Uncle Al") become predictable after a while. Having said that, "Uncle Al" can be very funny.

I think that the lightly-moderated sci.physics.research is about the level that ArXiv ought to aim for. If people want to make fools of themselves in public, then they should be allowed to do so, provided that they stay on topic and keep the personal abuse to a minimum.

13. **D R Lunsford**
August 2, 2004

Peter-

I have no idea how arxiv works. What I know about it comes from a friend who was stupidly blacklisted – I mentioned him in the "ACKNOWLEDGEMENTS" section. It could be just that petty, or it could be that a reappraisal of Weyl's theory in a new context is too much for them to swallow. All I know is – it's not string theory, it's not a Kaluza approach, the idea is inherently interesting, the calculations are correct, and the interpretation is as conservative as possible. There is no actual reason to reject the paper, particularly since the older theory lives in it as a first approximation. On the other hand there is a lot in it that is very suggestive of possible ways to make progress in understanding gravity and field theory together, from a conformal standpoint.

To be sure I never pressed the issue because the whole episode seems sordid in some way.

The preprint was immediately accepted by CERN without any complaints. In any case I think CERN automatically serves preprints of the usual journals.

-danny

14. **Peter**
August 2, 2004

Hi Michael,

I won't divulge my confidential sources, but a copy of the e-mail Susskind sent out to a large distribution list made its way to my inbox. If you think the tone of Susskind's arxiv posting was unscholarly, you should see the one that was rejected.

One unexpected aspect of doing this weblog has been that tricky questions of journalistic ethics arise. Should I repeat things people tell me privately? Probably not without asking them. How much of something that is forwarded to me can I make public if the original sender didn't intend to put what he wrote on the internet. What if he originally tried to put it on the internet but was thwarted and instead sent it to a lot of people? Shouldn't I help him out? By making it public or by keeping it private? Complicated questions….

15. **JC**
August 2, 2004

It seems like for many folks, the more indefensible their position is on something that is controversial, the more they resort to personal ad hominem style of attacks when defending their position. I always found it amusing in working up folks of this sort into a huge ad hominem attack frenzy, to the point that they're about to punch me in the face over it. It may very well be the case that in our human brains, our emotions can greatly overpower our own "logic".

It seems kind of weird and amusing at the same time, in watching string theory and loop gravity folks throwing ad hominem personal attacks at one another over various "ideological" type of issues in approaches to doing quantum gravity research.

Will a huge ad hominem flamefest between string and loop folks, and/or between pro and anti anthropic folks, be the final "end battle" which destroys the legitimacy of string theory and other forms of quantum gravity research as we know it?

16. **Michael Williams**
August 2, 2004

Where did you hear that his first hasty reply had been rejected by the arXiv? The new paper certainly seems to be written in a rather unscholarly tone.

17. **Thomas Larsson**
August 2, 2004

Does anyone know where Ginsparg stands on string theory?

On the one hand, it has been claimed that the Arxiv may in the end turn out to be string theory's most important contribution to science. So in some sense Ginsparg is a string theorist, and the phrase "Ginsparg archipelago" resonates somewhere in the back of my head (these are probably some isolated c=1 CFTs, perhaps associated with the E's of some ADE classification). OTOH, I think that he coauthored the infamous "Desperately seeking superstrings" article in Physics today in 1986, after which Sheldon Glashow came out as a string critic.

18. **Thomas Larsson**
August 2, 2004

A year or two ago I commented on spr that Smolin's review of quantum gravity looked like a declaration of war on string theory. Smolin denied that, claiming that many of his close friends are string theorists. The exchange can probably be found somewhere on the web if you really want to read it.

Anyway, even if that was true, it is hard to avoid the impression that his last paper really *is* a declaration of war on string theory in general, and on the anthropic principle in particular. Apparently Susskind draws the same conclusion.

19. **Peter**

August 2, 2004

Hi JC,
I think it is very unlikely that the powers that be at the NSF and DOE will step in and start defunding this kind of research. They generally rely on a system of peer evaluation, which has allowed string theory to do well as string theorists generally evaluate other string theory research highly. So the real question is whether the united front of string theorists will crack further. How many string theorists are willing to give a low score to grant proposals to do “anthropic” research?

This is the real significance of Smolin’s recent paper. He is making a strong argument that a lot of people are no longer doing science, and this is a huge threat to them, in particular to their NSF or DOE funding. This is why you see Susskind so upset that he writes bizarre articles and launches attacks on Smolin.

20. **Peter**
August 2, 2004

Hi Danny,
No, you’re the only example I know of where someone has had a peer-reviewed article rejected by the arxiv. By the way, do you know who it is who is now making these decisions about what to accept and what to reject? Is it Paul Ginsparg, who set up and runs the thing, or someone else?

It seems to me that rejecting Susskind’s article opens up a whole can of worms for the arxiv, and I wonder what criteria they used to reject it. Up until now they could claim that they were just rejecting based on the lack of certain kinds of academic affiliation, but here they’ve rejected something presumably based on it not being scientific. But if they start really rejecting things from string theorists whether or not they are scientific, this is just the beginning.

21. **JC**
August 2, 2004

Peter,

It sure seems like many of these anthropic and anti-anthropic papers over the last year or so, read almost like a “Pot Vs. Kettle” competition, especially when it’s between different quantum gravity camps (ie. strings vs. loops).

What do you think the government grand funding agencies (ie. NSF or DOE) will do, once they catch on to all this anthropic silliness going on in string theory and other quantum gravity research areas?

22. **D R Lunsford**
August 2, 2004

Peter-

You say you’ve “heard of several non-mainstream physicists” etc. etc. – but do you know of any examples of papers that are already published in reputable peer-reviewed journals being rejected from the archive? I find myself in just this situation, and while I try to maintain a good humor about it and not take it too seriously, still I would not mind having the work properly dissected, particularly since there are mathematical aspects of it that need to be investigated, that are, for various reasons, not in my reach.

Given that a great deal of the archive in the last few years is devoted to string theory, the collapse of one can hardly avoid impacting the other.

23. **JC**
August 2, 2004

Years ago somebody showed for a joke, the correlation of crashes of the stock market and/or companies, with things like building really tall buildings and/or a company putting their name on a sports stadium. The classic case is that of Enron going bankrupt a few years after sponsoring the Enron field stadium in Houston, Texas. Another classic case is the stock market crashing in 1929, after the Empire State Building construction was proposed. In more recent times the Asian financial markets crashed in 1997 after the Petronas twin towers (in Kuala Lumpor) construction was proposed. They also showed for a joke, how the rises and falls of Donald Trump’s fortunes were highly correlated with the up and downs of the real estate markets in america.

The rationale that’s usually given to explain this correlation is that many grandiose ideas and stupid things are proposed and done, during times when the economy is booming.

Another joke correlation was how a company would decline and fall into problems, after when the company’s CEO and other upper management were on the front cover of magazines like Time, Newsweek, BusinessWeek, Fortune, Forbes, etc … During the 1990’s, Bill Gates picture showed up on the cover of Time Magazine and subsequently Microsoft nosedived from the anti-trust case against it. Something like in 1999, Jeff Bezos (CEO of Amazon.com) showed up as “man of the year” on the front cover of Time Magazine, and the dotcom bubble imploded shortly thereafter.

In a similar joke-like manner, there’s a spurious correlation between the idea of Zwiebach’s “string theory for undergrads” course & textbook, and the subsequent decline of string/M theory into the anthropic mess. Or earlier from the 80’s era, there’s a spurious correlation between the idea of Kaku’s “intro to superstrings” textbook or Luest & Theissen’s intro to string theory book, and the subsequent decline of string theory around 1990. From the 1970’s era, there doesn’t appear to be any “textbooks” on string theory. The closest I can think of offhand would be Paul Frampton’s book on “dual resonance models”, which looks like it was published just right around the time everybody was abandoning string theory in 1974.

It seems amusing that a highly speculative field subsequently comes crashing down and declining after a “textbook” on it is proposed and written.

Perhaps there’s some truth to the notion of

“history repeats itself, first as low comedy and then as mindless farce”

(attributed to Karl Marx)?

24. **JC**
August 2, 2004

This sure sounds a lot like a major decline of quantum gravity, falling into a downward spiral into the abyss. Something has really gone astray when the “experts” start to sound more and more like crackpots.

At times I’ve noticed in politics when somebody’s popularity is falling, many of their press releases become more and more difficult to differentiate from “satire” press releases (ie. Matt Drudge style), or political news stories on “serious” 24 hour news channels (ie. CNN, MSNBC, etc …) starts to resemble the stuff on late night television comedy shows (ie. John Stewart, Bill Mahr, Dennis Miller, etc …).

It would be interesting to see what will happen to quantum gravity research, if this stupidity persists for several years.

Beauty, Fashion and Emperors

August 4, 2004
Categories: Uncategorized

Roger Penrose has a new book out in England, called "The Road to Reality". It is 1000 pages long and is now ranked number 17 on Amazon's UK site. There's a review of the book here.

It sounds like the book contains all sorts of things, including some of the material about string theory that Penrose has presented in public talks various places about "Fashion, Faith and Fantasy in Modern Physical Theories". One version of these talks is available online from Princeton. By "Fashion" Penrose is referring to string theory, and he considers the question of why it is so fashionable. String theory has been heavily sold as "beautiful" and to some extent Penrose seems to go along with this, but his invoking of the term "fashion" indicates an awareness of how problematic notions of "beauty" can be. The latest fashionable clothes are heavily promoted for their beauty, although after a few years, when they become unfashionable, this beauty is no longer so obvious."Beauty" is very often a social construct, with many people willing to agree that something is "beautiful" if everyone around them is saying so. Recall the story of the emperor and his fashionable outfit.

I've never understood these claims that string theory is "beautiful", and was again struck by this when I got ahold of a copy of Barton Zwiebach's new book on string theory aimed at undergraduates called A First Course in String Theory. Most of the first 270 pages of the book are devoted to working out in detail the quantization of the bosonic string in light-cone gauge, and I find it hard to believe that anyone finds this a beautiful subject. It is mathematically rather complicated and not that interesting, and has no real connection to any observable physics.

Later on in the book Zwiebach does devote a fair amount of space to trying to connect string theory to the standard model, mainly using the construction of intersecting D6 branes. At the end of this section, he acknowledges that this construction is truly hideous and looks all too much like a Ptolemaic use of epicycles on epicycles to explain planetary motion, saying "the models seem contrived, at least in the sense that they are engineered to give the physics that we observe, rather than obtained naturally as the simplest solutions of string theory". He quotes Alfonso the Wise (1221-1284) as having said the following about Ptolemaic epicycles:

"Had I been present at the creation, I would have given some useful hints for the better ordering of the universe."

He tries to end on a more optimistic note, hoping that some deeper meaning of string theory will emerge with more work, quoting Maimonides as follows:

"In the realm of Nature, there is nothing purposeless, trivial or unnecessary"

which begs the question of whether string theory is part of the "realm of Nature".

   August 20, 2004

   There are several reviews in top UK newspapers of Penrose's "The Road to Reality", many are referenced from here (including one by John Gribbin):

   http://www.321books.co.uk/reviews/the-road-to-reality-by-roger-penrose.htm

2. **Chris Oakley**
   August 6, 2004

   I do not believe that Newton or Einstein, or most others who have made significant contributions to science have been significantly cleverer than their contemporaries. What they have tended to bring to the party was independence of mind. They come up with things that the others could have come up with but did not because they were not asking the right questions. This quality enables them to ignore what people around them are saying and just figure things out for themselves. Following this principle – the Sinatra doctrine – they end up being either much more right or much more wrong than average (Einstein managed both). Although I cannot claim to have all the answers in this regard, it seems to me that the research machine as presently structured, is not an efficient factory for research ideas. If the tenured professors, who make almost all the decisions about the direction of research, were infinitely wise there would not be a problem. The reality though is that their students may be able to do better, and if they can, and end up losing the support of their supervisors as a result then they have no choice other than to leave. This kind of hierarchical structure may work for the military, but it does not work in areas where creativity and lateral thinking are an important element.

3. **erinj**
   August 6, 2004

   But imitation is the sincerest form of flattery, and surely the fact that Newton's words live on after over 300 years is testimony to the impact his life and work made upon Western civilization and, more broadly, humanity. I don't believe that these comments are poking fun at Newton the person, but rather at his legacy, which I think is as vast as any one human being has ever left to us.

   As you rightly imply, Chris, none of us are likely to leave such an enormous and influential legacy behind, and I believe that anyone who has studied any physics very likely has the utmost respect for Newton. I know I do, and for me this made such remarks more interesting: in fact, I found your analogy involving Newton's famous quotation fascinating. I recall (perhaps incorrectly) that the `beach' quotation originally appeared in a letter Newton wrote to somebody. How likely, though, are we to quote passages from Newton's Optiks or Principia Mathematica today I wonder?

   As far as I know, Newton was not known for his humour during his lifetime, and even had a dour expression (I would think this fitting given how seriously and deeply he must have contemplated things). I recall reading that his theory of universal gravitation was subject to ridicule after it became famous, yet Newton was far more concerned with his ongoing arguments involving fellow natural philosophers such as Hooke and Leibniz.

   "Have legs, use legs."

   – Sir Isaac Newton

4. **Chris Oakley**
   August 6, 2004

   I just got a message from Isaac Newton through a medium:

   You guys are really beginning to piss me off. Yes, I wrote that thing about the pebbles and seashells. And the stuff about giants. But that doesn't mean you're entitled to *twist my words in ridiculous ways just to amuse yourselves. Have **you** got a unit of force named after you? Did **you** figure out the universal law of gravitation? Thought not. So maybe if **you** come up with some great new physics, preferably something where you get the number of dimensions right (three space, one time, in case you've forgotten) then you might, and I say **might** be in a position to fun of me.*

5. **Arun**
   August 6, 2004

   And for those stupified by string theory : If I haven't seen further than others, it is because I stood in the footprints of giants……

6.
   August 5, 2004

   "…wandering in the car show room and diverting myself and now and then finding a shinier car or a faster SUV than ordinary…"

   Argh! I get the "half-asstrophysicists" thing now. Excuse me for not being up to speed on US slang :s

7.
   August 5, 2004

   Yes, I too spent time watching The Flintstones as a youngster, but they were all repeats on British television, so by then they were probably `classics', considered worthy of repeating. I'd really like to see the towering giant become a loud and aggressive promoter of string theory as he gets older, shouting his defence of it in television interviews, though I doubt it would come to that.

   By the way DR, was "asstrophysicists" a typo?

8. **D R Lunsford**
   August 5, 2004

   Ok can't resist…

   Chris made me think of Newton in a modern context

   "To myself, I have seemed but an itinerant contractor, stubbing out a bummed cigarette on the threshold of the loading dock, while all before may lay mostly undiscovered the great parking lot of truth."

9. **D R Lunsford**
   August 5, 2004

   Start of a Gell-Mann lecture on string theory at Maryland – "I see we have a mixed audience of astronomers, physicists, and half-asstrophysicists…"

   -drl

10. **Peter**
    August 5, 2004

    I often tell people I learn a lot from these comments, never expected to be learning Flintstone trivia. What is with all you people, are you as old as I am so also spent your childhood watching Flintsone cartoons (or I guess maybe they are classics and go on and on)?

    I loved the Gell-Mann quote, which was new to me. Ah, for the glory days of particle physics, when the leaders of the field were obnoxious, competitive, entertaining megalomaniacs. Now, we just have one person towering over a bunch of dwarves, and he's a very nice, polite, soft-spoken guy.

11. **erinj**
    August 5, 2004

    Thanks, will do. If anything, I suppose the current state of this thread of comments seems to indicate that it's quite easy to go astray from `The Road to Reality' – in both senses 🙂 Reminds me of the office banter that used to go on whilst a research student, taking a break from the equations 🙂

12. **Chris Oakley**
    August 5, 2004

    No – "The Flintstones at Viva Rock Vegas" was a live action prequel to the 1994 film, but IMHO much better. It got panned by the critics, but they know nothing. It came out about 4 years ago. Get the video out and tell me what you think … although I suggest by e-mail rather than as a comment on a physics web log (however subversive it may be).

13. **erinj**
    August 5, 2004

    I thought `Pebbles' was Fred and Wilma's daughter… or was that `Bam Bam'? Maybe `Bam Bam' (the one who wielded a club) was Barney Rubbles' son? What was `Viva Rock Vegas', Chris? I don't remember that, but it's gotta better than the live action film (though I thought Halle Berry as `Sharon Stone' was good). Wasn't `Dino' the name of Fred and Wilma's pet purple dinosaur?

14. **Chris Oakley**
    August 5, 2004

    "Pebbles" was their boy, wasn't he? We're getting way off topic, but am I the only one who thinks that "Viva Rock Vegas" is the best Flintstones thing ever?

15. **erinj**
    August 5, 2004

    I dunno about you, but all these comments about pebbles made me think of the Flintstones.

16. **Chris Oakley**
    August 5, 2004

Danny and Steve –

Thank-you for sharing your (most profound) insights with me. I'm sure that Sir Isaac, tracking Peter's web log from his office in that great university in the sky, is regretting ever saying a damn thing about Oceans of Truth.

17. **Steve**
    August 5, 2004

    "If I have seen farther than others it is because I am surrounded by dwarves"
    Murrey Gellmann

18. **D R Lunsford**
    August 5, 2004

    Renorm: Pretending you can play with pebbles that are infinitely massive.

    Strings: Pretending that pebbles can fly.

    Branes: Pretending that flying pebbles can sing.

19. **Chris Oakley**
    August 5, 2004

    Without wishing to take the analogy too far –

    Renormalization: Pretending your rough pebbles are smooth.

    Superstrings: You never walked on the beach at all. You only dreamed it.

20. **D R Lunsford**
    August 5, 2004

    Right! – and I think it goes on, "If I have seen farther than others, it was only because I stood on the shoulders of giants."

21. **Chris Oakley**
    August 5, 2004

    You mean this one?

    "I do not know what I may appear to the world; but to myself I seem to have been only like a boy, playing on the seashore and diverting myself and now and then finding a smoother pebble or a prettier seashell than ordinary, while the great ocean of truth lay all undiscovered before me."

    Sir Isaac Newton

22. **D R Lunsford**
    August 5, 2004

    Nice quote – on the other hand we have Newton, who actually accomplished some physics – who said "Hypotheses non fingo" – a modest admission that he wasn't God or even privvy to His Thought, just a working stiff attempting to understand how the planets move the way they do. He also said in effect "I couldn't have done this without your help" to Galileo and Kepler. In these days when it's popular to bash Einstein and Dirac, that quote – the "great ocean of truth" one – seems much more powerful to me.

    I sometimes wonder if obession with the ineffable realm of abstraction is a sort of drug addiction that is clouding the collective judgment.

23. **Peter**
    August 4, 2004

    Hi Eric,

    Wonderful quote. Your book gives an excellent and precise explanation of the way in which good physics really is "beautiful" or "elegant", along the lines of Leibniz.

    For more about Eric's book, see something I wrote a few months ago here

24. **Eric Baum**
    August 4, 2004

    God has chosen the world that is the most perfect, that is to say,
    the one that is at the same time the simplest in hypotheses and the
    richest in phenomena.

This Week's Online Conferences

August 6, 2004
Categories: Uncategorized

A couple conferences going on this week have already put some of the talks online.

SLAC has a summer school each year, aimed more at experimentalists than theorists. This year's topic is "Nature's Greatest Puzzles" and there are quite a few interesting talks already online there.

The Michigan Center for Theoretical Physics is hosting this year's String Phenomenology 2004 conference. The "Landscape" seems to be a big topic; two online talks are Michael Douglas's, which is more or less the same as his one at Strings 2004 a few weeks ago, and Michael Dine's. Dine seems optimistic that the Landscape will lead to predictions, saying

"If we adopt the anthropic viewpoint, we may be lead to predictions – perhaps the first predictive framework for string theory"

Before taking this too seriously, one should note that Dine has been giving review talks about "superstring phenomenology" and claiming that predictions are right around the corner since before most of our incoming students at Columbia were born (see his 1986 Erice lectures, no, they're not online, this was way before the arXiv).

And I'm headed off soon for a short vacation out of the range of the internet, back late next week.

Comments

1. **JC**
   August 15, 2004

   Just to be silly about the "137 loop" QED argument in my previous post, let's change one of the assumptions.

   In the case of an exploding number of Feynman diagrams at n-loop order, if we have instead have (n!)^2 diagrams at the nth order of perturbation theory (instead of n! diagrams in my last post), then the A_n's should be proportional to (n!)^2 after all the Feynman diagrams are summed up at n-th order.

   In this case the R_n ratios will become

   R_n ~= alpha * n^2
   (with all other assumptions the same).

   For divergence the R_n's are greater than 1.
   So we now have n^2 greater than 1/alpha, which now says the "QED series" will start to diverge after n = 11 loops.

2. **JC**
   August 15, 2004

   Peter,

   I thought about the "137 loop" assertion thing for QED. Here's sort of a naive argument that I can think of offhand.

   We start with a QED perturbative series

   "QED series" = sum_{n=0 to infinity} C_n

   where
   C_n = A_n * alpha^n,
   alpha = fine structure constant

   From a naive look at the explosion of the number of Feynman diagrams at each order of n-loops, there appears to be n! number of diagrams for the nth order in perturbation theory. Just summing up all the Feynman diagrams at n-loop order, the coefficient A_n should possibly be proportional to n!. So we factor out n! from A_n as

   A_n = B_n * n!

   So now C_n = B_n * n! * alpha^n

   Now we look at the ratio R_n between succesive orders in perturbation theory as

   R_n = C_n/C_{n-1} , where n = 1 to infinity
   R_n = [B_n/B_{n-1}] * [n!/(n-1)!] * alpha^{n-(n-1)}
   R_n = [B_n/B_{n-1}] * n * alpha

   For convergence, we want R_n to be always less than 1. If we naively say that all the B_n's (left over after factoring out the alpha^n and n!, from the C_n's) have roughly the same order of magnitude each, then the ratios [B_n/B_{n-1}] will be approximately an order of magnitude 1.

   (If the B_n's all have the same order of magnitude that is not of "order of magnitude" 1, then the overall "order of magnitude" can be factored out from the overall "QED series" expansion).

   With these naive assumptions, now the ratios R_n become

   R_n ~= n*alpha

   For divergence, R_n will be greater than 1.
   n will be greater than 1/alpha = 137.
   Hence above n=137 loops the "QED series" will start to diverge.

3. **Aaron**
   August 15, 2004

   The hierarchy problem is really just dimensional analysis. It doesn't depend on any details of a theory of quantum gravity. It's just that, in natural units, the natural scale of things is the Planck scale and one might like an explanation of why the ew scale is so much less than the natural scale.

   The technical naturalness problem also doesn't depend on the theory of qg. The divergence in the Higgs mass is there in the low energy theory.

   Lastly, some theories of SUSY breaking do have an intermediate scale.

4. **Peter**
   August 15, 2004

   Hi Aaron,

   "There may be no hierarchy with the GUT scale, but there certainly still is one with the Planck scale."

   Umm, maybe that's why my initial comment that you objected to saying that the hierarchy problem went away if you didn't believe in GUTs had a parenthetical caveat "ignoring gravity…"

   The hierarchy problem for GUTs is a well-defined one since a GUT is a well-defined theory that includes the standard model with electroweak symmetry breaking. To have a hierarchy problem involving the electroweak scale and the Planck scale, first you need a well-defined unified theory that includes quantum gravity and the standard model, including an explanation of the electroweak scale. Some of us don't believe this exists. All supposed candidates for such a theory have a far more serious problem, the vacuum energy problem. You have to first figure out why the absolute value of the effective potential is completely wrong before worrying about its second derivative.

   Then again, the latest trend seems to be to announce that the anthropic principle solves all such problems, so we can stop worrying about them.

5. **JC**
   August 15, 2004

   Aaron,

   Will the hierarchy problem with the Planck scale disappear if gravity is just strictly a classical force with no quantum counterpart?

   Are there any simple ways to "preserve" naturalness when SUSY is broken?

   I haven't checked the literature lately, but has anyone showed that supergravity can easily deal with the hierarchy/naturalness problems? Or is supergravity coupled to Yang-Mills theory just another disaster with the same hierarchy problems between the electroweak, GUT, and Planck scales?

   As a side note, are there any speculative particle models which have an "intermediate" scale that's higher than the electroweak scale but lower than the GUT scale? If there are any from the past, have they all vanished into the dustbins of physics history?

6. **Aaron**
   August 15, 2004

   There may be no hierarchy with the GUT scale, but there certainly still is one with the Planck scale.

   There are really two kinds of naturalness problems. One is to ask what stabilizes the Higgs mass against loop corrections which tend to drive it up to the Planck scale. The other is what explains the hierarchy between the weak scale and the GUT scale.

   SUSY has some nice features regarding the naturalness problems (and nice features not involving the naturalness problem) which I think I've discussed here before. As I think I've also said, some of these nice features have proved to be less nice than they first appeared. But such is life. When you break SUSY, for example, I think the naturalness problem can easily reappear, but I don't want to make any big pronouncements about SUSY breaking because I'm not really up on it.

7. **JC**
   August 14, 2004

   Peter,

   What's the exact argument for the QED perturbative series diverging beyond 137 loop order? I remember seeing this "137 loop" assertion over the years as if it was some folklore wisdom. I never figured out an easy semi-rigorous argument to justify it.

8. **Peter**
   August 14, 2004

   It almost certainly is just an asymptotic expansion. What determines the running of the coupling constants is the beta-function and presumably the perturbation expansion for this is just an asymptotic expansion. But one expects the situation to be like in QED, where the expansion is expected to be good up to an order that goes like the inverse of the coupling constant, i.e. 137 in QED. So, roughly in this case one expects the perturbation calculation to be good up to an order given by the inverse of the coupling constants in the range that you want to follow how they run. This should be less than 137, but still probably much larger than the order to which one can realistically do the calculation.

9. **JC**
   August 14, 2004

   Peter,

   If the 3-loop calculation (or for that matter higher loops) changes the 2-loop result significantly, will some folks try to argue that peturbative expansion is really just an "asymptotic series" that starts to break down early and diverge? Besides being rhetorical, are there any good estimates as to what loop order the perturbative SUSY calculations will start to break down due to asymptotic nature of the series expansion?

10. **Peter**
    August 14, 2004

    Hi Aaron,

I'm not sure what you mean by the "hierarchy problem". I was referring to the problem of keeping the electroweak and GUT scales separate, i.e., the electroweak scale being so small in GUT scale units is technically "unnatural" and requires fine tuning. By definition this problem disappears if there is no GUT scale. Supersymmetry solves it (kind of, there's something called the "mu-problem" of it reappearing) by pairing the electroweak Higgs with a fermion whose mass is small because of chiral symmetries. Technicolor solves it because running of the coupling constant makes the coupling strong at exponentially smaller scales than the unification scale (also this is why the small size of the strong scale in GUT units is not a problem). But if there is no GUT with symmetry breaking occuring at a high GUT scale, there is no problem.

The coupling constant unification you mention is far and away the best evidence for a GUT (specifically a supersymmetric GUT), but, using the two-loop results, it is far from convincing. I don't know if anyone has done 3-loops but one wouldn't expect 3-loops to change the 2-loop results much. If it did one would have to worry about whether the whole perturbative set-up was making any sense.

11. **JC**
August 14, 2004

Aaron,

Has anyone calculated the SUSY 3-loop result, or for that matter any other higher loop result? If so, does it improve or worsen the coupling constant convergence scenario?

12. **aaron**
August 14, 2004

If you ignore GUTs, the hierarchy problem does *not* disappear.

The reason a lot of people believe in GUTs is that the couplings of the standard model, when you run them to high energy, *almost* meet. Now, there's no particular reason for three lines to almost meet, and no one likes coincidences. Thus, it's not implausible to believe that the couplings really do unify, that the reason for this is a GUT, and that some higher energy stuff fixes the running of the couplings.

For a long time, supersymmetry seemed to be exactly that higher energy stuff. It causes the agreement of the couplings to improve significantly. The one loop calculation works almost perfectly. Unfortunately, as I understand it, the two loop calculation ruins the agreement which is one reason why people are somewhat less sanguine about SUSY these days.

13. **Peter**
August 13, 2004

Supergravity was certainly the most popular idea about unifying gravity and the standard model during the late seventies, early eighties, but it never dominated things the way string theory has. By 1984 it was kind of killed off by

1. Witten showing that you couldn't get the kind of chiral spectrum you needed if you compactified 7 of the 11 dimensions of 11d supergravity on a smooth manifold.

2. Calculations showed that potential counterterms appeared in higher orders, so presumably supergravity was not a renormalizable theory.

Actually, what people are almost always doing when they say they are working on "M-theory" is really just 11d supergravity. Now it's back with a vengeance, people just stopped worrying that the compactification manifold can't be smooth.

14. **JC**
August 13, 2004

Peter,

On a similar note, was there any silly hoopla surrounding supergravity in the mid-late 1970's and early 80's, before string theory got popular? Only thing I can recall offhand was reading some 1980 speech Stephen Hawking made which advocated supergravity as some sort of "grand unified theory", when he first got the Lucasian chair.

15. **Peter**
August 13, 2004

Oops, correction, SO(10) is rank 5.

16. **Peter**
August 13, 2004

The choice of those GUT groups predates their use in string theory. To fit SU(3)xSU(2)xU(1) into a simple group in a way where they commute with each other, you need a group of at least rank 4 (the sum of the ranks of those 3 groups). SU(5) is probably the simplest example of such a group. SO(10) is also of rank 4, and has the added advantage that you can fit all the particles of a single generation in one irreducible representation (the 16 dim spinor rep).

The simplest examples like SU(5) just with the Higgs sector needed to get the standard model can be ruled out because they predict something (proton decay) that doesn't happen. The problem with most possible GUTs is that they don't really predict anything. Depending on how you break the symmetry you can get pretty much anything. It's kind of bogus to claim that these are really "unified" models, because you have to assume some complicated Higgs mechanism to break the symmetry. You end up adding lots of new parameters to the standard model, not explaining any of the ones you've got.

Yes, if you don't believe in GUTs (count me in..), the hierarchy problem goes away (ignoring gravity…), and thus one of the main motivations for supersymmetry.

Pink Floyd and Led Zeppelin certainly bring back memories from high school ("Stairway to Heaven" was the theme song of my High School prom, shudder….). I think Kiss appealed mainly to those a bit younger than me, or with different interests. Never paid much attention to Blue Oyster Cult.

17. **JC**
August 13, 2004

Peter,

Is the only reason why anybody bothers paying attention to GUTs like SU(5), SO(10), E_6, etc … along with their SUSY versions, is mainly due to the gauge groups which show up in string theory like SO(32), E_8 x E_8, etc …? Have any of these GUTs beyond SU(5) been experimentally ruled out yet? Or are there so many free parameters in these GUTs that anybody can "fudge" their way through and get an answer that isn't ruled out by experiment? I always found adding in tons of free parameters to be somewhat on the distasteful side.

If GUTs were wrong from the very beginning with no basis in experiment or even reality, wouldn't this remove one of the major theoretical arguments in favor of low energy supersymmetry (ie. naturalness)?

On a different note, were rock bands like Pink Floyd, Led Zeppelin, Kiss, and Blue Oyster Cult very popular when you were in high school?

18. **Peter**
August 13, 2004

Actually SU(5) was even before my time, 1974, when I was still in high school. Throughout the late seventies there was a lot of work on SU(5) and other GUTs, but they were nowhere near as dominant as string theory is today. They were just one of several popular ideas to work on (instantons, supergravity, lattice gauge theory, etc.). Once the experimental results started coming in (around 1980?) showing that protons didn't decay at the rate SU(5) predicted, interest went down, although there continues to be lots of research in GUTs, partly since they are supposed to be the effective field theory for whatever string theory is supposed to explain the world.

19. **JC**
August 13, 2004

Peter,

When the SU(5) GUT was first around, did it have the same hoopla and propaganda surrounding it, like string theory in the 80's and 90's? Was it taken seriously at all at the time? Or did Sheldon Glashow have such a huge influence that people were willing to read and/or believe anything he said and wrote about?

20. **Peter**
August 13, 2004

The problem, as with Douglas, is how to weight the probability of all these vacuum states. In KKLT, the hope is that all continuous parameters are fixed, so your only choices are discrete, and you can assign every choice the same weight (although without a more fundamental theory that determines how the universe settles into a single vacuum, there's no real reason to believe this).

If you start with a GUT with a large gauge group and try and break its symmetry with a Higgs sector, problem is there are lots of parameters associated with the Higgs. How you choose these determines what the low energy physics looks like. How do you weight these possible choices of parameters? Best guess is they should all be around the one scale in the problem, the GUT symmetry breaking scale, but then you can't explain why the electroweak scale is so low. This is the problem supersymmetry is supposed to address, but that solution doesn't really work.

21. **Arun**
August 10, 2004

Re the Douglas talk : suppose we take a QFT with a very large gauge group, with many possible ways of symmetry-breaking. We then try to catalog vacuums by the same criteria that is suggested – a symmetry-breaking resulting in particular low energy parameters is more "natural" if many vacua produce these parameters. From a QFT perspective, will it be true then that we live in a unnatural vacuum?

22. **JC**
August 6, 2004

It sure sounds like Dine is taking the same approach that many economists take when doing economic forcasts. Many economists frequently just keep on making the exact same forcast year after year according to their own particular biases, hoping that it will become "true" one day. This type of mentality is just like an old broken clock that is always right two times every day.

Twentieth Anniversary of the First Superstring Revolution

August 12, 2004
Categories: Uncategorized

Today a symposium is being held in Aspen to celebrate the twentieth anniversary of the "First Superstring Revolution". The canonical story of this "Revolution" is that twenty years ago this month, on a dark and stormy night at a workshop in Aspen, Michael Green and John Schwarz completed a calculation showing that gauge anomalies canceled in a specific superstring theory, thus changing physics forever. The more complete story of what happened at that time goes more or less as follows:

By 1984 Witten had been taking some interest in superstring theory for a while, giving a talk on the subject in April 1983 at a conference on Grand Unified Theories, but not publishing anything about it himself. In 1983 at the Shelter Island conference he had shown that the popular unification idea of the time, using supergravity on higher-dimensional spaces and the Kaluza-Klein mechanism, could not give the kind of asymmetry between left and right handed particles that occurs in the standard model (this has had a revival in M-theory, which these days invokes singular compactification spaces to get around Witten's no-go theorem). The failure of supergravity ideas had gotten him interested in superstring theory, but he was concerned about the issue of gauge and gravitational anomalies in the theory, anomalies that he worried would render the theory inconsistent. In his 1983 paper about gravitational anomalies with Luis Alvarez-Gaume, they noted at the end that these anomalies canceled in the supergravity theory in ten dimensions that is the low energy limit of the type II superstring. This theory didn't allow for low-energy gauge theories so wasn't useful for unification. Witten suspected that the type I superstring (which could be used for unification) would have insurmountable problems with anomalies, but the Green-Schwarz calculation showed that these anomalies could be canceled for a specific choice of gauge group.

Evidently Green and Schwarz talked to others about their new result at the 1984 Aspen workshop, but I would suspect that no one was very impressed (if anyone who was there knows differerently, I'd be interested to hear about it), since superstring theory was generally considered pretty much a far-out, highly unlikely idea. Green and Schwarz were well aware that their only real hope for getting attention was to get Witten interested, so on September 10th they sent him a copy of their paper via Fed Ex (this was before e-mail) at the same time they sent it off to Physics Letters B. Witten immediately went to work full time on superstring theory, with his first paper on the subject arriving at Physics Letters B on September 28th. I think this is really the point at which one should date the First Superstring Revolution.

Witten was at the height of his influence, and the news that he was now working on superstring theory spread very quickly through the particle theory community. I had just finished my graduate work at Princeton and was starting a post-doc at the Institute for Theoretical Physics at Stony Brook when I heard the news. Over the next six months to a year I remember hearing from a couple colleagues who had gone down to Princeton to talk about their work with Witten, only to hear from him that, while what they were doing was all well and good, the future was in superstring theory, so they should drop what they were doing and start working on that.

My own attitude was that it didn't look like a very promising idea. It was a complicated theory and didn't really explain anything at all about the standard model. I figured that there would be a lot of smart people working on it for a while and within a year or two either they would get somewhere with the idea and it would be clear I had been wrong, or they wouldn't, and everyone would lose interest. Neither I nor anyone else could conceivably have guessed that 20 years later superstring theory would still not explain anything about the standard model, but would completely dominate particle theory.

One reason for this is the string theory hype machine continues in high gear. The University of Chicago has issued a press release telling us that "growing numbers of physicists see superstring theory as their best chance" to formulate a theory of everything. Jeff Harvey is quoted as saying that "It?s an intellectual enterprise that?s extremely exciting and vigorous and full of ideas", which is very different than what I hear string theorists telling me in private.

Comments

   August 24, 2004

   Danny, Chris,

   The only TV shows and documentaries I remember seeing on PBS when I was a kid, were mostly space and/or NASA oriented ones. I guess I missed all the shows that were on particle physics, as well as many of the biology related ones.

   The only other science related documentary from that time I really remembered were ones about the Manhattan Project and the making of the nuclear bomb. At the time I didn't really know what the significance of the Manhattan Project was in the context of World War 2, but I had a "morbid" fascination of the pictures and footage of the mushroom cloud explosion and the subsequent shock waves at the Trinity test site. It was many years later when I started to understand what the destructive power and significance of the nuclear bombs were really all about.

2. **D R Lunsford**
   August 23, 2004

   JC – as a kid (teen) I well remember the NOVA episodes about the gauge revolution – interviews with Feynman, Glashow, Weinberg etc. etc. Compared to today's pabulum (did you see that abortion by Greene?) they were outstanding shows.

   I also remember "The Ascent of Man" and "America", miniseries on PBS. I think these shaped my whole intellectual outlook way before college. So there was good stuff on the TV back in the day.

   The awful "Cosmos" series was a watershed. Since then it's been mostly downhill for "hard" science.

   -drl

3. **Chris Oakley**
   August 22, 2004

   Maybe that's the advantage of having fewer channels in the U.K.: if the BBC decides that it wants to try to educate you then there are fewer alternatives to switch to. The most prominent science/medicine documentary series was/is a BBC one called "Horizon". This was much the best (the commercial channel ITV had a series called "World in Action" but the brow was significantly lower both in choice of topic & presentation). Horizon programs were and probably still are "must see" for A-level (16-18 yr old) science students. They were generally topical and informative, although were structured like investigative journalism and would not normally provide the level of technical detail that one would find in a "Scientific American" article.

4. **JC**
   August 22, 2004

   Chris,

How common were science type of shows on British television in the 1970's?

I guess where I grew up in north america, I hardly ever saw any science shows when I was kid, largely because my folks didn't have cable TV for a long time and when they finally did get cable TV, they were always watching crap TV and seemed to have very little to no interest in science type of TV shows. The only channel from that time which had science type of shows every once in a while, was mainly the publicly funded PBS affiliate. Even then most of the shows on PBS were crap for the most part too.

The only way I found out about science in those days was mainly from reading Scientific American, which my father had a subscription to and he left them laying around on the coffee table in the living room. Sometimes I would go to the local public library and borrow books about physics or science in general, where most of these books were largely descriptive with very little to no math.

5. **Chris Oakley**
   August 22, 2004

   What sparked your interest in particle physics originally?

   Simple really: the popular science programs on TV. It seemed like a happening area and I liked the idea of it being the most fundamental of sciences. There really was a lot of coverage in the media and the main players (Feynman, Gell Mann, etc.) came across as interesting and entertaining people.

6. **JC**
   August 21, 2004

   Chris,

   What sparked your interest in particle physics originally?

   If I didn't know any better, the 1970's looked like it was the heyday for experimental particle physics and the Standard Model. If I was around your age or Peter's age, my interest would have probably been sparked from seeing the successes of particle physics in those days.

   In my case I came across several Scientific American articles on particle physics when I was in high school. At the time I thought it was fascinating that most of matter and the forces of nature could be explained by a small number of fundamental particles. It sure looked a lot better and more "compact" than the periodic table, which I was learning at the time in my high school science and chemistry classes. Not knowing any better at the time, I thought Feynman diagrams looked really cool and was fascinated by how one could calculate a lot of physics by just writing down a bunch of squiggly looking diagrams. It sure seemed a lot more interesting than the science class experiments I was doing at the time, like masses hanging on springs, measuring pendulums, concave & convex mirrors and lenses, etc …

   In fact in high school, I actually hated math and science for the most part. When I was a freshman in college, I also hated physics! All those freshman and sophomore introductory physics courses seemed so boring and tedious at the time, that I thought about quitting and not returning to college after the term was over. I thought it seemed like a waste of money at the time, in paying tuition for a bunch of boring and tedious classes which I had very little to no interest in. It felt like I was a sucker and/or a glutton for punishment at the time.

   During that summer when I was thinking about not going back to university in the fall, I actually went to a nearby college library and tried to find some books about particle physics and how to do Feynman diagram calculations. (I was bored that summer and didn't have much else to do). Besides reading the first two or three chapters (usually some qualitative discussions of the elementary particles, interactions, and/or hadrons, with very little math) of several graduate level particle physics books, I got lost very quickly afterwards mainly from the mathematics level being way beyond my ability at the time. Though by skipping over most of the math I didn't really understand at the time, I was amazed at how the final answers for many Feynmann diagram calculations looked kind of simple and had close agreement with the quoted experimental data. Not knowing any better at the time, I thought the form of many of those final answers for cross sections and decay rates could be guessed by just naively looking at the dimensional units of the possible quantities involved, and getting the final expressions to have the same units as a cross section or decay rate. At the time I was wondering why it involved a lot of tedious nasty looking math just to eventually get a numerical coefficient, for the final expressions with forms which could otherwise be guessed from dimensional analysis and semi-intuitive arguments.

   With some advice from my parents and ignoring my misgivings and gut feelings at the time about the tedium and boredom of college, I decided to go back to college that fall, hoping that I would one day be able to understand how to do Feynman diagram calculations. It took another few years of undergraduate physics before I was able to understand how Feynmann diagram calculations were actually done.

   Years later I heard about string theory also from reading some Scientific American, and thought the idea looked neat at the time. I guess I fell for the propaganda and hoopla surrounding it at the time, to the point of literally being "converted" overnight on the spot and becoming a "true believer" in string theory. I was definitely quite naive and clueless at the time. I even bought a copy of the Green, Schwarz, and Witten (GSW) book on superstring theory, despite not knowing a thing about string theory. This may sound kind of silly today in hindsight, but at that time I literally thought that GSW's "superstring theory" book was like "the Holy Bible".

7. **Chris Oakley**
   August 21, 2004

   I think that this goes back to Peter's earlier point that in the 1970's elementary particle physics really looked like it was motoring, whereas now it looks like it is sputtering. Brian Greene's efforts to get the public excited about the subject are heroic and commendable but it really would make all the difference if the experimentalists were part of the journey. If I were 25 years younger I would probably be looking to get into molecular biology or computer science and not particle physics.

8. **JC**
   August 21, 2004

   Thomas, Chris,

   I wonder how much the ratio of "genius" to "non-genius" in the population has changed over the years, or whether it's a ratio that remains more or less constant with time. Except maybe in another time, place, and circumstances, the "genius" may not be recognized as easily and/or is squandered and wasted away.

   One ominous example in the 1900-1902 period would be the case of Heinrich Himmler who was born on Oct 7, 1900, and later became the head of the Nazi SS, Gestapo, and was the main architect behind the "final solution" holocaust. Whether this was a satanic-like "genius" for "evil" is debatable, but arguably this could be the classic textbook case of a "genius" that was squandered and wasted away.

   In more recent times, other cases of "genius" being squandered and wasted away would perhaps be the case of hardcore computer hackers who like breaking into computers and/or stealing data, such as Kevin Mitnick or Kevin Poulsen when they were younger.

   If there's less kids going into science and engineering these days, perhaps some of the future "geniuses" will end up in non-science areas like business, law, high finance, etc … instead of physics areas like quantum gravity and string theory.

9. **JC**
   August 19, 2004

   Chris,

   I remember going through several old books and papers on analytic S-Matrix theory from the 1960's, when I was bored one afternoon.

   In one approach, it turned out they took the approach of "extracting" some results from quantum field theory (QFT), and then throwing away the QFT afterwards. At the time it sure seemed like they were "cheating" when they were trying to do analytic S-Matrix theory which didn't believe in QFT, but they were using the very same QFT to "extract" results from!

   I spoke to several older particle theory professors who were around when analytic S-Matrix theory was at its peak heyday during the late 1950's and 60's. They all mentioned that Geoff Chew's "axioms" for the analytic S-Matrix were just "too general" to get any useful results from. Since nobody was really getting any useful results from just looking at Chew's axioms alone, many folks ended up going back to QFT in an attempt to "extract" some useful results, literally as an act of desperation towards the end in the late 1960's. That was probably the breaking point which marked the beginning of the end for analytic S-Matrix theory as a viable framework for particle physics.

   This sort of thing reminds me of the attitude many economists had towards math when economics was first starting to use "advanced math" extensively. At the time, economists had the mentality of using the math to "extract" useful results and then throwing away and "burning" the math afterwards.

   At times I wonder if string theory has reached its "breaking point" yet, and whether there is a single event when could be marked as the "beginning of the end" of string theory as a viable framework for a quantum theory of gravity. If I didn't know any better, the anthropic junk sure looks like it could be something which may mark the "breaking point". The point if and/or when Witten abdicates from string theory would perhaps be the "beginning of the end" for string theory. The earliest possible date I can envision would perhaps be shortly after the LHC is producing data, and there's no supersymmetric partner particles and/or there's no "light Higgs" found in the data.

10. **Chris Oakley**
    August 19, 2004

    I can well believe that Landau might have made that proposal. Of course the whole "S-matrix" phenomenon of the sixties was based on the notion that quantum field theory did not really exist.

    As for renormalization, my views are (hopefully, by now) well known although I might post more detailed stuff on my web site about what I think of "effective field theories with an unknown ultraviolet completion", and why. BTW this is a great phrase, but I think "arbitrary set of rules inspired by but not derived from quantum field theory" is more accurate.

11. **JC**
    August 19, 2004

    Chris,

    Didn't Landau make the proposal of burying quantum field theory forever?

    I think it was in some paper where Landau did some calculation which showed that if you tried to eliminate the scale dependence in the coupling constant of quantum electrodynamics after using the renormalization trick, the only way possible he found was to make the coupling constant zero?

12. **Chris Oakley**
    August 19, 2004

    …*infinity problems which held up progress in quantum field theory for almost 20 years, until Feynman and Schwinger came along with the renormalization "crutch"*.

    It is very likely that banging your head vigorously and repeatedly against a brick wall is likely to lead to brain damage. People were looking to create quantum field theory in the image of quantum mechanics, and it does not seem to have occurred to them that the reason that they were unable to do it was because it was *not possible*!

    Take this, for example:

    $H = H_0 + V$

    This is a tremendous equation for quantum mechanics, but a diabolical one for anything relativistic. If we were being relativistic we ought to write

    $P_\mu = P^0_\mu + V_\mu$

    … but the the idea of a "free" and "interaction" three-momentum seems to be singularly unhelpful, so we carry on with the original equation, using the interaction picture derived from it that is horribly unrelativistic and just block our ears when the mathematical mines start to go off.

    The lesson? Don't get too hung up on formalism. Symmetry and consistency are more important. The formalism can be adjusted to fit.

    IMHO, the same considerations apply to quantising gravity: it could just be that no-one has been able to do this simply because it cannot be done! Formal quantisation simply does not work. What would make much more sense would be to be a little more practical. Do we really need all that much anyway? After all, in the absence of any experimental knowledge about quantum gravity all we require is the classical limit, which need not even be GR – an SR gravity theory that reproduces the experiments would do just as well.

13. **JC**
    August 19, 2004

    Thomas, Chris,

    Perhaps some people's genius becomes forgotten by history largely because they were born in a different time and place, and/or it was squandered and wasted away?

    Maybe if folks like Witten, Polyakov, etc … were born in Germany or Austria around the same time as Pauli, Wigner, Heisenberg, etc … their genius could have been recognized if they worked on the foundations of quantum mechanics during the mid 1920's?

    On the other hand, if folks like Pauli, Heisenberg, Wigner, Dirac, etc … were born around the same time as Witten, Polyakov, Schwarz, Gross, etc … (ie. around the 1940's and 50's), perhaps they would have become just "another face" in the large crowd of particle and/or string theorists during the 1970's and 80's? Maybe the competition in the 70's and 80's was a lot more intense than in the 1920's?

If Hitler was assasinated before 1933 or shortly after he became chancellor of Germany, perhaps Germany would have remained as the “Weimar Republic” well into the 1940’s with no war, no Nuremberg race laws, no holocaust, etc ..? If this would have happened, perhaps there would have been no mass defection of scientists to America, while Germany would have possibly remained the world’s powerhouse in physics and math, as well as no nuclear or hydrogen bombs being built?

If there’s a wholesale abandonment of string theory from Witten abdicating from it, how many folks will still be actively working on it other than perhaps Schwarz, Green, and maybe Lubos Motl and a few other unnamed “string fanatics”?

On a silly note, if Lubos Motl was born in Austria (ie. Czechoslovakia was still a part of Austria in 1901) around the same time as Pauli, Dirac, Wigner, etc … perhaps he would have became a “quantum theory fanatic”, or even a “quantum field theory fanatic” despite all the infinity problems which held up progress in quantum field theory for almost 20 years, until Feynman and Schwinger came along with the renormalization “crutch”. In this case his “quantum fanaticism” would have largely been right for most of the rest of his life.

14. **Chris Oakley**
August 19, 2004

To be precise –

Pauli: born 24 April 1900
Fermi: born 29 September 1901
Heisenberg: born 5 December 1901
Dirac: born 8 August 1902
Wigner: born 17 November 1902

I saw Dirac in person once, in 1981, where he gave a talk at Edinburgh University while I was at a summer school there. He wrote down his equation, in components, using alphas and betas – no gammas, of course (you can’t teach an old dog new tricks) and talked about how he arrived at this equation through considerations of beauty and symmetry. Considering the bluntness of some of the things he is famous for saying, he struck me as a delightful man. Wigner I saw at a conference on Group Theory at ICTP in Trieste in 1983, but did not speak to him as I could not think of a particularly intelligent question to ask or intelligent comment to make.

Thus Quantum Mechanics, being developed between 1925 and 1928 by three of these men, plus the relative “old man” Schroedinger (he was in his late thirties) was mostly a children’s crusade. There is no denying their brilliance, but nonetheless this still does say to me that (i) they were lucky to be born at this time and (ii) it is time that our society acknowledged that young people are, or at least should be, the driving force behind frontier research.

15. **Thomas Larsson**
August 19, 2004

JC,

Re people who are born at the right time. Arguably almost half of the top ten theorists of the twentieth century (Dirac, Heisenberg, Pauli, Fermi, with runners-up like Wigner and von Neumann) were born in 1901 or 1902. Nobody doubts of course that they were among the smartest people of their generation, but anyway. What are the odds that such brilliance would be concentrated to 2% of the century?

16. **Chris Oakley**
August 18, 2004

On second thoughts the scepticism/credulity scale ought to be dimensionless (a bit like probability). We’ll call the quantity C (=Credulity).

C = 0 – You believe nothing
C = 1 – You believe everything

These are obviously the limits to the allowed values.

However, as a matter of convenience in representing extremes of scepticism and credulity without having to use very small numbers or numbers very close to one, one could define a transformation

C = atan(WM)/pi + 1/2

The quantity WM (the Woit-Motl index) then is unbounded. Negative values are known as “Woit” values and positive values are known as “Motl” values.

17. **D R Lunsford**
August 18, 2004

Leading to “Boil’s Law”

WM = const

so a nanoMotl is the same thing as a gigaWoit.

-drl

18. **JC**
August 18, 2004

The “Motl” becoming the unit for scientific fanaticism!

1000 Motls = 1 kiloMotl

😉

19. **Chris Oakley**
August 18, 2004

Yes – the “Woit” could be a unit of scientific scepticism

1,000 Woits = 1 KiloWoit

20. **D R Lunsford**
August 18, 2004

JC,

IOW the times make the men? This is the “misanthropic principle” 🙂

I don’t think we should project the failures of current efforts onto the past. In any case we don’t need even 1 more Pauli – at this point we need 1000 Woits.

21. **JC**
August 18, 2004

Chris,

Perhaps there’s a lot to be said that being in the right place at the right time, makes a huge difference. If somebody like Sir Issac Newton was born a hundred years earlier, perhaps today all the physics and math with Newton’s “name” would have somebody else’s name in place of Newton. I suspect the same thing if Einstein, Schroedinger , Heisenberg, Dirac, Pauli, etc … were born in a different time and place. If Einstein never wrote the letter to president Franklin D. Roosevelt and/or Hitler created a nuclear bomb before the Americans, the world of physics may very have become “Nazified” with the names Einstein, Pauli, etc … purged away from physics history in a Nazi revisionistic rewrite of physics history?

Just to be silly, if Lubos Motl was born 100 years earlier perhaps he would have been an Austrian “aether” fanatic?

22. **D R Lunsford**
August 18, 2004

Chris –

Much more important to the US gov’t in that time frame were radar, sonar, and aeronautical technology. The US still imagined it had the atomic genic bottled and there were no plans or funding as yet for the “super”. That needed a few more years to develop.

-drl

23. **Chris Oakley**
August 18, 2004

JC,

If you want my honest opinion, the thing that caused the increase in government funding after WW2 was the fact that people were impressed by the achievements of physicists during the war. My apologies to any Japanese people who might be reading this who have some connection to the horrendous and unforgivable events of August 1945, but however destructive this episode may have been, it clearly impressed everyone, turning the likes of Oppenheimer, Fermi and Feynman into minor celebrities. I seriously doubt that governments would have been prepared to commit billions of dollars to particle physics twenty years later had not these events taken place. I know that there have been a few practical things that have come out of the study, but it would be foolish to pretend that these would justify such enormous expenditure.

My earlier point, although somewhat flippantly made, was not about government funding *per se*, but about how the money is spent. It is a very simple truth that one is more mentally agile when one is younger and I maintain that this agility would generally be better deployed in doing research in the ways that one sees fit rather than in devising especially ingenious ways of grovelling to the establishment. Having a more rapid turnover of research staff, however it is achieved, would help a lot in preventing ossification. Power and influence needs to be shifted to younger people. I do not have all the answers about *how* this can be done, but it certainly needs to be done in some way.

24. **JC**
August 18, 2004

Chris,

The only other thing I can think of if there’s no tenure for professors, would perhaps be a lot more competition amongst folks fighting for various lecturer/researcher jobs. The immedidate consequence perhaps would be a lot more “resume padding” type of research papers being produced.

I think it would also be highly dependent on how the selection process for new faculty worked. If the selection committee consisted of people who were around for a long time (ie. after several consecutive re-appointments), then these “old timers” may have a conflict of interest where they would prefer to hire a crappy or crackpot researcher who wouldn’t be able to compete against them, and hence less of a threat to the old timers’ job re-appointment prospects. I can’t really see an easy way out of this conflict of interest, unless there’s some sort of “outside” independent selection committee making the selections, with no conflicts of interest.

It seems like when many folks get tenure, some slow down and don’t publish as many papers. In fact some folks seem like they fell off a cliff after getting tenure, and hardly published anything afterwards. Seems like many folks have less motivation afterwards and/or have different priorities, when they are not “under the gun” any longer after getting tenure. Some folks seem like they “burned out” by the time they got tenure, and hardly produced anything of significance afterwards.

Perhaps it’s not so surprising as to why there’s some tenured folks who end up as “deadwood”, who look like they had all the passion and soul beaten out of them. I knew many folks over the years who were computer whiz kids in the past (ie. programming stuff since they were 12 years old) who ended up going into the computer/hi-tech profession as adults. After a many years, a large number of them seemed to really dislike and started to really hate computers. It seems like for many “dream job” type of professions, a lot of folks become “deadwood” after many years where they have less interest and very little to no passion left for the job, while just “going through the motions” to get things done. (ie. “dream job” professions like music, sports, acting, writing, etc …). Maybe this is a sign of job “burnout” for many folks?

25. **JC**
August 18, 2004

Chris,

Do you think progress in particle physics and quantum field theory would have progressed as fast as it did over the last 50+ years (ie. after Sputnik), if there was no tenure and/or very little to no government funding for physics?

Looking at the pre world war 2 generation, there didn’t seem to much extensive government funding of physics at the time either in America or Europe. It seems like many universities were focused more around teaching than the heavy research focus after Sputnik.

When the center of extensive physics activies was still in Germany and central Europe before Hitler took power, the Privatdozent (ie. sort of like a postdoc with some assistant professor duties) were frequently unpaid academic jobs, where they usually had to find other sources of income like teaching courses or family support. It seems like the generation of quantum theory pioneers in the 1920's could come up with groundbreaking research work, with many folks being an unpaid or a lowly paid Privatdozent with very little to no direct government funding. At times I wonder if the German Privatdozen system was implemented in America along with no post-war boom in science funding after world war 2, would particle physics have progressed as fast as it did?

26. **Thomas Larsson**
August 18, 2004

I would say this though: I went to a talk by Chris Isham about 20 years ago where he wrote down the algebra of GL(4,R) and the transformation law of a vector in the fundamental representation. He then announced that he had just quantised gravity. I could not see it, but maybe there were fifty steps missing that were obvious only to him.

It is the full diffeomorphism group – general covariance – that is relevant to general relativity. GL(4,R) is a subgroup, whose algebra is generated by vector fields of the form x^i d/dx^j. Many properties can be deduced from this subgroup, but not all; e.g., GL(4,R) cannot distinguish a connection from a tensor field of type (1,2), symmetric in the lower indices.

I don't understand the import of the Virasaro algebras, or the Kac-Moody algebras. I don't think that I'm incapable of learning this, but I can't find any coherent presentation of why these things are physically important and interesting.

The physically most important application, in the sense that it makes predictions that are in agreement with observation, is in 2D statistical mechanics. Lowest-weight irreps of the Virasoro algebra with L_0 eigenvalue = h (i.e. L_0 |vac> = h |vac>) correspond to fields whose correlation functions decay as G(x,y) ~ |x-y|^-2h. There are standard ways to relate these h's to other critical exponents, which have been intensely investigated, both theoretically and experimentally. The discrete spectrum of critical exponents predicted by CFT has been perfectly confirmed. If you compare with exact solutions of integrable lattice models, there are *infinitely* many numbers which agree *exactly*.

A good online presentation was written by Ginsparg.

27. **Peter**
August 17, 2004

Thanks for the correction about the circumstances under which Greene and Schwarz sent Witten their paper. I was hoping if I had any of this wrong someone who knew more about what happened at Aspen would correct it, and said so in the posting. If I've gotten anything else wrong about this, I'd be interested to know it.

28. **Jeff Harvey**
August 17, 2004

The statement that Green and Schwarz knew they had to get Witten interested and so sent their paper to him is simply false. I was at Princeton when Witten heard about their work, through Larry Yaffe who was at the Aspen Center for Physics during the summer of '84. After hearing about anomaly cancellation, Witten asked G&S for a copy of their paper by FedEx. I also disagree strongly with the statement that people were not impressed by this work independently of Witten. Dislike string theory all you want, but please don't try to rewrite history.

29. **JC**
August 17, 2004

Chris,

At this point I'll remain anonymous. I can't have any of my colleagues (both present and former) knowing that I read and post to this blog.

30. **Chris Oakley**
August 17, 2004

JC,

How do we know that you are not an "insider" making maximum use of your anonymity here (Sheldon Glashow, maybe?)

Incidentally, I would dearly love it if low-ranking academic staff did not feel constrained by career considerations in their choice of research. My dream is a Utopia like the world of "Logan's Run" (great film, by the way, apart from that annoying silver robot) where everyone over the age of thirty is eliminated. People would not then have to worry about getting a tenured job because there *wouldn't be* any tenured jobs. They would be forced to leave and do something useful with their lives instead.

31. **JC**
August 17, 2004

Chris,

Perhaps folks who are still "insiders" in academic physics/math, are more likely to say the "party line"?

Repeating the same "status quo" dogma over and over again like a broken record, hoping one day it will eventually be perceived as "the truth". It seems like in any large cohesive group of people, conformity to a particular "ideology" is the biggest factor which keeps it together.

On the other hand, former "insiders" and/or "outsiders" are more likely to "speak their minds" with very little to no self-censorship?

You just have to read books written by former politicians after when they were ousted, in how they show their displeasure at how things were done and/or the gross incompetence of the folks running the government. Perfect example of this is former US treasury secretary Paul O'Neill's memoirs of his two years in the Bush administration, after he was fired at the end of 2002. His book was talking about all the stupidity and incompetence that went on behind closed doors with Bush and his cabinet. I would be almost willing to bet that one of the big reasons why US defence secretary Donald Rumsfeld hasn't been fired yet for the Iraqi postwar disasters, is largely because the Bush administration doesn't want Rumsfeld yet to write his memoirs and/or to go on television criticising Bush and his cabinet, in a style similar to the memoirs of former US defense secretary Robert McNamara (who oversaw the Bay of Pigs, and Vietnam War disasters), especially before the upcoming presidential elections this November.

I can imagine for “insider” folks who have very little to no political power in academia (ie. grad students, postdocs, faculty who don’t have tenure yet, etc …), they don’t want to say anything which may compromise their future prospects in academia. For people who are no longer “insiders” or who were never “insiders” at all, there probably won’t be any major consequences for yelling “the emperor has no clothes on” in public, or being branded as a heretic or traitor by their former colleagues.

Perhaps there’s a lot of truth to the Machiavellian notion of “keep your friends close, but keep your enemies even closer to you”. Former “insiders” and/or “outsiders” can become loose cannons.

32. **D R Lunsford**
August 17, 2004

I’m unemployed and have been for more than a year – all my posts are out-of-pocket 🙂

Yes, that was exactly what he was doing as far as I can tell. But physics seems to be post-modernized, where simply saying “there exists an N-bein formulation” is not good enough or important-sounding enough.

-drl

33. **Chris Oakley**
August 17, 2004

Danny,

I am sorry, but once again I have to plead ignorance on all counts. This sounds a lot like treating gravity as a gauge theory with a gauge group of GL(4,R) – similar to the vierbein formalism – but that is as far as I go.

By the by, how many of us commentators are actually professional (as opposed to wannabe) physicists/mathematicians?

Me: Programmer/quantitative analyst working for a Japanese bank in London.

You: Software developer working in the U.S.

JC: Obviously an old-timer like us. Background in particle physics but otherwise unidentified – something to do with the Second Coming, perhaps?

Thomas Larsson: Working for a Swedish company that makes motors, by the look of it, but obviously with a very strong mathematical/physics background.

And why do our employers allow us to spend a significant portion of the day doing stuff that is clearly not work related?

34. **D R Lunsford**
August 17, 2004

Chris, check out this post from SPR:

A thought just occured it me. Isn’t it possible to eliminate the metric field g in general relativity in a simple way? Just introduce a GL(4,R) connection with the tangent bundle TM acted upon by GL(4,R) and insist every point has at most an SO(3,1) holonomy. For generic connections, this would determine g up to a global rescaling factor. In fact, since we’re making restrictions on the holonomy, this formulation would suggest we work directly with Wilson loops and lines instead. Also, generic connections would give rise to torsion.

..stifles cough..

Perhaps you should have paid attention to Isham, you blighter!

(Serious note: Math is dangerous in the wrong hands. Don’t do this at home. Save it for the office.)

-drl

35. **Chris Oakley**
August 17, 2004

Thomas,

At the moment I can only manage silence. The scorn will have to wait until I have learned more about Virasoro algebras.

I would say this though: I went to a talk by Chris Isham about 20 years ago where he wrote down the algebra of GL(4,R) and the transformation law of a vector in the fundamental representation. He then announced that he had just quantised gravity. I could not see it, but maybe there were fifty steps missing that were obvious only to him.

36. **D R Lunsford**
August 17, 2004

I don’t understand the import of the Virasaro algebras, or the Kac-Moody algebras. I don’t think that I’m incapable of learning this, but I can’t find any coherent presentation of why these things are physically important and interesting.

I would not be too concerned over silence out of SPR – it’s mostly struggling students I think. I have always enjoyed your posts, when I could understand them.

-drl

37. **Thomas Larsson**
August 17, 2004

Tell us more.

OK, although I have become reluctant to do so. I have tried to make the point on spr for the past three years, and so far only met with silence and scorn.

We know that the groups of diffeomorphisms and gauge transformations play an important role in general relativity and the standard model, respectively. We also know that the representations that are relevant in quantum theory are projective and of lowest-energy type. So unification of the symmetry principles would amount to the construction of projective, lowest-energy representations of the diffeomorphism and gauge groups.

On the Lie algebra level, this means that one must generalize the Virasoro and affine Kac-Moody algebras to several dimensions, and construct interesting classes of representations. On the surface this looks impossible, in view of two no-go theorems:

1. The diffeomorphism algebra has no central extensions except in 1D.

2. In field theory, there are no diff anomalies in 4D.

These two theorems are correct, but the axioms are unnecessarily strong; the keywords are "central" and "in field theory".

The standard objection is that diffeomorphisms and gauge transformations are *gauge symmetries*, which are not genuine symmetries but rather redundancies of the description. Perhaps so, but I believe that in order to understand what is described, it helps to understand the description. Moreover, even if the total diff anomaly should cancel (which I don't believe), subsystems must have a non-zero anomaly. Ironically, the prototype model here is first-quantized string theory, which can be regarded as quantum gravity in 2D. The ghost sector has central charge c = -26, so the requirement that the total central charge vanishes leads to bosonic strings living in 26D. Hence the coordinate subsystem has a non-zero central charge c = 26.

Alas, unification of the symmetry principles is not the same thing as unification of the theories themselves, and I am stuck at this point. Nevertheless, I believe that the study of mathematical objects which naturally arise in experimentally proven physics has a physical value, even if no specific predictions have yet come out of it. At any rate, what can you demand from a theory which is 20,000 man-years younger than string theory?

Here are some references. The last one is an attempt (and only that) to apply the formalism to physics.

38. **JC**
August 17, 2004

I always wondered when did this "mentality" of adding in zillions of new particles and forces into a theory, become an "acceptable" practice in particle theory research?

Back in the days of Pauli, he jokingly thought that creating a new particle (the neutrino) which could not be observed, was the ultimate "cardinal sin" in physics.

In other physics fields outside of particle theory, I get the sense that objects and/or entities which have very little to no experimental basis are generally NOT taken seriously at all. Folks in many of these other physics fields seem to be a lot more skeptical of speculative ideas and theories, compared to particle and gravity folks.

39. **Chris Oakley**
August 17, 2004

Having discovered the correct unification of the symmetry principles underlying GR and QM, I think that I have strong reason for this position.

Tell us more.

40. **Thomas Larsson**
August 17, 2004

JC,

Going back to the original topic of this thread, what are your thoughts on what would have happened if Witten had never advocated nor worked on string theory in the first place. (This is sort of a "what if" scenario in an alternate world).
…
One non-obvious scenario I can think of in this "alternate world", would be perhaps a faster decline of particle theory due to a lack of many interesting problems to work on.

Maybe people would be taking general relativity and the standard model more seriously. Not only phenomenologically, but as something which might be quite close to the final answer. After all, there is no clear experimental evidence that anything more is needed. For sure, there are a few question marks, like dark matter and dark energy, but no clearcut disagreement with experiments. Besides, the standard model have shown an extraordinary ability to mend its cracks before.

There are of course two strong theoretical reasons against this idea: GR and QM are mutually inconsistent, and the SM is somewhat ugly, with 25 free parameters (used to be 19) and a totally ad hoc gauge group. This indicates (to me) that we need a chunk of new mathematics, which would make the combination of GR and QM consistent and beautify the SM, rather that loads of new physics for which there is zero experimental support. Having discovered the correct unification of the symmetry principles underlying GR and QM, I think that I have strong reason for this position.

The standard objection is of course that people thought that the end of physics was at sight already a century ago. But the situation was really different then, with many unexplained phenomena already at low energies. The impressive experimental agreement of GR and SM is true magic and mystery.

– Perhaps nobody would have even heard the word "GUT" (grand unified theory) being used after the experimental proton decay result ruled out SU(5)?

Other GUTs, especially SO(10), were quite popular already around 1980.

41. **Chris Oakley**
August 17, 2004

What would have happened if Witten had never advocated nor worked on string theory in the first place.

I think that in this scenario the Berlin Wall would never have come down, and Lubos Motl would have been a Czech Freedom Fighter. He would have been captured by now and would be doing Supergravity calculations in his prison cell to pass the time, no doubt advocating, with his familiar unwavering certainty, that Supergravity is the language in which God wrote the world.

One non-obvious scenario I can think of in this "alternate world", would be perhaps a faster decline of particle theory due to a lack of many interesting problems to work on.

There is no shortage of interesting problems to work on, and I doubt that there will ever be. But if particle physicists are so content to break the basic rules of mathematics then *of course* they will soon end up with something that is not worth bothering with.

42. **D R Lunsford**
August 17, 2004

Peter – a friend told me that the really hard part of PhD Princeton was making and firing the minature brass cannon 🙂

BTW I asked my advisor in 1984 what he thought of string theory. He was in a position to know.

"It's horseshit."

"I agree."

That was the extent of our discussion of string theory 🙂

43. **JC**
August 16, 2004

Going back to the original topic of this thread, what are your thoughts on what would have happened if Witten had never advocated nor worked on string theory in the first place. (This is sort of a "what if" scenario in an alternate world).

The obvious answer would be only a small minority of folks around John Schwarz and Michael Green working on string theory. A silly case would be Lubos Motl never being a string fanatic, but perhaps being a fanatic in something else.

One non-obvious scenario I can think of in this "alternate world", would be perhaps a faster decline of particle theory due to a lack of many interesting problems to work on.

– SUSY possibly could have been a non-mainstream topic in particle theory, if string theory wasn't there to give support to its advocates?

– The non-renormalizable 2-loop pure quantum gravity result of Sagnotti in 1985, along with the non-renormalizable divergences in higher loop supergravity could have brought a lot of "quantum gravity" research to an eventual flatlining? Perhaps supergravity would have then faded away quickly into the dustbins of physics history shortly thereafter as another failed attempt at a "unified field theory"?

– Perhaps nobody would have even heard the word "GUT" (grand unified theory) being used after the experimental proton decay result ruled out SU(5)? There would be very little motivation to look at more complicated GUTs, if there were no string theory results of SO(32) or E_8 x E_8 gauge groups to motivate further inquiries into the GUTs which were the low energy effective theories from string theory?

Can anybody else think of anything that would have either faded away and/or would have never been that popular if string theory was never popular in the first place?

On the surface, it seemed like string theory opened up a huge "treasure trove" of new exciting problems to work on at the time, while stuff like GUTs, supergravity, etc … were falling out of favor.

44. **JC**
August 16, 2004

The book "Disciplined Minds" reads like a semi-serious study of "Dilbert-ism", with some reactionary "Marxist" sounding overtones.

45. **Thomas Paine**
August 16, 2004

Sorry, forgot to give the URL of the book mentioned in the previous post:

http://disciplined-minds.com/

46.
August 16, 2004

Since the discussion here steered towards the qualification exams in Physics, thought I would recommend the book "Disciplined Minds", by Jeff Schmidt, who got his Ph.D. in physics from UC Irvine. He devotes considerable number of pages to the physics quals in the states. Has some thoughts similar to ones discussed here.

47. **Thomas Larsson**
August 16, 2004

I can boast that I made an attempt to learn string theory before the revolution. In the summer of 1984, I spent some time in the library doing leasurly reading, trying to learn about things that seemed cool. Among other things, I spent some time with John Schwartz' 1982 Physics Report. Alas, this stuff was way above my head at the time. Besides, I was specializing in statistical physics, and particle physics and gravity were only side interests.

Instead I spent most of the summer reading Mandelbrot's Fractal geometry of nature, which was at a more appropriate level. What I didn't realize at the time was that many interesting fractal dimensions can be computed with string theory methods. The catch is that it only works for planar graphs, essentially because you can regard the plane as a string worldsheet.

48. **Chris Oakley**
August 15, 2004

Maybe Mrs. Thatcher got to hear of Salam's comment (as you can imagine, a complete anathema to a grocer's daughter) as 1984 was about the time that she drastically reorganised the way in which the UK contributes to CERN, treating it as a standard part of the science budget rather than a special case.

49. **Thomas Larsson**
August 15, 2004

I remember that Weinberg was in Stockholm in December 1984 (as a former Nobel laureate, he has a permanent invitation to the Nobel party, and he usually shows up when one of his old buddies gets the Prize, which makes him a rather frequent visitor; in 1984 it was Rubbia and van der Meer). Anyway, I remember him predicting that one of the young bright string stars would win the Prize in 1991. Well, 1991 came and went, and the leading string theorists are perhaps still bright but definitely no longer young, and their Nobel prizes seem more distant than ever.

Btw., Salam was also in the panel, and he said something which struck me as one of the most foolish things I ever heard. He said that society should be grateful to its big spenders, like experimental particle physics, because as society becomes richer it will run out of things to spend its wealth upon. I'm still waiting for a politician to complain about resources being too plentiful.

50. **Maynard Handley**
August 14, 2004

> Chris,
>
> Seems a lot of the sociology behind physics research is along the lines of "monkey see, monkey do" or a "pied piper" luring away kids. Arguably one can see that in many other activities in the world, as in the "copycat" syndrome when something very popular and/or profitable comes up.
>
> At times I wonder how much of the string and particle community is exactly that of "monkey see Witten's work, monkey tries to do Witten's work".

……………………………

Especially pertinent to this is this
http://www.johnkay.com/society/348
which reviews a new book by J K Galbraith on the nature of conventional wisdom in finance.
Physics likes to believe that its practitioners operate outside the rules of normal human psychology and sociology, something that I've not noticed as especially true.

51. **Chris Oakley**
August 14, 2004

JC,

I think that you've grasped my essential point. This is not to say that there should be *no* bookwork, it is just that the majority of the marks should be for the problem, which it should not be possible to answer unless one has actually *understood* the material. Call them silly if you like, but the examples you give are exactly the kind of thing I had in mind.

52. **JC**
August 14, 2004

Chris,

If you were the professor making up some of these particle theory or gravity exam papers for the tripos III, what sort of trick problems would you put on it that would require some ingenuity and/or lateral thinking (which are not of the "$500 parrot" or "regurgitation" variety)?

If I didn't know any better, the only "trick" questions I can think of offhand would be mostly hypothetical "what if" types of problems. Perhaps silly ones like:

– "Imagine if the gluon is not a gauge field in qcd, but is really a scalar field with an SU(2) symmetry in the scalar fields. (a) Write down a possible renormalizable "scalar qcd" Lagrangian and the Feynman rules from it. (b) Calculate various tree level quark-antiquark scattering amplitudes. etc … etc …"

– "Imagine if parity is really conserved in the weak interactions. (a) How would this change the V-A interaction picture? etc … etc …"

– "Imagine if in the Standard Model, the up, down, strange & charm quarks all had the same identical non-zero mass, while the top & bottom quarks have the same identical mass but heavier than the masses of all the other quarks. (a) Are there any new symmetries, which are not present in the regular Standard Model? (b) Write down the tree level electron + positron –> quark + anti-quark scattering amplitude. (Electron mass can be taken as "small" relative to quark masses). etc … etc …"

– "Imagine if QCD had a gauge group of SU(7) and 23 vertical particle families, instead of the normal QCD SU(3) gauge group and 3 generations of vertical particle familes in the Standard Model. (a) Write down the Feynman rules. (b) What is the new beta function, and how does it compare to the normal QCD Standard Model case? etc … etc …"

– "Imagine if the electroweak gauge group is really U(1)xSU(3) instead of U(1)xSU(2). (a) Is there a Higgs breaking pattern which produces a massless photon? (b) If there is a massless photon in part a, what are the other gauge bosons? If there is no massless photon, what are the gauge bosons anyways after Higgs breaking? etc … etc …"

I just made these up out of thin air. Not really all that brilliant or even that insightful, when all I did was just do things like change the group structure and/or properties of various particles.

Anybody else have a better criteria for particle physics and/or gravity problems which require some ingenuity and/or lateral thinking, besides just copying problems out of some old long forgotten research papers from many years ago?

53. **abc**
August 14, 2004

Recent princeton math quals are here: http://www.math.princeton.edu/graduate/generals/

A click on a name gives a summary of that session. Some are quite fun to read actually: "Can you give a heuristic proof of Fermat's Last Theorem? — this last one was asked by Aizenman, the physicist!! Wiles and Faltings seemed only slightly amused." 😉

Reading the begining of David Nadler's one, it looks like the level did go down a bit as compared to some decades ago…

Harvard is here: http://www.math.harvard.edu/graduate/quals/

I couldn't find the physics ones.

54. **Chris Oakley**
August 14, 2004

Hello JC,

If you do mathematics research (including mathematical branches of theoretical physics) at Cambridge then getting a "distinction" in their part 3 exam is more or less a requirement. In my year there were about 56 of us taking part 3 with "applied" options and about the same number taking the "pure" options. Of the "applied" group, about 13 got distinctions, although not all of them stayed to do PhDs in Cambridge. The more informal structure you discuss with assignments, etc. was not possible because of the competition involved. Having said that, a small part of the course was an "essay" (mine was on SU(5)), but most of the marks were based on 15 hours in the exam room. Outside of Cambridge, part 3 is largely ignored. The first year of a graduate course achieves the same purpose elsewhere and arguably more efficiently as without the need to photographically memorise lecture notes one can concentrate on understanding rather than rote learning. I remember being at interview at Sussex University and Tony Leggett telling me that Cambridge expected the rest of the nation to await the results of the part 3 exams before awarding research places, but their time scales were such that they were unable and unwilling to do this.

One advantage of a parrot test is that it is easier for the examiners. If you pose a question that can only be correctly answered if the student has understood the material, as opposed to having just memorised his/her lecture notes, then fifty students will give fifty widely different answers and a lot of time will be spent by the examiner chasing blind alleys in the responses, just to make sure that they *really were* blind alleys.

The other problem is that the more advanced the course, the smaller the gap between examiner and student, and therefore the smaller the right of the examiner to judge.

Cambridge is cynical about this: the message is just this – doing well in our memory test is a necessary hurdle and if you don't like it, then just go elsewhere.

BTW: I am not sure I agree with the point about there being a limited number of bite-size questions one can ask in a graduate exam. It may just be that more ingenuity/lateral thinking is required.

55. **JC**
August 13, 2004

Peter,

How recent and widespread has it been for math departments to move away from the comprehensive/preliminary exams tradition, to just students passing a certain number of courses? Are there any particular strong reasons for this change?

Over the years, I remember overhearing several older physics professors talking about how even the Princeton and Harvard comprehensive/preliminary exams for PhD students, have been getting "watered down" and "easier" or "less demanding" over the years. Has this sort of thing been happening too over the years in math PhD programs?

I remember several professors I knew who did their math PhDs at Harvard in the 60's and early 70's. They all mentioned that the math comprehensive/preliminary exams at the time were really demanding and "killer". (Whether they were exaggerating things deliberately, I don't know). They said that it was common for many students to quit grad school by the time they completely passed all of their exams, largely due to reasons like burnout and/or a subsequent loss of interest in math grad school. They thought that it was the math department's way of weeding out as many students as soon as possible, and that the folks who didn't flunk out or quit were the "cream of the crop".

August 13, 2004

Chris,

Was there any purpose and/or advantage in doing the tripos III exams? Did the doctorate program at Cambridge or other British universities require it as a prerequisite? Was there a thesis and defense required for the tripos III?

On the surface, for stuff like quantum field theory, particle theory, general relativity, etc … it seems like it would be more practical if the course material was done as assignments and perhaps a final take-home exam and/or an oral exam. Except for the more "trivial" quantum field theory and particle theory problems, there doesn't seem to be many "insightful" problems that are doable in a timed 3 or 4 hour examination setting (ie. problems that are more insightful than the "regurgitation" or "$500 parrot" variety).

I remember in one graduate course I took which covered things like scattering theory, second quantization of the Maxwell field, Dirac equation, etc … (the sort of stuff covered in Sakurai's "advanced quantum mechanics" book), we were given a take-home exam which had one really long nasty calculation to do. It turned out it took most of us around 40-50 pages to do this calculation from start to finish, for which we were given a week to finish it. The professor didn't think a timed 3 or 4 hour exam format was practical for this particular course. All other courses I took afterwards like quantum field theory, particle theory, supersymmetry, Lie group theory, etc … were mostly just assignments and sometimes an oral exam or presentation. In fact many of the course assignments were just "optional" and the professor frequently didn't even care whether anybody handed them in or even did any of them. A few courses didn't even have any assignments or exams. At that level the professors just assumed the students had enough self-motivation to figure things out on their own, and didn't feel that it was worth their time to make up assignments for the students.

57. **Chris Oakley**
August 13, 2004

Part 3 was the closest to an "arts" exam in a science subject that I have ever experienced.

I.e. mostly short questions, which required long answers which were entirely bookwork.

E.g. Q. 2 of "Advanced Quantum Field Theory", 1981

"Explain how the Higgs mechanism works in the Salam-Weinberg model, including a brief discussion of the physical motivation for the structure of the symmetry in the model."

You can give a "perfect" answer to this just by memorising your lecture notes, and that is what I think they wanted you to do. A $500 parrot (see below) would be able to do this.

I chose to actually digest the information and produce an answer which may or may not have corresponded to my lecture notes. Maybe that is why I did not do especially well.

58. **JC**
August 13, 2004

I came across Cambridge's web site that has old copies of the mathematics tripos III exams.

http://www.maths.cam.ac.uk/ppa/PartIIIyy.html
http://www.maths.cam.ac.uk/ppa/

The quantum field theory and particle physics exam papers look like they're just generic problems almost straight out of field theory books like Peskin & Schroeder or Ryder, and particle physics books like Griffiths or Halzen & Martin. The general relativity and comology exams look like they're just generic problems out of various books like Weinberg, Wald, etc … and other GR and cosmology textbooks.

To top it off, there's even exam papers for supersymmetry and string theory! It looks like they aren't much more than the sort of problems and calculations straight out of the Polchinski and Wess & Bagger textbooks.

Though if I was writing any of these relativity and/or particle theory related tripos III exams today, I think it would be a matter of me being able to write out the solutions as fast as I can in 3 or 4 hours. Whether or not I (or anybody else) actually learned anything, is another question.

I've always noticed over the years that folks doing very well on physics and/or math exams, has very little correlation to their understading of the subject in general. I knew one guy that did very well in all his undergrad and masters level math and physics courses, but it turned out he was good at memorizing many solutions and guessing at answers, but not really understanding what he was doing. When he started doing research, he literally slammed into a wall and didn't know what to do, like a "deer in the headlights". He ended up dropping out of grad school without even starting on any research projects.

59. **Peter**
August 13, 2004

I don't know much about what is going on in physics departments these days, but the math department here has moved somewhat away from this kind of system towards one where the students just have a pass a certain number of grad courses.

When you look at exams of this kind, you realize that most physics problems are either basically trivial and can be solved in a couple lines, or quite difficult and would require several days of work to solve correctly. There's only a limited number of non-trivial problems that can be solved in a half-hour or so, these end up being used over and over again, often creatively dressed up to look different.

60. **JC**
August 13, 2004

Peter,

Sounds like the same sort of comprehensive exams I remember having to write in graduate school.

Years later I came across several books that were a compilation of problems from exams of this sort: one from was University of Chicago, another was from Princeton, and two additional books looked like they were from Stony Brook. There was a further series of books that looked like they were compiled in China, from many graduate level comprehensive/preliminary exams from many American physics PhD programs.

Over the years I saw many other physics comprehensive/preliminary exams of this sort from many other universities. It seems like many of these exams (even recent ones from Princeton), were recycling many of these problems every 15-20 years. Not too many really "original" looking problems that stood out over the years.

I always wondered what the origins of these sorts of exams are, and whether they are still just a "custom" that is done to this very day. Several physics PhD programs don't even have these exams anymore! Only other reason I can think of for them still being done today, is as an easy way of weeding out the weaker and/or lazy students.

I wonder if these sorts of exams are also commonly done in physics graduate programs overseas, say in Britain, Japan, and continental europe. One case I can think offhand would be the notorious series of Landau exams which Laudau used as a prerequisite for entry into his research group. Another set of exams that looked similar on the surface to the american preliminary/comprehensive exams, would perhaps be the "tripos" series of exams at Cambridge. Anybody know more about these Cambridge "tripos" exams, and how they compare to the comprehensive/preliminary exams done in American universities?

61. **Peter**
August 13, 2004

Actually a book has been published containing many of the problems from these exams, on Amazon you can even see the table of contents. It is called "Princeton Problems in Physics"

From what I remember, the topics covered on the prelims were mechanics, EM, quantum mechanics and stat. mech., at the level of a standard first year graduate course. The generals covered solid-state physics, special and general relativity, nuclear physics, particle physics and atomic physics. No QFT. These were exams everyone had to take, both experimentalists and theorists, so they weren't heavily theoretical.

62. **JC**
August 13, 2004

Peter,

What exactly was covered in those preliminary and general exams that physics grad student had to pass in their first and second years at Princeton? Would it be stuff at the level (or slightly higher) of Jackson (E&M), Goldstein (classical mechanics), Merzbacher and/or Sakurai (quantum mechanics), etc …? Was anything like quantum field theory covered (ie. at the level of Peskin & Schroeder, Ramond, and/or Weinberg's books)?

63. **Peter**
August 13, 2004

I don't know how much physics Witten took as an undergrad at Brandeis, but he majored in history and minored in linguistics. His father, Louis Witten is also a physicist, does general relativity, so he probably learned some physics early on. After Brandeis he seems to have spent a little time as a grad student in economics at Wisconsin, and worked on McGovern's 1972 presidential campaign. He enrolled at Princeton in the applied math program, which allows you to work in many different departments, then ended up shifting over to physics.

Princeton has a very serious set of preliminary and general exams that grad students have to pass in their first and second year. I certainly learned a lot of physics studying to pass those exams, and I'll bet Witten did too.

Up until the whole string theory thing, it's really clear why Witten was so respected. His papers are marvels of clarity compared to most people's, and many of them contain remarkable insights into the still mysterious problems of how to understand QFT non-perturbatively. There's no mystery at all about why many physicists and mathematicians think so highly of him, his intellectual accomplishments are just huge, even if they are not to everyone's taste. His impact on mathematics has also been huge, he richly deserves the Fields medal he got.

One sad thing about the dominance of string theory is that it has so overshadowed his best work. Within string theory he has done quite a lot, but you could argue that others have done more important work there than him (Green, Schwarz, Polchinski, Maldacena).

64. **Chris Oakley**
August 13, 2004

A typical reaction to my research work between 1984 and 1987 was the following: "You are wanting to abandon a theory that has been verified to eleven places of decimals. The burden of proof is therefore on you. You must at least deliver results to the same degree of precision before you can expect anyone to sponsor you."

Whether the anomalous magnetic moment, etc. can be calculated to the required accuracy in my approach is still an open question. No-one has been working on it. On the other hand the approach works in obtaining basic scattering amplitudes and is content to reside in 3+1 dimensions.

In regard to Superstrings, there is *certainly* no guarantee that the standard model or even, it seems, general relativity will be reproduced (despite the fact that producing a quantum theory of gravity was part of the original motivation), and yet it seems to get pretty much all the sponsorship.

I call this inconsistent, and I call it stupid.

I was a bit more pig-headed than average, but I wonder how many other young people (as I was then, anyway) have had good ideas quoshed because Ed Witten or whoever else who happened to decide the direction of research did not think it was cool.

65. **JC**
August 13, 2004

Chris,

Seems a lot of the sociology behind physics research is along the lines of "monkey see, monkey do" or a "pied piper" luring away kids. Arguably one can see that in many other activities in the world, as in the "copycat" syndrome when something very popular and/or profitable comes up.

At times I wonder how much of the string and particle community is exactly that of "monkey see Witten's work, monkey tries to do Witten's work".

66. **Chris Oakley**
August 13, 2004

The Ed Witten phenomenon reminds me of a joke:

A man goes into a pet shop to buy a parrot.
"How much is that one?" he asks.
"Five hundred dollars," says the sales assistant.
"*Five hundred dollars!?* for a *parrot*?"
"Ah yes, but she can touch type, and take dictation."
"And what about this one?"
"Seven hundred dollars."
"*Seven hundred?* That's ridiculous!"
"I know that sounds a lot, but this parrot is fluent in three languages and knows how use Word and Excel."
"And this one?"
"A thousand dollars."
"A *thousand*. What does he do, then? Write operas?"
"Actually we don't know what he does. But the other two call him 'Sir'."

When I was a graduate student (1980-1984) it was no exaggeration to say that Ed Witten was the single most influential mathematical physicist. Although I am not sufficiently *au fait* with his work to say whether this was justified, I would venture the observation that the emphasis was, and remains *mathematical*, i.e. pretty mathematical constructs appeared to excite him more than having the theories make contact with reality. It was the – in my view – excessively theoretical nature of his work that put me off joining the bandwagon.

67. **JC**
August 12, 2004

Peter,

I remember hearing stories about Witten majoring in something like history or political science when he was an undergrad. Did he take any physics courses at the time? If not, was he literally a "self taught" guy who taught himself everything he needed to know about undergraduate and graduate level physics, by cranking out zillions of problems and reading some papers on his own?

68. **Peter**
August 12, 2004

Witten was very clearly the leading figure in particle theory before string theory, during the period 1980-84. It's because of this that the string theory idea took off so fast. By 1984 everybody was looking very carefully at anything Witten was doing and often immediately going to work on it themselves. It's very hard to over-estimate his influence at that time.

He got his Ph.D. in 1976, and very much impressed the faculty when he was a student. I first met him
when he was a post-doc at Harvard in 1978, and was just starting to make his reputation. By 1980 he was already a young star and Princeton offered him a tenured professorship even though he was only a post-doc.

69. **JC**
August 12, 2004

Peter,

How popular was Witten in the particle theory community before string theory got popular? I knew someone who knew Witten personally in the 1970's before he was a superstar. In those days he thought Witten was definitely above average, but he didn't think was a superstar or Einstein-like genius at the time. If nothing else, he thought that Witten could have at least gotten an assistant professor job at a place like Princeton or Harvard in those days.

Correction

August 17, 2004
Categories: Uncategorized

Jeff Harvey sent in a comment correcting me on a point of history in my last posting. I'd read somewhere about Green and Schwarz fed-exing their paper to Witten, and had assumed this was their idea. Harvey, who was at Princeton at the time, recalls that it was Larry Yaffe who brought news of Green and Schwarz's result from the Aspen Workshop to Witten at Princeton, and Witten was the one who asked Green and Schwarz to fed-ex him the paper.

Harvey also strongly disagrees with the statement that people were not impressed by the work independently of Witten. He was at Princeton at the time, so knows far more about what attitudes there were. For those who weren't at Princeton or at Aspen, news of Green and Schwarz's paper and Witten's arrived more or less at the same time (they were published in the 13 and 20 December issues of Physics Letters B, the preprints were circulating in October). At that time any new paper by Witten was a major event, especially one in which he took up a new topic. I stand by my recollection that for people I was talking to at the time, the fact that Witten was working on the subject overshadowed the Green-Schwarz result itself.

Update:

This morning I tracked down my original source for what happened at Aspen. It is John Schwarz's article entitled "Superstrings – a Brief History", published in the proceedings of a conference on the history of particle physics held at Erice in 1994. The volume is entitled "History of Original Ideas and Basic Discoveries in Particle Physics" and contains many things very much worth reading. Schwarz describes in detail what happened at Aspen, ending with the following remarks:

"But still, given our previous experiences, neither of us had any idea of how sudden and enthusiastic the response of the physics world would be. In my opinion this was largely due to the influence of Edward Witten, who immediately grasped the implications of our result. Without that, string theory would probably have emerged much more gradually. As soon as our letter came off the printer we sent Witten a copy by Federal Express. (This was before the days of TeX and email!). I am told that the next day everyone in Princeton was studying it. Our letter on anomaly cancellation was submitted September 10, 1984. The deluge began 18 days later with Witten's letter suggesting ways to compactify SO(32) superstrings to get anomaly-free theories in four dimensions."

This is what led me to believe that it was Schwarz and Green's idea to Fed Ex Witten their paper. Presumably Harvey is right that he had asked them to do this. But that's about the only thing that I think I got wrong in the original posting.

Comments

1. **JC**
   August 21, 2004

   Anybody have any good guesses as to how physics could have turned out in an alternate world, if George McGovern had won the American presidency in 1972 against Nixon, and Witten became a presidential speech writer and/or got a low level post in the McGovern administration?

2. **Peter**
   August 17, 2004

   I don't think there ever has been anyone quite comparable to Witten. Einstein never had the same sort of influence, and he was always kind of working off by himself, whereas Witten has always been very much in the mainstream of what the majority of the field is doing.

3. **D R Lunsford**
   August 17, 2004

   All this hero worship is missing the point. String theory *as physics* was a ridiculous idea at face value. I don't know how I knew this, or how my advisor knew it, or why we were right – but my absolute initial reaction was one of total, utter disgust that such a thing would be taken seriously. Now, in the course of learning a lot of things that were complex, weird, or both, I *never* had this kind of visceral reaction to anything but string theory. The idea of setting the pointer of physics back to before Democritus was, in itself, ridiculous on the face of it, without further consideration. The world could *never possibly* have been arranged like that.

   My question is – why is this aspect of physics – that is, intuition – practically ignored? Physics is not mathematics, it's not even really *similar* to mathematics. Physics is about the actual world and its patterns. To get at these patterns, you need something other than the ability to crank out vast amounts of math, be it ever so interesting.

   rant

   Something pathological got into physics, and I would like to know when and where. Note that if you succeed in demolishing the entire string society, you'll still be stuck with dark matter, inflation, the first three minutes, Euclidean continuations, wave functions of the universe etc. etc. etc. String theory in itself is not the problem – it's a kind of uncritical global credulity that affects all intellectual endeavor.

   /rant

   -drl

4. **JC**
   August 17, 2004

   Peter,

   Can you think of anybody else in recent times, who had the sort of influence Witten had over the last 25+ years, in the sense of "monkey see Witten, monkey tries to do Witten's work"?

   I can't think of anyone offhand in physics history, other than maybe Einstein.

5. **Peter**
   August 17, 2004

   Without Witten, I think Green and Schwarz would have slowly gotten more attention for superstring theory, partly because no other ideas were really working. Their anomaly cancellation result would have helped get some attention, but on nothing like the scale that Witten's interest generated. It might still be percolating along as a subject with a relatively small group of people working on it.

It's very hard to guess what would have happened to particle theory without the dominance of string theory. Witten did amazing work relating QFT and mathematics during the late 80s and early 90s that was completely independent of string theory (including the work that got him the Fields medal) and presumably he would still have done this. My own prejudice is that if he hadn't put so much effort into string theory, and instead had put it into the new insights into QFT and math that he was getting, he and others following along with him would have achieved even more along these lines and the field would be in much better shape.

6. **JC**
August 17, 2004

Peter,

Do you think string theory would have faded away with a whimper or would have died a painful death, if Witten never became a huge advocate of string theory? It sure seemed like nobody really paid attention to Schwarz and Green for more than a decade, when they were working on string theory in obscurity during the 1970's and early 1980's.

7. **Peter**
August 17, 2004

Hi JC,

Particle theory in general has always been quite faddish, although often the fads have been driven by a new experimental result, or by the appearance of a good explanation of some previously unexplained experimental data. I don't know of any previous example in the history of physics of the whole field swinging so quickly behind a very speculative idea without experimental backing.

't Hooft's work certainly generated interest in the Weinberg-Salam model, which had been pretty much ignored until then. It was quickly followed by asymptotic freedom in 1973 and the "November revolution" in 1974 when the J/Psi was discovered. The standard model did quickly fall into place during 1971-74 and then dominate particle theory, but this was a series of related theoretical discoveries finding quick experimental support, a situation much more comparable to QM in 1925-26 to string theory in 1984.

8. **JC**
August 17, 2004

Peter,

Can you think of any other scenarios in the past which had tons of people jumping onto the same bandwagon after a particular paper was published, similar in spirit to how string theory became very popular after the Schwarz-Green result?

One that I can think offhand would be perhaps be the 't Hooft result which showed that gauge theories are renormalizable. Perhaps other cases would be the BCS superconductivity paper, or going as far back to the original Heisenberg & Schroedinger papers on quantum mechanics along with Wolfgang Pauli's review paper on the subject.

Smolin and Susskind at the Edge

August 19, 2004
Categories: Uncategorized

John Brockman at his "Edge" web-site has put up an exchange between Smolin and Susskind about the "multiverse" and the anthropic principle. This includes the page and a half paper by Susskind that was rejected by the arXiv. Susskind seems quite willing to give up the idea that a physical theory should be falsifiable, so his response to Smolin's argument that his use of the anthropic principle is not falsifiable is basically "Yeah, and so what?".

To Smolin's claim that non-falsifiable theories aren't really science, Susskind answers by listing several prominent physicists (Weinberg, Polchinski, Linde, Rees), their titles, affiliations and prizes they have won. He then announces that since these prominent people agree with him and think the anthropic principle is science, Smolin should just shut up. I don't know about other people, but one reason I went into physics was that it was supposed to be a subject where issues could be decided by rational argumentation, not appeals to authority. That doesn't seem to be the case anymore.

Comments

1. **serenus zeitblom**
   August 22, 2004

   "To the extent that this is supposed to be taken as "scientists have little to learn from philosophers, and philosophers have much to learn from scientists" it is simply false"

   In general, I agree. But there are bad philosophers just as there are bad physicists. On this *specific* issue, namely declarations that things we cannot see [yet] are "unscientific", too many physicists tend to quote bad philosophy. The example of quarks is canonical. I really liked Susskind's
   "Throughout my long experience as a scientist I have heard un-falsifiability hurled at so many important ideas that I am inclined to think that no idea can have great merit unless it has drawn this criticism". I think that hits the nail on the head.

2. **Chris W.**
   August 22, 2004

   Susskind said: "Let's not put the cart before the horse. Science is the horse that pulls the cart of philosophy."

   To the extent that this is supposed to be taken as "scientists have little to learn from philosophers, and philosophers have much to learn from scientists" it is simply false, in light of the entire history of physics. Of course it probably expresses the attitude of most of the last 2-3 generations of physicists, and I have seen a statement by Witten to the effect that he and most of his colleagues see little to interest them in recent work (of the last two centuries?) in the philosophy of science.

   My point is that no one seriously interested in a problem like quantum gravity can afford to adopt the narrow perspective of a specialist, or to be complacent about questions of epistemology. John Wheeler has cautioned against any physicist adopting this attitude, although given the vastness and technical complexity of the field, and the demands of modern research as a career, it is perhaps inevitable that such attitudes will be fairly widespread.

   The contrast in outlook between Smolin and Susskind on this issue is quite obvious.

3. **serenus zeitblom**
   August 20, 2004

   I must reluctantly confess that I found Susskind surprisingly reasonable. Surely he is right when he says "Good scientific methodology is not an abstract set of rules dictated by philosophers. It is conditioned by, and determined by, the science itself and the scientists who create the science." It is good to see somebody explicitly refuting people who drone on about how things beyond the horizon can never be seen, hence theoretical efforts to determine what is there are "not science". What crap! On the other hand, S does fall right off the cliff when he claims "the black hole controversy has largely been resolved." The only question here is whether Susskind really believes such blatant nonsense.
   The other strange thing was that Susskind was so polite. He only starts to sound like Lubos Motl right at the end. In fact, right at the end he sounds so much like LM ["Smolin's tendency to set himself up as an arbiter of good and bad science"] that it is now clear to which organ-grinder the monkey belongs.

4. **JC**
   August 20, 2004

   Thomas,

   What do you think of the CFT book by Ketov?

   Lately I've been slowly making my way through the book "conformal invariance and critical phenomena" by Henkel.

5. **Thomas Larsson**
   August 19, 2004

   Danny:

   Unfortunately I don't really have any good introductory references to CFT, since I picked up most of it from the original literature around 1986-1990. Conformal field theory by Di Francesco, Mathieu and Senechal is the canonical reference, but its intimidating thickness makes it more suited as a reference rather than as a tutorial.

   One probably also needs some general background on phase transitions, statistical lattice models, and renormalization in that context. The review series edited by Domb and Green, and later Domb and Lebovitz (or maybe Green and Lebovitz – anyway, one of the original editors died) is a classic, but maybe out of print. A more recent textbook is Scaling and renormalization in statistical physics by Cardy. It has the advantage that its size is manageble.

6. **D R Lunsford**
   August 19, 2004

   JC –

   Beavis and Butthead know their limitations. Uh huh huh, yeah. Shut up, Beavis!

(Seriously, there are lots of interesting *physics* questions that lofty fartknockers such as S&S might hold forth on at length.)

7. **JC**
   August 19, 2004

   D R Lundsford,

   How much is this different than two idiots like Beavis and Butthead arguing which rock music bands “Rule” (ie. Metallica, AC DC, etc …) and which rock bands “Suck” (ie. Billy Idol, U2, Boy George, etc …)?

   Or for that matter discussions between fans of various sports teams (ie. basketball, baseball, hockey, etc …) as to which teams “Rule” and which teams “Suck”?

   This seems to be very much a human thing that is independent of the field of interest or inquiry, whenever there’s disparities in opinions which are not backed (nor ruled out) by empirical data and/or the questions asked are too vague.

8. **D R Lunsford**
   August 19, 2004

   Thomas –

   To Glashow’s credit, he threw off his rope belt and robe and re-entered the mundane world:

   http://www.pbs.org/wgbh/nova/elegant/view-glashow.html

   And that 1988 paper on CFT by Ginsparg you linked is mighty interesting 🙂 Do you have a list of favorite references on this topic?

9. **Thomas Larsson**
   August 19, 2004

   “Is further experimental endeavor not only difficult and expensive but unnecessary and irrelevant? Contemplation of superstrings may evolve into an activity as remote from conventional particle physics as particle physics is from chemistry, to be conducted at schools of divinity by future equivalents of medieval theologians. For the first time since the Dark Ages, we can see how our noble search may end, with faith replacing science once again. Superstring sentiments eerily recall ‘arguments from design’ for the existence of a supreme being. Was it only in jest that a leading string theorist suggested the ‘superstring may prove as successful as God, Who has after all lasted for millenia and is still invoked in some quarters as a Theory of Nature’?”

   – Paul Ginsparg and Sheldon Glashow, Physics Today, May 1986.

   Some people are true visionaries!

10. **D R Lunsford**
    August 19, 2004

    1 word – scholasticism. They both sould like two Schoolmen going round and round about theophany or some such ridiculous arcanity.

    It would be very interesting to make a close comparison of scholasticism and this pseudoscientific form of debate. One thing’s certain – physics, at least as practiced by these two, is deader than Julius Caesar.

Comments From Larry Yaffe

August 19, 2004
Categories: Favorite Old Posts, Uncategorized

Jeff Harvey's comment that it was Larry Yaffe who brought news of the Green-Schwarz anomaly cancellation result to Witten gave me the idea of contacting Larry to get a first-hand recollection of what the reaction was at Aspen back in 1984. He was a junior faculty member at Princeton at the time and I knew him since I had been a grad student there and we both were working on lattice gauge theory. I've always respected his work and had noticed that he was someone who had never joined the string bandwagon, so I took the opportunity to ask him for his views on string theory. I think they're pretty reasonable and reflect the views of a lot of the sensible people in the particle theory community these days. He agreed to let me post them here:

"What Jeff Harvey related is correct: I was at Aspen when Green and Schwarz presented their anomaly cancellation result, and I told Ed and others about it a few days later when I got back to Princeton. (Of course, John and Michael may have sent Ed a copy of their paper completely independently. I don't know about that. But he hadn't seen it yet when I was asked "what's the news from Aspen?".)

As for whether it was Michael Green or John Schwarz who gave the seminar in Aspen, I think it was John — but I'm not 100% sure. (The different talks I've heard from John and Michael get mixed up in my memory.)

Concerning reaction to the Green-Schwarz result, my recollection is that there was relatively little immediate buzz about it at Aspen. John had a fairly diffident style of presentation, and I don't recall anyone jumping up and saying 'this will change the course of physics!'. As best as I can reconstruct my own reaction, it seemed like a technically slick calculation and a nice result but it wasn't, of course, addressing any of the conceptually hard questions about quantum gravity, and it seemed very far removed from the practical concerns of particle physics. But the reaction back in Princeton was different: Ed certainly saw the significance immediately and I think others did as well (certainly quicker than I did). I think the speed with which others in the particle theory community jumped into string theory had a lot to do with Ed's involvement and proselytizing, but I expect that even without his involvement, interest in string theory would have steadily grown, albeit slower.

Since you asked about my views on string theory, I'll try to give a summary. I think it is clear that:

String theory has been wildly over-hyped by some people. Even calling it a 'theory' is really a misnomer, given the lack of any adequate non-perturbative definition of string theory.

String theory has not yet made any convincing connection with the world we live in.

The predictive power (or the falsifiability) of string theory leaves much to be desired, especially in light of the emerging picture of the landscape of string theory vacua.

But at the same time:

The oft-repeated argument that string theory is the most promising framework we have for combining quantum mechanics and gravity remains true. Even though there is no real non-perturbative definition of string theory, I don't think one can dispute this assertion. (As an aside, so-called "loop quantum gravity" is an interesting one-parameter family of statistical mechanics models, but has not been shown to have anything to do with gravity. Does it have a large-volume limit? Does it have long distance dynamics described by some effective field theory plus classical GR? Who knows…)

The perturbative consistency of string theory, combined with all the consistency checks of the (largely unproven) web of duality relations, are compelling hints that there is something deep and meaningful to string theory, even though it remains poorly understood.

String theory has made remarkable contributions to mathematics, allowing previously unforeseen connections to be found between very different areas. This has shown up in new (provable!) results in enumerative geometry, Gromov-Witten invariants, mirror symmetry, etc.

String theory has given partial insight into a few conceptual questions involving quantum gravity, such as (the absence of) black hole information loss, via the connection between BPS states and extremal black holes.

Improved understanding of gauge theories, especially strongly interacting theories, is emerging from string theory via "gauge-string" (or AdS/CFT) duality. Understanding is, as usual, frustratingly incomplete, but I think the message that non-gravitational ordinary field theories, and higher dimensional theories containing gravity, can be different representations of the *same* physics is revolutionary, and hints at some synthesis we are far from understanding. I think this point is already somewhat lessening the split in the theory community between 'string theorists' and 'non-string theorists'.

Personally, I find this last point the most compelling reason to be interested in string theory, despite its lack of experimentally testable predictions. It is, of course, a matter of personal taste whether the 'pro' reasons to work on string theory outweigh the 'cons'. Some people are comfortable working on an intellectual enterprise whose connection with the real world may never emerge during their lifetime. Some people aren't — and that's fine."

   August 20, 2004

   I'm just correcting your misapprehension about the mentioned work. I've done the pro- anti- string stuff way too often to have any desire to get into it now.

2. **Thomas Larsson**
   August 20, 2004

   Aaron,

   I didn't claim to have a very good understanding about algebraic geometry. This was how I understood one of Witten's original papers, and he didn't say which xxx-Witten invariant he described there.

   But my main point was really that no mathematical discovery, however cool, is by itself evidence that this math has anything to do with physics. This is true for various invariants and dualities in algebraic geometry, as well as the higher-dimensional generalizations of Virasoro and affine algebras and their global group generalizations.

   For me to accept something as physics, something more is needed: experimental support. It seems to me undeniable that the groups of diffeomorphisms and gauge transformations play a significant role in experimentally confirmed theories. I don't see such a role for various dualities, Gromov-Witten invariants or mirror symmetries. But maybe its just me being too skeptical about hidden worlds.

3. **Aaron**
August 20, 2004

You're understanding isn't correct. I think you might be getting at issues in topological field theory where the correlation functions are independent of the metric. Donaldson-Witten theory is a twisted N=2 SYM, for example.

Gromov-Witten theory, mirror symmetry and the like come from topolgical versions of string theory where the worldsheet CFT is twisted into a topological theory.

4. **Thomas Larsson**
August 20, 2004

String theory has made remarkable contributions to mathematics, allowing previously unforeseen connections to be found between very different areas. This has shown up in new (provable!) results in enumerative geometry, Gromov-Witten invariants, mirror symmetry, etc.

My impression is that this has very little to do with physics, and not really that much with string theory neither (unless you define string theory to be whatever Witten does). My very limited understanding of these matters is that some correlation functions in N=4 SYM turn out to be independent of separation. This has two consequences:

1. These correlators are smooth (Gromov-Witten?) invariants of the underlying four-manifold.

2. We may freely move the points to convenient positions, probably very close to each other, where the correlators can actually be calculated.

This is wonderful in enumerative geometry, because it gives us calculable smooth invariants which you can use to prove a lot of theorems. But exactly the same properties seem to be rather useless in physics, where we usually want correlation functions to decay with distance.

5. **Tony Smith**
August 20, 2004

D. R. Lunsford asked whether my string = worldline model does such things as
"eliminate time", etc.
It does not, in my opinion. To see how it works in sufficient detail to answer
such questions, please read the entire CERN CDS preprint EXT-2004-031 at
http://cdsweb.cern.ch/search.py?recid=730325&ln=en

The spirit of the model is similar to that proposed by Elitzur and Dolev
in their paper at http://xxx.lanl.gov/abs/quant-ph/0207029
where they say:
"… we propose quantum mechanical experiments that yield inconsistent histories,
suggesting that not only events but also entire histories might be governed
by a more fundamental dynamics. …".

The basic idea is that each "entire history" would be represented by a "string".
and that the fundamental interactions of quantum theory are
not between mere point particles
but
are between strings/entire histories.

Elitzur and Dolev, in that article, describe
"… quantum mechanical experiments yielding apparently inconsistent histories …[which]… would give rise to an account like
"first a retarded interaction brings about history t1x1, t2x2, …
and then
an advanced interaction transforms this history into t1x'1, t2x'2 …"
and they say
"… Perhaps … changes affect not only events but also entire histories.
… Such a model will be better capable of explaining quantum peculiarities
of the kind described above, as well as a few other surprising results
discovered lately by similar techniques …".

Please note that the Elitzur-Dolev paper also discusses some aspects of
Hawking's recently recanted position regarding information loss in black holes,
but that aspect of the paper seems to me to be substantially independent
of their proposal that it is
interaction between entire histories (world-lines/strings)
and not
event-interactions between mere point particles
that is fundamental in quantum physics.

6. **D R Lunsford**
August 19, 2004

Tony –

Doesn't the usual argument against rigid bodies in relativity eliminate your interpretation of the world-line of a particle as a "string"? If not, then you are saying that a "stringicle" acts as a unit over its entire history – and that any creation-annihilation events in its history have to be included, extending the stringicle to another, to another etc. etc. So, in effect you're eliminating time, and returning to a Eucldidean-Pythagorean static world picture without dynamics. Odd how this matches the "back to Democritus" approach implicit in the "nothing but fibers and the void" approach.

7. **Tony Smith**
August 19, 2004

Larry Yaffe says "… String theory has not yet made any convincing connection with the world we live in. …".

While that may be true of conventional formulations of string theory,
what about formulations based on unconventional physical interpretations
of strings (such as strings = world lines of point particles) from
which string theory structures such as 26-dim spacetime, D8 branes,
and discretizing by orbifolding can be used to make models such as
that described in CERN CDS preprint EXT-2004-031 at
http://cdsweb.cern.ch/search.py?recid=730325&ln=en
?
There has been a small bit of discussion about that model on sci.physics.strings,
where the model itself is labelled "Speculation" and comments range
from
".. pure numerology … coincidence …"
to
"… a nice formulation of (bosonic) M-theory (as Susskind refers to the 27-dimensional theory), from where we work down dimensionally … to recover fermions …".
The above quotes are given without stating full detailed context in order
to illustrate the range of opinions that seem to exist about the model.
Anyone who is really interested in details should read that sps thread
and the paper itself, as well as related material cited therein.

Anyhow, the basic point of this comment is that even though Larry Yaffe
may be correct that current conventional formulations of string theory
have "… not yet made any convincing connection with the world we live in …",
his statement may not be correct with respect to some unconventional string-based models.

Myhrvold on the Anthropic Principle

August 19, 2004
Categories: Uncategorized

My old friend and Princeton roommate Nathan Myhrvold has written an excellent piece about the anthropic principle and the Smolin-Susskind debate that has just been posted on the Edge web-site. It seems to me to summarize the issues very clearly.

After getting his Ph.D. in quantum gravity at Princeton, Nathan went to work as a post-doc with Stephen Hawking, and one of the topics he worked on involved a possible mechanism for explaining the small size of the cosmological constant. Nathan left physics and joined with some of my other friends from grad school days to start a software company near Berkeley that they called “Dynamical Systems”. They soon sold the company and themselves to Microsoft, where Nathan ended up in the position of Chief Technical Officer. He periodicaly reminds me that if I had taken up one of his many offers to come work with them back in the mid-eighties, I could be obscenely wealthy too. At the time I remember it seemed clear that it was much smarter to stay as a postdoc at Stony Brook, being paid enough to live on and able to think about whatever I wanted, than to go to California to work twenty hour days writing operating system code and getting paid in worthless pieces of paper.

Oh, well.

   August 25, 2004

   The formalism computes tree level amplitudes of gluon scattering in SYM very efficiently. No conformal invariance needed. These diagrams are the same as in the conformal theory.

   For JC, the formalism reproduces the tree level amplitudes which is substantive in and of itself. Unfortunately, according to a followup by Berkovitz and Witten, it appears that the theory with loops will most likely reproduce the diagrams of conformal supergravity rather than those of N=4 SYM.

   So, it seems likely at this point that the original proposal will not reproduce all of SYM, but, again, that doesn’t mean that there will be no future results on the subject. You can read Witten’s original big paper (the first half is all QFT — no string theory) for some intriguing facts about those loop amplitudes you referenced.

   But, none of this changes the fact that the referenced paper is all about the very physical idea of doing scattering computations in Yang-Mills theory.

2. **JC**
   August 25, 2004

   Aaron,

   Do you know if anybody has been able to get Witten’s twistor formalism to work for the QCD 1-loop amplitudes and beyond?

   If Witten’s twistor formalism has any substance in the end, it should be able to reproduce the 1-loop formulas found by Dixon, Kosower, & Bern during the 1990’s.

3. **Chris Oakley**
   August 25, 2004

   How pessimistic is it to think that something in its initial stages will never be extended to compute diagrams involving things other than gluons?

   I am not claiming to be qualified to judge the details of this paper, but I would remind you that sooner or later conformal invariance must be broken as the world is quite obviously not conformally invariant. Penrose’s group worked for decades on ways of putting in masses and did not come up with anything very convincing. Maybe Witten’s team can do better, and I would be delighted if they could, but as things stand, this is a huge, and possibly insurmountable barrier.

4. **Aaron**
   August 25, 2004

   “Thanks for that. Once again we see Witten et al, given a choice between physics and interesting math choosing the latter. ”

   Interesting math? That paper gives new ways of doing computations in QCD. I consider that pretty damn physical. Don’t you think that’s at least somewhat interesting?

   You can’t compute everything using this method, but I’m really astounded that you immediately dismiss it as ‘interesting math’. Did you read the paper?

   And how pessimistic is it to think that something in its initial stages will never be extended to compute diagrams involving things other than gluons?

   Your comment frankly couldn’t be more inapposite.

5. **JC**
   August 24, 2004

   Danny, Chris, Steve

   I remember years ago stories about some younger particle theory professors attempting to teach quantum field theory (QFT) courses in a “modern” context.

   There were guys who started off with the path integral on the first day, and didn’t really mention much of the old canonical quantization way of doing things. By the end of the 1st semester, they were already finished covering numerous tree level calculations in phi^4, QED, and even some electroweak and/or QCD Standard Model stuff. Some folks even got as far as covering the renormalization of phi^4 theory or even QED in the 1st semester!

   After about a month or so into the 1st semester, almost all of the experimentalists were scared off and subsequently stopped attending the lectures and/or dropped the course. By the time it was the 2nd semester of the course, the only folks left mostly consisted of theory students interested in particle physics and/or condensed matter. Mid way through the 2nd semester, many of the condensed matter folks disappeared too.

   It seems like teaching QFT starting off with the path integral is almost like the equivalent of “culture shock” for many students.

6. **Chris Oakley**
   August 24, 2004

   Danny,

   Thanks for that. Once again we see Witten et al, given a choice between physics and interesting math choosing the latter. Twistor space cannot deal with massive particles. This is unfortunate as not only is there clear experimental evidence for massive particles, but a lot of these masses have been measured to a high degree of precision. Maybe they can have massive particles as some kind of composite, but I am not aware of any developed theory that works on these lines. Maybe someone can prove me wrong – ?

7. **D R Lunsford**
   August 24, 2004

   Attn Chris – a paper you may find interesting:

   http://xxx.lanl.gov/abs/hep-th/0403047

8. **Chris Oakley**
   August 24, 2004

   I like Weinberg QFT Vol. 1 a lot. I think that this is better than any other text book I have looked at. The later volumes I have not studied in detail, but one gets the impression that he is really trying to make sense of the material, and not just reproducing the results of other's scientific papers. One also gets this sense from Bjorken and Drell – although these books can be annoying – but precious few others. Regarding Steve's point about people not wanting to question Feynman-Dyson perturbation theory, I have the following comment: they question practically everything else! It seems however that this one thing is taboo. It is like a tower of Hanoi after ten turns – people fear that the tiniest disturbance in the air will cause the whole thing to collapse and they will no longer be able to talk about the "most accurate" or "best" theory of all time. Personally, I am not bothered as I never thought the tower existed anyway, except in people's minds.

9. **D R Lunsford**
   August 24, 2004

   Weinberg is very odd as a writer. His book on gravity goes to great lengths to establish his heterodox opinion that "gravity is not geometry", then he develops gravity as geometry in the most impeccable way. There is some of that in his QFT books.

10. **Steve**
    August 23, 2004

    I quite liked a book called "Quantum Field Theory of Point Particles and Strings" by B. Hatfield (some of it anyway). The last couple of chapters introduced perturbative string theory in a way that was much clearer to me than GSW vol 1. Ryder was also quite a good book and readable.

    All QFT books are much of a muchness though and just present the usual sequence of stuff: free scaler, fermion, em fields, commutators, then Feynman-Dyson perturbation theory, S-matrix, phi^4 theory, QED, Feynman rules, vacuum polarisation etc. Then same results via path integrals, then renormalisation/regularisation. As a student, you never really get any clear or deep explanations in any text as to why you are even doing/learning this stuff in the first place.

    I have never really enjoyed perturbation (it can also cause blindness:)or the whole Feynman-Dyson formalism. Quite tedious to learn. Amazingly, it works out though and lots of things can be computed to high accuracy in the end so students/authors don't seem to question it or some of the underlying dodgy math. It is very entrenched in the theoretical physics culture so people like Chris who have chosen in the past to question aspects of it, won't go down well with the establishment or journal editors. There is probably room for another QFT book if someone can put a new modern twist or approach on the subject with some vitality. Weinberg's volumes were good but he is very much from the old school.

    A big problem now though for the S-matrix formalism, and esp. for string theory, is you can't actually define it on deSitter space, the space on which we appear to actually reside.

11. **JC**
    August 23, 2004

    Dan Lunsford,

    I skimmed the Jauch and Rohrlich book many years ago, but didn't read it closely enough. On the surface it looked like it was written in a style and spirit similar to Heitler's book.

    In the intermediate zone of "advanced quantum mechanics" before quantum field theory (QFT), I really liked Paul Strange's "Relativistic Quantum Mechanics: with Applications to Condensed Matter and Atomic Physics" book. It seems to cover many of the same sorts problems as undergraduate quantum mechanics, except done for the Klein-Gordan and Dirac equations. It attempts to explain intuitively what's going on in various relativistic systems, which seems to be glossed over in most other "advanced quantum mechanics" books. Main thing I liked about Strange's book was that it covered many relativistic quantum problems such as bound states for various potentials.

    Most other "advanced QM" books seem to only really cover the Klein-Gordan & Dirac equations for various scattering processes and sometimes the hydrogen atom, with a view towards quantum field theory. For a long time I always felt that the study of bound states in relativistic quantum mechanics and/or quantum field theory, was generally neglected in favor of scattering processes.

12. **D R Lunsford**
    August 23, 2004

    JC – I've tried to answer this post 3 times, and I just don't know. A lot of QFT is "overconceptualized" and one ends up with too many mantras. I'd frankly admit that it was a mess.

    Did you ever see the book by Jauch and Rohrlich? (Theory of Photons and Electrons)

    It's remarkable that none of us can think of a totally acceptable text. This contrasts very strongly with GR, where one has any number of good texts, from all points of view.

    BTW there is an intermediate zone, "Advanced Quantum Mechanics", that is relatively neglected. There's a bool by Schwabl I like. A good QFT book would I think build on that.

13. **JC**
August 23, 2004

Danny,

If you wrote your own textbook on quantum field theory (QFT), what would you do to make the presentation better than other books like Ryder, Weinberg, Heitler, Kaku, etc …?

Originally I found the Ryder book the easiest to read when I was first learning QFT. Over the years I haven't really found any QFT books that I really liked a lot. Though if I had to pick a book, it would be either Ramond's field theory book or Veltman's "Diagrammatica".

14. **Chris Oakley**
August 23, 2004

This whole notion of using power series expansions in the free field grew out of my complete failure to get to grips with Feynman-Dyson perturbation theory. The more I tried to understand it, the less clear I was. This meant either one of two things: either (i) I was stupid or (ii) there was something wrong with it. It was not just conceit that made me decide on the latter: one thing about good scientific theories is that they are robust. Renormalization theory is not robust. If you take the limits in integrals in weird ways then you get weird answers. To say "well don't take the limits in weird ways" is not acceptable. If it matters then the likelihood is that the limit does not exist and the whole thing is mathematically meaningless.

Anyway … the power series method is, under certain circumstances at least, consistent and comprehensible. Also I do not see why there should be a problem with the notion of an interacting field being a sum of tensor products of free fields – one can still see interactions taking place, and what is more, I do not see why the Wigner arguments about unitary irreducible irreps of the Poincare group should suddenly cease to be valid just because there are interactions. After all, all Wigner is doing is organising the vector space of a relativistic quantum mechanical system in a particular way and I see no reason why this should not be one that involves interactions. It is a bit like coupled oscillators in mechanics – just because one can pick out normal modes with their characteristic frequencies, etc. it does not mean that the individual oscillators that comprise the system have ceased to exist.

To answer the questions: (i) where it has gone – it is a structure that does not necessarily fall apart when one examines it carefully & is capable of generating scattering amplitudes that agree with tree Feynman graphs; (ii) where is is going – two-body bound states could be examined now; the anomalous magnetic moment of leptons could be calculated once it is clear how to represent the classical EM field … a number of things …

I suppose that if I had not been so easily discouraged I would have just hammered away at this regardless, but the fact was that I got very tired of being the only one saying these things and having programmed computers from the age of 11 it was easy to do this for a living and be thanked and paid properly for doing it. However this in no way means that I changed my mind about any of the physics issues. If anything the last 17 years of "fundamental" physics research has vindicated what I thought then. You cannot make a silk purse out of a sow's ear, as they say.

15. **D R Lunsford**
August 22, 2004

Chris –

The 1986 paper is extremely interesting. Could you summarize your attitude at this moment about where this has gone, and could go? What most needs to be done?

-drl

16. **JC**
August 22, 2004

Chris,

I wonder how much of the quantum field theory (QFT) framework as we know it today, is heavily biased from the Feynman perturbation theory picture. It seems like research into almost all other possible alternatives to QFT are largely ignored by the mainstream and/or are on the fringes of the physics community. (Only big exception would perhaps be string theory).

Do you know of any alternatives which does NOT use the "particle == field" correspondence, besides the string theory picture of particles corresponding to various string and/or brane excitations?

One of "promises" of string theory in the 1980's that I really bought into at the time, was the idea that string theory could eventually explain the results obtained by renormalization in QFT. That "promise" seems to have fallen by the wayside over the years, where today not many string folks seem to like to talk about it.

With various stopgap measure like renormalization and path integrals, at times I wonder if we're even looking at the correct degrees of freedom in QFT. Years ago I wondered why nobody has found an easy way to get quark bound states of mesons and baryons directly out of QCD, other than perhaps the lattice gauge theory folks running computer simulations and seeing the bound states. I felt that if there was a good direct QCD and/or electroweak derived model for hadrons, you should be able to easily see why the proton and neutron are relatively stable while the pi mesons, hadrons with strange quarks, etc … are all unstable, and where one could easily calculate their decay rates and bound state energies.

17. **Chris Oakley**
August 22, 2004

Danny,

No, you have not asked that before, so no apology required. My May 84 paper does not do much other than establish that you can expand an interacting quantum field in powers of the free field, and thereby calculate (interacting) matrix elements by inspection. One can do the same thing for any fields whose field equation has some characteristic coupling and which is such that the equations reduce to free field equations when this coupling goes to zero, so obviously it could be done for Yang-Mills as well. The nearest I have got to actually studying Yang-Mills in this framework was when I was looking at chiral fermions with a minimal coupling to a vector field; unfortunately I probably have not retained my notes (this was 1987) but I seem to remember finding that one had to have a vector self-coupling exactly on the lines of a Yang-Mills if one was to satisfy the requirement that fields (anti)commuted for spacelike intervals.

I am not working on it now, as (when I am not writing trading systems for banks) I am still trying to get basic stuff like the classical limit of a quantum field clear in my mind.

18. **D R Lunsford**
August 22, 2004

Chris –

Sorry if I asked this before, but can you do for any Yang-Mills field what you did for phi4 in the May '84 paper? Are you working on that?

-drl

19. **Chris Oakley**
August 22, 2004

I've noticed over the years that many particle physics books (and even many review papers) seem to gloss over most of the QFT background, and frequently just goes straight into stating the Feynman rules and calculating Feynman diagrams. It seemed like the Feynman rules and Feynman diagram calculation prescriptions literally popped up out of thin air from nowhere, with very little to no theoretical justification on the surface (ie. just "take our word" for it, type of arguments).

Ahem, excuse me, but they might as well do this. The Feynman rules and renormalization prescription are all that they have. A connection with QFT is only possible if one permits the mathematically unpermissible, namely infinite subtractions.

The case against renormalization is argued at boring length on my web site (and will be argued at even more boring length when I have time to write the next installment), but let me add this snippet: *there is no such thing as an infinite constant*. If one has a divergent loop diagram then it is not acceptable to treat it as an "infinite constant" (to be cancelled by a counterterm) plus a finite functional part. Infinity plus an arbitrary function of any variables in the universe can be called infinity with no less justification. The "renormalized" amplitude can therefore have a functional dependency on variables that never even entered the original equations!

20. **D R Lunsford**
August 22, 2004

JC –

I think it would be hard to improve on a combination of Ryder, Weinberg, and Heitler, but there really isn't an ideal single-volume treatment. I wish Ryder were fatter (more topics). I really love that book. As Chris suggests, Ryder places Wigner's work in a prominent position.

I like the Kaku book as well, but it's not a good textbook. I really think there is still room for a better textbook.

21. **JC**
August 22, 2004

Chris,

Years ago I wondered about what it would take to write a book on quantum field theory (QFT) for undergrads. I was thinking of something along the lines of a QFT book which would be relatively "painless" to read, like the undergraduate particle physics book by David Griffiths. Of all the books I came across over the years on particle physics, the Griffiths one was the easiest to read and was relatively "painless" in comparison to most other books on particle physics.

I've noticed over the years that many particle physics books (and even many review papers) seem to gloss over most of the QFT background, and frequently just goes straight into stating the Feynman rules and calculating Feynman diagrams. It seemed like the Feynman rules and Feynman diagram calculation prescriptions literally popped up out of thin air from nowhere, with very little to no theoretical justification on the surface (ie. just "take our word" for it, type of arguments).

In QFT books which cover some particle physics, a lot of the really dense "difficult to understand" stuff seems to be largely justifying the perturbation theory prescriptions for doing the actual Feynman diagram calculations. I don't know how it can be done offhand, but the challenge would perhaps be in coming up with a presentation which makes the dense "difficult to understand" machinery of QFT more transparent in an "easy to understand" language to a reader who only knows some undergraduate level quantum mechanics, electromagnetism, classical mechanics, and maybe statistical mechanics.

The simplest way I can think of offhand in presenting the "difficult to understand" machinery of QFT, would perhaps be looking at a single real scalar field theory with a phi^3 interaction as a simplified pedagogical example with the least amount of baggage to carry along.

I took a look at Heitler's "quantum theory of radiation" book recently again, and noticed a lot of the classic quantum electrodynamics (QED) results were obtained from a first quantization framework, without really using QFT. It seemed like a messier formalism to do QED calculations, though Heitler did attempt to explain things in a more intuitive semi-classical picture than I've seen in modern QFT and particle physics books.

22. **Chris Oakley**
August 20, 2004

Hi JC,

The book would be a formal text whose thread would run somewhat like this:

1. Wigner unitary irreps of Poincare group, up to and including norms of vectors in these. Vectors in irreps as classical particles/fields. NB: First draft here (excluding classical limit arguments):

http://www.cgoakley.demon.co.uk/qft/RQM.pdf

2. Fock space as sums of tensor products of these vectors; Creation & annihilation operators defined from Fock space as per nice argument given in Weinberg Vol. 1 pp. 173-174; Identical particles and exchange symmetry; Quantum fields as 4D Fourier transforms of annihilation/creation ops; Spin-statistics theorem.

3. "Toy" interacting models with interacting field as sum of products of free fields in various configurations; calculation of scattering amplitudes using correspondence with time-dependent perturbation theory in ordinary QM.

4. Quantum Electrodynamics.

At this point I get a bit vague … I need to understand better how to get classical electrodynamics from the quantum one.

Er … that's it so far. You understand that a lot of this is about providing a framework on which to build. This may well go in the direction of quasi- or non-local field equations to avoid infinities popping up. As you see, I have at no point formally quantized a classical field as I don't believe that one needs to although I will do it for interest at some point.

23. **JC**
August 20, 2004

Chris,

If you wrote a book about particle physics and/or physics in general, what would it be about?

24. **Peter**
August 20, 2004

The book you mention, “Nobel Dreams”, is by Gary Taubes (the mathematician Cliff Taubes’s brother). It was written during the mid-eighties and is quite entertaining. I read it a long time ago, and from what I remember it is very hard on Carlo Rubbia, to the extent of being pretty unfair. Rubbia is an overbearing guy, but he was the one who got the collider built at CERN that discovered the W and Z. Not at all clear that someone without his will-power could have done this.

I remember taking a class from Rubbia when I was an undergraduate. He was commuting back and forth to CERN and some days didn’t quite make it, but was quite a force of nature. I remember once when I was sitting in the second row I asked a question. He then pushed aside the seats in the front row to get to me, and gave me a vigorous answer right in my face. He really wanted to answer the question, but is was a bit of a scary experience.

25. **JC**
August 20, 2004

Wasn’t there a book titled something like “Nobel Dreams …”, which discussed the dark side and politics of experimental particle physics research?

26. **Peter**
August 20, 2004

Hi Chris,

I should point out that I don’t have a tenured position at Columbia, although it is essentially a permanent one, which is the most important thing.

There’s a long on-going story about my attempts to write a book about some of these issues. I’ll tell this sometime when the situation is clearer about what is going to happen with that project.

27. **Chris Oakley**
August 20, 2004

Peter,

If the press were to ask me what I thought about string theory I would probably answer something on the lines of the following:

“I haven’t studied it, but I have trod in it.”

The problem is that my views carry very little weight. I could not get research posts after 1986 and have been out of the subject for over 17 years. They would probably just decide that my views were simply sour grapes. You, on the other hand, are a tenured professor at a prestigious university and as such, people *do* listen to what you have to say.

As for finances, maybe there might be some mileage in a popular science book arguing against the superstring collective insanity – ?

Even if it does not make you rich, it would make you feel better.

28. **D R Lunsford**
August 19, 2004

FWIW, I think you came out on top, money or no, to have avoided being tainted by Microsoft. Some things are more important than money (GASP).

A generation of people who sought to make an honest living at IT have suffered for those riches they enjoy.

The Linear Collider Will Be Cold

August 20, 2004
Categories: Uncategorized

For many years now, the highest priority of experimental particle physicists for a next-generation accelerator project has been a new electron-positron linear accelerator. The last high energy electron-positron collider, LEP, reached a total energy of 209 Gev before being shutdown in 2000. To get to higher energies than LEP, a ring isn't viable because synchrotron radiation losses go as the fourth power of energy, so a ring with much higher energies than LEP would use an intolerable amount of electric power.

A linear collider, where you build two linear accelerators and collide their beams together, doesn't have the synchrotron radiation problems (although the electric power demands are still a problem since the beams you accelerate only can collide once, not many times like in a storage ring). There have been several competing designs for a linear collider, with one of the main difference in the designs being whether the RF accelerating structures are superconducting ("cold") or room temperature ("warm"). These designs all are for a machine that would start out with a total energy of 500 Gev and ultimately reach 1 Tev. A committee was formed called the "International Technology Recommendation Panel" (ITRP), and it has issued a press release announcing its decision today. The ITRP came down on the superconducting side; this is a design mainly developed at DESY in Hamburg as part of the TESLA project.

The German government has decided to use the TESLA technology to construct a free-electron X-ray laser at DESY called XFEL. They have done this in a way that would allow XFEL to ultimately be upgraded to a linear collider at DESY, but have put off any decision about whether to actually fund and build such a machine.

The ITRP decision will allow work on a final design for the linear collider to begin, but the trickiest questions still lie ahead. Where will the thing be built and who is going to pay for it? The order of magnitude of the cost is $5 billion and the general assumption is that this will be an international collaboration. Besides the possibility of siting it at DESY in Germany, sites that have been discussed in the US mainly are at Fermilab in Illinois (being pushed by Fermilab), or somewhere in California (being pushed by SLAC). Even the most optimistic time scales for designing, funding and building a linear collider don't have it running until late in the next decade. More realistic might be the mid 2020's. The question of where the machine is located is crucial to the long-term future of the SLAC and Fermilab laboratories. If it is at their site or nearby they have an assured future, if not their future becomes much more problematic. CERN has its own design for an even higher energy linear collider called "CLIC", but CERN's funds for the forseeable future are committed to constructing and funding the LHC, as well as possible future upgrades of that machine.

There's a bewildering array of web-sites with information about this, including the new International Linear Collider Communication and linearcollider.org ones, another one at SLAC, one at Fermilab (which seems kind of out of date..) and Michael Peskin's home page. This last one contains links to many talks by Peskin about the physics to be done by a linear collider as well as a web page of links to other information about the linear collider.

The ITRP decision was announced at one of the year's biggest high energy physics conferences, the ICHEP being held now in Beijing. The web site for that conference contains many talks giving the latest results from experimental groups around the world. Unfortunately, as far as I can tell there's nothing very earth-shattering being reported.

   All this talk about theory/ego shit, and not a single comment (informed or otherwise), thus far, about any, possible, experimental light to be cast upon our darkness

Smolin on Loop Quantum Gravity

August 22, 2004
Categories: Uncategorized

Larry Yaffe's comments about string theory reflect well mainstream opinion in the particle physics community. On matters of fact I think what he has to say is pretty accurate, but I disagree with some of his statements that reflect not facts but scientific judgements. Of his positive comments about string theory, the ones about its impact on mathematics and about AdS/CFT are right on target. For an interesting talk explaining the status of attempts to use AdS/CFT to say something about QCD, see Larry's colleague Matt Strassler's talk this month opening a workshop in Santa Barbara (don't miss the heated exchange at the end of the talk about whether or not this is all just supergravity).

Larry's comments about "compelling hints" that there is something "deep and meaningful" to string theory and that it has provided "partial insights" into conceptual problems in quantum gravity are hard to to argue with. But while these hints seem to point in the direction of the existence of an interesting 11 dimensional supersymmetric theory, they provide no evidence that it has anything to do with the standard model. Quite the opposite, the evidence of the "landscape" suggests that any attempts to relate such a theory to the real world produce a framework that is completely vacuous, and can never explain anything (or, equivalently, can explain absolutely anything you choose).

The one place where I think I really disagree with Larry is his claim that, indisputably, "string theory is the most promising framework we have for combining quantum mechanics and gravity". This "most promising framework" locution has been around now for nearly twenty years. It was justifiable when people were just starting to try and understand the implications of superstring theory, but the failure of twenty years of effort by thousands of very talented physicists has to be taken into account. The fact is that despite all this effort, string theorists still don't have a consistent theory of 4-dimensional quantum gravity and prospects are not promising that this situation is going to change anytime soon.

As part of this "most promising" comment, Larry has critical things to say about loop quantum gravity. I'm no expert on this myself, but, like many theorists, he seems to me to be holding string theory and loop quantum gravity to quite different standards. Lee Smolin recently wrote to me and Larry to respond to Larry's comments, he allowed me to reproduce his e-mail here:

"Dear Peter and Larry,

Thanks for the comments, most of which I agree with. But in case either of you are interested, Larry's comments about loop quantum gravity do not reflect the real results.

A side effect of the sociology of string theory seems to be that there is as much ignorance of the genuine results concerning loop quantum gravity and other approaches to quantum gravity as there is overhype in string theory. It is fascinating that, just there are results that are believed to be true in string theory, despite never having been shown, there are results that have been shown, in some cases rigorously, in lqg, about which many people seem not to have heard about, in spite of being published 5-10 years ago on the archive and in the standard journals.

To combat this I wrote a recent review hep-th/0408048 which I would gently suggest reading before making public pronouncements about the status of the field. There are also good reviews on the rigorous side by Ashtekar and Lewandowski and by Thiemann, as well as two textbooks in press from CUP, one from Rovelli and one more rigorous from Thiemann.

Larry says of LQG that it "has not been shown to have anything to do with gravity. Does it have a large-volume limit? Does it have long distance dynamics…"

Can I mention some of the results that show that lqg quite definitely is a quantum theory of gravity, with details and referenceds in the paper? Larry, if you think any of these results are wrong, please tell us on what step of what calculation or proof someone made an error. Otherwise, we invite you to study the results and the methods by which they were gotten. You might surprise yourself by coming to agree with us, after all this is just quantum gauge theory, but in a diffeomorphism invariant setting rather than on a background manifold.

A key result is the LOST uniqueness theorem which shows that for d >=2 the hilbert space LQG is based on is the UNIQUE quantization of a gauge field that carries a unitary rep of the diffeo group, in which both the wilson loop and non-abelian electric flux operator are well defined operators. (see the paper and references for the precise statement).

Given that GR and supergravity are well understood to have configuration spaces defined as configurations of gauge fields mod diffeos, to which the theorem applies, this implies that the hilbert space used is uniquely suited to the quantization of those theories.

It is further shown that the hamiltonian contraint of GR for d=3+1 is rigorously defined on the hilbert space of diffeo constraints, allowing exact solutions to all the quantum constraints to be constructed.

As far as the path integral is concerned, using the method of spin foam models, based on the observation that GR and supergravity in all dimensions are constrained topological field theory, leads to rigorously defined path integral measures corresponding to the quantization of these theories. There are in addition rigorous UV finiteness results. There are also results that establish correspondences with Regge calculus in various limits.

These results all are quite sufficient to establsih that these theories are precisely the quantization of GR or supergravity. Surely this has something to do with gravity.

Regarding the low energy limit, more explicitly, there are several classes of candidate ground states that have the property that 1) measurements of coarse grained geometrical operators agree with classical flat or deSitter spacetime, up to small fluctuations. 2) small excitations of the gravitational degrees of freedom, which satisfy the constraints to linear order in l_Planck/wavelength have two spin two massless degrees of freedom per momentum mode (i.e. the gravitons are recovered for wavelengths long in planck units, again showing this is a quantization of gravity.) 3) after coupling to any standard matter field, excitations of the ground state yield a cutoff version of the quantum matter field theory on the classical background, cutoff at the planck scale because of the finiteness of quantum geometry.

The classes of states these statements characterize are a) coherent states, b) eigenvalues of coarse grained 3-geometry (sometimes called weave states) and c) for non-zero cosmological constant, the Kodama state.

I would think that finding explicit states with these properties proves that at least linearized gravity and effective field theories correspodning to qft on background manifolds is recovered. Certainly this is again something to do with gravity.

In addition, we can mention 1) the black hole results, which give an exact description of the quantum geometry of an horizon, in agreement with all semiclassical results and 2) the loop quantum cosmology results, which again recover all results of semiclassical quantum cosmology and go beyond them in the context of a rigorously defined framework. Again, some things to do with gravity.

See my paper for complete references.

I'm sorry for the tone, but one loses patience after 15 years. We have always been careful to state results precisely with full qualifications and never to overclaim. By now there are sufficient results that I think the many good people who are working hard in this field deserve to have their results much better known.

As always, I and my (rapdily growing number of) colleagues are happy to talk to anyone and go anywhere to explain the results and the methods by which they were gotten.

Indeed, the number of invitations for talks at places that previously expressed no interest previously is growing. I'd certainly be glad to recommend good speakers who could educate your department about the state of art in quantum gravity.

Thanks,

Lee

   would the resolution of the Poincare Conjecture have any effect on string theory?

   Mathematical Mystery Believed to Have Been Solved
   The Scotsman ^ | Mon 6 Sep 2004 | John von Radowitz
   http://www.freerepublic.com/focus/f-news/1208744/posts
   http://news.scotsman.com/latest.cfm?id=3461424

   One of the seven great unsolved mysteries of mathematics may have been cracked by a reclusive Russian who is not remotely interested in the ?560,000 prize his solution could win him, it emerged today.

   The Poincare Conjecture involves the study of shapes, spaces and surfaces and makes predictions about the topology of multi-dimensional objects.

   Basically, it says that a three-dimensional sphere can be used in an analogous way to describe higher-dimensional objects that are impossible to visualise.

   Since Henri Poincare suggested the theorem in 1904, some of the greatest mathematicians of the 20th century have struggled to prove it either right or wrong.

   All have failed. But now the world of maths is buzzing with the news that an answer might at long last have been found.

   Dr Grigori Perelman, from the Steklove Institute of Mathematics at the Russian Academy of Sciences in St Petersburg, has published two papers offering a solution to a larger-scale problem called the Geometrization Conjecture.

   This is also concerned with geometry, and experts say that contained within it is proof that the Poincare Conjecture works.

   If Perelman can satisfy his peers that this is the case, he stands to win a one million dollar cash prize from the Clay Mathematics Institute in the United States.

   The Institute is offering million dollar prizes for solutions to each of the mathematical conundrums it calls the Seven Millennium Problems.

   But there is a more fundamental problem the general community of mathematicians needs to solve first. Perelman does not seem to be interested.

   Dr Keith Devlin, a leading mathematician from Stanford University in California, explained: ?He?s very reclusive, and won?t talk to anyone. He?s shown no indication of publishing this as a paper, and he?s shown no interest in the prize whatsoever.

   ?Has it been proved? We don?t know, but there?s good reason to think it has been. My guess is that in about 12 months people will start to say okay, this is right, but there?s not going to be a golden moment.?

   Dr Perelman published his two papers in November, 2002 and March last year.

   A third is yet to be published.

   By all accounts, Poincare will come out of the first two papers, said Dr Devlin.

   If the conjecture was proved it would have profound ramifications, he told the British Association Festival of Science at the University of Exeter.

   Scientists working on the frontiers of cosmology and physics frequently dealt with hyperdimensions. A solution to the Poincare Conjecture would greatly increase their understanding of the shape of the universe.

   Dr Devlin compared proving Poincare with setting off an avalanche. If you are on top of a mountain, and it is spring, and you jump up and down, a little bit of snow moves. But at the bottom a whole lot of snow comes down.

   ?It can?t fail to have enormous implications; it will just be huge.?

   He said solving mathematical problems such as the Poincare Conjecture was more like writing a story than doing a sum, which was why it took so long.

   ?It?s just so damn complicated, he said. It really can take two or three years to certify the thing.?

   Proving the Poincare Conjecture would be the first great mathematical breakthrough since Andrew Wiles solved Fermats Last Theorem in 1994.

   This year, Professor Louis de Branges de Bourcia, from Purdue University in the United States, claimed to have proven another of the Millennium Problems called the Riemann Hypothesis.

   The hypothesis is a 150-year-old theory about Prime Numbers ? numbers that divide only by one and themselves and are considered the atoms of arithmetic.

   De Branges claimed to have confirmed a conjecture made by the German mathematician Bernhard Riemann in 1859 about the way prime numbers were distributed.

   But, unlike in the case of Poincare Conjecture, the worlds mathematicians are becoming increasingly convinced that he has got it wrong.

   Marcus du Sautoy, Professor of Mathematics at Oxford University, said: ?The mathematical community is sceptical whether the methods of Louis de Branges are capable of proving the Riemann Hypothesis.?

   If de Branges turned out to be right, it would have a dramatic impact on both global business and national security.

Encrypted codes are based on the randomness of prime numbers. If a system could be found that made them predictable, no secret would be safe.

?What mathematics has been missing is a sort of maths prime spectrometer, like the machine chemists use to tell them what things are made of,? said Prof du Sautoy. ?If we had something like that it would bring the world of e-commerce to its knees overnight.?

   August 24, 2004

   Hmm Urs, 1+1 has always appeared to me as pathological. But yep, I can not remember any arguments about the gauge invariance of the area operator, so perhaps you are right about having a problem there. I believe that Rovelli did, in a different focus, a proposal about how general transformations should affect to the eigenvalues and to the mean expected values of an area operator, I can not tell if it applies here.

3. **Urs Schreiber**
   August 24, 2004

   For something different: I have listened to the talk by Strassler (on what AdS/CFT has to say about QCD) that Peter provided a link to. Very intersting. We had recently discussed that topic here already.

   It is indeed not true that only supergravity plays a role in these calculations. In particular anomalous scaling dimensions of operators on the SYM side is matched to at least first non-sugra order on the string side by a whole small industry. Search the arXive for papers by Tseytlin and by Zarembo (2004), for instance.

4. **Urs Schreiber**
   August 23, 2004

   Sorry, that link was supposed to be:
   [Phoenix Project/Master Constraint Programme]

5. **Urs Schreiber**
   August 23, 2004

   Is it clear that area is quantized in LQG?

   I know that the area operator constructed in LQG has discrete spectrum (BTW, which spectrum precisely? Last time I checked there were at least two different 'proposals' for this spectrum.)

   But the area operator is not gauge invariant, but has single spin networks as eigenstates. But any state that actually solves all of the constraints, including the Hamiltonian constraint (if it can ever be defined) must be a superposition of spin network states (first of all it must be a knot state (solving the spatial diffeo constraints), but surely even a superposition of knot states) and most probably (nobody knows!) a continuous superposition.

   This means that it is not clear that on physical states the area operator has any eigenstates at all.

   Often LQG properties are argued in terms of spin network states. But these are just a particular choice of basis – of the *kinematical* Hilbert space. Statement like 'the universe is a huge spin network' or things like that make an unjustified identification of a choice of basis with a physical observable.

   BTW, does anyone know about the status of the '[Phoenix Project/Master Constraint Programme]' to actually construct the Hamiltonian constraint? As long as this hasn't been done it seems pretty vain to discuss any properties of LQG.

   BTW, as I discuss [here] the 1+1D example once again helps to understand the situation: When you decide to restrict to the space of spatially rep invariant functions in 1+1 D gravity and then try to apply the Hamiltonian constraint as an operator on that, you know you cannot succeed. That's because this amounts to imposing the constraints

   L_n – \bar L_{-n} for all n

   together with

   L_0 + \bar L_0 .

   The first infinite set of constraints can be imposed all right, and even with the methods used in LQG, because these generators have no anomaly among themselves. But then standard results in 1+1d gravity tell you that the Hamiltonian constraint L_0 + \bar L_0 cannot annihilate any of the resulting states.

   I am speculating that this is in fact the reason why Thomas Thiemann in his LQG-string paper decided not to precisely follow the standard LQG procedure (which consists of applying the quantized Hamiltonian constraint as an operator on the space of spatially rep-invariant states) but decided to treat both L_n and \bar L_n by 'relaxed canonical quantization'.

6. **Alejandro Rivero**
   August 23, 2004

   Independently of LQG, the interesting issue of having a quantum of area is that is can be used to singularise 4D over any other number of dimensions (we want Newton constant to have units of area). If strings had some way to justify the right compactification, ie to justify 4D, I could understand the criticism of the foamy world. But as it stands, LQG holds a very interesting card in his hand.

7. **Urs Schreiber**
   August 23, 2004

   Thomas –

   let's try to avoid bickering and general accusations and just focus on the discussion of some technical facts and problems. I'd be very interested to see Lee Smolin reply here (maybe mediated by Peter Woit).

   You claimed that something is a problem for string theory and I asked you to please demonstrate it. Your reply

   > As all string theorists, you consistently require much higher standards from the competition than from yourself.

   leaves me in puzzlement. From past discussions I can guess that you are thinking that somehow results about anomaly cancellation for chiral fermions have to do with anomalies in the canonical quantization of gravity. I frankly admit that I don't see what you have in mind. But if you can make it precise you should probably do so and show it to somebody who knows more about it than I do.

It is precisely this problem with discussing full 1+3d nonperturbative quantum gravity that makes me rather wish to discuss a toy example like 1+1d gravity. All open questions of LQG are also non-trivial and unsolved in this context.

8. **Thomas Larsson**
August 23, 2004

Urs,

I do indeed agree with your claim that for an understanding of a non-perturbative quantization of gravity it should be very helpful to have an idea of the existing quantum reps of the symmetry generated by the classical constraints (though I would not call that alone a quantization of gravity, as you sometimes do).

I have never claimed (I hope) to have quantized gravity. I do claim, however, that I have succeeded in quantizing *the symmetry principle* underlying gravity, and I believe that this will prove to be an essential ingredient in quantum gravity itself.

But I don't claim that I know how to similarly 'fix' the LQG approach in higher dimensions. If you do and if you think that you can make a nonperturbative quantization of the action of closed string field theory and if you think you can deduce some kind of problem for string theory from that please do so and let us know about your result.

As all string theorists, you consistently require much higher standards from the competition than from yourself. I create (not alone, but anyway), the mathematics that makes it possible to discuss diffeomorphisms on the same footing as conformal transformation, and you say this may be interesting if I also succeed in using this to quantize gravity. The last guy who succeeded in creating both mathematical infrastructure and physics was called Newton, and I think that my results may be valuable even though I am a lesser soul than him, especially since everybody else has failed to make any progress towards on quantum gravity. Not even Einstein created his own math; Ricci and Levi-Civita created tensor calculus for him to use.

Meanwhile, you seem completely undisturbed by the fact that string theory makes no testable predictions whatsoever and that recent landscape ideas show that it never will, a situation which Witten describes as "[String theory] is also more predictive than conventional quantum field theory." I don't believe in LQG, but as long as Smolin does not claim that LQG is more predictive than field theory, he deserves good marks for honesty. Misrepresentation is Fraud's cousin.

BTW, did you see our comments on your 2-form gauge theory over here? (Possibly you were on vacation when these were posted.) Since you are only using a 2-form B you have to face the problem that the surface holonomies that you compute are not independent of the 'parameterization' of your surface, i.e. of the order in which you multiply the group elements on the plaquettes.

The amplitudes depend on the triangulation (or quadrangulation, rather); even the number of indices depends on that. This is why it's only the lattice model, were there is a canonical triangulation, that is well defined. However, there is no order dependence in the sense of non-associativity. Contraction of all index pairs associated with internal links is order independent; finite sums can be performed in any order.

9. **Urs Schreiber**
August 23, 2004

Thomas,

there is non-perturbative quantization of gravity, where we try to solve the canonical constraints exactly, and there is perturbative quantization, where we compute quantum corrections to classical solutions. The discussion here is about how to do the non-perturbative quantization.

I do indeed agree with your claim that for an understanding of a non-perturbative quantization of gravity it should be very helpful to have an idea of the existing quantum reps of the symmetry generated by the classical constraints (though I would not call that alone a quantization of gravity, as you sometimes do).

This is precisely what I claim is missing in the LQG approach, and in the special case of 1+1 dimensions one indeed finds that the idea you are proposing gives us the correct constraint algebra (namely the Virasoro algebra), while LQG misses it.

But I don't claim that I know how to similarly 'fix' the LQG approach in higher dimensions. If you do and if you think that you can make a nonperturbative quantization of the action of closed string field theory and if you think you can deduce some kind of problem for string theory from that please do so and let us know about your result.

BTW, did you see our comments on your 2-form gauge theory over here? (Possibly you were on vacation when these were posted.) Since you are only using a 2-form B you have to face the problem that the surface holonomies that you compute are not independent of the 'parameterization' of your surface, i.e. of the order in which you multiply the group elements on the plaquettes. To ensure well-defined surface holonomy you'd need to add a 1-form A and the condition B+F=0 and then you'd make contact with Girelli&Pfeiffer's work.

BTW, one maybe interesting piece of trivia in the triangle of topics constituted by LQG, strings and non-abelian 2-form field theories is the following:

If we restrict as in LQG to spatial rep-invariant states we obtain, in 1+1 dimensional gravity, the so-called *boundary states*. A particularly natural such state is the loop space function which assigns the holonomy of some connection A to a loop. Incidentally, this function is precisely the boundary state which describes a non-abelian 2-form B = -F_A .

See this entry and hep-th/0408161 for the details.

10. **Thomas Larsson**
August 23, 2004

Urs,

The following statements are almost identical:

1. LQG is only quantization in a weaker, nonstandard way. In particular, if the quantization of 3+1D gravity in any way resembles quantization of 1+1D gravity on a world sheet, then the diffeomorphism constraint should acquire an anomaly which cancels against ghosts.

2. All symmetries, including gauge symmetries like diffeomorphisms, need representations of lowest-energy type.

Thus, apparently to your great embarrassment, we are saying roughly the same thing (except that ghosts are problematic, because normal ordering doesn't just ruin nilpotency but makes the BRST operator ill defined). However, spacetime diffeomorphisms do not use lowest-energy representations in string theory neither, although it does treat worldsheet gravity in this correct way.

So exactly why do you expect LQG people to take your argument seriously, if you don't take the logical implications seriously yourself?

11. **Urs Schreiber**
August 22, 2004

When quoting results about uniqueness of the Hilbert space in LQG it must be emphasized that the quantization presciption used there is not what is usually called canonical quantization, and by this I mean differences over and above the ambiguities of canonical quantization itself. LQG uses ‘relaxed’ canonical quantization where not both of canonical coordinates and momenta are represented as operators on a Hilbert space.

To me this is the crucial but hardly ever emphasized assumption in LQG. Some people in LQG that I have talked to didn’t even realize that this is a controversial step. It seems that people expected that it is obviously fine to use this ‘relaxed quantization’. But it is known that when applied to systems whose standard quantization we do understand quite well, like the free particle and even 1+1 dimensional gravity coupled to scalar matter, the ‘relaxed canonical quantization’ gives grossly different results than usual quantum theory (e.g. that obtained from path integral quantization).

So no matter what one can prove within the LQG framework it is a fact, confirmed for instance by Thomas Thiemann and Josh Willis themselves, that LQG changes the usual rules of quantization.

I know that the idea is that in any theory with such a ‘relaxed’ canonical quantization a limit exists where the ordinary quantization is reobtained. But apparently the only paper investigating this idea is the ‘Shadow States’ paper by A. Ashtekar, Josh Willis and Fairhurst. But the construction done in that paper explicitly makes recourse to quantum effects of the standard quantum theory, so that this does not prove anything.

Of course it is true, as Thomas Thiemann has put it, that only experiment can show if standard quantum mechanics still holds at the Planck scale. But

1) if a propsal for quantum gravity does use non-standard quantum theory this should be made quite clear to everybody, so that people are aware of such a step

2) it would be nice if there were some kind of hints how the non-standard quantum theory used can flow to the standard theory in some limit. Otherwise even the theoretical motivation to believe in the viability of the non-standard approach is weak. To date no such evidence has been given, and indeed I consider the results given in the ‘Shadow states’ paper as a counterexample.

12. **Aaron**
August 22, 2004

Lee Smolin seems much more sanguine about the state of things than some of his colleagues. This is the first I’ve heard anyone claim that lqg has any semiclassical limit. Can one compute graviton scattering? I’ve also been under the impression that the Hamiltonian constraint remains (as of last May, at least) quite mysterious.

Finally, as for the black hole results, from the reading I’ve done, they’ve been deeply unimpressive, not the least of which because they don’t actually appear to be done in any theory I’d call lqg. Put another way, I don’t see how any black hole state was constructed in any theory. Instead what seemed to be done was to take a spacetime with a black hole, cut out the black hole, quantize what remains, *discard degrees of freedom associated with the bulk* and get a result proportional to the area of the horizon. Forgive me if I don’t find that result very impressive.

The Landscape in Scientific American

August 23, 2004
Categories: Uncategorized

The latest issue of Scientific American is devoted to articles about Einstein and his legacy. One article in the magazine doesn't really have much to do with Einstein and I believe would make him gag if he were still around. The article, entitled "The String Theory Landscape" is by Raphael Bousso and Joe Polchinski. In it they claim credit for the pseudo-scientific idea of "explaining" the value of the cosmological constant by the existence of the "landscape" and the anthropic principle. It's sad to see this nonsense being purveyed by the most respected and well-known popular science publication in the US.

For something more sensible about the anthropic principle, see a recent column from Nature.

Comments

1. **D R Lunsford**
   August 30, 2004

   Not at all. It's precisely the opposite IMO – they've been so poisoned by Bourbakian formalism that they've lost their esthetic judgment and are willing to "settle for less".

   My own "feeling" about this is – why should we expect our little efforts to somehow be vastly different from past efforts? That is, whatever works will almost certainly fit nicely into the existing pattern of development, going right back to Air Earth Fire and Water.

   To be more precise – a good theory needs a unique context. Every theory to date has provided its own unique context. This even goes for phenomenological theories that work (e.g. BCS – Cooper pairs – WGS – Higgs mechanism etc.)

   The thing that gives GR a unique context is background independence.

2. **Chris Oakley**
   August 30, 2004

   Well, OK, but then what is it that you are looking for? Interesting mathematics or physics? It seems that fundamental physics has reached its present impasse exactly because people have been – to use Newton's image – too busy picking up and examining pretty mathematical seashells rather than trying to build a fully consistent understanding of the physical world.

3. **D R Lunsford**
   August 30, 2004

   I would not consider it to be gravity, period. There is already a formulation like this for classical GR, which also is not gravity.

   Change of space element as in the Pluecker line geoemtry – say, building spacetime and matter from twistors anf getting some sort of quantification from that – might barely make it under the wire.

   -drl

4. **Chris Oakley**
   August 30, 2004

   If someone came up with a QG model where gravity was just another field on a Minkowski background, which was such that the classical limit gave one Newtonian gravity with light bending, etc. would people just dismiss it as too boring? I ask this question seriously. The main approaches to QG at the moment (Loops and Strings – NB: in alphabetical rather than slice-of-science-budget order) were inspired by, rather than derived from known physics, and in neither case has it been demonstrated that GR emerges as a classical limit. And with regard to Danny's requirement of background independence, given that SR is one of best verified theories yet, is this requirement not more to do with a feeling of mathematical "rightness" rather than any physics?

5. **D R Lunsford**
   August 29, 2004

   In short – anything that claims to extend or sharpen GR will certainly be background-free – that is the unique context that GR introduces. (Every real theory introduces a new physical context.)

   -drl

6. **JC**
   August 29, 2004

   Danny,

   What would be the dire consequences of a quantum gravity NOT being background free?

   I never quite understood the arguments in favor of background independence in quantum gravity. On the surface they so far seem like hand waving arguments, which extrapolate classical general relativity notions and impose them by "decree" in the quantum regime.

7. **D R Lunsford**
   August 29, 2004

   The essential thing about gravity, quantum or not, is background-freeness. Clearly you're never going anywhere without that as the central idea. That's what makes GR what it is. All this obessive "quantum gravity" kvetsching is just misguided. That will probably take care of itself in it the long run, and probably fix field theory as a side effect. The absolutely key thing is background-free field theory.

8. **Thomas Larsson**
   August 29, 2004

Of course, this is a danger for all research in quantum gravity. I find myself thinking that we need a radically simpler and deeper insight into the problem very soon, or we need to let the field lie fallow for a while. Perhaps a shock will come from outside that brings this about.

When all contrieved ideas have failed, maybe people will have to turn to the obvious ones. Like the quantum representation theory of the diffeomorphism group might be useful for understanding diff-invariant quantum theories.

There is of course no guarantee that this is the right thing to do. But it seems to me that good new ideas are in short supply indeed. When the old ideas have failed to describe the physics of our universe (and why else do string theory leaders focus on other universes?), what's the alternative?

9. **Chris W.**
August 28, 2004

Back to the Landscape — I just came across this remark supposedly made by Bill Clinton in another context:

"When ideologues find themselves in a hole, they dig harder."

The manifestation of this in string theory is that its adherents seem to be convincing themselves that they making headway with every interesting new *mathematical* result, and the mathematical territory they have opened up seems to offer an unlimited supply of them, enough of which offer hints of real physics to continue reinforcing the ideology.

Of course, this is a danger for all research in quantum gravity. I find myself thinking that we need a radically simpler and deeper insight into the problem *very soon*, or we need to let the field lie fallow for a while. Perhaps a shock will come from outside that brings this about.

10. **Chris Oakley**
August 28, 2004

Matt:

QED is obviously part of a bigger theory, and, who knows, maybe it is a limiting case of some as-yet-undiscovered Planck-scale dynamics. In the absence of any observational data about quantum gravity, the imagination can run free. AFAIC people can construct whatever theories they like about QG, provided that they have the right classical limit and do not contradict QM. My personal preference is toward simpler rather than more complicated ones, but that is just me.

One must, however, make a distinction between approximation and inconsistency. Non-relativistic mechanics works fine when motion is not relativistic. Classical electrodynamics works well when the number of photons is large. Na?ve QED, OTOH fails at *all* energy scales, and can only be rescued by mathematics that would get you an "F" if you were to do it in an exam.

Steve:

Would you agree that the natural ultraviolet regulator in QFT is provided by spacetime foam with a lower bound l_{b} acting as a natural cutoff ?

Under no circumstances! *A posteriori* tampering with a theory that has failed to give the correct, or even a finite answer can never be acceptable.

All the problems in field theory and qft (and yes string theory) no doubt arise from having a static deterministic classical background manifold which is an ok approximation at large scales/low energies. Thus the bag of mathematical tricks needed to make qft theory work.

You are asking me to abandon Minkowski space just because an approach to QFT that I would not have expected to work, does not work. I refuse to do it.

11. **Steve**
August 27, 2004

Chris et al.
Would you agree that the natural ultraviolet regulator in QFT is provided by spacetime foam with a lower bound l_{b} acting as a natural cutoff ?(Where this would be the Planck scale typically). This is not a new idea and was considered decades ago by Salam I believe. Not much subsequent work on the idea really (an old paper by Smolin, and some others, and a paper by L H Ford).

One might try and formulate QFT or classical field theory on a fluctuating/stochastic classical geometry rather than a smooth deterministic manifold. Hard vertices in Feynman diagrams should then get smeared out. Of course this was one of the motivations behind perturbative string theory but the idea can exist outside of string theory when one tries to accomodate the presumabley discrete or foamy micro-structure of spacetime. Delta function singularities associated with propagators in qft should be regulated in a natural way.

As for classical electrodynamics and the problem of point charges, the introduction of a lower bound l_{b} in spacetime or 3-geometry corrects it quite easily. Delta functions simply get smeared out into very narrow highly peaked Gaussians of width l_{b}. If G(x-y) is a simple Green's function for an electrostatic potential \phi(x)where

nabla^{2}G(x-y)=-delta^{3}(x-y)

then this simply becomes a nonlocal Laplace field equation, smearing out the delta fn. into a very narrow Gaussian of width l_{b}:

nabla^{2}G(x-y)=-Aexp(-(x-y)^{2}/l_{b}^{2})

A point charge then gets smeared out into a ring or a "string". The corresponding classical self energy is also finite and becomes infinite only as l_{b}–>0. There is an old paper by a guy called Namsrai that considers this and the subsequent theory of QED that follows (might be in the archive as a scanned pre-latex entry). Such nonlocal electrostatic equations are used for real in computational chemistry in order to accomodate the finite size of ions, large charged molecules or charged polymers in solutions, which can be modelled as charged strings.

All the problems in field theory and qft (and yes string theory) no doubt arise from having a static deterministic classical background manifold which is an ok approximation at large scales/low energies. Thus the bag of mathematical tricks needed to make qft theory work.

12. **Matt**
August 27, 2004

Chris —

If you'll accept that classical electrodynamics need only be a limiting case of QED (one might even say, suggestively, an effective theory), why do you think that QED needs to be “fixed” rather than only exist as a limiting case of some fundamental theory of quantum gravity?

Matt

13. **Chris Oakley**
August 27, 2004

…fixing QEM means first fixing CEM

What you are saying is pretty much the received wisdom on the matter, and I do not agree with it. Classical Electrodynamics only needs to exist as a limiting case of Quantum Electrodynamics. In any case, Classical Electrodynamics only breaks down in situations where QED would be expected to take over, i.e. point charges. Fix QED and you automatically fix CED.

14. **D R Lunsford**
August 27, 2004

Chris –

Dirac was none too happy with classical EM, which is also horribly broken. He tried on three different occasions spanning 50 years to fix it.

As Einstein said, “the electron is a stranger in electrodynamics”. IMO nothing short of the full background-free Monty will ever fix it, and that fixing QEM means first fixing CEM.

Still, the *forms* of EM persist – so the *structure* of the theory is (almost) right.

-drl

15. **Chris Oakley**
August 27, 2004

Thomas,

I don’t want to go on about this too much as we are getting off topic, but clearly Feynman, Schwinger and Tomonoga were not proud of the infinite subtractions they had to do and were looking for a future development to correct this. The future, or at least 57 years of it, has just said, “well it was good enough for Feynman, et al, so it’s good enough for us”. My point is just that, in fact, it was *not* good enough for them, and they *were* looking for something better.

16. **Thomas Larsson**
August 27, 2004

Chris,

There is certainly room for improvement of the standard model; e.g., I believe that understanding the group of gauge transformation may cast light on things like confinement and renormalization. However, an improvement would not make the standard model wrong, like special relativity didn’t render Newtonian mechanics wrong. Incomplete, yes, but wrong, no.

17. **Chris Oakley**
August 27, 2004

A website dedicated to slaying the standard model would rightly be laughed at.

Read the Nobel prize speeches of Feynman, Schwinger and Tomonoga and decide for yourself whether or not they saw room for improvement in QED.

18. **D R Lunsford**
August 27, 2004

Thomas, I heartily concur – in fact Peter has brought back my enthusiasm for discussing physics, starting with his courageous posts to SPR.

I have access to some excellent forum software that runs (flawlessly) on Linux. I’m sure if we put it up, and created some topics, the boards would be jammed with conversations.

If you want to see it in action go to z spot iwethey spot org.

-drl

19. **Thomas Larsson**
August 27, 2004

In general, the important question is how to deal with the fact that the academic power structure in particle theory is now completely dominated by an entrenched cadre of people devoted to a failed dogma. Trying to set up a new, alternative power structure looks near to impossible, but the current one is based on such a shaky foundation that its collapse sooner or later seems inevitable. The question is how to help that process along so it happens before we’re all dead and gone.

Peter, I think you underestimate your own power. You, and this forum, are undoubtedly starting to wield non-neglible power, for the simple reason that you are right and people know it. Of course, pointing out that the emperor is naked will only be taken seriously if he really lacks clothes. A website dedicated to slaying the standard model would rightly be laughed at.

20. **D R Lunsford**
August 27, 2004

ROFL!

21. **Chris Oakley**
August 27, 2004

I’m not convinced by Vafa’s argument. When Dorothy entered a parallel universe, the first thing she found was a wicked witch.

OTOH the aliens, good and bad alike, may have left our universe because they found it too boring ("What, the Earth-bars don't serve Ammonia? The Earthlings can't levitate? Nobody smokes Magnesium? … Let's get out of here!")

22. **D R Lunsford**
August 26, 2004

OMFG! The "Over the Rainbow" Hypothesis!

Das Regenbogens?berf?hrungshypothese!

23. **Chris W.**
August 26, 2004

From a footnote in physics/0308078:

"Cumrun Vafa thinks that the fact that we do not see aliens around could be the first proof of the existence of brane worlds: all advanced aliens would have emigrated to better parallel universes (our Universe has zero measure)."

Read it and weep…

24. **Peter**
August 25, 2004

Hi Chris,

A conference devoted to alternative to string theory would in principle be a good idea, but someone with funding and credibility has to be willing to organize it.

Conferences tend to fulfill two separate kinds of functions.

1. Allowing people working on the same topic to get together, talk and find out what each other are doing.

2. An important social function of determining power and status within the community. This is determined by who gets invited, who gets invited to speak, who hangs out with whom, etc.

One problem with an alternatives to string theory conference would be that mostly people not doing string theory are doing very different things, with very different philosophies, and it's unclear how much they really could communicate usefully with each other. The loop quantum gravity community is one of the few that has enough people to do this usefully, and they have their own conferences.

If a conference were organized by people or an institution with little or no status in the particle theory community, it couldn't fulfill the social function. It would be completely ignored by mainstream physicists, no one would care who was invited or who spoke. Networking at the conference wouldn't be very helpful as you would be meeting people who have as little power as oneself. Keeping the crackpots from dominating the thing would be no easy task either.

In general, the important question is how to deal with the fact that the academic power structure in particle theory is now completely dominated by an entrenched cadre of people devoted to a failed dogma. Trying to set up a new, alternative power structure looks near to impossible, but the current one is based on such a shaky foundation that its collapse sooner or later seems inevitable. The question is how to help that process along so it happens before we're all dead and gone.

25. **Chris Oakley**
August 25, 2004

Peter,

It seems to me that it might not be a bad idea to organise an "Alternatives to Superstrings" conference/workshop. What do you think?

26. **D R Lunsford**
August 24, 2004

On the "Science Channel" tonight (formerly "Discovery Science") Hawking is repeating the party line, CC, canceling to 120 places not enough, accelerating, string theory takes us close, nothing left to discover, etc. etc. etc.

Is it possible to just have a science show that DOESN'T have an obsession about "it all"?

Hawking, Galileo, and Einstein are described as "daring revolutionaries, scorned tradition, brilliant radicals" etc. etc. More BS. Einstein scorned tradition? Which one? The guy in Manhattan who owns the bagel shop?

27. **Peter**
August 23, 2004

I'm certainly no expert either, but my impression was that the answer to this question is that these solutions are not static, but metastable. Sooner or later they tunnel to zero energy.

28. **Steve**
August 23, 2004

In concede I am no expert in these matters and my knowledge is probably out of date by now, but how can one use "The String Theory Landscape" to justify a cosmos with a tiny positive lambda (ours)?

A clear-cut no-go theorem (e.g as discussed by Maldacena and others) states that you cannot compactify 10-dimensional superstring effective actions (or supergravity) on static internal compact geometries, down to 4 dimensions and then get an induced positive potential or CC in the dimensionally reduced effective string action (leading to accerating cosmological solutions or deSitter space). Even Witten says he doesn't know how to get deSitter space or a CC out of even classical string compactifications. ("Quantum Gravity In de Sitter Space" preprint.)

Also, a small cosmological constant or potential term in a dimensionally reduced effective string action will manifestly break S-duality (at least for toroidal compactifications). In some ways that might be good since very small numbers in physics (e.g. non-zero particle masses for example) seem to be associated with broken symmetries. One can compactify string actions on time-dependant internal hyperbolic spaces for example (relaxing the constraints of the no-go theorem) and try to get accelerating cosmological solutions that way, but I just don't get all this "Landscape" reasoning to "explain" a small CC.

I heard a bit about the Stanford stuff and flux compactications but it seems very artificial. A whole anthropic dogma seems to be emerging based on this "Landscape" though. Even with a vast landscape of solutions/vacuua for 4-dimensional string theory, based on known compactication technology, surely none of them should have a small CC? I admit I have lost the plot now with string cosmology, not having followed any literature for quite a bit, although I don't think the subject is developed enough to really deal with such cosmological issues with any real confidence anyway. Maybe Urs or someone can enlighten/update me here or point me to some useful preprints? (which I would welcome).

I still believe the CC (or dark energy if you prefer) is a hard number that has to be (somehow) rigorously calculated or explained and not "anthropicised" away.

29. **D R Lunsford**
August 23, 2004

The funny thing is – I wrote this paper which shows that in order for Riemannian geometry to be a proper limit of Weyl geometry, lambda=0 – and this was already known by Pauli in the 4d context long, long ago.

Never was so much effort spent by so many on something so zero. The CC is nothing but an artifact of an assumed global symmetry, and somehow it got promoted to God in the Machine.

A scientifically honest person must spend his days filled with Sartrian nausea at such a spectacle.

30. **Peter**
August 23, 2004

Maybe, but religious fanatics will always be with us and can generally be easily ignored. More serious is the abandonment by leading physicists of the scientific method for understanding the world in favor of a dogma which explains nothing and for which there is no evidence. And it's not even a very attractive or satisfying dogma.

31. **JC**
August 23, 2004

Any bets the anti-science religious fanatics will use articles like this to justify their religions and/or ideologies, or as a way to discount "science" as irrelevant?

New Word Enters English Language

August 25, 2004
Categories: Uncategorized

A new preprint by Tom Banks is out, about his idea of "Cosmological Supersymmetry Breaking". One notable aspect of the paper is a new terminology to describe Weinberg's "prediction" about the cosmological constant. Since the term "anthropic principle" normally applied to this has acquired a bad odor as it becomes clear it is not science, Banks decides to come up with a different name for the argument. He refers to it as the "galactothropic principle of Weinberg". Let's see if this catches on…

Comments

1. **D R Lunsford**
   August 29, 2004

   I hated Dr. Faustus. If you want to read a good book about a composer's life, try "Jean Christophe" by Romain Rolland. And it's French! Impress your Republican friends!

   (This public service message brought to you by Citizens Against Post-Romantic Fulmination.)

2. **Urs Schreiber**
   August 28, 2004

   > WHAT DOES LEVERKUHN DO FOR A LIVING

   Let me tell you that pretty much all I know abut this novel is its title:

   'Doktor Faustus. Das Leben des deutschen Tonsetzers Adrian Leverkühn, erzählt von einem Freunde'

   (where this friend is of course your namesake).

   'Tonsetzer' is an old-fashioned (and maybe never really popular) word for composer.

   Is anyone feeling this is getting off-topic?

   Ok, let's see how we get from literature back to physics: A couple of weeks ago I read Leon de Winter's 'God's Gym'. Among other things a tragic car accident gives rise to some general philosophy – and to a discussion of – string theory.

   Oops, again off-topic… 😉

3. **serenus zeitblom**
   August 27, 2004

   Ok, now you are free to correct the numerous shortcomings in my English texts… 🙂 (And in fact I'd appreciate it.)

   Sorry, English isn't my native language either!
   I have struggled to understand that wonderful book in both German and English and I am afraid that I have not succeeded in either case…..for example, Urs, WHAT DOES LEVERKUHN DO FOR A LIVING, that's what I would like to know!

4. **Steve**
   August 27, 2004

   This universe (or the region we occupy in the parameter space or "landscape")is not exactly conducive to intelligent life or even life itself at a simple level. Statistical mechanics can allow complex structures to briefly arise here and there before entropy washes them out, some of which (like us) can briefly be aware of their existance and the universe they find themselves in. But the frigid interstellar spaces are not exactly awash with radio signals from other intelligent civilisations, and all the other worlds we have discovered and explored in this solar system and elsewhere are just balls of molten/frozen rock or poison gas. It is a very very harsh and forboding place.

   There are so very many vagaries and frozen accidents that have led to our existance as an intelligent species. For example, some 6 million years ago severe drought turned the dense forests in Africa into savannah so the apes were forced to come down out of the rapidly vanishing trees.
   If we run the whole history of the earth again there is no gaurantee that any intelligent life (or even the simplest life)would arise on this planet at all, and it will be the same elsewhere. There would be many universes in the parameter space/landscape that still allow complex structure to form and some of this structure could end up "self-aware" but it does not at all follow that we would recognise it as life or it would recognise us. The Hoyl and Weinberg arguments therefore just state that bound structures like carbon nuclei, and stars and galaxies can form and the parameters we have allow layers of complex structure to briefly evolve.

   In a universe where electrons/fermions feel nuclear forces for example, there would just be nuclear physics and gravity and no complex structures like molecules, cystals, planets, life. I am not even quite sure what I am arguing about now:) However, I am not convinced such other universes or a "landscape" exists though and we need to explain why this one is the way it is with these parameters without anthropic arguments.

5. **Fabien Besnard**
   August 27, 2004

   I would like to comment about the scientific status of the anthropic argument. All the known constants of physics (including some integers like the number of dimensions, the signature of the Lorentz metric, etc…) live in a rather huge parameter space P. All I have seen so far are hand-waving arguments claiming to show that only a small neighbourhood of the known point in P we occupy gives rise to a universe with enough carbon production to host (intelligent) life. First I would like to know if someone claims to have investigated all of the parameter space, because as I remember, only a few constants are varied at the same time (sometimes only one at a time !). Also, I think this kind of argument overestimates our ability to draw complex conclusions from first principles. Would one be really able to calculate how a universe would be like with only the standard model, GR, (even less likely : string theory ?) and a point somewhere in the parameter space ? One thing that history should have taught us is that Nature has always more imagination than we do. I do not think we can seriously claim to know every possible way for a universe to host intelligent life. Is carbon really necessary ? It makes me think of these old sf movies where alien creatures are obviously humans in disguise : our imagination never goes very far from where we stand.

August 26, 2004

"….I always wondered whether some of the old technical terms in math and/or physics, had a German origin. Terms like: ansatz, eigenvalue, eigenfunction, zitterbewegung, bremsstrahlung, etc

It seems like the usage of German words in math and/or physics, became less and less common after World War 2…."

Hmmm…Seeing how Germany was the science mecca post WWII with the US assuming that role in the post war era, I'd say that makes perfect sense.

7. **JC**
August 26, 2004

Urs,

I always wondered whether some of the old technical terms in math and/or physics, had a German origin. Terms like: ansatz, eigenvalue, eigenfunction, zitterbewegung, bremsstrahlung, etc …

It seems like the usage of German words in math and/or physics, became less and less common after World War 2.

8. **raj**
August 26, 2004

>Milky way translates to Michstrasse not Milchweg – the 'milky street'!

Milchstrasse, not Michstrasse. "Mich" is the accusative of "Ich" ("I"). "Milch" is "milk"

9. **Chris Oakley**
August 26, 2004

Re: Humor – actually the *Schlaf-mit-Ihren-Frauen-Prinzip* did make me chuckle … BTW Danny – why don't you have a web site? There are physics web sites out there that make mine look tame, but I still read them … you really ought give us a comprehensive "DRL's view of the Universe" rather than the snippets we get here.

10. **D R Lunsford**
August 26, 2004

Humor Urs. Humor.

11. **Urs Schreiber**
August 26, 2004

Milky way translates to *Michstrasse* not *Milchweg* – the 'milky street'!

And unless the milkman serves a homosexual household it will be the *Schlaf-mit-Seiner-Frau-Prinzip*, or, if he is good, the *Schlaf-mit-Ihren-Frauen-Prinzip*.

Finally we learn that 'Serenus Zeitblom' has read Thomas Mann but is not a native German speaker. 😉

Ok, now you are free to correct the numerous shortcomings in my English texts… 🙂 (And in fact I'd appreciate it.)

I don't know what a good German translation of 'galactothropic principle' would be.

First of all 'anthropic principle' is just *anthropisches Prinzip* in German.

Next 'galactothropic' seems to be ill-motivated all by itself, after all the '-thropic' comes from the second half of Greek 'anthros' or something like that, doesn't it? Better would be the 'galactic principle' or the 'galactocentric principle', I'd say.

But in my opinion it would be even better to realize that all these principles are really known as 'deduction from observation'. Something is observed (the existence of human beings, of life, of galaxies) and conclusions about future observations are made from that. There is nothing more common in science:

I observe that the photographic plate has been darkened and deduce that some radiation must have hit it. Should I call this the 'photographicplatethropic principle'? 😉

12. **serenus zeitblom**
August 25, 2004

Menschenmilchwegzentrumsprinzip!
That is not the correct translation of galacto-anthropic. It should be "Milchmannprinzip". Also known as the Schlafmitihrerfrauprinzip.

13. **JC**
August 25, 2004

Heh. Sounds like a semi-Orwellian attempt at whitewashing the anthropic principle.

What would be amusing is if there ends up being a "thought police" which attempts to stop and/or discourage all uses of the word "anthropic" in string theory, while the underlying research work is exactly that of the anthropic principle.

14. **D R Lunsford**
August 25, 2004

These things sound better in German!

Menschenmilchwegzentrumsprinzip! Jawohl, ich glaube streng daran!

DPF 2004

August 31, 2004

The Division of Particles and Fields of the American Physical Society has been having its annual meeting at UC Riverside during th past few days, and some of the plenary talks have been put on-line.

Particularly interesting is the talk by Jamie Rosenzweig about Advanced Accelerators: Near and Far Future Options. It reviews ongoing development of existing technologies for use in the next (post-LHC) generation of accelerators, including the superconducting RF cavity technology recently chosen for use in a possible electron-positron linear collider. But it also covers some of the more exotic acceleration technologies that people are thinking about, including optical lasers and plasma wake-fields. Some of these technologies, if they could be made to work, hold the promise of creating much higher accelerating gradients and might allow the construction of much higher energy linear accelerators. The future of particle physics may end up depending on the success of these efforts.

The review of New Models of Electroweak Symmetry Breaking is interesting, although mainly in that it shows that the ideas going around about this aren't very compelling, and perhaps some dramatically new ones are needed. The reviews of heavy flavor and neutrino physics give a good idea of the current experimental situation. Still to be posted are talks by Clifford Johnson on "Current Trends in String Theory" and by Sean Carroll on cosmology. Carroll also has an interesting discussion of the current state of tests of general relativity on his weblog.

Comments

1. **Matthew Nobes**
   September 4, 2004

   Conceptually the charmonium states can be thought of like positronium (that's the reason for the name), but you cannot use a pure 1/r potential in a model. Model calculations typically use a 1/r + r or 1/r+log(r) potiential, where the latter term "mock's up" confinement. Even then you have to account for relativitic corrections, which can be quite large for charm. For the bottom system, the potiential model approach works better.

   This only works because the quarks are heavy, so essentially non-relativistic. You cannot use this approach for bound states with light quarks, or to compute decays. But, to the extent that a 1/r + r potential is "funky QED" it can be done for heavy quarkonium states.

2. **Steve Lidia**
   September 3, 2004

   If you're interested in advanced accelerators, you might want to consider coming to our 'Advanced Acceleration Concepts' Workshop. It's held in the US every other year – this year's was hosted by Brookhaven Nat'l Lab and held at SUNY Stony Brook. There's a good website if you want to see the range of topics and interests covered – http://www.bnl.gov/atf/AAC04.htm .

   Also – you might want to visit the physics dept. at Columbia. Tom Marshall has been a long-time participant and contributor to this field.

3. **Chris Oakley**
   September 3, 2004

   My point was just that the spectrum of c/c-bar resonances look a lot like the energy levels of positronium, so there must be something going on that is similar in terms of the binding force. Someone gave a talk about the similarities when I was at Oxford 20 years ago, but I can't remember all the details.

4. September 3, 2004

   Well on refreshing my memory there are other resonances for c-cbar states, see here:

   http://www.e835.to.infn.it/people/gollwitz/pdg_charmonium.html

5. September 3, 2004

   Chris,

   Charmonium is just another name for the J/psi meson (c-cbar). It's made in electron-positron scattering and decays into pions, so
   something like

   e+e- –> c-cbar = J –> pions

   -drl

6. **Matthew Nobes**
   September 3, 2004

   It's remarkable that any experimental information at all could be pulled from the theory, and to be honest I don't know exactly how this was done. Someone?

   By hook and crook. Before QCD there was the SU(3) models of Gell-Mann. And the whole current algebra programme. Both of these produced information that follows from symmetry considerations in QCD. Then there was Bjorken scaling, which pointed the way to the full theory of QCD.

   Nowadays, there are plenty of ways to extract information from QCD

   1) Perturbation theory for high energy processes

   2) Lattice calculations

   3) Effective field theory analysis (chiral perturbation theory, heavy quark effective theory, …)

7. **Chris Oakley**
September 3, 2004

You really can't even naively imagine QCD like "a strong funky QED"

Charmonium?

8.
September 3, 2004

Chris,

You really can't even naively imagine QCD like "a strong funky QED" because the basic interactions are completely different, i.e. in QCD one has gluon loops as well as quark-antiquark pairs in the vacuum.

Plus, the coupling is on the order of 1 rather than 1/100, so even the simplest calculations are intractable.

It's remarkable that any experimental information at all could be pulled from the theory, and to be honest I don't know exactly how this was done. Someone?

-drl

9. **Chris Oakley**
September 3, 2004

I am a bit rusty, so can someone remind me why one could not have quarks being extremely heavy with extremely high binding energy, making it always energetically preferable to produce composites in scattering events rather than lone quarks?

10. **Peter**
September 3, 2004

With strongly interacting relativistic particles like quarks or gluons, you really can't usefully think about the mass of a state as being a sum of masses of its composites and a potential energy contribution. In the limit of massless quarks the spectrum includes:

1. massless pions that are in some sense composites of two quarks.

2. massive baryon states that are in some sense composites of three quarks.

3. massive "glueball" states that in some sense have no quarks.

There's no way of understanding these things in terms of free particles bound by a potential. For one thing, as you note, you can't even define the mass of an unbound quark since such a state carries infinite energy.

11. **James Graber**
September 3, 2004

Although I've heard something like this before, and even read articles by Frank Wilczak on the same subject, I still find Matthew Nobes' comment hard to understand. A helium atom and a neutron weigh less than a deuterium atom and a tritium atom. The difference, the binding energy, is available to be released by a fusion interaction. Similarly, a neutron weighs more than a proton plus an electron plus a neutrino, and hence decays with a positive release of energy. The rule is mass of bound particle equals mass of constituents minus mass equivalent of binding energy. Therefore if two or three massless quarks are stably bound together with a positive binding energy, it would appear that the bound meson or nucleon should weigh less than zero. What gives?

I guess it somehow relates to "asymptotic freedom / infrared slavery" and hence the quarks are only massless when confined, but are actually infinitely massive when deconfined. Could one then say that most of the mass comes from the fact that the quarks are only imperfectly confined? At least this way the binding energy has the right sign. In this way of speaking, the "massless pion" is massless only because the two infinitely massive quarks are bound together by an equally infinite amount of binding energy.

Jim Graber

12. **Matthew Nobes**
September 2, 2004

Well, the standard model does not predict masses for the elemtary particles, that much is true. It is interesting to note though, that if you take QCD with two massless quark flavours, you still get a theory that roughly approximates the real world. That is, very light pions (in this case massless) and nucleons with approximately the right mass.

This is because most of the mass that we see around us is actulally the binding energy of the gluons in protons and neutrons. The actual masses of the up and down quarks contribute very little to this.

Now of course it's very hard to predict the proton mass using QCD, even with just two flavours of massless quarks. But it is possible in principle, and it's something that can be done in the framework of QCD alone.

13. **Peter**
September 2, 2004

In the standard model, the masses of elementary particles are the product of the electroweak vacuum symmetry breaking mass scale and the strength of the coupling of the particle to the field causing the symmetry breaking. No one knows why either of these two factors take the values they do.

14. **Tim M.**
September 2, 2004

I haven't studied particle physics (or any advanced physics) and have a simple question: do any theories predict masses of particles? From what I understand, this is cited as a failure of the Standard Model, so I am curious to know if other theories predict masses for any of the elementary particles.

15. **Peter**

September 1, 2004

Hi William,

I may take you up on that offer next time I'm in Berkeley. I've never understood why this sort of research doesn't get more attention given its potential importance.

16. **Simplex**
September 1, 2004

Sean Carroll's DPF talk on cosmology has now been posted.
(You say "still to be posted" so this is an update)

17. **william barletta**
September 1, 2004

It is great to see such a nice plug for advanced acclerators in your blog. These devices have still a long way to go to be useful for particle physics. However I expect that they will be the basis of a user facilty for other fields of physics in the next decade. If you visit LBNL, we will be happy to give you a tour of our laer wakefield laboratory.

Self-congratulatory Meta-post

September 1, 2004
Categories: Uncategorized

When I first started this weblog I thought very few people would be interested in reading it. I've been very pleasantly surprised both by the general high quality of the comments people contribute and by the ever increasing number of people reading "Not Even Wrong". For the last few months I've been running a program that gathers statistics from the web server logs. Here are the monthly numbers for accesses to the main weblog page:

May: 4532
June: 7194
July: 8697
August: 10427

These numbers don't include a lot of the traffic, which consists of people coming directly to one of the postings, via a Google search or a link from somewhere else.

Comments

   September 7, 2004

   Arivero*Last year I proposed a parallel example: alchemical transmutation in grounds of the general theoretical principle of preservation of energy is viable (Mercury, Hg 201, transmuting to gold, Au 197, plus He and electron debris), but no mechanism is known to achieve a decent rate*.

   It is funny that you would speak on alchemical associations, and make it sound like cold fusion transformations? 🙂

   Blackholes reproduced for inspection?

   One has to wonder then, which method will help us find this free energy source? Maybe it calls for a philosophers stone(a new quantum theoretical position)?

2. **Alejandro Rivero**
   September 6, 2004

   It doesn't fit here. The CF dispute was about experimental procedures, not about theoretical or mathematical issues. Of course theories were proposed, but it was not the relevant point.

   The theory part of experimental procedures is touchy thing; you are expected to have a valid or credible mechanism and also to verify experimentally its collateral consequences.

   Last year I proposed a parallel example: alchemical transmutation in grounds of the general theoretical principle of preservation of energy is viable (Mercury, Hg 201, transmuting to gold, Au 197, plus He and electron debris), but no mechanism is known to achieve a decent rate.

   Re cold fusion

   Julian Schwinger invested a significant effort in an attempt to understand cold fusion. (This episode is described, with a palpable twinge of embarrassment, in Milton and Mehta's Climbing the Mountain)

   As Schwinger:

   1) remained true to quantum field theory, defying the dictates of fashion

   2) evinced considerable scepticism about theories that invoked things that could not be observed and/or vaulted over many orders of magnitude in energy or whatever without a thought

   perhaps cold fusion has found its spiritual home on this site. Let's see what happens.

4. **Chris W.**
   September 4, 2004

   September 4, 2004

   I found your site vis-?-vis a search on mathematics blogs. Well I like physics too so I started reading it. Still haven't found any math blogs unfortunately.

7. **sol**
September 3, 2004

Most would know me as a hobbist, and outside of academia. I like exploring the world you gentlemen venture into.

Like someone else said, keeping current with the information is nice.

This trend with the educators showing there ideas is a nice way to see what the thinking is from those different perspectives.

I can't speak with any authority, although the models of discovery on the issues of quantum gravity, and depending on which model you choose, I think the desire and interests are the same all around, to trying to find a way to describe the nature of the geometry at planck length.

Am I wrong about this?

Those statistics of site visits is a testament to the way the internet can work espcially if your posts are linked from other sites. This drives the hits, and the hits the information you are supplying.

Even knowing your bias Peter and some of the others that post here, no one can be faulted for looking for a method. Even Lubos. What personality issues might rub others, should not deter one from the value of information that is put across.

I like the blog set up as well, even though I have used other site characteristics for demonstrations to learn. Good on you, Sean and others.

8. **Alejandro Rivero**
September 2, 2004

Thomas, I was not using charge eigenvectors. For the fermions I was counting mass eigenvectors, or subspaces if you want to account for degeneracy due to charges (but note mass and charge does not commute). Well, that is 12 fermions. For the bosons I was counting the number of generators in U(1)xSU(2)xSU(3), that is 12 again. Sorry the different criteria, but in both cases I was avoiding the use of charge eigenstates.

Now, how should strings organise this experimental input? I would welcome something between F-theory and heterotic strings. I'd assume, from the evidence both in NCG and deconstruction, that Higgses are similar to spatial coordinates, each complex higgs doublet providing four of these. Then 4 space time plus two Higgs doublets make 12 "coordinates". Thus the question is how to arrange these 12 "coordinates", 12 fermions and 12 bosons. I'd put the SM bosons instead of the bosonised fermions of heterotic strings, and I'd join the 12 coordinates with the 12 SM fermions to make superfields.

This is, I am inclined to believe, from experimental and mathematical input, that the maths of string/M/F theory are not completely wrong, but that the physical interpretation is completely, completely different of the ones they are trying.

9. **Arun**
September 2, 2004

Seems obvious to me that that string theory should be explored, and who better to explore it than those who believe in it? A theory of everything with no experimental signature is discouraging to be sure. But are there any objective arguments that that some other set of problems will be more fruitful to attack?

But he who believes in a speculative theory should not disparage other people's exploration of other approaches, e.g., as in "if it is not string theory, it cannot be a description of gravity". Pointing out the shortcomings of other approaches, specifically, LQG, is, of course, a good thing to do. But then, one should do it for the theory one believes in as well. Sound scientific skepticism is a virtue.

-Arun

10. **Thomas Larsson**
September 2, 2004

Alejandro,

Sorry, but I don't understand what you are saying. Should the coordinates in the superspace of the heterotic string be identified with physical particles? Surely at least four bosonic coordinates should be identified with the spacetime that we know, love and inhibit.

Besides, how do you count? Each quark has 3 color * 2 spin degrees of freedom, and the electron has two spins. So with that counting, you have 15 fermionic dofs *per generation*, not counting anti-particles? Moreover, you probably should count the graviton and Higgs particle as well. They have of course not been seen experimentally, but something like that must surely be there.

11. **Alejandro Rivero**
September 2, 2004

Well, as I have just stated, the experimental input is that there are 24 different kinds of particles, and the bosonic string has 24 transversal directions.

Say this, I agree that string theory researchers have a very strong tendency to neglect experimental input. They just got fortunate that the theory itself have some appreciation for it.

12. **Thomas Larsson**
September 2, 2004

I suspect that this blog has a large audience of believers in string theory [like me]

Serenius, while I don't doubt your sincerity, I seriously don't understand how you (and others) can believe in string theory.

We all know that string theory makes no hard predictions (hence the name of this forum), but it makes quite a few soft predictions, e.g. supersymmetry, extra-dimensions, new gauge bosons, a negative cosmological constant, new long-range forces (massless scalar particles associated with moduli), etc. The most striking thing with these soft-predictions is that *none* of them has been confirmed by observation, and some (the negative cosmological constant and perhaps also supersymmetry) may even be in direct conflict with experiments.

Does this not count? Maybe I'm no longer a physicist, but whatever physicist is still left in me reacts strongly when people simply ignore experimental information. There is no doubt that string theory is in apparent disagreement with experiment, and by far the simplest explanation for apparent disagreement is that it is due to real disagreement.

String/M theory may be the language in which God wrote the word, but experiment is the language with which He communicates with mortals. And He seems to say very clearly that general relativity and the standard model are very special.

13. **Alejandro Rivero**
September 2, 2004

On the positive side, LM insistence has carried me, and I suppose more people, to read the GSW (volume 1, only…), a task I had been escaping from for years.

BTW, Comparing the heterotic string with the real experimental input of the standard model (12 fermions and 12 bosons) one suspects that the M stands for "Missing". They must be looking for a missed theory with 12 fermionic degrees instead 10. Or they should.

14. **Chris Oakley**
September 2, 2004

"LQG is not string theory, and therefore it can't describe gravity"—you know who

Motl is sort of like the bouncer to the superstring night club – guaranteed to be loyal, provided you keep paying him, and always ready to keep out or evict those who refuse to abide by the rules of "the management".

Once again, though, I pose the question, what has this got to do with science?

15. **Arun**
September 1, 2004

Hehe, I suggested "used car salesman" not as a path to career success, but as a good fit with a known set of obnoxious characters.

16. **JC**
September 1, 2004

Main thing I like about this blog is how some folks are willing to "call a spade a spade" (even when it's "unpopular" to do so in some circles), and pointing out when the "emperor has no clothes on". Sort of like a physics version of Bill Mahr's "politically incorrect" show.

Speaking of Lubos Motl, if I never heard of the guy originally, I would have thought he was a "cartoon" character of some sort. Sort of like a cross between Wile E. Coyote and Charles Manson, except fanatical about string physics instead of violence.

17. **serenus zeitblom**
September 1, 2004

"If he ever considers a career outside of physics, I suggest used car salesman"
Sorry, you are wrong. No offence to Peter, but I think that the popularity of this blog owes much to the sheer *incompetence* of string theorists as salesmen. As someone said to me, "I don't think that string theory is wrong. But when I read sci.physics.strings, I wish it were!" [That was in the days when postings at sps averaged more than one or two a day, as at present.]Another good reason to read this blog, even if [as is my case] one does not agree with much of what is said here: where else can you get the latest news? How else would we learn about the adventures of El Susskind? If LM had any sense, *he* would be broadcasting all this stuff over at sps instead of [ab]using it as a place to humiliate people whose papers offend him. I suspect that this blog has a large audience of believers in string theory [like me] who use it as a news service, because no believer is commenting on the latest developments!

"LQG is not string theory, and therefore it can't describe gravity"—you know who

18. **Arun**
September 1, 2004

I too give up on Lubos Motl.

If he ever considers a career outside of physics, I suggest used car salesman.

19. **D R Lunsford**
September 1, 2004

Chris –

Even in a pefect world this site would be fun. It's like having a beer with physics buddys. If only Peter would install a pool table!

-drl

20. **Chris Oakley**
September 1, 2004

Peter,

I too have nothing but praise for this weblog, but it does beg the question – Why should it be necessary? Why should a large number of otherwise extremely smart people be so soft-headed that they are unable to tell the difference between science and mathematical speculation, fact and fiction? If the research establishment is sending a large number of its best minds off on a wild goose chase then is it these young people's fault for not rebelling, or is it the academic system's fault for not teaching or encouraging criticism of itself?

Could it be that the academic system considers that there are things that are more important than advancing physics?

21. **BB**
September 1, 2004

Hi Peter,

I must congratulate you on the quality of the website. I am an ex-particle physicist and find myself in agreement in much of what you say, most of the time. My philosophy wrt string theory is the same as with other fields—I just enjoy learning about new non-trivial ideas, be it condensed matter, or string theory or algebraic geometry (some day I hope to understand it!). But the zealotry is unbearable.

I am no longer in academia, but am very keenly interested in what real progress is being made—the hype from the real thing. Of course, I look at arxiv, but my time is limited, sadly. So I really appreciate the varied variety of posts (as opposed to a String Theoy blog)—the recent DPF post is an excellent example.

I happened to find your website by chance via Google (perhaps a Motl related search? :)). You have no idea how much I appreciate reading your posts and the follow-up comments; you often make my day!

Please keep up the great work!

BB

This is my favorite physics site, because it’s sincere and specific. Well done sir!

Perelman and the Poincare Conjecture

September 8, 2004
Categories: Uncategorized

One of the great stories of mathematics in recent years has been the proof of the Poincare conjecture by Grisha Perelman. This has been one of the most famous open problems in mathematics and has been around for about one hundred years. In technical terms the conjecture is that if a space is homotopically equivalent to a three-dimensional sphere it is homeomorphic to the three-sphere. In less technical terms it says that if you have a bounded three-dimensional space in which all loops can be shrunk down to points, it has to be the three-sphere. In dimensions other than three the analog conjecture has been proved, but the case of three dimensions has resisted all attempts to solve it.

Perelman spent time as a visiting mathematician at Stony Brook, Berkeley and NYU, then went back to St. Petersburg where for eight years he seemed to disappear from mathematics research. In November 2002 he posted a preprint on the arXiv, which quickly drew a lot of attention. He seemed to be claiming to have a proof of an even more general conjecture than Poincare, known as the Thurston Geometrization conjecture, but the way his preprint was written, it wasn't clear whether he was claiming to really have a proof. The method he was using was one pioneered by my Columbia colleague Richard Hamilton, called the "Ricci flow method". This involves something like a renormalization group flow to a fixed point (for more about this, see the talks by Ioannis Bakas at a recent conference in Crete). If you start with an arbitrary metric on a space you think might be a three-sphere, the hope was that Hamilton's Ricci flow would take you to the standard metric for the three-sphere. Hamilton had made a lot of progress using his techniques, but as far as pushing them through to give a proof of Poincare, he was stuck.

In the spring of 2003, Perelman traveled to the US and gave talks at several places, including a long series at Stony Brook. By then he was explicitly claiming to have a proof, but few of the details were written down, although he did post two more preprints to the arXiv. His talks were major events in the math community, and at them he was able to answer anyone who asked for details on specific points of his argument. He gave a somewhat informal talk at Columbia one Saturday, a talk that I attended sitting next to Hamilton, who was hearing Perelman speak for the first time. Hamilton was clearly very impressed, and soon thereafter he and most other experts began to become convinced that Perelman really did have a way of proving the conjecture.

By now the situation seems to be that the experts are pretty convinced of the details of Perelman's proof for the Poincare conjecture. The full Geometrization conjecture requires some more argument and I gather that Perelman is supposed to at some point produce another preprint with more about this. A workshop was held a couple weeks ago about Perelman's work at Princeton and several people have been carefully working through the details needed to be completely sure the proof works. For this material, see a web-site maintained at Michigan by Bruce Kleiner and John Lott.

One interesting part of this story is that the Poincare conjecture is one that the Clay Mathematics Foundation has put a one-million dollar price tag on. There's an elaborate set of rules that Perelman should follow to collect his million dollars. This is supposed to begin with the submission of a detailed proof to a well-known refereed journal, something Perelman hasn't done and shows no signs of doing. As far as anyone can tell, his attitude is that he's not interested in the million dollars. If you look closely at the rules, it doesn't necessarily have to be Perelman who writes up the proof. Someone else may do it, with Perelman still getting the money. Ultimately the question of the million dollars is to be decided by the Scientific Advisory Board of the Clay Mathematics Institute, and one question they will have to face is whether to split the award between Perelman and Hamilton.

Another interesting question concerns the Fields medal, the most prestigious award in mathematics. These are awarded every four years at the International Congress of Mathematicians, the next one of which will take place in Madrid in the summer of 2006. One stipulation for the award of the Fields medal is that a recipient must be under the age of 40. Seeing Perelman speak, I had assumed he was already at least forty, but this is not so clear. No one seems to be sure exactly what his age is and whether he will be under 40 in 2006. Some news reports from spring 2003 referred to him as being in his late 30s or even 40, some recent ones claim that he is now 37. His first scientific paper was published in 1985, so he would have had to have been 19 or younger at the time to be under 40 in 2006. If Perelman really is under 38 now, he's a sure thing for a 2006 Fields medal.

For a really dumb news article about this, go here (no, proving the Riemann hypothesis won't bring down the internet, and Perelman's Poincare proof won't explain the nature of the universe).

Comments

1. September 15, 2004

   Here is the link to the scores for that 1982 Olympiad

   http://www.srcf.ucam.org/~jsm28/imo-scores/1982/scores-order.html

2. September 14, 2004

   As a non-mathematician, I'd sure like to see this thread grow before it gets replaced by something else. These blogs (the good ones) are like gardens where the new blossoms crowd out the old ones, so you end up with only the topmost flowers. What a waste.

   This place needs a forum.

3. **Peter**
   September 14, 2004

   Ooops.

   I just accidentally deleted two interesting comments. They pointed out that Perelman was the winner of the Math Olympiad competition in 1982, that if he was under 17 then he would be under 41 in 2006, and that Noam Elkies came in 4th behind Perelman that year.

4. **dolt**
   September 10, 2004

   There is a nice, short article in Notices by John Milnor on the Poincare conjecture and Hamilton's work and a few words on Perelman's results, which I found helpful.

   http://www.ams.org/notices/200310/fea-milnor.pdf

   The nice property of Ricci flow equation is that is it like a heat equation (clear in the weak-field approximation, see Bakas). Just as heat flows from hot to cold so object gets uniform in temperature, the Ricci flow behaves similarly so "curvature tries to become more unoform", though there are several complications. My understanding is that Perelman showed how to take care of all that.

The article also seems to suggest that the choice of the Ricci flow equation chosen by Hamilton was analogous to Einstein's derivation of his field equation: essentially R_{ij} is the unique 2-index
tensor arising naturally from the first and second order derivatives of the metric. Persumably all other terms that can be written (terms of higher order in the Hilbert action in an effective field theory approach) will contain no additional geometric information.

I am merely scratching the surface, I am sure, but very interesting stuff…

5. **dolt**
September 10, 2004

Peter,

Many thanks for your patient explanations; you are an invaluable resource! I will try to get a hold of the original references and try to understand it better. At least, now I have a pretty good chance of understanding it!

6. **Peter**
September 9, 2004

Just talked to Richard about this since he was upstairs at tea. He started work on this in the late seventies and didn't hear about the connection to the renormalization group and non-linear sigma models until many years later. He thinks the first time these equations occurred in physics were in Dan Friedan's thesis (1980), which he only heard about years later.

7. **Peter**
September 9, 2004

As far as I know, the way Hamilton and Perelman are using these equations has nothing to do with the fact that they are approximate renormalization group equations for a non-linear sigma model. (If I see Hamilton maybe I'll ask him if he knew about renormalization group eqs. when he started studying this equation). For them, the important point is just that the topology of the manifold doesn't change as you evolve the metric according to the Ricci flow (at least until you hit a singularity in the solution of the PDE). The idea of the proof of geometrization (drastically over-simplified…) is to show that, no matter what metric you start with, you end up at one of the finite number of possibilities on the list that Thurston conjectured were all the possible topologies of 3d manifolds. Solutions to the Ricci flow eq. certainly do develop singularities, which is one of the things that makes this very hard.

8. **dolt**
September 9, 2004

I read with great interest the talk of Bakas and tried to understand Perlman's papers.

I have a basic question that perhaps somebody can answer.

I understand that the Ricci flow equation is nothing but a 1-loop RG equation of the 2-dim (world-sheet) sigma-models with target space metric G_{\mu\nu}(X), i.e., \beta(G_{\mu\nu})= -(Ricci Tensor)_{\mu\nu}. The higher order terms are nonzero, but may be neglected for weak curvature. This Ricci flow equation is the basis for Perelman (and Hamilton's) analysis.

How does this 1-loop approximate result become the foundation of studying geometry, especially global toopolgical questions like the Poincare conjecture.

Issues like manifold surgery, Thurston geometrization conjecture are definitely way over my head.

Thanks

9. **Thomas Larsson**
September 9, 2004

Re age limits:
I think Nobel's will stipulates that the Prize should go to the person who, within the appropriate field, has made the most important contribution to the benefit of mankind *during the past year*. One may argue whether academic research really benefits mankind the most – the Swedish inventors organization challenge that, arguing that society benefit more from inventions (like those of AN himself) than from basic research. Be that as it may, it is still hard to argue that your average Nobel laureate did his best work during the last year.

10. **Peter**
September 9, 2004

Thanks for pointing this out, the link to the conference with the Bakas talk should now work correctly.

11. **dolt**
September 9, 2004

The link to Bakas' talk is broken.

I thank you for your field-theoretic explanation of the general idea of the method of Perelman's proof (and the work of Richard Hamilton).

dolt

12. **Peter**
September 8, 2004

It looks like most of the recent media articles were generated by a program at the British Association Science Festival in Exeter a couple days ago called "Million Dollar Maths" where Perelman's proof was discussed by Keith Devlin.

I've been hearing more about Perelman recently from my colleague John Morgan, who was involved in the recent workshop in Princeton. He was the one who told me that Perelman might be young enough for the Fields medal, something I hadn't realized.

It has suprised many people during the last few months to see that maybe Perelman won't bother to write a real paper about this and really doesn't seem to care about the money.

I don’t know if there will ever be any sort of definite point at which people working on Perelman’s papers announce that, yes, it is a proof. As far as I can tell, everyone now believes Perelman’s Poincare result (if not the full Geometrization), so how the story of the million dollars plays out will be interesting to watch.

13. **Suresh**
September 8, 2004

btw why is there a sudden burst of interest in the poincare conjecture again ? has there been a recent verification of the proof ? I have been reading about Perelman’s proofs for at least a year now.

14. **Peter**
September 8, 2004

It is kind of dumb, and most recently this was made clear when Wiles proved Fermat’s last theorem, but was too old for a Fields. The positive argument for this age cut-off is that all too often what happens with these prizes is that a bunch of old guys sit around and decide to give prizes to each other. The age cut-off is a way of ensuring that recognition goes to people who have recently done something exciting and are not already well-established.

15. **D R Lunsford**
September 8, 2004

Age discrimination is a terrible problem in IT work. I can’t believe the Fields Medal is tied to an arbitrary number! What’s the point of that?

Grothendieck Biographical Article

September 14, 2004
Categories: Uncategorized

The latest issue of the Notices of the AMS contains the first part of a long biographical article about Grothendieck written by Allyn Jackson. Evidently Winfried Scharlau is writing a biography of Grothendieck, and Jackson's article is partially based on materials he has gathered. Much of this material is brought together at a website maintained by the "Grothendieck Circle".

This issue of the Notices also contains a short expository piece on one of the most abstract ideas due to Grothendieck, that of a "topos". Illusie was a student of Grothendieck's, and Jackson's article has some of his reminiscences about what that experience was like. Illusie's piece is not very accessible; a better place to try and get some feeling for these ideas is Pierre Cartier's Bulletin article.

Comments

   October 1, 2004

   Regarding books on algebraic geometry, I'd like to point out two sources not mentioned above.
   a) EGA – This is Grothendieck's monumental work and probably not what most people are looking for since it is extremely detailed, formal and dry. But if you prefer abstract nonsense, who knows? This might just be your thing since it is pretty easy to read.
   b) Algebraic Geometry and Arithmetic Curves – This relatively new Oxford University Press title does a fine job of explaining schemes in the first 7 chapters before delving into details about arithmetic curves. Complexity wise, this comes somwhere between Hartshorne and EGA (EGA being way too detailed, Hartshorne being way too dense). This will also be more useful if you're a number theorist since Liu, unlike Hartshorne, does not shy away from char. p and, in fact, devotes many sections/examples to it.

   September 16, 2004

   Levi, Dan

   Years ago I went through the 2nd volume of Shaferevich's "basic algebraic geometry" books, which covered algebraic geometry from the complex manifold perspective like Griffiths & Harris' book. At the time I ended up glossing over the chapters on schemes, largely out of laziness.

   For the entire time I was in college (both undergrad and grad school), I never really appreciated the notion of abstract math which didn't involve doing heavy computations. When I took math courses like abstract algebra and real analysis, I was always thinking to myself "what's the point of this junk?!?!?!" Even doing particle and/or string theory research, most of it was largely doing computations and not really much hardcore abstract math.

   It was after grad school when I started to look at abstract math again like algebraic geometry, commutative algebra, number theory, category theory, etc … and started to appreciate it a lot more. I guess it came with some mathematical maturity and a change in perspective, that I started to appreciate abstract math more. It took me awhile to become adjusted from the heavy computation mentality to a mindset of proving general theorems and seeing the "beauty" in it. I even went back to some old books on general topology and functional analysis and started to see them in a new light, in comparison to when I previously thought it was all a "waste of time" in the past.

   I guess the only way I can describe "beauty" in abstract math, would be similar how an artist or musician sees "beauty" in a particlar piece of art or music. To a person who has no interest in math, art, or music, they would not see much "beauty" in it and wonder "what's the point" of it all.

4. **D R Lunsford**
   September 16, 2004

   I find the biggest barrier to *any* math learning in a modern context is that *all* of it seems dry and lifeless as presented – of course it is anything but, only the formalist methods of presentation just make it seem so IMO. I wish there were a modern Klein or Weyl running around. This seems to be a niche that someone should fill.

   I was told by a former Princeton math PhD that oral tradition is now essential in math, and that learning from textbooks without some personal mentor is very hard. In Klein's day, his "Vorlesungen" were taken directly from his personal style, so the presentation and the results were mixed in a way that made for exciting reading. We need something like that again IMO. Shlomo Sternberg comes close to filling the bill. Harris tries, but assumes too much of readers with my level of patience and skill.

5. **JC**
   September 16, 2004

   I always found the biggest barrier to understanding scheme theory and/or the more abstract formalism of algebraic geometry, was a solid understanding of commutative algebra. Years ago I worked through Atiyah's book on commutative algebra, which I thought was kind of dry and boring at the time.

   Awhile ago I went through Diers' book "categories of commutative algebras" which seems to make the subject more interesting and less dry, though I don't know how much more useful it is for understanding algebraic geometry.

6. **D R Lunsford**
   September 16, 2004

   There is a smaller book called "Algebraic Geometry – A First Course" by Harris alone that is good, and is accessible to physics types (i.e. me). At one time I had the preposterous idea of mastering scheme theory.

   -drl

7. **Levi**

September 16, 2004

JC–Some friends and I are currently reading “Basic Algebraic Geometry” by Shaferevich. It may not be what you are looking for, though, since it makes a concerted effort to be no more abstract than is absolutely necessary.

8. **sol**
   September 15, 2004

   First off, I appreciate the information in your article on Grothendieck. I am deeply interested in how different minds came to discover the foundational values of mathematics, albeit from the sidelines, of your perspectives and collegues, Peter.

   As a general reader of Smolin’s, Three Roads to Quantum Gravity I saw this same road taken, and assumed the essence of his distilliation, was topos theory.

   http://math.ucr.edu/home/baez/topos.html

   For more information I added this to my main page because of this set relationship I found being demonstrated in the developement of LQG perspectives in terms of quantum gravity.

   At a fundamental level of this association was quantified in terms of quantum grvaity, then I saw computerization deeply valued in relation to discriptors of that early uiverse.

   Like gamma ray detection, we saw the deeper fundamental realites emerge on the Windows of the universe. We might have to wait, to go deeper then this?

   I found it difficult to find some comparison on how such a view could have been exemplified, so by studing the Glast perspective I found a general relevance, that would have supported LQG.

   But did this go far enough? I see the limitations now, in relation to early universe perspective?

   The universe had to be smooth at its most earliest time?

9. **JC**
   September 15, 2004

   The “easiest” books on algebraic geometry I’ve come across over the years would be “ideals, varieties, and algorithms” by Cox, Little, & O’Shea, and perhaps the two undergradate books by Reid on algebraic geometry and commutative algebra. None of them seem to really go into the more abstract formalism of schemes, advocated by Grothendieck.

   I’ll take a look at Eisenbud & Harris’ book on the geometry of schemes.

10. September 15, 2004

    JC: Eisenbud, Harris: “The Geometry of Schemes” seems to be a more accessible introduction to the language, with examples and motivation behind the ideas. Relatively cheap, too…

11. **JC**
    September 14, 2004

    Peter,

    How common is it for physics folks to change into math? What’s the most popular area of math that physics folks like to change into?

    In recent years, the cases of physics folks changing into math that I’ve heard of were frequently some string theory folks who changed into some algebraic geometry areas related to Calabi-Yau manifolds (ie. the sort of stuff in the language of Griffiths and Harris’s “principles of algebraic geometry” book). I haven’t personally come across many physics folks who changed into the more abstract algebraic geometry stuff (ie. the more abstract Grothendieck style, such as in Hartshorne’s book). Though on the surface, I can understand why string folks would prefer the “Griffiths & Harris” language of algebraic geometry. Last time I tried to tackle Hartshorne’s book, I still found it a difficult read.

    Anybody know of an easier book than Hartshorne, which covers the more abstract Grothendieck style of algebraic geometry?

CERN at 50

September 16, 2004
Categories: Uncategorized

This month is the 50th anniversary of the formal founding of the CERN laboratory near Geneva. There's a very interesting article in Physics World about CERN and its future plans. LHC construction seems to be proceeding more or less on schedule, although there has been a delay in beginning to install the magnets in the tunnel due to problems with the distribution line that will provide liquid helium to the magnets.

Jos Engelen, the chief scientific officer of the lab, is quoted as wanting to see any decision about building a linear collider wait until 2010 or so. The scientific reason for this is that it may take that long to for the LHC to produce results, and the sort of linear collider one wants to build may depend upon these, e.g. on the mass of the Higgs. CERN has its own linear collider technology called "CLIC" which it is working on. CLIC is quite different than the TESLA superconducting cavity technology developed at DESY and recently endorsed by the ITRP committee charged with evaluating which technology to go ahead with. CLIC uses a second electron beam to accelerate the main beam and in principle is capable of higher accelerating gradients than TESLA. Whereas a machine using TESLA technology would probably have an energy of 500 Gev, upgradeable to 1 Tev, CLIC might be able to reach 3-5 Tev. CERN is now increasing the resources devoted to the CLIC project, and clearly hopes that a delay in the decision about whether to build the linear collider would give them time to develop and prove the viability of CLIC.

   The subject of this post is experimental particle physics, so I'll perversely take the opportunity to draw attention to two theoretical papers that I find very intriguing. I hope nobody is too annoyed; according to SPIRES-HEP neither paper has been cited by anyone but the author, who does not appear to have any academic affiliation:

   > Spin foams, causal links and geometry-induced interactions (hep-th/0403137)
   > ABSTRACT: Current theories of particle physics, including the standard model, are dominated by the paradigm that nature is basically translation invariant. Deviations from translation invariance are described by the action of forces. General relativity is based on a different paradigm: There is no translation invariance in general. Interaction is a consequence of the geometry of spacetime, formed by the presence of matter, rather than of forces. ….
   >
   > Relativity in binary systems as root of quantum mechanics and space-time (hep-th/0408116)
   > ABSTRACT: Inspired by Bohr's dictum that "physical phenomena are observed relative to different experimental setups", this article investigates the notion of relativity in Bohr's sense, starting from a set of binary elements. ….

Motl on String Field Theory

September 17, 2004
Categories: Uncategorized

Lubos Motl has an interesting post on sci.physics.stringsthat gives a detailed explanation of the current state of string field theory.

One way of motivating quantum field theory is to start with a "first-quantized" quantum theory of particles (perhaps defined by integrating over paths), then "second-quantize" by considering a quantum theory of fields, where the fields are defined on the space the points in the path move in. The natural generalization to string theory would be to start with the "first-quantized" theory of strings given by doing path integrals over the possible worldsheets traced out by the moving strings (these are conformal field theories), then "second quantize" by quantizing fields defined on the infinite dimensional space of loops. It has always been a hope of string theorists that this would somehow give a true non-perturbative definition of string theory.

Lubos explains what some of the problems with this idea are. For one thing it is in conflict with the M-theory philosophy that a non-perturbative theory should involve on the same footing not just strings, but also higher dimensional "branes". He goes on to speculate about what can be done about this problem, saying that perhaps one shouldn't be trying to find a fundamental set of degrees of freedom and an action functional of them. Instead maybe one just needs to find a set of self-consistent rules, which will be obeyed by all sorts of different degrees of freedom. As he notes at the end, this is similar to the old "Bootstrap Philosophy" of Chew and others that dominated thinking about the strong interactions during the 1960's. It didn't work then, and I'll bet it won't work now.

   September 18, 2004

   Yawn.

4. **Ted Erler**
   September 17, 2004

   Most of what Lubos says I agree with.

   However, I think that the string community has been a little over critical of string field theory. Many theorists would even like to forget its existence, frequently saying that string theory has "no nonperturbative definition."

   As far as we know, Witten's cubic open bosonic string field theory gives a full nonperturbative definition of open+closed bosonic string theory. This is not to say that every concievable nonperturbative result in string theory has been reproduced in string field theory. It just means that we have no definitive argument that such nonperturbative information is not there, in principle.

   String field theory is a very complicated formalism and is far from unique. There are an infinite number of string field theories, each corresponding to a choice of conformal background and a particular decomposition of the moduli space of Riemann surfaces. There are open string field theories, closed string field theories, open+closed string field theories, superstring field theories… Presumably, each of these could provide a nonperturbative definition of string theory, but certain features which might be obvious in one string field theory (such as the perturbative spectrum around its conformal background) may be quite nontrivial in another (one would first have to construct a classical solution describing the background, and then study fluctuations about this solution). All of these formulations are presumably related by a complicated field redefinition, but our current understanding is primative.

   Faced with this situation, most string theorists hope that a more elegant, background independent formulation of string theory will at some point present itself. Personally, I have been inclined to take string field theory seriously, hoping that graudually a deeper understanding of its complicated but presumably profound struncture will emmerge.

6. **JC**
   September 17, 2004

   How many places has Chew's "bootstrap philosophy" worked to even a small degree? The only cases I can think of offhand would be some semi-contrived two dimensional models which appear to be exactly solvable. (ie. quantum inverse scattering sort of stuff). Other than that, I would be hard pressed to think of anything else which was not a failure.

String Geometry at Snowbird

September 19, 2004
Categories: Uncategorized

Thomas Larsson wrote in a comment mentioning a news story that appeared early this past summer in the Deseret Morning News (yes, that's Deseret, not Desert; this is a name Mormons use to refer to Utah). The news story is about a conference on "String Geometry" held at Snowbird, Utah in June. Evidently at Andy Strominger's talk at this conference someone actually mentioned that there were people who were skeptical about string theory and asked him to comment. His response was that "I hope they're wrong, but I can't prove it, and I bet my life work on their being wrong" , which I guess characterizes the attitude of many string theorists these days ("things don't look good, but I've got too much invested in this to give up, so I'll keep on engaging in wishful thinking even though I no longer have much of an argument for why I'm doing this").

Many of the talks at the conference are online. These include a couple of interesting talks by Gukov and Spradlin about recent work on twistor theory and perturbative Yang-Mills amplitudes, as well as the usual Michael Douglas talk with its wishful thinking that analyzing the astronomically large "landscape" will somehow lead to some sort of prediction of something. There's also a talk by Radu Tatar about non-Kahler superstring theory backgrounds. I've always wondered about this since I hear from an algebraic geometer colleague that although no one knows whether there are an infinite number of Calabi-Yaus in the Kahler case, if you relax the Kahler condition there definitely are an infinite number of them. If these non-Kahler backgrounds make sense, you can stop worrying about whether the landscape contains 10^100 or 10^500 possibilities.

Tomorrow here at Columbia my colleague Brian Greene is giving a colloquium on "The State of String Theory". His abstract says he'll "assess both its current shortcomings and major achievements".

   Offend? I must up my flippancy daemon priority.

   But seriously, I like to know who's saying what.

2.
   September 23, 2004

   My apologies on not giving a name. My intent was not to offend. If it makes you feel better, I am not a regular poster being coy, but merely a casual reader who was posting a flippant comment. If I happen to post something of substance I'll be sure to give a name.

   But, since you asked, I'll just say that Georgi isn't a loon at all. Actually I loved the class I took with Georgi, and him as a person as well.

3. **D R Lunsford**
   September 21, 2004

   That is true, although I do have a nice letter from Georgi from my teenage days. He isn't (wasn't?) a loon. In fact I can't remember ever meeting a math/physics loon before the advent of this Internet thing.

   (Simple request – can we please use names here? There's nothing to be afraid of. I'd like to think/pretend this isn't the run-of-the-mill free- republic-type anony-blog.)

4.
   September 21, 2004

   "He's a loon with a professorship at Harvard.

   How'd that happen?"

   You've clearly not spent any time as a physics student at Harvard…

5. **Thomas Larsson**
   September 21, 2004

   Serenius, I have no doubt that most string theorists and LQG'ists alike are nice people. Motl may be an exception, but Gell-Mann does not give a particularly nice impression neither. This is not important. Besides, I think that Motl has a point about LQG, more politely expressed by Hellig-Policastro.

   Nobody doubts that most string theorists are nice and bright, only that they are right. To call Strominer a loon is certainly not fair.

6. **D R Lunsford**
   September 20, 2004

   He's a loon with a professorship at Harvard.

   How'd that happen?

7. **serenus zeitblom**
   September 20, 2004

   I don't think that Strominger's attitude is wrong. He has a hunch that string theory is right and he is following that up. He has infinitely more reason to be triumphal about [eg] black hole entropy than Lubos Motl or others of that ilk, yet I have never heard that he has tried to exaggerate the real but modest achievements of string theory in that direction. He's a good guy and a sensible one.

   Speaking of LM, this is from his proposed entry on loop gravity in wikipedia [the online encyclopaedia, http://en.wikipedia.org/wiki/Main_Page%5D:

   most loop quantum gravity advocates are not good physicists, and they try to avoid learning anything from particle physics and other fields even though it is clearly necessary for a proper understanding of many questions in quantum gravity. They believe that a very narrow-minded understanding of reality that they propose – and that has not made any real progress for decades – is everything we need. They are making incorrect mental links between different concepts and they are unable to learn better.

This was spiked by the wikipedia people on the grounds that it was “over the top”. LM has reached the stage where even non-physicists can tell that he’s a loon.

8. **Urs Schreiber**
September 20, 2004

It is due to phenomenology that N=1 susy to many people seems/seemed to be a very attractive property of an effective field theory of the fundamental forces.

The potential to shed light on the hierarchy problem as well as apparently better gauge unification properties are what made many people consider supersymmetric extensions of the standard model. And models like that drop out of string theory if six of ten dimensions are compactified on a CY manifold.

However, there is no known dynamical reason within string theory that six dimensions should spontaneously compactify as a CY space. This does not necessarily mean that such a dynamical mechanism does not exist, but these questions concerning the dynamical choice of string ‘vacuum’ are not at all well understood. For these reasons people just choose a CY compactification for phenomenological reasons and proceed from there.

This choice is compoletely analogous to (but somewhat more complex than) choosing a value for the parameter k in the Friedman-Robertson-Walker cosmological solutions of plain GR. For each value of k one obtains a valid solution, but one does not have (yet) a dynamical explanation why one value of k is observed in nature while the others are not. So one chooses the parameter that is preferred phenomenologically and then proceeds from there.

The math of supersymmetry as an abstract concept is extremely nice and supersymmetry concepts play an important role in many branches of physics and mathematics that are not directly related to high energy phenomenology. However, the supersymmetric extensions of the standard model and the scattering computations done in them are far from being very elegant. They have a plethora of free parameters and many new particles and interactions. Even though supersymmetry still ensures certain cancelations and makes some computations quicker, in general supersymmetry phenomenology is a *mess*.

9. **Dick Thompson**
September 19, 2004

Urs (or anybody), why is N=1 SUSY so compelling? Suely it can’t be because of phenolenology. Is it just that the math is graceful?

10. **JC**
September 19, 2004

Are there any backgrounds which break ALL the supersymmetry, without introducing any additional “diseases” to string theory?

11. **Urs Schreiber**
September 19, 2004

The condition that after the compactification of 1oD string theory down to four dimensions the remaining effective field theory has precisely N=1 supersymmetry is that the compactified 6 dimensions form a Calabi-Yau space, which is in particular Kähler. Relaxing that means not having N=1 susy in four dimensions (at high energy before 4d susy breaking).

In principle there is no compelling reason that the ten susystring dimensions must be compactified such that the resulting 4d theory has N=1 susy. This is just the scenario that people find/found most interesting. (Because susy in 4d is/was considered attractive and N=1 (as opposed to higher N) is the only choice not in contradiction with observation from the outset).

12. **JC**
September 19, 2004

Peter,

If you relax the Kahler condition, do you get an aleph_0 infinity of backgrounds or an aleph_1 infinity or beyond?

Physics wise what would be the dire consequences of relaxing the Kahler condition, besides definitely having an infinite number of backgrounds?

This Week's Predictions

September 20, 2004
Categories: Uncategorized

A new preprint by Michael Douglas indicates that, at least this week, the latest "predictions" from string theory are for:

1. No large extra dimensions.

2. No low scale supersymmetry.

So it looks like the "prediction" of the string theory "Landscape" will be that no physics related to string theory beyond that of the standard model will ever be observable. Thus the only "prediction" of string theory will be that you can never see any physics related to it. This kind of "prediction" is great since it proves string theory must be true. Either you don't ever see any effects of string theory in which case you have confirmed its predictions so it must be true, or you do see effects of string theory, in which case string theory is even more true.

Nothing really new at Brian's physics colloquium today. About 300 people showed up, which I think is probably a record for a physics colloquium. Brian doesn't like Susskind's "anthropic" arguments, which shows good sense. He still hopes that some new form of non-perturbative string theory will explain the standard model by picking out the right Calabi-Yau, but admits there's no known reason for this to happen.

   On September 25, 2004 03:56 PM Simplex said:
   …But if you have some articles by LQG people criticising string (besides Rovelli's Dialog) please let us know!…

   I don't know of any articles. I don't even read the archives regularly. I do however know several of the LQG principals and I've heard my share of "string theory is a horribly idea" tirades.

   Ironically, one of the most persecuted LQGists, Lee Smolin, is some one I've heard make comments similar to, "we have to take string theory seriously…".

3. **Thomas Larsson**
   September 27, 2004

   I am still not following your conclusions. For 2-d gravity string theory has the correct canonical quantization. That's what we talked about so far.

   I agree.

   When canonically quantizing gravity in 3+1 dimensions one finds that the commutator of the generators has divergences and hence cannot be well defined. LQG circumvents that by using a singular GNS representation where the generators themselves are not represented at all. By comparison with the 2d case one see that this step is not backed by ordinray QM. So the conclusion is that the LQG way to make canonical quantization of 3+1 D gravity work (work for the spatial diffeos that is -even with that trick the Hamiltonian constraint remains a problem) is using some very unusual notion of 'quantum'.

   One comment: the full Dirac algebra of ADM constraints is physically equivalent to the 4-diffeomorphism algebra. As emphasized by Rovelli, phase space is a covariant concept – the space of solutions to the classical field equations. We may label a solution by its positions and momenta at t = 0, but this is just one way to coordinatize phase space. However, some 4-diffeos do not preserve the standard coordinatization, so if we insist on keeping it, we must add compensating transformations, and we wind up with the Dirac algebra. But conceptually we are still dealing with 4-diffeomorphisms, and if we canonically quantize in the covariant phase space instead, that is our constaint algebra.

   So in conclusion we find that no way at all is known to apply canonical Dirac-like/inspired quantization to 3+1d gravity.

   Because there are additional anomalies which the standard formalism cannot handle.

   Although I don't know much about Liouville field theory, it seems to be some sort of archetype of an anomalously broken gauge symmetry. There is an extra mode, the Liouville mode, which becomes physical when D != 26. Analogously, we may expect that there are extra modes, which are passive in the classical theory, become physical when the diffeomorphism constraints are quantized.

   In fact, it is easy to describe these modes. To build representations of the diffeo algebra, we first of all need to expand all fields in a Taylor series around "the observer's trajectory" q(t), viz.

   f(x) = \sum_m f_m(t) (x-q(t))^m

   (We need some conditions on the Taylor functions f_m(t) to ensure that f(x) is independent of t). Classically, we can reformulate the field equations for f(x) as a hierarchy of equations for the Taylor coefficients – awkward but in principle straightforward. Upon quantization, the passive modes q(t) become physical – they have canonical momenta and are represented on the Hilbert space – in pretty much the same way as the Liouville mode.

   This is necessary in order to quantize a general-covariant theory in a way that represents the diffeomorphism constraints unitarily, because this is the way to build anomalous (and thus potentially unitary) representations of the diffeomorphism algebra. The need for such an expansion is clear since the anomaly is a functional of q(t). In string or field theory, where one never introduces this reference curve, the anomaly is invisible.

   In string theory the answer to this problem seems to be that the action for 3+1 d gravity is really embedded into a 'UV completion' whose path integral (namely the SFT path integral) can perturbatively be computed or which, for certain asymptotic backgrounds, can be computed non-perturbatively.

   If this means if and/or that the canonical Dirac constraints of gravity ever appear here is something that I don't see. You seem to think so but you haven't provided *evidence for it.*

One thing that can nicely be seen in the toy example of 1+1d gravity is that the Dirac prescription for quantizing constraints is just a first guess. The next best guess is Gupta-Bleuler quantization, which tells you that indeed not all states need to be annihilate by the constraints.

These may be regarded as different Virasoro representations. So from my point of view, the right way to quantize is to build unitary Virasoro representations.

But even that is based on ad-hoc assumptions. In the end it is the path integral that counts.

This is a bold statement – let's just ditch canonical quantization. It is nice that you make this assumption of string theory explicit.

Do you really believe that string field theory or M field theory will not have any canonical formulation?

I believe that before one can draw any conclusions from the results on diffeo algebras that you have in mind, one would have to understand if and in which way they are actually connected to a process called 'quantization'. Currently it seems that there is no such thing as Dirac constraints for gravity in more than 2-d.

I have previously claimed to have quantized general covariance, and associated quantum reps with any general-covariant theory. However, after having looked into the covariant phase space, I'm leaning towards the opinion that the construction in math-ph/0210023 is really an honest quantization of gravity, although the nomenclature in the paper is not quite right. Here what I do:

1. Start with some general-covariant theory, containing gravity and other fields.
2. Regularize the theory by expanding all fields in a Taylor series and truncate at some finite order p. This is the unique regularization compatible with diffeomorphisms.
3. Construct the space of functions over the covariant phase space, as cohomology spaces. The diffeo algebra acts on these functions spaces by Poisson brackets.
4. Replace Poisson brackets by commutators and represent the Heisenberg algebra on a Fock space. The diffeo algebra acquires an anomaly, so this must be quantization.
5. To remove the regulator, the anomalies must not diverge in the p -> infinity limit. Check and solve the conditions for this.

The cool thing is that these finiteness condition naturally require that spacetime has four dimensions.

There is a catch, though. I need twice as many variables as one would expect, so I really construct the ring of differential operators over phase space in point 3. But this is really the only way that my prescription differs from ordinary QM. In particular, since the regularized theories live in 1D, they don't need any renormalization beyond normal ordering.

4. **Urs Schreiber**
September 27, 2004

Hi Thomas –

I am still not following your conclusions. For 2-d gravity string theory has the correct canonical quantization. That's what we talked about so far.

When canonically quantizing gravity in 3+1 dimensions one finds that the commutator of the generators has divergences and hence cannot be well defined. LQG circumvents that by using a singular GNS representation where the generators themselves are not represented at all. By comparison with the 2d case one see that this step is not backed by ordinray QM. So the conclusion is that the LQG way to make canonical quantization of 3+1 D gravity work (work for the spatial diffeos that is -even with that trick the Hamiltonian constraint remains a problem) is using some very unusual notion of 'quantum'.

So in conclusion we find that no way at all is known to apply canonical Dirac-like/inspired quantization to 3+1d gravity.

In string theory the answer to this problem seems to be that the action for 3+1 d gravity is really embedded into a 'UV completion' whose path integral (namely the SFT path integral) can perturbatively be computed or which, for certain asymptotic backgrounds, can be computed non-perturbatively.

If this means if and/or that the canonical Dirac constraints of gravity ever appear here is something that I don't see. You seem to think so but you haven't provided evidence for it.

One thing that can nicely be seen in the toy example of 1+1d gravity is that the Dirac prescription for quantizing constraints is just a first guess. The next best guess is Gupta-Bleuler quantization, which tells you that indeed not *all* states need to be annihilate by the constraints. But even that is based on ad-hoc assumptions. In the end it is the path integral that counts. Evaluating the path-integral of 1+1d gravity correctly yields the BRST quantization, and this finally shows when and in which sense Dirac and Gupta-Bleuler apply. Since already in 2d the BRST quantization highlights a couple of subtleties that are missed with Dirac/Gupta-Bleuler, this teaches us to be careful with applying these methods to higher dimensions.

I believe that before one can draw any conclusions from the results on diffeo algebras that you have in mind, one would have to understand if and in which way they are actually connected to a process called 'quantization'. Currently it seems that there is no such thing as Dirac constraints for gravity in more than 2-d.

It seems to me that Urs Schreiber, Helling, and Policastro have shown that LQG seems to have made a wrong turn, in making an unphysical construction. Can LQG be rescued?

I think not. However, the substance of my critique of string theory (apart from the overselling and lack of experimental support, which everybody sees) is essentially the Helling-Policastro argument transcribed to 4D:

H-P: Any unitary representation of the conformal algebra in 2D on a conventional Hilbert space is necessarily anomalous. LQG does not admit such anomalies. Hence LQG is wrong.

Me: Any unitary representation of the diffeomorphism algebra in 4D on a conventional Hilbert space is necessarily anomalous. String theory does not admit such anomalies. Hence string theory is wrong.

Urs Schreiber claims that this argument does not apply to string theory, because only the perturbative definition is understood. This only reflects our limited understanding of a complicated theory and is no problem. However, if string theory does not admit a formulation in a conventional Hilbert space with a unitary action of the diffeomorphism group even in principle, then it breaks with conventional quantum theory far more than LQG. And if it does admit such a hypothetical formulation, then the 4D Helling-Policastro argument applies to it.

It seems to me that Urs Schreiber, Helling, and Policastro have shown that LQG seems to have made a wrong turn, in making an unphysical construction. Can LQG be rescued?

7. **sol**
September 25, 2004

I added this because it was important to dig deep for the positions Smolin has assume and for the general public this might not be apparent, so I of course went looking.

Sol2

A case in point, is the understanding of Smolin's position.

I have followed his thinking as a example of the rigourous, and summations, although at a much generalized level. I do not think I should have been faulted on this as a crank(an overall generalization) of those who have not developed fully from the roads GR has taught us. Including those who wish to try and make a discription of the gravity waves fit some gravitonic expression?

Smolin tells us that General Relativity is not about adding to those structures or even about substituting those structures for possible new structures. Of course, we must understand what he is refering to here .

The basis of Smolins position rejects the idea, that space and time are fixed. He believes it evolves dynamically. He then subcribes, in my way of thinking, to the value of using this structure(it is contradictory to me as I stated up in previous post about photon intersections[Glast limitations] and the intersection of gravtonic considerations.

In the methods explained in terms of Glast's experimental standing we see where this can be taken further? Smolin calls it a set of relationships between events that take place.

To place such attempts at rediscribing the nature of the spacetime fabric disturbs him?

http://www.physicsforums.com/showpost.php?s=5c7da106e4775f720f0aefeedf9be54e&p=308810&postcount=8

Are we to deny some method to geometrical expression classically defined and not consider this at the quantum levels?

What is Quantum geometry if we cannot linearly describe the action that is taking place at the most suttles levels of existance?

I would appreciate any corrections in my thinking.

ksh95 at September 25, 2004 01:02 PM says:
"In my opinion, both camps could benefit by worrying more about getting their own houses in order and paying less attentions to these petty squables."

Please point me to some criticisms of String by Loop Gravitists.
I see plenty of criticism of String but almost none from LQG researchers.
there was Carlo Rovelli's entertaining Dialog (between a junior researcher and a senior) but that was some months back and comparatively light reading.

Lee Smolin has joined in the widespread criticism of the Anthropic Principle but that is not String per se. Thomas Thiemann tried to bridge the gap inspired by a senior string theorist (Hermann Nicolai). I did not think his attempted bridge was at all hostile, though it did not get a very favorable response from string theorists.

What I hear in the way of "squabbling" is very one-sided. String folk like Lubos Motl giving many reasons why LQG cannot possibly be right.

I see little evidence to suggest that Loop people are wasting any effort on squabbling or on criticizing String. Their field is undergoing rapid change and growth, the production of papers has shot up in the past couple of years (although still very small by comparison with more established lines of research) and I do not imagine they have much extra time to devote to controversy.

But if you have some articles by LQG people criticising string (besides Rovelli's Dialog) please let us know!

9. **sol**
September 25, 2004

In all fairness, looking at how the history developed helps to shape the perspective in regards to the history of strings as it unfolds.

http://xxx.lanl.gov/PS_cache/hep-th/pdf/9909/9909016.pdf

For those inclined to developement a resource for continued reference to hold the higher road to edcuational value, I would draw your attention to the following post.

http://superstringtheory.org:8080/forum/edonline/discussion.jsp?thread=16

Regardless of the demeanor each discussion forum holds, this is an attempt to get minds to further embrace a place that would develope the conceptions beyond personal perspectives.

I defintiely need this spirit of cooperation to draw from.

Regards

September 25, 2004

As a condensed matter theorist I have no horse in this race so I feel I can offer an non-expert but unbiased opinion. Frankly, it seems like this whole quantum gravty enterprise could be headed south. String Theory's short comings are will documented. This website being an excellent example. Loop Quantum Gravity is facing some serious criticisms. Examples can be found in Urs's post below or in http://www.arxiv.org/abs/hep-th/0409182.

In my opinion, both camps could benefit by worrying more about getting their own houses in order and paying less attentions to these petty squables. Funding sources have neither infinite resources or patience. I hear there have been some great advances in AIDS research these days. Similarly, nano sized complex molecules seem poised to usher in the next era of ultra small electronic devices. If you people aren't careful you'll find the technologically relevent areas of physics moving into the engineering building, while all the high end theorists adjust to their new offices next to the philosophers.

Chris W. wrote:

> The string theorists who disagree should roll up their sleeves, grit their teeth, and demonstrate its insolubility. This would be an extremely interesting result. Unfortunately they apparently think it's so obviously true as to be not worth the effort

This is not quite true. There has been some input to LQG from string theory recently.

A while ago Edward Witten himself demonstrated that the Kodama state which Lee Smolin is so fond of is not normalizable and hence not really a physical state after all.

Then Hod and Dreyer and some other people became quite excited about a numerical coincidence between quasinormal mode spectra of black holes and BH entropy calculations in LQG. Motl and Neitzke published a paper (which is by now TopCited 50) showing that it is indeed just a numerical coincidence. Shortly afterwards it turned out that the entire entropy calculation in LQG was based on a wrong assumption.

H. Nicolai emphasized that LQG people should try to apply their methods to 1+1 dimensional gravity and see if any of the well known results could be reproduced. Shortly afterwards Thomas Thimemann did exactly that and found that the LQG method misses all the standard results. He used the GNS construction as well as Pohlmeyer invariants to do so.

I showed that the Pohlmeyer invariants that he used and could not quite quantize are quantizable in the standard non-LQG-like context. A while later it turned out that this result was already found in the 80s by Isaev, but apparently forgotten. A few days ago Helling and Policastro demonstrated how the GNS construction that Thiemann used leads to the ordinary non-LQG-like quantization when one uses a continuous GNS state instead of the highly singular one used by Thiemann, which is also used in full LQG.

There is a very simple argument that the standard LQG prescription to first solve the spatial diffeos and then impose the Hamiltonian constraint cannot work in principle in 1+1 dimensions. Thiemann circumvented this by including the Hamiltonian constraint in the GNS construction. It was clear that his singular construction has nothing to do with known physics, and indeed he admitted that it is motivated only by the speculation that such 'unusual quantum mechanics' might turn out to be correct at the Planck scale.

12. **Chris W.**
September 22, 2004

After enduring LM's sermon I perused some other recent sci.physics.strings threads and found one of the most lucid and informative discussions (by Urs Schreiber) of "background independence" in string theory that I've come across. Its relevance to the topic of this post is conveyed in the following remarks:

> String theory is nicely "background independent" in the first sense, even more so than ordinary GR, for instance. Not only is the metric a dynamical quantity, but even the number of (macroscopic) dimensions, the coupling constant, and to a large extend the entire field (particle) content of the theory is not a fixed ingredient of the Lagrangian but is dynamical.
>
> That's the very reason why one can even consider dynamics in the string theory "landscape". String theory is so immensely "background independent" in the first sense of the word that it is at present very hard to say anything about which values all these dynamical quantities it contains actually will obtain after some evolution. The landscape discussion is one of dealing with a theory which is highly background free, so that you first have to solve equations of motion to even be able to say something about the matter content of the theory. This is quite in contrast to other approaches to quantum gravity, which are often considered to be truly "background independent", where all the matter content, the coupling constants, the number of dimensions is fixed by hand.

I wonder if anyone in the string theory community would bother to articulate this if they weren't being pressed by the LQG'ers. By the way, I doubt that the present inability to identify a sensible classical limit in LQG will ultimately prove to be an insoluble problem; see hep-th/0404156. The string theorists who disagree should roll up their sleeves, grit their teeth, and demonstrate its insolubility. This would be an extremely interesting result. Unfortunately they apparently think it's so obviously true as to be not worth the effort.

13. **Arun**
September 22, 2004

This one by LM is another in the crusade to rid the world of LQG.

14. **raj**
September 22, 2004

Um, so, if there is no observable, how can the theory be–um–verified?

It strikes me that they are getting more and more into pseudo-physics

15. **peng**
September 21, 2004

blablabla
really good comments on problems that everyone sees.
however, not really constructive in any way.

16. **Peter**
September 21, 2004

Well, the "non-perturbative string theory will make everything work" line has been used for nearly twenty years, and has been a huge success for string theorists. I don't think they'll drop it anytime soon.

Witten's most important contributions to mathematics just use QFT, not string theory (Chern-Simons-Witten invariants of 3-manifolds, Seiberg-Witten invariants of 4-manifolds). Much of what people think of as string theory contributions to math are really 2d CFT, not string theory. Seems to me that if you're just doing CFT, you're doing 2d QFT, not string theory. You're only really doing string theory if you try and sum up contributions from different genus calculations. Some of the recent work in topological string theory does give things like Gromov-Witten invariants for all genera simultaneously, so seems to really be string theory.

17. **dolt**
September 21, 2004

I think the string theorists are entering very dangerous territory by the constant over-selling of what string theory can or cannot do. The hype over the supposed `Theory of Everything' is going to backfire and be detrimental to the lay public's perception of what physicists do.

I contrast the claims of string theorists with QED (anomalous moment of electron, etc), the 'standard model of strong and electro-weak interactions' (rho parameter test, etc). Pretty much everone thought (and knew) they were effective theories—hence the modest term 'model'. Considering what constitutes a model, much more is expected of a 'theory', let alone a 'theory of everything'.

Of course, the problem is the lack of dearth of unexplainable experimental data. So just say that strings/susy etc are one of the possible alternatives—nothing more.

Otherwise, string theory will be viewed as mathematical theology.

The only interesting results in string theory are those that are of interest to mathematicians. BTW, could anyone tell us how many of the new results of interests to mathematicians are of string theory in particular, not QFT? My understanding is that most (all?) of work of Witten of profound mathemtical importance are really based on applications of QFT. So Witten's work is of lasting importance in terms of his role in progress of mathematical physics, even if string theory does not work out; others, such as those based on 'string phenomenology' and the like, I am not so sure.

18. **JC**
September 21, 2004

Seems like "non-perturbative" is everybody's favorite buzzword and faint hope whenever they have run up against a brick wall and/or ran out of good ideas to work on in particle and/or string theory research. I wonder what they will think up of next, when the "non-perturbative" buzzword starts to wear thin and becomes too much like an excuse of "crying wolf". (That is without entering into the anthropic stupidity).

What the Bleep Do We Know?

September 27, 2004
Categories: Favorite Old Posts, Film Reviews

Last night I went to see a movie which was advertised as being about quantum physics, called "What the Bleep Do We Know?". I was expecting something pretty dumb, but am always interested to see what people think about quantum mechanics. The film surpassed all expectations; it was certainly the stupidest thing I can remember seeing in a movie theater, and that's saying quite a lot (I see a lot of movies…).

There was some sort of plot involving a woman photographer (played by Marlee Matlin), who wanders around and has anxiety attacks. Interspersed with the plot were interviews with various supposed scientists with something to say about quantum physics, consciousness, God, etc. On the whole they were a bunch of complete flakes, although one of them (David Albert) is a philosopher of science here at Columbia. Evidently Albert claims he was taken advantage of, that his interview was heavily edited to misrepresent his views.

The general idea was that since quantum mechanics supposedly says that there isn't one reality, but an infinite number of possibilities, one just has to be enlightened to an awareness of this, and then you can make whatever you want happen. Somehow the main character of the movie was learning these amazing facts about quantum physics, and this then helps her deal with her anxiety attacks, bad body image and sex addiction (the film really goes off the rails in a bizarre scene where she is the photographer at a wedding party that turns into a grotesque kind of orgy).

The film has a web-site, and there is a long article in Salon explaining that the whole thing is really the production of a cult based in the Pacific Northwest that believes that a woman named JZ Knight is able to channel a 35,000 year old mystic named Ramtha. She does play a large role in the movie and you can read all about her nonsense here.

The whole thing is really moronic beyond belief. One of the scientists interviewed is John Hagelin who, besides being part of the TM cult surrounding Maharishi Mahesh Yogi, presidential candidate of the Natural Law Party, and "Minister of Science and Technology of the Global Country of World Peace" is a rather prominent particle theorist. Prominent if you go by citations that is. His 73 papers are mostly about supersymmetric GUTs and considered quite respectable, with a total of over 5000 citations, including 641 citations for one of them alone.

Hagelin was a grad student at Harvard when I was an undergrad and I met him when we were in the same quantum field theory class. A roommate of mine was interested in TM and I think it was he who introduced us. I remember Hagelin wanting to discuss how quantum field theory could explain how TM'ers were able to levitate, something about how they did this by changing the position of the pole in the propagator. The fact that someone who spouts such utter nonsense can get a Ph.D. from Harvard and be one of the most widely cited authors on supersymmetric models is pretty remarkable.

Comments

1. **Fabio**
   October 6, 2004

   Of Hagelin's thousands of citations, how many are from the Ellis/Nanopoulous et al paper mill?

2. **diggingdeeper**
   October 4, 2004

   Hope you don't mind me butting in, just thought you might like to see these facts which are so far undisputed about the film.

   1. In addition to the films three directors, there were actors and others involved in the production who are long time "students" of Ramthas' School of enlightenment.

   2. A disproportionate amount of time was given in voice and film to Ramtha, Dr. Joe dispenza, and Miceal Ledwith.

   3. Dr Joe Dispenza and Miceal Ledwith are both long time students and "appointed teachers at Ramthas' school of enlightenment (RSE)

   4. Dr Joe Dispenza (the one who creates his day) has gone to court and testified that his teacher (ramtha) has told him that terrible times are coming and that he needs to protect his family. He also invested over $10,000.00 in an infamous scam that infected RSE and was touted by Ramtha as a vehicle to gain fabulous wealth and many of the schools membership lost substantial sums of money. Some lost their entire life savings.
   This is the person who teaches the brain science in RSE.

   5.Miceal Ledwith a clergyman with a rather dubious past (see http://unison.ie/irish_independent/stories.php3?ca=36&si=770458&issue_id=7565) is the one chosen by the film makers to be the theological spokesman. He is also the theologian in residence of RSE.
   He also has been marketing several products within the school and its followers. Guess that could not have been done to easily in the Catholic church.

   6. The following persons in the film have all spoken at RSE and sold books there.

   Fred Allen Wolf
   Dr Candice Pert
   Amit Gotswami
   John Haglin
   Joe Dispenza
   Miceal Ledwith
   and of course the big guy himself, Ramtha

   7. One of the scientists who was in the film and had never appeared at the school is Dr David Albert Professor and Director of Philosophical Physics at Columbia university.
   He has stated in several venues that his views were totally misrepresented in the film. He claims that in over 5 hours of interviews he explained to the film makers why their concept of how Quantum Physics works has virtually no support in the scientific community.
   He even called in to a radio program the director was on to discuss this and was cut off. The host of the show said this was done because it was "negative"
   so much for no good or bad, that is unless it is convienent.

   8. To date, there has been no response as to where the information which lead to the story about the indians not being able to see the ships of Columbus originated from. There appears to be no evidence to support this claim. In addition, the film mentioned "clipper ships" which were not even in existence at that time. Perhaps that is why they couldn't see them.

There were many more, but I will leave them for others. If anyone has any information to refute any of the facts laid out here, I will be more then willing to retract them.

They are relevant because of the deliberateness on the part of the film makers to keep certain facts unknown (ironically, it is I making the unknown know) and misrepresent others.

3.
September 30, 2004

I am glad that someone else thought that that movie was a bunch of garbage. I had it recommended to me by no less than three people. Everyone said that "you have to see this movie!" So I did. It was really hard to sit through. It was the biggest bunch of garbage that I had ever seen. Blech.

I guess the difference between me and those other people is that I actually have some grasp on the concepts that the movie was trying to talk about. Never mind that the movie didn't even have a plot.

4. **Peter**
September 29, 2004

Hi Lubos,

For many years in the early-mid-eighties, the Maharishi was pushing N=8 supergravity as the unified field theory, I remember a colorful poster explaining how it agreed exactly with his philosophy that many people posted on their walls. At some point I guess he updated it to string field theory and the version you provided a link for.

It's true that Hagelin stopped doing physics in the mid-nineties to concentrate on his other nonsense, but I can vouch for the fact that as early as 1978-9 he was heavily involved in TM and thought it had a lot to do with QFT. By 1984 he had moved to Maharishi University and started building up the physics department there. In the late eighties I remember seeing Maharishi University preprints, perhaps about flipped SU(5). The main weird thing about them was they were printed on pink paper instead of white.

5. **Lubo? Motl**
September 29, 2004

John Hagelin was obviously a good phenomenologists. Unfortunately he's written no papers after 1995, see

http://www.slac.stanford.edu/spires/find/hep/www?rawcmd=find+a+hagelin&FORMAT=WWW&SEQUENCE=

Well, people are able to undergo various transformations.

I want to mention another point – Maharishi Mahesh Yogi. Right after the Velvet Revolution in 1989 (the collapse of the Czechoslovak communism), many new spiritual and other directions were trying to find their ways to the new free countries.

A group of 3 Indian people claiming to be direct disciples of Maharishi Mahesh-Yogi visited our high school. They were spreading their methods of meditation – but that was not the main thing that impressed me. They were showing us the pictures of the waves converging to a point – a meditation trick – and this picture had a caption explaining that "the unified field theory has already been found". I was really impressed – and although it sounded totally crazy, the "Einsteinian language" that their brochures were using had nearly convinced me that they really know something about fundamental physics. 😉

It evaporated in a couple of weeks…

The web makes all such things available today, so I can give you a Google link to a page about Maharishis' unified field theory,

http://www.worldpeaceendowment.org/invincibility/invincibility6.html

6. **Alejandro Rivero**
September 29, 2004

Sol. you refer to the offspring of hep-ph/9803315. It was an interesting idea aiming to solve the hierachy problem, as announced.

On the other hand, one finds 3+1, or more concretely inverse square law, to be mathematically peculiar when it refers to gravity, ie when mass is the source of the force. Check my single page unpublishable http://dftuz.unizar.es/~rivero/research/simple.pdf

7. **JC**
September 29, 2004

Peter,

It was amusing when John Hagelin tried to run for US president representing the "Natural Law" party during the 1990's. A lot of the propaganda from them was hilarious, especially whenever candidates attempted to hold public speeches and performing demonstrations of "yogic flying".

If I didn't know any better, I would have thought it was something straight out of a "Cheech and Chong" movie.

September 28, 2004

Hi Matt,

No, that wasn't intended specifically as an attack on supersymmetric models; the fact that Hagelin worked on them isn't an argument for or against them. And while I don't think supersymmetric GUTs are anywhere near as promising as many people seem to think, they are a much saner idea than many that dominate research these days (take the Landscape, please…).

But whenever one is dealing with highly speculative ideas that have no connection with experiment, there's a danger of becoming delusional and thinking that you're doing real science when you're not. People tend to believe that the fact that a certain kind of research is pursued by sizable numbers of people with very good credentials is enough to mean it must be good research. I think it's a good idea for people to consider the example of Hagelin: he's completely delusional and has zero common sense, but able to function at a high level in the particle theory community. One should take seriously the danger that he's not the only one deluding himself.

10. **sd**
September 28, 2004

Matt, what is so nutty about Serge Lang's ideas about HIV and AIDS? He points out that Gallo et al anounced that AIDS is caused by HIV at a press conference, without there being a single paper published in a scientific journal substantiating this. Isn't Lang's viewpoint in line with the sort of criticism that string theory receives at this web site?

11. **Matt**
September 28, 2004

Is that last line — "The fact that someone who spouts such utter nonsense can get a Ph.D. from Harvard and be one of the most widely cited authors on supersymmetric models is pretty remarkable" — some sort of strange attack on SUSY models? Isn't that a bit like attacking algebra because of Serge Lang's nutty ideas about HIV and AIDS?

Hagelin might be crazy, but some of those papers are co-written by John Ellis and other respectable people. I'm not personally familiar with any of Hagelin's work but I'm sure there's some good physics in there.

12. **sol**
September 28, 2004

It took a while, but the comparison finally came through on the association of strings, as a quantum mechanical perspective, and the relationship to that movie.

From my perspective, once you had identtified Smolin's position(I gave this in previous post[**Posted by sol at September 25, 2004 04:18 PM**]), then you would know he holds Einsteins, in relation to the Solvay meetings, and strings have modified what Bohr and Schrodinger were doing in developing QM.

Yet, the battle still ranges, and we now know where we can class the distinctions of LQG and String theorists?

13. **Alejandro Rivero**
September 28, 2004

"Extreme quantum mechanics" could be the name of the speciality of SF writer (and physicist) Greg Egan. I suggest to read him if you want to know how QM is perceived in the SF community.

14. **sol**
September 28, 2004

Peter,

It took a while, but the comparison finally came through on the association of strings, as a quantum mechanical perspective, and the relationship to that movie.

It's okay to be cynical:)

I mean listen, you have very reputable individuals who believe in validation, as experimental proof. Who believe, in all kinds of things(God maybe?). That would be, very hard to quantify:)

Yet, they just do.

15. **Cosma**
September 27, 2004

I've not seen the movie, and don't intend to, but David Albert's book on *Quantum Mechanics and Experience* is one of the best things I've read on the interpretation of QM. If he says he's being misrepresented, I quite believe him.

2004 Nobel Prizes in Physics

September 29, 2004
Categories: Favorite Old Posts, Uncategorized

No, they haven't announced the Nobel prizes yet this year. The announcement of the physics prize is scheduled for mid-day (Stockholm time) next Tuesday. I have zero inside information about who is likely to get the prize this year, but in particle theory there is one obvious choice: Gross, Wilczek and Politzer for asymptotic freedom.

The discovery of the asymptotic freedom of Yang-Mills theory led very quickly to the realization that QCD was the right theory of the strong interactions, and this was what really completed the Standard Model. It is one of the most important discoveries of 20th century science. The calculation of the Yang-Mills beta function was completed about the same time by David Politzer (a student of Sidney Coleman's at Harvard) and David Gross working with his student Frank Wilczek at Princeton. Gross was actually trying to complete a proof that all QFTs had bad ultraviolet behavior; he still was suffering from the pre-QCD prejudice that the strong interactions could never be understood via QFT, that one needed instead to do S-matrix theory or string theory or something other than QFT.

I've always been surprised that a Nobel hasn't yet been awarded for this discovery. The only reasons I can think of are political ones:

1. Evidently 't Hooft had done the beta function calculation earlier, but hadn't realized how significant it was or written it up. He certainly didn't work out the experimental implications for deep inelastic scattering, which was what Gross, Politzer and Wilczek did. Unlike 't Hooft, they immediately realized the significance of the result. So the Nobel committee might have felt it that it would be unfair not to make an award to 't Hooft. But 't Hooft did receive the prize a few years back for his work on renormalization of Yang-Mills theory, so this reason should no longer hold.

2. David Politzer was made a tenured professor at Caltech at a very early point in his career, but hasn't done much since then. Some people might not be so happy about awarding him the prize.

3. There certainly are some people in the particle physics community who weren't personally fans of David Gross. I remember many years ago a lunch with one European physicist who claimed to be involved in the Nobel decision process, at which he vividly claimed that "David Gross will get a Nobel prize over my dead body!". He's dead now, so at least he's no longer an obstruction.

Anyway, Gross-Politzer-Wilczek is my bet for next Tuesday.

   Kinda like when Paul Newman got the Oscar (finally) for "The Color of Money". Well done Peter 🙂

6. **Thomas Larsson**
   October 5, 2004

   Congratulations, Peter, you were right!

   Press Release: The 2004 Nobel Prize in Physics
   5 October 2004

   The Royal Swedish Academy of Sciences has decided to award the Nobel Prize in Physics for 2004 "for the discovery of asymptotic freedom in the theory of the strong interaction" jointly to

   David J. Gross
   Kavli Institute for Theoretical Physics, University of California, Santa Barbara, USA,

   H. David Politzer
   California Institute of Technology (Caltech), Pasadena, USA, and

   Frank Wilczek
   Massachusetts Institute of Technology (MIT), Cambridge, USA.

   A 'colourful' discovery in the world of quarks
   What are the smallest building blocks in Nature? How do these particles build up everything we see around us? What forces act in Nature and how do they actually function?

This year's Nobel Prize in Physics deals with these fundamental questions, problems that occupied physicists throughout the 20th century and still challenge both theoreticians and experimentalists working at the major particle accelerators.

David Gross, David Politzer and Frank Wilczek have made an important theoretical discovery concerning the strong force, or the 'colour force' as it is also called. The strong force is the one that is dominant in the atomic nucleus, acting between the quarks inside the proton and the neutron. What this year's Laureates discovered was something that, at first sight, seemed completely contradictory. The interpretation of their mathematical result was that the closer the quarks are to each other, the weaker is the 'colour charge'. When the quarks are really close to each other, the force is so weak that they behave almost as free particles. This phenomenon is called ?asymptotic freedom?. The converse is true when the quarks move apart: the force becomes stronger when the distance increases. This property may be compared to a rubber band. The more the band is stretched, the stronger the force.

This discovery was expressed in 1973 in an elegant mathematical framework that led to a completely new theory, Quantum ChromoDynamics, QCD. This theory was an important contribution to the Standard Model, the theory that describes all physics connected with the electromagnetic force (which acts between charged particles), the weak force (which is important for the sun's energy production) and the strong force (which acts between quarks). With the aid of QCD physicists can at last explain why quarks only behave as free particles at extremely high energies. In the proton and the neutron they always occur in triplets.

Thanks to their discovery, David Gross, David Politzer and Frank Wilczek have brought physics one step closer to fulfilling a grand dream, to formulate a unified theory comprising gravity as well ? a theory for everything.

   October 4, 2004

   In my personal view,the Nobel Physics Prize for this year should be given to the scientists who work in the field of String Theory and the Yang Mill's Theory due to the significent effect by them to the theoritical Physics.But however ,I would also like to say that nowadays there are really no quite exiting news in those fields,then why don't we change our previous thought of the candidate and focus on some old famous scientists?
   I mean probably we may award ChenNing Yang and Mills for their proficient work in the Gauge Field Theory.Why not?

   Lubos Motl said:

   "I just don't understand how can you give a Nobel prize for testing an accepted theory a little bit further. I think that Nobel prizes can only be given for new discoveries, and this example is precisely a textbook example of having no new discoveries."

   Understand or not…

   Quote from

   http://nobelprize.org/physics/laureates/1993/press.html

   "Here a new, revolutionary "space laboratory" has been obtained for testing Einstein's general theory of relativity and alternative theories of gravity. So far, Einstein's theory has passed the tests with flying colours. Of particular interest has been the possibility of verifying with great precision the theory's prediction that the system should lose energy by emitting gravitational waves in about the same way that a system of moving electrical charges emits electromagnetic waves."

   I think prizes *should* be given to people who find cool ways to test theories beyond the regimes that were reachable before, whether the theories pass the test or not. This is a way to encourage experimentalists to think hard about new ways to push the limits, whether some theorists think it is worth it or not (didn't Pauli think measuring g was useless?)

9. **sol**
   October 2, 2004

   Some are behind the times here and in this article 2002, what is realized in 2004? The Perimeter institue and Smolin are well on top of the issue from a Glast perspective?

   Test of the Quantenteleportation
   over long distances in the duct system of Vienna

   Working group
   Quantity of experiment and the Foundations OF Physics
   Professor Anton Zeilinger

   Quantum physics questions the classical physical conception of the world and also the everyday life understanding, which is based on our experiences, in principle. In addition, the experimental results lead to new future technologies, which a revolutionizing of communication and computer technologies, how we know them, promise.

   In order to exhaust this technical innovation potential, the project "Quantenteleportation was brought over long distances" in a co-operation between WKA and the working group by Professor Anton Zeilinger into being. In this experiment photons in the duct system "are teleportiert" of Vienna, i.e. transferred, the characteristics of a photon to another, removed far. First results are to be expected in the late summer 2002.

   http://www.quantum.at/Kanal/

10. **Lubos Motl**
    October 1, 2004

    Dear Michael,

    yes, I was referring to rather specific experiments of Zeilinger et al. – some of them studied entanglement at distances of order kilometers.

    Well, you may say, together with some other physicists, that quantum mechanics could fail at distances of order kilometers. We think that it cannot. Well, physics has the virtue of having experiments. The experiments have been done, and you have been proved wrong. 😉

    I hope that this unsuccessful prediction of yours should at least reduce your self-confidence in claiming that amazing violations of quantum mechanics could be observed at distances of order 100 kilometers!

    But more generally, I just don't understand how can you give a Nobel prize for testing an accepted theory a little bit further. I think that Nobel prizes can only be given for new discoveries, and this example is precisely a textbook example of having no new discoveries.

    I also absolutely disagree with your statement that there are principles (you even say "a lot of principles") of quantum mechanics that have not been tested. What do you exactly mean? Quantum mechanics was *created* through experiments. When quantum mechanics was developed, even the most obvious conceptual steps in the theory were only done once the experiments showed that it was necessary. The statements called "principles of quantum mechanics" have been experimentally tested before the end of the 1920s. I just don't know what exactly you want to test today.

    There is no known theory that could explain the observed experiments in a consistent framework but that would violate a principle of quantum mechanics – and we can more or less show that such a theory can't exist.

    Best
    Lubos

11. **Michael Nielsen**
    October 1, 2004

    "Come on, Michael, there was just no way how quantum mechanics could conceivably break down at distances of order one mile."

    I'm not sure what you're referring to, here. Why did you pick "one mile"? Are you referring to a specific experiment? Or is this a general statement, that quantum mechanics can't possibly be wrong on everyday scales?

    Certainly, I think Zeilinger's done a lot of great work checking quantum mechanics in various regimes where it has never been tested before. Macroscopic superpositions of semiclassical states and controlled entanglement have only very recently been observed, and Zeilinger's been at the forefront of that effort.

    If you're saying that there's no way quantum mechanics could fail at distances on typical macroscopic scales, well, I disagree, and so do many other physicists. There are, quite simply, a lot of basic principles in quantum mechanics that have never been checked, or have been inadequately checked.

    "The value of Zeilinger's experiments is purely pedagogical, everyone around agrees with that, "

    I'm not sure who "everyone around" is, but I suspect only a tiny fraction of physicists would agree. Certainly, people I know within AMO physics – one of the largest subcommunities of physics – generally seem to feel that Zeilinger's work is important.

12. **Lubos Motl**
    October 1, 2004

    Come on, Michael, there was just no way how quantum mechanics could conceivably break down at distances of order one mile.

    Your approach "Zeilinger did not prove that QM works the way it does, it is just consistent" explicitly shows that you would be willing to spend new money to make similar experiments where the separation is 10 miles, 100 miles, and so forth.

    This would be a complete waste of the money, and it is not really true that these experiments would be probing a new regime. QED certainly works at distances of order miles.

    The value of Zeilinger's experiments is purely pedagogical, everyone around agrees with that, and the Nobel prize committees is not a bunch of lame journalists that could be fooled and confuse a funny experiment with a new discovery.

13. **Fabien Besnard**
    October 1, 2004

    Dolt : Alain Connes has a web site where you can find his latest papers : http://www.alainconnes.org/
    John Baez speaks of some recent math papers from time to time on his web page.

    On the whole I think Peter is right about the 'math style' but this is rapidly changing, I think mainly because of the increasing pressure to publish impressive number of papers.

14. **Michael Nielsen**
    September 30, 2004

    Lubos Motl: "Well, the website also suggests that Anton Zeilinger could be a conceivable candidate. His experiments are cute even though their value is purely pedagogical – they proved that quantum mechanics works the way that everyone well-informed has already understood in the late 1920s."

    No, those experiments proved that the real world works in a way consistent with a theory that's been known since the 1920s. This is a huge difference, especially since many of those experiments checked that theory in a regime that's never before been probed experibmentally.

15. **dolt**
    September 30, 2004

    Peter,

    Thank you very much for explaining the difference in the way mathematics and physics is done. I had not appreciated the significant difference in style.

Well, I will have to rely on the various mathematical awards to get a sense of what the community thinks the important papers have been
in mathematics.

MathScinet, as you said, needs institutional subscription. Too bad the mathematicians do not maintain their own webpages and post their papers! Some do (perhaps the younger ones), but most don't.

16. **Lubos Motl**
September 30, 2004

Hey Sol,

could I ask you to try to express at least one your ideas in a different way? I did not understand the meaning of a single sentence in your text. Who are those who "look at quantum mechanics"? Which viewpoint is outdated? Which Feynman's toy model are you talking about? What is the difference between your "new era" and the "old era"? Why is it related to all the previous questions?

Which "refinements of refined GLAST perceptions" are you talking about? Why do you think that this offers an insight to GR if it would contradict GR? Why do you think that these questions are related to string theory, and what do you mean by the "right" string theory?

Thanks,
Lubos

17. **sol**
September 30, 2004

If you noticed, Lubos constanty refers to the outdated viewsto those who look at quantum mechanical discriptions, even though there is a nice trail has been set up in Feynmen's toy model.

I think he is nicely trying to nudge people out of the "ancient views," to a more modern acceptance of quantum mechanical posturing, so that maybe the "new era," could have accepted other possibilties.

Maybe refinements in Glast gamma ray perceptions to have refined it to a much more deeper connection with GR?

I'm only speculating of course as to the "right" string theory:)

Maybe a NObel prize in this?

18. **Peter**
September 30, 2004

The main reason there haven't been many Nobel prizes in relativity is that there aren't a lot of unexpected experimental results. Pretty much all the experimental results agree with the GR prediction. About the only real non-GR prediction about gravity is Hawking radiation, but Hawking is unlikely to get a Nobel for this unless a radiating black hole is discovered.

The 1993 Nobel to Hulse and Taylor for measuring the effects of gravitational radiation on binary pulsars is one example of a relativity Nobel. Another example would be the 1978 Nobel for observing the CMB given to Penzias and Wilson.

Actually, another good bet for the Nobel prize this year would probably be for a prize for the WMAP experiment.

19. **Peter**
September 30, 2004

The culture in mathematics about preprints and papers is somewhat different than in physics. You can think of physics as being more "journalistic", with the emphasis being on getting something out there about the latest, hottest topic, in a form that as many people as possible can read, without overly worrying about whether it is completely correct.

Mathematicians are much more obsessed with writing something that is precisely correct; they often feel that they are writing for the ages, not just for the current fashion. The numbers of people working on any given topic is quite different in math and particle theory. Most mathematicians are working on problems that only a handful of other people around the world can understand the significance of, whereas for the latest fashionable theoretical physics topic there are hundreds if not thousands of researchers interested in following what is being done.

So mathematicians tend to be less interested in getting their work out quickly and having it widely distributed on the arxiv. This is changing as more and more of them see the advantages of this, but there still is a sizable part of the literature that doesn't show up on the arxiv (unlike the situation in particle theory). There isn't another large parallel preprint system, although the "MathSciNet" on-line version of Mathematical Reviews run by the AMS has very complete information about what papers are out there. But often you do need access to a library, or an affiliation with an insitution that is paying for electronic access rights to get to see papers.

Trying to put together a list of the most important papers in a wide variety of fields would be valuable, but it's very hard. To do this well you really would need a very wide range of expertise and spend some serious time looking into different fields and talking to the experts. Someone should do this, but I don't think I'm up for it. And of course the people whose papers you put on the list would be mildly pleased, but think it their due, while those you didn't put on the list would often become lifetime enemies.

20. **dolt**
September 30, 2004

Peter,

Here is a suggestion:

How about posting a list of important papers (in your opinion, or the experts) in mathematics and physics (as many subfields!) every year, say in December? Since you are in the math department, you have a rare opportunity of
sharing the progress in mathematics with us physicists. Of course, your post on Perelman is an excellent example.

BTW, I seem to find that mathematicians have not embraced the arxiv the way particle physicists have. Is that true? To someone outside academia, it is hard to get access to mathematical journals.
Or is there an alternate site where the papers are posted?

dolt

21. **D R Lunsford**
September 30, 2004

If not what Peter said, then I would think someone in materials research, magnetic or solid state. The development of disk technology has changed the world. (Last year was superconductors.)

22. **Thomas Larsson**
September 30, 2004

I'd vote for Belavin-Polyakov-Zamolodchikov, for the application of conformal field theory to 2D critical phenomena. 2D statphys is admittedly not the most important part of physics; e.g., it is of less physical importance than 3D statphys. Nevertheless, this is the only major theoretical discovery after 1980 which is also real, experimentally confirmed physics.

I will not make any bets, though. I have expected that BPZ would win the Prize for more than ten years, but it never happens.

23. **serenus zeitblom**
September 30, 2004

Politzer "hasn't done much"?! Well, I think all of us here would be delighted to have done so little!
By the way, re his famous work, what is impressive is not just that he has a paper that has been cited over 2000 times — what is even more impressive is that he *wrote it by himself*. Nowadays, when hardly anyone seems to be able to think for himself, that is really impressive.

24. **Matt**
September 29, 2004

other candidates for a QCD-like Nobel prize are usually out of the game ('t Hooft and Gell-Mann have already received one) – perhaps except for Bjorken.

How about Nambu? (I would love to see Bjorken get the prize, though.)

25. **D R Lunsford**
September 29, 2004

Good point _______.

I'd like to call you something other than _______, but you are too paranoid to be a person in this place of persons.

(WHY are people so afraid to use their names?)

26. **Lubos Motl**
September 29, 2004

David Gross was only added to the main "stock market" on a German Nobel prize toy website 2 days ago, but he immediately sold $50,000 of his stocks and is normally traded right now.

http://www.nobelpreisboerse.de/stocks.aspx?stc=1

You can buy the stocks of Gross and Wilczek! I think that they are much cheaper than the real value. 😉 Gross, Wilczek, and probably Politzer is both my wish as well as my bet for Tuesday – but the probability that a particular bet works out is always smaller than 50%, I would say.

But it has already been 5 years from 't Hooft and Veltman; other candidates for a QCD-like Nobel prize are usually out of the game ('t Hooft and Gell-Mann have already received one) – perhaps except for Bjorken.

Well, the website also suggests that Anton Zeilinger could be a conceivable candidate. His experiments are cute even though their value is purely pedagogical – they proved that quantum mechanics works the way that everyone well-informed has already understood in the late 1920s.

If a member of the Nobel prize committee reads this posting, they should know that the question whether David Politzer is included or not is probably secondary, and should not change the decision that Gross and Wilczek should be awarded this time.

27. **Anon**
September 29, 2004

Any thoughts on why the entire field of Relativity
has been short shrifted by the Nobel committees –
from forever?

Is it true that Chandrasekhar received the only
Nobel for (an application of) Relativity?

Some History

September 30, 2004
Categories: Uncategorized

There's an interesting new preprint by the historian of mathematics Erhard Scholz about the early history of the use of representation theory in quantum mechanics. Immediately after the beginnings of quantum mechanics in 1925, several people started to realize that the representation theory of the symmetric and rotation groups was a very powerful tool for getting at some of the implications of quantum mechanics for atomic spectra. One of the main figures in this was Eugene Wigner, who was trained as a chemical engineer, but worked on this topic with his fellow Hungarian, the well-known mathematician von Neumann.

Equally important was the role of the mathematician Hermann Weyl, who in 1925 had just completed his main work on the representation theory of compact groups, perhaps the most important mathematical work in a very illustrious career. Weyl was in close communication both with the group at Gottingen (Heisenberg, Born, Jordan) who were developing matrix mechanics, as well as Schrodinger who was working on wave mechanics. Weyl and Schrodinger both were professors in Zurich and knew each other well (Schrodinger's first paper on quantum mechanics thanks Weyl for explaining to him some of the general properties of equations such as the Schrodinger equation). In 1927/8 Weyl gave a course on quantum mechanics and representation theory, which became the basis of his extremely influential book "The Theory of Groups and Quantum Mechanics", first published in 1928.

Scholz has also posted another preprint about Weyl's work, one that focuses on how his conception of the relation between matter and geometry evolved from 1915 to 1930. Weyl worked on general relativity and wrote an influential book about it (Space-Time-Matter, 1918). At that time he, Einstein and others believed that matter could somehow be described by a unified theory expressed in terms of some generalization of Riemannian geometry. Perhaps particles were some specific singularities or special solutions to the non-linear equations for the metric. The advent of quantum mechanics convinced Weyl (unlike Einstein), that this was a misguided notion, that matter should be described by a complex wave function. The right mathematics was not the geometry of a metric, but (in modern language) the geometry of gauge fields and of sections of a vector bundle with connection. The close connection between the basic ideas of representation theory and of quantum mechanics was quite clear to him, so, unlike Einstein, he enthusiastically adopted the new point of view of quantum physics.

One part of the close connection between Weyl and the history of quantum mechanics isn't mentioned by Scholz. Weyl was not only a close friend of Schrodinger's, he was Schrodinger's wife's lover. Schrodinger didn't believe much in monogamy; it's a well-known story that he discovered the Schrodinger equation while on holiday in the mountains with a girlfriend.

   October 1, 2004

   would you care to share a recommendation?

   I would have to check. I certainly do not remember any 20 years ago, although Schiff chapter 7 goes some distance along this path.

3.
   October 1, 2004

   1. The theory of continuous groups and their unitary representations ought to be taught in undergraduate physics courses. It is not that hard and plays an absolutely crucial role in quantum mechanics. For example, the connection between angular momentum in quantum mechanics and the rotation group is more important than the connection with classical angular momentum and yet, in the course I was on, at least, the former was hardly mentioned.

   Chris,

   Are there any undergraduate level texts available? If so, would you care to share a recommendation?

4. **Lubos Motl**
   October 1, 2004

   Dear Thomas,

   I mostly agree with the statement about the evidence supporting QM and special relativity – although if I were describing these questions, I would probably separate these two things. (Also, I would use a less mathematical language.)

   We have a lot of evidence in favor of special relativity, including classical physics (which has no unitary representations), and a lot of evidence for quantum mechanics (in the nonrelativistic regime). Well, if we unify these two structures, we must introduce these unitary representations of the Poincare group, and this is what quantum field theory dictates. Well, we have a lot of evidence for quantum field theory, that goes beyond special relativity and quantum mechanics separately, too.

   I am not sure what (nontrivial) is meant by the unitary representations of the diffeomoprhism group in the second part of the text. If we require the representations to be unitary, it's because we want to get positive squared norms (positive – and conserved – probabilities) – which is a condition for *physical* states. However, physical states also need to be gauge invariant, and therefore they always form many copies of the trivial, singlet representation of the gauge group – at least of the part of the gauge group that is close to the identity (the part that is connected with the identity, and described by a normalizable wave).

   On the other hand, if you consider unphysical states in a formalism "before" you impose the physical constraints, there is no reason for the representations to be unitary. Indeed, the Hilbert spaces including the unphysical states are typically non-unitary representations of various algebras. For example, consider QED with all the time-like and longitudinal polarizations of a photon.

   All the best

Lubos

5. **Thomas Larsson**
October 1, 2004

2. The fact that "fundamental" particles/fields look a lot like the vectors of unitary irreducible representations of the Poincare group is an excellent endorsement for our theories of special relativity and quantum mechanics. Indeed, one seems to require little more than this representation theory to build up the whole of QFT.

This is indeed my understanding as well. This is my point in a post which I just sent to sps – let's see if LM accepts it. Anyway, I'm rather proud of the punchline:

At the most basic level, a quantum theory is defined by a Hilbert space and a unitary time evolution. If the theory has some symmetries, they must be realized as unitary operators acting on this Hilbert space as well. If time translation is included among the symmetries, which is the case for the Poincare algebra (and more subtly for diffeomorphisms), requiring a unitary representation of the symmetry algebra seems to be enough for consistency.

From this viewpoint, there is a 1-1 correspondence between general-covariant quantum theories (GCQT) and unitary representations of the diffeomorphism group on a conventional Hilbert space. Namely, if we have a GCQT, its Hilbert space carries a unitary rep of the diffeomorphism group. And if we have a unitary rep of the diffeomorphism group, the Hilbert space on which it acts can be interpreted as the Hilbert space of some GCQT. Since all unitary quantum irreps of the diffeomorphism group are anomalous, apart from the trivial one, all interesting GCQTs carry anomalous reps of the diffeomorphism group. So rather than being inconsistent, the second type of gauge anomaly is in fact a necessary condition for non-trivial consistency.

8. **D R Lunsford**
September 30, 2004

Weyl and Klein are my absolute heroes among the mathematicians.

I don't think it is quite right to say Weyl regarded "pure infinitesimal geometry" as "misguided". He was, I think astonished that it didn't work out as he originally thought – and it must have been on his mind all the time, because when the time came for the idea to reemerge in a new context (gauge theory), he was immediately on it. The idea behind PIG is after all incredibly simple – completely localizing the metric. How can it be that the simpler and more natural idea fails? I wish he were alive to see how his idea succeeds in the most remarkable way possible, by bringing matter into full equality with space and time, just as he wished.

When I was a student, my advisor said "Read Weyl. He writes for smart people." It was the best advice I ever got. Not only are the results intrinsically interesting, one has the feeling on reading Weyl that a great adventure is underway – that the author is not out to pound his vision into your consciousness, but to illuminate the world and its beauties. If only this spirit had become the consensus, instead of the self-indulgent formalism of Bourbaki.

Whatever

Categories: Uncategorized

Over at sci.physics.strings there's the scary sight of Lubos Motl agreeing with me in a posting about "Stringy Naturalness". Well, maybe he isn't directly saying he agrees with me, but "It would be too difficult for me to pretend that I disagree with these Woit's remarks" is pretty close. Lubos is criticizing the new sort of "naturalness" critierion advocated by Miichael Douglas in a preprint reviewing his recent work on the "Landscape". By this criterion a low energy effective QFT is more "natural" when there are more supposed string theory vacua that have this low energy limit. As Lubos points out, the danger with this criterion is that it tends to lead you to the conclusion that the most "natural" effective field theory is the one that is least likely to be able to predict anything new.

The posting immediately before Lubos's is from Michael Douglas himself, responding to an earlier thread. In it he explains the goal of his work as follows. He wants to estimate N_SM, the number of vacua consistent with the observed known Standard Model behavior, then

"Based on this information, we can decide whether we should continue the search for the right vacuum directly (appropriate if N_SM <= a few), look for additional principles to cut down the number (if N_SM is large), or give up and start making anthropic arguments or whatever (if N_SM is ridiculously large)." The posting immediately before Douglas's asks for "what would cause string theory to become nonviable and abandoned", but hasn't gotten any responses. An obvious response would be that if it becomes clear that string theory has so many consistent vacua that it can't ever predict anything, the theory would have to be abandoned. Neither Douglas nor others working on the Landscape seem willing to mention this possibility in public, the closest he gets is the line about having to "give up and start making anthropic arguments or whatever".

   >This behavior of a perturbation series isn't mysterious

   Well, at least it is to me. But I admit I haven't been studying this problem in details. I guess this has something to do with what Connes and Kreimer are doing.

2. **Peter**
   October 7, 2004

   Presumably the perturbation series for QED is divergent but asymptotic. This means that, while you can't get an exact result at finite coupling by summing the whole series, if you take the first few terms of the series you get something which approximates the exact result more and more accurately as you take the coupling to zero. This behavior of a perturbation series isn't mysterious. The exact result is not analytic at the point you are trying to expand about (zero), so the power series expansion doesn't converge. You see the same thing in simple QM examples with the quartic potential.

   In QED, for small coupling, the perturbation series gives quite accurate results for most everything you want to calculate. People doing string theory like to believe that perturbative string theory is a good asymptotic expansion for some quantitities (e.g. giving a graviton and reproducing GR at low energies), but not others (e.g. they would like to believe that it fails to describe the vacuum state). As far as I have ever been able to tell, this is purely a matter of wishful thinking and string theorists are promoting perturbative string theory when it gives them what they want, ignoring it when it gives them something they don't want.

3. **Fabien Besnard**
   October 7, 2004

   >More accurately, one can show that the terms in >the perturbation series for QED are finite and >well-defined at all loops

   But the series does not converge, does it ?
   It is still a wonder to me how the first few terms of a divergent series can give the right experimental results to 16 decimal places or something like that. Could it be that the perturbation series is not really self-consistent and would be made so only by including quantum gravity effects ?

4. **Peter**
   October 6, 2004

   More accurately, one can show that the terms in the perturbation series for QED are finite and well-defined at all loops, for superstring theory this has only been shown up to two loops, although people hope it is true for all loops.

   Non perturbatively, you can rigorously define QED with an ultraviolet cutoff (e.g. the lattice), but the evidence is that when you take the continuum limit, the renormalized charge goes to zero, and you end up with a non-interacting theory. This doesn't happen for QCD (related to why Gross-Politzer-Wilczek got a Nobel prize this week). QCD can be perfectly rigorously defined with a cutoff, and all evidence is that you get exactly the physics you expect when you remove the cutoff (although there is no rigorous proof of this).

   Non-perturbatively, no one has even a good conjecture about what the definition of non-perturbative superstring theory or M-theory is. It's a very different situation than QFT, not only can't you prove anything, you don't even know what it is you would like to prove.

5. **mitch p.**
   October 6, 2004

   It's my impression that perturbative QED and perturbative string theory are about equally well-formed mathematically – they both exist as formal series but there's no proof of convergence. But I'm not sure how the dualities, branes, "11-dimensional limit", etc., rate.

6. **Peter**
   October 6, 2004

   The definition of M-theory is not "a little vague", it is non-existent. "Something which is 11d supergravity in some limit" is not a definition, it is an expression of a hope that there is a definition. QFTs can be mathematically rigorously defined, although in interesting cases it is difficult to rigorously prove that they have all the properties one would hope for.

7. **mitch p.**
   October 6, 2004

What I think would be helpful is to have a taxonomy of field theories, broad enough to include M theory. Then we could see its place in relationship to the other possibilities. It appears to be a deformation or extension of 11-dimensional supergravity. Can we say what *sort* of deformation or extension? And do other theories of the same sort exist, but derived from simpler field theories? Do they feature objects considered to be uniquely M-theoretic, like D-branes or T-dualities? Can we say anything a-priori about the possibility of such objects appearing outside of the M-theory framework? Etc.

I take your point about M theory's definition (founded on the union of the moduli spaces of the string theories) still being a little vague. But it's not as if the existence of most ordinary QFTs can be demonstrated rigorously either.

8. **Peter**
October 6, 2004

This would be a lot more plausible if anyone actually knew what M-theory was. So far the existence of a theory anything like what you are describing is just wishful thinking.

9. **mitch p.**
October 6, 2004

I think of M theory as the "Monster Group" of field theories. Finite simple groups are famously classifiable into a number of infinite families, with 26 'sporadic' groups left over, of which the Monster is by far the biggest. The Monster has a little bit of everything in its makeup, so if you are trying to identify an unknown simple group and know just a few generating relations, there would be a reasonable chance that it looked like some part of the Monster. In the same way, M theory is a sort of field theory (under a generous definition that includes topological field theories, noncommutative field theories, etc.), and it features so many sorts of excitations that perhaps 'most' field theories resemble some M-theoretic vacuum.

So I'm sympathetic to the critical tone of this blog. I don't think we should *presume* that M theory is the final theory, when its bare empirical adequacy has not yet been demonstrated. However, if it does turn out that the landscape's bounty is so great as to render the theory almost unfalsifiable, I think it will still warrant much more respect than it gets here. It will depend on how many *other* (non-stringy) field theories are *also* capable of reproducing the Standard Model. If there are lots, then yes, M theory will not be so special. The capacity to include gravity might be decisive here (there's obviously an infinity of non-stringy field theories containing just the gauge forces). If LQG, the Visser/Sakharov 'emergent gravity' program, or some other approach to quantum gravity pans out, that will be a blow to string theory's proclaimed uniqueness. If the other approaches falter, that will strengthen the position of M theory. Even if there are a million distinct ways in which M theory might give us the world we see, it would then still be the favorite, no matter how unhappy we might be with that epistemic situation.

But this is all cart-before-the-horse. First let's do the job of seeing whether M theory can describe reality at all; if it can, let's find out all the ways that it can; and once we've done that, then let's have this discussion again.

10. **Thomas Larsson**
October 6, 2004

**Any* framework capable of reproducing the Standard Model (i.e. capable of predicting "anything we can observe"!), even one made of gremlins, warrants interest, simply because it might be the truth.*

Mitch, is string theory really capable of reproducing all aspects of the standard model? No unbroken low-energy supersymmetry, no new long-range forces (massless scalar particles associated with moduli), no new gauge bosons, an extremely long-lived proton? And a small and positive cosmological constant.

11. **sol**

Would you rather a soccer ball for describing the universe?

http://www.hep.upenn.edu/~max/wmap3.html

12. **D R Lunsford**
October 5, 2004

Chris W – wonderful post.

There is another argument (third?) against string theory that doesn't get any attention. I call it the "prima facie preposterous" argument. String theory is not only wrong, it's *wrong-headed*. The fact that it can't predict anything, that it can't reproduce the simplest physico-mathematical structures, that its most ardent practitioners are willing to resort to anti-scientific arguments and polemics, and that a sterile hermaphrodite is held up as a "theory of everything that will enable us to see God, and give him football betting tips", are all symptoms of having taken seriously a ridiculous idea. I can't think of ANY example in physics history in which a ridiculous idea was seriously considered. The orbs of Kepler actually led him to right answers, and the epicycles of Ptolemy represented a sane theory in its day, even an esthetic one.

13. **mitch p.**
October 5, 2004

Any framework capable of reproducing the Standard Model (i.e. capable of predicting "anything we can observe"!), even one made of gremlins, warrants interest, simply because it might be the truth.

The most recent overview of string phenomenology that I read (from late last year), says (page 7) that no-one has yet exhibited a string model manifestly capable of giving the right values for the fermion masses and CKM matrix elements. Researchers are apparently busier exploring the many paths to *qualitatively* reproducing the Standard Model (e.g. the gauge group). These debates about the phenomenological fecundity of the string landscape, and whether it invalidates string theory as science, may be a little premature.

14. **Chris W.**
October 5, 2004

To Mitch P: Peter is making a methodological and epistemological point, not an ontological one. He is *not* saying that "Since string theory can generate millions of models that resemble our observations, the world can't have a string-theoretic foundation".

He is saying that the theory in its current form appears to be effectively immunized against refutation, other than by observations that would also refute its predecessors (the Standard Model and general relativity). If someone makes new observations that are inconsistent with one string-theoretic model, then theoreticians can trot out another model accounting for the observations in question, which they might well claim to be equally consistent with the basic principles of the theory. Those principles are thereby insulated against any possibility of being contradicted by observations. The models take the fall instead, and no one worries much about it because there are so many of them to choose from.

That is, no one worries if they think the theoretician's objective is to be always ready with another model (derived from his favored *mathematical* framework) whenever previous models have trouble accounting for observations. This makes sheer mathematical richness a virtue, and indeed the mathematical richness of string theory is often proclaimed as an important source of its fascination.

However, physics and science generally are not simply exercises in applied mathematics, ie, in mathematical model building. In his early years Einstein was quite suspicious of mathematical formalism, and even in later years lamented having to respond to the ideas of people who in his words "can calculate but can't think". He was trying to get at fundamental principles, and it was vital to him that those principles be lucidly expressed and subject to empirical refutation as directly as possible. Ensuring that this is the case depends in part on a methodological commitment to avoid immunizing stratagems. This is tricky — one mustn't give up on a theoretical idea too easily — but it is arguably the most essential aspect of doing science.

To many people string theory continues to "smell" right. The question has become, "exactly how does it smell right; what are its central and distinguishing *physical* principles, and what are their unambiguously testable consequences?" In the 1980s it was often said by Witten and others that, unlike general relativity, string theory's central principles remained obscure, and a major goal of research in the field was to elucidate them. This goal seems to have dissipated, or to have degenerated into much aimless wandering in a vast mathematical wilderness.

Peter: You said, "The standard model QFT can predict anything that we can observe, using only of order 20 parameters." In the context of this discussion I feel compelled to amend this to the following: "The standard model QFT can account for anything that we *have* observed, using only of order 20 parameters." Presumably (one hopes!) there are observations we will make someday that the Standard Model cannot account for, over and above the values of the 20 parameters themselves, whose inexplicability motivates so much recent effort to go beyond the standard model. However, I think we can be rightly suspicious of the notion that there are a vast profusion of such observations yet to be made which require a far richer theoretical framework to understand. String theory appears to be just such a framework. I suspect that much of it will ultimately prove to be irrelevant to fundamental physics. I hope that in the midst of it (and in loop quantum gravity) are the outlines of a few key ideas that will prove essential and lasting.

15. **sol**
October 5, 2004

Gremlins

If we did not consider the alternate view of what the spacetime fabric could be, how would we ever consider step off points for consideration?

In quantum mechanics, the vacuum of space is not a vacuum; rather, it is field with virtual particles, such as the graviton. Light passing through this field of virtual particles is refracted, just as it is when passing through water or any medium.

The graviton, being the essence of gravitational force, would interact with (or slow down) those particles with greater gravitational potential. With mass directly proportional to energy, as expressed in e=mc2, photons of higher energy have greater gravitational potential than lower-energy photons — as if they "weigh" more.

The highest-energy photons would therefore travel through space more slowly than lower-energy photons. (This does not violate the constancy of the speed of light, for light travels at the same speed only in an absolute vacuum.) To detect the very slight difference in photon speed, one needs an extremely distant source emitting extremely high-energy photons: that is, the gamma ray burst.

http://www.astronomytoday.com/cosmology/quantumgrav.html

16. **Peter**
October 4, 2004

A "theory" that doesn't predict anything isn't a scientific theory, and if you spend your time studying a theoretical framework that is inherently incapable of predicting anything you're not doing science.

The standard model QFT can predict anything that we can observe, using only of order 20 parameters. Present day string theory predicts absolutely nothing at all, using a much more complicated theoretical framework than that of Standard model QFT. It's looking increasingly likely that this is because the string theory framework is inherently vacuous: to get the standard model out of it as a limit you have to assume the existence of such a wide range of vacuum states that you can't predict anything at all beyond the standard model (which is put in by assumption). All you have is a complicated way of parametrizing an infinite variety of possible extensions of the standard model. Unless you can figure out some way to use this to predict something, whatever you are doing, it isn't science.

What if I believe in gremlins and said that my theoretical framework is that everything is determined by the gremlins and that's all we can ever know. When you complained that my gremlin theory can never predict anything and never be checked, I could answer you:

"This doesn't make sense. There are a million ways that a gremin-theoretic world might look like the one we inhabit – therefore we don't live in a gremlin-theoretic world?"

Just describing the world in terms of fanciful abstract entities is not doing science. Finding a simple set of abstract entities that can predict new things we didn't already know about the world is.

17. **mitch p.**
October 4, 2004

"if it becomes clear that string theory has so many consistent vacua that it can't ever predict anything, the theory would have to be abandoned"

This doesn't make sense. There are a million ways that a string-theoretic world might look like the one we inhabit – therefore we don't live in a string-theoretic world? therefore we don't think about whether we live in a string-theoretic world?

A similar argument could have been used to rule out "quantum field theory" as illegitimate. "You can make a QFT do just about anything – what sort of scientific theory is that?"

18. **Fred**
October 3, 2004

Well, I don't think its entirely fair to criticize String theory quite yet. As with all new work in progress theories, there is still room for deeper principles that may eliminate all sorts of degenerate vacua. Brian Greene gave a lecture here a few weeks ago where he *optimistically* thought there was still room for different formalisms that could solve things in a more elegant fashion.

Michael is entirely in his right to publish papers exploring statistical values on the landscape. And how much fine tuning/philosophizing ultimately such a distribution would require. If you want to follow the math, then follow it wherever it may lead. It may end up actually falsifying what you set out to do.

More interesting to me, is that I have yet to see a convincing phenomenological model that actually reproduces a stable Standard model with even one single handpicked choice of vacua. That is, without the appearance of to many hard to believe artifacts. Say one that adequately satisfies bounds on proton decay lifetimes and with the desired suppression of flavor changing neutral currents. Jacques Distler had a blog about that some time ago.

I think the idea is if you can get close enough to SDM physics, than you can argue that there probably exists some similar, but different enough choice that does give the proper suppression. Then again, Distler said that even that was probably quite difficult (something to do with R-parity appearing only in very isolated parts of the moduli space)

19. **JC**
October 2, 2004

Imagine if string theory dies a painful death and gets "defunded" shortly after the LHC experiment goes online and rules out low energy supersymmetry. It would be hilarious if 70 years passes away, some future particle/gravity theorist stumbles across string theory by "chance" and resurrects it again as a viable quantum theory of gravity with no "living memory" of it's previous incarnations. (70 years into the future, all of the proponents of today's string theory would be either dead or retired with very little to no influence in physics research).

String theory then becomes like the Energizer Bunny which keeps on going and going and going … and refuses to completely die!

20. **Chris W.**
October 2, 2004

Or, to put it more starkly (and a bit sarcastically), string theory will become nonviable and deserving of abandonment when it becomes clear that its practitioners are unable to specify any other conceivable circumstances (logical or empirical) under which it would become nonviable. At that point it would be abandoned because, as a physical theory, it has become a bore, ie, it is no longer interesting as a basis for an empirical research program, and most young physicists are looking at alternatives (and are being encouraged to do so).

That situation has not arrived, but it has become worth worrying about for anyone who sees lasting value in the ideas and accomplishments of the field.

21. **dolt**
October 1, 2004

Actually, I am not that surprised. As you yourself pointed out some time ago, ignoring his rhetoric like "superstring theory is the language God wrote the world" and all that, he is actually very sensible.

Although I personally don't think string theory is ever going to explain particle physics, I do enjoy, and often learn from, Motl's observations, who I believe is a reincarnation of Pauli. Maybe just as Pauli was proven wrong on the utility of Yang-Mills theories (massless gauge bosons; confinement and SSB unknown to him), he may be wrong on LQG, despite some pretty good observations on the field.:)

My Life as a Quant

October 4, 2004
Categories: Uncategorized

Last week I was in a bookstore and ran across a new book by Emanuel Derman called My Life as a Quant: Reflections on Physics and Finance. Derman got a particle theory Ph. D. here at Columbia in 1973 when he was one of Norman Christ's first students. He then went on to post-docs at Penn, Oxford and Rockefeller and a tenure track job at Boulder. By 1980 he had decided he didn't want to stay in Boulder, partly because his wife couldn't get a job there, so he left academia for a job at Bell Labs.

In 1985 he went to work in the financial industry at Goldman Sachs, staying there until 2002, interrupted by a one-year stint at Salomon. He's now back at Columbia, teaching in the Financial Engineering program run by the IEOR (Industrial Engineering and Operations Research) department of the Engineering school. This kind of master's program is extremely popular; besides IEOR, the math and stat departments collaborate on a separate MA program in the Mathematics of Finance which has been wildly successful. Each year we get more and better applicants, and they seem to do very well on the job market when they get out.

The first half of Derman's book gives a good view of what it was like to be a theorist of the phenomenological variety during the seventies and early eighties. The second half has a nice description of the mathematical problems involved in pricing options and mortgage-backed securities, as well as many comments on what it is like to work in the financial industry. He was one of the earliest particle theorists to do this, but many others have followed him there in recent years, some of whom are regular commenters here.

Comments

1. **Chris Oakley**
   October 8, 2004

   Getting off topic, but wouldn't it be nice if in the presidential debates the candidates bragged about their ingenuity in avoiding draft to Vietnam rather than the heroic and selfless ways in which they served their country – ?

   "Every American can be proud of the way that, by getting a physics post-doctoral position at a young age I managed to avoid getting involved in that stupid civil war in Indo-China. It was not easy. It required resourcefulness and careful planning. My fellow Americans, by this I have demonstrated that I can look after my own interests effectively – have no doubts, therefore that you can trust me to look after the interests of the whole nation." [Applause]

2. **Peter**
   October 8, 2004

   Not very usual for someone to get a Ph.D. in one year. I think Christ was a student of T.D. Lee's and was also a Columbia undergrad. He may have just done much of the standard graduate program while an undergrad, then started grad school at a point when he was already doing research.

   Since this was the mid-sixties, there also may be a story about the draft there. My colleague John Morgan also got a very quick Ph.D. around that time, and I remember him telling me some story about this that involved avoiding being sent to Vietnam. Perhaps it was that, at least during certain years, grad students could be drafted, but if you were a postdoc, there was some way to get out of it.

3. **Tim M.**
   October 8, 2004

   Regarding Norman Christ: According to http://www.college.columbia.edu/bulletin/faculty/faculty.php he earned his doctorate one year after his bachelor's degree. Does anyone know about his early career? For example, how is this possible? Is this a phenomenal feat or commonplace? Maybe I should have posted this in the callow youth discussion.

4. **Thomas Larsson**
   October 5, 2004

   Gross, Politzer, Wilczek got the prize, we (which includes Peter Woit, me, and others) were guessing correctly this time. 😉 *More precisely, the committee chose correctly.*

   Old news, Lubos! I posted the press release after the appropriate blog entry an hour ago 🙂

5. **Lubos Motl**
   October 5, 2004

   Gross, Politzer, Wilczek got the prize, we (which includes Peter Woit, me, and others) were guessing correctly this time. 😉 More precisely, the committee chose correctly.

   Congratulations!

6. **sol**
   October 4, 2004

   I mean if you really think about it, you have to orientate this view around the very small, and one tends to think, "*is there some possible organization going on here*?

   Okay, maybe some of you don't, but I think quickly here of the math mind, and the ideas of negotiated processes, and again as quick, John Nash comes to mind.

   So I think this crossover is more then just being feed up with doing the search for the unifying principal in particle physics, and a transferance to real time functions, in bank processes?

   Imagine looking for this principle with Robert Laughlin.

   http://large.stanford.edu/rbl/lectures/index.htm

   So the one who controls the dollar, controls the reality? I think shifting sands/dollars in population, could have easily destroyed institutions, had minds set themself towards shifting those same dollars?

7. **Chris Oakley**
   October 4, 2004

   Oxford particle physicists I know who have ended up in finance:

   Guy Coughlan – at JP Morgan.
   Kelly Kirklin – formerly AIG, now back in physics
   Paul Miron – National Westminster (UK Bank)/UBS/Chase Manhattan. No idea what he's doing now.
   Me – Barclays/Citibank/UBS/HSBC/Nomura. Doing mainly financial software.

   Guy is a "risk metrics" guru at JPM. This involves, inter alia, treating the financial portfolio as a mathematical optimisation problem. A mixture of maths, programming and giving presentations to customers.

   Kelly and Paul were successful interest-rate swap traders. Mostly this was about trying to buy low and sell high and is more gamesmanship than mathematics, although they needed mathematics in the early days to set the trading book up (nowadays this is not a requirement as systems are better).

   I, on the other hand have never traded. This is not because I abhor the idea of becoming rich, it is just that since the age of 11 software has been one of my main interests in life. I have still not managed to build the perfect trading system, but at Nomura, at least, I gave it a serious try.

Gloating

Well, my prediction of who would win this year's Nobel prize in physics turned out to be correct. No, I didn't have any inside information about this at all. I suppose I should mention that many of my friends will not be so impressed by this feat since they have heard me make this same prediction incorrectly every one of the last 15 years or so. Sooner or later I had to be right, and it was dumb luck that it happened the first year I had a public forum in which to make this prediction.

Congratulations to Gross, Politzer and Wilczek!

Comments

1. **Lubos Motl**
October 9, 2004

I made the same prediction, and it seems more correct to say that we *had* some inside information about it, to some extent – certainly much more information than the average people on the internet who were also trying to predict.

The physics Nobel committee is not that different statistically from the community of physicists like us and they certainly had similar discussions – comparing QCD with some lasers or quantum entanglement experiments.

The confirmation of a prediction after 15 years is a good example that string theory can also be proved correct 15 years from now. A physicist must be often patient! 😉

Congrats to Gross, Politzer, and Wilczek.

2. **Peter**
October 8, 2004

Hi Chris,

Actually I do have a link to the Friedan paper, it's on

http://www.math.columbia.edu/~woit/reason.html

I probably should update that page, any other suggestions for what should go on it are welcome. Maybe the "Landscape" deserves a page of its own.

3. **Chris W.**
October 8, 2004

Sorry; I neglected to identify myself in the previous post.

4.
October 8, 2004

As Thomas suggests, subsection 1.6 of Friedan's paper discusses the failures of string theory at considerable length. His assessment is devastating. Consider this:

> In particular, there is no justification for the claim that string theory explains or predicts gravity. String theory gives perturbative scattering amplitudes of gravitons. Gravitons have never been observed. Gravity in the real world is accurately described by general relativity, which is a classical field theory. There is no derivation of general relativity from string theory. General relativity can be regarded as the large distance classical limit of quantum general relativity, if an ultraviolet cutoff is imposed to make sense of quantum general relativity. A cutoff quantum general relativity would give the same formal perturbative low energy scattering amplitudes for massless gravitons as does string theory. But it is illogical to claim, from this formal coincidence between two technical methods of calculating unobserved graviton scattering amplitudes, that string theory explains classical general relativity, or that string theory explains gravity, or that string theory is a quantum theory of gravity. String theory does not produce any mechanical theory of gravity, much less a quantum mechanical theory.
>
> In any case, a quantum theory of gravity is unnecessary. No physical effects of quantum gravity have been observed, and there is no credible possibility of observing any. What is needed is a theory which produces general relativity as an effective classical field theory at large distance. It might produce classical general relativity by producing at large distance an effective quantized general relativity that is deep in its classical regime. But what is essential to produce is the classical, mechanical spacetime field theory of gravity. String theory is only a perturbative theory. The widespread practice is to assume that there exists a nonperturbative formulation of string theory, and that this hypothetical nonperturbative formulation would be a quantum mechanical theory, microscopic in spacetime, invariant under some exact, fundamental spacetime supersymmetries. If such a nonperturbative formulation of string theory did exist, then it might well follow that the large distance physics in that hypothetical theory would be governed by supersymmetric spacetime quantum field theory, and that the fate of the degeneracy of the manifold of background spacetimes would be determined by nonperturbative field theoretic effects at large distance in spacetime in that supersymmetric quantum field theory. But it is only an assumption that there exists such a nonperturbative, microscopic, quantum mechanical formulation of string theory. Any reasoning about a hypothetical nonperturbative version of string theory is unreliable if it rests on the assumption of spacetime quantum field theory at large distance, without any way to derive spacetime quantum field theory from string theory.
>
> The assumption of fundamental, exact, quantum mechanical spacetime supersymmetry is a very strong extrapolation from perturbative string theory, where spacetime supersymmetry is only a perturbative symmetry of the scattering amplitudes in individual background spacetimes. Adopting this assumption requires accepting as inevitable the continuous degeneracy of the manifold of background spacetimes. An assumption as strong as fundamental spacetime supersymmetry loses credibility as a guide in searching for a theory of physics if it cannot lead to definite explanations of existing knowledge and definite predictions. There is certainly no physical evidence to support the assumption that spacetime supersymmetry is a fundamental property of nature. At most, it is possible that indications of approximate spacetime supersymmetry might be found experimentally in the not so distant future. Contrast the radical assumptions of the old quantum theory, which obtained credibility by giving definite explanations of the black body spectrum, the photoelectric effect, the Balmer series, the Rydberg constant, and much more of atomic physics, before eventually leading to quantum mechanics.

(**Peter**: Is there a specific reason why you don't have a link to this preprint [April 2002] on your home page? It would good to have it there with whatever editorial comments you feel like including.)

5. **Thomas Larsson**

October 8, 2004

Peter will enjoy the part where he says that every new revolution in string theory taught us a lot about string theory and was followed first by great excitement, and then disappointment as it was realized that nothing new had been learned about the real world.

String theory has introduced much interesting mathematics into physics. That this has not led to any new physical knowledge must be a disappointment to many. I suppose that different people handle this in different ways: Susskind and Douglas invent anthropic selection ideas, Motl makes increasingly ridiculous claims about how string theory is the maximally predictive theory, Friedan (who founded the string theory group at Rutgers and thus in a sense is Motl's scientific grandfather) is silent for 10 years and then proclaims that string theory is "a complete scientific failure", see hep-th/0204131, subsection 1.6. Different personalities, different reactions.

6. **String Theorist**
October 8, 2004

David Gross is having a huge celebration at the KITP in honor of his Prize (well it is ostensibly in honor of the opening of the new wing of the KITP, though the fortuitous timing is quite coincidental, if you are the type who believes in coincidences…) .

Steven Weinberg gave a beautiful talk on the
current state of particle theory,
http://online.itp.ucsb.edu/online/kitp25/
and used an analogy that I posted long ago on this forum: that we may be no more succesful in "calculating the electron mass" from some fundamental theory than Kepler was in "calculating the radius of the Earth's orbit" from some fundamental theory.

Peter will enjoy the part where he says that every new revolution in string theory taught us a lot about string theory and was followed first by great excitement, and then disappointment as it was realized that nothing new had been learned about the real world.

7. **Arun**
October 8, 2004

What are the features of an "interesting" problem (as when one says – most of the interesting problems are in molecular biology?)

I think some of the features are that the problem is not easy, but is within the realm of feasibility of solution, is within the reach of conceivable experiments, and that solving the problem leads to other interesting problems.

8. **D R Lunsford**
October 7, 2004

No one claimed that biology is not interesting, but when I was 5 the physical world was more interesting, and now that I'm 45 it's still just as interesting. Why quit because the problems are hard and the people are harder?

9. **Chris Oakley**
October 7, 2004

It could be just that Molecular Biology is where the interesting problems are these days.

10. **D R Lunsford**
October 6, 2004

Hi Thomas,

One of my professors used to say "When Mozart was my age he was dead for 4 years!"

To me, the most amazing feat of callow youth is the "Enzyklopaedie der Mathematischen Wissenschaften" article written by Pauli on general and special relativity when he was 19 and a student of Sommerfeld. This book instantly became the chief reference on the literature of relativity. It's still a valuable book. This was 1920 – there couldn't have been 100 people in the world who understood it.

Speaking personally, all the young genii I knew in school have burned out or turned to biology or the like. Harsh field this.

October 6, 2004

Another alternative is they could start awarding the prize posthumously. That way they could work their way back all the way through the 20th century.

12. **Peter**
October 6, 2004

Hi Thomas,

The student you're thinking of is John Moody. He was in the same entering class as me at Princeton and we spent a lot of time together there. I haven't seen him in quite a few years, but after Princeton, then Santa Barbara, he ended up going into CS (neural nets) and financial engineering. He now seems to be at Berkeley and has a web-page

http://www.icsi.berkeley.edu/~moody/

13. **Thomas Larsson**
October 6, 2004

It is striking how young these people were in 1973 – Wilczek 21, Politzer 23, and Gross 31. How many of you people did Nobel work at the age of 21?

I must have met Wilczek during the academic year 1982/83, which I spent as a graduate student at UC Santa Barbara. Wilczek had just been appointed professor there at the time. He must have been around 30 but appeared older, at least to a freshman like myself (he didn't have a whole lot of hair even then). Anyway, in the beginning of the winter quarter a grad student of Wilczek's by the name of Moody (his first name has completely slipped my mind) materialized. His job was to convince experimentalists to look for axions, which was Wilczek's pet idea at the time. The idea was, as this Moody fellow explicitly expressed it, that "they would find axions so that Frank could win a Nobel prize". Oh well, it wasn't necessary in the end, was it.

Axions are not the only hypothetical particles that Wilczek has cooked up. IMO the best so far is the vaderon, the carrier of the dark force. Named after Darth Vader.

14. **Peter**
October 5, 2004

Hi Danny,

Witten is responsible for new understanding of lots of different kinds of QFTs, problem is, not precisely the one QFT of the standard model. Off the top of my head, here are some examples:

Current algebra: the phenomenological model of pions. Witten solved the "eta-prime" problem, showing how the ninth Goldstone boson gets a sizable mass in this model. He also showed how the proton is a soliton in this model (the Skyrmion). This is very physical stuff, but not a fundamental model.

Seiberg-Witten solution of N=2 super Yang-Mills. Problem is that the Standard Model doesn't have N=2 supersymmetry. But this did revolutionize the field of 4-manifold topology in mathematics.

Cohomological topological field theories: Witten wrote down and solved a large class of QFTs whose observables are mathematically extremely interesting, although the models don't describe known physical particles. These include the 4d TQFT that gives Donaldson-theory, and the 2d QFT that gives Gromov-Witten invariants. The latter, which people now like to call "topological string theory" has lead to a lot of beautiful answers to enumerative problems in algebraic geometry.

Chern-Simons theory: This lead to great new math involving new knot invariants and connections to all sorts of other math. Physically he related a 3d QFT to conformal field theory (WZW models), giving new insights into both sides of the relation.

Other 2d QFTs: Many different examples, including pure Yang-Mills and the 2d version of Donaldson theory, which he used to understand the cohomology of certain moduli spaces. There is a huge amount of beautiful math here, and completely new ways of thinking about 2d QFTs, solving them exactly. Other examples include WZW models, the supersymmetric models leading to elliptic cohomology.

Personally I find it implausible that all these new ideas and ways of thinking about QFTs, some of which are quite close to the standard model, are not going to sooner or later give us new insight into the standard model itself. One problem is that almost all the community's effort has gone into trying to use these new ideas to do string theory, and that seems to be a dead end. This is speculative stuff and you're welcome to be skeptical until it proves its worth as physics, but if you believe as I do that great math and great physics are very deeply related, there is good reason to expect great physics to come out of this some day.

15. **D R Lunsford**
October 5, 2004

Hi Peter, I was watching the debate so let me ask you a debate question…

How can you "greatly deepen the understanding" of QFT without adding any significant knowledge about its actors, the fundamental particles? This is like saying "Yamaha greatly increased our understanding of internal combustion engines, without actually contributing any new performance enhancements".

Seriously, what exactly did Witten do that made QFT in 2004 better than QFT in 1984? Are we really better off than we were 20 years ago?

16. **Peter**
October 5, 2004

The fundamental problem is that there have been no real advances in particle theory since the Standard Model came together in 1973 (largely because of the discovery of Gross-Politzer-Wilczek). So, of necessity the Nobel committee has to go farther and farther back in time. In my original post I speculated about some reasons why this one took so long. It could just as well have been awarded 25 years ago in the late seventies.

Because of this, particle theory Nobel laureates are definitely getting older. You could also calculate the time interval between discovery and award of prize, and that has grown considerably over the years.

In another 25 years or so just about all of those involved in putting together the standard model will be gone (the grad students 't Hooft, Politzer, Wilczek are the youngest). If there is still no progress in particle theory, either there will be no more Nobels in the field, or the Nobel committee will have to change its standards and start awarding prizes for work that doesn't have experimentally testable consequences. If they have to do that, a good place to start would be with Witten, who has greatly deepened our understanding of QFT, although unfortunately mostly in ways that don't explain anything new about elementary particles.

17. **Fabio Lanzoni**
October 5, 2004

Why this year rather than any of the last, say 30? I can remember people speculating about Gross, Wilczek and Politzer winning the prize at least 15 years ago. It seems every year that goes by without a Nobel-worthy discovery in physics they have to reach further and further back in time. Has anyone accumulated statistics on the average age of a physics Nobel recipient vs. time?

KITP Conference on “The Future of Physics”

October 8, 2004
Categories: Uncategorized

The KITP in Santa Barbara is having a conference in honor of its 25th anniversary on the topic of “The Future of Physics”. Some of yesterday’s talks are already online. I’ve been watching Weinberg’s talk on “Where do we Stand?” this morning (a commenter also wrote in a little while ago while I was watching to recommend it). Weinberg gives a good summary of the present state of conventional wisdom about particle theory. He goes over the standard arguments that the standard model should be thought of as an effective low energy theory, and that doing so explains many of its features, with the two big exceptions of the scale of the vacuum energy and the electroweak symmetry breaking scale.

He promotes his “prediction” of the cosmological constant, and recalls that supersymmetry is the standard way of dealing with the low electroweak scale or hierarchy problem. But he then explains the problems with all known ways of breaking supersymmety, concluding that “no satisfactory theory of supersymmetry exists, where supersymmetry breaking is accounted for in the framework of particle physics.”

As for the “Landscape”, he notes that Gross hates it, says that “I don’t love it”, that it’s a disappointment, but one that we may have to get over. He makes some extensive comments about string theory, saying that it has had a history of advances leading to momentary optimism, but ultimately disappointment, with the bottom line that after 20 years we understand string theory much better but are no closer to contact with physics. He ends his comments about string theory with a rather weird remark that maybe it is wrong to look for a “guiding principle” behind string theory, that all there is to it is that it is the only way of extending the standard model to include gravity in 4d. I guess he is implying that string theory is not a fundamental beautiful theory, but, like S-matrix theory just a general framework imposed by consistency.

In general, Weinberg sounded to me old, tired and discouraged. Like just about all the leaders in the field, he refuses to publicly acknowledge the obvious possibility that the explanation for why string theory doesn’t predict anything or have any known fundamental principles is that it is just a wrong idea. He’s so discouraged about string theory that he has stopped working on it himself for the last fifteen years, but doesn’t have the energy or optimism to envisage any alternatives. He ends his talk with some real downers, one of which he calls the “LHC nightmare”, that the LHC will just see a single new scalar particle and nothing else. The second nightmare is that observations of the CMB will never see anything that tells us more about the early universe, just a 1/f spectrum, no evidence of the effects of gravitational waves.

All in all Weinberg ended up not giving a very optimistic view of the “Future of Physics”, but something closer to John Horgan’s argument about the “End of Physics”.

Tomorrow there will be a panel on “Field Theory and Mathematics” which should be interesting. Also, Witten will be talking on the “Future of String Theory”. It will be interesting to see if he is any more optimistic than Weinberg, and more specifically if he’ll come down on the Gross (“I hate it”) or Weinberg (“I don’t love it, but maybe it’s right”) side of the Landscape issue.

Comments

1. **JC**
   October 15, 2004

   In Mlodinow’s book “Feynman’s Rainbow”, in chapter 13 he described an encounter he had with Feynman when he tried to bring up the topic of string theory. It was kind of funny, with Feynman saying things like:

   “…. This whole discussion is pointless! It’s getting on my nerves! I told you – I don’t want to talk about string theory!”

   “My take? My take is that you hit a dry spell, and now you’re scrambling, trying to find something to work on!”

   “What’s wrong is coming to me to talk about string theory!”

   This encounter happened in late 1981, when hardly anybody really cared about string theory other than guys like John Schwarz and Michael Green.

2. **Chris Oakley**
   October 15, 2004

   Yes … sad, but true, even this desperate antidote of physical models that needed less than ten dimensions could not save the great man.

3. **Arun**
   October 15, 2004

   JC,

   OK, I do not know what Feynman did after he stopped coming to office; but his final office blackboard had stuff about the Baxter model and other 2-D exactly solvable models.

4. **JC**
   October 13, 2004

   Arun,

   There was a book “Feynman’s Rainbow” by Leonard Mlodinow which mentioned the same folklore in the last chapter on p. 166 (in the hardcover version)

   ” … He was now weak, in pain, and often depressed. But physics still brought him vigor. He continued to teach a course on quantum chromodynamics. And, in his last months of life, he finally decided to learn string theory. Murray taught him, in a private ‘seminar’ they held each week.”

   I don’t personally know Mlodinow nor do I know any of his “sources” for this particular piece of folklore about Feynman finally giving in and learning string theory. By the time I heard about this particular piece of folklore, it may very well have been a 2nd or 3rd hand account that took on a “life of it’s own”. Without mentioning any particular names, my sources were former colleagues who were in the particle theory group at Caltech around the time of Feynman’s death. At the time, I just took their word for it.

5. **Arun**
   October 13, 2004

"From some folklore stories I vaguely recall, allegedly Richard Feynman finally gave in and decided to learn string theory in the last few months of his life in 1987-1988."

As far as I know, that is not true. You might ask Sandeep Trivedi about it.

6. **D R Lunsford**
   October 12, 2004

   Lubos intoned:

   I apologize, but your possibilities 1,2 are just plain stupidities especially if you think that one of them is likely. Both of them are silly. What you're saying that contradicts the results of 20,000 papers or so. We know that a theory that unifies these things exists, and it is most likely unique because its consequences for any question that we have been able to answer were unique.

   Obviously, arguing by paper volume, "reductio ad cellulosum", is the stupid thing. There were no doubt 20k papers by the LMs of Lorentz' day stating why the deformable electron "was posited by God to make the ether perfect". And it's not at all obvious that GR and QM are "unified" because their individual structures are utterly different (at the moment). You must find an encompassing structure to make such a statement, and neither you nor any other stringers, have.

   *There was never any non-dynamical freedom in string/M-theory found ever. If something can be adjusted about your theory, you can always view it as a choice of the environment, and in principle, you can create another environment *physically* within the Universe with the first environment.*

   What?? Was there a point in this?

   The "mystery" of M-theory in 11 dimensions

   Yada yada yada,
   We all know this mantra.

   So we distinguish the "big M-theory" that contains all insights that string theorists ever studied, from "narrow M-theory" which is the UV completion of 11-dimensional supergravity. The latter is more or less understood and defined. The former is well-defined by hundreds of "patches" which beautifully fit together – the "transition functions" are the dualities – but we would prefer to describe M-theory "without patches", as a single whole – to reveal the rules that illuminate immediately why all these patches belong to the structure. This is what the question "What is string theory?" means.

   So! You should call it "U-theory" for "unworldliness":

   U = (F – ma) + (Rmn + 8piTmn) + (2+2-4) + … = 0

   There it lies.

   I think that you are completely wrong if you say that you are "not spending of huge amount of your time" with string theory. You ARE spending a huge amount of time, even more than me, by these philosophical worthless speculations and attacks. You are just not spending this time efficiently. If you spent the same amount of time with learning string theory, you would have known it better than me.

   And thank God for it.

7. **Chris Oakley**
   October 12, 2004

   No it wasn't … String theory is what killed him.

8. **D R Lunsford**
   October 11, 2004

   And I thought it was cancer. Live and learn!

9. **JC**
   October 11, 2004

   From some folklore stories I vaguely recall, allegedly Richard Feynman finally gave in and decided to learn string theory in the last few months of his life in 1987-1988.

10. **JC**
    October 11, 2004

    For people who don't believe in string theory, they would see it as hype and propaganda. For somebody who does believe in string theory, they would not see it as hype and propaganda. It's a matter of a difference of opinion for different people.

    As long as there isn't a death penalty for holding a particular opinion on some topic of interest, there's always going to be a spectrum of different opinions on a particular topic.

    There's some folks today who don't even believe in renormalization. Even more extreme are some folks who today still don't believe in quantum mechanics, for whatever strange reasons they have.

    Though I do agree with Lubos and others that a dearth of impressive new results (to spark a new string revolution) and the anthropic stuff in today's string theory, has curtailed the optimism of some people in the field in recent years. The anthropic stuff has certainly curtailed my optimism about string theory these days. I certainly would want to see some impressive new results to be optimistic about string theory again, like how optimistic I felt about the field during the mid-late 1980's and mid-late 1990's. There has to be a better way of doing things without invoking the anthropic principle.

    I'm sure John Schwarz must have had a lot of faith and optimism about string theory during the latter 1970's and early 1980's when only a handful of people were working actively on string theory, as well as dealing with Feynman's sarcasm and jokes directed towards him. I don't know if I could have maintained an optimistic spirit about string theory if I was in Schwarz's shoes during those days.

11. **Lubo? Motl**
    October 11, 2004

There is no hype and propaganda about string theory. People just try to explain why it is a fascinating and unique theory. In the middle 1980s or middle 1990s, people were more excited and the progress was faster, and therefore the comments about string theory were more optimistic. Today it's closer to the opposite. As Witten pointed out on the KITP conference, even string theory *enthusiasts* underestimate how rich and powerful string theory is – so speaking about hype and propaganda is not a reasonable description of reality.

12. **JC**
October 10, 2004

I get the sense most of the criticisms of string theory on this weblog is largely about the hype and propaganda surrounding string theory over the last 20 years. The discussions about specific technical details about string theory and field theory seem to be more neutral and less controversial.

It seems like advocacy of any particular strong viewpoint is always going to be a hotly debated, regardless of what the subject is. One just has to see the sort of heated discussions on the *.advocacy newsgroups in the comp.* hierarchy, or the sort of stuff that goes on in debating clubs and societies on any university campus.

13. **Lubo? Motl**
October 10, 2004

"The real LHC nightmare will be if it sees charged particles at 70 GeV and a scalar at 115 GeV."

Well, as far as this sentence goes, it could be a confirmation of the LEP's 115 GeV Higgs, plus – for example – selectrons at 70 GeV that were missed by LEP II, because of some reasons mysterious to me. That would be a cool victory rather than a nightmare. 😉

14. **Alejandro Rivero**
October 10, 2004

The real LHC nightmare will be if it sees charged particles at 70 GeV and a scalar at 115 GeV. THis is two doublets higgs but not SUSY, and besides it should raise doubts about the statistical methodololgy of LEP2

15. **Lubos Motl**
October 10, 2004

Hey Peter!

Not just Gross. I am also saying that the question "What is string theory?" is the most important one.

But you severely misunderstand this question. This question is not meant to say that "string theory probably does not exist" or "the theory is probably ambiguous" or even "string theory is probably just a dream and hope".

On the contrary. We already know a lot of very well-defined things about "something" and all these things fit together beautifully and exhibit a lot of quantitative agreements, miracles, uniqueness. But we still do not really know "why" all these things work so well, but we know pretty certainly that an answer exists – a scheme that organizes all the insights about string/M-theory that we have already gathered in a very coherent way.

I apologize, but your possibilities 1,2 are just plain stupidities especially if you think that one of them is likely. Both of them are silly. What you're saying that contradicts the results of 20,000 papers or so. We know that a theory that unifies these things exists, and it is most likely unique because its consequences for any question that we have been able to answer were unique. And it is a theory whose qualitative features reproduce everything we know in the real world.

There was never any non-dynamical freedom in string/M-theory found ever. If something can be adjusted about your theory, you can always view it as a choice of the environment, and in principle, you can create another environment *physically* within the Universe with the first environment.

There is some confusion about the meaning of the phrase "M-theory". Before M-theory in 11D was understood and defined (e.g. by the matrix model), people were dreaming about it. It was the only vacuum with more than 10 dimensions and it was reasonable to think that this is the real "mother" of all theories, and understanding physics in 11 dimensions exactly is enough to understand any other background in string/M-theory.

This is not how we view it today. The "mystery" of M-theory in 11 dimensions diminished significantly, and we view this 11-dimensional vacuum on equal footing with other, stringy vacua – e.g. heterotic strings in 10 dimensions. It's just *another* limit of the big "theory of everything", and it differs from most others because it has no strings and corresponding stringy perturbative expansion.

So we distinguish the "big M-theory" that contains all insights that string theorists ever studied, from "narrow M-theory" which is the UV completion of 11-dimensional supergravity. The latter is more or less understood and defined. The former is well-defined by hundreds of "patches" which beautifully fit together – the "transition functions" are the dualities – but we would prefer to describe M-theory "without patches", as a single whole – to reveal the rules that illuminate immediately why all these patches belong to the structure. This is what the question "What is string theory?" means.

I think that you are completely wrong if you say that you are "not spending of huge amount of your time" with string theory. You ARE spending a huge amount of time, even more than me, by these philosophical worthless speculations and attacks. You are just not spending this time efficiently. If you spent the same amount of time with learning string theory, you would have known it better than me.

You are free to only learn string/M-theory once someone computes the exact Universe around us by string theory, but be sure that it will be already too late for others (and you) to become significant contributors to the subject. Sure, if you're only want to be an (average) teacher, it is enough for you to only learn the things that have already been proved and awarded by the Nobel prize – and you can even end up with classical mechanics. But it's not enough to become a physicist that contributed to the human knowledge. The previous sentence applies not only to string theory, but to everything. It just happens that string/M-theory is the most (and perhaps, the only) reasonable path to progress in theoretical physics.

So I understand that your statement "string/M-theory is not well-defined" was just meant as an unphysical empty emotional rhetorical statement that should not be controversial because it was meant to express no idea whatsoever. In that case, I find this statement totally OK, but I am not interested in it. Any interpretation meant to make your statement meaningful leads to the conclusion that it is bullshit, but of course if you don't want me to study your statement seriously, I can just view it as a set of words that respect the English grammar, and everything's fine.

Best
Lubos

16. **Peter**
October 10, 2004

Hi Lubos,

The point I was making shouldn't be a controversial one. Listen to Gross's talk at the KITP conference. He lists one of the big unknown questions to be answered in the future as "What is String Theory?" and describes the current situation as something like "we have discovered a mathematical structure that has a life of its own, but we don't know what it is".

You know very well that when people say "M-theory" you have to figure out from context exactly what they are referring to. Often they are just doing 11-d supergravity, sometimes they mean a specific proposal for what M-theory is in a specific background, like the one you mention. The problem with the version of M-theory you refer to is that it doesn't work in a physically realistic background with 4 large and 7 small dimensions. Maybe there is such a version of M-theory, but for now its existence is just a hypothesis. I have no idea whether it exists, but from everything I've seen the two most likely possibilities are:

1. No such theory exists.

2. Such a theory does exist, but there are an infinite number of them, one for an infinite number of possible backgrounds, and such theories may be able to parametrize an infinite number of possible extensions of the standard model, but will have no predictive value.

Maybe I'm wrong, but it's perfectly rational for me not to spend a huge amount of my time becoming expert on the details of such theories until you or someone else comes up with a version of M-theory that can reproduce the real world and has some predictive value.

17. **Lubos Motl**
October 10, 2004

Peter, what you say – that there is no theory – is just a piece of bullshit, and the fact that you like to fool yourself with this bullshit only proves your laziness. That's it. There is nothing deep about it.

Take the BFSS Matrix model – I am just trying to calculate the exact black hole entropy including 1/4 out of it, for neutral black holes, and solve the model using a matrix counterpart of the state-operator correspondence. It is a super (and supersymmetric) well-defined QM model, whose basic variables are nine hermitean matrices X^i, their canonical momenta Pi^i with the obvious commutators, and 16 hermitean fermionic matrices theta^alpha transforming as the spinor, and the Hamiltonian is

H = P^- = Tr (Pi^2 – [X_i,X_j]^2 – theta.gamma^i.[X_i,theta])

Is that ill-defined for you? Physics in decompactified 11D M-theory is the large N limit. You can prove that this reproduces 11D supergravity at low energies – gravitons, multiparticle states, their correct statistics, gravitational scattering amplitudes. You can prove that this theory contains M2-branes with the correct dynamics, and you can prove, after deforming it to the pp-wave, that it also contains M5-branes with the right excitations.

I am just trying to solve the SU(N) Matrix model in a more or less full, exact form.

You can prove that this quantum mechanical model contains states with the same scaling laws, up to numerical constants, as the black holes in 11 dimensions. You can show that compactification of this M-theory on circle leads to another matrix model, which is the 1+1 super Yang-Mills on a cylinder, and this matrix string theory exactly agrees with light cone gauge perturbative calculations if you take the perturbative limit.

It's just bullshit and a lie to say that M-theory is not at all well-defined – or that it is just a collection of dreams. M-theory in 11D is perfectly well-defined, much like string theory is perfectly well-defined in all of its perturbative regimes, and in all these cases, we are already able to actually calculate a huge percentage of the questions. The only missing piece of the definition is a definition of nonperturbative string/M-theory on a *completely general* background – something that may be needed to understand the vacuum selection questions reliably.

Moreover, the very explicit Matrix model above can be shown to be related by dualities to other descriptions of string/M-theory, and you can go to AdS/CFT and others. Be sure that Weinberg knows all these basics of string theory, and the only reason why *you* want to disagree is that so far, you are lazy and you prefer to pray that string theory will die, instead of trying to reduce your 15-year-long delay in particle physics and learning string theory. It is much easier to pray that string theory will die instead of learning something.

Instead of expecting a smart person like Weinberg to distribute wrong, stupid, narrow-minded lies about "string theory being a wrong idea and a collection of dreams and nothing more", you should try to learn this amazing set of constrained, rigid, and interconnected ideas called string theory, and the matrix model could be a good starting point for you to learn it. Matrix theory was the framework that brought me to active work a couple of years ago, and it is exactly because it is so well-defined. I apologize, but only an idiot could say about this particular model that it is not well-defined.

Try to prove to yourself, to me, as well as others that you are not such a dumbass as D.R. Lunsford and many others. I think that you are much more intelligent, and be sure that there is nothing wrong if you are able to learn something new and change wrong opinions from the past, as opposed to insisting on your wrong position that string theory is a fad.

All the best
Lubos

18. **Lubos Motl**
October 10, 2004

Hi JC,

as Weinberg emphasized – in his talk that I liked – it is guaranteed that a relativistic quantum theory at low energies will always look as a quantum field theory. Using the tools of QFT, we can restrict some properties of higher spin fields.

Higher spin fields could be excited strings; extra components of gravity from deconstruction; many other choices. We would have to see exactly how they're produced, how they decay, and what are their quantum numbers. In general, higher-spin fields would look very stringy, and usual quantum field theorists – particle phenomenologists – rarely work with theories with higher spin fields. However, the details may be incompatible with any stringy models. I just can't give you a universal answer.

Massless higher spin particles should not exist because they require gauge invariance to decouple the negative-norm time-like modes, but such gauge invariance is incompatible with any interactions. Moreover, I don't know how would the LHC help you to produce new *massless* particles. The LHC is useful to produce new massive particles with the mass above hundreds of GeV.

All the best
Lubos

19. **Lubos Motl**
October 10, 2004

Dear Matt, your comments about the Higgs sectory in conformal technicolor are interesting. Won't you post them on sci.physics.strings? This is the kind of discussion that I would love to see there. See

http://schwinger.harvard.edu/~sps

to see different ways how to get to the newsgroup.

20. **Peter**
October 10, 2004

The problem with string theory is not that there's no guiding principles, but that there's no theory. M-theory is not a theory, but a hope that a theory exists. No one knows what the fundamental variables are or what equations relate them. By any definition of a scientific theory, it's not one. String theorists would like to believe that not only does the theory really exist, but it's beautiful and based on some simple principles. At the moment, this is just wishful thinking.

21. **serenus zeitblom**
October 10, 2004

I'm sure that Weinberg is right that there is no "guiding principle" behind string theory. But that's no big deal — none of our best theories has such a principle. Think of General Relativity, which just says that spacetime is curved and that this curvature is the phenomenon called gravity. Where is the guiding principle? It's just a clever and beautiful idea that happens to be right. All those "principles" of relativity, equivalence, Mach etc are all just historical junk of no physical importance. So if string theory has no awesome but ultimately trivial "principle" behind it, then it is in good company.

22. **JC**
October 9, 2004

Lubos,

How would string theory deal with a hypothetical LHC scenario where a set of "new" massive "gauge particles" are found, which have a spin of:

a – spin-2

b – spin-3, spin-4, or higher

Also how would string theory change if a massless spin-3 or spin-4 gauge particle is discovered, which is found to be significantly weaker than any of the other four known forces?

23. **Matt Reece**
October 9, 2004

I suppose it's true that one generally does have a new scalar field in these models, but these have a very different origin from the SM Higgs. In Randall-Sundrum type Higgsless models one has the radion to worry about, but it might be stabilized in some way such that the LHC does not see it. (Of course there are also RS models with a Higgs.) In the "conformal technicolor" approach, they predict a scalar resonance below the TeV scale, which would look approximately like a heavy Higgs with couplings that aren't quite the Standard Model values.

My inclination at this point is to say that it's an open question whether one generically expects a Higgs-like scalar to show up at the LHC even in "technicolor-like" approaches. The phenomenological difficulties in building a model with no such scalar are large, but it's not entirely clear yet that this is impossible.

As for motivation, I think these models are well-motivated in the sense that they're the closest we can come to a solution to the hierarchy problem that does not involve supersymmetry. (Well, that is not entirely true; there are also Little Higgs models, which lately it appears can be made consistent with experimental results so far.) Should the LHC see signs of a Higgs-like scalar but no SUSY, one must either admit to fine-tuning, or look for other new physics that explains the hierarchy. In this case it would be good to have examples like "conformal technicolor." But there is always the chance the LHC will see no Higgs-like scalar at all, in which case we would like to have at least some idea of what *any* model with unitary WW scattering but no Higgs-like scalar looks like. We're getting there, although as you say the examples are convoluted. One would ideally like to have such a model solve the hierarchy problem with no fine-tuning, but it's not clear we can do this yet.

Then, one could always take the position that everyone should just wait for the experimental results before going too far on some of these lines, as one experimentalist expressed to me, but I think we stand to learn interesting lessons in the meantime from trying to understand the space of possibilities.

24. **Lubos Motl**
October 9, 2004

OK, Matt (Reece), let me soften the statement a bit. The discovery of strongly interacting physics behind electroweak symmetry breaking would mean the expansion of some (as of today) very new models with approximate conformal symmetries in some energy regime, their AdS duals, and consistent incorporations of technicolor. I've heard a couple of talks about it. My feeling is that these models always require you to have some scalar field at the beginning anyway, and the physics of this scalar field just becomes complicated because of the strong interactions. My opinion is that these models are not terribly well motivated and unnecessarily convoluted – especially because the Standard Model with the fundamental Higgs works fine. But of course, I am slightly open-minded about that.

25. **Lubos Motl**
October 9, 2004

New generations, preons, new gauge groups.

A – If new generation(s) are found, it's not a big deal. The neutrino from this new generation can't really be light because the number of neutrinos lighter than the Z bosons is measured from the decay rate of Z, and the experimental result is 3+-0.01 or so. One can imagine a very heavy new generation with a heavy neutrino, but it just sounds weird – especially because the fermions, if they get mass through the Higgs, have Yukawa couplings to the Higgs proportional to their mass, and a fermion much heavier than the electroweak scale seems to imply a very large Yukawa coupling (greater than one), which seems to lead to Landau poles (divergence of the coupling at some slightly higher energy scale) and inconsistencies in the field theoretical description.

An explicitly seen new generation that is really similar to the known 3 generations would be weird, and it would probably be interpreted as an evidence for many Higgs doublets – and the new heavy generation would mostly couple to this much heavier Higgs doublet.

I don't know – it's a weird phenomenological gedanken experiment that would have no impact whatsoever on 99.9% of the string theoretical research.

B – On the other hand, preons would mean a significant shock for string theorists because – as of today – we have not seen anything like that in the stringy models. Especially the idea of a composite gauge bosons – made of spin 1/2 subparticles – seem very weird from the string theoretical point of view. If the experiments supported the thesis of some people that only spin 1/2 particles can be fundamental, string theory would be in trouble. String theory as we know it today pretty clearly implies that all light particles with spins 0, 1/2, 1, 3/2, 2 can be equally elementary.

Preons would be very hard to reconcile with string theory, I think – even though, obviously, a few people would try. This holds in all cases.

C – on the other hand, new gauge symmetries, new heavy Z' bosons, and so forth, would be compatible with strings, and they could tell us a lot about the origin of the gauge groups (geometry of the branes etc.). String theory can generate the Standard Model and bigger groups, but it can also produce some pretty different gauge groups, and in some 4D realistic SM-like models, the amount of new U(1) (broken) symmetries can be rather large. C would certainly be an interesting arena for string theorists and many people would become string builders, having a new material to explain.

26. **Lubos Motl**
October 9, 2004

If SUSY is found but Higgs is not, I don't have any immediate solution, but no doubt, all people in particle physics and string theory would try to explain why the thing that seems like the electroweak symmetry is broken. I think that string theorists and particle physicists would be comparably surprised why one of the more solid and older predictions is not confirmed while the newer one (SUSY) is. I think that the normal particle physicists would be surprised more than string theorists because they view SUSY pragmatically as a natural mechanism to protect the mass of Higgs, and if there is no explicit Higgs, their main reason for SUSY disappears. For string theorists, SUSY is first of all a natural and nice friend of string theory that makes it work better, and Higgses are independent.

At any rate, if SUSY is found, it will be a boost for the type of thinking led by string theorists because it will show that we are on the right track. The electroweak symmetry would have to be broken otherwise, or it will have to be shown as an approximate phenomenon.

Lubos wrote:

If (2) is realized and the Higgs is replaced by some more complicated physics breaking the electroweak symmetry, phenomenology will have very new, moderately interesting topics to study, and they will have very little to do with the teachings of string theory. String theory will be, in this case, disappearing from experiment-oriented physics departments, moving again to math departments – maybe even more rapidly than in the case (1).

I'm not at all convinced of this. If electroweak symmetry is broken in some way corresponding to new strongly interacting physics (a lot of the models being considered here involve new conformal physics, as suggested by Vafa, Strassler, and others), I think we might have to turn to stringy dualities to better understand these strong interactions. This is certainly true at large N (in the Randall-Sundrum models of this type that we have now, we find flavor-related difficulties in the third generation, just as in traditional technicolor, but it's not yet clear that these difficulties are insurmountable). Markus Luty and Takemichi Okui recently argued for the small N conformal case in a paper called "Conformal Technicolor," and there we have even fewer tools for understanding possible CFTs at small N. In general I think we have a poor understanding of the possible behavior of new gauge theories, and supersymmetric dualities have shed the most light on these issues so far. So, if confronted by data indicating new strong interactions, I think we'll have a difficult time figuring out what strongly interacting theory is right, and I think SUSY and string theory might give us the tools that allow us to do this. I also think such a scenario would be more than "moderately interesting," and I would greatly prefer it to clear evidence of SUSY (it would leave us with more fun things to explore).

28. **sol**
October 9, 2004

oops sorry…..that was suppose to be **back ground dependancy**

29. **JC**
October 9, 2004

Lubos,

On a slightly different twist, how would the string theory picture change in these hypothetical LHC scenarios (or a future particle accelerator):

A – a 4th vertical family of quarks/leptons is found

B – quarks and/or leptons are found to have an additional substructure, made out of "preons"

C – a "new" and different set of gauge bosons are found, which don't fit into any of the known theories like the standard model, grand unified theories, nor any of their supersymmetric extensions

30. **sol**
October 9, 2004

Lubos,

Linear extrapolation can only be done on back dependancy?

sol

31. **JC**
October 9, 2004

Lubos,

Just to be complete, how about an LHC scenario where no standard model Higgs is found, but SUSY particles are found?

32. **Lubos Motl**
October 9, 2004

Hi JC,

if the standard Higgs is found at the LHC, but no SUSY (and probably no other stringy things), then the activity, funding, and the number of new students going to string theory will decrease visibly.

People will have to live with the fact that the world is fine-tuned a bit, even as far as the mass of the Higgs goes, and they will create new models where various things are "unnaturally" fine-tuned. The influence of the anthropic principle will increase.

Those who survive in string theory will forget about phenomenology, and they will incline to mathematical aspects of string theory and the application of string theory to more formal questions related to mathematics and nice, but not realistic quantum field theories. Those that will survive in string theory, trying to match the experiments, will appreciate those who predicted that string theory naturally predicts SUSY breaking at very high energies (like Mike Douglas), but many people will be discouraged by this game.

Well, honestly, the activity in particle phenomenology, including all models with extra dimensions (which, to some extent, work *for* the LHC), will decrease even more in the case (1) – only the fathers of the Standard Model who have already made it will have a new confirmation that their theory is really far-reaching, and Higgs, Goldstone and some others will become hot candidates for a Nobel prize (after the Higgs experimental Nobel prize). The progress in particle physics will slow down even more than today, and the ideas about the new expensive colliders will probably be killed.

Unfortunately this is a very possible scenario although I've made a $1,000 bet against it (for SUSY) haha. Well, so if (1) occurs, I will also lose 1,000 dollars with Michal Fabinger but there will be more serious things haha.

Concerning your second choice. If no Higgs is found, there must be *something else* that corrects the unitarity in the WW goes to WW scattering. The pure interactions of the gauge theory, from the vertices that we know, just do not give you a consistent result. There simply must be some deviations from the no-Higgs standard model – simply because the no-Higgs standard model is not consistent; it is not unitary which means that it does not preserve unitarity (the total sum of probabilities of alternatives is not 100 percent).

If no SUSY, no extra dimensions or strings of course, but also no Higgs is found, the electroweak symmetry must be broken by other means. Let me declare technicolor to be the primary example – the Higgs may be composite and complicated enough so that it is not seen explicitly at the LHC. What happens with string theory if such scenarios get an experimental support? I think that it will suffer as much as in the case (1) because the composite Higgs models and stuff like that do *not* naturally follow from string theory (even though some people will try to make stringy models of technicolor); on the other hand, string theory has no problems with fundamental scalar particles and fields.

If (2) is realized and the Higgs is replaced by some more complicated physics breaking the electroweak symmetry, phenomenology will have very new, moderately interesting topics to study, and they will have very little to do with the teachings of string theory. String theory will be, in this case, disappearing from experiment-oriented physics departments, moving again to math departments – maybe even more rapidly than in the case (1).

As you can see, there is no permanent safety, and if you believe that string theory is fundamentally on the wrong track, you should also think that there are only 3-4 years left before string theory will be punished for that. Of course, such a punishment is never definitive – it is a crazy idea to think that a failure on one collider will remove *all* proponents of a model. One can always move the arguments to higher energies and make them less convincing, but still plausible. Maybe the next collider after the LHC could prove string theory anyway – it is a game of probabilities and arguments, and they are rarely 100% clear until the experiments are done.

Lubos,

33. **Peter**
October 9, 2004

Lubos's "less than" problem has been fixed.

34. **JC**
October 9, 2004

Lubos,

How would the string perspective change in the following hypothetical LHC scenarios:

1 – the standard model Higgs is found, but no SUSY particles are found

2 – no Higgs is found, and no SUSY particles are found

35. **Lubos Motl**
October 9, 2004

It ate my paragraph because after "d" I used the sign "is smaller", which is not compatible with HTML too well. Could not you, Peter, fix it, so that the sign "smaller than" would be translated to the appropriate HTML sentence, so that it's not interpreted as a HTML command?

I said that the models in d less than four dimensions are disconnected with reality, and their only virtue is that they are solvable. But Nature does not care whether we can solve something exactly. The qualitative conclusions from 2D gravity cannot be reliably extrapolated to 4D and other realistic spacetimes.

36. **Lubos Motl**
October 9, 2004

The anthropic principle cannot fuel a revolution or an explosion; the anthropic principle is, on the contrary and because of its very nature, a symptom of a *missing* revolution. If there will be many more years without really new and sharp results in theoretical particle physics, the anthropic principle will grow stronger, together with philosophical, non-quantitative hand-waving, and with satisfaction with not-too-impressive matches.

Well, to be honest, the revolution is not too likely to start with some lower-dimensional models in d less than 4 either because they are disconnected from the real world by their very nature, and the qualitative conclusions of these vacua can never be reliably extrapolated to real physics. Their only virtue is that many things are calculable exactly, but Nature does not care whether we can calculate something exactly.

There are potential sources of breakthoughs – discrete-like structures at the Planck scale (see Vafa et al. papers). Even if these things are relevant, they will be very different in details from all discrete approaches to QG that have been tried so far. An example – the "quantum of entropy" is often naively said to be log(2) or log(3) because the system is thought of as a system of discrete blocks with 2 or 3 states. I believe that it will be shown that the entropy of some special objects, such as extremal rotating black holes, is always a multiple of 2.pi (or at least a rational multiple of pi).

OK, let me say something about what I really believe. Below, there are two different scenarios, theory-dominated, and experiment-led. Let's start with the theoretical one.

I think that the next revolution – and not sure whether next year or in 20 years – will start with revealing some underlying "string theory" behind the theories which we do not consider to be stringy today – namely the CFT on the worldsheet. Well, N=2 strings whose target space behaves as a worldsheet of strings is the pre-example. This will allow us to interpret all effects on the worldsheet – handles, boundaries, crosscaps – as results of underlying "2D quantum gravity" that will have a more complicated nonlocal extension.

A new non-geometrical generalization of the principles of CFT will be found, and it will allow to extend the success of S-matrices etc. to the non-perturbative realm. A geometry-like original of dualities – such as E_k in supergravity – will be clarified. Non-perturbative physics on general backgrounds will become calculable, and supersymmetry breaking will be shown to be very different in details than previously anticipated. Realistic N=1 4D vacua with SUSY breaking will be connected and the potential will pick up a rather small number of priviliged points – close to the "heterotic strings on Calabi-Yau three-folds" and/or "M-theory on G2 manifolds" and/or "intersecting brane models with some warping". Two years after the beginning of the revolution, the people will calculate the masses of the heaviest quarks, the (small) QCD theta-angle, and other things, and they will predict the first new physics beyond the SM, which will be only confirmed several years later experimentally.

Meanwhile, the structure of M-theory in 11D will be solved exactly, and the position of poles of the scattering amplitudes in 11D will be known more or less exactly.

Alternatively, theorists won't be that fast, and the revolution will start experimentally in 2007, most likely with the LHC. A rather simple pattern of masses of superpartners will be found, together with supersymmetry, and it will match one of the popular SUSY scenarios within string theory. Alternatively, small black holes or excited strings are gonna be seen, and their precise patterns will be used to reversely engineer the shape of branes and hidden dimensions.

Most string theorists will jump on stringy phenomenology, and they will refine the models. It will be soon realized that these models have a very natural explanation why they're special from the string theory viewpoint, and the structure of the "landscape" will be viewed very differently than today. It will have a very hierarchic, organized structure, as opposed to the stupid chaotic democratic structure with 10^300 equal members, and the people will start to realize how the early cosmology "creates" the right compactification/branes naturally.

37. **JC**
October 9, 2004

Lubos,

What do you think will be the main ideas which will propel the "third" superstring revolution starting next year? Hopefully it will be something which does not involve the anthropic principle.

38. **Lubos Motl**
October 9, 2004

Hi JC,
that's a very nice gedanken experiment.

First of all, if they abandoned string theory, there would probably be some immediate reason for their decision, and be sure that I would study this reason in detail because this would become one of the most important questions. If the reason were right (or at least very convincing), I would join them.

Second, if I found this reason to be unconvincing or plain wrong, I would just declare that these guys got mad. I would probably also write a couple of humiliating articles about them (so be careful, Gentlemen!). 🙂 In some sense, it would be even more encouraging to do research, and I am sure that some young people would be attracted to the field *because* of the feeling of being highly original and dissenting, but it is likely that we would have no funding of it without these guys, at least for some time. 😉 Who knows.

This is not a truly realistic scenario. The reality is that the people will probably stay in the field, but they are reducing their optimism and excitement about more specific aspects of string theory and its subfields. Although all of them still certainly view string theory as a unified structure, a single theory, the opinion which directions of research and questions are "big" but also "doable" start to differ. It is completely obvious that the more thrilling period in the scientific field we live in, the more focused the research becomes. If less impressive results are created, the interests become fragmented, and it is the case of today.

The third superstring revolution should start roughly next year – by linear extrapolations of the 1st and 2nd revolutions, and also because 2005 is the World Year of Physics. 😉 So stay tuned.

All the best
Lubos

39. **JC**
October 9, 2004

Lubos,

Imagine a hypothetical scenario where guys like Gross, Witten, Schwarz, Greene, Polchinski, Susskind, etc … all abdicated from string theory and stopped believing in it. Would you personally continue doing string theory research if this particular scenario happened?

40. **Lubos Motl**
October 9, 2004

BTW, Peter, Weinberg, although he loves to attack nonsense – like philosophers 🙂 – is not fighting against string theory, and the reason is simply that string theory is not quite nonsense ;-), and he knows about it.

Weinberg wrote the foreward to the book "String theory" by Joe Polchinski:

"From the beginning it was clear that, despite its successes, the Standard Model of elementary particles would have to be embedded in a broader theory that would incorporate gravitation as well as the strong and electroweak interactions. There is at present only one plausible candidate for such a theory: it is the theory of strings, which started in the 1960s as a not-very-successful model of hadrons, and only later emerged as a possible theory of all forces. … There is no one better equipped to introduce… than … Polchinski … D-branes … Polchinski has a rare talent for seeing what is of physical significance in a complicated mathematical formalism, and explaining it to others. In looking at his book, I was reminded … Texas… where I had benefits from his patient, clear explanation of points that puzzled me in string theory. I recommend this book to any physicist who wants to master this exciting subject."

By the way, each string theorist is also using the name of 't Hooft roughly 3 times a day in average. We don't view him as a string theorist, but he would certainly joined the top ten if he described himself as a string theorist. 😉 't Hooft is teaching a course on string theory and has extensive lecture notes, see

http://www.phys.uu.nl/~thooft/lectures/string.html

The Dutch are very good in our field, I would say, and of course support of their leaders is helpful.

Sorry, Peter, but these people probably know more about string theory than you do. It is great to criticize nonsense, but it is also good to learn in advance whether something is nonsense or not.

41. **Lubos Motl**
October 9, 2004

Well, Edward Witten is (still, I hope) on our anti-anthropic side, although he is not as radical as Gross. 😉

Today, Weinberg is not a string theorist, and therefore he can afford a completely neutral – and to some extent detached – point of view. He knows that the progress in particle physics is significantly slowed down because of missing new experiments, and he also knows that string theory is the only really big idea/framework around, but it is not understood well enough to beat the absence of the new experiments.

Peter, I am pretty sure that if Weinberg thought that the reason why string theory is not connected to new experiments is different – namely that it is not the right idea – he would definitely say it. Instead, he says that he does not know, but he guesses that the prediction that the current string theory research will be viewed (in 100 years) as a heroic path towards the theory of everything is more likely (PBS, The Elegant Universe).

We would be happier if Weinberg remained in the business of quantum field theory because even though it is not the most intriguing era right now, it still looks much more interesting to many of us than the calculations of acoustic waves from early cosmology… 😉

SUSY breaking is a big issue. My feeling is that many people sort of think that they already understand at least some mechanisms of it quantitatively, but it's not quite my feeling, and I can still imagine that the correct final understanding of SUSY breaking will imply a small cosmological constant, for example.

42. **sol**
October 8, 2004

Peter

Weinberg is certainly one of the smartest people in the business, and he in general is a very clear and elegant expositor and thinker. Normally he's very skeptical of nonsense (see his public comments on religion), so I've always been surprised that he is not more critical of string theory. However, if anyone is a leading member of the particle theory establishment it is him, and I think he's not willing to countenance the idea that he and many of his colleagues have gone off on a 20 year wild goose chase.

In this same vein, I wonder why you have been so critical of string theory, and have remained silent on the issue of gravitational waves?

The relationship is obvious in terms of what is needed for proof, yet we have modelled a deeper reality in our methodology for proof?

I ask this in a nice way, to point out the discrepancy I see as a outsider, looking in.

43. **Peter**
October 8, 2004

Weinberg is certainly one of the smartest people in the business, and he in general is a very clear and elegant expositor and thinker. Normally he's very skeptical of nonsense (see his public comments on religion), so I've always been surprised that he is not more critical of string theory. However, if anyone is a leading member of the particle theory establishment it is him, and I think he's not willing to countenance the idea that he and many of his colleagues have gone off on a 20 year wild goose chase.

In my experience, good mathematicians and physicists often keep doing very original and impressive work into their sixties, but almost all slow down a lot when they hit 70 or so. Weinberg is 71.

While I find a lot of Weinberg's accomplishments impressive, I do find that I have a very different set of prejudices about particle theory. I came into the field just after the advent of the standard model, when people were just realizing how beautiful and geometric the model was. So my prejudice is kind of like Dirac and Einstein's: one should be looking for new beautiful, simple and powerful geometric principles as the way to make progress. My prejudice is also that QFT is not just an effective theory, but is the most fundamental theory we know of. The example of asymptotically free theories shows that QFTs can make perfect sense to arbitrarily short distances.

Weinberg began his career in the era of S-matrix theory, when the prejudice was that QFT could not be a fundamental theory, that it was just an effective theory at low energies. He never swallowed the full S-matrix nonsense, but has always thought of QFTs and geometry as being just low energy approximations to something unknown. His prejudice is that QFT is not fundamental, but a structure one is lead to by imposing consistency of locality, special relativity and quantum theory. This prejudice shows up in his comments against geometry in his GR book and in the way he does gauge theory in his QFT books. I think it is still showing up in his talk yesterday when he hypothesizes that string theory may also be some non-fundamental framework not based on a simple geometric principle, but whose necessity is imposed by consistency.

44. **Chris Oakley**
October 8, 2004

"Nonsense" does not quite get there.

"We think that SU(3)xSU(2)xU(1) is pretty good although there are a number of unresolved problems; we invented something called 'Supersymmetry' which is an interesting but thus far inapplicable idea; we can't seem to quantize gravity, what shall we do? I know, let's start again. Let's suppose that instead of point particles we have one-dimensional strings. Unfortunately it does not work in less than 26 dimensions. Is the theory wrong? No, the world must be 26-dimensional. Hey, if it's supersymmetric it could be only 10-dimensional! Great! Only six unobserved dimensions to explain away (plus the fact that the world is not supersymmetric, but never mind that). Oh dear, there seem to be five ways of doing this, what shall we do? How about adding another (unobserved) dimension? Great! Now what? Um …"

45. **Fabio**
October 8, 2004

I remember seeing a Feynman quote apropos string theory. He said something like: " when I was a young man, I heard all these old physicists saying all this newfangled stuff is nonsense. Now I'm an old physicist, and I must say I think all this newfangled stuff [string theory] is nonsense."

46. **JC**
October 8, 2004

It sure sounds like a lot of the older particle and/or string guys have fallen into the "old fogey" pattern of cynicism, after many years of hype which didn't pan out and the eventual letdowns. I wonder if this is an "age" thing in general, independent of the topic of discussion?

47. **Chris Oakley**

October 8, 2004

Anyone can give “state of the union” type speeches about their subject in general terms; the real test is when they talk technical. The vast majority of technical seminars I went to when I was in theoretical physics were incomprehensible to anyone who had not worked in the specific area related to the seminar. Not so Weinberg: he spoke with clarity and precision, and I was able to follow everything despite not being a specialist in all the topics that he covered. Being able to communicate effectively seems to me to be a trait of a good scientist. I seriously doubt that people can really have understood something if they are unable to communicate it in a comprehensible way.

48. **D R Lunsford**
October 8, 2004

He’s a curious fellow. In his gravity book, he goes to great lengths to explain how the geometric approach is wrong-headed, that Lorentz invariance and the Principle of Equivlance force gravity to be a spin-2 gauge field, then he gives the most perfectly geometric exposition possible. One can never really tell what he “believes” rather than “knows”.

49. **Rob**
October 8, 2004

For the record, I talked to Weinberg about a few things last weekend when he was here at the Perimeter Institute and he didn’t seem old, tired or discouraged. Indeed, I remember thinking that he had remarkable energy for someone who has been in the game so long.

Witten on "The Future of String Theory"

October 9, 2004
Categories: Uncategorized

Witten's talk this morning at the KITP on "The Future of String Theory" is now available. He only talked for about fifteen minutes and then took some questions. I thought it was a rather weird performance. Not only did Witten not really have anything to say about the future of string theory, he didn't even discuss the present state of the theory. The most recent thing about string theory he mentioned is the now seven year-old AdS/CFT correspondence. He drew the standard picture of Feynman diagram vs. string world-sheet, claiming it indicates that space-time is an "emergent phenomenon". He even noted that he has been drawing the same picture for nearly twenty years now and he still doesn't know in what sense this "emergent space-time" idea is true, although AdS/CFT is the closest thing to the kind of thing he is looking for. Now not only space-time is supposed to be "emergent", but so is the string itself, although he admits he doesn't know what this means.

Instead of looking optimistically to the future, Witten's talk was extremely defensive. He started off trying to defend why string theorists work on string theory (basically because it is a non-trivial extension of QFT, contains gravity and has lead to important mathematical results). Much of his very short talk was taken up by mentioning criticisms of string theory and giving unconvincing responses to them. He didn't say anything in the bulk of his talk about the Landscape or twistor string theory, or anything else going on these days in the field.

There were several questions from the audience. Someone asked him if he would still believe as strongly in string theory if the LHC didn't find supersymmetry. He somewhat evaded the question, saying he would be less optimistic about how well we can ever understand the world, but implying that he wouldn't consider this as evidence against string theory itself, repeating the same defense of why he did string theory that his talk started with.

The last question was about the anthropic principle and the Landscape. He began his answer with something like "Well…..(nervous laughter)… uh….." then finally said more or less "I'd be happy if it is not right, but there are serious arguments for it, and I don't have any serious arguments against it." So I guess he comes down on the Weinberg side ("I don't like it, but maybe we have to accept that our fundamental theory can't explain any of the things it is supposed to") vs. the Gross side ("people who think this way have given up doing physics").

Comments

1. **D R Lunsford**
   October 13, 2004

   Everyone knows that gauge invariance requires experimental support to be massless.

2. **Chris W.**
   October 13, 2004

   ..and, in light of the string theory landscape it is unclear what "massive experimental support" could ever mean. The landscape's partisans seem to be thrilled that it might contain a hill or valley that resembles whatever observations one might anticipate making.

   Even discounting the landscape, the profligate mathematical richness of string theory is a liability (and a distraction), not an asset. The theory doesn't appear to make any *new* experimental meaningful statements of the form "X can never happen", "X will never be observed", or "X must happen in situation Y". Cocky and dangerous predictions like that are what make a theory truly testable. To make them, string theory will have to become a very different sort of theory than the one we now have. That won't happen unless its practitioners make a deep commitment to making it happen. I don't sense such a commitment or the kind of active and imaginative critical effort it produces.

3. **Thomas Larsson**
   October 12, 2004

   If you were Witten, what would you do to "fix up" string theory as it's known today (besides fixing up diffeomorphism anomalies)?
   What would convince you to change your mind and be in support of string theory?

   In the unlikely event that string theory acquired massive experimental support, I guess that I would have to believe in it. But the present situation is rather the opposite.

   The construction of a quantum theory with some prescribed symmetries is, from my perspective, the same thing a constructing the representation theory of the group of symmetries. There is really a 1-1 correspondence:
   1. Given a quantum theory, its symmetry group acts by a unitary representation on the Hilbert space.
   2. Given a unitary representation of some group, the Hilbert space on which it acts is the Hilbert space of some quantum theory.

   In particular, the Hilbert spaces of the fully interacting gauge-invariant or diff-invariant theories carry unitary representation of the groups of gauge transformations and diffeomorphisms. Perhaps one should factor out gauge symmetries, although I don't see why – it is definitely not necessary for consistency (unitarity). But this is really irrelevant for the argument. The anomalies must be there at least before factoring them out, so if you cannot write down the anomalies in the first place, you lose.

   I am pretty sure that there is no way to fix string theory. The representations look the way they do, and their Hilbert spaces look rather like fixed versions of field theory. I don't see any way to "fix" SU(2) to allow for unitary spin-1/4 representations either.

   I don't have a clue what I would do if I were Witten, and I don't really care. It's not my problem.

4. **Peter**
   October 12, 2004

   Some comments about Arun's questions #2 and #3.

   There are two main ways people have tried to relate string theory (whatever it is…) to real-world physics. The first, and in some sense the oldest, is the idea that it provides a dual formulation of gauge theories like QCD. The latest version of this is the AdS/CFT correspondence, which some string theorists go so far as to take as an answer to the "What is string theory" question, defining string theory in terms of a QFT. I don't have any problem with this. It is a promising way to learn more about gauge theories like QCD, worth investigating and may lead both to better understanding of how to calculate things in QCD, as well as to a better answer to the question of what string theory really is and what it is good for.

   The second way people try to relate string theory and the real world is the one that has got the most attention over the past 20 years, and it's the one that I think is completely misguided. This is the idea that one can use anomaly cancellation conditions to pick out one or more supersymmetric theories in 10 or 11 dimensions with specified gauge groups, and that this will give a theory of everything. There are two separate kinds of arguments against this, besides the operational one of 20 years of failure to get anywhere.

1. Nothing comes out right: We live in 4 dimensions, gauge group SU(3)xSU(2)XU(1), non-supersymmetric particle spectrum. String theory predicts none of these things. If anything, anomaly cancellation predicts 10 dimensions, E8xE8 or SO(32), supersymmetric spectrum. To get things to look like physics you need to engage in complicated, ugly, ad hoc constructions (latest example is KKLT) that completely ruin any predictive power of the theory. This is extremely strong and convincing evidence that the initial idea is simply wrong. I don't understand why people refuse to admit this.

2. There is no good non-perturbative formulation that does what you want. The great dream of the subject is that there is some beautiful 11d theory based on some elegant principle that, once it is found, will automagically solve the problems in 1. I think there is zero evidence for this despite 20 years of effort, and at this point the people who go on about this are simply engaging in wishful thinking. Witten, Gross and others at some point need to either put up or shut up about this. If for twenty years now they haven't been able to find this wondrous new principle, they should admit it probably doesn't exist and do something else with their lives. The fact of the matter is that, mathematically, the standard model involves far deeper and more elegant mathematics than that used in string theory.

5. **JC**
October 12, 2004

Thomas,

If you were Witten, what would you do to "fix up" string theory as it's known today (besides fixing up diffeomorphism anomalies)?

What would convince you to change your mind and be in support of string theory?

6. **Thomas Larsson**
October 12, 2004

#2. he expands later to "What is the core idea analogous to the principle of equivalence in the case of general relativity?"
#3. he expands later to "Even if it occurs {i.e., we understand what string theory is}, and if string theory is on the right track, will we be able to learn how to use it to understand nature?"
…
But it seems that Peter thinks that #2 is also dubious? I had thought that while the final answers for #2 are not available yet, there is little doubt that there is something there; in fact the seeming wealth in an answer to #2 is why physicists study string theory, and why we have strong opinions that #3 will be answered in the affirmative.

Given that Witten and hundreds more of the world's brightest people have spent 20 years on #2 and still haven't figured it out, why do you believe that there is something there? And even if there is something, who will figure it out, when Witten obviously wasn't smart enough?

Witten may well be the smartest person since Aristotle, but that doesn't mean that Wittensian gravity is more successful than Aristotelian gravity. Besides, Witten at 55 is probably less smart than Witten at 35.

It is almost a theorem that string theory will fail. It doesn't account for the diffeomorphism anomalies in 4D which must be there in canonical quantization by analogy with the conformal anomaly on the worldsheet. Anomalies are non-negotiable things, and if your theory cannot describe all necessary anomalies, it is in deep trouble.

7. **Arun**
October 12, 2004

Don't let physicists, too, fall into the slick slide trap!

8. **Lubo? Motl**
October 12, 2004

I agree – industry seems to be a decade ahead of the physicists in presentations. The mathematicians, on the other hand, have not invented the overhead projector yet, and therefore they always prefer the blackboard.

Well, some of us are trying ;-), see

http://schwinger.harvard.edu/~motl/twistors.ppt
http://schwinger.harvard.edu/~motl/rutgers-talk.ppt

9. **Fabio**
October 11, 2004

Wow. Looking over some of the slides from the talks, the thing that impresses me most is how primitive they look (with the exception of t'Hooft's). Having been in industry for a decade or so I was sort of surprised to see that people would still scribble things on transparencies with markers for a conference talk. It's kind of quaint.

10. **Arun**
October 10, 2004

Just watched Gross's talk, very worth watching.

Witten had three questions at the start of his talk:

1. Why do physicists work on string theory?
2. What is string theory?
3. Can we connect string theory to particle physics?

#2. he expands later to "What is the core idea analogous to the principle of equivalence in the case of general relativity?"

#3. he expands later to "Even if it occurs {i.e., we understand what string theory is}, and if string theory is on the right track, will we be able to learn how to use it to understand nature?"

I had understood Peter's criticism of string theory to be basically centered on #3, i.e., his stand is that the connection of string theory to nature has been tenuous all through its history, and the situation shows no signs of improving. And if #3. has no good answer, then #1. needs an answer – why should physicists work on it?

But it seems that Peter thinks that #2 is also dubious? I had thought that while the final answers for #2 are not available yet, there is little doubt that there is something there; in fact the seeming wealth in an answer to #2 is why physicists study string theory, and why we have strong opinions that #3 will be answered in the affirmative.

I think asking the question #3 in the form of "what experimental results or observations in the next 10 years will help us decide whether string theory is relevant?" can be a useful scientific exercise; while attacking #2. is a waste of time.

-Arun

11. **Lubos Motl**
October 10, 2004

Dear Arun,

the emergent time is a great question – David Gross was exactly mentioning this puzzle in his talk at KITP.

Special relativity guraantees that if space is emergent, time must be emergent as well.

String theory in various formulations is Lorentz-invariant, and therefore it should agree with this principle.

However the specific formulations we have are able to show that *space* is emergent, but time is never emergent in these pictures. Well, if you have operators or wavefunctions or whatever, and even if you want to predict the future from the past, you need a concept of time.

It's not a contradiction. The manipulations that we are able to make with the space cannot be easily done with time – time is different in details, at the end, for example it can have an arrow (time-like intervals have a universal arrow, past vs. future, while spacelike intervals don't).

If one says that time is emergent, the idea of predicting the future from the past must be approximate and emergent as well. Well, it's not shocking if we study the S-matrix: it is the set of amplitudes between the infinite past and infinite future, and with infinite separation, time becomes sharp and well-defined much like space.

If we look at the gauge-fixed descriptions, such as the light cone gauge ones (Matrix theory, for example), the gauge-fixing always guarantees that there is a well-defined notion of time, and the other operators are simply functions of it.

There have been speculations, e.g. by Aharony and Banks, see

http://arxiv.org/abs/hep-th/9812237

that M-theory – and little string theory in particular – has some inherent non-locality in time. But these conclusions have not been universally accepted yet, I would say.

A few more comments: if you adopt the formalism of the S-matrix, the questions go away – the only invariant object is the amplitude at infinite separations both in space and time, and these emergent notions are "emerged fully" anyway.

However, the S-matrix is not enough to study cosmology. If we want to understand the early cosmology, it seems sort of necessary (or useful) to understand in what sense the time emerges after the Big Bang. It probably does not make sense to ask what was "before the Big Bang" or "before the Universe was Planckian in size" – because before this moment, the concept of time (and the word "before") had not emerged yet. Nevertheless there is a clear feeling that something is missing, and we should be able to say something about "which universes can emerge" from the Big-Bang and which cannot. And the answer about this Planckian super-early cosmology seems to require us to learn HOW time can be emerging and what is it emerging from.

Best
Lubos

12. **Arun**
October 10, 2004

Lubos,

It helps a bit. Let me ask: is the notion of time – smoothly flowing, continuous – essential to any formulation of string theory, or will it emerge out of string theory? Does the notion of time exist in quantum foam/quantum geometry?

-Arun

13. **Lubos Motl**
October 10, 2004

Gross's talk is very cool! Highly recommended.

14. **Lubos Motl**
October 10, 2004

Hi Chris,

thanks for your comment. Was this blog meant to debunk the subject? 🙂 Well, I think that this purpose belongs to the past. I view it as a place for philosophizing about some general questions of string theory and theoretical physics and its future, and especially about the importance of various ideas.

But if one looks at this blog, it is rather obvious that string theory *is* the most important set of ideas we have. Look at the percentage of the postings dedicated to the subject. 😉 Well, there are some essays by Peter that are just anti-stringy and that are "not even wrong", but this is just a natural component of this blog. This blog is not a refereed journal. Nevertheless, I think that there are also some entries in this blog that do have a meaningful content.

All the best
Lubos

15. **Lubos Motl**
October 10, 2004

We have an overwhelming evidence that specetime is an emergent phenomenon. It is not just some Witten's progressive idea, it is an idea that even Brian Greene always says for the popular audience.

The statement means that we should not think about the objects and events to take place on a well-defined background geometry. Quantum mechanics guarantees that the concept of completely smooth geometry is incompatible with quantum mechanics that make things fluctuate.

But string theory goes much further. Geometric descriptions, such as general relativity, are only approximations valid at very long distances. At very short distances, comparable to the “length of the string” (string scale) or “the smallest meaningful black hole” (the Planck scale), physics does not admit a simple description in terms of usual geometry. Geometry is generalized to something much bigger, and the difference between geometry and matter disappears – this is the content of unification of gravity with other forces and matter.

String theory implies a lot of dualities. For example, T-duality shows that the Universe with a circular dimension of radius R is physically indistinguishable from the universe with a circular dimension L^2/R, where L is the constant length associated with the strings (string scale). A radius smaller than L has identical physics as the inverse radius which is greater than L. If one compares these two equivalent universes, one must create a dictionary: for example, objects with momentum N/R in the “small” Universe map to string that are wound N times around the circle of the large Universe, and vice versa.

The momentum is the generator of translations, and you can see above that it behaves physically in the same way as the winding number (how many times a string is wrapped). It is just a matter of convenience whether we call something “momentum” or a “winding number” in these Universes with circular dimensions. Also, mirror symmetry analogously relates two very different 6-dimensional shapes (mirror duals) which nevertheless lead to identical physics if you put string theory on it.

The momenta etc. can have the interpretation of winding numbers, electric charges, and so on, in various equivalent descriptions of the reality. Different equivalent descriptions of reality do not agree what the spacetime geometry is. One of them can become much more reasonable than others, but it is only in the case in which the radii and size of this geometry are much greater than the fundamental scale (for example the string scale). In this case, one geometry is much more realistic and convenient description than others. But because I need the size of the geometry to be large, geometry is just an emergent phenomenon.

At very short distances comparable to the fundamental scale, geometry is replaced by a generalized, quantum, stringy geometry that contains much more stuff that we don’t usually consider to be “geometry”. Geometry becomes unseparable from other physical concepts, objects and phenomena.

The notion of topology of the space(time) manifold also makes sense as the approximation in the limit where we study the long-distance behavior only. At very short distances, quantum mechanics guarantees that even the topology is fluctuating (quantum foam) – one can imagine that the geometry at very short distances is non-commutative, although one must be ready that the word “non-commutative” in the most general situation must be extended and generalized.

Non-commutative geometry is something that allows one to replace functions on a manifold by discrete matrices – the smooth, commutative geometry appears for very large matrices.

Much like in the naive discrete approaches to quantum gravity (such as “loop quantum gravity”), the character of the spacetime is very different if we probe it with a very good resolution. However, the effects in string theory are not just that “space is made of atoms of space”. Instead, there are many new objects, fields, concepts appearing in this regime and all of them are “fuzzy” and mixed up in some way.

Does it illuminate the question?

16. **Chris Oakley**
October 10, 2004

If there is a source of disappointment, it’s the fact that the hundreds of smart people – old and renowned ones as well as the young ones – have not been able to make greater progress in the recent years.

Lubo?, I am glad that I am able to agree with you on something for once. What is the world coming to? The chief bodyguard of the superstring orthodoxy posts comments on a web log devoted to debunking the subject – ? Maybe that is a reflection of the state of affairs in fundamental physics – that we have to huddle together to protect ourselves from the greater threat of all becoming irrelevant.

17. **Arun**
October 10, 2004

“Space-time is an emergent phenomenon” – while even Witten doesn’t know what it actually means, what could it conceivably mean?

18. **Lubo? Motl**
October 10, 2004

Wilczek’s talk is very funny – he says that he will not allow his first Nobel prize to… Well, you should see it.

19. **Lubo? Motl**
October 10, 2004

I think that Witten’s talk is good and pretty optimistic! What are you talking about, Peter? Yes, it is a rather standard talk about uniqueness in quantum field theory and string theory, and about richness of string theory (underestimated even by the enthusiasts, as Witten points out), and about the stringy counterparts of the principles of GR, and what is string theory – and it does not cover the newest developments, but it is announced in the very first sentence, and this orientation of the talk is probably determined by the audience. I would almost certainly give him an “A” for this talk. 😉

I also think that his answers were very honest. If they ask him how (non)-SUSY on the LHC will affect him, he is realistic and talks in terms of “level of belief” and probabilities. Whoever expects some radical statements that one experiment will change totally everything about his belief system, does not really appreciate the huge number of very different rational reasons and insights behind Witten’s opinions.

Dear DRL, I have no idea what you find astonishing and infuriating. Maybe you misunderstood something? We just said that Witten is not pessimistic about string theory itself – that has displayed no real problems with its framework – but about the limited human abilities to study it, which have slowed down the progress in recent years, and it is not completely clear (and it is a matter of hopes) whether we will be able to do better in the future.

At any rate, it is an objective fact that the progress in string theory today is slower than in the middle of 1980s or middle of 1990s. One more thing about the intelligence of string theory vs. the intelligence of us: string theory is much smarter than all of us – me, you, but also Andy Strominger, Cumrun Vafa, or Edward Witten. I am sure that all of them – maybe except for you, DRL – would fully agree with this statement of mine, and some of them have said this statement themselves. You’re probably the only one who thinks that he is smarter than string theory – but this is, I apologize for being honest, a symptom of limited intelligence, not high intelligence. And if you ask why I feel the moral right to conjecture such things about you because of this single topic, it’s because I have known you for quite a while, so this judgement is not just because of this specific question!

If there is a source of disappointment, it’s the fact that the hundreds of smart people – old and renowned ones as well as the young ones – have not been able to make greater progress in the recent years.

20. **D R Lunsford**
October 10, 2004

Lubos, I find a statement like that both astonishing and infuriating. Who the hell are you to make statements about any single PERSON's intelligence, not to say the whole shebang? Not only do you claim to read God's mind, you know what he has in store for poor suffering Man.

I would not only be embarrassed to be credited with such a statement, I would be ashamed.

-drl

21. **Lubos Motl**
October 10, 2004

I agree that Witten's limited optimism stems from the limited human intelligence, not from defects in string theory. In some sense, there is a disappointment that all of us have not been able to go much further.

Brian Greene's TV example with the dog learning GR is very cute, but I still hope that despite the finite brains of all of us, we have some abilities to crack anything that makes sense in the future.

22. **Lubos Motl**
October 10, 2004

I don't believe that reasonable professional physicists believe that the principle of equivalence is unimportant as a foundation of GR. (Did the comment mean Hawking?)

Weinberg has been criticized for not sharing the "religious geometric" viewpoint about general relativity. But Weinberg's point is certainly not that the equivalence principle – or diffeomorphism invariance – is not important.

Weinberg's point – and I am sure that this is shared by an overwhelming majority of particle physicists and string theorists – is that general covariance is different in details, but otherwise it can (and it should) be treated with the same tools as other gauge invariances such as Yang-Mills invariance. Well, string theory unifies these two naturally in many "senses". 😉 Already the Kaluza-Klein theory unifies them, and string theory goes much further.

The special feature of gravity is only in its low energy manifestations – spin 2 fields and particles; coupling to stress energy tensor; geometrical interpretation of the gauge invariance. But these are just visual differences. In the fundamental way, gravity is not that different, which is why it can be unified.

23.
October 10, 2004

To be fair, Witten was talking to an audience who hadn't even heard of Ads/CFT, so you could not expect much. Two things stood out from the talk though: first, people like Witten *still* believe that the Principle of Equivalence is somehow the foundation of GR. People in that field stopped believing that decades ago [hint: search for the POE in Hawking and Ellis' book —from 1973!]. Second, Witten points out that the *real* reason Ads/CFT is interesting is because it might give us a dual to the actual spacetime in which we live. It's great that he says this. It would be even greater if people took his words to heart and actually tried to apply Ads/CFT in that way. I don't think that anyone really believes that *our* spacetime fails to be globally hyperbolic on cosmological scales, do they?

24. **Chris Oakley**
October 9, 2004

Following on from Danny's comments – though less eloquently – I knew that I had no future in the subject just from the kind of casual discussions I was having with my peers 19 years ago. I was a harsh critic, and remain a harsh critic, of things I perceived as inconsistencies in QFT. I worked on the principle that one should wipe one's bottom before thinking about powdering one's nose, which automatically ruled out spending time on grandoise super-unified schemes before basic mathematical problems were solved. None of my colleagues agreed with me on this, and when I would dismiss their string theoretical efforts as unmotivated and overly speculative they would take on the appearance and vocabulary of religious fanatics prepared to sacrifice all for some inexplicable but strongly-held set of beliefs. They are still doing it.

Fine … but don't pretend it's science.

25. **D R Lunsford**
October 9, 2004

Perhaps it is the recognition of hubris in himself and others. After all, what string theory proposed was 1) a revision of Democritus, thus a supposed "new beginning" for science 2) an abandonment of the essential idea of indentical particles and their statistics 3) a deliberate willful disregard of the scientific method in favor of a mediaeval-scholastic imposition of a false order – a return to "reading God's mind" 4) A PR campaign on the level of the Neocons to convince everyone that strings beget gravity, when this was never in fact true.

Wouldn't you be depressed to look in the mirror and know you took part in such a shell game – such a carnival ruse?

In a larger sense, the intellectual climate in the West seems utterly poisoned by fashion and faddery. Facts and imagination are so pre-post-modern.

26. **String Theorist**
October 9, 2004

Witten's disillusionment stems not from any defect in string theory itself, but from the limitation of human intelligence.

String theory exists, regardless of one's prejudices, and the question of whether the landscape exists is a scientific question, regardless of one's prejudices. (It is the question of what to DO about the landscape, if indeed it exists, that some people like to answer non-scientifically.)

We can't expect a dog to understand quantum mechanics, and it may be that we are reaching the limit of what humans can understand about string theory. Maybe there are advanced civilizations out there to whom we appear as smart as dogs do to us, and maybe they have figured out string theory well enough to have moved on to a better theory…

27. **Peter**
October 9, 2004

I know that Witten has been somewhat discouraged about string theory for a while, but still doesn't want to give up on it. Under the circumstances I would have been a lot happier to hear him say something like "things are discouraging for the following reasons, but I still continue to have hope for these other reasons. To continue to be viable, string theory needs to make progress on the following problems, and here are some ideas about them. What Susskind is suggesting about the Landscape is not science and I'd abandon the idea of string theory before going down that path".

In other words, I wish he had come down on Gross's side of the Landscape argument.

28. **Lubos Motl**
October 9, 2004

I am surprised that Peter Woit is surprised to see that Edward Witten and perhaps some others feel slightly disillusioned today. I thought that you, Peter, were following what's going on in psychology of our field, and you were even comparing the citations of the most cited articles in 2003 and 1996, for example. 😉 Yes, it's much less today, and our optimism is correlated with that, of course. It does not apply to some people ;-).

Witten would certainly like some experimental confirmation, too. Also, there is a lot of sense in which he deserves at least one Nobel prize, but clearly, without a breakthrough that will allow experimental verifications of predictions, it's hard to imagine.

Your description does not suggest that Witten's talk is something I can't miss, but because I know in which way you twist, I will try to watch it anyway. 😉

BTW Bush may have seemed uncertain, defensive, and feeling bad about the reports from Iraq in the first debate, but I think that he was slightly better than Kerry in the second debate.

29. **Peter**
October 9, 2004

I think you're very right that that's part of the psychology going on here.

And I should make clear that I don't think Witten is a cynic; I think he believes in what he says (although I wouldn't say the same about our current administration and what they say about Iraq).

30. **JC**
October 9, 2004

Perhaps being in "denial" is a very ingrained human trait, especially when one has invested a lot of time, effort, and pride into a particular endeavor. A very common manifestation of this is in the "sunk cost fallacy" where a person figuratively or literally "throws good money after bad money". On the stock market, it would be where somebody stayed with a crappy investment hoping to one day make back all the money they "lost" on it. Emotionally it's very hard for them to "sell" the crappy investment before reaching the break-even point, since selling and taking a capital loss would tell them that their personal judgement was "wrong" about it.

31. **Peter**
October 9, 2004

Witten's defensive performance reminds me of George Bush being confronted with the fact that the war in Iraq was based on a mistake and the whole thing seems to be going very badly and hasn't worked out at all as planned. Just like Bush, Witten appears to be unwilling to face up to what a disaster the current situation is, or admit that the whole thing may have been a mistake. Unfortunately, Witten's sticking to his guns and seeming highly unlikely to ever give up or acknowledge defeat is good for string theory, but bad for physics. If he ever gives up, string theory is doomed, but as he and others refuse to acknowledge what a disaster it is, the field of theoretical physics suffers immensely.

The way things are going, the endpoint is going to be that theoretical physics will be dominated by the endless study of a horrifically complex and ugly framework that can never explain anything, together with an associated "Landscape" ideology that justifies never having to relate the theory to the real world.

32. **JC**
October 9, 2004

Is this an ominous sign of an eventual day of reckoning for string theory? Or is Witten becoming very cynical about the whole enterprise altogether?

Wilczek Weblogs

Comments

1. **Lubos Motl**
   October 13, 2004

   Hi Sol, nope ;-). If you follow sci.physics.research, you of course know who is it.

2. **sol**
   October 13, 2004

   Lubos

   But what would you think if you met someone else, someone nice, someone who is around, namely someone who can be described as a leader of quantum computation, who argues that there is really no difference between renormalizable and non-renormalizable theories as far as predictivity goes (he immediately and explicitly gives you the Standard Model and quantized General Relativity with all counterterms up to five loops as examples) – and he even states that drawing a graph of a function (which is a part of the input of a theory) is giving you a more predictive theory than if you know the function analytically, as long as the analytical function looks too complicated to you?

   Who were you talking about here? Smolin and the Perimeter Institute?

3. **Lubos Motl**
   October 11, 2004

   Haha, sol, that's entertaining. The article explaining the problems of loop quantum gravity – the article that you presented to those guys on the other forum – was, of course, written by me as well. 😉

   A newer version of this article is today at

   http://en.wikipedia.org/wiki/Objections_to_the_theory_of_loop_quantum_gravity

   I am not surprised that those guys who want to promote loop quantum gravity dislike Wikipedia for having such articles. But fortunately it is impossible for them to hide knowledge from the internet users.

   All the best
   Lubos

   October 11, 2004

   lubos

   Also, I link Wikipedia because Wikipedia is free and relatively good. Most Wikipedia articles about string theory (and a nonzero part about adjacent fields of physics) were more or less written by me ;-), and your comments about "defaming them" sound very puzzling. Who was defaming Wikipedia?

   http://www.physicsforums.com/archive/t-42996_Strings_or_LQG_and_why???.html

   I hope that is the right thread(its been archived), but I went on to defend, encouraging others of expertise to add their's, for a truly wonderful reference point for consideration.

   http://superstringtheory.org:8080/forum/edonline/discussion.jsp?thread=16

   I hope you don't mind I added this post to the links in defence?:)

5. **Lubo? Motl**
   October 11, 2004

   Hype and propaganda? Come on.

   There is no hype and propaganda about string theory. People just try to explain why it is a fascinating and unique theory. In the mid 1980s or mid 1990s, people were more excited and the progress was faster, and therefore the comments about string theory were more optimistic. Today it's closer to the opposite. As Witten pointed out on the KITP conference, even string theory *enthusiasts* underestimate how rich and powerful string theory is – so speaking about hype and propaganda is not a reasonable or fair description of reality.

6. **Lubo? Motl**
   October 11, 2004

   Dear sol,

   it is not clear whether I understand you. But my blog, http://motls.blogspot.com/ , definitely allows replies of anyone, including anonymous users.

   Also, I link Wikipedia because Wikipedia is free and relatively good. Most Wikipedia articles about string theory (and a nonzero part about adjacent fields of physics) were more or less written by me ;-), and your comments about "defaming them" sound very puzzling. Who was defaming Wikipedia?

7. **Thomas Larsson**
October 11, 2004

This weblog thing is getting out of control.

This seems literally true for the program powering this weblog. It seems like Movable Type 2.661 cannot handle the number of replies to the entry "KITP Conference on "The Future of Physics"". Thus let me respond to JC here instead.

I get the sense most of the criticisms of string theory on this weblog is largely about the hype and propaganda surrounding string theory over the last 20 years. The discussions about specific technical details about string theory and field theory seem to be more neutral and less controversial.

My main criticism is quite technical. String theory failed as a theory of quantum gravity because particle physicists didn't understand that diffeomorphism anomalies exist in 4D – you need to go slightly beyond field theory to see them.

If you miss the relevant anomalies, you will fail.

8. **sol**
October 11, 2004

Well this is fine Lubos, but you have no place in which to respond?

Plus, I had been criticized greatly for using wikipedia in the **physics forum** for reference, so the authors of the sited revisons on those selective topics you have linked, would they have been inspected by yourself, so that this maybe referenced, quieting those whose comments defame the wikipedia references?

I assume because you had linked them it would be yes. Just reaffirming would help greatly.

Then we will have to see if Peter logs your site, on his.

Lubos

Emergent space and emergent time

In string theory, we now have overwhelming evidence that space is an emergent phenomenon. It is not just one of Witten's progressive ideas. Instead, it is an idea that even Brian Greene often explains to his popular audience. The statement means that we should not think about the objects and events to take place on a well-defined background geometry; we should not think about space and time as basic assumptions whose existence is guaranteed before we consider anything else.

The most delicate weblog thing, as fas as I now, is the string coffee and it is not working after all. Why should Wilczek risk his weblife?

Witten replaces WMAP

October 11, 2004
Categories: Uncategorized

Witten is giving a colloquium talk next week at Princeton on the topic of "Supersymmetry Pro or Con". His talk is a last-minute replacement for one about "Recent Results from WMAP" by Lyman Page. WMAP was supposed to report the results from the analysis of the second year's worth of satellite data early this year, but this has been delayed quite a bit already, and evidently is being delayed even more. Does anyone know why?

1. **D R Lunsford**
   October 14, 2004

   No – Pauli is right and Kaku – or whoever authored this quote (and I apologize in advance if Kaku was misquoted or not quoted) – is wrong.

2. **sol**
   October 14, 2004

   DRL,

   I was looking for specific quotes by Kaku, but immediately did not find it. I will supply when I do.

   However, since our universe obviously has 4 dimensions (3 spatial and one temporal), people were troubled by this extra 5th-dimension. Oskar Klein, a German mathematician, offered an explanation; the 5th dimension could not be seen because it was much too small. It had curled up, or compactified. For example, picture a garden hose. From far away, it appears to be a line (one-dimensional), but upon closer examination, one finds that it is a tube (a 2-D surface curled up).

   http://www.ecf.toronto.edu/~quanv/String/string4.html

   Is this a historical difference of opinion?

3. **sol**
   October 14, 2004

   I must apologize D.R. Lunsford for mispelling your name in post previous and ask you to click on Lubos's name on information you quote, that you took the statement from.

   The html has to be placed in front of each paragraph to show italiced statement. This did not come about and looks like my writing, when its not. I should have previewed, and then posted.

4. **D R Lunsford**
   October 14, 2004

   Sol,

   It is absolutely false in every detail.

   -drl

5. **sol**
   October 14, 2004

   D.R Lundsford,

   You must always look to how these statements are produced. As a laymen I am at the mercy of minds better educated, so I would look at your response to further my position of understanding.

   What do you think of this statement?

   By adding a 5th-dimension, Kaluza unified in one stroke Einstein's theory of gravity with Maxwell's theory of electromagnetism.

   regards

6. **D R Lunsford**
   October 14, 2004

   Sol,

   I take strict exception to some of your statements below , viz:

   Theodor Kaluza made a shocking suggestion back in 1919 when he proposed that the electromagnetic waves are actually ripples on the shape of spacetime in the 5th dimension. This "Kaluza-Klein theory" was the first serious proposal to unify gravity and electromagnetism.

   The first (and IMO only) "serious" attempt to unify EM and gravity, in the sense of an irreducible, background free theory where Am and gmn have equal roles, is Weyl's theory of 1918. KK theory is spurious unification, as can be seen by the simplest possible argument (given by Pauli) – *any* theory at all that can be made generally covariant, can be cast in Kaluza's form, where the extra fields appear as part of the metric. So for example I can immediately write down a spurious "unification" of gravity and the Dirac theory, where the extra components will look like

   (psibar ym psi) (psibar yn psi)

   KK theory is *not* unification in the same sense as, say, Maxwell's melding of electricity and magnetism.

In all cases, electromagnetism and gravity are unified into something like "generalized geometry".

Not so. It's Riemannian geometry. Weyl's theory, on the other hand, *is* a more general geometry.

I don't know how these false mantras become commonplace "knowledge", but it is not good for science. Trust but verify.

7. **sol**
   October 14, 2004

   Is this the same CM?

   Remember we are talking about the Loop Quantum gravity article.

   Charles Matthews
   *Guys, **I'm completely dumb in the subject** but I feel the article is simply too big. May be we should move most of it to something like Loop quantum gravity versus string theory? And let's decide upon quantum gravity and loop quantum gravity articles — they should be something like merged with this article. Having three articles with much similar content is really strange. I believe with can do it in a bloodless way.*

   *Disagree, having looked around. Loop quantum gravity at 42K is already longer than WP likes. It has various articles hanging off it, and I've done the work required to make this another of those. **Further, quantum gravity is not something that should be merged into an article on a particular theory**: it should be a top-level article setting the general scene. So in a sense I'm coming closer to what User:Lumidek suggested, just because this seems to be generating a great deal of interesting writing. Still needs work, of course. **Charles Matthews** 11:26, 10 Oct 2004 (UTC)*

   http://en.wikipedia.org/wiki/Talk:Objections_to_the_theory_of_loop_quantum_gravity

   I am amazed at your credentials and I do appreciate the work that your doing. Even you do not understand the wave you are caught in:)

   Resources for accurate information does require that we support free institutions that would cater to those less informed, and requesting, more information to draw from.

   If, the Third Superstring Revolution goes ahead as it seems it is unfolding, how would "Quantum gravity" serve as a heading and these two aspects of strings and LQG under it?

   The third String Revolution would continue to undermine current positions. Can we tolerate such speculation?:)

   I recognized Lubos work early in Wiki when none were the wiser. I can show this. I found this a admirable quality to do work, where none had not considered, where laymen like myself would draw from.

   By now, you should understand how you got where you are, by your commmenting.

   To Wiki and Beyond:)

10. **sol**
    October 13, 2004

    Well CW, it would be hard to classify your statement, since it didn't compute:) Not surprise eh?:)

    Lubos

    I was wondering if the string theory says that photons are actualy
    > waves in the space-time fabric.

    Photons have been quanta of electromagnetic waves since they were first proposed in the early 20th century. Theodor Kaluza made a shocking suggestion back in 1919 when he proposed that the electromagnetic waves are actually ripples on the shape of spacetime in the 5th dimension. This "Kaluza-Klein theory" was the first serious proposal to unify gravity and electromagnetism.

    This KK theory has become a part of string theory. In some cases (in some spacetimes that solve the constraints of string theory), the electromagnetism can be interpreted as curvature of spacetime (including an extra, hidden, small dimension). In all cases, electromagnetism and gravity are unified into something like "generalized geometry".

    Moreover, a photon, much like a graviton, can be interpreted as a string moving in space and vibrating in a certain way. Gravitons are always closed strings (circle-shaped loops) while photons can be both closed strings as well as open strings (in the braneworlds).

    > Also I would like to know if their is a theory that says, instead of
    > having many tiny strings, space-time itself would be The String and
    > what appeared to be tiny strings would be ripples (interference?)in
    > the space-time fabric.

    Actually, there is one proposal that sort of matches your – otherwise a bit confusing – remark. Some authors have proposed that the whole Universe started, a very short time after the big bang, as a single string. No four-dimensional spacetime really existed at that moment; the Universe could have been interpreted using two-dimensional theory describing two dimensions of stringy worldsheets (one spatial dimension, one time).

Moreover, in some sense, the spacetime is always made of strings – it is a condensate of strings organized in a very specific fashion.

See CW, if we didn't consider the spacetime fabric and its constituents, we wouldn't understand where the Perimenter institute leaves off(background independance), and strings begin.

Quantum entanglement(?), between gravitons and photons, and you can be sure my tones will be heard in some way, or seen in some kind of gravitational spectrum? Non?

I am still learning the language, but once I decipher it to the simple responses given by lubos, you can be sure CW I'll give you a key.:)

I take the hint all around.:) I'll be watching you CW for your contributions.

"That they might have extended the vision of what the cosmo is capable of, when they regarded strings as a quantum mechanical discritpion of that same universe?"

No offense, sol, but you wouldn't be a computer program designed to simulate a physicist, by any chance?

14. **Matti Pitkanen**
October 13, 2004

Dear All,

If I would be allowed to dream freely I would guess that Witten with his full authoricity would summarize briefly the same that I try to summarize below.

During last 25 years I have developed a unification that I call Topological Geometrodynamics based on the assumption
that space-times are representable as 4-surfaces in H= M^4xCP_2 (Cartesian product of Minkowski space and CP_2).

TGD can be regarded either as a generalization of string model by replacing string world sheet with space-time 4-surface or as a fusion of special and general relativities to obtain a Poincare invariant theory of gravitation.

In contrast to Kaluza-Klein theories, classical gravitation and gauge fields are unified in terms of induction of M^4xCP_2 metric and spinor structure. Standard model quantum numbers are understood in terms of isometry and holonomy groups apart from family replication. Color is not spinlike quantum number at fundamental level but analogous to rotational degrees of freedom of
rigid body. Baryon and lepton numbers correspond to different chiralities for H-spinors induced to space-time surface and quark and lepton numbers are separately conserved.

The basic (not the only one) conformal invariance is naturally associated with metrically 2-dimensional light like causal determinants (call them X^3_l) which by the general coordinate invariance can be selected as representatives of 3-spaces. This conformal invariance implies effective 2-dimensionality: the physics is coded by certain 2-dimensional sections X^2 of X^3_l so that a formalism reduces to a form very reminiscent of conformal field theories. Family replication corresponds to the different genera (sphere, torus, etc.) for X^2 and there is an argument explaining why only the 3 lowest genera are realized.

Super-conformal symmetry is a pure gauge symmetry and does not have imbedding space counterpart: no sparticles. There is Higgs which gives a dominant contribution to intermediate gauge boson masses but only a small contribution
to fermion masses: the rate for producing Higgs is about one percent from that predicted by standard model since Higgs-fermion couplings giving the dominant modes are weak.

The construction of S-matrix leads to a generalization of the notion of Feynman diagram. By the above mentioned conformal invariance all Feynman diagrams represented as light like 3-surfaces connecting initial and final states

are equivalent and fermions are “on mass shell” but not with respect to four momentum which does not appear at space-time level at all. Any generalized Feynman diagram is equivalent to a tree diagram. The notions of functional
integral and virtual particle become obsolete and S-matrix can be seen as a generalization of S-matrix associated with braids with braiding induced by hydrodynamical flow defined
by energy momentum tensor at the light like causal determinants.

Particle massivation can be understood as a
loss of correlations due to the ergodicity of this flow and p-adic thermodynamics constructed for a decade ago expresses this quantitatively and reduces the understanding of the ratios of elementary particle mass scales to Planck
mass scale to number theory.

There are four books about TGD and its applications at http://www.physics.helsinki.fi/~matpitka/ . The chapter “Overview about the Evolution of Quantum TGD” explains the evolution of the ideas can be found at http://www.physics.helsinki.fi/~matpitka/tgd.htlm#tgdevo .

With Best Regards,
Matti Pitkanen

October 12, 2004

They’ve been repeatedly delaying for quite a while now, and have been extremely good at not leaking any info. The simple explanation would just be that they have a lot of work to do and want to get it right; more exciting to imagine that they’ve discovered something unexpected, but we’ll just have to wait until they tell us.

Hidenaga Yamagishi

October 13, 2004
Categories: Obituaries

A special issue of Physics Reports has appeared entitled “Hidenaga Yamagishi’s World”. Unfortunately it’s only available online if you are paying Elsevier, so I won’t post a link (it’s volume 398, issue 4-6). This issue is a memorial to the Japanese particle theorist Hidenaga Yamagishi, who died tragically a few years ago.

Hide was in my entering class at Princeton and we spent a lot of time discussing physics together during our graduate student years and later. He was Witten’s first student, and Witten contributes a touching piece about Hide to the memorial issue, including the comment about his maturity “I suspect that to other students he must sometimes have seemed more like a professor than a fellow student”. I can vouch for the accuracy of that and recall that Hide was probably the one of my fellow theory students that I learned the most from.

Hide came to Princeton from the University of Tokyo, already with a strong background in quantum field theory and particle physics. He got his Ph.D. quite a bit faster than me, and left for a post-doc at MIT. Towards the end of my time as a post-doc at Stony Brook, he arrived there to take a tenure-track job in the nuclear theory group of Gerry Brown.

After I left Stony Brook and moved into the mathematics community, I didn’t hear much about what Hide was doing, until some point in the early-mid 90s when I heard from a mutual friend that he had gone back to Japan, perhaps had been ill, and didn’t really seem to be his old self. Around this time for a few years I got Christmas cards from him and he sent me a couple letters. The last one was in early 1998 and included a manuscript of recent ideas about the topological susceptibility in QCD, a topic we both had worked on and often discussed.

Hide’s thesis was about the effects of a magnetic monopole background on the quantum field theory of electrons. Witten discusses this a bit, but there is a much more extensive discussion in the introduction of the article by Goldhaber, Rebhan, van Nieuwenhuizen and Wimmer. To see some of what he was thinking about near the end of his life, see his article with Ismail Zahed entitled “Is Quantization of QCD Unique at the Non-Perturbative Level?”. They ask the interesting question of how well-defined the whole notion of the theta-vacuum is, given that BRST quantization only fixes invariance under infinitesimal gauge transformations, not addressing what happens with so-called “large” gauge transformations. The manuscript Hide sent me in 1998 was more along these lines.

   That should be Ismail Zahed. I actually had a look at some of the papers of Dr. Yamagishi … which I probably wouldn’t have if it weren’t for your blog. Thanks for keeping an informative blog.

Sean Carroll on the Landscape

October 15, 2004
Categories: Uncategorized

Over at Preposterous Universe Sean Carroll has some comments on the anthropic principle and the landscape.

He describes one extreme of the spectrum of opinion about this as people who think the whole thing is completely non-scientific, giving what he sees as being the two kinds of objections such people make, neither of which he thinks make sense. Since I'm one of these extremists, I think I should try and explain why and exactly what the nature of my objections are, since they're not exactly the ones Sean mentions.

The first objection Sean attributes to extremists like myself is that of accusing users of the anthropic principle of "giving up" by assigning the parameters of the standard model to a selection effect instead of calculating them. This is very much David Gross's objection, and while I would agree with it as a socio/psychological characterization of the behavior of Susskind et. al., my own version of this objection is a bit differerent. For any given supposed fundamental theory, some observables will be calculable from first principles, and others will be aspects of the particular state we are in, dependent on the history of how we got here. Given a particular observable, in some fundamental theories it may be calculable, in others environmental. But the theory is supposed to tell us which it is going to be. The standard model tells us that the earth-sun distance is environmental, and that the magnetic moment of the electron is calculable. It is silent about the origin of its 20 or so parameters, and whether they are environmental or calculable. It is one of the first jobs of any theory that purports to go beyond the standard model to give some sort of explanation of where these parameters come from, which of them are in principle calculable and which aren't.

The problem with the whole Landscape idea is that it is so ill-defined that it can't even tell you what things are calculable and what things are environmental. You don't know what the fundamental M-theory is that is supposed to be producing the Landscape and governing the dynamics of how the universe evolves in it. String theorists would probably claim that while they don't know exactly what the fundamental theory is, they may know enough about it to make conjectures about what the Landscape should look like, at least in certain limiting cases. The problem is that their conjectures not only don't allow them to calculate anything, they don't even allow them to determine what is going to be calculable. The problem with string theory is not that it can't calculate the vacuum energy, it is that it can't calculate anything. Some string theorists are now using the Landscape picture purely as an excuse to get them out of this embarassing situation. "Not our fault we can't calculate anything beyond the Standard Model, because maybe nothing beyond the Standard Model is calculable". If they had a well-defined fundamental theory which exhibited this behavior, one might take them seriously, but until they do, the whole picture is nothing more than an elaborate excuse for failure. A question that should be asked of anyone promoting this stuff: show us using string theory which of the Standard Model parameters are calculable and which are environmental. If they can't do this they shouldn't be taken seriously.

The second objection Sean attributes to the likes of me is that we object to the explanatory use of entities that are unobservable in principle, like multiple universes. This isn't really my objection to the Landscape. If a compelling fundamental theory existed that made lots of correct testable predictions, and such a theory predicted lots of unobservable universes, I'd happily believe in their existence. But, absent such a compelling theory, people who go on about unobservable multiple universes are not behaving very differently from those theologians who supposedly took an interest in angels and pins. Science is about coming up with explanations for the way the world works, explanations that can in principle be tested by making more observations of the world. If you've been working on a theory for twenty years and it has totally failed to make any testable predictions, you should admit failure and move on, not engage in elaborate apologetics for why your theory can't predict anything.

Comments

1. **D R Lunsford**
   October 20, 2004

   Thomas,

   Can your formalism be applied in a Weyl conformal space? The geometry is rather more natural than Riemann space because "metricity" is strictly local. The reducibility of the metric (9 direction cosines + volume element) is removed. I would expect the unit pseudoscalar to emerge prominently from the Clifford algebra of constraints in the correspondence you talk about. In the case that interests me (signature —+++), this looks like

   ```
   | iy5   0  |
   |  0  -iy5 |
   ```

   -drl

2. **D R Lunsford**
   October 20, 2004

   TL – rofl. That was classic.

3. **Thomas Larsson**
   October 20, 2004

   Urs,

   The Fock representations are constructed by first expressing the diffeomorphism generators in terms of canonically conjugate variables q and p, and then representing the q's and p's on a Fock space.

   In principle you can quantize in other ways, e.g. by looking at submodules of Verma modules or vertex operator algebras or Sugawara/coset constructions or whatever. For the Virasoro algebra this is equivalent, due to a quantum equivalence theorem which I think is due to David Olive.

   Look at the papers, for God's sake! 100 man-years of work by professional mathematicians is not necessarily invalided if a physics grad student doesn't immediately understand how to do things.

   I have posted a description of how to quantize in the covariant phase space on spr.

4. **Urs Schreiber**
   October 19, 2004

   Thomas –

   there is a misunderstanding here: The problem is not to find a representation of the constraint algebra alone. The problem is to find a representation of the embedding algebra of canonical data, i.e. the p and q. That of course is what gives rise to the divergences when the constraints are expressed in terms of these ‘p’ and ‘q’.

And that’s what makes the difference between quantizing a system on the one hand side or talking about abstract algebras on the other side.

5. **Thomas Larsson**
   October 19, 2004

   Urs,

   As far as I can see it is not known if there is any meaningful way in which the constraint algebra of pure GR in d=4 or higher could receive quantum corrections, since it seems to be impossible to find a weakly continuous representation of these constraints in terms of operators on some Hilbert space. No matter how the operator ordering is dealt with the commutators of the would-be constraint operators contain diverging quantities and are hence ill defined.

   The problem you point at here is of course the reason why people failed to generalize the Virasoro algebra to higher dimensions for 25 years. I found one of the extensions rather rapidly, but I was unable to find any interesting representations for seven years (1988-1995), precisely because I had to struggle with the problem you mention. In the end I didn’t solve it myself, but read about the solution in the Rao-Moody paper, and at that time I had already run out of funding. An irony is that Rao sent me a preprint of their paper in 1992, but I didn’t realize that they had solved the problem I faced.

6. **Thomas Larsson**
   October 19, 2004

   Ted,

   I think you would agree that the fact that a classical constraint algebra recieves quantum corrections does not mean that there is an anomaly in gauge symmetry.

   That is what I mean. But I could say that quantum gravity must have an “anomalous, global diffeomorphism symmetry” if that makes you happier. People say that the 2D Ising model at criticality has an “anomalous, global conformal symmetry”, but this is really only a game with words.

   In general, a true gauge anomaly is a bad thing, since unphysical (usually negative energy) modes do not decouple from the dynamics.

   The bad thing with chiral-fermion type gauge anomalies is lack of unitarity, which mathematically means a lack of unitary, lowest-energy representations. Virasoro type algebras have at least representations of lowest-energy type.

   Physically, what happens is this. The observer’s trajectory decouples classically; it will probably be a timelike geodesic but Einstein’s equations couldn’t care less. The quantum system cannot be observed without perturbing it, so these degrees of freedom no longer decouple. A classically unphysical mode has become physical upon quantization. Mathematically, this is crucial because the anomaly is a functional of the observer’s trajectory; first described in math-ph/9810003.

   I think the clearest way to understand whether gauge symmetry is anomalous is whether a quantum theory admits a nilpotent BRST charge. As you know, the worldsheet theory of a string does admit such a charge in the critical dimension, and in this sense gauge symmetry is not anomalous. Still, as you noted, the classical Virasoro algebra in the matter sector recieves a quantum correction, aka the central charge.
   As you mention, the constraint algebra of GR very probably recieves quantum corrections. However, is it known whether the theory admits a nilpotent BRST charge? If it does not, the theory is not gauge invariant at the quantum level and is probably not physically meaningful.

   There seems to be no BRST charge at all, nilpotent or not. Normal ordering gives rise to infinities. I disagree about physical meaningfulness, because I believe in locality. If general covariance remains a gauge symmetry after quantization, then there is no Hamiltonian, no energy, no time evolution, and no locality. This seems utterly unphysical to me.

   I don’t know of a calculation in string theory which clearly addresses the question you are asking, i.e. how the classical constraint algebra of GR is corrected quantum mechanically.

   I was not asking a question. Large classes of projective, lowest-energy representations of the diffemorphism algebra are known, cf. the references in my reply to Urs. They all satify the algebras described in physics/9705040 and math-ph/9810003. Besides, all possible extensions of the diffeomorphism algebra (by modules of tensor fields) were classified in

   A. Dzhumadildaev,
   Virasoro type Lie algebras and deformations,
   Z. Phys. C 72 (1996) 509–517.

   cf math-ph/0002016. The N-dimensional Virasoro extension are not quite tensor fields, but rather closed (N-1)-forms, but they are closely related to exact (N-1)-forms, and thus to (N-2)-forms. When N=1, a closed 0-form is a constant function is a central extension, but otherwise the extension is not central.

   My guess is you would have to consider this question in the framework of closed string field theory. However, there the gauge symmetry of 4-diffs is embedded in a complicated way in the huge gauge symmetry of closed strings, which includes not only gravitons but an infinite number of massive fields. Still—virtually by construction—closed string field theory is gauge invariant at both the classical and quantum levels. It is for the purpose of gauge invariance that the BV formalism is so useful for constructing the action of closed string fields.

   Why should string field theory be relevant for anything?

7. **Thomas Larsson**
   October 19, 2004

   Urs,

   As far as I can see it is not known if there is any meaningful way in which the constraint algebra of pure GR in d=4 or higher could receive quantum corrections, since it seems to be impossible to find a weakly continuous representation of these constraints in terms of operators on some Hilbert space. No matter how the operator ordering is dealt with the commutators of the would-be constraint operators contain diverging quantities and are hence ill defined.

   Sigh. The quantum representation theory the diffeomorphism algebra is equivalent to finding continuous representations of these constraints in terms of operators on some Hilbert space. The anomaly by itself is nothing, because it could easily lack representations; the Mickelson-Faddeev algebra, describing chiral-fermion anomalies, apparently does so. The important thing with the Virasoro algebra, in any dimension, is that it has a natural representation theory. Here are a couple of references:

OK, a caveat. The reps act on linear spaces rather than Hilbert spaces because of problems to define an inner product. The essential difficulty is finiteness, not unitarity, though. Finiteness is obtained by first expanding all fields in a Taylor series around the observer's trajectory (have I said that before?). This gives us a classical non-linear realization on **finitely many functions of a single variable**, which is precisely when normal ordering works. This is the crucial step which evades any no-go theorem that you can come up with.

LQG circumvents this on the technical level by dropping the assumption that quantization should use weakly continuous representations. For such reps no quantum correction is found. But dropping weak continuity means leaving the realm of well-established physics and in particular any relation to the path integral.

The lack of anomalies is a clear symptom of this.

I think with respect to Thomas Larsson's speculation that the existence of higher-dimensional Virasoro algebras with certain extensions implies anything about anomalies in gravitational theories it is important to note that the constraint algebra of any GR-like theory is not in general isomorphic (as a whole) to any diffeomorphism algebra, due to the special nature of the Hamiltonian constraint.

I have explained this several times. The Dirac algebra has the form it has because of the way we put coordinates on phase space. Some diffeos move us out of a fixed timeslice, and we must therefore add compensators to get back. 4-diffeos + compensators generate the Dirac algebra. But the physics cannot depend on our way to put coordinates on phase space. There is a covariant definition of phase space, as the space of histories. In this formulation, as in the Lagrangian formulation, the symmetries of GR generate precisely the 4-diff algebra.

But it does not really matter. Essentially I'm only saying this:
1. GR is a constrained Hamiltonian system with an infinite-dimensional constraint algebra.
2. Any reasonable quantum theory of gravity must have a classical limit with this property.
3. Infinite-dimensional constraint algebras generically acquire quantum corrections upon quantization. Conformal symmetry in string theory is only the simplest, and best known, example, but things do not miraculously getter simpler in higher dimensions.
Thus it must be possible to express anomalies in any reasonable quantum gravity theory, even if you think that they must be cancelled in the end. String theory does not satisfy this criterion.

The fact that in 2-dimensions (e.g. on the string's worldsheet) the canonical constraint algebra is isomorphic to two copies of lightlike 1-dimensional reparameterizations is due to the magic of conformal invariance in two dimensions and, as far as I am aware, does not have analogs in higher dimensions.

Of course not, and I never said that. What I do say is that because of this isomorphism, we can reinterpret CFT as diff-invariant QFT in 1D. Then generalize this to 4D.

Aware of that, Thomas Larsson speculated that his algebra might hence apply to the diffeo symmetry acting on the space of (classical) solutions to GR. I don't see what *this should mean in detail.*

math-ph/0210023

I find it interesting that and how higher-dimensional analogs of the Virasoro algebra exist, but it is far from clear that and how these play a role for quantum gravity. Cautious statements seem to be more in order that bold speculations.

Tell that to the guy at Princeton who talks about Theories of Everything and chants Magic and Mystery.

It is no speculation that the multi-dimensional Virasoro algebra is the *only* way to combine quantum theory, general covariance, and locality. People seem happy to state that there are no local observables in quantum gravity. Well, I'm not, and 't Hooft is even willing to introduce hidden variables to get locality. The lesson from CFT, regarded as a spacetime symmetry in 2D, is that locality is compatible with infinite-dimensional symmetries, but only in the presence of an anomaly. This is no speculation, but a well-known fact since 20 years, and it has been amply verified that nature behaves in this way in 2D condensed-matter systems.

October 18, 2004

Dear Thomas,
Let me see if I can clarify for myself what you're saying.

I think you would agree that the fact that a classical constraint
algebra recieves quantum corrections does not mean that there is an anomaly in gauge symmetry. In general, a true
gauge anomaly is a bad thing, since unphysical (usually negative
energy) modes do not decouple from the dynamics.

I think the clearest way to understand whether gauge symmetry
is anomalous is whether a quantum theory admits a nilpotent
BRST charge. As you know, the worldsheet theory of a string
does admit such a charge in the critical dimension, and in this
sense gauge symmetry is not anomalous. Still, as you noted,
the classical Virasoro algebra in the matter sector recieves a quantum correction, aka the central charge.

As you mention, the constraint algebra of GR very probably
recieves quantum corrections. However, is it known whether
the theory admits a nilpotent BRST charge? If it does not, the
theory is not gauge invariant at the quantum level and is
probably not physically meaningful.

I don't know of a calculation in string theory which clearly
addresses the question you are asking, i.e. how the classical
constraint algebra of GR is corrected quantum mechanically.
My guess is you would have to consider this question in the
framework of closed string field theory. However, there the
gauge symmetry of 4-diffs is embedded in a complicated way
in the huge gauge symmetry of closed strings, which includes
not only gravitons but an infinite number of massive fields.
Still—virtually by construction—closed string field theory is
gauge invariant at both the classical and quantum levels. It is for the purpose of gauge invariance that the BV formalism is so
useful for constructing the action of closed string fields.

–Ted

October 18, 2004

TL, thanks for an excellent answer. Yes, you did mention Ginsparg, thanks again.

-drl

11. **Thomas Larsson**
    October 18, 2004

    DRL,

    Do you have a good reference for anomalology? How is the "Dirac algebra of ADM (Arnowit-Deser-Misner?) constraints" equivalent to 4D diff? Is this a fancy way of saying there is an equivalent tetrad formalism and that the constraints become orthogonality and normalization conditions?

    In the Lagrangian formulation, GR is invariant under all 4-diffs. In the Hamiltonian formalism, you break this symmetry by specifying a timeslice where the canonical variables live. So the physical symmetries are 4-diffs, but some of them move you out of the chosen timeslice. Therefore you must add compensating transformations to get back to it, and the combination of 4-diffs and compensating transformations generate the Dirac algebra. But the compensating transformations don't really have anything to do with physics, only with our way of parametrizing the phase space. There is a covariant way to define phase space, namely as the space of solutions to the equations of motions, i.e. the histories. The constraint algebra in this covariant phase space are the 4-diffs, because here we don't need any compensation anymore.

    I find all this talk about constraints interesting but puzzling. I don't really understand this way of thinking. As far as I can tell, there really isn't a good Hamiltonian formulation of ordinary GR, that is, one with an indentifiable, unambiguous energy. When you say H, do you mean this in the more general sense of simply having a variational principle?

    The Hamiltonian constraint is probably the thing that I found most puzzling about GR. H = 0 seems to imply that there is no energy and no time. I now believe that this naive interpretation is indeed correct. The only quantum theories where a Hamiltonian constraint seems to be successfully implemented are various types of topological field theories a la Witten. Since the correlation functions in such theories are smooth invariants, they are indeed timeless.

    However, in the presence of an anomaly, the Hamiltonian ceases to be a constraint. One can no longer demand that diffeomorphisms annihilate the physical states, because that would mean that the anomaly, in the simplest case the unit operator, annihilates them. So further states become physical. In particular, one can now define the energy E of an eigenstate |psi> of the Hamiltonian by H|psi> = E|psi>.

    People might say that a diff anomaly means that things depend on the choice of coordinates. This is not true any more than for the Poincare algebra. There are three cases:
    1. No anomaly. The theory is then "coordinate free", in the sense that it can probably be formulated without coordinates altogether.
    2. An anomalous diff symmetry: The theory is then "coordinate independent". We must introduce some reference coordinate system, but our choice does not matter because everything is guaranteed to transform covariantly.
    3. No diff symmetry altogether. The theory can then only be formulated in a preferred coordinate system. This is not good.

    This line of thinking is very similar to how people think about conformal symmetry in statphys, I think. At least that is what shaped my worldview. In statphys, conformal symmetry is a spacetime (or spatial) symmetry, anomalies are always present, and the dilatation operator plays the role of the Hamiltonian. I think that I recommended Gispargs old reference before. Read that, imagine that he really talks about diffeomorphisms in 1D rather than conformal transformations in 2D, and generalize to 4D.

12. **D R Lunsford**
    October 18, 2004

    Thomas,

    Do you have a good reference for anomalology? How is the "Dirac algebra of ADM (Arnowit-Deser-Misner?) constraints" equivalent to 4D diff? Is this a fancy way of saying there is an equivalent tetrad formalism and that the constraints become orthogonality and normalization conditions?

    I find all this talk about constraints interesting but puzzling. I don't really understand this way of thinking. As far as I can tell, there really isn't a good Hamiltonian formulation of ordinary GR, that is, one with an indentifiable, unambiguous energy. 13. **Thomas Larsson**
    October 17, 2004

    Good morning, Lubos.

    Let me come back to the part that you said that you don't understand, namely quantization of constrained Hamiltonian systems with an infinite-dimensional constraint algebra. The string worldsheet with its Weyl symmetry is an important toy model, because it is the simplest example of such a system.

    We quantize first and impose the constraints afterwards. However, if the constraint algebra is infinite-dimensional, quantization of the fields alone (before ghosts) will yield an anomaly because of normal-ordering effects. This is a quite generic feature of any infinite-dimensional constraint algebra. On the string worldsheet, the coordinate fields have an anomaly c = 26. The LQG string is not string theory and conformal transformations may not play a role there. However, there is still an infinite-dimensional constraint algebra, and that is what matters. The absense of an anomaly is a very clear symptom that we are dealing with quantization in some diluted sense of the word, as Urs Schreiber noted.

    General relativity can also be cast in the form of a constrained Hamiltonian system with an infinite-dimensional constraint algebra, namely 4D diffeomorphisms or the physically equivalent Dirac algebra of ADM constraints. Therefore, canonical quantization and normal ordering of the fields alone will inevitably give rise to a diff anomaly. This general feature does not depend on the details of the Einstein action; the only thing that matters is that the ADM constraints generate an infinite-dimensional algebra.

    Any theory which purports to be a quantum theory of gravity must be possible to cast in this form, string theory, LQG, or whatever. The only assumptions are a Hamiltonian formulation, general covariance, and that we do real quantization rather than some diluted version thereof. In this situation we do get a diff anomaly, at least intermediately. Perturbative string theory might not see this anomaly, since it is only a first-quantized theory; first-quantized particle theory does not see any anomalies at all. But if string field theory does not generate a diff anomaly when only the fields are taken into consideration, there is no way that it can be considered as a quantum theory of gravity, because it violates the most basic properties that such a theory must have.

    I don't need to know the details about string theory to say that. It is simply a fact that quantization of Hamiltonian system with an infinite-dimensional constraint algebra must introduce anomalies in the constraint algebra.

14. **Thomas Larsson**
    October 17, 2004

This is something that you have been unable to understand at least for 5 years, as far as I remember: the local symmetries of a theory are a redundancy in the description, and they depend on the specific description – and the local symmetries are usually necessary to make a description with too many new variables consistent. But the gauge symmetry is not "measurable" in any way. The measurable things are only those objects in the coset/quotient "description divided by the local symmetries and redundancies".

This is true classically, because classically there are no anomalies, so you can always write down a nilpotent BRST operator and pass to the reduced phase space. After quantization, you can still do that if there is no anomaly. With an anomaly, you can not, because some (or all) gauge degrees of freedom become physical. Instead, your classical gauge symmetry becomes an anomalous global quantum symmetry. Neither possibility is inconsistent. It is important to realize that the classical limit of an anomalous global conformal symmetry is a conformal gauge symmetry, because all anomalies vanish in the classical limit.

But only if quantum gravity has a global anomalous diffeomorphism symmetry rather than a gauge diff symmetry can we resolve the conceptual difficulties: we get a real Hamiltonian rather than a Hamiltonian constraint, real time evolution rather than a gauge transformation, a local definition of mass, etc.

Concerning the Ising model – the "local symmetry" is not the usual local symmetry that we talked about before (one that must keep the states invariant).

That *you* talked about.

Of course, if you use the Ising model as a model of classical statistical mechanics, the rules are very different – but jumping from string theory to classical mechanics is not a controllable approach to a discussion.

The rules of classical statistical mechanics are very different from QFT? That's bad news for the people doing lattice gauge theory, isn't it?

The generalization of the Virasoro algebra may exist in higher dimensions, but it does not have the properties to lead to a generalization of string theory.

I'm not interested in generalizing a complete scientific failure. The physically successful theories are general relativity, the standard model, and conformal field theory applied to 2D statphys. I'm applying insights from the third theory to the two first.

15. **Peter**
October 17, 2004

One of the main contributions to science in recent years from string theorists has been assigning new meanings for the term "prediction". When Lubos and other string enthusiasts say that "string theory makes predictions", in old-style lingo this means roughly "if everything we would like to be true about string theory really is, then in principle one can use it to make predictions".

The Landscape crowd has yet another new-fangled notion of prediction. If there's an experimental upper bound on an observable, you say that the Landscape "predicts" that the observable will be some number less than the upper bound. See for example the many references to Weinberg's successful "prediction" of the cosmological constant.

16. **Matthew**
October 17, 2004

On the contrary, string theory predicts everything – its character certainly makes it the most predictive theory one can imagine.

Hi Lubos,

Pray tell, in light of your above comment, what is the "string theory" prediction for the SUSY breaking scale? Say accurate to 1%? Please make that a first principles prediction, starting with one of the five superstring theories, or better with "M-Theory", not some "string inspired" model.

Until you can actually *predict* parameters like that (or retrodict the parameters of the standard model), don't you think it's a tad bit early to be calling string theory "the most predictive theory one can imagine"?

17. **Lubos Motl**
October 17, 2004

That's right, Thomas. I don't understand the difference between being unable to write the anomaly in the first place, and having a theory in which the anomaly is guaranteed to cancel.

Conformal symmetry is a local symmetry obtained by switching from the Nambu-Goto action to the Polyakov action; the latter has new (auxilliary) degrees of freedom (the worldsheet metric), and they must be unphysical, which is guaranteed by the diff and Weyl symmetry which must therefore be unbroken. The residual symmetry from diff x Weyl is the conformal symmetry, and if it is broken by the quantum effects, it proves that diff x Weyl was broken, too.

But there is nothing wrong with theories that don't allow you to write a conformal anomaly in the first place. There are many descriptions of physics of string theory that do not require any 2D conformal symmetries – such as those from AdS/CFT – and they are equally consistent.

This is something that you have been unable to understand at least for 5 years, as far as I remember: the local symmetries of a theory are a redundancy in the description, and they depend on the specific description – and the local symmetries are usually necessary to make a description with too many new variables consistent. But the gauge symmetry is not "measurable" in any way. The measurable things are only those objects in the coset/quotient "description divided by the local symmetries and redundancies". All the physical states must be invariant under local symmetries, for example – they transform as the singlets. This makes the representation theory of local symmetries physically irrelevant – all these things are just auxilliary concepts that we encounter in the middle of the calculation, but that disappear in the final results.

If you criticize LQG for having no conformal symmetry, it is not a fair criticism. It is not only a criticism that "it is not string theory" – it would be a wrong criticism even in string theory because there are many (nonperturbative) descriptions of the same physics that do not rely on conformal symmetry.

Concerning the Ising model – the "local symmetry" is not the usual local symmetry that we talked about before (one that must keep the states invariant). If it were – e.g. if you use the Ising model as a part of string theory worldsheet action – then the total theory MUST cancel all anomalies in the conformal symmetry. Of course, if you use the Ising model as a model of classical statistical mechanics, the rules are very different – but jumping from string theory to classical mechanics is not a controllable approach to a discussion.

The generalization of the Virasoro algebra may exist in higher dimensions, but it does not have the properties to lead to a generalization of string theory. The direct generalization of string theory to higher-dimensional fundamental objects simply does not work because of hundreds of reasons, and if you still think that it is a straightforward thing to make a theory based on higher-dimensional replacements for strings, it proves that your knowledge these matters is highly superficial.

18. **Thomas Larsson**

October 17, 2004

String theory backgrounds do not have any anomalies in local symmetries. They don't have a conformal anomaly on the worldsheet. String theory is only called string theory if the perturbative portion of it is anomaly-free conformal field theory. Bosonic string theory in flat spacetime whose dimension differs from 26 is not a string theory.

You don't seem to understand the difference between writing down an anomaly and then cancelling it out, and being unable to write down the anomaly in the first place. LQG cannot write down the conformal anomaly in the first place. But neither LQG nor string theory can write down the diff anomalies in 4D, which exist mathematically (multi-dimensional Virasoro algebra), and must be present physically to ensure locality.

It's not clear to me why you want to extrapolate 2D conformal anomaly to higher (four) dimensions. It seems to me that you are confusing the worldsheet and the spacetime.

2D conformal transformations are isomorphic to (twice) 1D diffeomorphims. A general-covariant theory transforms covariantly under diffeomorphisms. I generalize this property from 1D to 4D.

The rest of your text is comparably weird. You seem to be looking for a theory that has an anomaly. Why do you want it? A theory with an anomaly in local symmetries is not really a theory, it is a garbage.

A local symmetry can very well have an anomaly, provided that you don't try to impose a physical state condition. It is then no longer a gauge symmetry on the quantum level. The prime example is the application of CFT to 2D phase transitions. E.g., the 2D Ising model has local conformal symmetry with an anomaly (c = 1/2), but it is perfectly consistent: it is unitary, and *realized in nature*. Ultimately, that's what physics is about. It is sad that you don't understand that.

But it is not a FLAW, as you seem to be saying, it is one of the critical virtues of string theory. Sorry, there may be someone else who will see something coherent in your text, but it does not make any sense to me.

Some people seem to think that locality is worth many sacrifices – 't Hooft even seems to be willing to give up quantum mechanics to get it. However, hidden variables are not necessary. You can combine quantum theory, general covariance, and locality, but only with a diff anomaly.

At any rate, it is easy to verify that a generalization of the Virasoro algebra exists in any dimension. It is thus a diff anomaly, something that Weinberg claims does not exist in 4D. Missing an anomaly is a gross oversight. Your reaction is in fact very LQGish: "I don't like this anomaly, hence it does not exist". It is good that you reveal your LQG mentality.

19. **Lubo? Motl**
October 17, 2004

Sorry, "Peter" should be "Thomas" in the previous post.

20. **Lubos Motl**
October 17, 2004

I was trying hard, but it's still not comprehensible to me what is the "missing anomaly syndrome".

Let me try to explain you a couple of elementary points, Peter.

String theory backgrounds do not have any anomalies in local symmetries. They don't have a conformal anomaly on the worldsheet. String theory is only called string theory if the perturbative portion of it is anomaly-free conformal field theory. Bosonic string theory in flat spacetime whose dimension differs from 26 is not a string theory.

It's not clear to me why you want to extrapolate 2D conformal anomaly to higher (four) dimensions. It seems to me that you are confusing the worldsheet and the spacetime. It's the whole point of perturbative string theory that the objects must be one-dimensional (therefore strings), and therefore the worldvolume is 2-dimensional (worldsheet).

Virtually nothing in perturbative string theory can be generalized to higher dimensions of the object. String theory has higher-dimensional objects, but they are never as fundamental as the string. String is the only object that can generate a consistent spacetime theory, and all the magic of 2D conformal symmetry and complex calculus is essential.

The rest of your text is comparably weird. You seem to be looking for a theory that has an anomaly. Why do you want it? A theory with an anomaly in local symmetries is not really a theory, it is a garbage. It is the reason why many things that we can write down are nonsensical at quantum level. Do you really want string theory to reproduce this garbage? The purpose of string theory is certainly NOT to reproduce any idiotic inconsistent pseudo-theory that someone invents. Indeed, many problems and inconsistencies are solved AUTOMATICALLY by string theory's basic rules. The framework just does not allow us to write down backgrounds that would have some kinds of problems that can appear in other theories.

But it is not a FLAW, as you seem to be saying, it is one of the critical virtues of string theory. Sorry, there may be someone else who will see something coherent in your text, but it does not make any sense to me.

21. **Thomas Larsson**
October 17, 2004

Lubos,
String theory suffers from a missing anomaly syndrome, very similar to Loop quantum gravity. It follows from the following observations:
1. In quantization of the string, a conformal anomaly generically arises. In the special case of c = 26, it can be cancelled against ghosts, but generically it is there, also when c = 26 before cancellation. You know this.
2. Things don't get simpler in higher dimensions. Canonical quantization gave rise to an anomaly already in 1+1D, so canonical quantization of a diff-invariant theory in 3+1D will also give rise to an anomaly. You realize this, because you are not foolish enough to believe that the anomaly will miraculously disappear in higher dimensions.
3. There are no diff anomalies in field or string theory in 4D. You know this (or if you don't know it, check out Weinberg's second book, chapter 22.

Taken together, this implies that canonical quantization in 4D must give rise to a diff anomaly which isn't present in string theory. This can mean one of two things
1. No second-quantized Hamiltonian formulation of string theory exists.
2. A second-quantized Hamiltonian formulation of string theory exists and is anomalous, which is inconsistent with the path-integral formalism.

Either way, this must mean that string theory is a very pathological theory. A missing anomaly is a very serious sickness in a theory. It was fatal for LQG, and it is presumably fatal for string theory as well.

22. **Fran?ois Belfort**
October 17, 2004

I read a book once where it was said that also pigs can say that the universe is made for them – thus one should call it the “porcine principle”.

An anthropic or a porcine principle is not a theory – it just says that the prediction must come out as observed. It is a test of a theory, or a test for consistency among observations.

Also talking about the existence of things that cannot be observed is impossible; “existence” is *defined* as what can be observed.

FB

23. **Lubos Motl**
October 16, 2004

Sean, I would probably disagree with your interpretation of Peter’s statement.

You say that he says that string theory is not a solid framework to include the anthropic reasoning. Even though I think that string theorists should avoid anthropic reasoning, it’s just not true that string theory does not allow you to put anthropic reasoning on firm ground.

On the contrary, it is the only known theory that offers a scientific encapsulation for all these ideas. In order to treat anthropic principle scientifically, you need a large number of Universes – solutions – and the existence of dynamical mechanisms to get from one to another, and so forth. This is possible in string theory.

You also need to assign some measures – probabilities of different Universes. This is of course the whole problem of the anthropic reasoning – what is a “generic” Universe? But if one accepts the highly controversial assumptions that each stringy vacuum that admits basic life-like things has the same weight, then it’s just true that string theory – with its discrete ensemble of vacua – gives you a more or less rigorous realization of this anthropic counting.

Once again, this counting seems unscientific to me by its very basic properties, because the “less predictive” vacua are favored – but nevertheless it seems clear to me that one can play this game.

24. **Lubos Motl**
October 16, 2004

Just like I agree with Peter’s algorithm to decide whether a scientific theory is nontrivially predictive and interesting, it seems to me that he does not quite understand some subtle issues about string theory.

First of all, it is not true that you can’t calculate vacuum energy in string theory.

In the Standard Model, which is a non-gravitational theory, the sum of the vacuum diagrams does not really matter because the vacuum energy has no effects in a non-gravitational theory.

However, if you couple such a theory to gravity, the vacuum energy does matter, because it curves the space. However, in quantum field theory, you can always add a counter-term and adjust your vacuum energy to whatever you want. You need fine-tuning, but you can always adjust such “constants” in quantum field theory.

That’s not the case of string theory. Here, you can really calculate vacuum energy, and in the simplest models, you obtain a far too huge value of the cosmological constant – assuming that some serious bug about our understanding of SUSY breaking don’t invalidate the whole conclusion.

In this sense, the CC problem in string theory is or was more serious because string theory is a very rigid theory that does not allow you to mess with the parameters.

Well, the anthropic industry in string theory is more or less meant to put the CC constant in string theory to a comparable level to the CC in field theory. The freedom to continuously fine-tune the vacuum energy in field theory is replaced by the large number of vacua in string theory – and you can really see that some of them are more or less guaranteed to predict a qualitatively correct value of the C.C.

You know, I am among those who believe that we don’t quite understand this counting, especially after SUSY breaking, properly, but the anthropic people will disagree. Shamit Kachru et al. will tell you how to calculate all possible contributions to the potential, and he will argue that nothing is neglected and all approximations they make are justified.

They will tell you that they have a full control over the class of the KKLT vacua (that was elaborated by Mike Douglas and his collaborators and others), and this full control allows them to state quite certainly that string theory *does* predict a large number of vacua – even those controllable ones form large classes.

Once again, Peter, you are absolutely wrong if you think that string theory’s nature is its inability to predict. On the contrary, string theory predicts everything – its character certainly makes it the most predictive theory one can imagine. In fact, the appearance of the landscape in string theory is a consequence of its strong predictive power – because some people just became convinced that a choice of one of a few “simple” and “natural” enough vacua is more or less guaranteed to predict an *incorrect* cosmological constant. This is why people start to propose the convoluted vacua that can give you, more or less by chance, a realistic C.C., too.

It’s wrong to think that string theory is less predictive than field theory. Even if you imagined that string theory could give you virtually any field theory at low energies, it is still *more* predictive because it is a UV complete theory containing quantum gravity – something impossible in quantum field theory. Its low energy physics may have many types, and in this sense the “Landscape” of stringy vacua is analogous to the “Landscape” of quantum field theories – with the difference that the landscape of QFTs has continuous parameters, while string theory only has discrete ones.

Best wishes
Lubos

October 16, 2004

Peter, your objections don’t seem to be to the anthropic principle, but to the claim that the string theory landscape provides a sensible framework in which the anthropic principle can be implemented. And I would agree, at least in terms of the current state of the art. Our disagreement is that I am quite optimistic about the prospects for string theory in the future, so I think it’s well worth pursuing. But right now we don’t understand nearly enough to go around using the landscape idea to make predictions.

Interview with Atiyah and Singer

October 17, 2004
Categories: Uncategorized

There's a fascinating interview with Atiyah and Singer now on-line. It was conducted in May at the time they were awarded the Abel prize. The interview and Atiyah and Singer's acceptance speeches are also available in video form.

The whole interview is very much worth reading and both Atiyah and Singer make extensive comments about the relation of mathematics and physics. Atiyah makes the provocative prediction that ideas from quantum theory will ultimately have a revolutionary effect on number theory, helping to understand why the Riemann hypothesis or Langlands conjectures are true. He notes that Wiles says this is nonsense. He also predicts that new progress in theoretical physics will come from a better understanding of classical four-dimensional geometry. By this I think he has in mind something like twistor methods. Singer's comments about string theory are probably typical of the attitude of many mathematicians. He says that, because of the Landscape "you cannot expect to make predictions from string theory. Its inital promise has not been fulfilled", but he still is an "enthusiastic supporter of superstring theory", largely because of the interesting mathematics it leads to.

Singer also makes the following sociological comment about mathematics, but I think what he has to say is also very true in physics:

"I observe a trend towards early specialization driven by economic considerations. You must show early promise to get good letters of recommendations to get good first jobs. You can't afford to branch out until you have established yourself and have a secure position. The realities of life force a narrowness in perspective that is not inherent to mathematics. We can counter too much specialization with new resources that would give young people more freedom than they presently have, freedom to explore mathematics more broadly, or to explore connections with other subjects, like biology these day where there is lots to be discovered.

When I was young the job market was good. It was important to be at a major university but you could still prosper at a smaller one. I am distressed by the coercive effect of today's job market. Young mathematicians should have the freedom of choice we had when we were young."

   Chris W.,

   I appreciate the link below you gave On the numbers.

   You know what is interesting to me, is how any number system could have began?

   If probabilistics determinations rules our lives, then what said that the Pinball drop could may have defined how life could have manifested, in the number sequence of this flower, and the number of it's petals?:)

   Pascal's Triangle

   If Ramanujan modulars functions can well serve to explain the string's world sheet, then how much more abstract are we going to get, if we wanted to apply some other kind of math to this function. Etc. Etc. Etc:)

   Quite early in my playing around with numbers, I was quite surprise to see how the Ancients used these numbers, as told by Manjul Bhargava. I seem to have a certainty affinity to rythmns, as well as the sequences describe by Manjul, may also be found in Pascal's triangle.

   The movie PI has some weird ideas here, but may not be so weird when considered in context of what rythmns are found, as patterns in life?

   To be caution for sure the slight's given to the Indian influence that Lubos warn's, John Baez, also gives us this in the link following the pinball at is source.

October 18, 2004

“Mathematics is always a continuum, linked to its history, the past – nothing comes out of zero” **Atiyah**

I found this very statement revealing.

One could not of denied any mathematical interpretation that would have arisen in theory, that could have postulated some emergent property out of string theory? Is this statement valid?

I thought I would challenged any mathematician then to discount the validation of string theory, if it did not emerge from some mathematical interpretaion, how it could not have been considered?

9. **Thomas Larsson**
October 17, 2004

Between 1870 and 1970, the number of freshly minted physics PhDs in the US rose from 1 to 10,000 anually. Today we have a steady-state situation, where each advisor can expect only one of her students to become an advisor, on the average. This is nothing to compain about. Exponential growth cannot be sustained forever, and the number of positions in academia has probably saturated.

10. **Peter**
October 17, 2004

Hi Lubos,

One sociological fact that Singer was referring to was that in the late fifties and early sixties, due to the huge expansion in the size of American universities, there were lots of jobs to go around. Since the competition for jobs was much less stiff, people could get away with being less focused on getting results quickly, so could take the time to learn about different fields and not stay so specialized.

I’ll go out on a limb and make a more specific conjecture along the lines of Atiyah’s comments about number theory. Maybe this is the kind of thing Atiyah had in mind, maybe not. From one point of view, the central object in number theory is the absolute Galois group of the field of rational numbers, and the study of its representations. Langlands theory relates these to other sorts of representations (“automorphic representations”). One point of view on particle theory is that central objects are the gauge and diffeomorphism groups and their representations. There are tantalizing analogies between these groups and the ones that appear in number theory. Perhaps new ideas about these representations coming out of a QFT framework may give new ideas about how to study the representations that occur in number theory.

11. **Peter**
October 17, 2004

I’m guessing Brian was referring to the “large extra dimensions” scenarios where there are effects that in principle could show up at the LHC when it starts collecting data in 2007-8. Here the idea is that some of the extra dimensions besides the four we know about are not all curled up and unobservably small, but instead we live on a 4d subspace of some higher dimensional space. One might see effects of this as energy disappearing from our 4d world as it moves into the other dimensions.

Most string theorists don’t actually seem to think that these scenarios are at all likely, but they do pull them out when they want to hold out hope that there will some day be experimental results relevant to string theory.

12. **Matti Pitkanen**
October 17, 2004

I find resonance with Atyiah’s vision about connections between number theory and physics.

Topological Geometrodynamics allows a formulation as what might be called a generalized number theory. p-Adic number fields and the requirement that real theory allows algebraic continuation to various p-adic number fields is an extremely powerful constraint.
The notion of infinite primes is second powerful notion and very physical: their construction is structurally equivalent to a repeated second quantization of a super-symmetric arithemetic quantum field theory with states labelled by primes.

TGD has inspired also a proposal for a proof of Riemann hypothesis based on a very simple conformally invariant dynamical system having zeros of Zeta as conformal weights. Rieman Zeta defines overlaps for general coherent states labelled by conformal weights z which are zeros z=1/2+iy of Riemann Zeta. Rieman hypothesis follows from the absence of state with negative norm (which corresponds to z=0).

M. Pitkanen (2002), A Strategy for Proving Riemann Hypothesis, math\@arXiv.org/0111262.

M. Pitkanen (2003), A Strategy for Proving Riemann Hypothesis, Acta Math. Univ. Comeniae, vol. 72.

The zeros of Zeta and their certain combinations appear also as conformal weights of super-canonical algebra playing together with Super Kac-Moody algebra a key role in TGD. Hermiticity requirement implies what I call conformal confinement: net conformal weights are real for physical states. For instance, quarks and gluons could have complex conformal weights and color confinement could reduce to conformal confinement.

For details see for instance

http://wwww.physics.helsinki.fi/~matpitka/tgd.html#mless .

http://wwww.physics.helsinki.fi/~matpitka/tgd.html#number .

13. **Rafael**
October 17, 2004

Your colleague Brian Greene came to Portland to talk about his new book. It was an interesting talk which he finished with a couple of statements. One of them was that there was going to be an experiment in the near future that could substantiate string theory because it predicts that under this experiment “energy would disappear.” No one asked him if String Theory was even still valid.

Do you know any more details about this experiment?

Thanks!

14. **Lubos Motl**
October 17, 2004

That’s very interesting.

Well, I don’t quite see the particular connections between various fields of mathematics and physics that Atiyah envisions, but he certainly has some reasons to talk about them. 😉 I might propose similar, but different connections, and no one else would understand me. 🙂

I would expect Atiyah to have more visions about higher-dimensional (e.g. seven-dimensional) geometry etc.

Concerning overspecialization, it’s of course a wrong tendency, but I don’t think that the change is due to a different social environment. People are just deciding differently today than they were deciding when Singer was getting started.

In my opinion it has two main (and related) reasons:

* there is a general (and probably true) feeling that the obvious “big questions” have been solved, and therefore people must attack smaller, more specialized questions

* people in average are less ambitious today than they were a few decades ago, and a bigger fraction of the talented youth with big goals is eaten by the commercial sector and similar enterprises

It’s not quite clear to me whether it is better if the good people try to concentrate at the top universities, or they spread all over the world (or at least over the country). Concentration may help communication, but of course the “second class” universities suffer.

Grothendieck and Motives

October 19, 2004
Categories: Uncategorized

The latest issue of the Notices of the AMS contains several things very much worth reading. There's the second part of a wonderful biographical article about Grothendieck written by Allyn Jackson (for some comments about the first part, see an earlier posting).

There's also an excellent short expository piece by Barry Mazur that explains a bit about one of Grothendieck's influential and still only partially understood ideas, that of a "motive". In algebraic geometry the standard ways of defining topological invariants of topological spaces are of limited use, and one wants a much more algebraic notion of such an invariant. This is what a motive is supposed to somehow provide, but to even show that such conjectural motives have the properties one would like requires solving perhaps the biggest open problem in algebraic geometry, the Hodge Conjecture.

Finally there's a thought-provoking piece called The Elephant in the Internet by Daniel Biss about the effect of the internet on the mathematics literature. It contains some comments about the difference between standards in physics and mathematics, including an analogy of mathematics as classical and physics as popular music. His conclusion that "our current relationship to the Internet has the undeniable effect of degrading the sacrosanct status of the mathematical text" seems to me excessive and it's a shame that he feels "hesitant to post my papers online; it always feels a little like leaving my infant in a dumpster." I have some sympathy for his worry that preprint archives and contact with the more journalistic physics literature may make the mathematics literature much less authoritative than it used to be (this was also the concern of a similar article by Jaffe and Quinn published in the AMS Bulletin in 1993). But the lost golden age that Biss yearns for was not so golden. Much of the math literature was written to very high standards of rigor, but often in ways that made such uncompromising demands on the reader that virtually no one who was not already an expert could hope to understand what was being said. The fact that the internet has provided venues for much sloppier, unpolished, but more expository articles also has its very positive aspects.

   October 21, 2004

   Just trying to keep pace Thomas Larsson:)

   *As physicists know, "accidents: do not appear without a reason. When performing a long and difficult calculation, and then suddenly having thousands of unwanted terms miraculously add up to zero, physicists know that this does not happen without a deeper, underlying reason. Today, physicists know that these "accidents" are an indication that a symmetry is at work. For strings, the symmetry is called **conformal symmetry**, the symmetry of stretching and deforming the string's world sheet*

   Hyperspace, by Michio Kaku, Page 173

2. **Chris W.**
   October 21, 2004

   John Moffat posted a preprint in August written along somewhat similar lines, although the tone of his introductory discussion was unmistakably negative — along the lines of "I'm not sure it's worth it, but let's take this idea [the multiverse] seriously and see what we can do with it." It's worth reading as a review.

3. **Thomas Larsson**
   October 21, 2004

   Here we go again. This time it's Dine.

4. **sol**
   October 20, 2004

   Since demystification is the desire, then what do we realize when math generates these principles that espouse new theories?

   Why 10 Dimensions?

   When strings vibrate in space-time, they are described by a mathematical function called the Ramanujan modular function.26 This term appears in the equation:27

   [1-(D – 2)/24]
   where D is the dimensionality of the space in which the strings vibrate. In order to obey special relativity 9and manifest co-variance), this term must equal 0, which forces D to be 26. This is the origin of the 26 dimensions in the original string theory.

   In the more general Ramanujan modular function, which is used in current superstring theories, the twenty-four is replaced by the number eight, making D equal to 10.28

   *In other words, the mathematics require space-time to have 10 dimensions in order for the string theory to be self-consistent, **but physicists** still don?t know why these particular numbers have been selected.*

   http://www.ecf.utoronto.ca/~quanv/String/string9.html

5. **sol**
   October 20, 2004

   In La Clef des Songes he (alexander-grothendieck)explains how the reality of dreams convinced him of God's existence.

   Do we see some pattern here when we consider Ramanujan's Modular Functions and the source from which these numbers were pulled? As if from some fifth dimensional realization(abstract realizations)?

   A recent author has suggested that math ability derives from the brain abilities used in social understanding. Think of living in a tribe or small town where "everybody knows everybody". By growing up in such an environment you know not only everyone else's name, but their preferences and personal characteristics. You are freely able to think what so-and-so and such-and-such would talk about if they had a conversation. And it is proposed that mathematicians have this same ability, only with the abstract things they think about and discuss, rather than people.

   http://superstringtheory.com/forum/metaboard/messages18/187.html

Maybe Peter, I could then have convoluted the math realm with further ideas here as expressed in the Elephant link.

Sometimes it appears as mysterious? But really, when you look at how a "Cab number" could have been calculated, one wonder 's what nonsense mathematicians could raise, without recognizing the consistancy of this math that comes into existance? 🙂

Witten Colloquium

October 21, 2004
Categories: Uncategorized

I was down in Princeton today and went to hear Witten's physics department colloquium on the topic of "Supersymmetry: Pro or Con". He spent most of the hour going over the 25 year-old hierarchy argument for supersymmetry (that supersymmetry provides a reason for the Higgs to be much lighter than the Planck scale, since it is paired with a fermion whose mass can be protected by an approximate chiral symmetry).

He gave the following arguments for believing in GUTs:

1. Can naturally get small neutrino masses via the see-saw mechanism.
2. Coupling constant unification to 1%
3. Tentative evidence from CMB that fluctuations come from GUT scale.

Actually none of these seem to me very convincing (and to claim 1% coupling constant unification I think he has to use 1-loop results, at 2-loops it is more like 5-10% off, but this may depend on exactly what you are comparing to what).

His points in favor of supersymmetry were:

1. Solves hierarchy problem.
2. Coupling constant unification again.
3. Prediction of top mass from supersymmetric SO(10) GUT.
4. Supersymmetry is consistent with all accelerator data.
5. Lowest mass superpartner a good candidate for dark matter.
6. Part of string theory.

Again none of these are really convincing. If you don't believe in GUTs, the GUT scale is irrelevant, and since we don't understand quantum gravity, the significance of the Planck scale is also unclear. I'm no expert on supersymmetric GUT "predictions", but they seem to depend on lots of choices for the details of the GUT, how its symmetry breaks, and how fermions get masses from the symmetry breaking. Saying that supersymmetry is consistent with all accelerator data is kind of strange since the standard model without supersymmetry is consistent with all accelerator data and there is no evidence for supersymmetry. You can guess what I think of his last argument.

His points against supersymmetry were:

1. The Higgs mass bound is already embarassingly high, need some fine-tuning to get a Higgs that massive in a supersymmetric theory.
2. Supersymmetry spoils many of the experimental successes of the standard model since it generically has experimentally disallowed amounts of violation of CP, baryon and lepton number conservation, flavor-changing neutral currents.
3. No good picture of how to break supersymmetry.

Well, for me the con has it over the pro, but Witten still seems to hold out hope that supersymmetry will be found at the LHC. At the end of his talk, he discussed what he called the "worst case scenario"; that LHC sees a Higgs particle, but nothing else: no supersymmetry, no technicolor, no Little Higgs, no extra dimensions. He said that if this happens people will look for anthropic explanations of the hierarchy problem, whereas if the LHC found something that explained the hierarchy problem, they might be encouraged to look again for non-anthropic answers to the cosmological constant problem (which he claimed was analogous to the hierarchy problem). He did say "I hope it is wrong" about the anthropic explanation of the cosmological constant.

On the anthropic front, Michael Dine is claiming that maybe the statistical analysis of the landscape will "predict" that supersymmetry breaking is at a low energy scale. The arguments he gives sound to me like a complete joke, and from what I remember Michael Douglas was recently claiming that the same kind of analysis indicated that supersymmetry was broken at a high energy scale. One other funny thing about Dine: he doesn't say that the landscape makes predictions, but that it is "the first predictive framework we have encountered". This is a guy who for nearly twenty years has been giving talks on "superstring phenomenology" and claiming that any day now string theory would make predictions. I wonder why in all of those previous talks he neglected to mention that not only were there no predictions from string theory, there wasn't even a "predictive framework".

   A new paper by Sean Carroll and Jennifer Chen deals with some of the same issues, and cites both DKS and Albrecht and Sorbo:

   Spontaneous Inflation and the Origin of the Arrow of Time (hep-th/0410270)

2. **Chris W.**
   October 25, 2004

   The authors of hep-th/0410213 acknowledge helpful input from Andreas Albrecht, who posted the following interesting preprint in May:

   Can the universe afford inflation?
   hep-th/0405270

   > Cosmic inflation is envisioned as the "most likely" start for the observed universe. To give substance to this claim, a framework is needed in which inflation can compete with other scenarios and the relative likelihood of all scenarios can be quantified. The most concrete scheme to date for performing such a comparison [due to Dyson, Kleban, and Susskind (DKS)] shows inflation to be strongly disfavored. We analyze the source of this failure for inflation and present an alternative calculation, based on more traditional semiclassical methods, that results in inflation being exponentially favored. We argue that reconciling the two contrasting approaches presents interesting fundamental challenges, and is likely to have a major impact on ideas about the early universe.

3. **Arun**
   October 25, 2004

   http://arxiv.org/PS_cache/hep-ph/pdf/0307/0307049.pdf

It has been shown that a SM electroweak fit including the anomalous magnetic moment of the muon a? and the branching ratio Br(b ! Xs
) yields a probability of about 5%. The total □2 is improved in the MSSM,
mainly because of a?, but the probability does increase only marginally due to the larger number of free parameters in the MSSM. However, in both cases the 3 □ discrepancy in sin2 □W from Ab
FB and ALR is
contributing to the low probability. Since at present no arguments to doubt any of the measurements can be found, we tested the Particle Data Group?s procedure to rescale the errors of these two measurements by the corresponding pulls. This yields considerably improved □2 values, both in the SM and MSSM, without significantly changing the fitted parameters.

4. **Chris W.**
October 25, 2004

Serenus: I should have remembered your comment and checked the URLs in it before I posted. You beat me to the punch on hep-th/0410213.

5. **Thomas Larsson**
October 25, 2004

It is strange that nobody seems to know about the 2-loop calculation. Maybe it is just a rumor. Maybe Witten didn't mention it because it isn't true, or because it is true but he doesn't know about it.

The relative error depends on how you parametrize things, but the comparison between the 1- and 2-loop results does not. If x = 1 + e and y = x^7, then y = 1 + 7e, so the error in y is 7 times bigger than the error in x. However, that the 2-loop error is ten times as big as the 1-loop error (if that is true) does not depend on parametrization, since (7e')/(7e) = e'/e.

6. **Thomas Larsson**
October 25, 2004

Lubos,

That the two-loop calculation was off by 10% is something that Aaron Bergman claimed in this forum – at least I, and presumably everybody else, interpreted him in that way. Maybe you should check with him.

7. **Chris W.**
October 24, 2004

See this:
Birth of the Universe from the Landscape of String Theory
(4 pages, posted 10/20/2004):

> "We show that a unique, most probable and stable solution for the wavefunction of the universe, with a very small cosmological constant …, can be predicted from the supersymmetric minisuperspace with N vacua, of the landscape of string theory without referring to the anthropic principle. …."

..from the abstract, with correction of typos. (The authors are at UNC-Chapel Hill; Laura Mersini-Houghton is an assistant professor there.)

String theory as such has little to do with their argument, other than providing a motivation for consideration of the landscape. The authors consider a SUSY minisuperspace, which leads to a lattice-like solution, and motivates them to employ a condensed matter analogy. It's only 4 pages long, and well worth reading.

Another recent analysis based on a condensed matter analogy has received some attention:

Cosmological constant and vacuum energy
(G.E. Volovik) gr-qc/0405012

8. **Fred**
October 24, 2004

I'd point out that neutrino masses are a complete mystery if you don't invoke a GUT theory.

Thats the one area the standard model notably fails experimental bounds, and why people should be interested in additions.

As far as SUSY goes, the coupling constant unification is a decent argument, but probably not the most convincing to me, particularly b/c its still a perturbative mess. However in GUT phenomenology there are various naturalness arguments in the Higgs sector, that favor (in simplicity) some sort of minimal SUSY model. Again the nastiness comes in the representation you choose, and I think its still pretty much an open question in physics phenomenology.

9. **Lubo? Motl**
October 23, 2004

That's very funny. Good joke. As far as the available data go, the previous posting could have been written by me, just to make fun out of myself – because everyone who is serious and observant enough knows that the arguments are usually on my side. 😉

10.
October 23, 2004

"I think you're right. Among thousands of exchanges I've had in my life, all of them had some facts and rational arguments."

Well, that's a good start! Now, the next thing for you to do is to have some of those facts and rational arguments on *your* side.

11. **Lubo? Motl**
October 23, 2004

Dear anonymous,

I think you're right. Among thousands of exchanges I've had in my life, all of them had some facts and rational arguments.

Once again: some more quantitative data on SUSY and gauge coupling unification are on motl.blogspot.com

All the best
Lubos

12.
October 23, 2004

In yet another piece of inadvertent humor from Lubos M, we have him writing about global warming on his blog:
"The actual reply from SHS has surprised me, shocked me, terrified me. It was a rather long e-mail, but it contained nothing else than personal insults against the four "sceptics" listed above"
Yes, it's a terrible thing when serious scientists are reduced to personal insults. Lucky thing that LM would never stoop so low, isn't it?

13. **Matti Pitkanen**
October 22, 2004

I am wondering why so few consider the possibility that the dead alley in the particle theory might derive from wrong assumptions, which were made already three decades ago and became soon sacred by the illusory belief on the linear progress of big science.

What created strong visceral reactions in me at that time was that quarks and leptons of single generation were forced into single multiplet although masses are widely different. The same was done even for different fermion generations having completely different mass scales. This
is certainly the least imaginative approach to unification that one can personally imagine. Therefore I believed that the observation that proton did not decay had been taken as an important message from the elegance loving Nature.

No one however cared although the message is easy to decipher: if quark and lepton numbers are separately conserved, they could do it as chiralities of 4+N dimensional spinors. Color would not be spin like quantum number but more like a partial wave in compactified dimensions. Completely different strategy to unification
would open up.

Anyone interested on details of this option can do this at
http://www.physics.helsinki.fi/~matpitka/ . See also
http://www.physics.helsinki.fi/~matpitka/newtgd.html for the newest developments in the understanding of particle spectrum and mass calculations.

It's the sol and Lubos core reference dump!

16. **sol**
October 22, 2004

Little attention has been given here Peter. As a method to testability, it had to be considered. They approached this properly and of course await for confirmation. It was not considered devoid, as a philosphical approach?

When symmetry breaks down, by Edward Witten

*Other ideas about electroweak-symmetry breaking go even further afield. **One line of thought links this problem to extra dimensions of space-time, subnuclear in size, but observable at accelerators**. This approach is probably a long shot, but the pay-off would be huge ? discovering extra dimensions could give us the chance for direct experimental tests of the quantum nature of gravity and black holes*

Some more quantitative comments about the gauge coupling unification

http://motls.blogspot.com/2004/10/gauge-coupling-unification.html

18. **sol**
October 22, 2004

Sometimes a nice [map](#) helps out for reference.

If all these events were taking place, lets say from a [true vacuum perspective](#), would this imply that the false vacuum existed in the first place?

19. **Lubos Motl**
October 22, 2004

I recommend the paper

http://arxiv.org/abs/hep-ph/9602206

and its references [1-4]. It makes it pretty clear the the unification works great if you compare the assumed values at the GUT scale, and the known value at the Z scale.

On the other hand, the alpha3 coupling at low energies is 12-20 percent different, which shows some neglected running at *low* energies, below the Z scale, and it is usually assigned to a light gluino.

It's sort of embarassing if it's true and Gordon Kane lives with his serious misconception. 😉

20. **Lubos Motl**
October 22, 2004

I think that I found the/a paper that contains a similar unusual statement.

It is the last (or 2nd last) paper of John Hagelin before he joined Maharishi Mahesh-Yogi. 😉

http://arxiv.org/abs/hep-ph/9406366

I leave it to the reader to decide whether this 10-page paper with 4 citations is trustworthy. I am not sure about the answer yet. 😉

21. **Lubos Motl**
October 22, 2004

So far, no one knows anything about it. I've asked a couple of phenomenologists.

All of them say that they did the 1loop calculation themselves, and they believe that the full 2loop result is even better – and the nice intersecting graphs we usually draw are the full 2-loop results.

At any rate, you are on the same boat with Gordon Kane about this ;-). On the other hand, it may be helpful if you found the scientific references containing this actual calculation – because once again, what two of you say sounds bizarre.

22. **Lubos Motl**
October 22, 2004

Thanks! I did not know that – and of course, I will recheck elsewhere.

We should be careful about two-loop results. Several years ago, Brookhaven claimed some deviation for the muon anomalous magnetic moment, or something like that, and it was used as evidence for new physics etc.

Finally it turned out to be a sign error in the theoretical 2-loop calculations.

I would still prefer to trust the 1-loop results more than the 2-loop results because they can be quite easily verified.

I agree that a 10% error in such a calculation is pretty large. Nevertheless, the running is better than in the pure SM, so in this case, it is still experimentally suggested that GUT prefers to get SUSY as its ally.

23. **Peter**
October 22, 2004

I could find a better reference, but here's a quote from Gordon Kane (hep-ph/0202185) (I seem to have been too kind to quote 5-10%)

"The supersymmetric gauge coupling unification misses by about 10%. More precisely, the experimental value of the strong coupling \alpha_3 is about 10-15% lower than the value computed by running down theoretically from the the point where the SU(2) and U(1) couplings meet. The details are interesting here — the one-loop result is somewhat small because of a cancellation, and the two-loop contribution therefore not negligible. If one only took into account the one-loop effect the theoretical value would be close to the experimental one, but the two-loop effect increases the separation."

I'll let my comments about the arguments for supersymmetry stand. I think all the arguments are very weak, the strongest is coupling constant unification, and even there, being off by 10-15% is not impressive.

If Witten really is quoting one-loops and ignoring two-loops, he wouldn't be the first one, but I don't think that's an honest thing to do.

24. **Lubo? Motl**
October 22, 2004

It looks like a good talk by Witten.

I agree with Witten's summary of the arguments for SUSY – and it even looks like the phenomenologists would agree, too.

Peter, could you give us some references about the 5-10%-off two-loop results on unification? I've never heard something like that, and it seems to be your only argument against SUSY (and GUT), except for totally unjustified nervous and hostile comments.

I understand your point of view "if I don't believe anything, I don't need to believe anything else". I just hope that you don't expect me to think that this set of arguments of yours goes too much beyond the thinking of the average monkeys. 😉

It's much easier to agree that the anthropic predictions of the SUSY breaking scale are vague hand-waving. But once again, being negative about everything does not solve anything, and you seem to be negative about everything.

25. **Peter**
October 22, 2004

I don't think there's been anything new about neutrino masses in quite a while. You can easily extend the standard model to incorporate neutrino masses in at least two ways:

1. Just add right-handed neutrinos with no charge under the standard model gauge group and then, just like the other leptons, Yukawa Higgs couplings give neutrinos mass. These couplings have to be much smaller than the couplings to the other leptons, but then again, no one knows why such couplings have such a huge range of values already in the standard model.

2. Add a right-handed neutrino with a lepton-number violating Majorana mass term. If you make this large enough you can generate small masses for the observed neutrinos through the"seesaw" mechanism.

SO(10) GUTs naturally contain a right-handed neutrino state with no SU(3)xSU(2)xU(1) charge.

26. **dolt**
October 22, 2004

Peter thank you for your summary of the colloquim and for stating the obvious!

But one definite pro for SUSY and string theory ("unique/parameter free"), which is left unstated is that they are great fields for publishing lots of papers! A definite pro when it comes to careers in academia these days and explains the herd mentality.

BTW, what is the latest on incorporating neutrino masses?

DMS

October 22, 2004

Very often a resort to anthropy is just a sign of lack of imagination. Even the landscape may not need it:
http://arxiv.org/abs/hep-th/0410213
and similarly the famed "cosmic coincidences" don't require it either:
http://arxiv.org/abs/astro-ph/0410508

On Beauty and String Theory

October 25, 2004
Categories: Uncategorized

One of the arguments often given for string theory is that it is somehow exceptionally "beautiful". This has always mystified me, since that's certainly not the way I would describe it. Over the years I've paid close attention whenever I see someone trying to explain exactly what it is about string theory that is so beautiful. Lubos Motl has just posted his own detailed answer to this question, something I read with interest.

As usual, Lubos is not exactly concise, so I won't quote him extensively, but let me try and summarize his arguments for calling string theory beautiful, together with some of my own comments.

1. Symmetries are beautiful and just about every symmetry you can imagine gets used somewhere, somehow in string theory.

Even Lubos is not so sure of this argument, since he says " I don't really thing that we view symmetries as the most important reason why string theory is beautiful". What is beautiful about symmetries is the way they constrain things. If your theory is based upon a simple symmetry principle (take for example gauge theory and the gauge symmetry principle), a huge amount of structure follows from a single, simple principle. String theory is not based on a simple symmetry principle, rather it is a complicated framework, into which you can fit all sorts of different symmetry principles. But because they are not fundamental, these symmetries don't constrain the theory much if at all. This is very different than the standard model, where at a fundamental level the theory is built around a single symmetry principle, one that governs a large part of the structure of the theory and its physical predictions.

2. The way in which "miraculous" cancellations occur in string theory, constraining the theory by only allowing it to make sense for certain specific choices.

The most well known example of this is the way in which anomaly cancellation picks out 10 dimensions and SO(32) or E_8 times E_8 for the superstring. This was the main reason people got so excited back in 1984, when they thought that the anomaly cancellation principle would give them a nearly unique theory that could be used to make predictions. If the anomaly cancellation principle had picked out four dimensions and SU(3)xSU(2)xU(1), that certainly would have been a beautiful explanation of why the standard model is the way it is. In the standard model itself, anomaly cancellation for the chiral gauge symmetry does work in an impressive way. If you take just the leptons or just the quarks, you have an anomalous theory, but the anomalies of the one cancel those of the other.

In string theory, all anomaly cancellation does is pick out a much too large dimension of space-time and a much too large gauge group. You can certainly embed the standard model in this structure, but you could also embed just about anything you want in it because there is so much room. In the end you are stuck with some version of the "Landscape", essentially an infinite number of different possibilities with no way to choose amongst them. The anomaly cancellation ends up providing very little constraint on what the structure of low energy physics looks like.

3. String theory is a unique theory that can predict everything about the physical world.

Lubos likes to go on about how unique and predictive string theory is. While I understand this is the dream of every string theorist, the reality of what they actually have is a long ways from what they hope is true. The vision of what they would like to be true may be beautiful, but the reality is something else. The reality is that there is no "unique" string theory that can reproduce the real world, just a dream that such a theory exists. And as for predictions of string theory, there are none. When Lubos says that "string theory predicts" things, what he really means is that if every thing he would like to be true actually were, then in principle you could predict things from string theory.

4. String theory manages to extend quantum field theory in a consistent way, something which is very non-trivial and the way this happens can be described as beautiful.

This seems to be Witten's main argument these days for promoting the continued study of string theory and I have a certain amount of sympathy for it. There certainly is something of interest going on behind the complicated framework that people are studying under the name "string theory" and maybe it will someday lead to insight into something about physics, most likely the strong coupling behavior of gauge theories. But the fact that there is interesting structure you don't understand doesn't mean that this structure has anything to do with a fundamental unification principle for physics.

5. There are beautiful connections to new pure mathematical structures.

The relation of string theory to mathematics is a huge topic, and I'll comment on it at length at some other time. In brief though, while I think string theory has been an utter disaster for theoretical physics during the past 20 years, it has lead to many interesting things in mathematics. However, most of these interesting things really come from 2d conformal QFT, and I would argue that it is QFT which is having a huge impact on mathematics, much more so than string theory. Witten's Fields medal was for his work on the relation of QFT to math, not for anything he has done using string theory.

Comments

1. **D R Lunsford**
   October 31, 2004

   Chris W – re those Smilga papers:

   Alright, I read these papers. I was disappointed.

   1) His main idea seems to be – 3d ang. momentum to SU(2) spin nets is the same as spacetime angular *and* linear momentum to SO(3,2) spin nets. This isn't true generally, so he spends most of his effort patching up the problems by contracting SO(3,2) to Poincare. This is a mistake – the idea itself is good, but the realization is not (see below).

   2) His transition from 2-spinors to 4-spinors is hand-waving nonsense. As we know, this amounts to going from the restricted Lorentz group to the full one including spacetime parity. The physical net gain is antimatter, which he never mentions.

   3) His identification of s_m4 with y_m is itself not correct, so he gets the Clifford algebra wrong. For the purpose of his application this is harmless, but for the purpose of the correct approach it's fatal.

   What's the correct approach? You need to do it for SO(3,3) – then one has real translations without the need for approximation, like this…

   The Lie algebra has terms that look like (indices go 1-4)

   [Jm5, Jn6] = i gmn J56 = i gmn M (mass!)

[Jmn, Jp5] = -i (gmp Jn5 – gnp Jm5)

[Jmn, Jp6] = -i (gmp Jn6 – gnp Jm6)

etc.

Calling Pm = Jm5 + iJm6 and Qm = Jm5 – iJm6 we see that both Pm and Qm represent translations abstractly, but they go off shell into complex spacetime, so one needs *two* of them in succession to get a *real* displacement. Since they are translations, they still commute. Thus one can build up finite translations in spacetime *without contraction*. This should allow one to build a 4-d checkerboard model on the lines of Gersh's and Feynman's 2-d model. One should also be able to construct a spin network model of the 6d spacetime. I've been meaning to do this but occupied with other things. Note that the Weyl theory on SO(3,3) – SO(3,3) neutrinos – leads to the Dirac theory on spacetime, with the two neutrino helicities correpsonding to positive and negative mass terms. A paper on this subject should appear soon.

-drl

2. **sol**
   October 29, 2004

   Thanks DRL for responding.

   I have to walk very slowly in these circumstances, being the layman, I am just learning to walk on these topics.

   Speculation?

   1. Background Independence And The Holomorphic Anomaly

   Finding the right framework for an intrinsic, background independent formulation of string theory is one of the main problems in the subject, and so far has remained out of reach. Moreover, some highly simplified special cases or analogs of the problem, which look like they might be studied for practice, have also resisted understanding.

   I assume a high energy consideration from the early universe.

   G -> H -> … -> SU(3) x SU(2) x U(1) -> SU(3) x U(1)

   Here, each arrow represents a symmetry breaking phase transition where matter changes form and the groups – G, H, SU(3), etc. – represent the different types of matter, specifically the symmetries that the matter exhibits and they are associated with the different fundamental forces of nature

   Some might have assumed a false vacuum as existing instead of "nothing", and from it, a true vacuum to emerge. This would encapsulate, and like bubble eversions, explain what would have been held to the brane, and what is allowed to roam in the bulk? I know this might seemed far fetched as I am trying comprehend the nature of of the abstract world given to defining feymans integral paths as loops, defined in that abstract geoemtrical thinking. This because of it's background dependancy, had to be modifed in order to to speak from the compactified dimensions, and find themselves revealled in spacetime. You see?

   I apologize to those of you who may find this easy.

3. **D R Lunsford**
   October 29, 2004

   Sol,

   You don't have to indulge in any speculation. If a theory has a Lagrangian and variational principle where everything in sight is varied, leading to equations involving all the elements, then that theory is background independent practically by definition. So for example the Einstein-Hilbert action is

   S = integral R sqrt(det(g)) dx..dt

   R is a function of g_mn and its first and second derivatives, and this appears again in the volume element sqrt(det(g)) – so the equations that come out of delta S = 0 are background independent. The Maxwell action

   S = integral Fmn Fab g_ma g_nb sqrt(det(g)) dx..dt

   leads to Maxwell's equations in vacuo and these are not, because the g_mn are not varied. You might ask what happens if I vary the g_mn in the latter as well as the A_n (F = curl A) – answer: because no derivatives of g_mn appear in the action the Euler equations are simply

   F_am F_mb + 1/4 F_mn F_mn g_ab = T_ab = 0

   F_mn,n = 0

   that is, the energy tensor for the EM field also vanishes, and so there is in fact no field.

   The best you can do with both, in the existing scheme, is to paste together an ad-hoc Lagrangian

   L = R + k W

   where k is an additive (dimensional) constant – one then can get

   R_ab – 1/2 R_mn R_mn g_ab = -k T_ab

   that is, the Einstein-Maxwell equations (Maxwell in curved space with the field energy as a source of curvature). So, Einstein-Maxwell is background free, but *not* unified, because the Lagrangian is not irreducible. To sum up, background-freeness is not a mystical property, it's simply the statement that all the essential elements can change from place to place.

   -drl

4. **sol**
   October 29, 2004

   Well let's see here. Neocons(playing with words very creative:)

The Problem of Dynamics in Quantum Gravity

The problem of dynamics in quantum gravity is still a big challenge. We don't know how to make spacetime a truly dynamical entity with local degrees of freedom while taking quantum theory into account. Neither string theory, nor loop quantum gravity, nor the spin foam and causal dynamical triangulation approaches have yet found a background-free quantum theory with local degrees of freedom propagating causally. We sketch some avenues for making progress in this direction.

As I was trying to comprehend how gravity was to be inclusive in string theory, it soon became apparent that it was background dependant. Truly as John Baez implies this is not desired, by others as well.

But if we assume background dependancy, then from what I understood, it became the background and the quantum mechanical discription of the spacetime fabric. Please anyone correct this perception if it is wrong.

Thus from this perspective, a emergent geometry would have been allowed to surface, where all other geometrical approaches, could not have been allowed?

Again this is not what is desired of string theory and the background independance is most preferred. I have many links on quantum grvaity that would innuadate your selection DRL.

I would rather a concensus on whether any geoemtry shall emerge(what shall emerge in the Third Superstring Revolution) and how it shall do that. If we do not consider this context, then we are left to consider, the value of glast determinations and the link Peter offerred.

Inside Gamma Sphere:

The device's 110 gamma-ray detectors point to the center of the spherical array, where a beam of nuclei from a particle accelerator smashes into a thin target. The collisions create unstable nuclei that decay by emitting gamma rays, an extremely high-energy form of light. Gammasphere catches and measures as many of the gamma rays as possible, so that scientists can study what happens to nuclei under extreme physical conditions.

http://www.symmetrymag.org/cms/?pid=1000017

Is this a bad thing? No it reaffirms the direction of glast on the cosmological scale and secures QF visionist on the roads to percieving how quantum grvaity makes sense leaving GR alone(Smolin's position ?).

But as I said, without th econsistancy of a geoemtry to emerge, there is no hope for a perspective to form around quantum geometry as a discritor of quantum gravity?

5. **D R Lunsford**
October 28, 2004

Chris O,

It's damned unbelieveable, what?

Strings depend essentially on KK theory, a failed attempt to extend Riemannian geometry to encompass the A field as part of an ersatz cylindrical metric in 5-d. The simplest contradictory logical loopbacks seem to be beyond the Greenes of the world. They remind me of our neocons.

Now there really *is* an effort to make quantum geometry, see for example

http://www.physics.gatech.edu/people/faculty/dfinkelstein.html

You won't find any hippocoprolitic stringism there.

-drl

6. **Doug**
October 28, 2004

drl wrote:

Furthermore, what sort of disingenuousness is it to say "field theory is ugly", when string theory would have to reproduce that same ugliness to be taken seriously? (It won't, but this is rhetoric.) Whatever next step turns out to be the right one, it will have things that look like gauge fields, energy tensors, etc. etc. and people will say "Ah! Now we know why field theory was that way – how beautiful!"

Great observation! As Hestenes, in his *New Foundations for Classical Mechanics*, observes: *"[Newton] deserves the title of "founder" (of classical mechanics) because he integrated the insights of his predecessors into a comprehensive theory."*

However, while your statement hits the nail right on the head, it also assumes that a successor will be successful, as was Newton, in moving modern physics forward "by integrating the insights of his predecessors into a comprehensive theory." This may not happen. As Hestenes points out, Newton did more than integrate these insights into a more encompassing theory, he launched "a well-defined program of research into the structure of the physical world."

The two great revolutions in physics of the 20th century, QM and GR, are the great insights to be integrated, but it may take a theory that does more than integrate them to move us forward, it may require a new "program of research into the physical world." Of course, that's a tall order, but it's the "new physics" everyone talks about these days, but in the true sense of the word; that is, in the sense of a new program of research, rather than new phenomenology.

That such a program would be characterized by the simplicity of geometry and the beauty of fundamental,powerful ideas, unencumbered by the excesses we see today, is certain in my mind. The mathematical indulgences and wild speculations so popular in normal science today remind me of the days when doctors proudly wore blood smeared smocks as testimony of their professional virtuosity. The irony is palpable.

According to Hesetenes, the central hypothesis of Newton's program "is that variations in the motion of a particle are completely determined by its interaction with other particles," and that [Newton's program of research] has been interpreted as a dictum: **to focus on forces.** He says, "The aim is to classify the kinds of forces and so develop a classification of particles according to the kinds of interactions in which they participate."

Perhaps, however, such a focus cannot deliver the goods. I think that Newton understood that force was a property of motion, and that motion was the proper study of physics, not forces, and that a new program of research, focusing on motion, that is, the reciprocal relation of space and time, may be more fruitful now than to continue the present course, as successful as it has been. We have explained the diverse properties of objects in our experience in terms of a few kinds of interactions among a few kinds of particles, but it appears that we have reached the limit of our methodology. Thus the challenge has reverted to the epistemological side of the reciprocal relation between methodology and science as described by Einstein. The old man, it turns out, was right on once again.

7. **Chris Oakley**
October 28, 2004

Cough *Splutter* Just a minute … until they've proved that they can get "classical" G.R. as a limiting case, String theorists have no right to claim this as part of their theory.

8. **sol**
October 28, 2004

Interesting link CW. It made me think, that the efforts that Einstein went through to quantize grvaity, had the opposite effect as well that they(Dirac, Bohr, Schrodinger) would work to understand GR as well

?The gravitational treatment of point particles thus brings in one further difficulty, in addition to the usual ones in the quantum theory.? This is rather curious coda since the above problems are really as relevant classically, and of course they are very different from the perturbative nonrenormalizability issues that have dominated all subsequent studies. After this pioneering foray, Dirac?s original publications in the field waned, apart from one later paper [17] on conformally invariant extensions of GR.

Now for me when a picture enters my mind, it is unassociative for a bit, but neuronically connected, and relevant. So to Mona Lisa's smile and the trampoline.

DRL,

Figure 10.1 *When standing on the Mona Lisa trampoline, the image becomes most distorted under your weight*

The Heart of Reimannian Geometry

This example cuts to the heart of Reimann's mathematical framework for describing warped shapes. Reimann, building on earlier insights of mathematicians Carl Friedrich Gauss, Nikolai Loachevsky, Janos Bolyai, and others showed that a careful analysis of the distances between all locationson or in an object provides a means of qauntifying the extent of its curvature…..

The Elegant Universe, by Brian Greene, page 232 & 233

One has to still endure the geometry that is progressive, and has developed along side of the physics. One does not disavow what the world of gauss(the roads leading too hyperdimensional space) is doing in light of Maxwell's gains. That any toy model is found correlated in relation to QFT, was a monumental effort by Kaku, in his loop calculations?

You see. So between Smolin who adopts the GR attitude of leave Gr as it is, a Einsteinain way, and strings to adopt, the quantum mechanical discription of the background, neither can reject the ideals of the quantization of gravity, and a geoemtrical perspective.

What geometry shall emerge?

"*But now, almost a century after Einstein's tour-de-force, string theory gives us a quantum-mechanical discription of gravity that, by necessity, modifies general relativity when distances involved become as short as the Planck length.* ***Since Reinmannian geometry is the mathetical core of general relativity, this means that it too must be modified in order to reflect faithfully the new short distance physics of string theory****. Whereas general relativity asserts that the curved properties of the universe are described by Reinmannian geometry, string theory asserts this is true only if we examine the fabric of the universe on large enough scales. On scales as small as planck length a new kind of geometry must emerge, one that aligns with the new physics of string theory.* ***This new geometry is called, quantum geometry***."

The Elegant Universe, by Brian Greene, pg 231 and Pg 232

Enjoy:)

9. **Chris W.**
October 28, 2004

Dirac's 1935 (!) paper is discussed in this short review by Stanley Deser.

10. **D R Lunsford**
October 27, 2004

Chris W – the work by Smilga seems to pick up on an idea of (who else?) Dirac, "The Electron Wave Equation in deSitter Space", and "On a Remarkable Representation of the 3+2 deSitter Group" (I think those are more or less the correct titles). The former appeared, I think, in either the Royal Society Proceedings or some Russian journal – the latter appeared in JMathPhys sometime in the early 60s I think. Dirac clearly was thinking about (anti)deSitter space in some detail, over a number of years.

I read these papers years ago in school, and filed them in the "very interesting" drawer.

Also interesting here is the dropping of the name Wyler and his work on the fine structure constant.

Again, nice papers, very nice.

-drl

11. **D R Lunsford**
October 27, 2004

Chris W – those are intriguing, related to what I'm working on now! Thanks for that.

12. **Chris W.**
October 27, 2004

The quote attributed below to Einstein ("any intelligent fool ..") actually seems to be due to E. F. Schumacher.

13.
October 27, 2004

DRL,

You can't do "new physics at the Planck scale", or anywhere, until there is new physics. The stringers have one thing right – this needs a new idea about matter. I have a *model that should be explored, and probably will be eventually. Like the things that preceeded it, it is evolutionary, not revolutionary.*

Doesn't all this radical talk ever get on your nerves? What I find most strange about the stringers is how they can be so satisfied with nothing but a lot of radical talk, triumphal hand-waving, and weird imagery.

Would I be wrong to say that quantum mechanics started off theoretically, and that in having developed, brought the science along?

For me, I am quite young in terms of my academic career but older in age, that if I did not find some consistancy in the way the geometry evolved, then yes, these abstract spaces that topological genus figures would never make sense. But, this is one end of the geometry that is revealled in the hyperdimensional realities, and might have found it's correlates, in the cosmos?

Klein`s Ordering of the Geometries

"*A theorem which is valid for a geometry in this sequence is automatically valid for the ones that follow. The theorems of projective geometry are automatically valid theorems of Euclidean*
geometry. We say that topological geometry is more abstract than projective geometry which is turn is more abstract than Euclidean geometry."

http://www.ensc.sfu.ca/people/grad/brassard/personal/THESIS/node21.html

So to me this geometrical math developing has to be based on the predessors somehow, and along side, the physics? Would you not consider Reinmann in the value of GR? His Teacher, Gauss?

Brane World models only carry this unique topology solution a bit further returning in part, though often modified in present format, to Klien's solution to the unification of gravity to electromagnetism through an additional dimensional set. ***The beauty of this path as we should rightly call it is that it is a natural progression of Einstein's dream of a pure geometric explanation for everything we see around us in nature."***

What do you think of this statement above?

I also draw your attention to Lubos's post and note the comments on Robert Lauglin.

What is the nature of the math that should emerge, if not by string theory?

Mathematics is not the rigid and rigidity-producing schema that the layman thinks it is; rather, in it we find ourselves at that meeting point of constraint and freedom that is the very essence of human nature. – **Hermann Weyl**

14. **Chris W.**
October 27, 2004

Speaking of economy of ideas, I urge readers of this weblog to take a thoughtful look at **these papers**, so far uncited except by the author himself.

In my humble (and relatively unschooled) opinion they are extraordinarily well conceived and superbly written. The author's professional career apparently began in the 1960s (in Germany).

15. **Frank**
October 27, 2004

Hmmmm…. Appealing to beauty is not neccesarily out of touch with reality. But it may be that for the time being our concepts and modells of beauty are inadequate, thus we have to resolve to patchworking.

Some more quotes:

"I think that there is a moral to this story, namely that it is more important to have beauty in one's equations that to have them fit experiments. If Schroedinger had been more confident of his work, he could have published it some months earlier, and he could have published a more accurate equation. It seems that if one is working from the point of view of getting beauty in one's equations, and if one has really a sound insight, one is on a sure line of progress. If there is not complete agreement between the results of one's work and experiment, one should not allow oneself to be too discouraged, because the discrepancy may well be due to minor features that are not properly taken into account and that will get cleared up with further development of the theory."
– P.A.M Dirac

What i think is most critically missing in physics today is search for simplicity. Many people are interessted in making bigger badder more complicated theories, a few are interessted in making existing ones more rigorous, but who is actually trying to simplify them?
Perhaps we are just not ripe yet to move in that direction.

"Any intelligent fool can make things bigger and more complex… It takes a touch of genius – and a lot of courage to move in the opposite direction."
– Albert Einstein

That to me rings to the core issue with Stringtheory.

…the expediency of renormalization seems to be a wart on the face of it

I'm glad I'm not the only one saying this. Having said that, in the (few) post-doc job interviews I had in 1984/5 I am sure I detected a groan when I said that my ambition was to "crack renormalization".

It is unfortunate that something that claims to be as brilliant and beautiful as string theory hopes at best just to reproduce all this garbage.

17. **D R Lunsford**
October 27, 2004

Doug,

Beauty in some sense = economy of ideas. Field theory is very economical in ideas. That it is phenomenology, is no fault of the thing in itself. And, in the context from which it emerged – utter pessimism about HEP – it was certainly beautiful in the sense that it gave reasonable answers.

Furthermore, what sort of disingenuousness is it to say “field theory is ugly”, when string theory would have to reproduce that same ugliness to be taken seriously? (It won’t, but this is rhetoric.) Whatever next step turns out to be the right one, it will have things that look like gauge fields, energy tensors, etc. etc. and people will say “Ah! Now we know why field theory was that way – how beautiful!”

I’ve never been the least bit impressed by Hawking, other than at his phenomenal virtuosity.

-drl

18. **Doug**
October 27, 2004

drl,
Personally, I think Hawking has a fairly solid point of view on the matters of modern physics. At least, I wouldn’t criticise his characterization of philosophical motivations for the pursuit of a unified theory seeing that he is sitting in Newton’s chair. After all, the man isn’t exactly an incompetent crank. However, that’s beside the point. In the matter of judging truth and beauty, clearly the standard model suffers from the fact that it is “phenomenology backed by simple, general ideas.” A theory able to calculate the masses of the particles from first principles would certainly be superior in this regard, and one would certainly like to see how those masses emerge in the generations they do. Also, the expediency of renormalization seems to be a wart on the face of it to my mind. However, some believe that “beauty is in the eye of the beholder,” but if this is true, I don’t believe truth could be beauty or beauty truth.

Regards,

Doug

19. **D R Lunsford**
October 27, 2004

Sol,

I hold quite a definite view of things, for which I can fortunately only blame myself. My view involves, not breaking, but encompassing Lorentz symmetry, which I see as an artifact of the separation of spacetime and matter.

You can’t do “new physics at the Planck scale”, or anywhere, until there is new physics. The stringers have one thing right – this needs a new idea about matter. I have a model that should be explored, and probably will be eventually. Like the things that preceeded it, it is evolutionary, not revolutionary.

Doesn’t all this radical talk ever get on your nerves? What I find most strange about the stringers is how they can be so satisfied with nothing but a lot of radical talk, triumphal hand-waving, and weird imagery. It’s like living on LSD and Hershey bars washed down with absinthe. I’m still grapping with the Mona Lisa trampoline, a decidedly disturbing hallucination for some reason.

Back to Lorentz invariance – you will *never* detect Lorentz symmetry breaking with *any* model of matter that posits a “form and substance” ontology, that is, matter of *whatever* shape cruising through spacetime of *whatever* structure, because Lorentz invariance arises *before* any specific form for matter is assumed. The Einstein-Weyl idea of matter and spacetime having a joint origin thus has to be right.

As far as S and S goes, I could not care less – all these folks are obviously on the completely wrong track and they bore me to tears. Our own Thomas Larsson is far more interesting.

-drl

20. **sol**
October 27, 2004

DRL,

I hate to rain on your parade.:)

*If Lorentz symmetry is broken by some mechanism originating at the Planck scale, is there any hope of detecting such an effect? Surprisingly, the answer is yes. Over the past decade **Kostelecky and co-workers have been exploring how a violation of Lorentz symmetry might provide evidence for new physics arising at the Planck scale**. However, rather than smash particles together at high energies to explore this, researchers are turning to ultrahigh-precision experiments at low energies to search for signs that Lorentz symmetry has been broken. The idea is that such low-energy effects are caused by corrections involving inverse powers of the Planck scale.*

Possible violations of Lorentz invariance are an ideal signal of new physics because nothing in the Standard Model of particle physics permits the violation of special relativity. Therefore, no conventional process could ever mimic or cover up a genuine signal of Lorentz violation.

Since a viable theory of physics at the Planck scale remains elusive, it is difficult to make precise predictions for the small corrections that could occur due to Lorentz violation. However, we can obtain a rough estimate. The rest-mass energy of the proton, for example, is about 1 GeV, and the ratio of this energy to the Planck scale is about 1 part in 1019. If an experiment with protons is sensitive to effects at or below this level, then it is effectively probing the Planck scale.

http://physicsweb.org/articles/world/17/3/7/1#pwfea1_03-04

One tends to accept that being in the unique position of holding no substantial view in regards to the evolution of thinking here, that you tend to look for the essence of things that might of been driving research and mathematics?

Lucky guesses?

Recognizing Smolin’s positon, and then Susskind’s would it hurt to include both in the analysis, and find yourself a onely sol, who wanders searching for how these abstract spaces answers the question of whether they are back ground dependant or not?

21. **D R Lunsford**
October 27, 2004

Hi Doug,

Let’s deconstruct this statement:

“The real reason we are seeking a complete theory, is that we want to understand the universe, and feel we are not just the victims of dark and mysterious forces.”

This sounds suspiciously like an apology for witch-burning. I never recall Dirac or Einstein stating the “real reason” they were so occupied. The “real reason” for their efforts was never in doubt.

“If we understand the universe, then we control it, in a sense.”

That’s very strange – I never knew physics was about control. I always thought it was about curiosity.

“The particles are grouped in an apparently arbitrary way..”

That is an interesting statement. I did not know until this very moment that the relevant gauge groups were arbitrary! That is fascinating!

“..and the standard model depends on 24 numbers, whose values can not be deduced from first principles, but which have to be chosen to fit the observations. What understanding is there in that?”

That’s the nature (ha ha) of a phenomenological theory. One gets the feeling that Hawking was just tossing word salad to come up with a justification for his Faustian ambition.

Now, for comparison we must cite the supposedly non-arbitrary “shuttlecock” model of Hawking, wherein the actual hyperbolic structure of the world is, “without any arbitrariness whatsoever”, converted to an elliptic one “just for the sheer rollicking hell of it”. Right.

-drl

22. **Doug**
October 27, 2004

drl,

The exact Hawking quote:
“The real reason we are seeking a complete theory, is that we want to understand the universe, and feel we are not just the victims of dark and mysterious forces. If we understand the universe, then we control it, in a sense. The standard model is clearly unsatisfactory in this respect. First of all, it is ugly and ad hoc. The particles are grouped in an apparently arbitrary way, and the standard model depends on 24 numbers, whose values can not be deduced from first principles, but which have to be chosen to fit the observations. What understanding is there in that?”

The link to the Hawking talk is here:

23. **D R Lunsford**
October 26, 2004

Arun,

I would not say that beauty in *anything* is ineffable – precisely the opposite, beauty is compelling and, usually, obvious. This does require some sort of aesthetic judgment, and the latter may be missing.

In the case of Kepler, I think you also have it backwards – he had a specific problem to work on, not an axe to grind. His polyhedric orbs were no different in principle than the Lorentzian deformable electron, and no longer lived. It was *because* of his orbs that he eventually made progress, not *in spite* of them.

24. **DMS**
October 26, 2004

“I wrote another article on motls.blogspot.com that clarifies some ridiculous statements made by Peter Woit about Witten’s reasoning being “unrelated” to string theory.”

I am sorry but I remain unpersuaded. By this logic, theta functions is really a part of string theory because theta functions arise in string theory! And so is algebraic geometry and so on.

People knew about a lot of stuff before string theory came along, and quite likely most of the neat mathematical stuff would have been discovered (like results that have made Witten justly famous) whether or not string theory was studied.

25. **D R Lunsford**
October 26, 2004

I have to admit the torrent of verbiage that issues from Bon-Motl is a source of continual wonderment and awe. So you see, string theory is not without interest.

-drl

26. **Lubos Motl**
October 26, 2004

I wrote another article on motls.blogspot.com that clarifies some ridiculous statements made by Peter Woit about Witten’s reasoning being “unrelated” to string theory.

27. **Arun**
October 26, 2004

Beauty in physical theory is an ineffable thing.

Its been a long time since I read about Kepler, but I think among things that he tried, and was excited about, was the possibility of relating planetary orbits in some way to the regular polyhedra, one inscribed into the next. Thus, the ratios of planetary distances from the Sun would be explained. But the culmination of his research was the laws governing planetary orbits in general, and not why the particular planetary orbits of the solar system had particular radii.

We do not think science has been held up or Kepler’s laws are ugly because we can’t explain the ratio of the distances from the Sun of Earth and Jupiter. We also see that Kepler did try to imagine a solution, a solution that we would find to be beautiful, if it was true!

String theory may appear to be beautiful too, once we find out what is proper for it to explain.

28. **Peter**
October 26, 2004

Hi DMS,

The result about infinitely many smooth structures on R^4 is just one aspect of Donaldson's results, and it's a hard one to visualize or say much about. You can think of R^4 as just a topological manifold, but you need to add some extra structure then to be able to differentiate functions (to even say which functions are differentiable and which aren't). You can think of this extra structure as a choice of coordinates, defined by choosing local coordinate patches. If you choose one global coordinate patch using the standard coordinates on R^4, that gives you one smooth structure, but it turns out there are other ways of putting coordinate patches on R^4 that give an inequivalent notion of which functions are differentiable. I don't know that anyone has explicitly constructed such things, Donaldson just proves that they exist.

More relevant are Donaldson's results about compact 4-manifolds. Here he produces a set of polynomials that are invariants of the smooth structure on the 4-manifold, and these can be used to solve problems in 4-d topology. The correlators in the N=2 twisted SUSY model are exactly the Donaldson polynomials. In general these can be hard to compute and prove things about. The big breakthrough of Seiberg-Witten was to relate the non-abelian N=2 twisted SUSY model to another dual one, where the gauge symmetry is Abelian, but there are monopoles. In this new "Seiberg-Witten" model, computations and proofs are easy.

29. **DMS**
October 26, 2004

Peter,

I very much enjoy your posts, especially this one and the previous one. I saw a lot of 'hype' when in grad school over string theory and SUSY and that proof was just 'around the corner', if not already there; I am still waiting. Nothing wrong in trying to see if a certain idea works, but please be honest about it. The gauge coupling unification bit is an example — choose a 'nice' parameter set to make your result really good, and omit mentioning that it does not look as good with a different set.

Like you I am not bitter. I am doing fun things, gainfully employed outside academia and getting the satisfaction of doing work that is actually tested. I try to follow recent developments (your blog helps!) and I see that I am not missing much.

Regarding Donaldson invariants, I realize that he proved that there are infinitely many manifolds diffeomorphic to R^4. (I guess the other famous result was Milnor's proof that there are 28 differentiable structures on S^7.) Could you explain what that means, maybe with a simple example? Somewhere I read, it means there are 'infinite number of ways to differentiate'—what does that mean?

Also, regarding Witten's method of getting them (and more invariants?) using his work on Seiberg-Witten theory, what are the topological correlators in the N=2 twisted SUSY that he is calculating?

Many thanks in advance!

DMS

Peter said:
Sure there's a personal reason behind my criticisms (and no, it's not that I'm resentful failure. Academia has ended up treating me far better than I ever expected. Lots of people go through life resentful that they've never had their talents properly recognized. I'm not one of them.) The reason is simple: I think what has been going on in string theory recently is an intellectual and moral disgrace, and it defiles something extremely important to me, the whole idea of trying to better understand how the universe works in an honest way.

This is a wonderful summation of how many of us *feel*. This is not just a matter of thinking – the intellectual fraud that is string theory stabs at the heart of science, in the sense that those who do science need at some point the judgment that derives from being *emotionally involved* with finding things out, and not just occupying an academic position.

-drl

31. **D R Lunsford**
October 26, 2004

The SM is not "ugly" and it's certainly not "ad hoc" – if Hawking said this it confirms my opinion that, as a physicist, he's a superior mathematician. The SM is phenomenology backed by simple, general ideas.

In contrast, string theory could not *possibly* be more postmodernly ad-hoc, and sets a new bar of loathsome ugliness, both in itself and in the culture it engendered. It is a ridiculous, poisonous, viral fiction.

-drl

32. **Peter**
October 26, 2004

Hi Francois,

I was referring to Witten's TQFT for Donaldson theory, which is a twisted version of N=2 supersymmetric Yang-Mills. This is a 4d Yang-Mills theory with fermions, the fermion charges are just somewhat different than in the standard model. Mathematically this theory has a beautiful interpretation as computing the euler class of a certain bundle.

33. **raj**
October 26, 2004

>I think the state of modern physics, now in the throes of two, incompatible, 20th century revolutions, is looking more and more pathetic from an outsider's point of view.

I tend to agree, to some extent. Physicists who rave over a theory merely because it is "beautiful" (a/k/a, full of jargon) instead of having something to do with reality (a/k/a, that it has some experimental justification) strike me as being, well, divorced from reality. One of the reasons that I found physics so interesting, when I was studying it in University in the late 1960s and early 1970s, was that it appeared to be *grounded* in reality. It is somewhat sad to see the discipline devolve as it apparently has.

34. **Thomas Larsson**
October 26, 2004

The circle is undoubtedly the most beautiful geometrical shape. Hence we conclude that planets must move in circles, or in circles around circles.

It is interesting that people like Motl, while promoting symmetry principles as an argument in favor of string theory, are vehemently opposed to the investigation of symmetries which are not restricted to one complex dimension. Perhaps this limitation to one-dimensional symmetries is a sign of a one-dimensional mind.

35. **Francois**
October 26, 2004

Hallo Peter, you just wrote

"The QFT whose observables are the fundamental 4-manifold topological invariants is mathematically very close to the QFT of the standard model. I find it hard to believe this is a coincidence. There's very deep mathematics, somehow related to supersymmetry, going on here, mathematics whose proper understanding might lead to new ways of thinking about the standard model."

Could you explain what you mean by the "closeness" in more detail? Apart from being enlightening in its on right, the answer would clarify the discussion on the beauty/ugliness of string theory.

Francois

36. **Peter**
October 26, 2004

Hi Z,

An interesting response, here's what I think about some of the issues you raise (although I really can't do justice to the whole issue of string theory and math, it's a long and complicated story).

I don't think 11d supergravity has had any appreciable impact on mathematics yet, or that it ever will (other than in perhaps indirect ways. People have and will continue to get involved in really interesting math sometimes because of questions that came up when they were looking at 11d supergravity).

About D-branes and CFT: depends what aspects of D-branes you mean. In some sense D-branes are just boundary conditions on CFTs on worldsheets with boundary. A CFT on a worldsheet with a boundary is still just a QFT of a certain kind. The only things that seem to me to definitely be non-QFT results are those involving summing over all genus worldsheets.

I think CFTs are of great importance not because they can be used to construct string theories, but because our understanding of QFT in general is very crude. By studying CFTs we can get a lot of insight into QFT in general, and hope to apply this to 4d QFT.

I don't think I dismiss all of string theory at every possible opportunity. My view of work that has come out of string theory ranges from very positive (CFT, mirror symmetry) to neutral (adS/CFT may solve QCD, may not, seems worth trying, but may not work) to very negative (the Landscape).

Sure there's a personal reason behind my criticisms (and no, it's not that I'm resentful failure. Academia has ended up treating me far better than I ever expected. Lots of people go through life resentful that they've never had their talents properly recognized. I'm not one of them.) The reason is simple: I think what has been going on in string theory recently is an intellectual and moral disgrace, and it defiles something extremely important to me, the whole idea of trying to better understand how the universe works in an honest way.

Of course I'm trying to "destroy the hype", and make no bones about it. I call things scientifically as I see them, but my point of view is a very specific one, that is not one you are used to hearing. With the most promising aspects of string theory, things like AdS/CFT, there are hordes of people willing to look at them from a very optimistic point of view, and emphasize the possibilities that they might lead to. I don't think it's my job to be as optimistic as possible about these things, there's plenty of that already.

Actually I've often written in a skeptical way about SUSY QFTs, especially about whether the MSSM or SUSY GUTs have anything to do with reality. On the other hand, at least in the form of twisted supersymmetry, there is amazing mathematics going on in certain SUSY QFTs, even though I don't think anyone knows how to properly relate the mathematics of these theories to physical reality. The QFT whose observables are the fundamental 4-manifold topological invariants is mathematically very close to the QFT of the standard model. I find it hard to believe this is a coincidence. There's very deep mathematics, somehow related to supersymmetry, going on here, mathematics whose proper understanding might lead to new ways of thinking about the standard model.

37.
October 26, 2004

I am definitely *far* from being an expert about the impact of string theory to mathematics, but I couldn't resist this. It would be great if some real experts gave definite examples, but here goes:

"However, most of these interesting things really come from 2d conformal QFT, and I would argue that it is QFT which is having a huge impact on mathematics, much more so than string theory. Witten's Fields medal was for his work on the relation of QFT to math, not for anything he has done using string theory."

I am not sure if this is just a statement about what has happened up to now, or meant to be a prediction about the future impact of string theory to mathematics. If it is the latter, it would be clearer if you made it more explicit. Do you, for example, predict that the 11-dimensinal aspects of string theory will not stimulate mathematics in any appreciable way?

More to the point: Well, the perturbative expansion of string theory happens to be given by 2D CFT. To say that these results really come from 2D CFT, not string theory, seems to me like saying these results actually come from calculus, not QFT. Do you think that the things that came "really from 2d conformal QFT", like mirror symmetry, would have come our way if we weren't looking at the 2D CFT from the point of view of strings propagating in background spaces?

Furthermore, I am not sure *what* you would consider something as coming from string theory, "not just 2D CFT". Would you, for example, consider mathematical developements related to D-branes to be coming from 2D CFT, not string theory, because D-branes were discovered by a CFT calculation?

On another note: Even though I would not consider myself an advocate of string theory, and am definitely against the fanatic approach some string theorists seem to be taking, it seems to me that many of the strong criticisms you make of the subject have some personal reasons in the background, which hinder your ability to be objective. It is obvious that string theory hasn't been able to live up to its premise yet, but stating this as an objective fact and debating about the it (and speculating on the future) is one thing, dismissing the field at every possible opportunity is another thing.

I can understand the arrogance of some string theorists pissing one off, but string theory is not bullshit, even if it turns out that it doesn't describe the universe at the most fundamental level.

You don't seem to attack the zillions of people writing papers about various SUSY field theories and exploring their properties, even though it is obvious that many of those theories do not contain the standard model. These people are trying to understand the dynamics of SUSY QFTs with the hope that this will eventually help us understand something about the universe. Well, helping understand dynamics of SUSY field theories is one of areas where string theory has achieved a lot. If you think this is rubbish, tell the same to SUSY field theorists!

Once again, even if string theory turns out not to describe the universe at the most fundamental level, I think even just AdS/CFT proves that string theory is a valuable subject that gives us fascinating insights about the structure of the theories we have been using as building blocks.

I don't think there is anything wrong about debating on the eventual success of string theory as a fundamental theory. However, it seems clear to me that what you are trying to do is not just that, but it is to "destroy the hype".

I don't have problems with the latter aim, either, per se, but I don't think the methods you use for that purpose are scientifically honest.

z

38. **Doug**
October 25, 2004

While I find your crusade against the indulgences of string theorists enlightening, I'm also reminded of Stephen Hawking's observation concerning the standard model: "It's ugly and ad hoc," he said. So the case you make may be a case of the kettle calling the pot black. I think the state of modern physics, now in the throes of two, incompatible, 20th century revolutions, is looking more and more pathetic from an outsider's point of view.

Einstein said that "the reciprocal relationship of epistemology and science is of noteworthy kind. They are dependent upon each other. Epistemology without contact with science becomes an empty scheme. Science without epistemology is — insofar as it is thinkable at all — primitive and muddled." Actually, I think we are seeing the wisdom of this observation more and more clearly today. To my mind, Keat's ode is still the most compelling, and relevant, dictum of all. Not just because it rings so true, but also because it is so concise.

39. **sol**
October 25, 2004

As I read Lubos's comments about the beauty, of simplicity, something came to mind of what was linked by Chris W. in regards to the number theory, and a related article about Mona Lisa and Math. It triggered the relation, to the following

On page 65 of Hyperspace by Michio Kaku, *he writes, "Picasso's paintings are a splendid example, showing a clear rejection of the perspective, with woman's faces viewed from several angles. Instead of a single point of view, Picasso's paintings show multiple perspectives, as though they were painted by someone from the fourth dimension, able to see all perspectives simultaneous*

Now I know there are a lot of good intellectual minds here. We cannot ignore I feel what could have existed in the realization of the compactified dimensions(how did you get there ?) as we view the four spacetime.

As you look through the historical, recognize the Euclide's fifth postulate, and recognize a geometry that was being lead through, or as Linda Henderson writes,"*the fourth dimension and non euclidean geometry emerge as among the most important thgemes unifying much of modern art and Theory."*

This might seem insignificant to many of you, but without it there is no possbility of entertaining the subjects of Cubist art perspectives and Monte Carlo effects of quantum gravity, as a perception that hopes to explain the geometry of a world that we are having diifficulty explaining.

I hope this idea of perception and the ideas of this simplicity is more or less asking that we look around the picture of Picasso, and see that the views of Mona Lisa smile, ask that we not look at her mouth directly.:)

Is this where the landscape issue originated?:)

Chern-Simons-Witten, Some History

October 26, 2004
Categories: Favorite Old Posts, Uncategorized

Lubos Motl is promoting a [revisionist history] of topological quantum field theory according to which it was all inspired by string theory. Unlike him, I was working on the subject at the time it was developed, and remember the history quite clearly. I've recently checked my memories against the literature, learning some more details of what happened back then. Here's an outline of the history of TQFT (or at least of one small part of it, the part leading to Witten's Chern-Simons theory):

1982: Witten comes up with a beautiful reinterpretation of Morse theory in terms of supersymmetric quantum mechanics, writing an extremely influential paper on "Supersymmetry and Morse Theory", which is published in a math journal, the Journal of Differential Geometry.

Spring 1987: Atiyah conjectures that Andreas Floer's new homology groups (inspired by Witten's supersymmetry and Morse theory paper) are the Hilbert space of a QFT. There are two cases where Floer theory works: 1+1 dimensions where the observables of the QFT would count curves (later to be known as Gromov-Witten invariants), and 3+1 dimensions where the observables count instantons (Donaldson invariants). Atiyah conjectures the existence of two corresponding QFTs, and also notes that the new knot polynomials of Vaughan Jones might correspond to a QFT in 2+1 d. He talks to Witten about this and gives an amazing lecture at a conference at Duke explaining these ideas. Witten tries to find a supersymmetric QFT that will do what Atiyah wants, but initially doesn't succeed.

Late 1987: Atiyah visits Witten again at the IAS and keeps after him about the TQFT idea. Witten finally realizes that things work if he uses a "twisted" version of N=2 supersymmetry.

February 1988: Two papers by Witten appear, one "Topological Quantum Field Theory" about the 3+1 d case, one "Topological Sigma Models" about the 1+1 d case. The second paper contains some vague speculation at the beginning about the relation of these "topological strings" to physical string theory, perhaps in some kind of "unbroken phase". At the end it also contains a sketch of an attempt to get Jones polynomials by using a 3+1d TQFT that would couple together his 3+1 topological gauge theory with a topological sigma model on the worldsheet swept out by a knot in 3 dimensions moving through time. This doesn't actually work.

Summer 1988: At a conference in Swansea, talking to Atiyah and Segal about Segal's ideas about conformal field theory and "modular functors", Witten realizes that the right theory to get Jones polynomials is a 3d QFT whose Hilbert space is the finite dimensional space of conformal blocks of a 2d WZW theory. He also realizes that one can think of the Lagrangian of this theory as being the Chern-Simons functional. His paper "Quantum Field Theory and the Jones Polynomial" appears in September. There's not a word about string theory anywhere in it and he has completely abandoned the idea of relating Jones polynomials to topological sigma models.

I was in Berkeley at MSRI for the academic year 1988-89. In January there was a workshop there involving Atiyah, Bott, Witten, and many other mathematicians and physicists. Initially many of the mathematicians were a bit skeptical, but by the end Witten had convinced the skeptics that what he had made complete sense, and they were very impressed. In the summer of 1990 he was awarded the Fields Medal for this work.

New ideas about relations between branes, topological strings, and Chern-Simons appeared about ten years later, and that's an ongoing story, one which Lubos conflates with what was going on in 1988-9 that got Witten the Fields medal. These are two completely different stories.

Comments

   DRL,

   I assume you understand the context in which the instrument is being offerred for introspection?:)

   [It is important that, while the argument presented in this paper can only be conclusive in a full treatment including gravity, it also indicates where one should look for a quantum mechanical theory that encompasses gravity. It makes clear that any approach to quantum gravity should treat matter and spacetime as two manifestations of the same thing. An approach that puts matter on a spacetime will encounter the cosmological constant problem.]

   So here we might find [Robert Hellings] currents comments on his blog hepful?

   He offers this link for [consideration] and for me Witten summarizes for us as well, in regards to Glast determnations.

   I would like to understand Robert's position very well.

   Leading to the undertsanding of kinetic potential values would say to me that the evolution of this instrument, is a continued effort of understanding Mercuries orbits? IN the quantum perceptin reductionistic physics asks us to consider something else, so while the quantum ranger suggests one position, we have to ask about the other?:)

   Oh priceless! I love the harpsichord reference!! Well done! So string theory fails the Bach test..

   "Which came first, the string or the plectrum?"

   -drl

3. **Quantum_Ranger**
   October 31, 2004

   Lubos – "regarding the predictivity of string theory: be sure that string theory predicts a precise value for the mass of the electron"

   The electron rest mass,symbolized me,as measured when its speed is zero relative to an observer?

   What came first, the string or the Plectrum?

   The precise value is based on the two paramiters of OBSERVATION and ELECTRON, one see's and one cannot be seen!

   Defining the accuracy is like stating that string theory, predicts and proofs the unpredictable, using observable quantities?, but only if one subscribes to the notion that this occurs as a process of 'Seeing' without looking!

Its ok if you dont look, but just incase anyone happens to be 'thinking' of looking, string theorists like to hedge their bets on every conceivable notion of WE TOLD YOU SO!

As if.

   DRL,

   Oops, I posted last my last comment in the wrong spot:)

6. **D R Lunsford**
   October 27, 2004

   Sol,

   In the same post you imagine the Mona Lisa on a trampoline, then let it drop in a sort of passive-aggressive way that Einstein was senile. The juxtaposition of these fantasies struck me as ironic.

   Forgive me for believing that Einstein will yet have his day. I do NOT forgive you for joining the ranks of Einstein and Dirac bashers.

   -drl

7. **Thomas Larsson**
   October 27, 2004

   I can think of no better way in which to steer promissing physics students AWAY from string faerie fantasies than to have them read the blog and usenet rantings of Lubos M-
   I often wonder if he is some kind of LQG activist using obvious reverse psychology on his readers to repulse them from strings- becasue that is what happens most of the time!

   /:set\AI:

   This idea has also struck my mind. However, in my experience things are usually precisely what they seem to be. In fact, this is one thing that makes me think that string theory is wrong. String theory seems to disagree with experiments, and thus I believe that it actually does disagree with experiments. LM seems to be a rabid string zealot, and thus I believe that he actually is a rabid string zealot. But I guess that only shows how naive I am.

8. **Aaron**
   October 27, 2004

   The citations for Witten's Fields Medal are available online here for the curious.

9.
   October 26, 2004

   DRL,

   Pardon me Sol, but it's hardly a discourse when factual evidence from a direct participant is attributed to cerebral intra-aural doo-doo. LM doesn't do discourse, he barks like a carvinal shill, and he's usually wrong to boot. You can't have a discourse with a living scowl.

   This is a sideline issue about Witten, but there are more important things that are mathematically being describe, and they seem to have a place in the hyperdimensional reality.

   A picture crossed my mind today with the Mona lisa on the trampoline. I do not think it so absurd that the definition of Ramanujan's modular functions point on the stringy world sheet less relevant then other topological considerations in that abtract space(I'm still learning).

   It had to be consistant with what we know, and accepting Einstein's position in regards to the beauty of GR(smolin's positon?), and attempts to explain these ideas on a quantum mechanical scale have been a most troubling issue to contend with.

   Einstein did it for the last thirty years of his life, and we would have those from the quantum mechanical perspective who would of thought Einstein Senile? Yet his concept was complete, yet he decides to contend with the issue of a quantum gravity perspective, for the rest of his life?

Why I needed to understand whether Peter supports Smolin.

10. **D R Lunsford**
October 26, 2004

Pardon me Sol, but it's hardly a discourse when factual evidence from a direct participant is attributed to cerebral intra-aural doo-doo. LM doesn't do discourse, he barks like a carvinal shill, and he's usually wrong to boot. You can't have a discourse with a living scowl.

11. **sol**
October 26, 2004

Unfortunately I have to add my comment here not to slight any individual, but to encourage two indiviudals to continue the discourse they are having, about views of Witten, regardless of whether the fields medal was awarded for this or that.

Those who intrude with comments, did not pay attention to the focus, on the landscape, instead focused, on the Mona Lisa's mouth:)

Maybe you like Salvador Dali's's version better?:)

Previous, a discussion took place here in Peter's Blog on Susskind and Smolin. I would like to know if Peter supports Smolin's position?

NATHAN MYHRVOLD

I found the email debate between Smolin and Susskind to be quite interesting. Unfortunately, it mixes several issues. The Anthropic Principle (AP) gets mixed up with their other agendas. Smolin advocates his CNS, and less explicitly loop quantum gravity. Susskind is an advocate of eternal inflation and string theory. These biases are completely natural, but in the process the purported question of the value of the AP gets somewhat lost in the shuffle. I would have liked more discussion of the AP directly

http://www.edge.org/discourse/anthropic.html#myhrvold

The thing I like about the oppositon of minds who embrace the Solvay attitude, is that it forces another to bring forward a history that few of us would have seen. So outside of the comments of opposing views what kind of harmony could have been produced?

So in following up, I thought it would have been a good opportunity to bring this debate forward again, in context, of opposing views?:) Why do you think Susskind wrong or Smolin wrong? Is there is a certain accpetance here, of what one chooses, that another view is recogized? A certain symmetry?:)Etc.

SMOLIN VS. SUSSKIND: THE ANTHROPIC PRINCIPLE

Leonnard Susskind and Lee Smolin

While this is a conversation written by physicists for physicists, it should nonetheless be of interest for Edge readers as it's in the context of previous Edge features with the authors, it's instructive as to how science is done, and it's a debate that clarifies, not detracts.

http://www.edge.org/documents/archive/edge145.html

Sorry for intruding, and all due respect to you both, Lubos and Peter.

17. **Peter**

October 26, 2004

Hi Lubos,

No, the Fields medal is not given for a single paper. Atiyah's address to the 1990 ICM about the award to Witten explains what work of Witten's mathematicians considered important at that time. String theory isn't mentioned. I can assure you from my many conversations with mathematicians about this around that time that the Chern-Simons theory stuff was the deciding factor in awarding him the medal.

Witten's work on the the positive mass conjecture and Morse theory, both using supersymmetry, were also cited by Atiyah. But this work was done around 1980, long before Witten got interested in string theory. It really has nothing to do with string theory, unless you adopt the attitude that string theory encompasses everything.

18. **Lubos Motl**
October 26, 2004

I found a web page that explains, in detail, that he received the medal also for his proof of the positive mass theorem, using supersymmetry – a clearly superstring-inspired proof – and the relations between supersymmetry and Morse theory. In that work he used a supersymmetric quantum mechanical model – which is a typical stringy approach because all other (nonstringy) people who are interested in SUSY are focusing on d=4.

19. **D R Lunsford**
October 26, 2004

Bon-Motl has once again invoked "argumentum ad cellulosum". My understanding is, if this happens 3 times in the same month, Einstein's ghost will tear the universe a new nether region and we'll all be sucked through it into the missing 11 dimensions, in a process called "Calabi YEOW". I mention in passing that Halloween is near, and toying with the unseen world at this dicey time is just plain uncivilized.

So, for God's sake, let's act before it's too late. Millions of lives are at stake.

20. **Lubos Motl**
October 26, 2004

One more comment, Peter:

This "Fields medal only" is a completely ridiculous game. By the way, can you show that the medal was given him for a specific paper? No one around is aware of it. I personally don't think that it is important for anything, but it seems that even these statements about the nature of Fields medal – is something that you invented.

21. **Lubos Motl**
October 26, 2004

Dear Peter,

I must admit that even though some of the contributors to my blog (comments) may be disappoitining, I don't have any morons comparable to DMS and similar stuff.

There is absolutely no way how could I ever lose this argument, and I am sure that you know it very well – unlike DMS, who probably really believes that your position is defendable. Of course, if someone has excrements instead of brain inside his skull, like DMS, he will never understand that maths and physics did not end in 1989.

I don't feel that it is quite appropriate for us to waste so much time with these idiots, but I must state it clearly, in a language that attracts enough attention, that this whole Peter Woit's way of describing history of maths and physics is simply a result of the fact that Peter Woit, as a talented mathematician and physicist, died back in 1989, and unless he will be able to wake up, he will never be able to say anything reasonable about physics and maths after 1989.

And be sure that physics of 1990s has brought many key new discoveries, much like physics of the 1980s.

http://www-spires.slac.stanford.edu/spires/find/hep/www?rawcmd=FIND+A+WOIT%2CP+and+date+before+2000

Best
Lubos

22. **Peter**
October 26, 2004

Hi Lubos,

As I said in my initial posting, the whole topic of the relation of string theory to mathematics is a huge and complicated one and I don't have the time or energy to do it justice now. However, as I also said in my initial posting, the work that mathematicians in 1990 thought was worth a Fields medal was not work that came out of string theory. You claim that I am wrong about this, I've presented a factual history to back up what I said. If you have any facts to demonstrate that the work for which Witten was given the Fields medal came out of string theory, let's see those facts. Show me a pre-1990 paper explaining Chern-Simons theory in terms of topological strings.

Peter

23. **DMS**
October 26, 2004

When losing an argument,

get personal

"1989: Peter Woit loses any contact with theoretical physics for at least 15 years. This prevents him from seeing all new important connections between these subjects that were found between 1989 and 2004."

or move the goalposts,

"Moreover, it's just incredibly silly if someone judges the importance of ideas according to some fictitious links between a specific paper and some medal."

or, better still, change the subject

"Moreover, this CS story is just one of tens of important examples how string theory – not just "field theory" – influences math. Another class of these influences is associated with mirror symmetry."

but never accept defeat.

24. **Lubos Motl**
October 26, 2004

I apologize that I must write it so explicitly, but it is sort of necessary.

Your history is missing one important entry.

1989: Peter Woit loses any contact with theoretical physics for at least 15 years. This prevents him from seeing all new important connections between these subjects that were found between 1989 and 2004. Some of these connections are described in my "revisionist" history. This lost contact with reality in science also implies that even in 2004, Peter Woit writes entries on his blog that are very far from being up-to-date. These entries may have been fair in 1989, but they don't express the correct relation between the ideas as understood in 2004.

Moreover, it's just incredibly silly if someone judges the importance of ideas according to some fictitious links between a specific paper and some medal. If you care about these irrelevant medals so much, there are also different stories.

In the spring 2004 or so, for example, Witten received the national science medal from the US president, and be sure that it was not mainly because of the only papers you want to see. No doubt, he is credited for many other discoveries that you don't want to see, and most of us think that these other discoveries are more important.

Today, it is also very important that the 3D CS-theory is the worldvolume theory living on the D-branes of the A-model, and it allowed completely new methods to calculate all these invariants – correlators of the Wilson lines etc.

Moreover, this CS story is just one of tens of important examples how string theory – not just "field theory" – influences math. Another class of these influences is associated with mirror symmetry. I hope that you would not argue that even *mirror symmetry*, which has been converted to many rigorous statements in mathematics, has nothing to do with string theory.

Symmetry Magazine

October 27, 2004
Categories: Uncategorized

SLAC and Fermilab have joined forces and replaced their "FermiNews" and "Beam Line" publications with a new one called "Symmetry". I like the title; it's nice to see that the major US particle physics labs are supporting a publication about group representation theory.

   A layman pondering apple pie

   The Nature of Quantum Mechanics by Gread't Hooft

   But below we have some guiding principals to live by?

   Question:**In conventional QM and QFT unitarity is the consequence of the time translation symmetry of the dynamics. In GR there isn't, in general, an analogous notion of time translation symmetry**

   A lot of people (in fact, most people) argue that this is not a problem. They are wrong. It is very closely related to locality. How can you have locality in a theory where there is no a priori notion of distance? This is really a serious difficulty, and it had made some deep thinkers (read: 't Hooft) so desperate that they are even willing to abandon quantum mechanics. In the beginning of the talk at(above links in my postings) , 't Hooft explains that he simply believes in locality, and that this is why he explores these weird ideas about hidden variables. It is interesting that the inventor of holography has such a strong belief in locality.

   It all sounds spooky to me. How do you identify the smell of apple pie? It tastes like…..?:) From one island to the next????

2. **sol**
   October 28, 2004

   Mathematics is always a continuum, linked to its history, the past – nothing comes out of zero *Atiyah*

   How soon I forget sometimes:)

   I have a story about two monkey's on a island that I thought funny, but hey, we can work with "shit for brains", like mom's apple pie wafting through the neighborhood.:)

3. **RT**
   October 28, 2004

   It's the trivial things in life that make the difference. The re-sizable/scrolling window is indeed a boon. Its former immutable form was almost as distressing as the recent (let's not mince words) 'shit for brains' interlude. Thanks

4. **D R Lunsford**
   October 28, 2004

   Thanks! That worked beautifully.

   -drl

5. **Peter**
   October 28, 2004

   Hi Danny,

   I made the change suggested on the link you posted, resizable comment windows seem to work now.

   About Atiyah's work:

   He's actually one of the clearest writers of any mathematician, so one piece of advice is to just get ahold of the five volume set of his collected works, and try reading, starting with the expository pieces he has written, of which there are quite a few. Unfortunately I don't know of many more readable expositions of Atiyah's work than his own. For certain specific things that have made their way into physics (such as the basic index theorem for the Dirac operator), there is some physics literature.

6. **D R Lunsford**
   October 28, 2004

   Peter,

   What would a set of books for "Atiyah 101" look like? I want to understand this business with the index theorem, at least as far as is necessary for physics.

   -drl

7. **D R Lunsford**
   October 27, 2004

   OT – Peter – try this:

   http://www.ericsiegmund.com/fireant/archivesmt/000342.html

8.

October 27, 2004

This nothing point(?) sure comes up a lot.:)

If you asssumed a false vacuum, and that a true vacuum could emerge, there really wasn't **nothing** at all?

In fact, our universe could once have been so symmetrical that it amounted to nothing at all. "Nothing" is as perfect a symmetry as you can imagine, since there's nothing you can do to it that makes a difference. This nothing would have been unstable, however?like a pencil balanced perfectly (which is to say, symmetrically) on its tip. And that means?as Frank Wilczek has put it?the answer to the question "Why is there something rather than nothing?" would simply be that "nothing" is unstable.

9. **Peter**
October 27, 2004

Hi Danny,
If someone can point me to a source of information that explains how to do this, I'll look into. In general I don't want to invest much time in messing with Movable Type. As far as I can tell the thing to do is to migrate this at some point to Word Press, a project that will have to wait for some mythical point at which I have some free time.

10. **D R Lunsford**
October 27, 2004

OT – Peter, is there anything you can do to MT so that IE popup windows are not fixed in size and menuless? It works fine on Linux but not on Windows (go figure).

(In case I was not clear, the posting window cannot be maximized or resized at all, in fact.)

-drl

11. **D R Lunsford**
October 27, 2004

Well I for one endorse the defense of Bumo-er-Lubos, and hope that he will not in future refer to excrements in any place or context.

But we should stick to physics, yes.

-drl

12. **CW**
October 27, 2004

..and he has been known to express his interest in loop quantum gravity by suggesting that its practitioners be deprived of research funding. (See some of postings on sci.physics.research.)

13. **Fabio**
October 27, 2004

You've got it backwards. It was Lubos who introduced "excrement for brains" into the discourse here. He's shown himself to be quite thin skinned and quick to go personal when someone starts to get the better of him.

14.
October 27, 2004

C'mon. Whoever is writing these mock Lubos Motl entries needs to stop. This blog is about physics, not mockery and insults.

Some of you might not realize that the reason why Lubos spends any time on this website is that he is, at least in part, sympathetic to some of its views. Quite reasonably, therefore, he is compelled to defend string theory and his research. His point of view is defendable.

It would be a shame if Lubos and other string theorists stopped using this website on account of unprofessional attacks. Let's keep our eye on what the real issues are and debate them.

15. **ltom sobul**
October 27, 2004

This is obviously an implicit endorsement of string theory by the two top US accelerator labs, since string theory has more symmetries than any other theory.

Georgi on “Women and the Future of Physics”

October 28, 2004
Categories: Uncategorized

Howard Georgi gave a colloquium at Fermilab last week, and the slides and video from his talk are now online. He has gathered quite a lot of interesting data about women in the various sciences at the undergraduate and graduate level, and he discusses his experiences at Harvard over the years as he became more aware of the problems experienced by women studying physics. As chair of the department and in other capacities, he has tried to understand why there are so few women studying physics, significantly fewer than in the other sciences, concluding that “Many of our women physics concentrators were trapped in an emotionally abusive relationship with the Harvard Physics Department!!!”. He also concluded that it was “past time to outgrow the hypermacho lone-ranger approach to physics”, and that this would make the field more fun for everyone.

The whole issue of why so few women study physics (and math) seems to me a complicated one since it is mostly about the very complex and tricky ways in which people deal with how others expect them to fit into certain behavior and roles appropriate to their gender. I don’t think the “emotionally abusive relationship” that Georgi describes the Harvard department as having with its students is limited to the female ones. While I can say that in many ways I very much enjoyed my time as an undergraduate there, the great majority of the faculty were less than friendly to the students (with Georgi a prominent exception), and the general level of social skills of both the faculty and many of one’s fellow students left a lot to be desired. According to Georgi, changes have been made to the culture of the place and it is much more encouraging of its students. This is part of a general trend at many US institutions, partly because of increased sensitivity to gender issues, partly just because the students are paying a lot more to be there than they used to, and their increased dollars get them increased attention and respect.

Then again, they now have Lubos Motl, so the Harvard department’s traditions of hyper-aggressive behavior have not totally been lost.

Comments

1. November 3, 2004

   The election is not that interesting. Get to it guys. As Kurt Kobain had it: here we are now, entertain us

2. **Matti Pitkanen**
   November 2, 2004

   drl: Matti – that is – well, not even wrong.

   I have no personal opinion about this. I just wanted to bring in a new point of view.
   I am not very convinced concerning the purely statistical criterion used. Believe or not, it was comparison of ratio for the lengths of index finger and ring finger: on the average 1 for math oriented and .98 for non-math oriented persons!

   Matti

3. **D R Lunsford**
   November 2, 2004

   Matti – that is – well, not even wrong.

   It is undeniably true that men are better at making cognitive maps. This is almost certainly related to skill at math, which is necessary for skill at physics theory. “Grothendieck believes…” SO? “Motl believes…” SO? I don’t give a fig what anyone believes.

   In any case, none of this means a damn thing. The phenomena are all there, not the least bit interested in the sex of the observer. The pebbly shore of the great ocean of truth is open to all waders.

   -drl

4. **Matti Pitkanen**
   November 1, 2004

   In the last New Scientist (20 October 2004) there is an interesting article “Career choice begins in womb” according to which a good mathematician or physicist might have a more feminine brain. There is evidence that men in these disciplines are being exposed to a female pattern of aestrogen and testosterone in the womb. The absence of women from mathematics and physics would therefore look even more a cultural phenomenon (around 1984 immediately after super string revolution I participated a conference in which there were around 100 men and not a single woman: quite an experience!).

   Grothendienck has mentioned that he believed of having more feminine than male brain. In some New Scientist for some weeks ago (unfortunately cannot give the issue number) there was a little article mentioning that mathematician’s brain hemispheres are in more intense communication making possible rapid interaction between holistic and analytic modes of thinking. Higher connectedness indeed characterizes feminine brain.

   Matti Pitkanen

5. **Plato**
   November 1, 2004

   Maybe the female and male tendencies use the neurons, to manifest ideas? That would mean gender, has nothing to do with what the brain manifests, just that it does?

6. **Frank**
   November 1, 2004

   An old problem…. but consider this angel: Why do we try to get more women into physics but, for example, vets or literature don’t try to get more men?
   In Germany there are more women then men studying to begin with. If you balance the sciences you’ll end up with vastly more women studying. This alone indicates that an isolated women oriented physics program must fail. You could also ask why so many men study physics, and try to curtail the male population in the degree. Doesn’t sound entirely logical does it?

   Any reasonable approach to the issue would by neccesity need to be interdisciplinary and look at both genders.

7. **sol**
October 31, 2004

Should read with link:

One hopes that finding psychological processes embedded in thinking might have found some benefit in seeing GHZ entanglement as a process that brings forth mulptiple firing of neuron connectors(maybe like a supersymmetrical reality without the brain burning up?).

8. **sol**
October 31, 2004

One hopes that finding psychological processes embedded in thinking might have found some benefit in seeing GHZ entanglement as a process that brings forth mulptiple firing of neuron connectors(maybe like a supersymmetrical reality without the brain burning up?).

I had this under the heading of Venn Logic and Transactional analysis

Human Experience Masks Inherent Patterns

Parent EGO

As we grow up we take in ideas, beliefs, feelings and behaviours from our parents and caretakers. If we live in an extended family then there are more people to learn and take in from. When we do this, it is called introjecting and it is just as if we take in the whole of the care giver. For example, we may notice that we are saying things just as our father, mother, grandmother may have done, even though, consciously, we don't want to. We do this as we have lived with this person so long that we automatically reproduce certain things that were said to us, or treat others as we might have been treated.

http://www.businessballs.com/transactionalanalysis.htm

In this the EGO states would be extremely important, and if such thinking is harmonically driven, then what would one hope to accomplish in the adult ego?

Sly words of Osama Bin Ladin, about kings, and states, in light of countries and their leaders? His distain for life, and we discover another Wotan as hitler disguised?

In cosmological proportions, does it matter if it is male or female? I don't think so, as the emergence of neurons are projected by the minds thinking?

So maybe in Sean's Preposterous universe, that CW just linked again, one might have to see the context of Andrey Kravstov's early universe as , the neuron connectors of the cosmos, as strings that eventually clump, as neuronic discriptors? Look at my comment there under Arrow of time.

Entropic consideration in belief structures, and ideas, theories, when at a early time, it was all one?

9. **Jesse**
October 31, 2004

Lubos wrote:
Observationally, the number of neurons is correlated with the probability that a person ends in physics.

What's your source for this claim? Do you believe there is less of a correlation between neuron number and the probability a person ends up in math? If not, why are there more women in math than in physics?

10. **sol**
October 30, 2004

I just wanted to share a interesting perspective.

DocN,

Jean Shinoda Bolen, M.D. Ring of Power was interesting.

Strange that we could have seen A Jungian Understanding of the Wagners Ring cycle, portrayed in todays world and how could have this been accomplished. But by re-introducing a fictional story and embueing it with the archetypal structures of what Jean Shinida Bolen called, "The Abandon Child, The Authoritarian Father, and the Disempowered Feminine."

I was very intrigued by the way in which this story was used and applied. A Alice in Wonderland Fairy tale and what could we have learnt? Is it unrealistic to give such fairy tales the substance of importance, not to have recognized the structures underneath, and to have recognized the way in which things could have been transmitted? Have mathematicians been guilty of same?

Another mask I suppose, but it gave the flare of understanding that we might of not grasped otherwise and how deep a impression(emotional imprinting) could have been dealt with such attempts?

I think we have learnt to conceal our histories in our view points. Learnt to build structures. Have we missed the emotive consequences of such attachments, of that same history?

Imagine, Mother branes and baby universes and the intellectuals have never really left home:)Abstract spaces, like dreams?

Mothers and Fathers are in all of us? As a harmonic principle, selective actions above intellectual considerations that are sound judgements(identified) particle considerations?:)

It's all creative math and Physics?????? about the nature's reality, recogizing these principles in our natural world.

Regards

http://motls.blogspot.com/

I've expanded my article, added links to many documents about the difference between male and female brains, and analyzed "aggressiveness, competitiveness, and arrogance".

12. **Arun**
October 30, 2004

Three proposed explanations for why the proportion in women in physics is small, that have been proposed are:

1. Nature (i.e., different biology of men vs. women)
2. Nurture (i.e., differences in how society as a whole brings up boys and girls)
and
3. The culture of physics itself (not the content of the science, but the way physics is taught, faculty are appointed, how groups of physicists interact among themselves, etc.)

Now, while the representation of women in the higher levels of mathematics seems to be as dismal as that in physics, at least as of 1997 in the US (see the graph http://www.physicstoday.org/pt/vol-53/iss-7/p52b.html)
women were taking about 45% of the bachelor's degrees in math as compared to less than 20% in physics.

It would be interesting to see arguments that these figures do not support the explanation #3; or that these figures do not rule out #1. and #2.

-Arun

13. **Lubos Motl**
October 30, 2004

Hi Arun! I've already answered this question many times.

Observationally, the number of neurons is correlated with the probability that a person ends in physics. There are good reasons to think that this correlation has a biological explanation, but the system under consideration is just too complex to make any definitive statements about it, and moreover it is not my field and you can ask specialists who know much more about the interplay between brain's anatomy and physiology.

On the other hand, there is no doubt that one of the most important evolutionary steps that we had to make since the era we were monkeys was a growth of the cortex – the advanced part of brain. Because of this difference, chimps and gorillas only have 7-9 billion neurons, and be sure that this is one of the numbers that makes a difference. (Rats have 65 million only.)

14.
October 30, 2004

"In contrast, 47 percent of physics faculty members in Hungary […] are women"

Although i don't know the 1994 data, but as a hungarian student, i can assure all of you that today, this is very far from reality. I checked the homepages of the three most prominent hungarian universities, and my guesses are about 5%, 5% and 10%, respectively (and these are upper bounds). Math depts are not better, either.

15. **Arun**
October 30, 2004

Sorry! Here is the
http://www.physicstoday.org/pt/vol-55/iss-5/p24.html

16.
October 30, 2004

That was supposed to be a hyperlink, right? The href attribute was omitted. -C

17. **Arun**
October 29, 2004

Physics Today, on the first International Conference on Women in Physics

Quote: Communication among physicists, particularly in the US, was described as "combat physics": At talks and in individual conversations, explains Kim Budil of Lawrence Livermore National Laboratory, "you'd like people to engage in scientific discourse, but it often goes beyon that to become a fight for ego, to decide who is the smartest person in the room."

Lots of other interesting stuff there.

-Arun

18. **Arun**
October 29, 2004

Lubos,

I'll ask again – how is the ratio of neurons between men and women's brains relevant to the observed gender ratio in physics?

-Arun

19. **Lubo? Motl**
October 29, 2004

Those things are certainly relevant if we want to study the physiology of brains, and compare different types of brains.

You must say "relevant for what" if you ask if something is relevant. You know that if it were totally irrelevant for anything, I would not have written it.

You have probably misunderstood why I said that comment about the countries. I said it because the American science – which happens to be the scientific community with the large portion of women, as you say – is one of the successful ones, and it is conceivable that the competitive environment that does *not* try to respect any quotas is one of the reasons why it's successful.

In other words, other societies can artificially attract proportional shares of different groups of the population, but such an engineering is counterproductive for science as such.

20. **Arun**
October 29, 2004

So, Lubos, you agree that the following is mostly irrelevant?

"The male and female brain work differently in details. The average male brane has 20 percent more neurons than the average female brain. The latter has more connections between the neurons than the male brain. When thinking about language, one can show that both female hemispheres, but only one male hemisphere, is active, and so forth."

Or do American brains have more neurons than brains of other folks? Does immigration to the US suddenly increase the number of neurons in the brain?

-Arun

21. **Lubos Motl**
October 29, 2004

Well, the percentages of women in individual professions are different in various countries, and the variations are clearly a result of a different culture and different policies.

But you may also want to notice that the results of scientific research in different countries are also different, and it is the same United States in which the results seem to be better.

If you want to do some social engineering, and you have the politicial power to do it – there is nothing easier than to attract more people from some category to some profession. You just define some new advantages, and so forth. I am just not sure whether you really want to do such a thing.

And don't forget that quotas are unconstitutional in the USA.

22. **Arun**
October 29, 2004

Some other opinions:

Women in Science blog

Stubborn Equation Keeps Women on the Minus Side

Is the physics classroom any place for girls?

23.
October 29, 2004

Very interesting links, Arun. I found the following quite perceptive:

"One Latina woman told Ong that in her all-female study group, women feel comfortable voicing their uncertainties and hunches with language like "I'm not really sure about this, what do you think?" However, they have found that those same phrases, in a mixed-gender group, more likely would be coded as "I don't know what I'm talking about, I'm really dumb," and so women who persisted in physics have learned to speak with more assertion when working with male peers."

However, she is wrong below 😉

"The woman told Ong she found an irony in this approach: Good scientists never claim to know something absolutely, but instead deal in degrees of uncertainty. "

24. **Arun**
October 29, 2004

And afterwards, Lubos, if he is so kind, can go over to MIT and quiz this physicist who wrote

Recruiting Women (to physics) Takes More Effort

Incidentally, these 1994 stats are interesting:

Of 20 countries surveyed for another paper cited by the authors, the United States was tied with Korea for the lowest percentage of women in physics faculties, at three percent, they noted. In contrast, 47 percent of physics faculty members in Hungary and 30 percent in the former USSR are women. In addition, only nine percent of US physics doctorates went to women during the period studied, though that figure was 21 percent for France, 31 percent for Brazil and 60 percent for the Philippines. Within America, some universities have made more progress than others in increasing the numbers of women in physics; "the variations from one school to another are enormous," Professor Dresselhaus observed.

Perhaps Lubos can explain these variations in terms of the different numbers of neurons in the brains of women from different countries. Based on what he wrote earlier, the average female/male ratio of number of neurons in Filippinos should be much higher than that for Americans.

In general, I am appalled that some people have such strong opinions without any regard for any data. On the other hand, this place is primarily for discussing string theory, so can anything better be expected?

25. **Arun**
October 29, 2004

Here is some actual research, and perhaps Lubos can interview the researcher for us, because she is in Harvard.

[Researcher Mia Ong: Physics ‘glass ceiling’ intact]

26. **Fabio**
October 29, 2004

I always had the impression that the Russian physics culture was more aggressive and macho than the American one, at least in the good old days of the cold war. How did women fare in that system? The only example that comes to mind is Kallosh.

27. **Lubos Motl**
October 29, 2004

I apologize, but as an alien I feel the moral right to say that the American self-confidence is one of the features – certainly not the only feature though – that makes America special in the modern world.

It’s perfectly fine if the students are quiet at all seminars and all classes. There’s nothing wrong with it, but there’s also nothing cool about it.

Vocal students that go over the edge may be counterproductive for the teacher and other students, but on the other hand, a certain degree of activity is nearly always helpful.

Most of European science is un-emotional, boring, lacking self-confidence and big ambitions. That’s just wrong, and God bless American science for its different atmosphere.

28. **DMS**
October 29, 2004

Interesting subject. I knew a couple of physics majors from Harvard and they echo what Peter said regarding faculty’s unfriendly attitude towards students. They did not feel they got what they paid for. Well, they are taxpayers (and some are even science advisors to senators and congressmen) and I am sure they are not as sympathetic to funding for theoretical physics, especially particle physics. It is best not to bite the hand that feeds. 🙂

Regarding rewarding of hyper-aggressive behaviour, that is partly an American phenomenon; I did not notice that too much from people of (most 🙂)other countries, but I may be wrong.

I also notice a lot more Asian women who take up hard sciences (electrical engineering, CS etc) than N American. One factor seems to me are the “women’s magazines” , which are anything but feminist. It is paradoxical since women’s rights are more advanced in US than Asia. But many women in US are in fields like medicine and law; is the culture less aggressive in such fields? From my experience, particle theorists are the most aggressive bunch 😉

Another factor is probably the teaching style, where often the teachers pay attention to the more “vocal/aggressive” students in the class, discouraging the quiter ones, be it male or female.

Actually, Georgi (with several female Ph.Ds who are faculty members)and S.T. Yau (Karen Uhlenbeck mentions the important role he played in her career when she was being dismissed by other male colleagues) are notable exceptions.

DMS

29. **Lubos Motl**
October 29, 2004

Many points are waiting here to be answered.

Concerning the discrimination in USA vs. Central and Eastern Europe: Arun, I said it because I believe that the higher employment and salaries of women that we “achieved” in socialism – with women who don’t have too much time for their children – is not such a great thing after all. I have no idea whether the American or European reality – concerning the respect to women – is “better”.

The ratio is female politicians is small almost everywhere, for example.

I agree with you that the level of women’s salary is the reason, and the perception of various acts being viewed as jokes is an effect, but unlike you, I am not so sure whether it implies that someone is more right. Don’t you think that you should ask: Aren’t those critics in Europe right? Is not our American feminist system ridiculous?

For the other participant: Well, if someone has other options, she (or he) can choose other options, does not she? It’s not clear to me what it means to “create an environment”. If it is a general feeling that an average woman is happier if she has a family etc., instead of physics career, then it is a general feeling, and her decision will be affected by her plans, her opinions, as well as general feelings of the people around. I don’t understand how someone wants to separate our culture from these decision.

I may also expect the physicists to be slightly antisocial, arrogant etc. – but the reality is very different. The physicists are usually very nice people. In many contexts, I view it as a symptom of a problem, but that’s a different issue.

Here we discuss the gender. I certainly don’t think that women have to be nicer than men, and if YOU believe the stereotype, then it is YOU who discriminates women.

Sorry, but the answer of the women who did not to too well at the exams is most likely rubbish. One can always invent a cheap justification of this quality to explain why she or he failed at the exams. My interpretation is that the women over there just had a smaller score than the men. That’s the experimental reality, and it is just pseudoscience and biased ideology if someone tries to invent a virtual reality behind it.

There exist exams in which women have a better score in average than the men, but if the previous group is more frequent, one should not immediately invent hypotheses that it is because of some “unfairness”.

I don’t believe that women and men in science are talking two different languages. In 2000, I remember a polemic I had with a crazy postmodernist on a party in San Francisco. He was wearing an obnoxious T-shirt with a coffee cup, if I remember well, and the T-shirt was expressing his opinion that science is arrogant (I forgot the details), and something like that. He claimed that he would always be able to figure out whether a physics paper was written by a female or male authors.

I am absolutely sure that I could give him a sample that he would guess much less than 50% correctly ;-), but unfortunately we lost e-mail contacts of each other.

These people are just incredibly stupid and obnoxious. They believe that physics is a matter of cultural creation, something invented artificially, something into which the scientists reflect their gender, race, and whatever else – and our physics, as we know it, is a male white physics that would differ a lot from a female black physics, for example. Of course, they believe so because they don’t believe in any objective reality or science. Don’t you agree that these people are just pompous fools and morons? I get very upset already when I realize that many of these people are able to acquire academic positions. 😉

30. **Chris W.**
October 28, 2004

The issue (Lubos!) is *not* one of providing special support for women so they can succeed in a demanding and competitive environment, and to prevent them from becoming discouraged and dropping out. The issue is creating an environment that talented, competent, and mature people can respect, ie, that they feel is worthy of their abilities and strengths, *knowing that they have other options*.

What Georgi is pointing out are fundamentally dysfunctional attitudes and behaviors, which are tolerated because, well, we expect physicists to be somewhat arrogant, antisocial, and clueless about the wider world (and sometimes just plain weird). More and more, that kind of excuse won't fly, if only because most employers can't afford it.

I recall reading a report on this topic in *Science* a number of years ago. It discussed a particularly demanding exam that students pursuing a physics Ph.D at Harvard were expected to take in the course of their careers there. It noted that female students tended not to do as well on the exam. The author of the piece interviewed some women in the physics department at the time and asked them about this. They said, yes, that was true, and it was because this particular academic gauntlet "was just too nerdy for an intelligent woman to take seriously."

Any professional subculture can become insular and obtuse. (Take stock trading and investment banking, for example.) That is really what is at issue here, not simply accommodating excluded groups. Of course admitting that one is a complacent member of a spoiled, insular, and obtuse subculture, and then doing something about it, is not easy.

—
It should also be noted that the place of fundamental research in our society is not so secure that its practitioners can afford to ignore issues like this. The demise of the SSC is an object lesson; there could be several more like it in our future, given the state of the federal budget.

31. **Arun**
October 28, 2004

Lubos:

You wrote : "….some quantitative measures show that women may be more "equal" in the Czech Republic – for example, their employment rate is higher, and the ratio of female over male salaries is higher than in the USA. No one considers these things to be overly sensitive issues in the Czech Republic, and everyone is making jokes about America where the feminists can sue you if you look at her inappropriately…".

You've put your finger on something important but IMO, you've got cause and effect reversed. Where women's employment rate is higher and salaries are more equal, discrimination seems like a distant joke, and no one is sensitive. Where discrimination is a reality, it hurts.

-Arun

32. **Dick Thompson**
October 28, 2004

Well it looks like the commenters have achieved their dream. A nice little flame war. I am waiting for Godwin's law to come into play

33. **Lubos Motl**
October 28, 2004

Dear DRL, if I imagine that you are an "intellectual", it's really not that hard to become a hyper-aggressive anti-intelectual. 😉

34. **D R Lunsford**
October 28, 2004

Mary,

Nerds of all sexes and colors are hated most everywhere. No monopoly for woman nerds. The US is fundamentally anti-intellectual. I've learned to cover up at work and not make waves.

PS I virtually offer to carry your books 🙂 Hang in there.

-drl

35. **Lubos Motl**
October 28, 2004

That's great that Mary wrote her statement – because it will force many of us to think about reality, and perhaps avoid a certain type of "help" that really does not help.

I totally agree that the girls don't need too much special treatment because of their hypothetical "weakness".

For example Melissa Franklin, my very interesting colleague, 😉 is a truly strong personality. She is one of the first female professors from some category – and under some circumstances, Peter Woit is – as a critic of string theory – a shy piece of soap compared to Melissa Franklin.

Melissa has no problem to sit with 11 string theorists to a table at the Faculty Club, and explain them that she thinks that they are symbols of degeneration of the physics community, and it's no fun to talk to them. In order to prove her point in detail, she picks a string theory postdoc and starts to ask him, at the end of the lunch, how is it possible that he did not say anything during the lunch! 🙂

Well, really, many women don't need any special legal support to get their point through.

What I find important is that the very feeling that the females are being positively discriminated must be pretty devastating for those ambitious girls who simply want to be equally good or better than their male (and other female) colleagues. By the positive discimination, they're being told: "If you do something fine or get a job or an award, it's just because you have this artificial support for your not having a penis." 😉

That's just an unpleasant state of affairs, especially because I know many girls in physics who simply do not need such an artificial support. Well, such affirmative action may help some other women to get the same jobs or awards as the talented ones, but I think it is just unfair, especially towards the talented females.

There should be no discrimination, neither negative nor "positive". We've lived in a regime based on the idea that the working class is being exploited by the "capitalists" and something radical must be done about it – and let me conclude that the idea that the females are being exploited by the men and radical actions must be taken – is a very similar idea that can lead to very similar results.

36. **Lubos Motl**
October 28, 2004

Yes, Arun, you are right that I don't know too much about the situation in American families, and how much the parents support the daughters to study physics, and so on.

But in the socialist bloc, we have just lived without this tension. Even though Americans often like to criticize some Czech traditions – e.g. when boys beat the girls during the Easter holidays 🙂 – some quantitative measures show that women may be more "equal" in the Czech Republic – for example, their employment rate is higher, and the ratio of female over male salaries is higher than in the USA.

No one considers these things to be overly sensitive issues in the Czech Republic, and everyone is making jokes about America where the feminists can sue you if you look at her inappropriately. 😉 The same situation like in Czechia is in Taiwan, for example, I was told by Melissa Liu, a female mathematician who has worked with Shing Tung Yau. Nevertheless everyone knows that the "natural" outcome will be that most girls will NOT choose specialized physics and engineering careers.

On the contrary, they will choose teaching (at high schools), and this may be a stereotype, but it may also be correlated with maternal instincts.

Also, if some parents just believe that a job is wrong for their son or daughter, they have the right to promote their opinion within the mantinels given by the law – they're the parents! And the children must often become rebels. At the end, I am pretty sure that every parent is happy if her or his daughter becomes a skillful engineer or physicist.

To summarize: I don't think that there is much difference between the characteristics of men and women in different Western countries – which again counts the Czech Republic, too. And we – from the Central Europe – probably have a more balanced point of view.

37. **Mary Messall**
October 28, 2004

As a female graduate student, I resent the crap I hear about women just thinking differently from men. I also resent the idea that women are just so much weaker and more sensetive that they can't take the competitive environment, and any suggestion that women should face, or do face, less strict standards of admission or success. And finally, I resent the notion that women are just so unable to stand up to men that they have let themselves be oppressed for centuries, and that the ghost of this oppression keeps them out of physics even now.

So what's my theory? Simple. It costs women more to be perceived as nerds than men, and physics is the nerdiest science. Popularity and attractiveness are status, for a woman. You want the rewards of status — a mate, the respect of your peers (especially other women, mothers and aunts and grandmothers and girlfriends), stimulating friends and politeness from strangers, self-esteem and etc — you'd better not be a bespectacled obsessed loner. Guys can get away with it, because status for guys comes from public success, money and power. Those things are available in academia.

The solution? I figure if we could just get girls to read more science fiction, the field would seem more glamorous. That's how I got sucked in, after all.

38. **D R Lunsford**
October 28, 2004

Yes, Peter I *insist* that these abuses against Lubos cease at once, at once I say, at once! It's plainly discrimination against expatriate short-fused addled tongue-tied hyperaggressive anintuitive Harvard physics professors. Shame on you.

39. **Arun**
October 28, 2004

Lubos,

You are a scientist. Why then is it an automatic assumption that the social situation in the US, the high-school teachers' attitudes to girls good in math and physics, parental attitudes, and so on are the same in the US as in the Czech Republic? I think the natural assumption has to be that it is different until proven similar.

(IMO, we lack a science of cultural differences because it is so difficult not to make these automatic assumptions.)

-Arun

40. **sol**
October 28, 2004

As most of you know I like to admonish multi dimensional perspectives :), so of course Mona Lisa's smile, as a movie should have been considered in context, as well:)

Traditions are keenly recognized over the last century, and I'd like to think, that mothering propective students, would have been more then saying okay, because of the rote system by which you eager students have memorized, I am going to break up this line of thinking, by presenting a whole new perspective(remembering the movie now:)?

The method of teaching changed ole tradition, and incorporated new facets of thinking. Gained a appreciation over artistic views, and mothers?

So we should find independance and brilliance based on the content and material of dissertation, rather then, what neurons fire more then likely(move your arm enough and you create the pathways), to what should fire outside of rote(creative potentials).

Of course we do not forget the foundation. Thanks Peter:)

Oh, I am male.

41.
October 28, 2004

Please Peter, stop the cruel digs at Lubos, lest you drive away this delicate flower for good.

42. **Lubos Motl**
October 28, 2004

It's great that I can confirm Peter's last sentence 😉 by the following comment:

The influence of feminism (and related ideas about the males exploiting the females, and similar rubbish) at the U.S. academic institutions is highly annoying and discouraging for an freedom-loving person. Of course, it is partly a matter of culture and traditions.

Let me tell you that my diploma thesis advisor in Prague – whom I consider my friend, and we wrote a textbook together – married my classmate. She simply fell in love with him during the first lecture, and finally it worked out.

I would personally find it highly disturbing if someone had the courage to publicly question their relationship just because it was a teacher and his student. Such a questioning simply violates what I consider to be a respect to basic human freedoms, and a respect to important relationships between the people – it's a disrespect to love.

Let me also say that today it is nonsense that the girls are discriminated virtually anywhere in physics. Average girls simply do not like physics as much as boys do, even if they are supported. This is an observable fact, regardless of its explanation. Genders have played slightly different roles in the society for centuries and millenia – but even if they did not, there are just so many biological differences that a different "typical" focus of the two genders just could not be surprising.

The male and female brain work differently in details. The average male brane has 20 percent more neurons than the average female brain. The latter has more connections between the neurons than the male brain. When thinking about language, one can show that both female hemispheres, but only one male hemisphere, is active, and so forth.

It's also very wrong and silly to create a false stereotype in which the teachers are trying to pick their students, and not the other way around. I know many more examples of the second category.

By the way, the physicists should be much more aggressive than they are today. There are some shining exception of physicists who know what they defend – and some of them are women. 😉

Physics Today on Ethics

November 4, 2004
Categories: Uncategorized

A correspondent points out that this month's Physics Today has a couple articles about ethical issues involved in how physics research is conducted in the U.S.

Most of this doesn't really apply to the kind of research I know best, theoretical research in physics and research in math. One main issue considered is the trustworthiness of experimental data, and as far as I can tell, in elementary particle physics the data is quite trustworthy. Since the collaborations that produce these results are so huge, many people are involved in going over any published result of any interest, so even if someone were tempted to fake or manipulate data, it would be hard to get away with.

Another issue of concern is the treatment of young experimentalists, who are often overworked and under-recognized. But the situation of theorists is generally different. In most cases the problem for them is thesis advisors who ignore them, not ones who pay close attention to what they are doing and make them work too hard. There is a fundamental ethical problem in the treatment of young theorists by the physics community, that of producing far more particle physics Ph.D.s than there are jobs for. This creates a brutal situation for young people, while it is to some degree in the interests of those who are established in permanent positions to let this go on.

The main ethical problem in particle theory research these days, a fundamental lack of honesty in how the results of this research are evaluated, doesn't seem to be addressed at all in the Physics Today articles.

Comments

1. **D R Lunsford**
   November 6, 2004

   Matthew,

   It's actually an exciting time to be a theorist, because everyone in academe is so out to lunch, there's plenty of open space for real work.

2. **Chris Oakley**
   November 6, 2004

   Matthew:

   Agreed – my statement should have been qualified accordingly (a lot of groups here in the UK work on lattice gauge theory). As you will have gathered, I was never tempted, but I do not deny that it connects directly with the experimentalists.

3. **Matthew**
   November 6, 2004

   Hi Chris,

   What is called "particle physics theory" now really belongs in the mathematics (or arguably even the theology) department, with "particle physics theory" as I understood it 25 years ago, which took a keen interest in experiments, virtually ceasing to exist. The result of this is that the experimentalists now do their own modelling, expecting little or no help from the theorists.

   Just to be somewhat more optimistic, there is a active phenomenolgy community in particle theory which still cares about experiments. Many of the people here at Cornell attempt to understand what will be seen in the next round of experiments at the LHC. Also, there is a large group of theorists (myself inculded) who interface with the ongoing b and c quark physics programs.

   Now, you don't see that in the popular press 🙂 which is mostly string theory focused. Of course, some of the models propose (large extra dimensions, for one) may be wacky, but they are testable at the LHC, and the people who propose them do make detailed (or as detailed as they can) predictions about how to do these tests.

   From my perspective, it's an exciting time to be a phenomenolegist.

4. **Fabien Besnard**
   November 6, 2004

   Hello everyone,
   I agree with Peter on the No of Ph.d/academic jobs issue. The problem is not that, in principle, there should be a perfect adequation betweens these two numbers. The actual problem is with the ratio. I don't know the figures for usa but in France, for mathematics, the ration is about 20/1 and this is ridiculously high. It's even worse in theoretical physics. For each academic position in any french university there is commonly over 150 candidates, many of them very good. It means 90% of the CV sent won't be considered as they should be : they are sent directly to the trash can if at first glance they boast fewer (maybe uninteresting and repetitive) published papers than the others. This is huge encouragement to uniformity of curiculum.

5. **Michael Williams**
   November 5, 2004

   Having damned the NYRB article with faint praise in my previous comment, I would like to add that it is very good on the universal scientific problem of priority and credit. Definitely worth a read!

6. **Michael Williams**
   November 5, 2004

   Followers of this discussion may find this New York Review of Books article interesting. It reviews a book and the Union of Concerned Scientists' paper on the Bush administration. As is often the case, the review (and possibly the book) assumes science is the same as medical trials, but it's interesting nevertheless.

7. **Fabio Lanzoni**
   November 5, 2004

I probly woulda still gotten my PhD had I known in advance I would not stay in academia; as Emanuel Derman says in his book, it's not a bad way to waste away your 20's. So I don't think its necessarily unethical to train more students than there are faculty openings, as long as you are honest with the students about their prospects.

8. **Chris Oakley**
November 5, 2004

Peter,

One would of course get the same problem if everyone with a classics or history degree wanted to be an academic, but most realise that this is not possible, or they want to do something different anyway. A PhD in mathematics or a "hard" science is however an asset in most cases if one chooses to go into the so-called "real" world, and the economic equation may work out to one's advantage even taking account of poor remuneration when one is a student.

I am not sure that universities can do anything much differently … ultimately one's product is only worth what people are prepared to pay for it and this applies as much to academic research and teaching as to cars or cosmetics. It seems inevitable that with limited money and a lot of people wanting to be academics, salaries will be driven down and people will be exploited. My only gripe is that the limited resources could be used better … i.e. more emphasis on new ideas and less on vested interests.

9. **Peter**
November 5, 2004

There isn't a direct economic reason for a particular faculty member doing theory to want to produce more Ph.D. students. But there are lots of indirect ones. For instance, if you want to be able to teach advanced graduate courses in your specialty, you need a large enough audience that will take the course. As far as the university as an institution is concerned, it has many direct economic incentives to produce as many Ph.D.s as possible:

1. Sometimes you can get either the student or someone else to pay large amounts of tuition dollars (e.g. the student may be on some sort of fellowship paid for by a grant or some other sort of outside money).

2. If they don't have outside money, you appoint students as teaching fellows, thereby getting employees who will work quite cheaply. Paying graduate students is not cheap, but it's a lot cheaper than hiring full-time regular faculty.

3. Once they get their Ph.D.s, students will join a large underemployed labor pool, and everytime you have a faculty job you want to fill, hundreds of them will apply for it, many of whom will be willing to take the job no matter how badly it pays. By handing out a lot of Ph.D.s you create a large pool of cheap labor.

University administrations are the ones that set the number of how many Ph.D. slots they have, departments basically always take as many as they can get.

10. **Chris Oakley**
November 5, 2004

I do not think that the "training more people than there are jobs for them" argument holds water. If it did, then we might as well give up altogether on the study of Classics, Philosophy and many other subjects where almost all the relevant jobs are just teaching the subject to others. Apart from subjects like Medicine, only a minority of students that will be expecting their degree course to be a specific vocational training. For example, the Aeronautical Engineering PhD's we hired at Nomura to do financial modelling were perfectly happy to leave air flow calculations behind them when they joined the company.

The problem with particle physics theory as I see it is that the nature of the beast has changed. What is called "particle physics theory" now really belongs in the mathematics (or arguably even the theology) department, with "particle physics theory" as I understood it 25 years ago, which took a keen interest in experiments, virtually ceasing to exist. The result of this is that the experimentalists now do their own modelling, expecting little or no help from the theorists. The problem is that, unaided, the experimentalists are less successful in getting the public's interest, so given the high costs involved, this can only lead in the long term to decline.

11. **Alejandro Rivero**
November 5, 2004

Well, about the data, I am a bit worried on the use of the concept of "confidence level", and the current methods seem to be a mix of bayesianism and standard frequentist approaches, plus some random 🙂 montecarlo comparisions. Not unethical, but enough to let people to choose the approach they feel better.

12. **JC**
November 5, 2004

Peter,

Are there "economic" reasons for established folks to produce many more PhD students than the number of available jobs? (ie. Do folks get more government grant money for producing more papers, theses, etc …?)

The Triumphs and Travail of the Theory of More Than Everything

November 4, 2004
Categories: Uncategorized

Shamit Kachru gave the physics colloquium at Rutgers yesterday. His title was “The Theory of More Than Everything” and I heard from people who attended that he was promoting research into the “Landscape” as a new model of how to do theoretical physics, especially cosmology.

I was down there today and heard two talks in the mathematical physics seminar, by Abhay Ashtekar and Tom Banks. Ashtekar’s talk was a standard exposition of a few of the basic ideas of loop quantum gravity, also reviewing an attempt to apply these ideas to cosmology. The talk by Banks was titled “Triumphs and Travails of String Theory”. The first hour was about the triumphs, giving a pretty standard survey of the supposed accomplishments of string theory. Banks emphasized the importance of supersymmetry, and described string theory as not quite background independent, but depending only on a choice of “asymptotic background”. He dealt with matrix models, holography, BPS states, dualities, getting gauge bosons out of string theory, and AdS/CFT.

His talk contained quite a lot of content, unlike some promotional talks of this kind, but it did come off a bit like an hour-long infomercial (“And, there’s even more! It slices, it dices, it ….”). The last five minutes were devoted to the travails of string theory, of which, according to Banks, there is really only one (although he did mention that the lack of observed supersymmetry is also a problem). The one travail is the fact that the cosmological constant seems to be positive, so the universe is de Sitter, not anti de Sitter or flat. This creates well known problems with defining an S-matrix. He went on to explain the “Landscape” idea with its de Sitter states that are only metastable, saying this “leads to a new philosophy of doing physics that many are exploring”. He didn’t seem interested in directly criticizing this new philosophy, but did end by promoting his own, different, ideas about how to deal with the cosmological constant problem.

During the question session afterward, someone asked if there was any overlap between loop quantum gravity and string theory. After some hemming and hawing by the speakers, Michael Douglas spoke from the audience, saying that since string theory was really 20 or so different kinds of approaches to quantum gravity, it was quite plausible that LQG was another related one.

   I thought Lubos and Peter might like a picture of the Landscape of the Week link:)

2. **Plato**
   November 7, 2004

   Dear Chris,

   OK – I’ll stop doing the book, provided that you explain what a “dimensional advocate” is.

   If we were to suspect that all matter distinctions existed in some other form then the solid things we see, we understand I think that before spit can bcome from saliva, one had to had the emotion first?:)

   Now if DRL was having a emotive experience, in his psychological state, the manifestation of the liquid(saliva) would have taken a condensation of thinking, to arive at such a conclusion.:)

   If such solid things are to be taken for granted, we then know that if DRL was a **dimensional advocate**, he would have known that the spit arises from thinking emotively:)

   LOL

3. **Chris Oakley**
   November 7, 2004

   My Dear Plato,

   OK – I’ll stop doing the book, provided that you explain what a “dimensional advocate” is.

   Do they for example charge less or more than ordinary lawyers?

4. **Plato**
   November 7, 2004

   I’m writing a book about Dionysus, loosely based on Jim Morrison (or should it be the other way round?).

   Chris please don’t.:)It takes all of ones faculties to enter into such allegorical states that you need some anchor, not drugs:)

   You see both Lubos and Peter are under the arch of science, yet they both move from different perspectives? Although they agree on (?)that science should validate?

   John Baez speaks on the abstractness of **quantum gravity** and we experience abstract values, in brane scenarios.

   So whose right? Whose on firm ground?

5. **Chris Oakley**
   November 7, 2004

   ‘…addicted to imaginary power and fractally vibrating nonsense, incapable of judgment, phase-locked into an eternal inward self-indulgent “journey of discovery”.’

   ‘… dimensional advocate?’

   ‘If you classify the 60’s and 80’s you have spoken to many who have travelled paths before you.’

What are you guys *on*, man, and more importantly, where can I get it?

I'm writing a book about Dionysus, loosely based on Jim Morrison (or should it be the other way round?). I won't need to take drugs to write the more high-faluting bits as I can just borrow phrases from the comments section of this blog.

6. **Plato**
   November 7, 2004

   DRL,

   The radicals of the 60s and the 80s have combined to breed a race of intellectual midgets, addicted to imaginary power and fractally vibrating nonsense, incapable of judgment, phase-locked into an eternal inward self-indulgent "journey of discovery".

   You failed to identify the relation I drew between Peter and LUBos. I asked if you applied the question which one would follow which process of thought. Lubos would point to heaven, while Peter would be showing his hands where?

   Plato knew of pythagorean studies.:

   Anyway you tried to compact a much information in a **short space of time(dimensional advocate?:)** as you could by using words that have deep association to your "**feelings about the views of strings**"? That it was hard to remove the emotive impact of your bias from the saliva you spit. I am sorry:)

   But this is a view, that **I have shown** and the struggle to this day:) Peter looks hard around, and some of the religious orientated although firmly attached to ground by Peter's Dialogue, recogize the need for defining this higher attribute?

   If you classify the 60's and 80's you have spoken to many who have travelled paths before you.

   Would you quickly denounce their contributions as we would in moving forward the thought experiments of Solvay?

   Although we would harbour differing points of view we do not denounce each other. We use each other to fuel what is truth? Right?

7. **D R Lunsford**
   November 7, 2004

   Oops – in my rant, I mistook "3 Minutes" with "Brief History of Time" – sorry. "3 Minutes" is a nice book on some level. I suppose all trimuphalism seems to get to me.

   I hate being mad. Science is supposed to be fun.

8. **D R Lunsford**
   November 7, 2004

   Pythagoras was a stringer! Oh how rich.

   This website illustrates all that is wrong with physics. A crew analogous to the Neocons has taken over, who must fill every moment with world-shaking radicalism and triumphalism, couched in the most airy-feathery faux-wonderment about things that are not real. "Light shining from the fifth dimension" – what sort of nonsense is that?

   This all seems to have started with the Dr. Seuss Lectures on Physics, otherwise known as "The Dancing Wu-Li Masters", and the Disney Guide to Cosmology, "The First Three Minutes" (a time formerly reserved for running trailers of coming attractions). The success of these meant it had became possible to fill the exquisite yuppie-radical bombasto-conservative mind with all manner of self-propagating nonsense. It is, after all, more fun for most to indulge in reflexive hallucinations rather than make the effort to get to facts – it is easy to bash Pauli and Dirac and Einstein and ignore what they say, because they are "establishment" figures ripe for a knockover, pitiful old-worlders from a nighttime of the soul. The febrile postmodern narcissist must always ponder the universe as revealed in his own reflection, distorted by passive consumption of endless surreal images that compete with his wan self-awareness in his infinite reflecting pool. It is not enough to let one's mind reach only to Vega – the narcissist-addict's grasp must extend to the far reaches of what passes for imagination.

   The radicals of the 60s and the 80s have combined to breed a race of intellectual midgets, addicted to imaginary power and fractally vibrating nonsense, incapable of judgment, phase-locked into an eternal inward self-indulgent "journey of discovery".

   It makes me ill. That's what I think.

9. **Plato**
   November 6, 2004

   Which is the String Theorist and which is the LQGist

   It seems the struggle is deeply embedded in consciousness? That we have brought forward age ole struggles, to do them all over again?

   What do you think?

10. **Mubos Lotl**
    November 5, 2004

    the parents of "Mubos Lotl" whom I assume is either Lunsford himself or someone very similar – should spank their son thoroughly

    Why, Lubos, do you deny writing the words I cited from your own blog? Perhaps you would like to explain their real meaning if I have misinterpreted them? That is, perhaps you can explain how being rude and obnoxious will help string theory to get moving again. AdS, here we come!

11. November 5, 2004

    It's true, Tom Banks is much older than he was 15 years ago.

12. **Plato**
    November 5, 2004

    Lubos
    Your questions may be fine, but they don't go as far as string theory, and I don't have time to explain vacuum bubbles in QFT now.

I was thinking of supersymmetrical reality.

Symmetry breaking, and I looked at the current universe, and it structures. For me, this evolution lead from Planck epoch through to cosmic clumping(cosmic string)from it's origination. Andrey Kravtsov images are really helpful along with Max Tegmarks research.

But yes QFT, in comsological proportions, had to be consistent with the dynamics of the universe?

I understand your time, and appreciate post.

Peter can clear up the identity of **name arranger** in a minute, using blogspot. Best not to speculate. Standards here of human beings, should be impeccable, dealing with such fine subjects.

13. **D R Lunsford**
November 5, 2004

Lubos, I have better things to do on my limited worldline than to mock you. When I want to point out how utterly clueless, arrogant, and annoying you are, I need not retreat behind a mocking alias.

14. **Lubo? Motl**
November 5, 2004

I don't know if physics should be like wrestling, but what I know is that D.R.Lunsford's parents – and the parents of "Mubos Lotl" whom I assume is either Lunsford himself or someone very similar – should spank their son thoroughly. They should try to avoid the evolution of their son to a moral and intellectual cripple. But it may already be too late.

15. **Lubo? Motl**
November 5, 2004

Hi Plato!
I was talking about papers of Tom (about background independence) such as

http://arxiv.org/abs/hep-th/0011255

See also his list of papers

http://www.slac.stanford.edu/spires/find/hep/www?rawcmd=FIND+A+BANKS%2CT+

Your questions may be fine, but they don't go as far as string theory, and I don't have time to explain vacuum bubbles in QFT now.

16. **D R Lunsford**
November 5, 2004

This issue of NEW is beyond surreal. Bon-Motl wants to make physics into wrestling.

I walk away, muttering, drooling, and weeping.

17. **Mubos Lotl**
November 5, 2004

String theory is in trouble at the moment, but recently an explanation for this has been given. According to Lubos Motl, "Current string theorists and physicists in general are just too "nice", and this atmosphere is correlated with the reduced amount of progress that we're doing (whichever is the cause vs. the effect). I know that Nima Arkani-Hamed agrees with me, for example, and the people who say the opposite statement seem to be disconnected from reality." According to my model, "niceness" is a scalar field generated by good-natured, polite string theorists, which has the effect of "uplifting" the anti-de Sitter background to an apparent de Sitter state. The solution is for string theorists like LM and Arkani-Hamed to go against their fundamental natures and adopt the manner of unusually obnoxious
10-year-olds. The result is that the vacuum will subside back into its natural AdS state. True, this will ultimately destroy the cosmos, but at least it
will reveal that string theory is correct.

18. **Plato**
November 4, 2004

Lubos*Tom has also investigated the question under which conditions you can create a bubble of a different vacuum within another vacuum/Universe*

During a first-order phase transition, the matter fields get trapped in a `false vacuum' state from which they can only escape by nucleating bubbles of the new phase, that is, the `true vacuum' state.

http://www.damtp.cam.ac.uk/user/gr/public/cs_phase.html

Do you have any other information resources that would help clarify this in terms experimental considerations like this membrane in a vacuum? (make sure you let it load)

Would it be wrong to think of (mem)branes in this context?

A few Saturdays ago, he had his heart set on bubbles. "We have a copy of ***C. V. Boys' book Soap Bubbles*** *here on the ISS. It was published in 1911 and it's still a wonderful treatise on thin films. Every space station should have a copy," he laughs. "I wanted to see what thin films and bubbles might do in zero-g and felt it was a topic ripe for discovery."*

http://science.nasa.gov/headlines/y2003/25feb_nosoap.htm

19. **Lubos Motl**
November 4, 2004

Tom Banks is a very nice person. I am happy that he keeps on emphasizing some ideas that are more important for him than many others.

Tom believes that supersymmetry may play a more fundamental role in the scheme of things than just a particular symmetry of physics. And he's studied the question of background dependence in depth. His remark that difference asymptotic boundary conditions define different superselection sectors that can be treated as separate theories is a very good remark.

Tom has also investigated the question under which conditions you can create a bubble of a different vacuum within another vacuum/Universe.

I am sure that Tom has said many things that most others don't emphasize enough.

The measure of importance that Mike Douglas assigned to LQG seems to be the maximum one can imagine to be realized – it would be just the 21st equivalent/related approach to the same theory of quantum gravity (called "String/M-theory"), if it's correct. Of course, I don't think it is, but the idea that LQG should be visualized as a structure comparable to the *whole* string theory is absolutely ridiculous. It's like comparing Castro's Cuba to the USA. In the best case, you may try to compare Cuba to Florida, or loop quantum gravity to D-branes on orbifolds (by Douglas and Moore), for example. Of course that the brane on orbifolds will still be a more important insight about quantum gravity than loop quantum gravity, and Florida will defeat the current Cuba. But at least, these are somewhat more reasonable comparisons.

20. **Peter**
November 4, 2004

I think the last time I heard him speak was nearly fifteen years ago, so my main impression was "Gee, the guy looks a lot older". To be fair, the extent to which he was trying to sell string theory was no greater than most other talks of this kind. He did try and pack more content in than many such talks, which is what gave the impression of relentless adding on of more wondrous features.

21. **JC**
November 4, 2004

Does Banks normally sound like a "used car salesman" type in his talks?

Khovanov Homology

November 8, 2004
Categories: Uncategorized

At his talk last year at the conference in honor of Gelfand's 90th birthday, Atiyah posed the question of whether there is a quantum field theoretic explanation of why the coefficients of the Jones polynomial are integers. Witten's Chern-Simons-Witten theory is a 3d QFT that computes the Jones polynomial (a topological invariant of knots or links inside a 3d manifold), but gives no obvious reason the coefficients should be integral.

One thing about the Chern-Simons-Witten story that has always bothered me is that, unlike his other TQFTs, this one is not of a homological nature. In the other TQFTs, the Hilbert space is finite dimensional because there are fermionic variables which cause cancellations such that only the homology of some complex contributes to the observables. To make any real sense of the idea of a path integral whose Lagrangian is the Chern-Simons functional, one has to do something like add a Yang-Mills term, then take a limit. By doing this one can move all but a finite part of the usual gauge theory Hilbert space off to infinite energy. It would be very interesting if there were a version of the theory which instead worked homologically like other TQFTs.

A hot topic in low dimensional topology recently has been the notion of "Khovanov homology", which associates to a knot a complex whose homology is the Jones polynomial. For an introduction to Khovanov homology, see papers by Dror Bar-Natan (a mathematician who was a student of Witten's) or Jacob Rasmussen. Bar-Natan has a lot of other material about Khovanov homology on his web-site.

One way of answering Atiyah's question would be to find a 4d TQFT whose Hilbert space is the Khovanov homology of the boundary. Maybe there is some sort of gauge-theory based QFT which generalizes the Chern-Simons-Witten theory and computes Khovanov homology. But after consulting the local expert on these things (Peter Ozsvath), it seems that no one knows whether it is even possible to reformulate Khovanov homology in any sort of gauge-theoretical terms. The only known definitions of it are kind of like the pre-Witten skein relation definitions of Jones polynomials. They are based on working with a projection of the knot onto two-dimensions.

A couple weeks ago Sergei Gukov gave a talk in the math department at UCSD with the title "Topological Invariants and Khovanov Homology", and perhaps his work has some relation to the above speculations.

Gukov is also the co-author of a paper that just appeared on the arXiv entitled "Topological M-theory as Unification of Form Theories of Gravity". Like M-theory itself, it appears that no one knows what "topological M-theory" is, but it is supposed to be some sort of seven-dimensional theory that is related to topological strings on 6d Calabi-Yaus in much the same way M-theory is a conjectural 11d theory related to 10d superstrings. Lubos Motl has even more questions about this than I do.

Proof of the Jacobian Conjecture

November 10, 2004
Categories: Uncategorized

The Jacobian Conjecture is one of the most well-known open problems in algebraic geometry. It now seems that a proof has been found by Carolyn Dean of the University of Michigan, for the case of polynomials in two complex variables (for more variables, many people believe it is not even true). For more information about this, see Graham Leuschke's weblog.

Dean hasn't published any papers in almost 15 years and is nominally a lecturer in mathematics education at Michigan. There have been many false proofs of this conjecture over the years, and if this one holds up it will be quite a story. The paper doesn't seem to be publicly available yet, but Dean will be lecturing on the proof at Michigan next month. One of the experts in the field, Mel Hochster, has gone over it carefully and is convinced it is correct. The rumor I hear is that it has been submitted for publication to the Journal of the American Mathematical Society.

Update: There's an announcement of Dean's talks posted on sci.math.research.

Update: Someone wrote in with a comment to another post pointing out that Dean has found a hole in her proof. For some more information about this, go here.

Comments

1. **Chris W.**
   November 15, 2004

   The contrasting examples of string theory and the Jacobian Conjecture (and the other notable recent achievements mentioned below) illustrate why physics is different, and arguably harder, than mathematics. Once a mathematical proof has been carefully reviewed and published it stands forever. One may argue about its significance, but one doesn't have to worry that it will be contradicted by existing or future observations.

   The other crucial point is that, as Shiing-shen Chern observed in an essay published during the Einstein Centennial year, mathematicians' problems, while often very difficult to solve, come to them more or less clearly formulated. In the natural sciences one must sometimes struggle for years to properly *formulate* the problem that needs to be solved.

   I would suggest that the epistemological pathologies of string theory stem from an inclination to evade those painful realities, knowing the enormous and often lonely dedication that went into the theory's early development. Also, one should consider the example of Einstein's lonely pursuit of a unified field theory in the latter part of his career, and the disdain with which he was treated by many younger researchers engrossed in the development of quantum mechanics and quantum field theory, with the support of an ample supply of experimental input. No one relishes being in Einstein's position for very long.

2. **Chris Oakley**
   November 15, 2004

   Did not Superstring theory come from a similar multi-year, fashion-resisting, career-endangering focus?

   It did, which only goes to show that when rebels become the establishment, they are even more reactionary than those they supplanted.

3. **Arun**
   November 14, 2004

   Did not Superstring theory come from a similar multi-year, fashion-resisting, career-endangering focus?

4. **mm**
   November 13, 2004

   One correction to the original post. There is no department of Math Education at Michigan. There is Math in LSA and there is the School of Education. Carolyn is a lecturer in the Math Department. Her research interests are listed as being in math education. Bass and Ball both have joint appointments in Math and Education. After she was denied tenure, she founded and initially was the director for MMSS, a summer program for high school students. I believe she has recently taught, among other things, honors calculus and math for future (elementary?) teachers.

   Carolyn had a postdoc at University of Chicago. She probably went to Michigan in 1989. She was definitely there in 1992.

   I agree with Graham's comments about tenure. It is perhaps bittersweet for Carolyn that she was aided in solving the Jacobian conjecture by being a lecturer at Michigan given that I am pretty sure that she was working on it while she was working towards tenure. Of course, it could just have been the passage of time. In any event, she could have chosen a research agenda with a shorter time horizon. Instead, she gambled and lost (the tenure game, at least).

5. **Graham**
   November 13, 2004

   As far as I know, Bass hasn't done any research mathematics in several years — he's been thinking about mathematics education, much of it with Deborah Ball. I would seriously doubt that he even knows Dean was working on JC.

   About Dean: I'm told that she has been at at Michigan since the mid-nineties, when she had a tenure-track position and was denied tenure. Her husband is also on faculty there (Stafford), which I imagine is part of the reason she's still there. I would be surprised if Michigan now hired her with tenure; it would be tantamount to admitting that they'd made a mistake. However, she is clearly a "serious mathematician", as one of your other commenters put it. The fact that she's not tenured does not detract in the slightest from her talent or skill or intelligence, only from her paycheck and job security.

   It is interesting that recent quantum leaps in mathematics have been due to people who showed exceptional ability to focus on one problem for years at a time, but it's certainly not surprising. In fact, this is in part what the tenure system is designed to encourage — having nothing to lose. If there were no such thing as tenure, Wiles would never have been able to devote years to working on the solution to an incredibly difficult problem — he would have had to show some progress on something in order to keep his job every year. Dean is in the same position for a different reason; she has nothing to lose because she's not regular faculty. Perelman, too — his position in St. Petersburg wasn't going to be taken away from him. Doing away with tenure isn't going to bring about this kind of freedom for everyone — for most of us, it would mean we'd have to work on simplistic problems that we knew we could publish on before the year's end.

6. **yuhan**
   November 13, 2004

   Peter,
   good to hear from you too.

   Actually I know little about Dean beyond some googling. And yes, I was wondering about the "tenure question" too which I'm sure must be a delicate one. But I didn't know that she had been thinking about the jacobian conjecture for several years. Tenacity!

   If I'm not mistaken, in some parts of europe there's more of math culture of keeping postdocs on practically indefinitely (at just slightly above a grad students level) and giving them a huge block of time to create a significant work. Is this correct?

   I must correct myself in my last post: Hyman is *both* at math and education at Michigan.

7. **Chris Oakley**
   November 13, 2004

   if you want grants, etc. you should be working on much shorter term projects. It's also remarkable that two out of three of these people didn't have a regular tenured position.

   Of the two functions of a University, namely teaching and research, the former IMHO tends to be done a lot better than the latter, possibly because it is easier to apply correction mechanisms when things start to go wrong. Research, OTOH, tends to be islands of excellence amid a sea of mediocrity, and the mediocre seems to be highly resistant to any attempt to reform it. I think that something needs to be done, but I am not quite sure what. My proposal was to abolish tenured positions. Then at least people who are useless will only allowed to be useless for a limited time. One of the most frustrating things possible for a young researcher with a new idea is people of this kind being in a position to block their every move. And these are tenured staff who more often than not would not be shortlisted if they were forced to reapply for their jobs. I do not believe that my suggestion would ever become a reality, but am interested to know whether those reading this blog (who I suspect may well be more critical of "the establishment" than average) either (a) think that there is a problem with academic research and (b) have any ideas as to what to do about it.

8. **Peter**
   November 13, 2004

   It is remarkable that the last decade has seen great progress in math (Wiles proving Fermat's Last Theorem, Perelman proving the Poincare Conjecture, now Dean the Jacobian Conjecture), all achieved by people willing to spend 7 years or more focusing on a single problem. That's not the way academic research is generally structured, if you want grants, etc. you should be working on much shorter term projects. It's also remarkable that two out of three of these people didn't have a regular tenured position.

   I think particle theory should learn from this. If some of the smarter people in the field would actually spend 7 years concentrating on one problem, the field might actually go somewhere instead of being dead in the water

9. **The Great Gazoo**
   November 13, 2004

   Does it seem strange that several conjectures have fallen in recent years due to mathematicians that have spent nearly a decade solely focusing on a single problem? This is an oddity isn't it? I mean don't mathematicians generally not pour all of their energy into one thing that may or may not pan out?

10. **Peter**
    November 12, 2004

    Hi Yuhan,
    Good to hear from you, and I'm glad you've been enjoying the weblog.

    I really don't know anything about Carolyn Dean, it sounds like you know more than I do. So I don't know whether Hyman was in any way involved in her work on the Jacobian Conjecture. It is an amazing story and a very impressive achievement. It will be interesting to see whether academia rewards her the way it should. Will Michigan give her a tenured position?

11. **yuhan**
    November 12, 2004

    Dear Peter,

    I've been a lurker, enjoying reading your blog, for some time now. But I am blown away by the news that Carolyn Dean proved the jacobian conjecture (not that I know her personally). I am wondering how she will be regarded — after all conventional wisdom has it that lecturers can't do research and here she has clearly outdone "serious mathematicians". She sure has a good brain and a good heart too considering her passion in running math summer camps for high school kids.

    Interesting thing is that our ex-columbian Hyman Bass, a key contributor to the jacobian conjecture, is also at Michigan but in the education dept. An internet search shows that Dean and Bass had contact in education forums. Any connection?

12. **Peter**
    November 10, 2004

    I don't know anything about Carolyn Dean personally, just that one place on the Michigan web-site refers to her as a "lecturer", another as a "visiting lecturer". As I'm quite well aware from personal experience, these kinds of titles can refer to all sorts of different kinds of actual positions. So the title doesn't tell you much, which is what I was awkwardly expressing.

13. **mm**
    November 10, 2004

    Just curious. What exactly did you mean by "nominally a lecturer"?

Provocative Comments From Veltman

November 10, 2004
Categories: Uncategorized

Martin Veltman gave a colloquium talk at Fermilab two weeks ago and, as usual, had some very provocative comments to make. At the end of his talk he made the claim that the only thing astrophysics has contributed to particle physics is information about the number of neutrinos (from Helium abundance observations). He claims "Apart from this, Astrophysics is so far useless to us."

He then gave some purported data about how particle physicists really felt about the impact of astrophysics and cosmology on their field. His slides say:

"Question put to many particle physicists: Do you feel that astrophysics and particle physics are joined at the hip?

Response:

Refusing to respond on the grounds that it is an obscene proposition (99.9%)
Do not know what you are talking about (9.671%)
Undecided (rest)

Questions put to particle experimenters:

Your experiment is justified by claiming that it will tell us about the first seconds of the big bang. Do you agree?

Response:

No (98.312%)
Do not know what you are talking about (1.671%)
Undecided (rest)

Do you feel that we need a new machine (linear collider) because it can be used to discover dark matter (dark energy)?

Response:

No (98.312%)
Do not know what you are talking about (1.671%)
Is this related to the death star of Darth Vader? (3%)
Undecided (rest)"

I think Veltman has a very good point. The particle physics community seems to have decided to try and sell the public on supporting particle physics, specifically a new linear collider, by claiming that such a machine will "solve the mystery of dark energy", find "extra dimensions of space", and tell us "how the universe came to be" (see for instance the HEPAP Quantum Universe report). This all sounds very sexy, but there's no good reason to believe that a linear collider will do any of this. Maybe this is the right way to sell the linear collider, but personally I'm rather uncomfortable with this level of hype and wouldn't want to be the one testifying under oath before Congress about this.

Veltman also comments that "It appears to me that the only viable solution is that this machine will be located in the US", but given the massive deficit the Bush administration has created and current political realities, I find it hard to believe we'll see the kind of budget increases for particle physics that would be required to make this happen anytime soon.

   November 18, 2004

   Since in 1 dimensions everything is pretty simple these susy field theories in 1+0 dimensions are not awfully exciting and you can get away with ignoring the susy that appears here.
   Or you may be inspired by it.

   The question is for how many years, decades and centuries inspiration is enough. Signatures for supersymmetry have had ample opportunity to show up in quite a few different types of experiments, in the 1/3 century that has passed since SUSY was proposed. No such signatures have been found. A common way of summarizing the experimental situation is to say that SUSY requires fine-tuning on the percent level. This seems like a serious critique of an idea which was mainly meant to cure fine-tuning.

   Anyway, we evidently have different opinions about how much inspiration should be constrained by experiments. I would like to know one things, though. The discovery of sparticles at the LHC would obviously be a great triumph for SUSY, and it would prove me dead wrong in many ways. But do you think that the non-discovery of sparticles at the LHC would in any way lessen the promise and importance of SUSY?

2. **D R Lunsford**
   November 18, 2004

   ,

   Thanks, that was very interesting, and you have an excellent way of explaining things (I imagine because you actually understand it).

   -drl

3. November 18, 2004

   Hi DRL –

   Ok, well, I am not going to try to further explain why {D,D} = 2Box is the algebra of worldline susy. Whoever does not believe it should check the standard literature.

Concerning your question:

There is nothing artificial (‘clever’) going on, I think. The point is that the standard Polyakov-like action of the single free relativistic particle is, when regarded as a theory defined on the worldline, a 1+0 dimensional field theory of a couple of bosonic fields (the coordinate fields) coupled to a lagrange multiplier in such a way that the whole thing can be regarded as 1+0 dimensional gravity coupled to massless scalars plus a ‘cosmological’ constant – on the worldline.

This is just a fact. This action is there and it describes known physics (for instance you can compute QFT loop amplitudes *in target space* from it) and it has this interpretation as a 1+0 dimensional field theory.

When this 1+0 dimensional field theory is susy-ed, which means that in addition to free bosons we allow free massless fermions propagating on the worldline, it gives us the action for single fermions in target space.

Up to this point one is firmly in the realm of known physics. All that has happened is that one has realized that single particle trajectories have field theoritic descriptions on the worldline – and supersymmetric field theories in particular. (Check Siegel’s book for instance for the superfield formulation of them.)

Since in 1 dimensions everything is pretty simple these susy field theories in 1+0 dimensions are not awfully exciting and you can get away with ignoring the susy that appears here.

Or you may be inspired by it. Turns out that in 1+1 dimensions susy field theories are still pretty simple, but taken as theories on the parameter space of single objects again (as we did before for the worldline), they are not just a curiosity but give rise in target space to perturbatively quantized superGR+YM.

This automatism that you cannot have a worldsheet which describes target space fermions without having it supersymmetric and hence have the target space theory supersymmetric is the reason why people say that string theory ‘predicts’ supersymmetry.

But one has to interpret this carefully. Just having the target space theory being supersymmetric (locally) does not mean that its physically relevant solutions exhibit this symmetry, as you know. Hence while the assumption of strings sort of ‘predicts’ that the world is locally supersymmetric, it does not (necessarily) say anything about the observability of globally supersymmetric solutions (which would give rise to superpartners observable in accelerators).

So, to make it very clear once again: Nothing of what I have said here is meant as a proof that target space supersymmetry exists. But since worldline supersymmetry does exist (since it is so trivial) the concept of supersymmetry seems very natural from some point of view. Even more since in 1+1 dimensions worldsheet susy does imply target space susy (while in 1+0 dimensions it only implies target space fermions.)

Make of that what you want.

4. **D R Lunsford**
November 18, 2004

“Bow out?” Why? this is very interesting and at least for me informative.

RE p. 134 – OK fine, now I see what you were getting at – but isn’t this just a clever jamming together of actions, one of which alone would lead to the Dirac (neutrino) equation and the other to a free classical particle?

-drl

5.
November 18, 2004

As I said, when you go from the vector fields to their Noether charges of the sigma model you get the quadratic terms (like (partial phi)(partial phi) for the Polyakov action).

The Dirac operator as well as its square that we are talking about all along are Noether charges of a sigma model action that come from vector fields of the sort that you are talking about.

As I said, you should consider the simple case of nonrelativistic supersymmetric quantum mechanics to clarify the picture.

There is one of your vector fields, namely d_t on the worldline. Its charge is the Hamiltonian H. You can write down the square root of d_t as usual, to get the ‘covariant’ superderivative D that satisfies {D,D} = i d_t . The charge associated with D is the supercharge Q. This has Poisson bracket {Q,Q} = 2H, giving the same algebra as your vector fields.

To summarize:

There are symmetry generators which are vector fields on super-parameter space and satisfy

{D,D} = i d_t ,

where the bracket is the super-Lie bracket of super-vector fields

These have associated conserved charges which have the Poisson bracket

{Q,Q} = H ,

which is the same algebra as that of the symmetries they come from (which is no surprise).

For the relativistic particle it is precisly analogous, only that here t becomes an unphysical parameter tau and H becomes a constraint (the KG operator).

All this is elementary and standard. I’ll bow out at this point.

6. **Thomas Larsson**
November 18, 2004

The {D,D} = 2Box algebra is just a truncation of the super-Virasoro algebra and there, too, as you know, L + \bar L is quadratic in derivatives.

There is some confusion here. The even generators of the super-Virasoro algebra are the vector fields
L_m = z^(m+1) d/dz + f_m z^m \theta d/d\theta,
which are first order (I don’t want to work out the constants f_m). L_0 is certainly not second order, not even if you add \bar L_m.

In fact, the superconformal algebra is the algebra of vector fields in superspace which preserve the contact one-form
\alpha = dz + \theta d\theta
up to a function. Vector fields are always first-order differential operators; this is the definition of a vector field.

We can also realize super-Virasoro as an infinite sum of bilinears, like
L_m = sum_n :a_n a_(m-n): + (n + km) :b_n c_(m-n):
i.e. as a subalgebra of gl(infinity). These may be viewed as vector fields acting on an infinite-dimensional vector space whose coordinates are modes with positive energy (m>0), and the negative-energy modes are derivatives. With that interpretation, some of the L_m's contain terms that are zeroth or second order, but L_0 only contains first-order terms.

7.
November 18, 2004

Danny –

Read on to p. 134. See exercise IIIB1.2 .

8. **D R Lunsford**
November 17, 2004

,

RE p. 132 of Siegel – all I see is typical particle actions on a trajectory. What does this have to do with KG and "adding Fermions"?

-drl

9. **Plato**
November 17, 2004

Thomas,

Regarding the third string revolution: a minimal requirement for a something to qualify as a revolution is that outsiders notice it. Most physicists of all kinds noticed that many particle theorists started to talk about strings in 1984, about branes in 1994, and about antropic selection in 2003. Much fewer outsiders, if any, has noticed the emergent spacetime.

—

Lubos,
What do you think will be the main ideas which will propel the "third" superstring revolution starting next year? Hopefully it will be something which does not involve the anthropic principle.
Posted by JC at October 9, 2004 10:24 AM

I have to give credit where credit is duein reference to Third Superstring Revolution

Identifyng this translation is necessary?

10.
November 17, 2004

Thomas –

don't mistake the symmetry generators in the Lagrangian, like partial_mu, with their corresponding Noether charges which generate them by means of Poisson brackets. Box is the (quantized) Noether charge of the partial_tau translation symmetry on the worldline and has no reason to be linear in derivatives.

So sure {D,D} = 2Box is a susy. Box is the wordline ADM Hamiltonian. And you really new this: The {D,D} = 2Box algebra is just a truncation of the super-Virasoro algebra and there, too, as you know, L + \bar L is quadratic in derivatives.

I bet once you think about this in terms of the nonrelativistic particle this becomes clearer: The Hamiltonian is quadratic in the momenta and still it generate time evolution.

And if you like, you can surely do some field theory using just worldlines, just like you compute string amplitudes just using worldsheets. This is known as the 'worldline technique' for field theory. See for instance vanHolten's hep-th/9408027 and references given there.

DRL –

N is a Lagrange parameter, the lapse function on the worldline, i.e. the single component of the worldline metric. It's presence makes this action equivalent to the (maybe more familiar?) NG-like action of the free particle.

All this is explained in introductory textbooks. For instance look at pp. 132 of Warren Siegel's book "Fields", which you can download for free at

http://www.imsc.ernet.in/physweb/Fields.pdf

11. **Thomas Larsson**
November 17, 2004

Particles on a world-line is first quantization – that formalism cannot account for creation and annihilation of particles. People invented something called quantum field theory to cure that defect in the late 1920s.

To consider the appearence of superalgebras as a hint of SUSY seems to me like a very long shot. {D,D}= Box and Box commutes with everything is a superalgebra, which is relevant for fermions and spinors whose physical relevance nobody has denied. This is not a supersymmetry because the d'Alembertian is a second-order differential operator, whereas in {Q,Q} = P_mu the RHS is a translation, i.e. first order.

However, I appreciate that people try to apply beautiful mathematical structures to physics, although most of the beauty of SUSY is inherited from its superalgebra structure. In fact, I discovered the higher-dimensional generalization of the Virasoro algebra because I wanted to apply it to quantum gravity. We now know that such an algebra exists and that it has a wonderfully beautiful representation theory which seems to fit the needs of quantum gravity exactly. This indicates to me that my original physical motivation was correct. So mathematical beauty is certainly an important search criterion, but it can never be a success criterion by itself. Even if EW says that it is magic and mystery.

It would of course be nothing wrong with SUSY, had it been seen in experiment. However, there are just too many experiments that should have seen signatures of SUSY but did not. The absense of sparticles is the most obvious one, but SUSY also suggests a light Higgs, proton decay, permanent electric dipole moments, WIMPs, a deviation in muon g-2, etc. None of these things have been seen, at least not conclusively, which to me is a clear indication that SUSY just isn't there.

I guess that my position is similar to Veltman's, expressed e.g. at the end of his book:
"The fact is that this book is about physics, and this implies that the theoretical ideas discussed must be supported by experimental facts. Neither supersymmetry nor string theory satisfy this criterion. They are figments of the theoretical mind. To quote Pauli: They are not even wrong. They have no place here."
I didn't make up this quote; it can be found in one of the reviews at the amazon.com link. Do you really think that you or your physics professor are competent enough to question the opinion of a Nobel laureate in theoretical particle physics?

Regarding the third string revolution: a minimal requirement for a something to qualify as a revolution is that outsiders notice it. Most physicists of all kinds noticed that many particle theorists started to talk about strings in 1984, about branes in 1994, and about antropic selection in 2003. Much fewer outsiders, if any, has noticed the emergent spacetime.

12. **D R Lunsford**
November 16, 2004

..so this L is 1/2N (ds^2 – m^2 N^2) ?

What happened to (grad N)^2 (Klein-Gordon)?

-drl

13.
November 16, 2004

Do you understand how the Klein-Gordon particle is described by the action

S = (1/2)\int dtau (N^-1 \dot X^m \dot X_m – Nm^2)

and how this action can be regarded as 1+0 dimensional 'gravity' coupled to scalar 'matter' (just formally)?

14. **D R Lunsford**
November 16, 2004

No I don't – "what" are you "adding", and to "what"? Explain it to me, without repeating the last two posts. Just jot down a few comments and I'll interpolate.

From my perspective, a Dirac particle is a solution to the Dirac equation in the usual Fock space treatment. It is a primitve object. Explain to me how it is not a primitive object. I don't know what you mean by "on the world-line" and so on.

-drl

15.
November 16, 2004

Do you know how the relativistic bosonic particle is described by a field theory of massless bosonic fields on the worldline (a 1-dimensional sigma-model)?

If you add massless fermions to such a field theory on the worldline it becomes supersymmetric on the worldline (a 1-D susy sigma model) and now describes fermions in target space instead of (or in addition to, depending on some details) bosonic particles.

16. **D R Lunsford**
November 16, 2004

a) if you regard the massless Klein-Gordon particle as a 1+0 dimensional bosonic field theory on the worldline and add fermionic fields on the worldline to it in order to get target space fermions (the Dirac particle) the worldline theory automatically becomes supersymmetric..

Umm.. what exactly does this mean?

-drl

17.
November 16, 2004

Thomas –

recall the previous discussion. Steve M said about
superalgebras appearing in nuclear physics:

> This doesn't 'prove' supersymmetry of course but makes its realisation in nature in particle theory, seem a whole lot more likely.

It was then said that if you are willing to take the mere appearance of superalgebras as a hint that supersymmetry will play a more important role (which you, Thomas, are not, but others might be) that then it would be 'more' interesting to consider worldline susy which indeed exists.

As you indicate by your reaction, and as was not disputed by anyone, this worldline susy is rather trivial and hardly a hint for anything.

But some people may find it amusing to note that

a) if you regard the massless Klein-Gordon particle as a 1+0 dimensional bosonic field theory on the worldline and add fermionic fields on the worldline to it in order to get target space fermions (the Dirac particle) the worldline theory automatically becomes supersymmetric

b) if you regard the bosonic string as a 1+1 dimensional bosonic field theory and add worldsheet fermions to it in order to get target space fermions the worldsheet theoy automatically becomes supersymmetric (this is how susy was found in the western hemisphere) and is quantumly consistent only if the target space solves susy GR+YM

c) if you regard the bosonic membrane as a 1+2 dimensional bosonic field theory and add worldsheet fermions to it in order to get target space fermions the worldvolume theory becomes supersymmetric and is classically consistent only if the target space solves susy GR+YM .

This is not a proof for anything and if you don't like it you are welcome to ignore it.

Others may find it noteworthy that while spacetime susy is a delicate issue, woldvolume (-line, -sheet) susy is inevitable, since in low dimensions adding massless fermions to massless bosons is (almost) bound to give susy, as is exemplified by the boring old Dirac particle. And here a small step in parameter space (going from 1+0 to 1+1) is a large step in target space (going from nothing at all to susy-GR+YM).

18. **Plato**
November 16, 2004

Thomas,

Plato, the Third Superstring Revolution, also known as the Anthropic Revolution, happened in 2003. The interpretation is that experimental agreement is now irrelevant. String theory is correct even though it disagrees with observation, because God created the Universe to be compatible with human life.

One thing I can tell you, though, is that most string theorist's suspect that spacetime is a emergent Phenomena in the language of condensed matter physics.**Witten**

I developed a post today on my blog, in response to your statement. Sometimes, the very language one uses, orders the sequences of thought in another way? I present this to you in this light, and hope you will read post when it materializes later.:) I am learning.

The substance of the official **Third Superstring Revolution** was posted on this Blog and officially(I recogize your statement) raises the line I have used of Witten.

Would you agree to entertain the **Third Superstring Revolution** in this way?

I might ask you then, that if this language had been changed, then what would the professor crossing the room mean? One would have look to what is materializing from condensed matter physics, by what is being presented, by Robert Lauglin. You see?

19. **Thomas Larsson**
November 16, 2004

Anonymous, the electron can to a good approximation be considered a free Dirac particle. The electron was discovered in 1895 and supersymmetry around 1970. Maybe this is an indication that having a Dirac particle is not sufficient for supersymmetry. However, I find it quite likely that electrons will be found at the LHC. If you wish, you may hail that as proof for supersymmetry.

Plato, the Third Superstring Revolution, also known as the Anthropic Revolution, happened in 2003. The interpretation is that experimental agreement is now irrelevant. String theory is correct even though it disagrees with observation, because God created the Universe to be compatible with human life.

20.
November 15, 2004

Hi DRL, {D,D} = 2 Box ! 🙂

21. **Plato**
November 15, 2004

Is it nice that Veltman recieved award with Gerard t Hooft in 1999? Is this correct?

IN response to Peter's post I posted about five threads in relation to what Peter and others might reconsider, as to the question of how we might look at quantum computerization(non)?

With the Third Superstring Revolution, what shall emerge from a change in Fundamental interpretation of Quantum Mechanics?

22. **D R Lunsford**
November 15, 2004

I'm sorry, but there is no Bosonic context for a Dirac particle. There is the old "neutrino theory of light" but those are not Fermions because of an implicit correlation that ruins the statistics.

Perhaps you could scribble here a few lines about the claim *infra*.

23.
November 14, 2004

If one really wanted to see 'formal' evidence for spacetime supersymmetry as in

> 'Superalgebras play a role here and there in physics, hence they are likely to also play a role in HEP.'

I would suggest to take the Dirac particle. It has worldline 1+0 dimensional N=1 supersymmetry in the 'right' sense. There is a Hamiltonian constraint which generates time evolution (the Klein-Gordon operator) and the Dirac operator is the corresponding supercharge.

This might be a coincidence of low dimensions. But one might take it as a 'hint' for spacetime susy that by just going from this worldline susy to an analogous worldsheet susy yields spacetime susy GR+YM .

24. **Thomas Larsson**
November 13, 2004

By definition, a Lie superalgebra is like a Lie algebra, except that some brackets are fermionic, so

[even, even] = even

[even, odd] = odd
{odd, odd} = even

A supersymmetry is a particular kind of superalgebra where some of the even generators can be identified with spacetime translations. Whereas superalgebras are a very beautiful and far-reaching generalization of Lie algebras, the extra translation condition that makes it into a supersymmetry does not seem particularly interesting.

But the two concepts are often blurred, as in the case of gold nuclei. One reason seems to be that supersymmetry has been more heavily sold.

25. **D R Lunsford**
November 12, 2004

I dont' see how you can have half a ball of wax. Please explain? How is it a superalgebra if

{Q, Qdot} not = some kind of translation

Perhaps I missed the definition of superalgebra.

-drl

26.
November 12, 2004

Yes, this 'supersymmetry' operation between nuclei has nothing to do with whether the (effective) field theory that describes the particles and interaction in our world enjoys symmetry under a graded extension of the Lorentz group (locally).

Graded algebras and Grassmann parameters are just concepts useful enough that they show up all over the place, not necessarily in the context of supersymmetry in high energy physics.

For instance in statistical physics many people will tell you that they are using 'supersymmetry methods' to evaluate their free energy or something. What they really do is conveniently express determinants as Grassmann integrals. So this method should rather be called a 'BRST-like method'. It has nothing to do with spacetime supersymmetry, either.

Of course some people feel inclined to argue that any piece of sufficiently nice mathematics should play a role in a TOE…

27. **Thomas Larsson**
November 12, 2004

To answer drl's question regarding what physical evidence points to supersymmetry, "nuclear supersymmetry" has been observed and verified experimentally. At Yale in 1990 it was suggested that supersymmetry effects might be seen in nuclear physics. A super-algebra was proposed that allows a nucleus with even nos of protons and neutrons(even-even), 2 nuclei with even nos protons/odd nos. neutrons (even-odd)and odd nos protons/even nos neutrons (odd-even), and an (odd-odd) to transform into each other via this supersymmetry algebra. Platinum-194(even-even), gold-195(odd-even) platinum-195 (even-odd) and gold 196(odd-odd)form such a supersymmetric quartet.

From what I've heard, this is not a supersymmetry, but rather an internal superalgebra symmetry. No bosonic subalgebra can be identified with spacetime transformations, which is the definition of a supersymmetry. An internal superalgebra symmetry does not necessarily imply superpartners of equal mass.

A genuine supersymmetry seems to exist in the tricritical Ising model in 2D, however; this is the CFT with c = 7/10. It is unclear to me what this supersymmetry corresponds to in experimental realizations such as a monolayer of Argon atoms on an inert graphite substrate.

Finally, I doubt that Lubos Motl will stay in his restroom for the rest of his life when no sparticles are found at the LHC. On the contrary, he will aggressively explain how absense of sparticles and extra-dimensions confirms that string theory is correct.

28. **D R Lunsford**
November 12, 2004

Steven M,

That's interesting, it means that SuSy works as a dynamical symmetry (like say isospin for a simple nuclear model). Of course it doesn't imply that the actual Bosons and Fermions of the world are related this way.

In the experimental situation described, how does the anticommutator

{Q_r, Qbar_sdot} = 2 sigma^a_r_sdot P_a (P_a = translation)

show up physically?

29. **Anonymous**
November 11, 2004

I don't want to comment on how much particle physics
has contributed towards astrophysics. One thing however is certainly true. in the last decade many experimental high energy physicists have switched over to astrophysics/gravitation experiments such as LIGO, GLAST, supernova csomology, CMB
experiments, TeV gamma ray astronomy experiments,
uhe cosmic rays, etc.
If no evidence for physics beyond the standard model is found by the time LHC starts I
expect more high energy physicists to switch over
to astrophysics. Also both Fermilab and SLAC
have set up astrophysics groups.
OTOH I don't know of a single example of an astronomer switching over to experimental high energy physics or
national astronomy institutes such as NRAO setting up a high energy physics group.

30. **Mubos Lotl**
November 11, 2004

Lubos Motl said: “I don’t care too much about dark matter – and I would agree with Veltman that the influence of astrophysics on theoretical high-energy physics has been small”.
Just to clarify: we string theorists don’t really care about dark matter and ESPECIALLY — Sean — we don’t care about so-called dark energy. String theory clearly favors a negative cosmological constant, so all current observations suggesting a positive one are clearly wild monkey speculations that have no connection with reality. String theory likewise says nothing at all about dark matter, so obviously it doesn’t exist.

31. **Steve M**
November 11, 2004

To answer drl’s question regarding what physical evidence points to supersymmetry, “nuclear supersymmetry” has been observed and verified experimentally. At Yale in 1990 it was suggested that supersymmetry effects might be seen in nuclear physics. A super-algebra was proposed that allows a nucleus with even nos of protons and neutrons(even-even), 2 nuclei with even nos protons/odd nos. neutrons (even-odd)and odd nos protons/even nos neutrons (odd-even), and an (odd-odd) to transform into each other via this supersymmetry algebra. Platinum-194(even-even), gold-195(odd-even) platinum-195 (even-odd) and gold 196(odd-odd)form such a supersymmetric quartet. Given the energy spectra of gold-196 the supersymmetry algebra gives the spectra for the other 3 nuclei in the quartet. Verified in the lab now by several groups. Other supersymmetric nuclear quartets have been found. This doesnt “prove” supersymmetry of course but makes its realisation in nature in particle theory, seem a whole lot more likely.
See
http://physicsweb.org/articles/world/12/10/3

32. **Hacik**
November 11, 2004

I believe expectations for the top quark mass were always “just around the corner”, creeping upwards year after year, until it was finally found. So there’s still hope.

33. **Matthew**
November 11, 2004

Just to rain on Lubos’s parade a little bit, most of the phenomenology talks here over the past couple of months have started out with why the current bounds on the Higgs mass strongly disfavour the MSSM. They don’t rule it out, but it’s strongly disfavoured.

My understand of the history is that SUSY has been “around the corner, next accelerator” since it was first dreamed up.

34. **Plato**
November 11, 2004

I thought I would add this in the hopes of “expanding” current limitations in matter considerations.

http://eskesthai.blogspot.com/2004/11/sound-waves-in-cmb.html

35. **D R Lunsford**
November 11, 2004

So Motl,

What physical evidence points to SuSy? Name one thing. One.

-drl

36. **Lubos Motl**
November 11, 2004

Of course that it will be shocking when SUSY is found. It will be so shocking that the people who have fought against SUSY will have to hide in their restrooms for the rest of their lives, Thomas. 🙂

At least I can’t really imagine how could you be able to appear publicly on the internet after your teachings will be devastated beyond reasonable doubts, and after everyone will see that you were trying to return the humakind to the Middle Ages. 😉

Moreover, it’s pretty likely that it will happen! SUSY is gonna be found, it will be dramatic, and string theorists are ready to take credit for it. 😉

37. **Thomas Larsson**
November 11, 2004

It’s easy to be provocative, as we know. If Veltman doesn’t think that astrophysics has contributed to particle physics, he must not care about the discovery of the muon, evidence for non-baryonic dark matter, dark energy, neutrino masses and mixings, constraints on everything from time-dependence of alpha to the mass of the photon, and just about all of general relativity. In the last thirty years, astrophysics has contributed enormously more to particle physics than ground-based experiments have.

In the last 30 years? Since November 1974? Even if you discount the J/psi, do you really think that beauty, top, W, Z, and the tau neutrino are nil? It may be easy to be provocative. Perhaps it’s also easy to win a Nobel, like Veltman.

38. **Sean**
November 11, 2004

It’s easy to be provocative, as we know. If Veltman doesn’t think that astrophysics has contributed to particle physics, he must not care about the discovery of the muon, evidence for non-baryonic dark matter, dark energy, neutrino masses and mixings, constraints on everything from time-dependence of alpha to the mass of the photon, and just about all of general relativity. In the last thirty years, astrophysics has contributed enormously more to particle physics than ground-based experiments have.

Of course you still need colliders at the energy frontier, and it’s misleading (although not completely dishonest) to sell them through the connection to cosmology. Denying that there is a connection is just dishonest.

39. **Thomas Larsson**
November 11, 2004

Lubos,

but of course I do care about the superpartners, if they exist, and/or the extra dimensions which would be even more shocking if they could be seen.

So it would be shocking if superpartners were seen? OK, I might agree on that, but I'm surprised that you think that it would be shocking if you won your experimental-susy-at-the-LHC bet.

Of course a linear collider must be built. I don't really care where, but it would be a disaster if this project were lost like the SSC, or apparently unable to produce any relevant information like Tevatron II. It is most likely the last big collider to be built in my lifetime.

40. **Plato**
November 11, 2004

Well I am on the outside looking in.:)

What value would Iscap be to the population of scientists then, and for that matter, subjects that would treat Bekenstein Bound, in relation to spin networks. You would have to throw John Baez in the bunch?

Would mathematicains then be left in abstract spaces not theoretically developing theIr math along side of the physics?

41. **Lubos Motl**
November 11, 2004

Of course that the linear collider would be built in order to learn the mind of God in the most scientific way possible. Do you think that these billions of dollars would be spent to learn the mind of Peter Woit? No! No one smaller than God is relevant in this game. 😉

Moreover, the linear collider has many advantages over the synchrotrons like the LHC. The latter is a hadronic machine, and the collisions are pretty dirty and most of the events are just pure QCD. Even if SUSY is seen, it may be pretty difficult to measure various parameters on the LHC.

On the other hand, the lepton machines are much better to measure the energy of all the particles in the game, and the date are sharper. It is hard to imagine that a useful new lepton machine could be built as LEP, and the natural step after the LHC is therefore a linear collider.

The linear collider would provide us with completementary information compared to the hadronic machines. I don't care too much about dark matter – and I would agree with Veltman that the influence of astrophysics on theoretical high-energy physics has been small – but of course I do care about the superpartners, if they exist, and/or the extra dimensions which would be even more shocking if they could be seen.

42. **Thomas Larsson**
November 11, 2004

I'm not so sure. The SSC was supposed to uncover the God particle, but it was cancelled anyway.

43. **Hackticus**
November 10, 2004

Physicist should just start sayin that their accelerators will "probe the mind of God" or somthin, they'll get all the money they want from this gumint. I'm sure Lubos would be happy to testify before Congress.

QCD and String Theory at the KITP

November 18, 2004
Categories: Uncategorized

The KITP at Santa Barbara is holding a conference on [QCD and String Theory](#) this week, and the talks have started to appear online.

Of the ones I've taken a quick look at so far, there doesn't seem to be any obvious recent progress on the 30-year old main question that everyone would like the answer to: can one find a reliable analytical technique for dealing with QCD in the infrared regiion where the effective coupling is strong? The best hope for this in recent years has been the AdS/CFT correspondence, but after seven years the state of the art there still seems to be a long ways from solving the problem one wants to solve (although it does give solutions to other problems). I'm looking forward to seeing what some of the later talks will have to say, including Larry Yaffe's one tomorrow on "Large N gauge theories: old and new".

Comments

1. **BEB**
   November 19, 2004

   Actually, contrary to what Strominger and Motl may think, some physicists (even string theorists!) do consider it to be among the "top ten "millenium problems" posed:

   "Can we quantitatively understand quark and gluon confinement in Quantum Chromodynamics and the existence of a mass gap? "

   http://feynman.physics.lsa.umich.edu/strings2000/millennium.html

   Most of the other problems seem to be string theory inspired, and some (like 1 and 7) frankly not answerable, IMHO. They do not have the flavor of Hilbert's problems of really encompassing the breadth of the subject. I would have expected a better list.

   What are some of the more important subjects to pursue? String "phenomenology"? Glad I am not the one being brainwashed and be led astray.

2. **Peter**
   November 18, 2004

   The problem with QCD isn't that there's no rigorous proof of confinement, it's that there's no controlled analytical approximation that captures what is going on in the theory at long distances. Lacking this, there's a real sense in which we don't understand quantum gauge theories. For QCD itself, maybe we don't care that much since we have lattice calculations, and the evidence for the theory is so overwhelming we don't really need to extract more predictions from it to compare with experiment.

   But it's an important part of physics and we really should be able to understand what is going on there. The best bet for this kind of understanding has always been to find a consistent 1/N expansion of the theory, probably using string theory methods. AdS/CFT is tantalizingly close to getting somewhere with this, it's surprising to me there hasn't been more progress recently. I don't think Strominger is helping the situation if he is dismissing the importance of this problem and encouraging students instead to concentrate on the doomed project of unifying the Standard Model and gravity via some sort of 11d supersymmetric M-theory.

3. **Lubos Motl**
   November 18, 2004

   One thing that Peter is not able to appreciate is that the character of the *important* questions is changing with time, as our understanding becomes deeper.

   In fact, this question of confinement was *exactly* the example used by Andy Strominger last week when he was explaining the situation of string theory to the new grad students.

   He said that when he was a student, the most important question in theoretical physics was to prove that QCD confines at low energies. "It's still an interesting question and you may get 1 million USD from the Clay Institute if you solve it," Strominger said, but he explained that we simply have overwhelming evidence that confinement is true and QCD works, and we must simply move on.

   I totally agree with Strominger on this point. There are many other important questions whose answers we really do not know, and answering them would be much more important than to find a rigorous proof of some answers that we're anyway pretty sure that are correct.

4. November 18, 2004

   That pretty much summarizes all progress in string theory since the 1980's: never solving the problems you thought you wanted to solve, but finding solutions to problems it never occured to you to ask.

String Theory and Philosophy

November 18, 2004
Categories: Uncategorized

From Sean Carroll's weblog I see that he's in Austin now for a session at a meeting of the Philosophy of Science Association. Philosophers of science seem to actually write up their talks in advance, and many of the talks for this meeting are already available online. Poking around on their website with papers from earlier conferences, I ran into one on Scientific Realism and String Theory by Richard Dawid.

Dawid appears to have swallowed the hype about string theory hook, line and sinker. He believes that string theory exhibits a new paradigm of how to do physics, one where the idea of being able to calculate anything about the real world and compare it to observations is passe. All that matters now is "theoretical uniqueness", that one's theory is the only possible one. He doesn't seem to notice that there's something kind of funny about people claiming that they have a wondrous unique theory, but don't know quite what it is and can't calculate anything about the real world with it. The S-matrix theorists of the 60s also promoted the idea that they had a wondrous unique theory, but didn't know quite what it was. Probably one can dig up philosophy of science articles from that period about how a whole new paradigm of how to do science was required.

Dawid also seems to believe that the dualities of M-theory imply the "dissolution of ontology", that "the ontological object has simply vanished". In reality, what has vanished is not the ontological object, but the theory.

Over at Robert Helling's web-site you can read an example of the latest philosophical excuses about why string theory now can't predict anything, together with implausible wishful thinking about how this might change since "It's just at this stage we are not yet powerful enough to make these kinds of predictions".

For the life of me I can't figure out why smart physicists and philosophers can't see the obvious fact that is staring them in the face. You don't need a new paradigm of how to do science, the old one works just fine. If you have a conjectural theoretical scientific idea, there are two ways in which it can turn out to be wrong. Either it predicts something that disagrees with experiment, or it is so vacuous that it predicts nothing. The evidence is now overwhelming that, if string theory is consistent at all, it is wrong for the second reason.

Update: Dawid actually has a whole fancy web-site about Realism and String Theory. He also has a newer paper on Undetermination and Theory Succession from a String Theoretical Perspective.

The PhilSci archive does have another paper about string theory, one by Reiner Hedrich entitled Superstring Theory and Empirical Testability. Hedrich is much less credulous than Dawid, noting about superstring theory "above all, it has fundamental problems with empirical testability – problems that make questionalbe its status as a physical theory at all."

   November 21, 2004

   Arun,

   As noted earlier in Peter's blog, there are recent mathematical advances which required concentrated work for several years of silence for the authors.

   There is no doubt in my mind the contemplative thinking asks that we recognize the essence of any equation, and a lot of times. The mind clicks a notch, when sitting by a stream(ask witten), and the mind had disassociated itself, from such efforts.

   There is a always a incubative time for consideration, as you quote saids. I thought, all mathematicians had good focus?

2. **Arun**
   November 21, 2004

   Are there reasons other than the overselling of string theory that the situation hold that Peter describes?

   For instance, perhaps string theory presents research problems that are more likely to reach fruition in one post-doc term than other areas?

   As noted earlier in Peter's blog, there are recent mathematical advances which required concentrated work for several years of silence for the authors. Are there sociological factors operating in physics that preclude the kind of work that might be needed for such breakthroughs?

3. **Thomas Larsson**
   November 21, 2004

   Steve M.,

   Peter is of course completely capable of answering for himself, and has already done so. My perspective is somewhat different, in that I have a well-developed suggestion for the missing mathematical structure.

   Let's also assume absence of any new experimental guidance, then what alternative mathematical structures or approaches in our opinion (ie non string theory) would have enabled a viable leap (or even step) beyond the SM or GR? I assume you would approve of deeper investigation into the mathematical underpinnings of the SM like gauge fields/YM and Dirac operators, but people have looked (are looking) at this anyway surely?

   I have looked one particular mathematical underpinning of the SM and GR since 1987, but despite rather remarkable progress the physics community has been completely uninterested. From this I have concluded that people who already know the correct Theory of Everything have simply no interest in learning about new mathematics, not in the 80s and not now. Mathematicians have in my experience always been much more open-minded, perhaps because everything that I have done has also been worked upon by some mathematicians because of its intrinsic mathematical interest.

   More precisely, I'm talking about the quantum representation theory of the correct constraint algebras of GR and the SM. The constraint algebra (in covariant formulations) of GR is the group of 4-diffeomorphisms, and the constraint algebra of the SM is the group of gauge transformations based on SU(3)xSU(2)xU(1). Upon quantization these algebras acquire quantum correction, making them into higher-dimensional analogues of the Virasoro and affine Kac-Moody algebras. That such algebras exist, and that they have an interesting representation theory is by itself some kind of mathematical success.

   This goes beyond field theory, because a 4D Virasoro algebra is a diffeomorphism anomaly in 4D, something which can not exist within field theory. Nevertheless, there are no assumptions about new physics here. 4-diffeomorphisms and SU(3)xSU(2)xU(1) gauge transformations are simply the correct constraints of GR+SM. So one reason why people have failed to go beyond GR+SM might be that there isn't anything there; at least there are no conclusive experimental hints. There are some well-known mathematical problems, e.g. that GR and QM are inconsistent and that the SM is somewhat ugly (although by no means as ugly as string theory), but this may well be explained by the fact that people have missed the existence of the relevant anomalies.

In the absence of experimental guidance in 25 years now surely all possible alternatives are just wishful thinking too and can't make any predictions either? Everything else that has ever tried to go beyond the SM and GR has run into their own technical brick walls too so you can't really just single out string theory esp when it was the most promising.

I don't think that loop quantum gravity is particularly promising neither. However, when evaluating the promise of an approach it is not fair only to judge the physical achievements (string theory: 0, LQG: 0, me: 0), without taking into account the amount of time and funding invested in it. Public spenders must expect public scrutiny, and big public spenders must expect more public scrutiny than small ones. If the funding to LQG were raised to string theory levels, e.g. by redistributing funding from string theory, and LQG didn't make any spectacular progress after a decade neither, then it would be fair to criticize it too.

Another intrinsic aspect of string theory is the consistent overselling for the past 20 years. I always felt dubious about a theory without experimental support, but what convinced me that string theory is not only wrong but detrimental to science was a Physics Today article by Gordon Kane in 1997, entitled "String theory is not only testable, but super-testable". The title vividly illustrates the complete discrepancy between the hype and the actual achievements. In this respect, string theory is totally unique in serious science, and can only be compared to pseudo-science.

4. **Peter**
November 20, 2004

Hi Steve,

A couple comments. You're right that my own point of view is that, given the lack of experimental guidance, the most promising thing for theorists to do is to try and learn more about the mathematical structures used in the standard model and see if new and better ways of understanding them can be found. There seem to me to be quite a few things of this kind to investigate, but I can tell you from personal experience that if you try and talk to most theorists about these issues, they're really not interested. The attitude has become very widespread that the only possible mathematically sophisticated approach to particle theory is string theory, and that anyone who thinks otherwise is just too stupid to be a string theorist. Throughout the late eighties and into the early nineties, besides doing string theory, Witten came up with a lot of new ideas about gauge theories, but for the last ten years or so he seems to have decided to devote his full energies to string theory.

I don't think there's only one thing people should be working on. In the absence of any particularly promising idea, which is where we are now, they should be trying out a wide range of different things. But there needs to be a much more honest process of recognizing when ideas don't work and moving on to try something else. What's completely dysfunctional about the field is the way it continues to be dominated by the idea of unifying the SM and gravity in an 11d M-theory of some kind, long after it should be clear this can't work. It would have been unreasonable to demand predictions from string theory during the first few years that people were seriously looking into it, but twenty years later, the fact that it can't produce a single prediction of any kind should count very heavily. String theorists should be honest about how bad the situation is, and stop heavily hyping and promoting the theory unless they can make some real progress with it.

The main question facing the field seems to me to be that of how to encourage more people to try different things, and not just stick to one failed idea because it is what every one else is doing.

5. **Steve M**
November 19, 2004

Peter, I am curious about something. Let's suppose we could turn the clock back 20 years to 1984 and let's imagine that Green and Schwarz never did their famous Colorado calculation. String theory remains a backwater of physics in the 80s pursued by only a few diehards. So the question is: how would you have liked physics to have evolved–if you had had your way–to the present day, and would the situation really be any better than it is now? Or perhaps even worse? Let's also assume absence of any new experimental guidance, then what alternative mathematical structures or approaches in our opinion (ie non string theory) would have enabled a viable leap (or even step) beyond the SM or GR? I assume you would approve of deeper investigation into the mathematical underpinnings of the SM like gauge fields/YM and Dirac operators, but people have looked (are looking) at this anyway surely? In the absence of experimental guidance in 25 years now surely all possible alternatives are just wishful thinking too and can't make any predictions either? Everything else that has ever tried to go beyond the SM and GR has run into their own technical brick walls too so you can't really just single out string theory esp when it was the most promising.

November 19, 2004

DRL,

I do not want to defer on recognizing your enthusiam either:)

The increasing complexity, of what one might reveal of the cosmo, with a microcosmic view, had me consider how either the string theorist or the LQGist might interpret, that same cosmos. Gamma detection is one view right.:)

There are obvious attempts to interpret quantum gravity. I was looking for how they might view the picture supplied in my previous post.

If it is becoming increasing complex , the basis of their **determnations** would have to have a foundation to begin with, right?

Mathematically, how could two views of picture supplied in previous post, be so different, and are they?

As I stand, under the arch of reason, I am asking about **that one thing**. City Slickers, was very interesting from my historical perspective:)

7.
November 19, 2004

Lubos,

String theory, once it's understood completely, cannot really be an approximation of anything deeper – it follows from its basic mathematical features.

Can you explain this in more detail for a layman?
(layman = math grad student, in this case)

8. **Lubo? Motl**
November 19, 2004

Hi,

I just want to say that I've seen your replies, and I find it inappropriate to answer this kind of feedback.

All the best
Lubo?

9. **Chris Oakley**
November 19, 2004

String theory, once it's understood completely, cannot really be an approximation of anything deeper – it follows from its basic mathematical features. There were many complicated historical coincidences that have led up to this point – namely string theory – but once we know that it's a fact, there is some sense in which it could have been derived without explicit data from experiments, by "pure thought" much like many ancient philosophers were dreaming.

I am going to go into suspended animation for a few decades. Could someone please revive me when Harvard physics professors start doing science again?

10. **Thomas Larsson**
November 19, 2004

But this feels worse, as it is based on what is being peddled by very smart and established people. Someone once told me that in the 80s David Gross predicted that string theorists would be able to predict the quark mass matrix within a decade. It is safe to say that that day will never come.

Stephen Weinberg was here in Stockholm in December 1984, attending the Rubbia-van Meer Nobel party. At a colloqium he predicted that some smart young string theorist would win the Nobel Prize in 1991. Well, that prediction was at least falsifyable.

11. **Chris W.**
November 18, 2004

This old [post]() by Michael Nielsen has some relevance to this discussion. (Don't ignore the comments.)

So does this well-known [commentary]() by Albert Einstein.

12.
November 18, 2004

"What sort of scenario do you have in mind? How could string theory be proved irrelevant?"

Bon Motl believes string theory follows rigorously from the existence of God. So, if you can just disprove the existence of God, then even he will admit string theory is irrelevent.

13. **Chris W.**
November 18, 2004

Of course that all these conclusions would break down in the (unlikely) scenario that string theory will eventually be proved irrelevant.

What sort of scenario do you have in mind? How could string theory be proved irrelevant? I can't imagine what a "proof" of irrelevance is supposed to mean here. On the other hand, I can imagine how the majority of theoretical physicists might lose interest in string theory's continued development, even in the absence of such a "proof".

And, while I'm at it, how would we know that string theory is a "fact"? We don't know that any scientific theory is a fact. Theories may successfully *account* for facts, but they are never known to be facts themselves. That they have achieved some empirical success can certainly be a fact; indeed, these successes are among the more important facts that we hope to explain with subsequent theories.

Of course, if a theory has never achieved any empirical success, or at least no *unique* empirical success, it is more likely* to be regarded as irrelevant, simply because it offers nothing that calls for a explanation.

(* Physical theories often retain some relevance as sources of ideas for building new theories, but in this respect they share the stage with many ideas from mathematics, philosophy, and even engineering.)

14. **D R Lunsford**
November 18, 2004

Plato,

While I admire your enthusiasm, you have absolutely no idea about what is going on in physics. You should keep that in mind before posting.

-drl

15. **D R Lunsford**
November 18, 2004

My feelings about philosophers are usually negative, but this guy was able to capture some important philosophical differences between string theory and previous pictures how to do science that should undoubtedly affect the way how philosophers think about science and its developments.

And this is what I specifically detest about you folks – as if you, who have predicted nothing, and accomplished nothing, and DO nothing other than produce hot stupid uninteresting AIR, have the right to stand in judgment on the methods of Newton, Einstein, Maxwell, Faraday, Hertz, Kelvin…

You in particular, Motl, have never written a scientific word worth reading, notwithstanding your "lofty" position. Your bombast and bluster are nothing but a cover for your empty sophist's self-indulgent house of cards. You will never accomplish anything in science – your very presence is an affront to reason.

You toss around the word "old fashioned" like a radical's gas cocktail thrown through the window, a crazy Bolshevik on a mission from your "God". Save me from the "good" people.

16. **plato**
November 18, 2004

Maybe people just do not like dealing with the **complexity** of the issues?

We all like solid things, we just don't know how they got that way from a earlier time?

As a outsider, it is not to hard to maintain a view of the arguements that are presented when theoretical minds engage themselves.

Maybe it as easy as saying that the following picture, can be taken one of two ways? Are The extremities of these theoretical positions, presenting themselves this way?

I thought of putting the old woman versus beautiful woman picture, that changes when perspective is changed. But the picture choosen, should do.

17. **Lubos Motl**
November 18, 2004

My feelings about philosophers are usually negative, but this guy was able to capture some important philosophical differences between string theory and previous pictures how to do science that should undoubtedly affect the way how philosophers think about science and its developments.

Of course that all these conclusions would break down in the (unlikely) scenario that string theory will eventually be proved irrelevant. However, if it's relevant, the various standard old-fashioned ideas must be revisited. Every previous theory was an approximation of a better theory. String theory, once it's understood completely, cannot really be an approximation of anything deeper – it follows from its basic mathematical features. There were many complicated historical coincidences that have led up to this point – namely string theory – but once we know that it's a fact, there is some sense in which it could have been derived without explicit data from experiments, by "pure thought" much like many ancient philosophers were dreaming.

Of course, these statements are just "in principle" because – first of all – history was very different and observations were totally essentially for us to move in essentially the right direction and – second of all – we still don't know exactly how to complete string theory in such a way that the true quantities in the Universe can be calculated with the desirable precision.

I am not gonna comment on Peter's conjectures about what's the reason why string theory "is wrong" because I think that these comments of Peter are stupidities that simply don't deserve my time right now.

18. **BEB**
November 18, 2004

Well said, Peter.

I think I am seeing another example of the over-selling that will ultimately backfire. The previous one being some of the things said in support for the SSC (that it could lead to cure for cancer!). I too wanted the SSC, but I wanted us physicists to be honest about it.

But this feels worse, as it is based on what is being peddled by very smart and established people. Someone once told me that in the 80s David Gross predicted that string theorists would be able to predict the quark mass matrix within a decade. It is safe to say that that day will never come.

Or maybe the problem is me; I do not believe strongly enough in the "rapture" from "faith-based" physics;)

November 18, 2004

The opening paragraph of that Dawid opus made me laugh out loud. What a pile of garbage. I can't believe people get paid to make up this tripe.

More Hype On Its Way

November 21, 2004
Categories: Uncategorized

The latest trend among prominent theorists seems to be the writing of popular books hyping the unsuccessful speculative ideas they have been working on. Two new examples of this have been pointed out by Lubos Motl over at sci.physics.strings.

Both of these books are due to appear at the beginning of next May. One, by Leonard Susskind of Stanford, is entitled An Introduction To Black Holes, Information And The String Theory Revolution: The Holographic Universe. The second, by Lisa Randall of Harvard is called Warped Passages : Unraveling the Mysteries of the Universe's Hidden Dimensions.

Randall's book presumably is not so much about string theory as about the idea that we live on a brane inside a higher dimensional space. As far as I can tell, there's even less evidence for this idea than there is for string theory itself. I don't know exactly what her attitude about string theory is, but at a public debate at the Museum of Natural History here in New York a few years ago, I remember that she scornfully dismissed the argument that string theory predicts gravity, saying something like "Yeah, it predicts ten-dimensional gravity."

Comments

November 24, 2004

   Steven Hawking has already achieved notoriety as a gangsta rapper. As for Lubos's band, if he changes the name of his newsgroup to alt.religion.strings instead of sci.physics.strings then I don't mind playing the Sax for him (I'm a bit rusty, but I could brush up).

2.
November 23, 2004

   The physics community has spent the past half century or so basically living off the glory of having created the atomic bomb. A few farsighted physicists have recognized that this will not last forever and that physicist will have to find a new way to market themselves to the public: as entertainers! Steven Hawking's greatest contribution to physics is in pioneering this transition. Susskind and Randall are the latest to hop on the bandwagon and show great promise for creating appealing public personaes. Lubos is well positioned to follow in their footsteps provided he develop some distinctive peronality "hook" that will resonate with the public. Perhaps he could take up dueling or wear an eye patch, or start a rock band with some Harvard postdocs.

3. **wino**
November 23, 2004

   "Sorry that post came out pompous sounding. I just mean that folks don't need to be "protected" from popularizations of speculative physics."

   It is not a question of "protection" of the lay public from "speculative physics"; it is a matter of clearly distinguishing between speculative physics and physics. There are lots of beautiful ideas, which turn out not to have anything to do with reality; they are not physics.

   When one throws about about grandiose terms like the "Theory of Everything", the impression is that it fully describes and explains the world in detail; no hint of speculation here. This is very different from say, electrodynamics, or the standard model, which are in some sense correct in a very detailed sense (precision measurements), (though that does not necessarily mean they explain all of condensed matter physics, biology or chemistry in detail, as practitioners in those fields will argue).

   Of course, I must reserve judgement on the books until I have read them. But the track record in recent times of what appears in popular science magazines (like Scientific American) about such subjects does not inspire much confidence.

4. **D R Lunsford**

10. **Thomas Larsson**
November 23, 2004

Lubos, a couple of days ago you frankly asserted that SUSY *will* be seen, and that I would have to stay in the restroom for the rest of my life. Evidently you get cold feet as soon as somebody calls your bluff. Oh well, its your credibility…

11. **Lubos Motl**
November 23, 2004

Thomas, certainly not.

If we see supersymmetry, it will be a good circumstantial evidence that we are on the right track. It won't really prove string theory – one can really think about SUSY independently of string theory; it will just increase the value of string theory's stocks.

If the LHC does not see supersymmetry, it will be a discouraging news, but it certainly won't prove that string theory is wrong. First of all, SUSY can be broken at slightly (or much) higher energies than the LHC scale. Second of all, it is an open question whether there exists inherently non-supersymmetric backgrounds in string theory. The only fact is that SUSY is important for us to have a mathematical control over what happens in string theory.

Moreover, it is still possible that the LHC will not see SUSY, but it will nevertheless PROVE string theory – by seeing the excited strings, and/or various detailed phenomena related to extra dimensions. Of course, an excited string mode is a more typically stringy phenomenon than SUSY itself.

12. **Thomas Larsson**
November 23, 2004

Lubos,

Would you state for the record that the discovery of superpartners, or not, is a lithmus test for string theory? If sparticles are discovered string theory is probably on the right track, but if no sparticle is found within five years after the LHC is commissioned, then string theory has been disproven?

For the past 20 years, Witten has repeatedly stated that string theory makes one postdiction, gravity, and one prediction, supersymmetry. Are you willing to stand up and proclaim that if Witten's single prediction fails at the LHC, then string theory has failed?

13. **wino**
November 23, 2004

I think the books that are being talked about here are not science fiction, they belong to the category of "scientific fiction" 🙂

What the string theorists (posting here, and in general) do not understand/realize is that they are ultimately going to cause great damage to the public perception of what physicists/scientists do (non-string theorists, in particular) and what physics/science is all about. By lowering the bar on what constitutes "physics" to such an extent that it is not terribly important to do things testable in the foreseeable future, is to do great disservice to the testable theoretical work (verified and falsified) done in so many sub-fields. Forget Peter Woit, a layman (taxpayer) will ultimately wonder if there is any difference between string theory and theology. I know it is an unfair comparison, but it will be an increasingly harder case to make as the great claims being routinely made cannot be proven. By peddling "sexy" stuff, of course book sales will be good, but this will be at a cost in the future: damage to credibility of science. Then, we physicists will be under siege, not unlike the biologists these days.

I have not seen the books, but I suspect they will
convey the impression that these are verified and tested ideas and gloss over (or even mention) the obvious problems, such as the wide variety of outcomes from "unique string theory". Even if they sell it as a really good piece of mathematical physics, it will be alright. But no, I suspect, it will be the pretentious and condescending "Theory of Everything", the "final word" with "a few details" left to be worked out. This is in sharp contrast with popular books on QED or GSW model, or even pure mathematics (Wiles) which are much more intellectually honest.

14. **Lubo? Motl**
November 23, 2004

Thomas Larsson, I have not read Lenny's book, so how can I criticize it? This would probably be your approach to criticize books that you have not read. Anything that is connected – at least by some vague link (like the name of the author) – with string theory immediately becomes a target of your criticism, even though you have no idea what it actually is.

This is the stupid, blinded, fundamentalist way to judge the world around – it is your way, Thomas and Peter. Sorry, but we're at a slightly different level. I apologize, but this way of approaching reality is one of the main reasons why the two of you are viewed as morons and your opinions do not have much value.

I suppose that Lenny will also write about the landscape, but my assumption is still that it will be mainly a book about holography and string theory and such, and because I know Lenny, I expect this book to be a good book. But I just can't tell you before I see it, do you understand this point???

15. **Lubo? Motl**
November 23, 2004

Chris Oakley, you misunderstood the identity of different people on this board. Peter Woit has been criticized by non-string-theoretical particle physicists, such as Matt, as well as by string theorists.

It's just the stupid belief of these hard core Woit believers that Peter Woit knows what he's talking about. He has no idea where string theory is and what it is, but he also has no idea about current particle physics and its real tasks for the future.

Peter Woit does not really understand the hierarchy problem, which is pretty bad for a person who tries to write something about particle physics.

16. **Lubo? Motl**
November 23, 2004

I have not answered these things – right now I'm on a modem. 😉

Sorry, glueless, but your basic assumptions and understanding of the meaning of popular books is absolutely wrong.

Popular books must ALWAYS be focused on the current cutting edge research and the future, otherwise they can't really be popular and virtually no one will read them.

You are also absolutely confused if you call the material of Brian Greene's book "fringe science". Fringe science means something absolutely different. Brian Greene describes the *mainstream* science, and it is just your personal problem if you have not been able to understand that string theory is mainstream.

Other people raised a lot of totally ridiculous points that people are only writing popular books when their best years are over. Of course that some people can only afford to write a book that will be popular *after* they become famous, but it by no means implies that they cannot make other important discoveries in the future.

I find your criticisms to be a complete misunderstanding of the role of science, its popularization, the interests of the readers, and the books themselves – and it seems as a waste of time (and cents for modem) 😉 to reply. It's pretty clear that an average person with some common sense understands what drives the books and what's important much better than you do – so try to ask average people on the street if you want to have at least a glimpse of an idea.

Best
Lubos

17. **JC**
November 23, 2004

My impression is that this place seems to resemble a "mob of kangaroos", with very little order and a very fleeting loyalty of any sort. It resembles less like a cult with a "high priest" as its leader.

If this was a political party of some sort, it would confirm the idea that "loyalty" cannot be "bought" but can only be "rented out" temporarily. (In a metaphorical sense, that is).

18. **Chris Oakley**
November 23, 2004

There are a number of posts earlier by String theorists attacking Peter's real or perceived views on what needs to be done next in particle physics phenomenology. I feel that these miss the point. Any one of you could give your views on any subject at all, and anyone else could pick holes in it. This is part of the whole process. The thing that Peter is objecting to, and the reason for the title of the blog, supported by his so-called "loyal following" (which I am afraid, apart from agreement on the one issue, is in practise not likely to be much more loyal than a herd of cats) is the way in which the devotees of one highly speculative approach seem to have hi-jacked the subject, thereby, given the limited resources available overall, all but silencing new proposals that do not fall within the String theory umbrella. *These critcisms are long overdue*.

19. **Peter**
November 22, 2004

John Horgan has a nice description of string theory and the like as "science fiction in mathematical form". Personally I have nothing against smoking dope, watching Star Trek and thinking about how cool all the multiple universes and extra dimensions are. But the reason I went into physics was that it was science, not science fiction.

If people want to write books about things they think are cool, but not likely to be right, they should acknowledge that they are writing science fiction, not science. Right now, I think more and more people can't tell the difference.

20. **Aaron**
November 22, 2004

Well, I disagree about the desert of books between Feynman and the present. There are plenty of books devoted to general relativity, cosmology and the standard model.

You'd like books on TQFT, condensed matter and CFT, I see. Good luck selling those books. Hell, if anyone could write a popular book about TQFT, I'd be impressed. It's the sexy stuff that sells.

And really, I don't understand this word 'hype'. People aren't writing these books to get more funding or anything like that. Many scientists really do like to share what they're working on with other people. Hell, when I had a blog once upon a time, I wrote a long post on faster than light travel in physics. Has that been 'vetted'? Is it likely to be right? Of course not. But, it's cool stuff, and I thought it would be fun to share it.

So, are braneworlds likely to be right? No. But are they cool? Yes. Could they make a good book? Definitely.

Lighten up. Physics is supposed to be fun. People being excited about their work is a *good* thing.

21. **Bob McNees**
November 22, 2004

The notion that "Writing popular books is something physicists usually do when their most productive years are behind them" is absurd. There are a lot of very active scientists who, like Aaron points out, are excited about sharing the ideas they are working on. For the most part our work is supported by government agencies like the NSF or DOE. So the public thinks that fundamental science is a worthwhile endeavor and they're willing to fund it. Some of us are grateful for that, and we'd like to explain what it is we've been doing.

Also, I'd like to see you tell Lenny that his good years are behind him.

22. **glueless**
November 22, 2004

Lubos and Aaron,

You haven't answered Peter's seemingly
obvious point, about the disproportionate
number of books devoted to new-age physics
written by current leading practitioners.
To some extent this is a trend in all of
academia (professors retaining literary
agents hoping to cash in a la Schama or
Norman Diamond), and the accelerated
publication and funding cycles leading
to excess hype.

Here is an experiment you could try;
certainly in the Boston area
Lubos can check that the following is true:

Go to a non-technical bookstore with a popular physics section. You will find that there are
several books on material that is speculative,
fringe, or simply unproven — written by current working theorists. e.g., Smolin on loop gravity,
Greene on strings, Maguiejo on variable
speed of light, and now the Susskind and Randall
books. By contrast, there is LITTLE OR
NOTHING available, let alone written by leaders
in the field, about established but no less
exciting subjects like the standard model, conformal field theory, quantum topology a la Atiyah and Witten, condensed matter theory,
etc. The one such popularization I can remember is Lederman's reminiscences published a few years ago. The math section had some books on knot
theory that, in passing, mention TQFT, but that's
about it.

There is a "big desert" of (non)publications
between Feynman's QED popularization, and
the new-age books of Greene et al.

It's hardly a matter of self-appointed guardianship of the public or scientific morals.
There is a general tendency to hype results
(or theories without "results" in the
ordinary sense of the word) before they
are vetted in the traditional ways.

23. **Peter**
November 22, 2004

Hi Aaron,

I think this is kind of repeating myself, but, no, I don't think particle theorists should all be thinking about mathematical foundations and not trying to extend the standard model in some phenomenolgically useful way. The fact of the matter is that there isn't much in the way of promising new ideas around, so people should do a wide range of different things, trying to come up with something new. But whatever they do, they should be honest with themselves and with others about the prospects for the ideas they are working on. Despite many years of work on large extra dimension scenarios, as far as I can tell there's nothing even close to a compelling model of this kind and virtually no one I know of would be willing to bet any significant amount of money on the LHC turning up evidence for these scenarios.

24.
November 22, 2004

Writing popular books is something physicists usually do when their most productive years are behind them. So I can understand Susskind, but Randall should still have a few good years left in her.

25. **Aaron**
November 22, 2004

Some people have proposed giving up on SUSY to solve the hierarchy problem and just using it to achieve unification of the couplings and maybe a dark matter candidates.

Now, the motivation for this work was anthropic, but it's important to say that it's perfectly legitimate to consider it as a fine tuned model with definite predictions for what will happen at the LHC. I find the anthropic verbiage that accompanies a lot of this sort of work distasteful, but I don't see why we shouldn't look at fine tuned models that have experimental consequences.

I share Matt's astonishment that Peter would rather have the high energy physics community mucking around with the mathematical foundations of the standard model rather than trying to extend it in ways that have definite, observable consequences within the decade.

As for writing of the books, if Peter wants to be the self-appointed guardian of the public interest, so be it, but might I suggest that maybe the reason people want to write books is that they are excited about their ideas and want to share them with the public?

Well, that and money.

26. **D R Lunsford**
November 22, 2004

I have the perfect title:

"Malice in Wonderland"

"Being the story of a six-foot clueless scowl"

27. **JC**

November 22, 2004

Lubos,

Since you seem to like to write a lot, have you ever thought about writing a popular press book on string theory in the form of a personal autobiography?

28. **Thomas Larsson**
November 22, 2004

Matt,

The experimental situation is often summarized as "Supersymmetry requires fine-tuning at the one percent level". Has this any relevance to SUSY as a solution to the hierarchy problem?

Lubos,

Earlier you have been quite critical about the Landscape and the Anthropic Principle. It seems like Susskind's book is mainly about such ideas. Is there any reason why you promote it now?

Peter,

Another interesting energy scale is the cosmological constant (or CC^(1/4)) at about 10^(-3) eV, close to the estimated neutrino masses.

29. **Plato**
November 22, 2004

I wonder how they ever arrived at here? Maybe this is better?

30. **Peter**
November 21, 2004

Hi Lubos,

The Planck mass is not necessarily the fundamental mass scale governing quantum gravitational effects. This is only true if you assume that whatever physics is producing the coefficient in front of the low energy effective Einstein Hilbert action is some combination of one particular mass scale and some dimensionless numbers of order one. The large extra dimensions scenarios evade this, and you can imagine otherways of evading it. For instance the dimensionless numbers that enter into the calculation of the effective low energy theory may be exponentially small. I wouldn't be entirely surprised if the fundamental scale at which quantum gravity became relevant was a TeV, but I don't find the large extra dimension scenarios very convincing (they're kind of ugly and they don't predict anything).

Believe it or not, I had heard somewhere that fermion masses came from Yukawa couplings to the Higgs…. My point was that we know that these dimensionless numbers (ignoring issues about neutrino masses) range in values over many orders of magnitude: the ratio of the electron mass to the top quark mass is about 2 x 10^-6. Given the experimental fact that such small dimensionless numbers occur in the theory, I'm not sure why one should take seriously issues like the "little hierarchy" problem of the Higgs VEV being 40 times smaller than one might expect.

31. **Lubos Motl**
November 21, 2004

Your point 2 is even more ridiculous, Peter. Writing cheap articles "string theory is bad" for some of your idiotic readers is a profession that you mastered well, but particle physics is something very different, it seems.

The little hierarchy problem is a small artifact of the hierarchy problem that survives even if we solve the usual hierarchy problem in one of the standard ways.

But why do I say that your comment 2 is ridiculous? Because you're treating different masses as "mass scales". They may be mass scales, but according to the Standard Model or derived theories, they're not "fundamental mass scales" in any way. The electron mass is small because the Yukawa coupling of the electron with Higgs is a small *dimensionless* number.

You've probably never heard of it, but in the standard model the masses are not fundamental parameters – they arise as the product of the Higgs vev and the Yukawa couplings.

It's just a dimensionless parameter that is small – one that can be perhaps extracted from string theory in the future (the intersecting brane models have the most natural explanation of the exponential smallness of the Yukawa couplings). But the only real *dimensionful* parameter in these masses is the electroweak scale, i.e. the Higgs vev.

The neutrino masses are a bit more subtle, and the see-saw mechanism relating their size to the GUT scale (where the electroweak scale is in the middle) is the most reasonable description of their smallness.

3. I am amazed how you're already scared – we would say in the Czech Republic that you've been shitting to your pants 😉 – by the two new popular books. You have not even seen them yet, but you already know that they're overhyped bad books. I think that all these morons who take your opinions about physics seriously must be incredibly stupid indeed because you are telling them quite explicitly that your opinions have nothing to do with reality – you judge books that you have not seen at all (not even the table of contents), and you are not even trying to hide it.

The people are promoting extra dimensions, supersymmetry, and holography because they are the dominant ideas in the current research and the people interested in fundamental physics should know about it. If there were other major important ideas for particle physics beyond the Standard Model, ones unrelated to string theory, people would write about them in their books, too.

32. **Matt Reece**
November 21, 2004

By the way, I also will try to address your comments more later, but don't have time at the moment. Just thought that a clear statement of the little hierarchy would help clarify that discussion.

33. **Lubos Motl**
November 21, 2004

Peter, note that almost every time the discussion becomes a little bit technical and concrete – and not just your permanent complaints "string theory is so evil, evil, evil" – your comments start to be a bit ridiculous.

What does it mean "I don't believe the hierarchy problem should be treated seriously?" You don't need to have grand unification to realize that there's something like the hierarchy problem. You can also work with the Planck scale.

It's the very logic of effective quantum field theory that it's valid up to some energy scale, but not higher. If we want to say that a field theory is valid even at higher energies, we must explain how its parameters are protected.

In the conventional quantum field theory approaches, the electroweak scale simply can't be the ultimate fundamental scale of Nature because this would mean that physics of QFT breaks down here and we have nothing to replace it with.

Even in the most low-energy gravity scenarios of string theory, we want to describe the accelerator physics with an effective field theory.

The fundamental scale where notions of geometry break down is the Planck scale. You can just calculate where the quantum corrections to gravity become of order 1 – and you will get the Planck scale, which is about 10^19 GeV. You don't need to assume anything special about supersymmetry or unification – the question "where gravity gets strongly coupled" is a totally meaningful basic question, and it has the usual answer "the Planck scale".

The extra large dimensions scenarios are those in which gravity gets strongly coupled earlier or much earlier – i.e. at lower energy scales. But at any rate, there is a huge numerical ratio between the Planck scale and the electroweak scale, and this ratio must agree with whatever scientific theory you use, and it is a nontrivial constraint especially for natural theories.

A solution of the hierarchy problem is the same thing as understanding some details behind the electroweak symmetry breaking – you don't seem to appreciate that it is the same thing. Right, in the Standard Model we don't understand at least something about the electroweak breaking, e.g. why the Higgs (if it's elementary) remains light, and this is why we study the hierarchy problem.

It is impossible for a physicist to present no solution of the hierarchy problem, and simultaneously say that it is not a problem. It's only possible for an anti-physics terrorist, not for a scientist. 😉

34. **Matt Reece**
November 21, 2004

You say:

"I'm not so sure either that there's a "little hierachy" problem either. We've got mass scales of all sorts going from neutrino masses to a wide range of lepton and quark masses, and also the strong interaction scale and the electroweak symmetry breaking scale. It's not clear to me that the way to think about any of this is that there is one underlying scale and then try to understand why some things occur at much lower mass."

I don't see how you address the little hierarchy here. Simply stated, these are known facts:

– the Higgs vev is 246 GeV, setting the electroweak symmetry breaking scale.
– precision measurements of electroweak observables or four-fermion couplings generally put the scale of new physics at > 5 – 15 TeV.

Taking an effective field theory viewpoint, one must write down all operators allowed by symmetries, and the coefficients of these determine the energy scales at which new physics must enter. *Even restricting to operators consistent with SM symmetries*, experiments suggest they are suppressed by scales of 5 – 10 TeV.

I don't see how one can avoid the conclusion that either there is finely tuned physics associated with EWSB, or there is some mechanism that stabilizes the Higgs mass enough to solve this "little hierarchy." (Granted, the fine tuning implied here is *much* less than that implied by assuming a GUT, but it's there, and the experimental evidence here is much stronger.)

35. **Peter**
November 21, 2004

Hi Matt,

Unfortunately I only have a few moments to respond to what you wrote right now, sorry, it deserves more. A few quick comments:

1. You're right, I don't believe the "hierarchy" problem should be taken as seriously as it is, not until we have better evidence for the existence of a GUT scale. The significance of the radiative instability of the Higgs mass is highly unclear, it is just one of many indications that we don't really understand electroweak symmetry breaking.

2. I'm not so sure either that there's a "little hierachy" problem either. We've got mass scales of all sorts going from neutrino masses to a wide range of lepton and quark masses, and also the strong interaction scale and the electroweak symmetry breaking scale. It's not clear to me that the way to think about any of this is that there is one underlying scale and then try to understand why some things occur at much lower mass.

3. My comment about extra dimensions was in the context of the news that Lisa Randall has written a popular book on the subject. I agree that some of the things you mention may be worth investigation by someone, but that doesn't mean anybody should be writing a book for a popular audience about how great these ideas are. The popular literature on string theory is virtually uniformly full of highly overhyped and misleadingly optimistic portrayals of string theory. I think these do a huge disservice to real progress in physics, and the Susskind and Randall books sound to me like they will be more of the same. Physicists have got to get a lot more honest with the public and with themselves about what the prospects are for most of the ideas they are working on. People who want to should go ahead and study complicated, ugly models involving supersymmetry, extra dimensions or whatever. They may very well end up learning something important that will give insight into the electroweak symmetry breaking problem. But they shouldn't promote this work to the public until they have something a lot more convincing and solid than what they've got now.

36. **Matt Reece**
November 21, 2004

I should clarify that I don't mean to say that the original Randall-Sundrum model is very much like technicolor, but some RS-type models are. But the original RS model still does involve coupling the SM to some CFT. The 4D way of thinking about generating these exponential hierarchies is through some large anomalous dimensions. Some of Matt Strassler's papers along these lines are interesting. I really think that Randall-Sundrum models and AdS/CFT are very powerful tools for studying field theory.

(The canonical reference for anyone who wants to start to read about some of this is probably the paper "Holography and Phenomenology" by Nima Arkani-Hamed, Massimo Porrati, and Lisa Randall, hep-th/0012148.)

37. **Matt Reece**
November 21, 2004

[continued]

Now, if you ask most of the people who work on extra dimensions in particle physics whether they believe there's good evidence for whatever model they're working on, they will say no, of course not. We don't believe that we can construct the *right* theory of physics up to 10 TeV or so at the moment, but when the LHC turns on we'll start getting all sorts of evidence pointing toward that theory. Either we can do nothing in the meantime, or we can try to start understanding the space of possible answers. And extra-dimensional theories are powerful tools for building new *effective* field theories valid up to several TeV. It's up to you whether you take the five-dimensional character seriously, but it gives us an alternative weakly coupled description where we can calculate things that are not calculable in the four-dimensional description. Extra dimensional thinking has also led to the idea of "deconstruction," which is another useful tool for studying four-dimensional field theories.

While I would expect some of your blog's readers to object to the idea of building effective field theories valid up to some energy scale, since many of them seem not to believe in renormalization, I would think you understand field theory well enough to know that this is a sensible approach. Instead you seem to want to critique both the top-down approach of string theory *and* the bottom-up approach of particle theory. That doesn't leave much.

I really think you misunderstand the attitude of many of us who study various sorts of theories. Even if our universe is not supersymmetric, or does not have large extra dimensions, that doesn't make studying these models worthless. In the past five years alone I think our appreciation of possible physics we could see at the LHC has grown vastly. People will be a lot more cautious about calling interesting events SUSY now, I think, because we realize that there are other realistic models, like little Higgs models or extra-dimensional models, that can give you the same sorts of results.

One can make this sort of argument not just for extra-dimensional theories but for SUSY as well. Even if there is no SUSY at low energies, you can't dismiss work like Seiberg's discovery of dualities between different SUSY QCD theories. This is important stuff about the qualitative behavior of field theories, which we don't understand well at all. The non-SUSY case is just really hard, though, while SUSY gives powerful constraints that make things easier to study.

I think at this point many of us working in particle theory take a pragmatic view. There are many possibilities for what can happen beyond the TeV scale, and sitting around thinking hard about what we already know just isn't enough to tell us what they are. Only experiment will settle that. But we want to get some idea of the possibilities, and this is what we're doing, with any tool we can find. Some of the models are ugly, some are implausible, but from an *effective field theory* point of view what we're really doing is looking at the different sorts of completions of the Standard Model up to the scale of several TeV that can alleviate the problems in the SM (like the hierarchy problem).

I have some sympathy for your viewpoint that the mathematical structure of the SM is interesting. I like geometry. If I weren't doing physics, I would probably be doing geometry or topology of some sort. But I don't think that thinking about these issues is going to be especially helpful for understanding particle physics at the TeV scale. (How do you see the hierarchy problem geometrically? It's inherently quantum, not classical. If you have a nice geometric version of it, great, I'd love to hear it, but I'm doubtful.) I think most particle theorists are taking a very pragmatic approach that will hopefully give us all the insights we need to start interpreting the LHC data when it turns on.

In short, I don't think your attacks on the state of particle theory are justified, and I wish you would at least get a better sense of what's going on and what the attitudes of particle theorists are before you start caricaturing us as being convinced that extra dimensions will be discovered at the LHC, or some such nonsense.

Matt

38. **Matt Reece**
November 21, 2004

Peter,

I find this post a little ridiculous. In the past you've said (something like) that you think that electroweak symmetry breaking is the central problem in particle physics today. Well, many of us who are working in particle theory agree with you. And I expect Lisa Randall is one of them.

You say about "the idea that we live on a brane inside a higher dimensional space" that "there's even less evidence for this idea than there is for string theory itself." I think this indicates that you're missing the point, and further that you're rather out of touch with the particle physics community.

Do you agree that there is a hierarchy problem? OK, so you're skeptical of GUTs. Fair enough. But there is certainly at least a little hierarchy problem. There's good *experimental evidence* for this. The Higgs mass is radiatively unstable, so either you must accept the distasteful idea that it is finely-tuned (some phenomenologists have been thinking along those lines) or you must start looking for explanations of the little hierarchy. One of the simplest is supersymmetry, but you don't like this idea. OK, again, fair enough, it involves predicting a plethora of new phenomena we haven't seen yet.

So, what are other ways of solving the hierarchy problem? One of the oldest ones (going back to Susskind and Weinberg in 1979, although some people had thought along these lines before) is that it is dynamically broken through technicolor. Unfortunately it's very hard to build a model of technicolor without lots of difficulty satisfying electroweak precision measurements, or flavor problems.

Lisa Randall and Raman Sundrum gave us a very nice alternative solution to the hierarchy problem, namely that it comes from warped space. But, because of Maldacena's AdS/CFT duality (which again, you've admitted is one of the most compelling reasons to study string theory), this is really just another type of technicolor! Again there are difficulties with electroweak precision measurements and flavor, but they take on a different character in the 5d picture, and some of us are thinking about both how to solve them and how they relate to older technicolor ideas.

[let me break this off here and continue in another]

39. **Peter**
November 21, 2004

Hi Lubos,

I think the Billy Cottrell story deserves more prominent display, so I'll post something in a minute about it. Thanks for pointing it out!

40. **Lubos Motl**
November 21, 2004

You know, Lisa's book has a lot about string theory, too – especially D-branes and their history, relations to p-branes, and so forth.

Sure, I will ask her what she exactly thinks about string theory's prediction of gravity.

Incidentally, Peter, string theory was proved to be physics in the courthouse – a trial about SUVs ;-), read http://www.pasadenastarnews.com/Stories/0,1413,206~22097~2541722,00.html

I think that it's OK to promote idas, even those not well-established ones, as long as you honestly say that they're not proved, and as long as you describe honestly how much your viewpoint is shared by other scientists.

Such books are written in the people interested in physics – which does not just mean the boring proved physics from the textbooks, but also the current cutting-edge and future physics!

41. **Peter**
November 21, 2004

Hi Lubos,

Thanks for the more detailed description of Randall's book. But I still think there is something wrong with writing books for a popular audience promoting speculative ideas for which there is no experimental evidence.

I don't think I misinterpreted what she had to say about the "string theory predicts gravity" argument, but she's your colleague, so perhaps you could ask her yourself and report back.

42. **plato**
November 21, 2004

Peter,

To remain dimensionally connected, it should be **Line Hook and Sinker**? Hopefully my blog will update by the time one looks, as a title should appear when being looked at, as such.

Sorry Lubos for following your posts, it just seems that when I am ready I find you had already done so.

The Comments about Lisa Randall seemed to say the same thing to me.

What exactly is the hierarchy problem? was a legitmate question?

43. **Lubos Motl**
November 21, 2004

Lisa Randall is a phenomenologist, the most cited high energy physicist in the last 5 years, and a string-theory-friendly phenomenologist.

I don't think that the sentence "Yes, string theory predicts ten-dimensional gravity" was her dismissal of string theory's predictions of the low-energy spectrum. You might have misunderstood her answer.

Her book is very advanced and it covers all the things that the laymen interested in particle physics should know – the hierarchy problem and proposals to solve it, with the emphasis on supersymmetry and extra dimensions in particular.

Of course, the book will be too difficult for your fans who always say "Yes Yes Mr. Woit" on your pages – like the moron signed "JC" before me. Don't you think that something is wrong with the things you write, Peter, if you attract this type of people?

I don't know if the book will be an easy reading for yourself, Peter, but I am sure that her book is a must read for all non-professionals genuinely interested in particle physics – not just string theory – and in fact, it's useful for professionals, too. It's been useful for me.

It's a book that goes beyond all popular books on particle physics published so far – and it has many witty metaphors in it, too.

I have not read Lenny's book yet.

Is this "advocacy" (via popular press books) a sign of desperation amongst gravity/string theorists? Or is there something deeper going on here?

Autistic String Theorist Accused of Ecoterrorism and Being a Police Informant

November 21, 2004
Categories: Uncategorized

In the comment section of the last post, Lubos Motl points to the story of Billy Cottrell, a young string theorist at Caltech accused of being involved in the vandalism of SUVs. Evidently he has now testified against others at his trial, so the "Free Billy Support Network" (which was asking people to send string theory papers to him in prison) has been disbanded and he is being referred to as a "police informant".

Despite being a string theorist, Cottrell seems to not be the brightest bulb around, having supposedly used a Caltech computer he was logged into to send an anonymous e-mail to the media claiming responsibility for the SUV vandalism.

The local Pasadena newspaper's report on his testimony at his trial says that he corrected Judge Gary Klausner "when the judge asked if string theory, Cottrell's focus at Caltech, is "an area of physics.'

"It's the area of physics,' Cottrell said."

His lawyers "attributed his odd behavior in testifying to Asperger's syndrome", a mild form of autism.

Funny, Cottrell isn't the only one who goes on like this about string theory. Maybe there's a lot of autism going around.

   November 24, 2004

   I hope he languishes in jail for the rest of his life as an example to the other anarchists who want to destroy this country. If they were serious about helping working people, they wouldn't put construction workers at medium-sized businesses out of work by bankrupting businesses with their nihilistic vandalism.

   Smash the ELF.

2. **Lubos Motl**
   November 23, 2004

   Asperger's syndrome was really a not-quite-working attempt of Billy's attorneys.

   I don't know whom you think you've insulted. Autism is an unusual condition, but the people with autism have done a great deal of work for the humankind.

   It's not quite clear whether they have done more for the humankind than the string theorists combined – but it is pretty likely.

   In this sense, it would be hard to be insulted by this comparison. On the other hand, I think that the people who have autism will not be insulted by a comparison with string theorists either.

   So if I summarize – you did not do anything wrong even though you wanted to. 😉

3. **plato**
   November 23, 2004

   Hate, when that happens:)

   http://eskesthai.blogspot.com/2004/11/mathematicians-and-physicists-do-is.html

4. **plato**
   November 23, 2004

   I think I have a better defintion of a rebel here

   I decided to change the subject from a**u**tistic to a**r**tistic. Is that okay?

   In Canada, BC challenged the right of government to help fund autistic rehabilitation for those who need this help, and the Provincial Government won.

   This sets precedence in Canada, although new challenges will be forth coming.

   We have a different view on heathcare then you Americans. It was established by a very good citizen, like Tommy Douglas.

   Today it is being eroded by the very powerful elite, with plans to move towards American systems. Ole Tommy would not of be very happy and it is the little people who will again gather to make sure all are equal.:)

   The Republic, is very interesting written work by Plato.

5. **Peter**
   November 22, 2004

   I don't think I was either joking about autism or making fun of those who suffer from it, and I apologize to anyone who feels that I was.

   On the other hand, I definitely was making fun of string theorists. Sorry you were offended.

6. **Bob McNees**
   November 22, 2004

   "Funny, Cottrell isn't the only one who goes on like this about string theory. Maybe there's a lot of autism going around."

That is funny, Peter. Especially the part where you joke about autism. Family and friends of autistic people everywhere salute your discriminating use of completely appropriate comparisons.

7. **Fabio**
   November 22, 2004

   Sorry Matt, my bad.

   Still, shouldn't you be studying for quals or something?

8. **Fabio**
   November 22, 2004

   Looking at Mr. Cottrell's extracurricular activities, as well as Matt's and Lubos's frequent long-winded postings on this forum, one can't help but conclude that string theorists have alot of free time on their hands, and that there are better ways of spending it than working on "the language in which god wrote the universe".

9. November 22, 2004

   Well, in general ethics and moral seems to be quite independent of talent.

10. **Thomas Larsson**
    November 22, 2004

    but Billy instead wanted us to go back to two dimensions and focus on Teichmueller theory.

    Teichmueller wasn't God's best child neither, sending his Jewish colleagues at Goettingen to Auschwitz, before he disappeared on the eastern front.

11. **Tim M.**
    November 21, 2004

    Indeed there is much autism: the second Google hit when searching "not even wrong" is a link to a book on Amazon about autism called Not Even Wrong.

12. **Mubos Lotl**
    November 21, 2004

    ">"He has a hostility toward anyone with different views,' Riordan said.
    >"It's a dripping hostility, it's powerful sarcasm, it's a passionate
    >self-belief.'"

    Obviously not a physicist.

13. **Lubos Motl**
    November 21, 2004

    Right, the opposite holds for me, too! 😉 I still find it more likely that I would share the opinions about string theory, maths, and physics with Billy rather than the opinions how to deal with the SUVs.

    Peter Woit is the ideal mixture because he has terrorist opinions both about SUVs as well as about string theory. 😉

14. **Lubos Motl**
    November 21, 2004

    Fascinating, Matt! BA about p-adic numbers in string theory is really cool. I hope that he will have access to the arxiv in the prison. 😉

15. **Peter**
    November 21, 2004

    Hi Matt,

    Thanks for the interesting story about Billy Cottrell. I still think he and I may share opinions about SUVs more than we would share an opinion about math and physics.

16. **Chris W.**
    November 21, 2004

    In a free market, SUV owners will decide for themselves what is easy to pay for. Ask the airlines (and their laid-off former employees) how easy it is to pay for fuel with crude at $45-60 a barrel.

    For now, consumption is declining seasonally, and oil prices are slacking off somewhat. The bottom line remains that increasing production and low prices cannot be taken for granted anymore, even if one assumes that the Mideast remains (relatively) stable. That assessment comes from the oil industry itself, which has been bailing out of some recent allegedly major oil finds that haven't panned out:

    > "One simple fact has never changed. Before oil can be produced it must first be found. Global oil discoveries peaked in 1964 and have been declining for 40 years. M. King Hubbert predicted the US oil production peak to occur 40 years after US oil discoveries peaked around 1930. He was right. Last year not a single field of 500 million barrels was discovered (for the first time since the 1920s) anywhere on the planet. The world uses a billion barrels of oil every eleven and one half days. We are now roughly 40 years after the peak of global discovery. This simple arithmetic has never changed. The outcome hasn't changed either."

17. **Lubos Motl**
    November 21, 2004

    It's easy for Billy to find time for such things, and it's also easy for the SUV owners to pay for the gasoline even if the price doubles. Don't be ridiculous, Chris.

18. **Chris W.**
November 21, 2004

How would a grad student in physics at Cal Tech find the time to run around the Los Angeles area spray painting and/or torching SUVs?

Anyway, such symbolic acts are becoming irrelevant. Given the way fuel prices are rising, SUV owners are going to start torching their own vehicles and buying gas-electric hydrids with the insurance payout (if they don't get caught).

19. **Lubos Motl**
November 21, 2004

Poor guy who had no other choice. He faced up to 40 years in prison, for the damage of 2.3 million dollars on the SUV.

If I were left-wing, I would have definitely tried to help him out of his troubles!

Could he get amnesty? He may deserve one for knowing that string theory is not just "an area of physics" but also "the area of physics"! 🙂

http://www.aiada.org/article.asp?id=4998&cat=Industry

http://portland.indymedia.org/en/2004/11/303898.shtml

Now he does not need it because he has become a police informant, and hopefully he will help to catch all these other ecoterrorist assholes. 😉

20. **Matt**
November 21, 2004

Billy and I were undergrads at Chicago at overlapping times. He wrote his BA thesis on "tachyon condensation in p-adic string theory," working with Freund, IIRC, so he was already quite into string theory at the time. (Apparently the mathematics actually simplifies in the p-adic case. I assume this was some calculation in string field theory, but I don't really know.)

I recall him as being highly talented in mathematics. The one class I took with him was a small (about six students, I think) proseminar on low-dimensional geometry and topology, taught by Benson Farb, focusing on Thurston's book. At one point there was a vote on what topic we should focus on for the last few weeks. Most of us wanted to study the eight Thurston three-dimensional geometries, consistent with the original plan for the course, but Billy instead wanted us to go back to two dimensions and focus on Teichmueller theory. At the time I knew little about string theory and this was somewhat mysterious to me, but in retrospect I know why he was so insistent. Still, he was outvoted.

Anyway, there isn't too much point to this anecdote, but Peter, you and Billy might have more in common with regard to thinking about the relationships between mathematics and physics than you would expect.

21. **Matt**
November 22, 2004

I'm a bit confused by that last comment — I'm not a string theorist (I'm a particle theorist, and just in my first year of grad school), and I've rarely posted long comments here.

Time Magazine Article

November 23, 2004
Categories: Uncategorized

For a depressing look at where theoretical physics is headed, see this new article from Time magazine. I agree with the analysis of it posted here.

Comments

1. **plato**
   November 29, 2004

   raj,

   Maybe from the outside perspective us commoners wonder whether the strategies to defining the physics has fallen short of the continued attempt to define it's geometry?

   Having attained certain perspectives, leading developement to the abstractness of the math used, has some way divorced itself, from what Peter demands, and yet all engage, in this strange language?

   Sometimes the fictional stories are better suited to the constrants applied these mathematicians, that everyone wants to know, what the heck they are seeing?

   Alice(**M**alice to some) presents all kinds of possibilties, and in the heart of Glast valuations, a good understanding of our universe?

   But truly, it goes much deeper then the Glast perspective? They have to agree that they all have a piece of that elephant and that spectrum continues to be much greater involved??

2. **raj**
   November 29, 2004

   >Physics is hard. Do it or shut up.

   Um, no. Or, well, maybe. Why should physics be hard? At base, physics relates to the interaction among things. Why should that be hard?

   The problem is that professional physicists apparently want to make physics *appear* to be hard. Hard to do. Hard to understand. So, when they publish an interesting result, they start in a way that basically causes most people to tune out.

   Professional physicists should seriously consider trying to figure out how to explain their discoveries to the "common"–or, let's say, educated–person.

3. **plato**
   November 25, 2004

   So which end of the elephant are working from DRL?:)

4. **D R Lunsford**
   November 24, 2004

   Well I can't get all depressed about the state of physics. This attitude is so self-indulgent – it's as stale as the denial-laden homilies of the stringer crowd.

   Physics is hard. Do it or shut up. This kind of whining is embarrassing.

   -drl

November 23, 2004

Physicists need some sort of validation. Since it no longer comes from experimentation, seeing their names in the paper alongside prominent cranks will have to do.

New U.S. Science Budget

November 23, 2004
Categories: Uncategorized

The U.S. Congress has finally gotten around to producing a budget for fiscal year 2005. Some information about the budget numbers for scientific research is available here and here.

The NSF budget for research and related activities is being cut by .7% from its FY 2004 level, the first such cut in many years. The other main part of the NSF budget, that devoted to education, is being cut even more. A few years ago Congress passed a bill that was supposed to double the NSF budget over several years, but that bill is now very much no longer operative. It's not clear yet how physics and math specifically fare under this new budget, presumably we'll find out in the next few days.

The bulk of particle physics funding comes from the DOE Office of Science, and there the budget situation is brighter, with an increase of 2.8% for FY 2005. Again, the details of exactly what is being funded and what isn't should soon be available.

Update: More about the new NSF and DOE budgets can be found here and here.

Comments

1. **Chris W.**
   December 4, 2004

   [..from Sean Carroll. The following are excerpts from articles on the NSF budget, with *emphasis* added.]

   June 5, 2002 — By an overwhelming vote of 397 to 25, the U.S. House of Representatives passed a bill that authorizes a $2.5 billion increase in the National Science Foundation (NSF) budget over the next three years. Under the legislation, the NSF budget would increase by 15 percent per year, from $4.8 billion in FY 2002 to *$7.3 billion in FY 2005*. The bill would put NSF on track to double its budget in five years. The NSF authorization bill, which is entitled the ?Investing in America?s Future Act of 2002? (H.R. 4664), must still be considered by the Senate.
   .. . .

   December 3, 2004 — **The Cost of Congressional Caprice** (The New York Times)
   .. . .
   If only the bill were a mere laugh riot. But the truth is that the measure, cobbled together from 13 bills that Congress failed to weigh separately and thoughtfully, legislates the costs of next year's government by blindfold and bludgeon.

   Nowhere is this more graphic than in the shocking cut that Congress levied on the National Science Foundation, the research dynamo that does so much to feed the nation's economic growth through breakthrough advances in science and technology. Its budget will be $105 million less than last year's, even as lawmakers spared an estimated $15.8 billion for a record 11,772 pet projects. This binge of bipartisan pandering to voters includes such national priorities as renovating the Hot Springs bathhouses in Arkansas and bolstering the Paper Industry International Hall of Fame in Wisconsin.

   The science cut may seem minor in the context of the foundation's total, more than *$5.4 billion*. But it signals harsher times to come. For the past two years, a profligate Republican Congress has allowed the deficit to balloon by papering over such factors as the open-ended cost of the Iraq war and the revenues lost because of the Bush tax cuts. Now leaner, meaner government has become the rhetorical rage, with basic institutions like the Environmental Protection Agency and the affordable-housing program joining the science foundation in taking hits.
   .. . .

   — — — — — — — — — —
   The FY 2005 budget was already going to fall well short of the $7.3 billion that was authorized by the House (but evidently not passed) in 2002, without the cut relative to FY 2004. What's up? From an interview one year ago:

   > **[Terrence] McNally**: What I haven't heard quite yet is the point which you make very strongly in the book, that the purpose behind the tax cuts is to bankrupt the government, to undermine social programs, so that no one who comes into office after them will have an easy time restoring them.
   >
   > **[Paul] Krugman**: I'm not making that up. That's exactly what the lobbyists and the others behind these people say. The program that the Administration is following looks as if it was designed to implement their ideas. I think it is.

2. **Lubo? Motl**
   November 24, 2004

   Dear Hacik,

   as you can see by looking at the words more carefully, "conservativism" is derived from the word "conservation".

   So energy conservation is a conservative value, much like PCs. 😉

   Thanks for your understanding.
   Lubos

3. **Hacik**
   November 23, 2004

   Energy conservation is so PC and left wing Lubos, I'm surprised to hear you buying into it.

4. **Lubos Motl**
   November 23, 2004

   You cannot create energy because of a principle that is called the energy conservation law. 😉 You can only convert energy from a less useful form to a more useful form – and the energy that our experimental friends will use to initiate collisions that will lead to production of Kaluza-Klein modes – with energy escaping to extra dimensions – is certainly more useful energy than any energy that you've used in your life. 😉

If this scenario is correct, a couple of megajoules will be enough to create a Nobel prize. 😉

5. **Hacik**
   November 23, 2004

   The DOE should get out of the particle physics business altogether. The purpose of the DOE is to create energy, not make it disappear into hidden dimensions.

6. **Lubos Motl**
   November 23, 2004

   It sounds kind of logical that the DOE funding is more stable in this situation because this department has a more "strategic" character. I would probably agree that the big budget deficit is not an ideal moment to increase funding of pure abstract science too much, and it would be nice if the deficits were reduced once again.

   America spends too much – and the trade gap is very big, too. You, Americans, should reduce your eating of everything else from the world. 😉

Review Article About the Poincare Conjecture

November 30, 2004
Categories: Uncategorized

An excellent review article about the state of the proof of the Poincare conjecture by my colleague John Morgan has recently appeared. For more background on this, see an earlier posting. Morgan is a topologist, and his article contains an excellent survey of what this all has to say about the topology of three-manifolds. This past semester he has been teaching a course in which he has gone through Perelman's proof very carefully. So far it all holds together.

Comments

1. **Deane**
   December 1, 2004

   Peter,

   I sure wish I had the time to drop by and ask Hamilton and Morgan more questions about this.

   You indicate that the crucial gaps are analytic.
   This surprises me. It's not the geometric or
   topological arguments that are unclear?

   Any chance you could be more specific about what
   kinds of techniques in analysis that Perelman is using and that people are uncomfortable with?

2. **Peter**
   December 1, 2004

   After further consultation with experts I think it would be fair to say that the situation is something like this:

   Parts of Perelman's outline have been filled in and people agree on them. But the status of other parts is still unclear and no one is about to claim yet that a complete proof exists. One problem is that Perelman is using some difficult techniques, for which it is not clear that there are adequate references in the literature. So filling in the details of his proof is a very non-trivial business. To start with you have to become an expert in the techniques he is using, and then you may need to do some hard work checking that these techniques really do work exactly the way they are supposed to.

   So the problem is that the work that needs to be done is quite difficult and requires some real expertise in some little-known techniques in analysis. And some of the experts may not be too motivated to do this, since if they invest the time needed there is a serious danger that either Perelman will scoop them by producing his own full proof (no one knows if he plans to do this and he is not saying), or their work will not be very valued by anyone, since people will think that all they did was work out details already known to Perelman.

3. **Peter**
   December 1, 2004

   Problem is that at this point if X writes up a detailed proof no one is likely to refer to it as the "Perelman-X" proof, especially since so many people have now been going through the process of working out the details for themselves.

   If X were to do this, I think it would be viewed more as a piece of exposition, rather than original research, and the reward structure of the field is such that expository work is not very highly valued.

4.
   December 1, 2004

   Peter wrote:
   ….I don't think the math community will be completely satisfied that there's a proof until someone (or a group) finally writes out a real, detailed proof, and I don't know if anyone intends to do this anytime soon….

   Hmmm, that seems funny to me. Since Perelman only produced an outline, I would think some one would want to do the legwork and share the glory. I would have guessed mathematicians would be interested in filling the "whoever" slot in the Perelman-whoever proof of the Poincare conjecture.

   After all, that's a hell of a paper for a struggling post doc looking for a job.

   ksh95

5. **Peter**
   November 30, 2004

   Hi Deane,

   I don't know of anyone now willing to stand up and make that claim. The problem is that Perelman has really only produced an outline of a proof, so a lot of work is necessary to fill in the details. Some people like Morgan are working on it and they haven't found any problems. I haven't talked to Hamilton about this, but I'd suspect he's more interested in trying to do something new than in filling in the details of Perelman's outline.

   I don't think the math community will be completely satisfied that there's a proof until someone (or a group) finally writes out a real, detailed proof, and I don't know if anyone intends to do this anytime soon.

   Peter

6. **plato**
   November 30, 2004

   I do not mean to interrupt thought processes here in regardng Poincare conjecture, but a little history was importnat for the commoners(me) to be exposed to a way of thinking that few can concieve of. I assumed all mathematicians and physics people are blessed with such insight?

> *The discovery of non-Euclidean geometry shocked them into understanding their error in expecting to determine the "perfect state" by reasoning alone. On the other hand, non-Euclidean geometry showed us that the human mind can defy intuition, common sense and experience in order to experience what worlds reasoning could create. The historian of mathematics, Morris Kline, summed up the meaning of these new geometries. The importance of non-Euclidean geometry in the general history of thought cannot be exaggerated. Like Copernicus' heliocentric theory, Newton's law of gravitation, and Darwin's theory of evolution, non-Euclidean geometry has radically affected science, philosophy, and religion.* ***It is fair to say that no more cataclysmic event has ever taken place in the history of all thought.***

But that's not the point I wanted to raise. It had to do what might be concieved of this wonderful world abstractually creating a road to GR which continues to expand. I know I am probably wearing peoples patience thin who are well educated and very articulate in the mathematical realms, and realms of physics, but has no one consider the context of the way in whch we can now see, in relation too, Einstein's realization of that extra dimension? Could have led to a more comprehensive view of where Einstein left off?

So one saids, "extra dimensions," one would have to engage the new world of non-euclidean with some good understanding to meet these new mathematics I am seeing developed here. By others along side of that physics.

I hope this post is acceptable here, as a form of a question, about why Peter you will not accept those extra dimensions?

7. **Deane**
November 30, 2004

Peter,

This article gives the status of Perelman's
proof as of last August. Is anyone
(Hamilton, in particular) ready yet to proclaim
Perelman's proof complete and correct?

Paul Baum on Baum-Connes

December 1, 2004
Categories: Uncategorized

I was down in Princeton at the Institute yesterday and heard two interesting talks. The first was the beginning of a series of four lectures by Paul Baum about the Baum-Connes conjecture, the second was by Chris Woodward about "equivariant localization". I'll write a bit about Baum-Connes here, perhaps something about the topic of Woodward's talk in a second posting.

The Baum-Connes conjecture was first formulated in 1982 by Paul Baum and Alain Connes in an unpublished paper.Roughly it says that the K-theory of the reduced C* algebra of a group G is identical with the equivariant K-homology of a certain sort of classifying space for the group. Equivariant K-homology classes can be represented by certain generalizations of the Dirac operator, and the map to the K-theory of the C* algebra is given by taking the index of the operator.

There's a huge literature about this by now and a few years ago Nigel Higson put together a detailed bibliography. Some recent expository articles about the conjecture include an ICM talk by Higson, a survey talk by Wolfgang Lueck, and a book by Alain Valette.

The conjecture remains unproved for discrete groups in general, and Baum said that he suspects it is not true in full generality, invoking what he called "Gromov's principle". According to Baum, this principle states that "No statement about all finitely presented groups is both non-trivial and true." While the conjecture has been proved for some classes of discrete groups, there are many for which it is expected to be true but remains unproved (e.g. SL(3,Z)). For a while it was thought that the conjecture applied also to groupoids, but counterexamples for groupoids have been found.

I've always been fascinated by part of the philosophy behind the Baum-Connes conjecture, which is to use equivariant K-homology, classifying spaces and Dirac operators to get information about representation theory of groups in cases where little is known about this representation theory. This is in some very vague sense related to what seems to me to be going on in QFT, where Dirac operators and path integrals over the classifying space of the gauge group (the space of connections) are somehow related to the representation theory of the gauge group. The Baum-Connes conjecture itself just involves locally compact groups and thus doesn't say anything about gauge groups, so it is not directly relevant to the case that may be of interest in QFT.

   Gromov's principle can be used as a jumping off point for some very interesting discussions. Let G be a discrete group. BG is defined as any CW-complex which is connected, and has G for its fundamental group, and has all higher homotopy groups zero. We can then take the homology or cohomology H*(BG). On the other hand in the realm of pure algebra we can write down a complex whose homology is H*(BG). It is a theorem that these two are the same — and this is valid for any discrete group. Of course many mathematicians would declare this to be trivial. But it took the best mathematicians of the nineteen-thirties (e.g. Heinz Hopf) much thought and much work to figure this out. So a lot of the content of Gromov's principle hinges on exactly what we mean by "non-trivial". Another issue with GP is what "about" means. In the last of the four lectures at IAS I'll give two statements which are relevant to Baum=Connes for
   discrete groups and which are true for all discrete groups. In the sense that Gromov had in mind these are undoubtedly trivial statements.But it took my co-workers and me quite a few years to figure this out and to come up with the proofs. So in the colloquial sense that mathematicians use the term "non-trivial" these statements are (it seems to me) non-trivial. So exactly what does "non-trivial" mean in Gromov's principle. Perhaps it means a statement which tells us something really deep and really meaningful about all discrete groups. Gromov is probably right about such statements.

   Peter Woit's comments about QFT suggest that someday we might have something like Baum-Connes for gauge groups. I hope this happens. It might be really fascinating.

Witten Localization

December 1, 2004
Categories: Uncategorized

The second talk I heard yesterday at the Institute was by Chris Woodward from Rutgers. What he was talking about was a conjectural formula whose origins go back to a truly amazing paper by Witten from 1992 entitled Two Dimensional Gauge Theories Revisited.

There are quite a few very interesting things about this paper, but one of its ideas has become influential in mathematics under the name “Witten localization”. This involves a new principle for calculating integrals of equivariant cohomology classes. Before Witten’s work, it was well-known among mathematicians that such calculations could in many cases be reduced to a “localized” calculation about the fixed point set of the group action. This is related to the Atiyah-Bott version of the Lefschetz fixed point theorem they discovered in the mid-sixties, to general arguments about equivariant K-theory and fixed points due to Atiyah and Segal, as well as to the Duistermaat-Heckman theorem and generalizations due to Berline and Vergne. For some expositions of this material, see the paper by Atiyah and Bott published in Topology in 1984, and the book Heat Kernels and Dirac Operators by Nicole Berline, Ezra Getzler and Michele Vergne.

Witten’s idea involved a new localization principle, where integrals of equivariant cohomology classes can be localized about zeroes of the moment map rather than fixed points of the group action. This is sometimes referred to as “non-abelian localization” since it applies directly to non-abelian group actions, whereas the earlier fixed point formulas typically looked at the fixed points of actions by abelian groups.

One of the main applications of Witten localization by mathematicians has been to use it to prove in various contexts that “quantization commutes with reduction”. For physicists this is the idea that, given a classical mechanical system with a gauge symmetry, one hopes to get the same result either by first imposing constraints and then quantizing, or by quantizing and then imposing constraints. Even in the context of finite-dimensional classical mechanical systems, that this should be true is a very non-trivial mathematical statement. For a survey of some of this, see an article in the Bulletin of the AMS by Reyer Sjamaar.

Witten’s original paper applied his ideas to the calculation of the Yang-Mills partition function in two dimensions. This uses the fact that the space of connections for a non-abelian gauge theory in two dimensions is an infinite dimensional symplectic manifold, with moment map the curvature of the connection, something first observed by Atiyah and Bott in the late seventies.

Woodward’s talk involved an integration formula similar to Witten’s original one, for details about it see his recent paper. This kind of formula was also studied by Paul-Emile Paradan, see this paper and a recent detailed summary (in French) by Paradan of his work.

Woodward’s work is also motivated by trying to understand the 2-d Yang-Mills partition function as an integral in equivariant cohomology. He and Constantin Teleman have done work on a K-theoretic version of this, see their joint paper as well as Teleman’s contribution to the proceedings of the conference in honor of Graeme Segal’s 60th birthday, and his talk at the KITP in Santa Barbara last year.

String Theory Gets Real – Not

December 3, 2004
Categories: Uncategorized

A recent issue of Science magazine has an article about the "Strings and the Real World" workshop at Aspen this past summer, entitled String Theory Gets Real — Sort Of. A more accurate title for the article might be "String Theory Would Like to Get Real — But Can't Because it Doesn't Work".

The article claims that up until recently string theorists were not even trying to connect string theory with experiment, but "Now a small but growing number of them are trying to forge connections between string theory and detailed data". This is really nonsense. There have always been plenty of people doing "string phenomenology", but it has always been a doomed subject, for reasons I've gone on about at length here and elsewhere. The article does mention the problem of the Landscape with the increasingly standard loony comment that "physicists may have to rethink what it means for a theory to explain experimental data". This is absurd. There's no question about what it means for a theory to explain experimental data and the simple fact of the matter is that this theory can't do it.

There's also a claim that "the cosmological constant now appears to be real, and string theorists hope to calculate its value". This misunderstands the whole Landscape argument, which tries to justify why no one can ever hope to calculate this value.

The article also includes a sidebar which tries to explain why young people go into string theory. It quotes a Penn postdoc, Brent Nelson, as saying that he read about string theory as a teenager and couldn't believe so many people accepted something so outlandish. But he went into string theory anyway, and now says "I haven't learned enough… I still don't know why I should believe". Sorry Brent, but no matter how long and hard you stare at this particular emperor trying to appreciate the beauty of his clothing, he's still going to be naked as a jaybird.

Finally, when asked how many revolutions will be needed to make string theory work, John Schwarz says "I don't know, but I think we'll need many more". At about a decade per revolution, it looks like Schwarz now doesn't expect to live to see this happen. Neither do I.

2. **Lubos Motl**
   December 6, 2004

   "God that failed" – like the communist ideology – is a pretty good formulation that keeps the reader interested. It's obvious that a good journalist would always ask this question in this way.

   However, if you open The Elegant Universe by Brian Greene, for example, you will see a lot of comparably elegant possible criticisms against string theory (Chapter 9). 😉 String theory is undermining science like medieval theology; string theorists should not be allowed to convert sensitive students into perverse deviants etc. 🙂

   Of course that these questions and strong words are said exactly because the answer that they suggest is probably not true, which is the truly exciting part of the story.

3. **Chris Oakley**
   December 6, 2004

   Is string theory the physics equivalent of The God That Failed, as some people used to say about communist ideology?

   It is interesting that Scientific American should ask a loaded question like this. Maybe the tide is finally turning, and not in favour of those who think we need to change the dictionary definition of science.

4. **plato**
   December 4, 2004

   A perfect opportunity Peter, to tell them what you think?

   It is truly an exciting time in cosmology where experiments have produced and are continuing to yield an abundance of precision data. Similarly, collider experiments at Fermilab, SLAC and CERN, as well as precision low?energy experiments, have the potential to make remarkable new discoveries in particle physics in the next five years. Hence **string phenomenology** is both a timely and exciting topic of a workshop in 2005.

5. **Lubos Motl**
   December 4, 2004

   Concerning the interview with L. Krauss.

   I think that it is still an interview with a string theory layman. It's great to say that string theory has not revealed the nature of dark matter, but on the other hand it is not the most straightforward question that string theorists should ask.

   Eventually, unless the MOND-like theories will turn out to be right, the dark matter will just be *something*, a new particle (like bino, a superpartner), and there won't be too much to learn about other physics from this single piece of information.

   Krauss describes LQG and string theory almost on equal footing, which is of course ridiculous, but at least, he mentions the obvious fact that string theory has led to interesting mathematics, unlike loop quantum gravity.

Is there someone here who believes that LQG has led to interesting mathematics?

6. **plato**
   December 4, 2004

   Maybe they didn't understand the essence of the blackholes and the mathematical framework that was to go along side of the physics?:)

7. **Chris W.**
   December 3, 2004

   You know, Peter, I sense an increasing ennui spilling out into the popular science press, and a tinge of cynicism in the comments of journalists in spite of themselves. Another example occurs in this interview with Lawrence Krauss:

   > **SA**: Is string theory the physics equivalent of The God That Failed, as some people used to say about communist ideology?
   >
   > **LK**: Not exactly. But I do think its time may be past. String theory and the other modish physical theory, loop quantum gravity, both stem from one basic idea: that there's a mathematical problem with general relativity.
   > The idea is that when you try to examine physical phenomena on ever smaller scales, gravity acts worse and worse. Eventually, you get infinities. And almost all research to find a quantum theory of gravity is trying to understand these infinities. What string theory and what loop quantum gravity do is go around this by not going smaller than a certain distance scale, because if you do, things will behave differently. Both these theories are based on the idea that you can't go down to zero in a point particle, and that's one way to get rid of mathematical infinities. The main difference, I think, between the two theories is that string is intellectually and mathematically far richer.
   > String theory hasn't accomplished a lot in terms of solving physical problems, but it's produced a lot of interesting mathematical discoveries. That's why it fascinates. Loop quantum gravity hasn't even done that, at least in my mind.

   With respect to his comments on LQG, I'll have to bite my tongue for the moment.

Shiing-Shen Chern 1911-2004

December 5, 2004
Categories: Obituaries

Shiing-Shen Chern, one of the great geometers of the twentieth century, died last Friday at Nankai University. He was 93 years old. An article about his life is posted on the website of MSRI, the mathematics institute in Berkeley of which he was the founding director.

A lot of what I know about geometry was learned from his beautiful short book entitled "Complex Manifolds Without Potential Theory", published by Springer in 1979. Some of his most important work concerned the topology and geometry of fiber bundles, and its significance can be seen in the number of crucial ideas of this field that carry his name, for instance: Chern classes, the Chern character, Chern-Weil theory, the Chern-Simons secondary characteristic class.

Update: The New York Times has an obituary.

1. **D R Lunsford**
   December 15, 2004

   OK, much better,

   Chern classes (and characters) are a way of systematically classifying the possible types of field configurations: trivial (0), monopole (1), etc..

   *In other words, the monopole is in the *pure gauge theory without matter* (like instantons in Y-M).*

   Thanks, much clearer.

   -drl

2.
   December 15, 2004

   Maybe the confusion here is over the term "monopole". For lay physicists, it implies some sort of source.

   However, in this case, it is the *gauge field* A_{\mu}(x) that can have "monopole-like" properties, i.e., the field strength corresponding to the gauge configuration falls off like a monopole; it is as if there was a monopole at the origin causing this field.

   Chern classes (and characters) are a way of systematically classifying the possible types of field configurations: trivial (0), monopole (1), etc…

   An example is from the Fubini-Study metric (U(1) over S^2):
   F=(2i rdr d\theta)/(1+r^2)^2. Integral of (iF/2\pi) is -1; there is no "charge"!

   In other words, the monopole is in the *pure gauge theory without matter* (like instantons in Y-M).

3. **D R Lunsford**
   December 14, 2004

   Peter,

   Below, you used the example of the Dirac monopole to illustrate a Chern class. What I was saying is – apparently you can use this classification to distinguish between the end of a long string of end-to-end magnetic dipoles, and the (on the face of it) equivalent distribution of acutal poles. This isn't obvious and depends on the duality invariance of the energy tensor.

   What you just described was simply Gauss' theorem, other than the integer part.

   (I just used Maxwell as an example because it has a potential theory.)

   -drl

4. **Peter**
   December 14, 2004

   Chern classes are purely topological. All they do is look at the field strength on a sphere, and use it to tell you the number of monopoles inside the sphere (and that this is an integer).

   So this has nothing to do with the Maxwell equations, Chern's formalism doesn't care at all whether the field strength satisfies any equations at all. Neither does it have anything to do with the sources that occur in the Maxwell equations.

5. **D R Lunsford**
   December 14, 2004

   Peter,

   I don't think I was clear. Let's just say we replaced every pole by a charge and so, in the magnetodymanic world we'd have

   E = -D x A
   B = -Da – dt A

   and of course Maxwell is

   div E = 0

div B = m

curl B – dt E = 0
-curl E – dt B = M

with D^2 A = M etc.

In this world electric charges are associated with a singular magnetic vector potential. Because the energy tensor is duality invariant, nothing is any different as long as you stick to countably many discrete charges.

The point is, Maxwell-Lorentz really needs a density as a source, not a countable collection of poles each carrying a singular potential.

So the Chern must say something about the *sources*, in terms of how they can be locally "smeared out".

-drl

6. **sd**
December 14, 2004

Chern classes and Chern-Simons theory are discussed in Baez and Muniain, Gauge Fields, Knots and Gravity.

7. **DMS**
December 14, 2004

Peter,

Many thanks for the pointers on Index Theorem; Freed's notes look very nice!

DRL-

Here is a rough way to understand the Chern class.

Consider D=det(I+(i/2pi)F), where F is the curvature 2-form transforming as UFU^{-1} under gauge transformation U. Note that D is invariant under gauge transformations.

But D can also be expanded as a polynomial in F, in terms of homogeneous polynomial, P_j(F), of elements of F of order j. The j-th Chern class is the cohomology class determined by P_j(F), which is clearly independent of gauge (connection) choice .

8. **Peter**
December 14, 2004

Actually the syllabus that's up for that course is for the entire year. In the first semester we just did general manifold and bundle theory, will start next semester with Riemannian geometry, hope to get to the index theorem at the end.

There are quite a few good books about the index theorem from various perspectives. For the point of view I'll be taking in my course (if I get to this…), a good reference is Dan Freed's notes that are on the web, see his webpage for a whole course he taught on the index theorem:

http://www.ma.utexas.edu/users/dafr/Index/index.html

For the more abstract K-theory point of view, it's hard to beat some of the expository things Atiyah wrote about this. There are several such articles in Volume 3 of his collected works, one (Classical groups and classical differential operators on manifolds) in Volume 4 (this last one is highly recommended)

9. **DMS**
December 14, 2004

I just looked at the table of contents and excerpts of Morita's book on amazon and it looks like it is clearly written and even I should be able to grasp its contents!

But, unfortunately, no discussion of the Atiyah-Singer Index theorem, which you covered in the first part of your course.Do you know a good reference for that (that does more than just quote the theorem "analytical index=topological index")?

Perhaps there is a book that gives a glimpse of whatever has been happening since then in modern geometry (heard Gromov has done a fair bit, of which I know little).

10. **Peter**
December 14, 2004

Since my last class for the semester was yesterday, right now I'm just enjoying not having to think about geometry for a while, and being able to get to work on other projects. I don't intend to write up notes for the geometry course this year (it will continue next semester) for several reasons:

1. I'm way too busy.

2. This is the first time I've taught this, and whenever you teach something for the first time, you only realize after you've started explaining some topics that there is a better way of approaching things.

3. While there's no book out there I'm completely happy with, there are quite a few good ones of various kinds, and pretty much everything I've been talking about is covered reasonably in one or another. One book I've grown to like as I have looked at it over the semester is "Geometry of Differential Forms" by Shigeumi Morita. In the case of the representation theory course, the standard books didn't cover much of what I wanted to explain (especially connections to physics).

If I teach the course again (probably not for a few years), then maybe I will try and write up some formal notes for it.

Danny,

For better or worse, mathematicians have a whole apparatus for dealing with vector potentials and field strengths that avoids having to introduce singular vector potentials when the field strength is not singular. From this point of view Dirac singularities come about because you are trying to write down a trivialization of a topologically non-trivial bundle. When you do have a topologically non-trivial bundle, like in the case of a monopole, basically you can't choose the same gauge globally, unless you are willing to introduce singularities. By thinking of a choice of gauge as something you can only do locally, you avoid the whole problem of these singularities.

Peter

11. **DMS**
December 14, 2004

Actually, it would not be a bad idea if Peter (who may have a lot of time on his hands :)) could write up some notes on the Modern Geometry course he is teaching for the current (and next?) semester . Just like he did for the Lie group and representation course.

12. **D R Lunsford**
December 14, 2004

If I understand your previous reply, Chern classes are a formalization of what Dirac did when he concocted his "singular potential" by imagining the A field associated with an infinitely thin, infinitely long solenoid stretching off to infinity. Now why couldn't one just write

E = -curl V
B = -grad v – dV/dt

and pretend charges are "Dirac electropoles", thus replacing the nice potential A with a singular one V? Is it because you could not smoothly pack these electropoles into a volume and come up with an average density (you'd have "singular potential hair" – the electric solenoid strings) uniformly stretching out to infinity)? So is Chern theory must basically be a theory about the nature of sources…

-drl

13. **Peter**
December 13, 2004

I've put off writing about the geometric Langlands conjecture for a little while, partly because I wanted to take some time to see if I could understand it a bit better. But also I couldn't help myself from writing about the latest on the Landscape.

Chern's title is a somewhat strange one. I think he was trying to indicate that he concentrates not on the theory of holomorphic functions, but on the complex geometry in the sense that a complex manifold is one where you can consistently locally choose complex coordinates. Of course once you do this, you can't really avoid thinking about holomorphic functions. But a lot of what Chern studies involves complex vector bundles over complex manifolds, but not necessarily imposing the condition that these are holomorphic vector bundles (i.e. the transition functions you use to glue together the bundles may not be holomorphic).

14. **D R Lunsford**
December 13, 2004

BTW I meant to ask the meaning of the title "Complex analysis without potential theory". Doesn't analyticity imply potential theory?

-drl

15. **Peter**
December 13, 2004

Actually I was just about to write something about the Langlands program and physics. Either later today or tomorrow.

I hadn't heard about the hole in Dean's proof, will add an update to that weblog entry

16. **DMS**
December 13, 2004

Hi Peter,

I second Levi and drl; I enjoy your mathematical posts, especially when I can understand a significant portion 🙂 I think it is especially useful for physicists who would otherwise think that there is not much in mathematics outside current fashions in string theory-related mathematics (typically those results derivale using analytic methods).

Someday, maybe take up what was it about Grothendieck's work (schemes, Grothendieck group, etc.) that makes it so powerful even now (like Voevodsky's Field medal work). Or Langland's conjectures and their impact on mathematics, so we physicists can appreciate more the remarkable work being done in other areas of mathematics. In such instances, your dual background in math and physics is very helpful.

PS: Sorry to hear about a loophole in Carolyn's proof on the Jacobian conjecture; hope she fixes it.

17. **D R Lunsford**
December 12, 2004

I love the mathematical asides – otherwise I'd probably never know what was happening out there.

-drl

December 12, 2004

Thanks for the encouraging comments about the more mathematical postings. I certainly intend to continue to write more things of that kind.

19. **RT**
December 12, 2004

I wholeheartedly endorse Levi's comment; the postings that generate the least polemic and diatribe are almost invariably the most interesting

20. **Levi**
December 12, 2004

Peter,

In the comments to the post “String Theory at 20 Explains It All-Not” you note that there aren’t many comments when you post on the subject of mathematics and the mathematics of quantum field theory.

I hope you realize that a lack of comments doesn’t necessarily indicate a lack of interest. It often just indicates a lack of controversy. I wanted to mention this since your (too infrequent) posts on mathematics are my favorite posts on this blog.

21. **Peter**
December 8, 2004

Hi Danny,

Too bad you’re not near here, I just spent the last week or two lecturing about Chern classes in my graduate geometry class.

A good reference for physicists is

Eguchi, Gilkey and Hanson Physics Reports Vol. 66, number 6, 1980

There are also various books about geometry and topology for physicists that should discuss this.

To understand what is going on, first think about U(1) gauge theory. The field strength is a closed 2-form, so represents a cohomology class of the manifold. Physically, if you consider a sphere S^2 in R^3, integrating the field strength 2-form over the sphere counts the number of monopoles inside the sphere. So this cohomology class (the first Chern class) detects the non-trivial topology of a U(1) bundle on a sphere surrounding a monopole.

For U(1) you just get the first Chern class, for U(n) you get n different Chern classes, basically by taking powers of the field strength (=curvature) and then taking a trace. The algebra gets a little intricate, but it’s basically the algebra of symmetric polynomials.

Peter

22. **D R Lunsford**
December 8, 2004

Does anyone have a good reference for the appearence of Chern classes in physics? I’m extremely foggy on this stuff (mainly because I can’t understand modern math langauge and have no access to the oral tradition required to translate it).

-drl

23. **Deane**
December 6, 2004

This is easily proved:
http://www.genealogy.ams.org/html/id.phtml?id=6424
Note how many mathematical grandchildren he has!

24.
December 6, 2004

Sad news indeed. He seems to have been generous and an excellent mentor as well. Among his many outstanding students was the Fields Medallist Shing-Tung Yau of Calabi-Yau fame.

String Theory, at 20 Explains It All – Not

December 7, 2004
Categories: Uncategorized

This morning's New York Times has a long and prominently placed article about the 20th anniversary of the "First Superstring Revolution". The Times has a long history of producing overhyped uncritical articles about string theory, for a classic example, see "Physicists Finally Find a Way to Test Superstring Theory". This one does allow some critical voices to be heard, including Lawrence Krauss, who is quoted as describing string theory as a "colossal failure" (which is different than a miserable failure)

Krauss is also quoted as saying "We bemoan the fact that Einstein spent the last 30 years of his life on a fruitless quest, but we think it's fine if a thousand theorists spend 30 years of their prime on the same quest."

Witten is quoted extensively, but he doesn't sound very optimistic these days, saying "It's plausible that we will someday understand string theory", and making the rather weird statement that string theory is "so vast, so rich you could say almost anything about it" (for instance that it is a colossal failure?). He also seems to have given up on the idea that there is some fundamental new symmetry underlying string theory, instead putting his hopes on the existence of some new principle for constructing space and time.

The article also says that few theorists will give up on string theory when supersymmetry is not found at the LHC, with Witten interpreting this not as evidence that string theory is wrong, just that unfortunately it will be harder to get experimental evidence for it than he had hoped. String theorists in general seem to have trouble getting their minds around the idea that it is even possible the theory is wrong. Jeff Harvey does admit that sometimes he wakes up thinking "What am I doing spending my whole career on something that can't be tested experimentally?", but the question of "What am I doing spending my whole career on a colossal failure?" doesn't seem to keep him awake nights.

The article ends by quoting an exchange between Steve Shenker and my colleague Brian Greene. Shenker quotes Churchill, describing the state of research into string theory as "perhaps it is the end of the beginning". Brian seems to be one of the few string theorists around willing to actually consider the idea that the theory might be wrong, arguing that if string theory is wrong, it would be good to know this soon so physics can move on.

   December 15, 2004

   I am surry in my previous post I missed the PI:

   "G=1/2N
   N=exp(2/3*\alpha)"

   It should be
   N = PI * exp(2/3*\alpha)

   G is a dimentionful value and N is a dimentionless value. Does it really bothr you that in
   G = 1/(2N)
   I simply omitted the units that should follow 1/(2N). Is that a problem, 99.999% of physicists do not include notations of kg, meter, second in the equations they derived. I never see that as a problem.

   There is a reason for that specific form of exponent exp(2/(3*alpha)). These are not arbitrary choosen numbers, they are not any arbitrary fractional number. I can tell you it's related to the 3-D space and 4-D spacetime. But it is simply not possible to discuss all details of a great theory in short messages on a BLOG web page. Youc an discuss the basic ideas and give some typical calculations, but you simply can't go into too details.

   I have shown how I obtained the precise value of proton mass. I would have also shown how I derived the EXACT mass of the neutron, based on known half life of nutron being 1013 seconds. It has 9 places of effective digits and is well within the experimental error of the best known experimental value.

   I did not use any fractional number or expansion series. The calculation is extremely simple, and has physics reasons behind it. It is definitely and absolutely no coincident when you get a number accurate to the 9th digit, and matches NIST experimental values exactly.

   I respect Peter's request. I will refrain from posting more about my theory today. I will discuss how my neutron mass is calculated and give the detailed description, at a later time, if there is any curiousity.

   December 15, 2004

   Someone wrote:
   "Now in the natural unit let Newtons constant G be

   G=1/2N
   N=exp(2/3*\alpha)

   …………
   G is dimensionful and N is dimensionless–you can't equate dimensionful and dimensionless quantities! All you get for G is a dimensionless number thats wrong. In natural units (hbar=c=1)
   G still has units of m^{2} or cm^{2}so you still cant equate it to N or alpha in any way unless you have an extra factor that makes it dimensionful. Even then what you get is a total rubbish and meaninglessly contrived "formula" for G that could have been contrived in countlessly many ways from alpha.

   There is no mathematical basis, proof, derivation or justification or reason for presenting your N other than it will give the numbers you want by working backwards. Why not N=pi exp(4/5alpha) or
   N=pi exp(1/10alpha)? Since there is no rigorous derivation or justification then these are just as good. But those simply dont give the answers you want or the "mysterious coincidences" do they?

   Contrived numerical "coincidences" involving the fine structure constant are very easy to make up. For example, I can quickly make up my very own "magic N" right now and get a "theory". Lets see…if
   N=exp(9593/(10000 * alpha)) then calculate
   M=m_{p}* N were m_{p} is the proton mass I get

M=(1.67^{-24}g) exp(131.4241)
=1.99 x 10^{33} grams, which is the exact mass of the sun, assuming I have'nt made any mistakes. So what?! Totally meaningless since I just made N up to get the right answer I wanted, via 30 secs on a calculator. With a little more and time you can contrive really good ones and its made easier by the fact you are calculating very big or very small numbers. The trick is to take as many decimal points in the accepted values and work backwards. The fine structure constant is actually interesting but this is all nonsense.

3. **plato**
December 14, 2004

We need a way to measure NCG in the microstates.

If gravity is strong, there would be indication that such a resonance curve would have revealled itself? Spectrally, your Guitar would make wonderful music?:)

An important feature of atomic spectra that arises from relativity is fine structure – so called because what at first appears to be a single line in a spectrum is actually seen to consist of two or more closely spaced lines when analysed with high precision. Fine structure arises because the electron has an intrinsic angular momentum or spin that interacts with the magnetic field that is produced, for example, as the electron orbits the nucleus at relativistic speeds. The strength of this interaction is characterized by the fine-structure constant, a, given by e2/2e0hc, where e is the charge of the electron, e0 is the permittivity of free space, h is Planck's constant and c is the speed of light. This dimensionless constant has a value of around 1/137. The equations for fine structure contain a factor of a2, so the spacing between the lines is suppressed by over a factor of 10 000.

4. **Quantoken**

Plato:

I was aware of all the noises about changing alpha or other fundamental physics constants.

It's all nonsense. There hasn't been any solid experimental data showing alpha is ever changing. Any miniscue "change" observed are just experimental errors. Actually the very notion that alpha could be changing would be strange for any one to have, except for that the SuperString camp probably need to have that changing alpha, just as they desperately need to find a decaying proton.

Should alpha be different billions of years ago, then shouldn't it also be different today but at a location billons of light years away? The special relativity tells us time and space are all relevant. Two different time can well be transformed to two different location in another reference frame. So if alpha is different in different part of the universe, then there could be no physics because you no longer have a set of physics laws that are consistent within the whole universe.

Alpha could never be change and should have the same value here or there, now or billions of years ago. I have demonstrated that alpha is directly related to the size of the universe, because the big N can be calculated easily from alpha. And the radius of the universe equals to a trivial factor times the big N. If you measure the size of the universe from different location, you would get the same number, and hence the same alpha. For the same reason alpha should be the same at different times.

Some in the establishment crackpot science even suggested C be changing over time. That's absord!
How do you know one meter billions of years ago equals to one meter today, and one second time billions ago is the same as one second today? You need that scale consistency to make a meaningful comparison between a speed value billions of years ago and a speed value today. Otherwise you can't even do a comparision and find out any change. And what could provide that ruler that is consistent? Any ruler made of materials could change, even the space itself could be expanding or shrinking, according to theoretists, so light speed in vacuum is the ONLY ruole you can rely on for such a comparison.

So by that notion, the vacuum light speed has been a DEFINED VALUE and it could never possibly change. For the same reason, the time scale, which rely on atomic clocks, would not change either. So the physics that atomic clock rely on, including the alpha, can not change. So these physics constant can not change because they are the very things that define the scale of length, time, and mass.

Alpha does not change, hbar does not change, C does not change, G does not change, the Universe radius does not change. They are all connected and they have been in this universe even before there was space and time. and they can not change.
Without them being constant by definition, we don't even have rulers and clocks for any physics measurements.

December 14, 2004

Not in natural units and not in QED where the fine structure constant is the coupling constant. I also meant dimensionless physical quantities Y are the dimensional multiples
Y=X* habr^{a}*c^{B}G^{c} for some suitable exponents a,b,c.

6. **plato**
December 14, 2004

Changes in the Fine Structure constant?

7. **Quantoken**
December 14, 2004

Matt also said:
"Natural or Planck units ONLY work when you have combinations of hbar,c and G that are dimensionless multiples as discussed."

I say: go figure and try to come up with a combination of hbar, C and G that is DIMENTIONLESS. Because if you do find such a combination, except for the trivial one hbar^0 * C^0 * G^0, then they will have to return all Nobel physics prizes ever awarded.

You can't find such a dimentionless combination out of hbar, C and G and nothing else. I thought your physics teacher should have taught you that in high school physics.

Quantoken

8. **Quantoken**
December 14, 2004

Matt:

I am curious where did you go to school and who taught you physics and how you get your degree, if you have one. They need to recall you for a failed physics education.

Alpha is the fine structure constant and it is a dimentionless physics constant. As such, the value of alpha never changes, regardless of the unit system you adapt, and regardless of any physics theory you develope. On another planet if there's intelligent life developing a different set of science, they will find alpha to be the same value.

Physicists like to write alpha as alpha = e^2/(hbar*C), for the convenience of calculation, Because normally to get quantities like interaction energy, the change e most times occur in the form of e^2. So any time you see a e^2 you do the calculation using the help of alpha. But you never actually plug in the e value in columb to calculate.

To do the calculation strictly in MKS unit sets, there are additional factors to be inserted in the formula, it is not just e^2/(hbar*C). It is actually e^2/(4*PI*Epsilon0*hbar*C). When you counted every thing in, alpha is still a dimentionless number, and remains unchanged under any unit system.

Quantoken

9. **Matt**
December 13, 2004

You defined a quantity in your natural units as

Mo=m_{e}/alpha=1.248 x 10^28kg = me *137

where m_{e} is the electron mass in kg and you used alpha=1/137. I just checked that on my calculator.

However, in natural units with hbar=c=1 (and leaving G fixed and NOT equal to one as you prefer) then
alpha=e^{2}, where e is the charge of the electron. Since alpha=e^{2}/(hbar* c) = 1/137 it is NOT dimensionless in this unit system when hbar=c=1.

You can't have a computation where hbar=c=1 AND alpha=1/137 like you have done, even if G is not set to one…even if you forget G exists! When hbar=c=1 then the quantity you computed is actually Mo=m_{e}/e^{2}, which of course is not in kg. Nothing you say therefore makes any sense at all especially the statement "Assuming the electron mass is equal to the fine structuree constant in natural units" (your words).
It is electron charge that is related to alpha in any unit system and not electron mass.

However, you also take your Mo and compute
an Eo=Mo*c^{2}then define a ro=hbar*c/Eo but you then used the FULL values of habar and c again when you already said these quantities where defined in "natural units" of for hbar=c=1! But it is all academic anyway since you can't define Mo in the first place using your own natural units!

Also your N =exp(2/(3alpha)) can't be defined in your natural units of hbar=c=1 since the exponent now has units of e^{-2} where e is the electron charge. Again, thats with hbar=c=1 and G left alone and NOT equal to one! Since you can't define N when hbar=c=1 then you cant define your G as G=(1/2N) either. When hbar=c=1 then N must have units of m^{-2}or cm^{-2}if G is a gravitational constant.

Natural or Planck units ONLY work when you have combinations of hbar,c and G that are dimensionless multiples as discussed. Even if your choice of natural units is only to set hbar=c=1 as you say and leave G the same you are still wrong since again alpha is still then not equal to 1/137 and your N is simply not defined since you can only take the exp of a dimensionless quantity.

I will quit here for good I think since I really don't want to clog up Peter's blog with all this pointless discussion or encourage any more. The readers here can easily decide for themselves about what is wrong or not even wrong.

10. **Quantoken**
December 13, 2004

Matt:

Before you further distort my words. Let me make one thing clear. My natural unit set is NOT the same as the claimed natural unit set on the textbook, which was obtained by setting hbar=C=G=1, i.e., the Planck Scale.

My natural unit set do NOT set G=1, that's a big difference. Just ask theorists why their calculation of vacuum energy or the cosmological constant is always off by a huge margin of 120 orders of magnitude? Why they can never get the number right? Because they used G as if it is a microscopic constant, stupid!

G is not microscopic constant! They can replace G and use the height of Mount Everest, or the mass of the moon instead in their calculation of vacuum energy, and it would not be better or worse than using G in their calculation. All of those are macroscopic numbers and they shouldn't use them to compute physics at microscopic scale.

Do you realize physicists are in a dead end for this 120 orders of magnitude problem? Or are you going to deny existence of this problem altogether?

Quantoken

11. **Quantoken**
December 13, 2004

Matt:
Why do you have to distort what I said in order to argue with me? My original wording is:

"But first let me adopt a set of natural unit, the unit is derived by setting HBAR and C to be exactly one, and assuming the electron mass is alpha, the fine structure constant, when measured in the natural unit:

m0 = Me/alpha = 1.2483×10^-28 kgs
E0 = m0*C^2 = 1.121928×10^-11 Joules
r0 = (HBAR*C)/E0 = 2.81794×10^-15 meters
t0 = r0/C = 9.39964×10^-24 seconds

r0 happen to be the classical electron radius, but don't read too much into it. There is nothing classical.

Now, in the natural unit set, let the Newton gravitational constant G be defined as:

G = 1/(2*N)"

Clearly, I fixed my natural unit set by setting the numerical value of hbar and c to be one, and fixing the numerical value of electron mass to be equal to alpha. Once you fix the three, you get a natural unit set because there are three measurements to be fixed, the length scale, the time scale and the energy/mass scale.

In the later formula I said in the context of natural unit set:
G = 1/2N

Clearly in no way did I imply G is dimention-less. G has an implied unit which I stated to be that constructed from the natural unit. So my formula tells the numerical value of G, in natural unit set.

The important thing is this is not just an arbitrary unit set. The time and length scale is the correct scale at which time and space lose continuity.

It remains that my theory arrives at the exactly correct CMB temperature, which no ther theory can. And as a bunus I also gave the correct solar constant in the same set of calculation.

Quantoken

12. **Matt**
December 13, 2004

Total nonsense Quantoken. For one thing, in the forum web pages you quoted, farther down in the thread in your first post, you begin by totally abusing the natural unit system. You defined c=hbar=1 then formed a “dimensionless quantity”
G=1/(2N) where N is a dimensionless number, which you give as
exp(2/3 * \alpha) where alpha is 1/137 and G is Newtons constant. However, when hbar=c=1 then G is about G=2.5 x 10^{-70}m^{2}. Note the units now. G is still dimensionful! N would have to have units of m^{-2}or cm^{-2} in this system and is therefore not dimensionaless. If you set hbar=c=G=1 then your number N is just N=1 and won’t give you the answers you want and then contradicts the value of N given by your exp formula. The rest of your derivation then falls on its face. All you did here was essentially take the accepted values of the constants or what you are trying to calculate, altered them at so many decimal places then worked backwards to contrive a “formula” that calculates them “with great accuracy”. There is no theoretical basis or underpinning to any of it.

All physicists know that it is virtually impossible in this natural system of units to use dimensional analysis or to check results for consistency even if you intend to put back c and h and G. The system only works in the first place because for all suitable exponents (A,B,C) and (A’,B’,C’) the interesting physical quantities are dimensionaless multiples of
M_{P}^{A}*L_{p}^{B}*T_{p}^{C}
= hbar^{A’}* c^{B’}* G^{C’}
where M_{P} is the planck mass, L_{P} is the planck length and T_{p} is the Planck temperature.
It is useful and elegant in quantum gravity and cosmology if done right. However, I see from previous posts that explaining anything concrete to you is like trying to nail a rice pudding to the wall.

13. **Quantoken**
December 13, 2004

Now I am going to give a detailed rebuttal to Mr. M-?’s comment on CMB. First quoting his words:

“Yes I CAN honestly say the CMB is NOT star radiation since the CMB is homogeneous and isotropic to an astonishingly high degree. That is, it is the same everywhere in the universe and in every direction. This has been measured with great precision. It is in thermal equilibrium, is blackbody and is absolutly uniform! It is also part of the horizon problem in cosmology, which inflationary models seek to address. The CMB background also has Gaussian fluctuations, which have been measured.

The energy density of starlight falls off as the inverse square so that far from a star, at a distace R, the luminosity is L/4 \pi R^{2}. At sufficiently large distances (and the interstellar spaces are pretty large!)then L–>0. Total radiation from all stars in the universe or a galaxy cannot reach thermal equilibrium and is NOT homogeneous and isotropic. If you have a spherical cluster of millions of stars then the radiation density or luminosity at R (say with respect to the centre of the cluster) is different from the radiation density/luminosoty at some R’. Far from the cluster the radiation density falls to near zero. Hence you need a big telescope to see it!

An infinite, eternal, static and Euclidean universe full of eternal stars can reach thermal equilibrium but then every line of sight would then terminiate at a star’s surface and the night sky would be blazing white and not dark. This is the Olbers paradox and is in direct contradiction obviously to what is observed. The resolution is that redshift effectively cuts off the infinite energy density of starlight.

Also The “M” in CMB stands for “microwave” and stars emit mostly in the visible and IR in case you hadnt noticed. The reason the CMB is “microwave ” is because it has been redshifted. It is a remnant of the time radiation and matter decoupled as the universe expanded. That is why is it so astonishingly homogeneous and isotropic. There is no other possible expanation for it and is the strongest piece of evidence for the Big Bang. Along with predicting redshifts of galaxies and the correct ratios of hydrogen to helium.”

Here are my comments:

I accept every observational facts you cited. But I reject every interpretations of them cited from standard textbooks. I agree that any sounding theory must be self-consistent, and be able to account observational facts without contradicting OTHER known facts. The textbook explainations do not meet this later criteria.

The textbook has NOT been able to explain away where does all the regular star radiations go? Unless you have a giant blackhole to suck up all star radiations, they should still be there and should be observed, in the right amount of energy density per unit volume. The CMB happen to provide the correct amount of energy accounted for the star radiations. we know the CMB is virtually all the radiation energy there is filling the cosmos space. All other frequency spectrums only acocunt for a very small proportion of all the radiation in the universe.

My theory, on the other side, do account for the homogeneous and isotropic and blackbody radiation spectrum properties of the observed CMB, and do not need to answer the puzzle where does all the star radiation go. Because star radiations ARE the source of CMB.

In my theory, star radiation do shift to the lower frequency end as they travel through the space for billions of years. This redshift, having nothing to do with Dopler Effect or gravity red shift, is made necessary by a fundamental requirement of my theory, that the quantum information in the universe is a conserved amount. If star lights do not red-shift, we would be able to obtain information from any arbitrarily far away distance, and hence the amount of information would not be a fixed amount, but rather an infinite amount.

Quantum information conservation not only leads to the Hubble Redshift we observe. It also leads to the conclusion that the observable universe is neither expanding nor shrinking. Hence the radius of the universe will not change. Therefore the relationship between G and the universe radius that was discovered by Paul Dirac is NOT just a coincidence that we happen to live at a time when the universe happen to expand to the correct radius for that relationship to be true. Instead it is not coincidence at all and the relationship reflects a fundamental physics principle that has always been true, regardless of what time we live in.

Remember the Mach principle which says the whole mass of the universe caused gravity and inertia?

Once again, my theory accounts for all observation facts and makes precise predictions, without any self-consistency problem. I just have not got a chance to reveal the full details of my theory, yet. Given time, I will do it. If you are serious in pursuing scientific truth, please reserve your judgement until you learn the full details of my theory.

Now, can any one do me a favor, and show a calculation of star radiation energy. And see what's the energy density is when averaged over the volume of the universe? Such calculation should be easy, given the known radius of the universe, the critical density according to Einstein Equation, and the baryon density being about 5.4%, and we know the radiation of a typical star like our Sun, which at 2×10^30kg mass, shines 1360 watts per square meter, at a distance 1.496×10^11 meter away from its center.

Can any one do such a calculation and compare the result with CMB energy density?

Mr. M-? said:

"So if I am "clueless" and a "moron", as you put it then I am in good company.(Here is another one for you–the average stellar mass is (hc/G)^{3/2}]/m_{p}^{2}=3.77 x 10^33 grams)"

I say: Sigh! Why do you have to invite insults to youself, by volunteering yet some more solid evidences that you are indeed incapable of doing the kindergarten arithmetics, even with a scientific calculator right at your hand.

Your calculation is simply not right. Let me teach you a bit arithmetics for free, even though Einstein would have done that for some coockies from a little girl.

(hc/G)^{3/2}]/m_{p}^{2}
= (2*PI)^(3/2) * (hbar*C/G)^(3/2) / (m_proton)^2
= 15.7496 * m_planck^3 /m_proton^2

Go find the Planck Mass and Proton Mass at this site:
http://www.physics.nist.gov/cgi-bin/cuu/Value?eqplkm|search_for=Planck+Mass
http://www.physics.nist.gov/cgi-bin/cuu/Value?mp|search_for=proton+mass

The result should be:
(hc/G)^{3/2}]/m_{p}^{2}
= 15.7496 * (2.17645×10^-8 kg)^3 / (1.67262171×10^-27 kg)^2
= 5.8039×10^31 kg
= 5.8039×10^34 gram

Your number 3.77×10^33 gram, is simply not right.
Even give you the benefit of doubt that you confused h and hbar, which is differ by 2*PI, the result would have been 3.685×10^33 gram, not 3.77×10^33 gram. I do not know how you could get the decimal numbers wrong by that much, with a computer sitting right in front of you.

There is a subtle difference between order of magnitude coincidence and exactly match to the precision of several decimal places. The later could not be by chance.

I never said I will not comment on the CMB thing, but I said I will save it until we have clarify the issue whether you are capable of doing simple math calculations. Looks like you don't.

So I will get back to discuss the CMB in just a little bit. Meanwhile why would I want to juin the establishment science camp and wasting my lifetime, without finding any real scientific truth, when I already have a decent job and marvelous income, doing the kind of things I like and at the same time I can do my own scientific explorations and find the real truths?

Quantoken

15.
December 13, 2004

Dear Quanto
It is clear any dialogue with you is pointless.
First of all the relation between proton mass and Hubble constant was discussed by Weinberg, Hermann Bondi (Cosmology, 2nd edition Cambridge University press, chapter III, 1960)and by Dirac.
So if I am "clueless" and a "moron", as you put it then I am in good company.(Here is another one for you–the average stellar mass is (hc/G)^{3/2}]/m_{p}^{2}=3.77 x 10^33 grams)

My comments on the CMB are matters of undeniable fact you can find in any basic textbook. Your not responding to it proves you don't actually understand the nature of what the CMB is.

I gaurantee that you won't ever find anyone anywhere with any real physics/math education who will ever take you seriously. Perhaps if you could tell us your degrees, institutions attended, papers published in peer-reviewed journals, or articles in the Arxiv (even if only one or two) then your opinion might carry some weight. BUT this is how science and mathematics is done and why it is so remarkably successful as a dynamic mode of human thought. The system is not perfect but it is the best there is and in the end it always works. Calculations, even simple arithmetic ones, can only presented within a rigorous, coherent and logically self-consistent structure or framework with reference to previous work. You have not done that.

If you think I was "rude" then submit your "piece of gold" arithmetical calculation to Physical Review or Astrophysical Journal then you might get some really rude replies. Of course, predictably, you will view all this as the "physics establishment" out to get you or censor you. You could never accept that you are just spouting ignorant self-deluded nonsense or are just plain wrong, but would only accept that you are being rejected or persecuted on "political reasons".

If you want to do science you have to go through this long hard route just like to be a heart surgeon takes 10 years of hard work and dedication at medical school! Self-taught surgeons are avoided. This is how science works and the only way it can work…something you don't seem to understand. Frankly I am getting really tired of crackpots always pushing "their theories" and I have already given you more time than anyone else would or will.

16. **plato**
December 13, 2004

Quanto,

You are running up against a well established trend of developing insight that has fallen short by some of our most profound mathematical minds here:)

Even I, as a commoner like to embrace all of them(theoreticists and mathematicians a like) and try and keep them in line, with a encapsulated view of reality, but first we have to contain the legitimacy of what is being relayed.

It has to all make sense?:)

17. **Quantoken**
December 13, 2004

Further commenting on M-"". He said:

"Also The "M" in CMB stands for "microwave" and stars emit mostly in the visible and IR in case you hadnt noticed. The reason the CMB is "microwave " is because it has been redshifted. It is a remnant of the time radiation and matter decoupled as the universe expanded. That is why is it so astonishingly homogeneous and isotropic. There is no other possible expanation for it and is the strongest piece of evidence for the Big Bang. Along with predicting redshifts of galaxies and the correct ratios of hydrogen to helium.

The mass of the proton can easily be evaluated from Mp=Ho^{2}/GN, where N=baryon number density, Ho is the Hubble constant and G is Newton's constant. The mass of a typical elementary particle is (h^{2}H_{o}/Gc, where h is Planck's constant. So what?? These are well known. And you can replace Planck's constant h with e^{2}/c=137h, the fine structure constant. These numerical coincidences have been known for a very long time."

Looks like that's further evidence M-"" does not know how to do simple arithmetic calculations. If that is not the case, please plug in some real numbers and show us exactly how you calculated the Mp from hubble constant and baryon number density, and what is the value of Mp you obtained that way. Also you seem to have no clue that astronomers first tried to obtain baryon mass density based on observation data, then try to use that, plus known Mp, to calculate baryon NUMBER density, instead of the other way around to obtain Mp.

I obtained a precise value of Mp based on first principle, to an accuracy of many decimal places.
I would be happy if you can show me that your calculation is only off by one or two orders of magnitude.

I would have answered to your comment on CMB and star radiations. But since you are so clueless, I will save that till you can show me that you are capable of doing the kind of elementary school arithmetics, that Einstein taught an eight year old kid in exchange for her sweet cookies, in his late years.

18. **Quantoken**
December 13, 2004

Mr ""(noname) said:
"Your 'derivation' of the proton mass is of course total bunk"

I am sorry. But tat's very rude and uneducated behavior on your part. Your comments only shows how ignorant you are. You have no idea what I have been taking about. You are totally clueless and you still feel you can make judgement of my theory. I am sorry you are such a M-?!.

An educated scholar would never be shy to admit things he doesn't understand, and would not comment on something until he learns at least some basic facts of the thing he is going to comment on.

I put a piece of gold in front of you but you could not recognize it, because you are blind. I have shown you how I obtained the precise mass of the proton, detailing every single step, though the computation is so simple there is really not that many steps to shown.

Wouldn't you at least politely acknowledge the fact that there was no math error in my calculation? Or you are unable to verify and make a judgement on my math?

Let me give you a hint. The spin state of proton is an external state, so it has nothing to do with proton mass. The "states" I was talking about are the internal, intrinsic states, which certainly can not be observed directly, but has to be infered from other facts. It's just like Quarks, they can never be observed as stand alone particles but their existence can only be infered from other experimental evidences.

Most physicists agree protons, as well as some other fundamental particles that can change. The fact that they changes implies that they have some sort of internal structure. Seeing those particles as point particles and hence there are no structure to be found of those particles in our 4-D spacetime, some of the physicists turn towards some presumably exist additional dimentions to look for that intrisic internal structure. That's the whole idea where Super String theory came from.

That's where the science made a wrong turn. Why do one need additional dimentions to provide background for some sort of intrinsic structure? You don't need to. You can have structures without a spacetime background, and certainly without a 11 dimentional super space.

It's rather illogical to me that physicists can accept the idea that below a certain small scale, the space and time loses continuity, and hence no longer exist, however they still can not accept the idea that you can have physics structures without spacetime background at all.

Also amazing to me that they believe the Planck Scale is the cut off, hence below Planck Scale there is no longer a continuous space and time dimentions, and hence these 4 dimentions no longer exist. However they believe in the other 6 dimentions, each though not longer than the Planck Scale, could still be continuous and meaningful, even if they are smaller than the Planck Scale!!! I do not know how their logic works.

At scales smaller than the discontinuity cutoff scale, both space dimention and time dimention are no longer meaningful physically, and hence physicists must throw away any equation that involves space and time, and use a brand new concept to construct some new physics.

That's the whole idea of my GUITAR theory, Generalized Universal Information Theory And Relativity. My theory has resolved all the puzzles the extablishment theories could not resolve, and has succesfully been verifies by many precise calculations.

Unfortunately it does not seem that there are any one here who can understand it. I meantioned the Bekenstein Bound, and it does not pull a ring for any one. Hasn't anybody heard about what Bekenstein Bound is? Also hasn't any one heard that Einstein said "God does not toss a dice". Hasn't any one heard about Paul Dirac's Large Number Postulation?

I do not just had a dream one night and came up with my new theory. Everything in my theory is solidly based on previous researches by well known scientists.

Quantoken

19.

December 12, 2004

Your ‘derivation’ of the proton mass is of course total bunk. The nuclear dipole moment of a proton in a magnetic field forms a 2-dimensional Hilbert space of states +> and ->, which can be identified with qubits 1> and -> as the basis for a quantum computer for example. You can calculate Shannon or Von Neumann entropies for qubits. Your entropy formula is wrong (the Von Neumann one is the correct one in this context of quantum information using the density matrix) and even if you can compute the quantum entropy associated with the states of a proton that has absolutely nothing to do with its rest mass!

20.
December 12, 2004

Yes I totally agree. I did say “eternal stars”. But as a resolution I was thinking more along the lines of the redshift argument in Weinberg’s Gravitation and Cosmology, pages 611 and 612. Olbers paradoxes are only relevant for steady state universes that have existed for an infinitely long time.

21. **cragwolf**
December 12, 2004

This is the Olbers paradox and is in direct contradiction obviously to what is observed. The resolution is that redshift effectively cuts off the infinite energy density of starlight.”

Actually, the resolution of Olber’s paradox lies in the finite lifetime of stars. Expansion contributes no more than a factor of a few. See papers by Wesson and Harrison on the subject. Or just read the relevent sections out of Harrison’s textbook, “Cosmology: The Science of the Universe”.

22.
December 12, 2004

“Can you honestly say that CMB is NOT star radiation…where does all the star radiation go?”
………………
Yes I CAN honestly say the CMB is NOT star radiation since the CMB is homogeneous and isotropic to an astonishingly high degree. That is, it is the same everywhere in the universe and in every direction. This has been measured with great precision. It is in thermal equilibrium, is blackbody and is absolutly uniform! It is also part of the horizon problem in cosmology, which inflationary models seek to address. The CMB background also has Gaussian fluctuations, which have been measured.

The energy density of starlight falls off as the inverse square so that far from a star, at a distace R, the luminosity is L/4 \pi R^{2}. At sufficiently large distances (and the interstellar spaces are pretty large!)then L–>0. Total radiation from all stars in the universe or a galaxy cannot reach thermal equilibrium and is NOT homogeneous and isotropic. If you have a spherical cluster of millions of stars then the radiation density or luminosity at R (say with respect to the centre of the cluster) is different from the radiation density/luminosoty at some R’. Far from the cluster the radiation density falls to near zero. Hence you need a big telescope to see it!

An infinite, eternal, static and Euclidean universe full of eternal stars can reach thermal equilibrium but then every line of sight would then terminiate at a star’s surface and the night sky would be blazing white and not dark. This is the Olbers paradox and is in direct contradiction obviously to what is observed. The resolution is that redshift effectively cuts off the infinite energy density of starlight.

Also The “M” in CMB stands for “microwave” and stars emit mostly in the visible and IR in case you hadnt noticed. The reason the CMB is “microwave ” is because it has been redshifted. It is a remnant of the time radiation and matter decoupled as the universe expanded. That is why is it so astonishingly homogeneous and isotropic. There is no other possible expanation for it and is the strongest piece of evidence for the Big Bang. Along with predicting redshifts of galaxies and the correct ratios of hydrogen to helium.

The mass of the proton can easily be evaluated from Mp=Ho^{2}/GN, where N=baryon number density, Ho is the Hubble constant and G is Newton’s constant. The mass of a typical elementary particle is (h^{2}H_{o}/Gc, where h is Planck’s constant. So what?? These are well known. And you can replace Planck’s constant h with e^{2}/c=137h, the fine structure constant. These numerical coincidences have been known for a very long time.

Basically, everything you have said is not even “not even wrong”

23. **A.Nonymous**
December 12, 2004

Quantoken: your numerical result looks ok, but while you’re not telling us how you compute your number of possible states of a protons you’ll understand that we can only reserve our judgments. Have you written down the *details* somewhere ? (If not, the group sci.physics is unmoderated.)

24. **Quantoken**
December 12, 2004

Before I start to calculate the proton mass, a quest that no establishment theories ever dreamed of accomplishing, but so trivial in my theory, let me explain the main concept of my theory.

1.The universe is composed of nothing but quantum information, or quantum entropy. The entropy is measured in qubits, if the system takes one of two possible states, it’s one qubit. i.e., one qubit is ln2 entropy when using the traditional entropy definition of ln Omega.

2.The amount of quantum information is exactly integers of qubits. That’s the source of quantization of all physical observatives.

3.”God does not toss a dice”. The total amount of quantum information is a CONSERVED quantity, it never increase or decrease. In fact it could not possibly increase or decrease because quantum information do not exist in a space time background, hence there is not even a concept of increase or decrease.

4.Spacetime, and other observable properties of the physics world are just statistical manifestations of quantum information. Theories like the Bekenstein Bound, provides hint how to relate quantum information and use them to construct space time. Specifically, it can be described by a model where all quantum information distribute on the surface of a 4-D spacetime volume.

For point particles, it’s measured mass is associated and proportional to its intrinsic internal quantum information.

Now consider protons. Starting with an eight fold structure. I fugured out the number of possible states a proton can sit in to be 1, the base state, plus 3 kinds of excited state, each contain 5! possibilities, and one another kind which has 7! possibilities. Plus the charge can be in one of two different states. So the total number of states are:
S = 2 * (1 + 3*5! + 1*7!)
That’s how you calculate the proton mass. You can find the answer using a calcul

S = 10802

Measured in qubits, that's
S = ln 10802 / ln 2 = 13.399011

That would be equal to the proton mass. i.e., the
proton mass is 13.399011.

Remember I use the Natural Units, whose unit of mass equals to the electron mass divided by fine structure constant.

If you want SI unit,
Mp = 13.399011 * m0 = 13.399011 * 1.24831335×10^-28 kg
Mp = 1.67262×10^-27 kg

The published proton mass is at:
http://physics.nist.gov/cgi-bin/cuu/Value?mp|search_for=proton+mass

(1.67262171 x10^-27 kg)

You make the judgement.

25. **Quantoken**
December 12, 2004

What do you mean "back of envelope" calculations? Do you remember Occram's Razer? All things considered, the simplest theory that gives the correct answer is the correct theory.

OK, so my calculations takes the back of an envelope, so what they leads to the correct answer. OK, so Super String calculations are complicated. To calculate amoung some 10^123 different super string "landscapes" you probably needs to construct a quantum computer using the whole resource of a galaxy, and you still won't be able to come up with an answer. Not a correct answer, not even an incorrect answer. Nothing. Not even wrong.

That's what I call crackpot science when you can't even come out with a reality-relevant answer, be it right or wrong, given 20 years of development and after consuming thousands of the best intelligent minds on this planet. As I asked, how many multiples of the already spent in-vain efforts does it take the scientific community to waste, before you will finally give up?

You know, the special and general relativity was not developed by one of those thousands of people who had worked in the field for decades. They were developed by a little third class patent clerk whose name was never known. Who failed the colleage entrace exams, who could not even find a job teaching in high school, and who would probably never been able to publish anything in today's environment despite of much wider access to information. Next year is the centenual anniversary of his great discoveries.

My theory is not a back-of-envelope theory. It takes more papers to write down. But the main idea and some of the typical calculations are indeed simple enough to be written on a few pages.

Next, I will show you one more thing that's trivial, but has puzzled the physicists for so longer they no longer seen to be bothered any more.

I am going to show you exactly how much the mass of a proton should be, and why, and it's ratio to electron mass. Starting with a slightly different "8 fold method". And yes the main calculation can be written on the back of an envelope. And there will be no adjustable parameter.

26. **Chris Oakley**
December 12, 2004

Quantoken –

Saying that the big bang theory is wrong does not make you a crackpot, but claiming that you have an "ultimate correct answer" when all you have is a few plausibility arguments and back-of-envelope calculations does. Take your business elsewhere.

27. **Quantoken**
December 12, 2004

Plato said:
"You must have a "compass" and have a way of knowing your coordinates from your passenger's seat?:) Maybe "making coffee" and taking on stewardess functions as well?:)"

Are you sure you are not losing a bit of intelligence by knowing too much contemporary junk science? Like, here is a trivial question, do you know whether there exists a way how to get from point A to point B, without the aid of any type of manual or machine powered transportation carrier?

A sane person with the slightest intelligence would tell you directions without help of a compass, and without a need of coordinates. Actually the concept of directions like North, South, East, West were formed way back before compasses were invented and the concept of coordinate system was formed. Actually compasses do not tell you the directions, it merely tells you which way the north geo-magnetic pole is. On modern airplanes they no longer use a compass for navigation helps.

My theory is still in development, I do not expect it to explain every thing yet. But at least it explains some of the important things very well, that other theories fail to explain. There is not another theory which can calculate the correct CMB temperature. There is not another theory which gives the correct cosmological constant but mine can. There is not another theory explaining exactly what is the origin of gravity, but mine can.

The CMB temperature is certainly not the most important thing. As I said, the important thing is what we observe. We know stars radiate energy. No theorist can deny that. We can calculate how much energy stars radiate, and again there can be no dispute regarding the star radiation energies. These energy do not disappear. And the star radiation energy come up to be exactly the right amount of energy in the CMB background.

So can you honestly say CMB is NOT star radiation? Can you still continue to insist that CMB is the remains of BigBang? If you attribute CMB to BigBang, you've got to tell me where does all the star radiation go? Where are they now? All swallowed up by a giant black hole?

And I haven't even started to talk about my theory yet. I just gave a few calculations that any one with a calculator can verify and check against the most accurate experimental results.

Unfortunately the PhysicsForums web are so paranoid that once I uttered a word suggesting the BigBang was wrong. They immediately banned me before I could utter the first word explaining exactly what my theory is based on.

I have not started talking about my theory yet. But I can tell you it is based on what Einstein says “God does not toss a dice.”, it is also based on the Bekenstein bound and what is meant by “God does not toss a dice.”

Both the Super String Theory camp and Loop Quantum Gravity camp are wasting their time without the possibility of achieving any meaningful physics results, because they are working on the wrong scale, the Planck Scale. They keep wondering why their calculation of vacuum energy is off by at least 120 orders of magnitude, without realizing they used the wrong constant in their calculation.

The space and time loses continuity and hence is no longer meaningful, at a scale far higher than the Planck Scale.

Quantoken

28. **plato**
December 11, 2004

More Comedy Then:)

You must have a “compass” and have a way of knowing your coordinates from your passenger’s seat?:) Maybe “making coffee” and taking on stewardess functions as well?:)

Quanto as much and pleasing that these equations might be consistent with one more “prospective view,” without gravity in the understanding, how would you explain resonance curve?

*Since Reinmannian geometry is the mathematical core of general relativity, this means that it too must be modified in order to reflect faithfully the **new short distance physics** of string theory.*Brian Greene

Without the “potential” of the supersymmetical reality, you would have no consistent way to view the cosmo, yet, you recognize the temperature values as important?

Just wondering?

29. **Chris Oakley**
December 11, 2004

Hi Quantoken –

In regard your “ultimate correct answer”, thanks for the welcome comic relief. The discussion was getting too intense.

30. **Quantoken**
December 10, 2004

Let me comment on the dispute between Peter and Lubos. Lubos seems to suggest that for any one to have the qualification to even criticise Super String Theory one has got to be an expert in the field first, or else he/she should shut up.

Nothing is more absord than that logically. Surely ANY ONE can criticise SST, even one who know little physics. The important thing is SST has NOT delivered anything that it promised, and it has not proven itself to be a relevant physics theory of this physics world. It may be a good mathematical theory but so far there is no evidence it has anything to do with physics at all. That’s an accepted and undisputed fact.

Let me use an analog: As a passenger I boarded an airplane, and found it’s heading to the wrong direction. Shall I have the right to question and challenge the captain, or should I shut up because I absolutely no nothing about how to fly an airplane, and have not read the first few pages of the pilot manual? Surely I do, because it does not take an export to figure out that the pilot is not delivering what he is expected to deliver.

Let’s face it: SuperStringTheory is most probably wrong and is not going any where. Now let me ask this question: Suppose it is wrong. What does it take for the scientific community to recognize it as a colossal failure?

Certainly, several thousands of scholars of some of the best intelligences on this planet wasting the prime of their lifetimes without achiving anything physically significant, is still not enough to convince them they are on the wrong track. How about 3 generations of best scientists wasting their lifetime in an invain search for an ultimate theory in super string for over a hundred year, just to find out they are wrong?

Or how about 10 generations and a few hundred years? How much is too much? How long is too long? At what end of a fruitless pursuit, will superstring theoriests finally ackowledge that they have been all wrong and they have wasted their intelligence their whole lifes?

Serious I want to know the answer. How many more years should we continue to try, before finally giving up? Maybe you will give up whe the tax payer money runs dry?

Both SST and LQG are wrong all the time. I have the ultimate correct answer. The evidence being I have been able to calculate a number of important parameters of the universe to an amazing precision, including figuring out the exactly CMB temperature and solar radiation constant, with very simple calculation. See:

31. **D R Lunsford**
December 10, 2004

This is what I mean, Lubos. Obviously, to anyone with a functioning mind, Larsson not only knows what HE’S talking about, he knows more about what YOU’RE talking about than YOU do. So to flame him like this makes you look ridiculous, like one of those snapping little toy dogs giving a big dog the business, while the big dog just yawns and thinks – “mmm snack”.

What I want to know is – how long have you been bamboozling your colleages, fellow students, parents, neighbors etc. etc.? You make a good Czech hockey player – you know, irritating and fast…

-drl

32. **Lubos Motl**
December 10, 2004

I'm somewhat uncertain whether it is reasonable to reply to pitiful creatures such as the Gentleman signed as "Thomas Larsson" below.

Nevertheless, even most of children interested in physics who are above 10 years old with IQ above 90 know that string theory predicts consistent dynamics of quantum gravity as well as all required physics of the Standard Model in the appropriate regime.

Some of the solutions of string theory are *pure* Standard Model at low energies, see e.g. the recent intersecting braneworld paper by Christos Kokorelis.

http://arxiv.org/abs/hep-th/0412035

But we don't know whether we should expect a pure standard model – SUSY and GUT at higher energies is more attractive because of many reasons.

Aaron Bergman has written a lot of relevant technical comments, and I encourage all participants with IQ above 70 to try to read and understand Aaron's comments as opposed to the idiotic rants signed by "Thomas Larsson".

33. **Thomas Larsson**
December 10, 2004

DMS,

Your wait for "ST-implies-SM-gauge-group" will be a long one. Because honestly speaking, ST can be used to derive any possible gauge group, not just the standard model—this is "prediction" for string theorists.
…
Clearly, there is nothing "unique" about this contrived construction. But throw in enough buzzwords (like branes, orientifolds), and you will silence the doubters by hiding the arbitrariness and keep harping about the "uniqueness of string theory". This is dishonesty, plain and simple

That Motl decides to lie about string theory predicting the SM is somewhat surprising. After all, it is not a sofisticated lie, it is just a plain **stupid** lie, which any non-specialist can see through. This is really stupid, because it leaves the impression that lying is all that string theory is about. What is even more surprising is that the rest of the string community seems perfectly happy to let this barking Harvard puppy define the public image of a string theorist. (It seems like he has been forced to retract his "interesting" opinions about women, though.)

(although Prof. Motl does surprise on occassion, as on the anthropic stuff),

I think we should be grateful to Susskind and Douglas to make string theory's inability to explain any experimental data manifest and quantitive. Today it takes days or maybe even months to work out the properties of a compactification (with the wrong sign of the CC). Even if you could automate this process to only take a fraction of a second, covering a Landscape of 10^1500 vacua will still take significant time; remember that our universe is only 10^80 seconds old. I think that the prospects of not making any progress in the next 10^1500 seconds might deter future students. Or does anyone believe that string theory will pick up steam once Witten retires?

34. **Aaron**
December 10, 2004

Just to get this out of the way, I'm not Lubos, and I'm not speaking for him.

To respond, here are a few examples. The relationship between Chern-Simons theory and the open topological string was derived by Witten from applying his open string field theory of the full string theory to the topologically twisted model.

Later Gopakumar and Vafa took Maldacena's ideas from AdS/CFT and applied them to large N transitions in topological strings. This led to the conjecture that the Chern-Simons theory on S^3 is equivalent to closed topological strings on the resolved conifold, (The transition here is the 'conifold transition' from T*S^3 to O(-1)+O(-1) -> P^1.) This has consequences for Gromov-Witten invariants.

If I remember, there are other conjectures that come about from embedding the topological string in the full string theory and using the various known facts (especially dualities) about the full string theory. I think the existence of Gopakumar-Vafa invariants follows from such embedding.

Marcos Mariño covers a lot of this in hep-th/0406005. Is that what you wanted?

35. **plato**
December 10, 2004

JC,

Arguably there's a fine line between a genius and a crackpot. The genius turns out to be correct in the long term, while the crackpot remains a "madman" forever.

So was Einstein a Genius, or a madman? If his last thirty years were unproductive, maybe a madman?:)

Einstein's search for a unified theory is often remembered as a failure. In fact, it was premature: physicists first had to understand the nuclear forces and the crucial role of quantum field theory in describing physics–an understanding that was only achieved in the 1970s.

So you see, you might of thought of him as a madman all the while, you just didn't understand him:)

36. **mathematician's query.**
December 10, 2004

Aaron and Lubos,

yes, as a mathematician I am well aware
that Gromov-Witten invariants, etc originated
(or were re-born) in physical models, notably topological theories. Many mathematicians
are also keenly interested (and participating in)

the prospected construction of "topological M-theory"
a la Okounkov, Nekrasov, Vafa, and others.

My question, however: what, SPECIFICALLY,
does Lubos have in mind when he claims that
such results are simply "truncations" of work
done in string theory. There is a huge and
obvious difference between
A. "truncating" the whole theory to form a
toy model, but using techniques specific
to the toy model to get results (e.g. as a test
for the larger theory), versus
B. taking a "truncation" of results in the big
theory to get results about the toy models.

My impression (from talks by Vafa, for example) is
that it's mostly A that's been done. Lubos
appears to be claiming that B happens, so that successes in Gromov-Witten theory, etc are also successes of string theory. I'm asking what is the situation from the point of view of someone who works
on string theory.

So far the only answer from Lubos was to call
me an idiot. Which only tanks his credibility
further.

37. **D R Lunsford**
December 9, 2004

Yes JC, but someone like LM is just wrong, period. He doesn't have a secret plan to save physics from the North Viet Cong and the insurgents. What he claims is just wrong. Peter doesn't go around claiming things that are flat wrong.

The funny thing is, I think LM would be better off if he'd get behind something that isn't so easily dismissed as nonsense. I'd rather believe in something completely implausible rather than in something that is demonstrably wrong and even anti-scientific.

-drl

38. **JC**
December 9, 2004

Plato, et. al.

Some folks like to bury their heads in the sand, for whatever reasons. Whether they are being in "denial" or are in a genuine state of "ignorance is bliss", is debatable.

Whether they are right or wrong in the long term, they are entitled to believe whatever they want. In the end, who really cares what anybody else thinks?

Arguably there's a fine line between a genius and a crackpot. The genius turns out to be correct in the long term, while the crackpot remains a "madman" forever.

39. **plato**
December 9, 2004

JC

Nobody is holding a gun to your head and forcing you to listen to Peter and/or Lubos in the first place.

Why would anyone ignore the basis of what is happening between these two gentlemen/unless you choose **not** to bury your head in quantum geometry?:)

Einstein refused to accept the quantum mechanical positions, but we have seen how things have progressed?:)

40. **JC**
December 9, 2004

As far as I'm concerned, people are going to say whatever they want. If you don't like what Peter and/or Lubos is saying or not saying, you're entitled to say whatever you want. Or for that matter, one is also entitled to completely ignore Peter and/or Lubos, or anybody else for that matter.

Nobody is holding a gun to your head and forcing you to listen to Peter and/or Lubos in the first place.

41. **Lubos Motl**
December 9, 2004

the Higgs mass.

the lightest sparticle mass.

OK, now I've defused all criticism once and for all. I never thought it would be so simple! 😉

42. **Chirally Challenged**
December 9, 2004

Lubos can defuse all criticisms once and for all by telling us the Higgs mass.

And for encore, the lightest sparticle mass.

43. **Aaron**
December 9, 2004

Responding to:

> Lubos, are you saying that there is
> specifically stringy reasoning involved
> in things like TQFT, Donaldson/Seiberg/Witten
> theory, Gromov-Witten invariants and other
> much-admired offshoots of string theory?
> i.e. where you think in terms of the full
> string theory, get some idea/result and
> degenerate back to the purely topological or conformal theory?
> We can all admire Vafa et al, but it's not
> clear to me how much (if at all) the spectacular
> successes in mathematical toy models have to
> do with strings per se.

As regards to anything related to the topological string (Homological mirror symmetry, Gromov-Witten, Gopakumar-Vafa, Donaldson-Thomas, yadda yadda yadda) many (if not most) of those spectacular successes were originally derived using intuition from string theory and were later (sometimes) proven to be correct by mathematicians. I think if you ask any mathematician who works on those areas, they will tell you that physical reasoning has been extraordinarily fecund.

44. **plato**
December 9, 2004

As a commoner(a child of the universe and a impressionble one) it has become important for me to distinquish where the **pulse** is in these exchanges:)

If both areas deal in mathematical structures then it would be essential that a common bond be linked through the mathematics? If agreement is struck in theoretical advances, then supportive features of the physics would be important?

Where Brain Greene had made such a statement about moving on if such a concept as strings/Mtheory was resolved, Lubos also made same. Being critical of what one has gained in information about subject would seem important to me, to make a careful assessssment?

But I am more intrigued about the advances of quantum gravity and the perspectives forming around this. Why are not, all models attack with such vigor? I have many links you can choose from:)

Do you not all have the same departure point?

I think I will post Smolin and Susskind exchange again, to hone up on what's going on.

It's good to see that both have agreed on some basis to move from and that Peter is asking questions. What other theory asks the question about the unity and arises from the planck epoch in a systematic way?

45. **Lubos Motl**
December 9, 2004

Haha, Peter, you're funny. You probably think that it is completely OK to misunderstand this statement, but you're wrong. Misunderstanding this statement means that you had to misunderstand the whole picture.

You know, one can follow some formulae on 6 pages, but if one does not understand why these formulae are written down, then it's completely useless – it's like the basic school kids who memorize something that they don't understand.

OK, you should not be intimidated by the first sentence you don't understand. You should try at least 150 pages of Zwiebach. Do it for me! 😉 And don't cheat – you know very well that the first 6 pages of the book are NOT string theory yet.

46. **Peter**
December 9, 2004

OK Lubos, I checked a few more pages in Zwiebach, and you're right. When I get to page 6 he writes "String theory is an excellent candidate for a unified theory of all forces in nature". Yup, there's a statement I don't understand.

47. **Lubos Motl**
December 9, 2004

Sorry, Peter, but I said – and I still say – that you don't understand the first *pages*, not just one page. Be sure that one page is not enough.

Indeed, you have written a lot of rubbish about string theory. And it's also true that the people may decide for themselves which writing is more scientifically reliable.

No doubt, there exist intellectual dwarves who will say "Peter Woit is the more trustworthy party about string theory". You know very well that I don't care a single bit about what complete idiots are thinking.

What I would find more disturbing would be if an *intelligent* person happened to attend your blog and if she were manipulated into thinking that your rants are relevant for science. That would be sad.

This is why I find it very important to emphasize that you, Peter Woit, have no idea what string theory is.

48. **DMS**
December 9, 2004

DRL—

Your wait for "ST-implies-SM-gauge-group" will be a long one. Because honestly speaking, ST can be used to derive any possible gauge group, not just the standard model—this is "prediction" for string theorists.

The rough explanation is that you get a U(N) Yang-Mills fields on the world-volume of N coincident D-branes. By a suitable kind of D-brane configurations, the standard model gauge group can be easily arrived at. A nice discussion can be seen in Chapter 15 of Zweibach's book, though I am sure there are summer school articles in arxiv that show the same. Furthermore, on intersecting D6-branes wrapped on a 6-torus (with orientifolds , to be precise) the standard model with fermion content can be "derived". But " little details" like symmetry breaking etc. remain to be worked out.

Clearly, there is nothing "unique" about this contrived construction. But throw in enough buzzwords (like branes, orientifolds), and you will silence the doubters by hiding the arbitrariness and keep harping about the "uniqueness of string theory". This is dishonesty, plain and simple (although Prof. Motl does surprise on occassion, as on the anthropic stuff), so it is not surprising to see personal attacks on Woit.

DMS

49. **Peter**
December 9, 2004

I just checked the first page of my copy of Zwiebach's "A First Course in String Theory", and I'm pretty sure I understand it.

As for the rest of Lubos's claims, by now there's a huge amount of material about string theory written by me and by him on our weblogs and various other places on the internet. People can judge for themselves which of these two bodies of writing is scientifically more reliable.

50. **Lubos Motl**
December 9, 2004

I did not make any attacks. I am just carefully explaining to everyone on this forum that Peter Woit has no idea about string theory.

In my opinion, it is extremely important to say so because many people who attend this blog – obviously and provably – don't realize this fact.

Peter Woit never studied string theory, he never understood even the first pages of the most elementary textbooks for the undergrads. Obviously this implies that he could have never written a paper about it and his opinions about string theory are scientifically irrelevant.

It's nothing personal. I insist that if Peter were honest, he would emphasize his ignorance about the field at the beginning of every single article that he writes.

51. **D R Lunsford**
December 9, 2004

Lubos,

I'm sick of your attacks on Woit. You know, some of the gibing here and there, between us in particular, is harmless. But make no mistake, you don't match up to Peter when it comes to having clues. Stop embarrassing yourself. Compared to Peter, you're a nuisance ankle-biter.

And I'm waiting for my ST-implies-SM-gauge-group paragraph.

-drl

52. **Lubos Motl**
December 9, 2004

Dear Michael Nielsen,

I think that you are confusing science and politics. Pro/con discussions don't necessarily advance science in any way. Sorry, but I think that it is just a wrong approach from you if you rely on the pro/con discussions.

The approach of a scientist is to find the relevant facts and data, and make his own conclusions using the brain. It's certainly impossible to do so if you rely on low-brow discussions between the people like Peter Woit who like to talk about string theory, but who have almost no idea what it is.

All the best
Lubos

53. **Lubos Motl**
December 9, 2004

Dear "",

you're choosing just the kindergarden mathematical toy model. String theory has much more impressive results than your brain is able to comprehend, and therefore it's completely meaningless to discuss with you about these larger achievements.

And yes, Cumrun Vafa's discoveries are certainly and always based on string theory.

Best
Lubos

54. **Thomas Larsson**
December 9, 2004

Peter's comment reminds me of that scene in Monty Python's "Life of Brian" where they ask
"What did the Romans ever do for us?"
Yeah, what? Apart from…

String theory undeniably brought a lot of popularity to the anthropic principle. This achievement makes at least some people happy. Though the same people are probably not overly fond of Lawrence Krauss, who has dared to criticize creationism despite being a layperson on Christian science.

55. **Peter**
December 9, 2004

Hi Michael,

Thanks for your support!

Peter

56. **Peter**
December 9, 2004

Hi Richard,

Actually I've posted several things of the sort you suggest recently. Besides the comments on Khovanov homology (by the way I met Khovanov for the first time this week, he was here at Columbia giving a series of talks), I also wrote about the Baum-Connes conjecture and Witten localization. I certainly intend to do more of this and to when possible make more explicit the links I see between these kinds of mathematics and basic questions about quantum field theory.

But you'll also notice that virtually no one comments on those posts, and part of the reason for this I understand quite well, and it has to do with why I think it's worth my time to complain about what string theory is doing to physics. It takes a non-trivial amount of time and effort to absorb new mathematical ideas and by so dominating the mathematical end of particle theory for twenty years, string theory has monopolized the time of the mathematically sophisticated members of the community. It has also quite literally driven out of the field a lot of people who were interested in other sorts of ideas about how to apply mathematics to questions in particle theory.

The mathematically interesting aspects of string theory form an incredibly difficult and complex subject. Mastering this area at all is a full-time job and if you do that you're not likely to have the time to learn other things (be they Khovanov homology, Baum-Connes, Witten localization or whatever). After many years I've become convinced that as long as string theory so thoroughly dominates the field, it will remain very difficult to get anyone to do the hard work and take the time necessary to learn other more promising subjects.

So, I've decided to spend my time not only pursuing the ideas about mathematics and its relation to quantum field theory that seem promising to me, but also pointing out the "colossal failure" of the string theory project. If particle theorists acknowledge what has happened to their field, they may finally be able to move on to something more promising. More concretely, as long as smart young theorists who want to work on the interface of math and physics find that they can get a job if they work on something related to string theory, and can't if they work on something not related to string theory, the field is going to continue to stagnate.

Peter

57. **Michael Nielsen**
December 9, 2004

In reply to Richard:

As a physicist who works in a field completely unrelated to string theory, I'm very interested to hear discussions (both pro and con) of the worth of doing string theory.

In my opionion, people like Peter Woit, Urs Schreiber and Co are doing a useful service to the physics community by carrying on this sort of public debate in a spirited but relatively civil manner.

58. **Richard**
December 8, 2004

If you think string theory is crap – don't tell us about it. Explain what you think is important in your area. What recent progress has there been in non-perturbative QCD? (quite a bit in lattice QCD, but I don't think that's what you reccomend everyone spend their time on) I found your article on Khovanov homology to be really interesting. Why don't you focus your writing on similar uplifting topics?

Just a thought
– Richard

59.
December 8, 2004

Lubos, are you saying that there is
specifically stringy reasoning involved
in things like TQFT, Donaldson/Seiberg/Witten
theory, Gromov-Witten invariants and other
much-admired offshoots of string theory?
i.e. where you think in terms of the full
string theory, get some idea/result and
degenerate back to the purely topological or conformal theory?
We can all admire Vafa et al, but it's not
clear to me how much (if at all) the spectacular
successes in mathematical toy models have to
do with strings per se.

To put it another way, suppose topological
M-theory is built tomorrow as a grand unified
theory of the "interesting to mathematicians
aspects of string theory". Would string theory
have anything further to say to mathematics
or would we (mathematicians) only have to
know about the topM-theory?

All the best,

60. **D R Lunsford**
December 8, 2004

Dear Bon-Bon,

Where exactly is this prediction? Just copy down the paragraph in which is appears.

-drl

61. **Lubos Motl**

December 8, 2004

Dear “”,

string theory has nothing to say about physics for those who don’t want to listen or those who can’t listen.

Incidentally, the prediction of realistic string models for the low energy gauge group is SU(3) x SU(2) x U(1).

As explained on my blog, the comparison of the rivalry between USA:Cuba could be more realistic than Microsoft:Apple.

All the best
Lubos

62. **Steve Esser**
December 8, 2004

I was entertained by the article’s bit on comparing string/LQG to Microsoft/Apple.

63.
December 8, 2004

Dear Prof. Bully from Harvard,

Come up with a definitive,*unique* prediction of the standard model gauge group and fermion content or parameters (promised by one of the string leaders in the mid-80s), then I will believe your sermons on string theory. Till then, string theory has absolutely nothing to say about physics. Mathematical beauty (some of it debatable) is not reality; otherwise the world would be superconformal.

The so-called superstring phenomenology, such as the brane models, is a joke that may fool a few people all the time. Most have a brain, you know, and are not sheep uncritically following whatever a shill may say on the subject.

The fact is that string theory ideas are being featured alongside religion in popular media as an explanation of the universe. Enough said.

64. **D R Lunsford**
December 8, 2004

Why our own pResident has given us the perfect description of ST:

“Catastrophic success”.

Logorrheically,

65. **Lubos Motl**
December 7, 2004

Dear “”,

thank you, even though there is only “” to thank for. The only thing I can say about your “” is “”. Zero. Ero. Ro. O. 😉

Lubos

66.
December 7, 2004

Lubos, your argument is deeply uninteresting and essentially superficial.

Or is it deeply essential and superficially uninteresting?

67. **Lubos Motl**
December 7, 2004

On my blog (Unity of strings) it’s argued that Peter’s separation of string theory to “success” and “colossal failure” is inconsistent.

68. **Lubos Motl**
December 7, 2004

Let me be more specific why all of these effects of string theory on strongly coupled gauge theories and on mathematics ARE derived from string theory as a theory of quantum gravity including gauge theories with fermions etc. – such as the Standard Model:

1. The strongly coupled limit of the gauge theory, according to the AdS/CFT correspondence, IS a theory of quantum gravity. For example, the N=4 d=4 super Yang-Mills is equivalent to type IIB on AdS5 x S5. In early 1998, you could have said that it is just type IIB supergravity, except that today we know a plenty of ways how you can see that the gauge theory is dual to the whole of string theory, including the excited strings. The strings are dual to operators like Tr(ABCDNBBBBCSB) where the letters are fields in the adjoint representation.

The same statement holds for the strongly coupled dual of any other theories that are studied, and if you ask sufficiently deep questions, you’re guaranteed to need the whole string theory. The quantum gravitational phenomena that you can see from the conformal field theory include topology change inside asymptotic AdS spaces, see Maldacena et al. recent paper, as well as black hole thermodynamics and other things typical for “quantum gravity”.

2. Mirror symmetry is a relation between two Calabi-Yaus that look geometrically different, but give you the same physics if you compactify string theory on them. By “physics” I mean that they will predict identical results for scattering of gravitons and Standard-Model-like quanta if you use the Calabi-Yaus as compactified manifolds. The Calabi-Yau compactifications are exactly the same compactifications that were used for 10+ years as the unique way to derive the real Universe – the Standard Model (or SUSY GUT) plus quantum gravity – from string theory.

If you want to study some mathematical questions about the geometry of Calabi-Yaus only, you truncate the full string theory onto topological string theory. It still has a lot of stuff, but it's clearly just a truncation, and all string theorists that work on topological string theory realize that there is a lot of stuff in string theory outside topological strings.

All these dual pictures to tasks in mathematics and gauge theories are very specific configurations in the full string/M-theory, and it is absolutely impossible to understand their physics and mathematics correctly without knowing that there is a consistent theory of quantum gravity that admits 10- or 11-dimensional vacua but that also predicts gauge-theory-like matter in its various compactifications.

69. **Peter**
December 7, 2004

Hi Lubos,

I don't think I've made an error in logic. Thinking about 10 or 11 d strings/M-theory may lead one to interesting things (in math or gauge theory) even though your original motivation turns out to be a wrong idea.

Actually, I think string theory has been such a success as math precisely because it has failed so badly in its original motivation. If in late 84-early 85 people had found some Calabi-Yau and some version of string theory on it that allowed the calculation of the parameters of the standard model, mathematically the whole field of string theory might have lead to a lot of information about one Calabi-Yau, and not much else.

Because string theory doesn't work as intended, string theorists have spent 20 years thinking about a wide array of mathematically very complex and rich structures. Coming at these structures from a very different perspective than the traditional mathematical one has lead to a lot of interesting new mathematics. The colossal failure of the string theory unification project as physics has ended up benefiting mathematics quite a bit.

70. **Urs**
December 7, 2004

Peter's comment reminds me of that scene in Monty Python's "Life of Brian" where they ask

"What did the Romans ever do for us?"

Yeah, what? Apart from…

71. **Lubos Motl**
December 7, 2004

Dear Peter,

if you say that 1,2 are OK and 3 is wrong, then you must be doing an extremely trivial error with your brain, and I hope that you will be able to fix it. All the successes in 1,2 do follow from specific refinements (or truncations) of the vacua in 3 that you deny.

Best
Lubos

72. **Peter**
December 7, 2004

I suppose I should write a macro so that whenever I write anything about the disastrous effect of string theory on particle physics it includes the disclaimer:

1. No, I'm not talking about the effect of string theory on mathematics, which, on the whole has been very positive.

2. No, I'm not talking about the idea of using string theory to get information about strongly coupled gauge theories, which has had some real successes.

3. Yes, I am talking about the idea that there is some fundamental 10 or 11 dimensional supersymmetric theory of extended objects which explains both quantum gravity and the standard model.

It's clearly point 3 that Krauss was referring to as a "colossal failure" and anyone who has read more than a few postings on this weblog would be well aware of points 1,2,and 3. The NYT article was not about whether string theory was successful as mathematics or whether it was promising as a way to solve QCD. It was very explicitly about the status of string theory as a unified theory and that is the issue to which my posting was addressed.

The view, prevalent among more than a few mathematicians, that since important new ideas about algebraic geometry and other parts of mathematics have come from work motivated by string theory, there must be something to the idea of string theory based unification of gravity and particle physics, seems to me to be deeply superficial and essentially uninteresting.

73. **anon_mathematician**
December 7, 2004

As a working mathematician, I want to reiterate a point that has probably been made here many times—-string theory is a fantastically vibrant and deep mathematical enteprise, radically changing and increasing our understanding of basic mathematical objects (notably curves and higher dimensional algebraic geometry, but also impacting on representation theory, the social acceptibility of homotopy theory, and the relationship of hard analysis to understanding new algebraic structure—analysis is less useful these days, though that will eventually change).

These insights come from a completely different intellectual tradition (often denigrated as "physical intuition").

It may be that string theory has no relation to the physical world; it clearly isnt testable yet. But mocking the whole enteprise is deeply superficial, and essentially uninteresting.

And a field which has so greatly changed the way we understand fundamental mathematical objects (some studied for centuries) probably has something to say about the observable world too…

74. **Aaron**
December 7, 2004

It's referring to a recent paper that claims that BF theory shows up in a conjectured thing called "topological M-theory". BF theory shows up in relation to LQG, but i think it’s more than a bit of a stretch to say that LQG (which is a much wider construct than just BF theory) is part of string theory.

The BF part of LQG isn’t the controversial part. It’s the quantization procedure that a lot of people have trouble with.

75. December 7, 2004

Interesting to read that now string theory considers
LQG also to be a part of string theory. From the screed of in Wikipedia and elsewhere, it seemed that string theorits thought that LQG was complete garbage. What is going on??

76. December 7, 2004

Peter,

Don’t you realize that whatever meaningful you and other naysayers will write, or will think about can all be explained by a speck in the vast rich holographic, hetorotic, D-brane landscape of conformally invariant matrix theoretic, dual of the compactified intersection of the F and M theories, upto a trivial combined S-U-T-duality that is unimportant for galactotrophic effects?

77. **Lubos Motl**
December 7, 2004

Hi Peter,

i don’t think that the comment about “colossal failure” by L. Krauss – who has otherwise nothing to say – is a punch line of the article that one can use to create a meaningful review of the article.

You’re confused if you’re combining the statement about the “colossal failure” with thinking of the string theorists. Of course that this is not how a physicist who continues to work in the field may be thinking. We’re just trying the best ideas we have, and this is why we still work on string theory.

I agree with Brian that it would be great to know that string theory is a wrong theory of Nature if it were so. However I don’t think that this would mean that everyone would “move on”. String theory would still remain an important mathematical structure that would be investigated.

I wrote an entry on my blog about this article, too.

Best
Lubos

Nobel Lectures

December 10, 2004
Categories: Uncategorized

The winners of this year's Nobel Prize in Physics gave their Nobel lectures in Stockholm on Wednesday. The lectures of David Gross and Frank Wilczek are available on-line, for some reason that of David Politzer isn't, at least not yet.

Over at Sean Carroll's Preposterous Universe there's a first-hand report about the lectures from Thomas Larsson (who often comments here). It's in the comment section of this post. One interesting detail from Politzer's talk was that Coleman had originally assigned the beta-function calculation to Erick Weinberg (who is now my colleague at Columbia over in the physics department), but Erick already had enough material for his thesis and wanted to move on.

Update: Politzer's lecture is now available at his web-site.

   Still, I never forgot the way he insulted his hosts.

   -drl

5. **Chris Oakley**
December 13, 2004

   Danny –

   I cannot possibly agree with your comments about Gell-Mann. In my opinion, the 1969 Nobel prize is the only particle physics Nobel prize since the war that has been deserved. Gell-Mann has this remarkable ability to find simplicity amid the confusion and complexity of experimental data. At a time when the bulk of theoretical activity is devoted to doing the exact opposite, his contribution ought to be appreciated that much more.

6. **ksh95**
December 13, 2004

   Why is NGC 7603 the most interesting object in the sky?

Which seems more likely to you?

1.)That one little speck in the sky is an optical illusion, and NGC 7603 is actually composed of several distinct objects, at different distances, along the same line of sight.

-or-

2.)That one little speck in the sky is exactly what it looks like. NGC 7603 is actually one object, and volumes of data supporting the big bang are are wrong.

7. **plato**
December 13, 2004

DRL,

Of course Gell-Mann, the very prototype of the quick-witted, stone-hearted, insightless boor, referred to "half-asstrophyisicists" – and now the army of mediocrities streaming into the academic world from PhD programs have usurped even those jobs.

It's a sick world.

Why don't you tell Brain Greene that you think this holds no value?:)

8. **D R Lunsford**
December 13, 2004

DMS,

The Motloids of this planet also deliberately inhibit science by denying telescope time to "controversial" researchers, and even by blindly refusing to look at things like NGC 7603 (IMO the most interesting object in the sky). Of course Gell-Mann, the very prototype of the quick-witted, stone-hearted, insightless boor, referred to "half-asstrophyisicists" – and now the army of mediocrities streaming into the academic world from PhD programs have usurped even those jobs.

It's a sick world.

-drl

9. **DMS**
December 13, 2004

Actually, Einstein's example is rather interesting.

Sir Edmund Whittaker in his detailed survey, A History of the Theories of Aether and Electricity, Volume II, included a chapter entitled "The Relativity Theory of Poincare and Lorentz", a clear attempt to deny any credit to Einstein. When Einstein was asked about this, he said something to the effect that he did not really care about the "priority" or "recognition", and that he knew what he had done and was pleased about it. It also seems to be the case that the Michelson-Morley experiment played no role in Einstein's developing SR.

He was perhaps an exception; most scientists today would jealously fight for priority over any little thing they did (boost up the citation numbers). So not only was Einstein a great physicist, he was a remarkably wise and modest human being as well (ok, he was not a perfect husband, and there are the anti-Einstein "writers", debunked by Einstein scholars http://physicsweb.org/articles/review/16/4/2) , a rarity at any time and place.

But, of course, nowadays, we have string theorists who are to be compared in genius directly to Newton.

10. **Lubos Motl**
December 13, 2004

I can give you Einstein's quotes that are saying the same thing as me. But I am afraid that it is useless to make any discussions with you, DRL.

11. **plato**
December 13, 2004

DRL,

The comments Lubos is making about the quest to understand NATURE are valid. I understand, at the "heart of the matters," there are **these qualities** students have about their professors?:)

Maybe we could call this bloggery, a psychological drama, where Mutt and Jeff are just the "innate," one sided feature of a coin on Monday, and another, on Tuesday?

Is it not known, all do not fair thee so well in times?:)

12. **D R Lunsford**
December 12, 2004

Rick,

Motl is that type of scientist that Einstein specifically despised – the quick mind without insight, blind and hungry for power and fame. He is NOT representative of physicists – he's representative of Bon-Motl.

Of course, our society turns out these blustering faux-macho clueless dorks by the tens of thousands.

-drl

13. **Lubos Motl**
December 12, 2004

Rick, it's not just personal glory, money, and fame – it's the understanding of Nature itself. Many physicists are also doing physics as their job – it's a form of career, and be sure that it is better for them to have interesting result.

Whatever the motivation is, it is absolutely clear that a physicist *wants* to find interesting results, and if (s)he does not want, (s)he should not be a physicist!

Of course that most of us are happy if someone else finds something interesting, but we would be even happier if we found it ourselves. I don't believe that either of your friends is happier if someone else finds something out – if they are saying it, then – I apologize – your friends are liars.

14. **Rick**
December 12, 2004

Prof. Motl, you have such an average sense of values. Your comment is depicting physicists as if all of them are chasing after personal glory. Maybe you're right, in the average. There are people who just enjoys doing physics, and happy to know even if it's their friends who discovered something. Your comment is such a disgrace to them. Maybe I am not practical when concerned with monew issues. But I don't want to sell my sould to fame or money.

15. **Lubos Motl**
December 12, 2004

Come on, Robert, it's ridiculous. Every theoretical physicist would love to be the discoverer of the asymptotic freedom or any other important insight, for that matter.

It is not just about the 400,000 dollars that Erick Weinberg rejected. It is about the fun of learning important secrets of Ms. Nature as the first one. Learning Nature is the real fun. It's a very special feeling, and no doubt, the physicists are doing physics because they want to find something interesting.

If a physicist pretended that he or she did not want to be the father or mother of QCD, I would not believe it anyway. It would be such an incredible hypocricy!

16. **Robert**
December 12, 2004

Prior to this, I have never felt that I could, in any way, be professionally competent to comment on the internecine abuse dispensed between the pro and anti string camps manifest on this blog. Professor Motl's most recent remark, about Politzer, Weinberg, the beta function , and who got to check it out, highlights an atrophy of the spirit that shows why theoretical physics is chasing itself up its own fundament.

17. **Lubos Motl**
December 10, 2004

Haha, the decision of Erick Weinberg was not one of the smarter ones. 😉

Landskepticism

December 13, 2004
Categories: Uncategorized

Tom Banks has a new preprint out, entitled Landskepticism: or Why Effective Potentials Don't Count String Models. In it he argues against the idea that one can use effective potentials to study the supposed "Landscape" of different vacuum states of superstring theory. His preprint, like most of the literature in the field, is kind of a bizarre document which doesn't even look like a conventional theoretical physics paper. In the course of twenty pages he only really manages to write down one equation (and it's just the Schrodinger equation).

One of his claims is that it doesn't make any sense to think of what is going on as one string theory Hamiltonian with a huge number of possible vacuum states. Instead one has to think of a huge number of possible string theory Hamiltonians, one for each asymptotic background. So I guess that's it for the "uniqueness of string theory".

He gets kind of vehement: "the concept of an effective potential on moduli space as a tool for finding string models of gravity, is a snare and a delusion, fostered by wishful thinking, and without regard to the actual evidence in front of us." Sounds kind of like things I say… He footnotes this "Perhaps some over the top rhetoric is in order".

On a different topic, he claims that the Weinberg "prediction" of the cosmological constant doesn't hold water, since if you allow both the cosmological constant and other parameters to vary, then typical values of the cosmological constant allowing galaxy formation will be orders of magnitude larger than the observed value.

I shouldn't give the impression that Banks is opposed to string theory. Like everyone else, he doesn't even mention the possibility that it might be wrong. He has his own ideas about holography and cosmological breaking of supersymmetry, which he alludes to at the end.

His paper is based on a talk he gave at a String Vacuum Workshop in Munich three weeks ago. Kind of scary to see how many theorists are now working on this nonsense. At first I was worried to see my old friend and fellow Princeton student Costas Bachas's name on the list of participants. Costas always seemed to me one of the more sensible theorists around, even if he did work a lot on string theory. Then I noticed that he wasn't giving a talk, just leading a discussion on the topic "Does the 'String Vacuum Project' make sense?" Wonder what their conclusion was.

Update: For Lubos Motl's take on this paper (Banks was his advisor), and the news that Nima Arkani-Hamed has gone over to the dark side, go here.

Comments

1. **D R Lunsford**
   December 15, 2004

   It should be sternly pointed out that astrophysicists are even worse – right this minute the HST should be collecting spectra from objects like NGC 7603, but you can't even get a post in edgewise on sci.astro.research about it. Like Pope Paul V and his hatstand minions, they refuse to look through the telescope at something that will require some new thought. This is directly connected, at least culturally, to the ST crackup IMO.

   -drl

2. **Chris Oakley**
   December 15, 2004

   Peter –

   Right on.

   (I was going to make the same comment, but you said it so much better).

3. **Peter**
   December 15, 2004

   There's nothing wrong with some people working on some aspects of string theory that are interesting. The fundamental problem is the overhyped, aggressive and not very honest way string theory research has been pursued and promoted, driving out other ideas.

   On the other hand, there really is something very wrong with the whole Landscape business and I don't think any legitimate scientist should be working in this area. Writing rambling papers about multiple universes with no solid basis and no plausible hope of ever predicting anything puts one deep into crackpot territory. It's a complete disgrace that leading figures in the field of particle theory are doing this. Whatever you want to call what they are doing, it is not any sort of legitimate scientific activity. If you really believe that the idea of string theory leads one inexorably to the Landscape picture, as a scientist one has to admit that this means that string theory really has failed. People are so desperate to avoid facing up to this failure that they are willing to throw out all the standard norms of what it means to do science. This is a complete disgrace.

4. **Thomas Larsson**
   December 15, 2004

   Arun, we know that 20,000 man-years of string theory work by some of the smartest people on this planet only resulted in anthropic nonsense (and some cool but physically irrelevant math). Unless you are a good deal smarter than Witten, why should you succeed where he failed?

5. **Arun**
   December 15, 2004

   Steve M writes that something good "has much more chance of happening if people dont all go down the landscape route, and start writing waffling philosophical and "statistical" papers all the time with one or two equations, and accepting that nothing can ever be calculated."

   I think Peter W. is saying something similar – that something good has much more chance of happening if people dont all go down the string theory route….

   Sometimes I get the impression he wants to shut down the whole string enterprise, but that I would not agree with. But there is some happy medium between being a crackpot and bowing to every current fashion.

6. **Steve M**

December 15, 2004

At least Banks believes the whole concept of the Landscape is not well established. Until there is a much firmer and deeper nonperturbative understanding and grasp of string theory one cannot really talk seriously about "string cosmology". Some very powerful underlying selection mechanism may yet emerge in string theory that yields a monovacuum theory. Perhaps this is (very) wishful thinking but has much more chance of happening if people dont all go down the landscape route, and start writing waffling philosophical and "statistical" papers all the time with one or two equations, and accepting that nothing can ever be calculated. I think string theory (and string theorists) can still do better than that. Also I dont think that sort of stuff will attract to the field or inspire the talented young people going into graduate school either.

It is frustrating for everyone in physics and cosmology I think, not just string theorists, since these are very deep and very hard problems conceptually and technically. I also think too much importance and significance has been attached to the whole recent KKLT construction though. This is admittedly a very clever albeit Rube Goldbergdish piece of mathematical technology after all. So much very fine, artificial and careful tuning involving flux compactifications, turning on fluxes, anti D3 branes to break susy and lift ads to metastable ds and all that. (phew!:) There could still be some general underlying flaw in it that could kill off the landscape idea and that should be intensely considered and studied. There could even yet be other ways of evading the desitter no-go compactification theorems. If landscape doctrine takes over then the field will probably end up as little more than philosophical and metaphysical debate. Essential names like Witten, Gross, Maldacena etc will probably drift off into other things mathematically and you wont see them at "String Vacuum Workshops"…the sort of guys the field still really needs probably more than ever.

7. **D**
December 14, 2004

Schmeltzer's crank page was hilariously applied to Bank's paper ipse, to wit,

No equations
No apparatus
Old theory (Democritus) wrong for wrong reasons
Captial letters (oh wait, that was a slideshow)

8. **Peter**
December 14, 2004

I've corresponded with 't Hooft a bit about string theory and he seemed rather skeptical about many of the claims of string theorists, but interested in learning more about the theory. Here's an analogy about string theory he gives in his popular book about the standard model:

"Imagine that I give you a chair, while explaining that the legs are still missing, and the the seat, back and armrest will perhaps be delivered soon: whatever I did give you, can I still call it a chair?"

He refers to string theory as not really a "model" or a "theory", but a "hunch".

9. **Peter**
December 14, 2004

Dear Quantoken,

Please stop repeatedly posting about your theory on my weblog. That's seven postings today alone, none specifically about the Banks paper that is at issue.

Peter

10. **Quantoken**
December 14, 2004

What is gravity?

Both Super String Theory and the Loop Quantum Gravity claimed they have derived gravity in their theory.

Gravity is reflected in the constant big G.
The G can not be zero, for then there is no gravity. The G has to be its current know value to provide the currently known gravity.

"Having derived gravity" means in the final equations they derive, must contain a G. How did they get an equation containing G? If you start with a calcuolation process and secretly inject the G into your equation at some point, then certain you end up with a set of equations that contain G. That's really not a derivation of gravity, because the G you end up with is the same G you initially inject arbitrarily. If your injected G happen to zero, you end up with nothing.

I can not accept the claim that Super String Theory or Loop Quantum Gravity derived the gravity, because they secretly injected the G in the first place, by using the Planck Scale, which already contains a G.

My GUITAR theory is the only known theory that truely derived gravity. Because using first principle, I obtained the numerical value of G, from alpha. I did NOT secretly inject G like the establishment camp do.

Shame on the establishment camp that they first secretly injected G and then claim they have derived gravity in their theory.

The correct theory is, in natural unit set:

G = 1/(2N),
N = PI*exp(2/(3*alpha))
alpha = fine structure constant = 1/137.03599911

December 14, 2004

To move physics forward one has to ask some of the most profound questions in physics. One has got to question those things that too many people take for as granted, without a second thought. It's just the same as Newton asking "why Apples fall to the ground." Or Einstein asking "What exactly does it mean the two clocks have the same time." Laymen took these things for granted and never give them a second thought. But if you do you find there is physics there.

One question I have been asking for a long time is, WHAT IS MASS EXACTLY?

We know there's inertia mass and there is gravity mass. The general relativity's equivalence principle tells us the two masses are equivalent. They are equal at all times. But what I found is even that is not right. There are never two different masses. There is neither inertia mass, nor gravity mass. There is only a geometric mass, which is defined by spacetime curvature. Geometric mass is the only mass that actually exists.

How come? First let's look at what defines inertia mass. What it says is if something has mass it has inertia. It keeps moving with the same speed until it is pushed by a force. When it is pushed by a force, depending on how much its mass is, it has an acceleration inverse proportional to its mass. That's Newton's second law. Inertia mass is determined by force and acceleration.

In that sense, Newton's Second Law is actually not a physics law, it is just a logic definition defining what is inertia mass, using the concept of force and acceleration. M = F/a, by definition.

So then we have to ask what is FORCE any way. Force is the kind of effect that makes an object accelerate. If we see something accelerating, we say there is a force acting on it, if the object is not accelerating, then we say there is no force.

So force is defined by inertia mass and acceleration. We are back to square one. mass is define by what is force. And force is defined by mass. So exactly what are they.

Certainly you can say force is gradiant of potential energy. But that does not resolve the problem. I will ask you what is energy then. Energy is just mass according to Einstein's E=MC^2. So again you are defining force using mass. We are still back to square one in trying to come up with a definition of fundamentally what is mass.

The conconsion is inertia mass really do not exist, unless other physics properties associated with mas exists.

The situation is only slightly better when we look at gravitational mass. The gravitational mass is the property that causes things around it to accelerate gravitationally. So this is probably the only way out finding an exact definition what exactly is mass.

According to GR, the gravitational field is equivalent to an acceleration field. So gravity is really geometry effect of spacetime curvature.

Therefore, I think the mass is really geometric mass. Mass does not cause spacetime curvature. The mass IS the spacetime curvature itself. The mass is a geometric property of the spacetime.

This is why the Bekenstein Bound is important. In Bekenstein Bound, it provides a relationship between entropy, the mass/energy, and a geometric length parameter. If I can attribute mass to geometric mass, and make it purely a spacetime property, then, the Bekenstein Bound tells us the relationship between spacetime and the entropy.

The Bekenstein Bound provides us a hint how spacetime can be constructed purely from quantum information, which is neat.

That's one of the fundational principle of my GUITAR theory. Quantum information is the only real physical existence. Spacetime is constructed from quantum information, and mass/energy is merely a geometric property of spacetime.

And everything can be boiled down to just a few dimentionless fundamental constants, especially important is the fine structure constant alpha.

I have shown that using just alpha, and nothing else, I can calculate the radius and mass of the universe, the CMB temperature, and I can even calculate the exact mass of protons, among other things.

"Equations of string theory"

Write down the equations of string theory.

I sumbit that a real set of equations is always needed to describe what is really happening. If you can't describe what is happening, you don't really have any equations.

Here, just for contrast, are some equations:

Rmn = (2R/w) (FmaFan + 1/4 FabFab gmn) – (1/2W) {Dm,Dn} W

1/g d/dxm g R F nm = 5/4 Dn W

OK there are some equations. Show me the string theory equations.

I totally agree with Aaron. Physics should ONLY study the things in this universe that we can observe. A criteria separating real science and crack science is that real science makes predictions that can be verified by observation data to be either right or wrong. If you can not make predictions or your prediction can not possibly be checked in anyway, then it's crack science.

All those speculations about multiple universes and possible universes with alternative physics laws, are crackpot science. They say all kinds of different things about how the other universes could be like so they do make a bunch of "predictions". However, all their predictions are totally irrelevant, because the "other universes" does not belong to this world. So we have no direct or indirect way of observing any of them, and exam any of the predictions. Anything that can not possibly be checked or be otherwise falsifiable, are crackpot science.

Therefore all the talks of the Super String Landscapes, are crackpot science. You can talk all your talk and say all you want to say, but at the end of day, really none of the landscapes exists because none of them is verifiable, in this world. They are neither true nor false. They can't not checked for truthfulness and they are not science.

Any talk of an alternative universe is nonsense and none-science. We should talk only about this universe. That's all we ever know and to us that's all the existences. Nothing else exists outside this universe.

Quantoken

15. **Aaron**
December 14, 2004

The problem is worse than that. It simply doesn't make any sense to talk about the probability of us being in some universe or another. We are in a particular universe, so we have a probability of one of being in that universe. Counting all the vacua you want won't change that fact. If someone out there is sitting in a 'rare' universe, and they try to make 'predictions' based on vacuum counting, they'll be wrong.

And how do we know we're not that person?

16. **one mathematician's opinion**
December 14, 2004

re: Aaron's comment on "predictions"
from statistics of vacua (being worse
than landscape)…

Virtually any specific mathematical
object that one can write down,
such as a solution of equations
of string theory, will tend to be
either "very special" or
"very generic". Things in
between are rare. The trouble
with using statistics of the generic
case for prediction is that it's also
rare to know which case one is in.

18. **Quantoken**
December 14, 2004

OK, I checked against all your links. Out of three URLs you provided, you mis-spelled two of them and only one worked straight. So you have a pretty good crackpot score already, Mr. M-?

Baez's index system is reasonable in most part, although I do not agree with them all. It's probably discriminative to none-English speakers when he said mis-spelling the name of Einstein etc was worth 5 points each.

I think I am scoring pretty poorly on the Baez index. The BigBang would score much higher. With tens of thousands of people working on BigBang, it failed to have made any verifiable predictions so far and each time some new observation data comes up that goes against the BigBang, they need to patch it up with something else.

Has BigBang been able to calculate a correct CMB temperature, for example? No. But I arrived at the exact correct CMB temperature. The remaining discrepancy between my calculation result and the observed data is well within the experimental error of the observational data. So here is one prediction I make here:

As experimental techniques improve and the experimental error is further reduced, the more accurate CMB temperature measurement in the future will approach my calculation result!

Here is another prediction:
The CMB temperature will remain unchanged thousands or billions of years from today. According to BigBang, CMB will be cooled down over time. According to my theory, that will never happen.

Here is one more prediction:
Physicists eventually will find BigBang as well as SuperStringTheory all wrong, eventually.

Can you say I am not making predictions?

The only thing I am scoring badly is the publishing factor. I certainly have not published anything on any journal. Not even ARXIV. They now use an endorse system and unless you are already in the establishment camp and agree with everything in the main stream, you can't get an endorsement and can't publish anything on ARXIV. Also they require you to use LATEX format and you have to write up exactly in the style they require. I do not have the time to learn LATEX and formatting my document the way they want. Remember, I do NOT make a living out of this. This is just my spare time entertainment.

My GUITAR theory does not compradict quantum mechanics or gravity laws in any way or form. Those are well established theory with solid experimental data backing. On the other hand, BigBang and SuperStringTheory are NOT well established theory. SuperString has no experiment backing at all. BigBang needs to have so many adjustable parameter to fit itself against experimental data.

My GUITAR theory has only one adjustable parameter, the fine structure constant, which is really not adjustable at all since it has been fixed precisely by experimental measurements. So, I have absolutely NO adjustable parameter but yet I came up with so many correct calculation results that match experimental data exactly.

22. **Quantoken**
December 14, 2004

Thanks, that was a good joke. Indeed you can build a GUITAR when you go beyond just the strings. The establishment camp finds there are more than 10^122 different strings but they still haven't figure out how to built a guitar with that many strings 🙂 What is the use of strings if you can't built something useful out of them?

I do not just one day had a good dream and come up with this GUITAR (Generalized Universal Information Theory And Relativity) theory. The fact is, every little pieces of this GUITAR are based solidly on previous research by well respected physicists. All I did is connecting the dots and put the puzzle together into one piece.

The fundations of GUITAR theory ranges from Eddington's postulation that star radiations heat the space to a uniform temperature of 3K, to the Mach's principle that consider the gravity to be the result of collective interactions of all masses in the whole universe, to Einstein's famous notion that "God does not toss a dice.". To Paul Dirac's Large Number postulation. To the Hawking Blackhole Entropy Bound, to Bekenstein Bound. To the holographic principle.

None of those are invented by me. But I am the only one who successfully linked all dots together, arrive at a self-consistent picture which agrees with all observation facts, and directly leads to precise and unambiguous calculation results that have been accurately verified by experimental datas.

I obtained the exact observational radius and observational age of the universe. The precise baryon density value of the universe. The exact CMB temperature which agrees with observational data exactly, and the exact solar radiation constant of 1360 W/M^2. I derived the precise mass of protons based on first principle. I linked the value of G directly with the size of the universe, and everything is linked to the fine structure constant alpha = 1/137.03599911. It's a tremendous amount of success and its amazing one simple theory can come up with such a rich collection of results in so many different places!

December 14, 2004

JPC:

You are absolutely right in saying "One good place to start is to insist that new theoretical approac hes be finite, background independent, and inherently quantum from the start, as it appears nature is."

The Generalized Universal Information Theory And Relativity (GUITAR) is such a theory. It starts with the basic assumption that everything in the universe are just quantum information. The total quantum information in the universe is a finite and conserved integer quantity. Spacetime background comes as statistical manifestations of the quantum information, as are all measurement quantities.

More over, I have correctly calculated many important parameters of the universe, using very simple assumptions and methods, and they all match actual measurements precisely, including the radius of the universe, the gravity constant, the CMB temperature, the solar constant, and the exact mass of proton.

The fact that total quantum information is an integer directly leads to the quantization of the physics world. The finite-ness of quantum information leads to Heisenberg Uncertainty Principle. The conservation of quantum information leads to a limited and closed spacetime by curvature, and it naturally leads to gravity. The same conservation also leads to energy conservation and other conservation laws in physics. The very notion that spacetime background is a statistical manifestation of quantum information leads to various entropy bounds like the Bekenstein Bound, the Hawking Blackhole Entropy. Although they all need to be modified to be in the 4-D spacetime, instead of merely in the 3-D space. In the case of Bekenstein Bound, the correct form is an equality, not an upper bound.

I do not understand why physicists are so stubburn when they keep hitting the same wall when they keep getting that 120 orders of magnitude discrepancy. Do they have the ability to infer from a wrong calculation result that they must be wrong on where they start, if the mathematics of their calculation could not be wrong?

Have any one noticed many many coincidences related to alpha? For example the CMB temperature equals to the boiling temperature of water times alpha. The natural abundance of element U235 equals to the U238 abundance times alpha, etc.

26. **DMS**
December 14, 2004

Which Weinberg paper is being talked about here? Does the paper "ANTHROPIC BOUND ON THE COSMOLOGICAL CONSTANT" (sadly the paper is pre-arxiv and not scanned) place bounds on the fine structure constant as well? or is that a different paper?

27. **JPC**
December 14, 2004

It's quite interesting to read all of the dramatic to and fro on this and other blogs about the state of theoretical physics these days. I was a graduate student in the Harvard physics department c. 1984 when it was quite clear that the phenomenologists and standard model guys had reached the end of their run, no new experimental data was forthcoming, and graduate students despaired of anything to do.

This was just about the time string theorists started to arrive on the scene to a hostile reception from the old guard. The motivation for studying strings back then was it looked like a way forward – although forward to what nobody could be sure about. It seems silly to retroactively assault the motives of physicists at that time who began to study the subject. People like Coleman were unsure of the basic program but thought it would be a useful exercise to investigate it.

However, at this point in time, it's clear that things have gone awry, and that course corrections need to be made in the allocation of resources to other potential ways forward. Non-tenured academia has always been a fear-based culture, susceptible to bullying, group-think and political correctness. True leaders in physics need to de-couple from the sunk cost of string theory, mathematical arcana, and prematurely self-congratulatory conferences and books and re-attach theoretical physics to the natural world, especially as new experimental data becomes available over the next decade.

One good place to start is to insist that new theoretical approac hes be finite, background independent, and inherently quantum from the start, as it appears nature is.

28. **Aaron**
December 14, 2004

Having talked to someone who has worked through Weinberg's paper, my impression is that it isn't a prediction of anything. Rather, it's a clever experimental bound on the fine structure constant. So, I agree with Banks on that subject.

Banks is far from alone with his distrust of landscaping, although most probably don't agree with the details of his particular views. Most people would rather just go on with their own work rather than argue it out on the arXiv or in the newspapers, however.

What's much worse than postulating the existence of the landscape, in my opinion, is the attempt to make 'predictions' by counting vacua. As you might guess, not everyone agrees with my opinion on this subject either.

29. **plato**
December 14, 2004

Tom Banks must have the evolution of the Curvature Parameters, I am sure:)

Now, how would you take all this, to such small distances and come out with some intact view of the geometry taking place?

You needed a microscopic view of the cosmo, which seems to be lacking for some?:)

Bubbles just encapsulate it all. Which mathematics would you need to geometrodynamicallydescribe this movement?

Help:)

30. **plato**
December 14, 2004

Peter your real instigator aren't you?

Testing the principles of the Higg's field, psychological drama manifestation, of a professor crossing the room?

If Lubos is a associative professor, then, who is the professor?:)

The effect?

The interaction of educated people, are truly fascinating to me. Climatic stories, seem awfully familiar, when taken in context of the bell curve.

Statistically, you would have a hard time of ignoring the total view.:)A Steering Boid? hahaha

31. **D R Lunsford**
December 14, 2004

Peter,

Look at this – http://online.itp.ucsb.edu/online/colloq/banks1/pdf/Banks2.pdf

It’s more stream-of-consciousness random emission of buzzwords – my adviser used to call this kind of thing “word salad”.

I looked at numbers of his papers on arxiv. They all seem to have been made by cutting and pasting standard formulas from Messiah, Dirac, and other elementary textbooks after changing the symbols around. In other words, it’s all bullshit.

Langlands Program and Physics

December 14, 2004
Categories: Langlands

One of my minor hobbies over the years has been trying to understand something about the Langlands conjectures in number theory, partly because some of the mathematics that shows up there looks like it might be somehow related to quantum field theory. A few days ago I was excited to run across a web-page for a workshop held in Princeton earlier this year on the topic of the Langlands Program and Physics. Notes from some of the lectures there are on-line.

Unfortunately, after reading through the notes, I'm afraid there's relatively little there about the potential intersection of the ideas of the Langlands Program with Physics. From the physics end of things there are some pretty illegible notes of a lecture by Witten about the Langlands Dual Group in Physics. Part of this story involves the Montonen-Olive duality of N=4 supersymmetric Yang-Mills. This duality interchanges the coupling constant with its inverse, whiile taking the gauge group G to the Langlands dual group (group with dual weight lattice). The symmetry that inverts the coupling constant is actually part of a larger SL(2, Z) symmetry.

One possible explanation for this SL(2,Z) symmetry is the conjectured existence of a six-dimensional superconformal QFT with certain properties. Witten explains more about this in his lectures at Graeme Segal's 60th birthday conference in 2002. His article from the proceedings volume, entitled "Conformal Field Theory in Four and Six Dimensions" doesn't seem to be available online, but his slides are, and they cover much the same material. There has been a seminar going on at Berkeley this past semester in which Ori Ganor has been giving talks on this topic.

While the occurence of the Langlands dual group and SL(2,Z) symmetry are suggestive, the relation of this to the full Langlands program seems to be a bit tenuous. There is however a much closer relation between 2d conformal field theory and the Langlands program, a relation which is part of the story of what is now known as "Geometric Langlands".

Some of the other lectures at the Princeton workshop give a good explanation of the standard Langlands duality conjectures, although I'm not convinced that many physicists will find them easy going. These conjectures posit a duality between two very different kinds of group representations associated to a one-dimensional field (a number field or function field of a curve over a finite field). On the one side one has an analytic object, an "automorphic representation" on a space of functions on a group G(A), where G is a group over A, the adeles of the field. On the other side one has an arithmetic object, representations of the absolute Galois group of the field in the Langlands dual group to G. Typically this duality is used to get information about arithmetic objects using the more tractable analytic objects. The most famous example of this is the Taniyama-Shimura-Weil conjecture relating the arithmetic of elliptic curves to modular forms, which Wiles (with Taylor) was able to prove enough of to use it to prove Fermat's last theorem.

In general the Langland conjectures for the case of number fields remain an open problem, but for the case of function fields of a curve, they have been proven for G=GL(n) by Drinfeld for n=2 and Lafforgue for general n (which got both of them Fields medals). The geometric Langlands program involves reformulating the function field case in such a way that it still makes sense when you replace the curve over a finite field by a curve over the field of complex numbers. This idea goes back to Drinfeld and Laumon in the 1980s, and has evolved into a specific conjecture which was recently proved by Frenkel, Gaitsgory and Vilonen.

I confess to still being pretty mystified by this subject. The analog of the arithmetic side is clear enough, it's a homomorphism of the fundamental group of the curve into the Langlands dual group, or equivalently a vector bundle with holomorphic flat connection. But I still don't understand the analog of the analytic side, which is some sort of D-module over the moduli space of bundles over the curve, broken up into "Hecke eigensheaves". My colleague Michael Thaddeus explained to me today over lunch what a "Hecke eigensheaf" is supposed to be, but there's a whole web of relations of this to representations of affine Lie algebras, CFT and vertex operator algebras that neither of us understands very well.

While I don't understand this material, I do hope to find time in the future to try and figure some of it out. Various sources that seem to explain this are the following:

Edward Frenkel's web-site at Berkeley contains a lot of interesting material. Many of his papers are on this topic, especially relevant is his Bourbaki seminar report on Vertex Algebras and Algebraic Curves.

Another relevant web-site is that of David Ben-Zvi at Texas. Look at his very informal surveys of Langlands theory written in 1995 before he gets too embarassed by the mistakes in them and takes them down. He is joint author with Frenkel of a book Vertex Algebras and Algebraic Curves.

There's an on-going seminar on geometric Langlands at the University of Chicago which has a web-page.

Kari Vilonen has a web-site devoted to geometric Langlands and its relation to physics.

MSRI ran a workshop on Geometric Aspects of the Langlands Program in 2002 and the talks are on-line.

As usual, Witten has a hand in all of this, see his remarkable paper "Quantum field theory, Grassmanians and algebraic curves", Communications in Mathematical Physics, 113 (1988) 529-600, and his contribution to the 1987 conference "The Mathematical Heritage of Hermann Weyl" entitled "Free fermions on an algebraic curve".

For a different conjectural relation between Langlands and QFT, see:
Mikhail Kapranov, Analogies between the Langlands correspondence and topological quantum field theory, in Functional Analysis on the Eve of the 21st Century, Vol. 1, Birkhauser, Boston, pp. 119-151.

   December 19, 2004

   If this were a moderated usenet forum you'd be told that your posts violate netiquette

   As to reading my stuff:)No!No! think of content first, then who wrote it.:)

   One of the things I had found was to respect people thoughts and if such a link of paragraph was to be read of theirs, then it must lead back to site where it was taken.

   I wanted to respect the source of information and places, so this compromise was thought of. If you do not like the "source," then I can not be faulted on its content. Only, that I linked it?

   So your rules of netiquette do not apply, hence the moderated usenet forum rules do not apply also. Your software should not support this if this is to be taken as netiquette issue. This is easily solved.

   In all cases, I link to the sources as best as possible with secondary links sometimes to source as well.

Interesting site of yours, with some debate about it's authenticity and law? Copyleft idealism?:)

2. December 19, 2004

   'Plato', since you haven't noticed yet: Posting hyperlinks that stretch over several lines is not a good thing to do if you want anyone to read your stuff and to take you seriously. If this were a moderated usenet forum you'd be told that your posts violate netiquette. Here this does not happen as others are violating basic principles of netiquette (and of civilized behaviour) even more.

   December 19, 2004

   > A.J. Tolland just explained us this stuff – he was excited that Peter Woit writes about his math research.

   What is this referring to? A talk at Harvard by Tolland? Or anything online?

4. **plato**
   December 18, 2004

   Hmmmm……interesting.

   To construct a consistent theory of all kinds of matter and all interactions, including gravity, is generally regarded as the ultimate goal of theoretical high-energy physics and is likely to remain so for a long time. But the development of theoretical physics is notoriously difficult to predict, and it is not easy to formulate a research plan that can be followed for several years, comprising both a main goal of great scientific value and concrete partial goals that can be achieved in a more limited time. Still, it seems essential to have at least a rough plan for the future, although one must be prepared to be flexible about it when this is needed. In the following, I will therefore try to give such a plan

5. **Lubos Motl**
   December 17, 2004

   A.J. Tolland just explained us this stuff – he was excited that Peter Woit writes about his math research.

   Peter asks too many questions, many of them have a very well-known answer.

   The six-dimensional theories that explain the SL(2,Z) symmetry of N=4 Yang-Mills in d=4 are a completely inevitable part of string/M-theory, and there is extensive literature about them. See the (2,0) theories.

   Obviously, Tolland et al. have had many more things to say.

6. **D R Lunsford**
   December 16, 2004

   Plato-

   You ask where to begin? Where most of the rest of us began – with friction problems, inclined planes, and our own common sense and respect for our scientific forebears. Throw in honesty and hard work and you may get somewhere.

   -drl

7. **D R Lunsford**
   December 16, 2004

   Plato,

   He's not "just" looking – he's NOT LOOKING AT ALL. No one in the usual gang of suspects is looking at anything except their own twisted hallucinatory reflections. These people are actively trying to destroy Western science, a collective creation of millenia that is disgraced by their presence.

   -drl

8. **plato**
   December 16, 2004

   DRL,

   Greene is justing pointing, and reveals a deeper concept. Oracle or not, the question is on how we percieve the implication AGN Jets in a consistant mathematical framework?

   If we deal with microstates, can we ever associate such math structures to explain this consistancy on a macroscale?

   I am in a space(between metric points) where NCG is operating and do not know how to express myself:)The point is where to begin? Yet the dynamical relations of the torus and spin, direct the jet?

   So if we accept euclidean postulates to the fifth, GR to gravity, Reimann sphere, why not here in this diagram(?) U(1) and say we see it in the jet?

9. **D R Lunsford**
   December 16, 2004

   Dear Plato,

   Greene is a carnival-barking buffoon – you might want to consider that before setting him up as your oracle.

   Yours,

   Ari

10. **plato**
December 16, 2004

Poster below:)

Without repeating ole cliche's and sounding like some repetitive impressionist, might we be masking the intent of what one might be saying?:)

I know it is very difficult to find the center, and topologically, impress the idea of "AGN jet" as a continued geometrical expression as well?

As part of, some continued function of the mathematical expressions that you fellows seemed engaged in?

I think Greene was specific on this point?

In fact, in the reciprocal language, these tiny circles are getting ever smaller as time goes by, since as R grows, 1/R shrinks. Now we seem to have really gone off the deep end. How can this possibly be true? How can a six-foot tall human being 'fit' inside such an unbelievably microscopic universe? How can a speck of a universe be physically identical to the great expanse we view in the heavens above? (Greene, The Elegant Universe, pages 248-249)

Updating on Blogs are slow so this link should encapsulate more of the idea that I am trying to express.

I mentioned Sklar before, in a topological expressed post, along side of the Kein bottle. Part and parcel of this continued evolution geometrically?

Sometimes the poets have it right:

Things fall apart; the centre cannot hold;
Mere anarchy is loosed upon the world,
The blood-dimmed tide is loosed, and everywhere
The ceremony of innocence is drowned;
The best lack all conviction, while the worst
Are full of passionate intensity.

Being a non mathematician I am interested in how these visulaizations are generated, so of course I wonder sometimes at statements Peter is making about CFT. This statement below is taken from thread of that discussion. You have to understand the expectancy has a predictive quality about CFT's future?:)

New non-geometrical generalization of the principles of CFT will be found, and it will allow to extend the success of S-matrices etc. to the non-perturbative realm. A geometry-like original of dualities – such as E_k in supergravity – will be clarified. Non-perturbative physics on general backgrounds will become calculable, and supersymmetry breaking will be shown to be very different in details than previously anticipated. Realistic N=1 4D vacua with SUSY breaking will be connected and the potential will pick up a rather small number of priviliged points – close to the "heterotic strings on Calabi-Yau three-folds" and/or "M-theory on G2 manifolds" and/or "intersecting brane models with some warping". Two years after the beginning of the revolution, the people will calculate the masses of the heaviest quarks, the (small) QCD theta-angle, and other things, and they will predict the first new physics beyond the SM, which will be only confirmed several years later experimentally.

I was looking for "some consistent method" that would tie together the vast framework of mathematicals in relation to our understood physics approach?

Is that unrealistic?:)

When looking a Klein ordering of Geometries, I had not see any other method that would point to this consistancy, so I am lost when it comes to all the facets of the maths that could be generated.

Maybe lacking a physics approach, mathematics has become limited(like string theory?:) and is no more then a abstract realm that people like to venture, as would artists who have found relevance to signatory styles of expression? There pictures are very unique sometimes like the move to non-eucidean views of Gauss who kept us in suspence?

You would have to forgive my ignorance here, and I fall back on DRL's encouragement for attempting to comprehend?:)

The gravitational collapse.

How would you define it, if you had a consistent geometrical method from it's previous developement??:)

If you look to the cosmo, where else will you find the counterparts of this expression of that same mathematics? I believe some have under estimated the value the comsological palette has in which to test the mathematics it is using.

That is my guess, as suspected, I too have no qualifications to speak on this, although I have a keen eye for artistic styles of expression(Penrose and his tillings? Arthur Miller, Gabriele Veneziano-The Myth of Beginning of Time. Scientific America, The Time before Time, May 2004)

If you think any of these gentlemen deficient in the use of artistic expression even cubist art in relation to the monte carlo effect, maybe the total value of the new math [that must emerge will have to wait for another Reinmann?:)]()

I don't see how moonshine could be related to the Riemann hypothesis, but who knows. Since it is a story about CFT and an interesting group, it may well somehow be related to the Langlands story.

In any case I think the motivation for studying moonshine is that it is (merely!) interesting mathematics. I wasn't aware of any evidence that the CFT involved could be used to explain anything about the real world.

15.
December 15, 2004

"In that interview, Atiyah made more extensive comments than Singer predicting that new ideas in number theory would come from physics. He explicitly mentioned the Langlands program, so was probably thinking about the same things I've written about here. He also mentions the Riemann hypothesis, perhaps thinking of Alain Connes's work on this subject, which has some physics motivation.

But it sounds like he tried this idea out on Andrew Wiles, who was very skeptical about the whole idea that number theoriists would learn very much from physics."

Yes, sorry, I meant Atiyah.

Do you have any idea if these things (Langlands, Riemann) with regards to their possible connections to physics have anything to do with the moonshine connections to string theory? Which further begs the question if string theory is wrong then what does that say for moonshine – merely interesting mathematics?

16. **Urs**
December 15, 2004

Sorry, forgot to insert my name. That last comment was of course from me.

17.
December 15, 2004

Actually, B takes values in Lie(H) and A in Lie(G), but otherwise, yes.

Note that for the application to Montonen-Olive duality -> 6D SCFTs -> M2s on M5s the kernel of t is nontrivial (in general) as descibed in hep-th/0409200. (We already noted [recently]() that semisimplicity does not seem to allow the observed n-cube scaling for these systems.)

In fact, the kernel of t in these situations is nothing but the abelian group in which the abelian 2-gerbe associated with the bulk of the membrane is associated. This makes it plausible that the abelian 2-gerbe holonomy over the bulk times the nonabelian 1-gerbe holonomy over the boundary can be given a well-defined meaning.

But I agree without you having to convince me: That constraint is unexpected. If you can find a nonabelian gerbe without that constraint but with self-dual 3-form field strength, please drop me a note! 🙂

18. **Thomas Larsson**
December 15, 2004

Let me see if I get this straight. B takes values in H, A in G, and the kernel of the homomorphisms t : H -> G is an abelian normal subgroup of H. So if H is semisimple then the closed surface holonomy is indeed zero?

19. **Thomas Larsson**
December 15, 2004

Oops, sorry. I evidently didn't read you whole post.

20. **Thomas Larsson**
December 15, 2004

But can you have non-zero surface holonomy if the surface has no boundary?

21. **Urs**
December 15, 2004

Thomas –

B is not auxiliary. The constraint says that its image under the Lie algebra homomorphism dt : \h -> \g (which I chose as dt = ad in my previous comment) can be expressed as the curvature of a \g-valued 1-form. The part of B in the kernel of dt is not restricted. By comparison with abelian gerbes which have B_i but not A_i (not to be confused with a_ij) it follows that if anything deserves to be called auxiliary then it is A_i.

The constraint implies that surface holonomy over closed surfaces takes values in the kernel of the homomorphisms t : H -> G, which is an abelian normal subgroup of H. Nothing implies that this holonomy has to vanish.

But I'd be glad to know if this constraint can be relaxed. However, it follows independently from results on standard path space connections, from categorification of ordinary gauge theory and is also the only known solution to the self-duality constraint for nonabelian gerbes. (The use of weak structure 2-groups instead of strict ones in 2-bundles, or equivalently of 'dynamical' group products in nonabelian gerbes relaxes it a little, though.)

22. **Thomas Larsson**
December 15, 2004

I do have a nonabelian surface holonomy for nonabelian 2-bundles and nonabelian gerbes for the case ${ad}(B_i) + F_{A_i} = 0$,

Urs, I really don't understand the logic behind this. Doesn't B = F(A) mean that B is an auxiliary field, completely determined by A? So you basically have a gauge theory with a 1-form connection. For such a theory, are not the only gauge-invariant quantities line holonomies?

It seems to me that your surface holonomy should equal the line holonomy of its boundary. In particular, can you associate a non-zero surface holonomy to a closed surface?

23. **Peter**
December 15, 2004

In that interview, Atiyah made more extensive comments than Singer predicting that new ideas in number theory would come from physics. He explicitly mentioned the Langlands program, so was probably thinking about the same things I've written about here. He also mentions the Riemann hypothesis, perhaps thinking of Alain Connes's work on this subject, which has some physics motivation.

But it sounds like he tried this idea out on Andrew Wiles, who was very skeptical about the whole idea that number theoriists would learn very much from physics.

24.
December 15, 2004

Is this the same connection between number theory and physics that Singer talks about in his Abel prize interview?

25. **Urs**
December 15, 2004

> Part of this story involves the Montonen-Olive duality of N=4 supersymmetric Yang-Mills. This duality interchanges the coupling constant with its inverse, whiile taking the gauge group G to the Langlands dual group (group with dual weight lattice). The symmetry that inverts the coupling constant is actually part of a larger SL(2, Z) symmetry.
>
> One possible explanation for this ${SL}(2,\mathbb{Z})$ symmetry is the conjectured existence of a six-dimensional superconformal QFT with certain properties. Witten explains more about this in his lectures at Graeme Segal's 60th birthday conference in 2002. His article from the proceedings volume, entitled 'Conformal Field Theory in Four and Six Dimensions' doesn't seem to be available online, but his slides are, and they cover much the same material.

The abelian case is well understood. The ${SL}(2,Z)$ symmetry of abelian YM follows (at least classically obviously) from realizing it as a toroidal compactification of the theory of an abelian 2-form with self-dual field strength in six dimensions, where the ${SL}(2,Z)$ is just the modular group of the internal torus.

It is *believed* that something analogous holds true for *non*abelian (super)Yang-Mills (for any A-D-E gauge group), i.e. that its Montone-Olive symmetry comes from a toroidal compactification of some 6-dimensional theory involving a non-abelian 2-form.

In this set of slides, Witten calls this nonabelian 6D theory a *nonabelian gerbe theory*. But certainly that is just a name, to be filled with content, right?

The most glaring problem with making this concrete seems to be this:

What precisely is the duality condition in the nonabelian case and under which conditions can it be imposed?

When I talked to nonabelian gerbe people about this, one thing they said is that it is not clear that in the nonabelian case the self-duality should still be ordinary Hodge self-duality, but that it might involve in addition to the Hodge star an operation on the Lie algebra factor. But I am not quite sure what that should be.

In lack of a better idea, let me assume in the following that we want ordinary Hodge duality. Now, one sufficient condition fulfilled by an ordinary bundle to admit a self-dual field strength is that the field strength transforms covariantly.

So if $U = \lbrace U_i\rbrace_{i\in I}$ is a good covering of the base space with open sets and F_{A_i} is the field strength on U_i, then on double overlaps

\[
F_i = g_ij F_j g_ij^{-1}\,,
\]

obviously.

Since the covariant transformation respects Hodge self-duality, it is consistent to impose Hodge self-duality in overlapping patches U_i.

It is not clear at all that this remains true in general for nonabelian gerbes!

For nonabelian gerbes the general transition law for the nonabelian 3-form field strenth H_i has a covariant part

\[
H_i = g_ij(H_j) + …
\]

plus a mess of noncovariant terms

\[
\cdots + \mathbf{d} d_{ij} + [a_{ij},d_{ij}] – A_i(d_{ij}) + \cdots
}]

and in particular involving this term

\[
\cdots + (F_{A_i} + {ad}(B_i))(a_{ij}) \,.
}]

(The notation here is taken from equation (55) in hep-th/0409200.)

Suppose we want H to be Hodge self-dual and hence H_i to be Hodge-self-dual on each U_i. This implies that on every double overlap all these additional terms in the above transition law have to be self-dual by themselves!

So self-duality on H implies further self-duality conditions on the fields A_i, B_i, a_{ij}, d_{ij} (which are the connection 1-form, it's 2-form cousin and two 'transition forms' that measure the failure of A_i and B_i to transform as usual.)

But these fields don’t transform covariantly themselves. So the self-duality condition on them involves still more conditions, now on triple overlaps. And so on. It is a huge mess of ever more complicated conditions that arise this way. (Unless there is some simplifying principle hidden in them, which I currently cannot see.)

It will be hard to find solutions to these conditions. One solution, though, is easy to see. Obviously, for H to be self-dual it is sufficient that

$$
d_{ij} = 0
$$

(actually this seems to be easy to weaken somewhat)

and

$$
{ad}(B_i) + F_{A_i} = 0 \,.
$$

The big question is: *Are there any further restrictions on the cocycle data of a nonabelian gerbe that would allow Hodge-self-dual H?* In particular, are there any with ${ad}(B_i) + F_{A_i} \neq 0$?

The above choice is curious, since it implies that, while A_i and B_i are nonabelian, H_i takes value in an abelian subalgebra of the full nonabelian Lie algebra.

It is also the only case so far in which we know (so far) how to associate a nonabelian 2-holonomy with the nonabelian gerbe. (A paper on that is due out by end of the year. Really, I should not be blogging but be working on that…)

The existence of that nonabelian 2-holonomy seems to be, apart from the self-duality of H, a further important condition on whatever Witten may mean by nonabelian gerbe field theory:

We known that when lifted to M-theory these nonabelian 6-D theories come from stacks of coinciding M5s with M2s ending in them. The action of these M2s should involve the abelian *volume holonomy* of an abelian 2-gerbe characterized by the 4-form dC_3, where C_3 is the supergravity 3-form potential, over the world-volume of the membrane, call that suggestively but by abuse of the integral notation $\exp(i \int_V C_3)$, times a *non*abelian surface holonomy of the nonabelian 2-form living on the M5s over the worldsheet of the boundary of the M2, call that ${Tr}{hol}_{\partial V}(B)$.

Due to global issues (completely analogous to how the coupling of the string to an abelian 2-form involves abelian gerbe holonomy) the product

$$
\exp(i \int_V (C_r)) {Tr}{hol}_{\partial V}(B)
$$

has a couple of subtleties. (For the case of 1-dimensional lower these, and their solution, are nicely discussed in the above mentioned paper by Aschieri& Jurčo).

Therefore, in order to understand nonabelian theories in 6D (and, incidentally, the general configuration of the fundamental objects of M-theory) it would be very helpful to have a notion of nonabelian surface holonomy ${hol}_{\partial V}(B)$ that makes the above expression well-defined.

I do have a nonabelian surface holonomy for nonabelian 2-bundles and nonabelian gerbes for the case ${ad}(B_i) + F_{A_i} = 0$, i.e. for the only known case in which the existence of a self-dual 3-form field strength is known. But I have not yet checked if it makes the above action for the M2 brane globally well defined.

(also posted to the String Coffee Table)

The First Evidence For String Theory?

December 16, 2004
Categories: Uncategorized

I was wondering why there were lots and lots of hits on this weblog today coming from Google searches for "first evidence for string theory". It looks like the answer is this lead article from the latest New Scientist magazine. I don't have access right now to the full article, but it's clearly based on the usual cosmic string hype. After all, according to the author, string theory "is our best hope of understanding how the universe works", so anytime astronomers see something unusual, what else could it be but a string?

Update: I finally got ahold of a copy of the full article. It is based on two separate anomalies seen by astronomers. The first is called "CSL-1", which was first reported nearly two years ago. It appears to be two nearly identical galaxies right next to each other, but the authors of a paper about it would like to believe there is some inter-galactic cosmic string producing two images of a single galaxy via gravitational lensing. Even if you believe this, there's no evidence this is a fundamental superstring, even Joe Polchinski doesn't think so (see Lubos Motl's excited posting about "astronomers prove string theory").

The second observation actually has nothing to do with the first (despite what the opening sentences of the story suggest). It's of a quasar called Q0957+561A,B that really is a gravitationally lensed object. One thing I don't understand is that in the case of CSL-1, the fact that there are only two images is taken as evidence that a string is doing the lensing (and claims are made that lensing by point like objects only produces odd numbers of images), whereas for Q0957+561A,B there are only two images, but an intervening galaxy, not a string, is what is doing the lensing. For the quasar pair, some changes in brightness by about 4% have been observed, so it has been suggested this is due to a nearby cosmic string (inside our galaxy, within 10,000 light years) which is moving around in our line of sight with the quasar pair.

I'd be curious to hear what professional astronomers think of this. To me it looks like just more string theory hype, and I now suspect that for the indefinite future, whenever an astronomer somewhere, somehow sees something anomalous, we're going to be subjected to claims that "strings have been observed!!".

   "People tell me not to superpose any theoretical prejudice on their claim that their zodiacal sign is important to their destiny"

   Existence of a destiny is already a theoretical prejudice.

4. **Arun**
   December 20, 2004

   DRL,

   People tell me not to superpose any theoretical prejudice on their claim that their zodiacal sign is important to their destiny.

   This web-page from Jodrell Bank Observatory
   http://www.jb.man.ac.uk/booklet/GravitationalLenses.html
   says:

   "…it appears that approximatly one distant radio source in 500 is split into multiple images due to lensing by a foreground galaxy."

   Therefore a quasar and a foreground galaxy lining up seems to be relatively common, and there will be even more cases where one is in the periphery of the other.

   -Arun

5. **D R Lunsford**

December 20, 2004

The authors are observational astronomers – their job is to stoke the theoretical engines, not design them.

See the later papers, mentioned below.

My own opinion is that we are seeing the effect of joint gravitational/electromagnetic physics. However, the most important point is to take the observations at face value, and not to superimpose a theoretical prejudice.

does not dare conclude that the objects in NGC7603 are physically connected.

7. **Arun**
December 20, 2004

What are plausible mechanisms for intrinsic redshifts that would apply purely in quasar neighborhoods, and not hit anything else in astrophysics?

8. **D R Lunsford**
December 20, 2004

Arun said

I disagree that I've complicated things. In my opinion, you're putting the cart before the horse. How do we first show that the quasar and galaxy are physically associated..

At some point it becomes a matter of good judgment. When you see exact "chance" lineups again and again, the chin stroking begins…In the case of some of these objects, there are *clearly* whiffordills of matter streaming from one to the other. In the case of NGC 7603, this matter bridge *itself* contains two more interesting objects. Sometimes a cigar is just a cigar..

The other way to proceed is to say – here is a model of how quasars and galaxies are physically associated, e.g. quasars are ejecta from galactic cores. One immediage prediction is then that there should be star-like objects that are associated with a galaxy like the anomalous redshift quasars are; but are blueshifted relative the galaxy, because there is no reason that ejecta should always be directed away from us or traverse to our line of sight.

Agreed – and it is entirely possible for quasars to have a high intrinsic redshift, because of unknown physics, that swamps any blueshift Doppler-originated blueshift. Indeed the strange appearence of peculiar galaxies leaves one with the powerful impression that something very different is taking place from what we see in our placid corner. Again – all that needs to be shown is physical association of discordant Z objects. The origin of Z is then up for grabs. (Note you can still have the Hubble and Doppler Zs – just that it's not the whole story.)

If you or Arp or whomever finds such stellar objects, I bet the whole community will pay attention. If Arp has not ever even attempted such a survey, then I must count him among the cranks.

I'm sure Arp would love to do just that. Anyone who could produce "Atlas of Peculiar Galaxies" is permanently out of the crank ranks.

-drl

9. **Arun**
December 20, 2004

DRL,
I disagree that I've complicated things. In my opinion, you're putting the cart before the horse. How do we first show that the quasar and galaxy are physically associated?

Merely observing two objects along the same line of sight cannot tell us that they are physically associated. Physical interactions between the galaxy, gaseous filaments, and quasars are not observed/observable.

The standard model in fact says that since the redshifts of the quasar and associated galaxy are so different, it is merely happenstance that they appear together in the sky, and they are not physically associated. One way of overturning this is to show that the statistics of such anomalous redshift objects is observed to be different from what one would expect. Absent that, the standard model accomodates these "anomalous" objects quite well. The ratio of such objects to the number of gravitational lensing candidates should be computable.

The other way to proceed is to say – here is a model of how quasars and galaxies are physically associated, e.g. quasars are ejecta from galactic cores. One immediage prediction is then that there should be star-like objects that are associated with a galaxy like the anomalous redshift quasars are; but are blueshifted relative the galaxy, because there is no reason that ejecta should always be directed away from us or traverse to our line of sight. If you or Arp or whomever finds such stellar objects, I bet the whole community will pay attention.

If Arp has not ever even attempted such a survey, then I must count him among the cranks.

I might also add that the location relativity, which is a natural derivation from the fundamental principle of my GUITAR theory, also predicts the Pioneer Spaceship Abnormal Acceleration, and it gave the correct quantitative prediction as observed.

The predicted "acceleration", based on my calculation, is:

(4/PI)*C^2/(Radius of Universe)

This acceleration quantity does not depend on the spaceship's location. It always point to where the observe is located.

Please note the radius of universe is calculated from alpha, in my natural unit system:
Ru = PI * N
N = PI * exp(2/(3*alpha))
The length unit is equal to classical electron radius. That doesn't mean it's classical, but it's value happen to be calculated the same way as classical electron radius is defined.

It is not purely a numerology coincidence that I got the exactly correct neutron mass, a 9 digits accuracy, among other amazingly correct predictions. It is a real science that describes the nature correctly.

Yes, Arp is flat wrong with some of his ideas – but he's also an absolutely first-rate astronomer with a great track record, who has been "flat ostracized" by the clergy for speaking blasphemously.

BTW Q, SHUT THE F*CK UP ABOUT YOUR "THEORY" – TAKE IT TO SPR OR THE LIKE.

-drl

15. **Quantoken**
December 20, 2004

I have read about Halton Arp's point of view and things like "tired light". I do not agree totally with him. But it is definitely wrong that a well established astronomer be deprived his observation time and his right to look at the sky and study his theory further.

According to the Copernicusian, we do not live in a special time or special place in the universe. It's absolutely true we do not live in a special generation of human history.

Of course our generations are more advanced than the middle age. But of course future generations thousands of years later would be more advanced than us, too. Frankly, future generations will look at the way how true science is suppressed in the 20-21st century, the same way we look at how the establishment suppressed the opposite ideas in the Middle Age, if not worse.

We truely do not live in a special era.

Now on the Hubble Redshift. It is an observational truth that there do exist such a red-shift that is approximately proportional to distance. That should not be questioned. What needs to be questioned is how to interpret that distance correlated redshift.

I do not think the standard interpretation of Doppler Shift is right. Now do I think the tired light model is right.

We assume that the frequence of light from remote location would not otherwise change, unless there's either Doppler Effect, Gravity Redshift, or other physical reasons to cause it to change.

But I have the opposite idea. I think the light itself doe NOT change! The frequency does NOT change. What changes is the ruler that we use to measure that frequency!!!

What ruler do we use to measure frequence? We measure frequence by counting number of waveforms per second. So we need to have a clock to measure time to measure frequence!!! I think the very ruler that we use to measure time, the clock, has changed from the remote location to our location.

Yes, I am talking about relativity. Not Einstein's Relativity, but a more fundamental relativity. Time is different not only when measured on different reference frames. Time is also different when comparing two clocks billions of light years apart.

And just like the case of special relativity. This difference is relative: We see a remote clock billions of years away runs slower than our clock. But the other civilization billions of years away also see our clock as running slower than theirs.

This location related special relativity, relative to Einstein's inertia reference frame related special relativity, was neccesated, and predicted by the fundamental principle of my GUITAR theory, which believs that the total quantum information of the universe HAS to be conserved, which directly leads to a closed spacetime of the universe.

Certainly, in a closed spacetime, you can not have time propressing at the same pace at all locations! What I mean is you can not have a universal time and at the same time have a close 3-D space. It is that simple. Spacetime is one piece and you really can not separate the two and treat space and time differently. That's what Einstein told us.

My theory of relativity therefore also answers the observed super nova "time dilation". Of course time dilates, because clocks at remote location runs slower than ours!!!

GUITAR is a self consistent theory and agrees with all observed facts, and have made many amazingly precise predictions, including precisely calculated the CMB temperature, solar constant, proton and neutron mass, within the error bars of observational data.

December 20, 2004

Arun,

You complicate the issue needlessly. The main point is that quasars are assumed to have high cosmological redshifts, that is, they are far away. The only *first* thing that needs to be shown is that quasars are physically associated with galaxies having a widely discordant redshift (and that peculiar galaxies of discordant redshift are physically associated) – once this is accepted the search for causes can begin. Personally, I *do* think it is new physics – namely, these are situations in which the linking of gravity and light would be expected to show up. Perhaps it can be explained as standard plasma phenomena on a large scale, perhaps not. The main point is that something other than cosmical distance with Hubble's law is contributing to the redshift. Certainly, nothing will happen as long as pressure from the BB clergy prevents a campaign of observation of these objects. Ask Arp where he'd like to begin, and turn him loose.

-drl

17. **Arun**
December 20, 2004

A quick take on anomalous redshift objects:

The anomalous redshift examples consist of quasars with a high redshift, seemingly physically associated with a galaxy of low redshift.

a. Chance juxtaposition – the association is apparent, not real. If things line up often enough for us to have gravitational lensing candidates, then surely things line up often enough to have these anomalous examples; presumably we can work out the statistics.

b. Suppose the quasars are associated with galaxy. Then their high redshifts are either due to their velocities or are intrinsic to them.

b1. E.g., suppose quasars are ejecta from galactic cores. Then we should find also stellar objects associated with galaxies that are blueshifted relative to the galaxies.

b2. Suppose the redshifts are intrinsic – then a blue shift survey would find nothing.

b2a. It could mean Hydrogen is emitting its Balmer spectral lines inside a deep gravitational well; so quasars are super massive objects associated with a galaxy. Perhaps just as exotic as quasars in the standard model, where they are superbright and very far away. Now the quasars are associated with the galaxy by filaments of gas, and we should observe acceleration of the gas into such supermassive objects.

b2b. New physics – this is dubious – which of the very well understood laws regarding electromagnetic radiation would you want to abrogate?

The very first question I'd ask to someone who is pointing to anomalous redshift examples is – has the corresponding blueshift survey been done?

18. **JC**
December 20, 2004

It seems like the word "terrorist" is slowly losing it's original meaning, in the same way the meaning of words like "Nazi", "fascist", "commie" and "communist" changed over the 20th century. People are using "terrorist" to label their opponents in the same way folks used "Nazi" and/or "communist" to slur their opponents during most of the 20th century, where their opponents are anything but fascist or Marxist in political ideology.

19. **Matti Pitkanen**
December 20, 2004

It seems that this is the correct moment to inject really provocative experimental findings. I cannot resist the temptation to also say few words about TGD based model for findings. The model provides support for the role of magnetic flux tube structures (having cosmic strings as a limiting case) as carriers of dark matter in quantum states of astrophysical size. The ratio v_0^2= G/R^2, where R is CP_2 length, essentially the ratio of the cosmic string tension to string string tension, appears also as a basic parameter of the model, so that I can argue that the injection is loosely related to
the topic of the discussion.

1. Are planetary orbits Bohr orbits?

The basic finding is that there is evidence that planetary orbits correspond to Bohr orbits in a gravitational potential when Planck constant is replaced with a gigantic "gravitational Planck constant. For various kinds of experimental evidence (our planetary system, radii of exo-planets, matter in galactic halo, morphology of large scale astrophysical objects) see the article

D. Da Rocha and L. Nottale (2003), Gravitational
Structure Formation in Scale Relativity, astro-ph/0310036,

D. Da Rocha and Laurent Nottale have proposed that Schroedinger equation with Planck constant hbar replaced with what might be called gravitational Planck constant hbar_{gr}= GmM/v_0 (hbar=c=1). v_0 is a velocity parameter having the value v_0=about 145 km/s. This is rather near to the peak orbital velocity of stars in galactic halos. Also sub-harmonics and harmonics of v_0 seem to appear. The support for the hypothesis coming from empirical data is impressive. Nottale and Da Rocha believe that their Schroedinger equation results from a fractal hydrodynamics.

2. Is dark matter in quantum states of astro-physical size?

Many-sheeted space-time however suggests that astrophysical systems are not only quantum systems at larger space-time sheets but correspond to a gigantic value of gravitational Planck constant. This would imply astrophysical quantum coherence lengths and times. The gravitational (ordinary) Schroedinger equation or Bohr rules would provide a solution of the black hole collapse (IR catastrophe in case of hydrogen atom) problem encountered at the classical level.

The basic objection is that astrophysical systems are extremely classical. Many-sheeted space-time predicts however macro-temporal quantum coherence in the scale of life time of gravitational bound states. The resolution of the problem inspired by TGD inspired theory of living matter is that it is the dark matter at larger space-time sheets which is quantum coherent in the required time scale.

3. Beraha numbers and quantization of Planck constant

I have proposed

[see the chapter "Intentionality, Cognition, and Physics as Number theory or Space-Time Point as Platonia" at http://www.physics.helsinki.fi/~matpitka/tgd.html#intcognc%5D

the possibility that Planck constant is quantized and the spectrum is given in terms of logarithms of Beraha numbers

B_n= 4cos^2(pi/n), n>=3.

associated with both the so called type II_1 factors of von Neumann algebras, braid group representations, and quantum groups. The lowest Beraha number B_3 is completely exceptional in that it predicts infinite value of Planck constant.

The inverse of the gravitational Planck constant could correspond a gravitational perturbation of this as 1/hbar_{gr}= v_0/GMm. The general philosophy would be that when the quantum system would become non-perturbative, a phase transition increasing the value of hbar occurs to preserve the perturbative character and at the transition n=4–>3 only the small perturbative correction to 1/hbar (3)=0 remains. This would apply to QCD and to atoms with Z>137 as well.

4. The parameter v_0 in terms of the ratio G/R^2

TGD predicts correctly the value of the parameter v_0 assuming that cosmic strings and their decay remnants are responsible for the dark matter. v_0 is essentially the ratio sqrt(G)/R, where R is CP_2 size: v_0^2 gives also the reduction of cosmic string tension from its stringy value 1/G consistent with the velocity of orbiting stars in the galactic halo.

The harmonics of v_0 can be understood as corresponding to perturbations replacing cosmic strings with their n-branched coverings so that tension becomes n^2-fold: much like the replacement of a closed orbit with an orbit closing only aftern turns. 1/n-sub-harmonic would result when a magnetic flux tube split into n disjoint magnetic flux tubes.

5. Quantum model for evolution of planetary system

The study of inclinations (tilt angles with respect to the Earth's orbital plane) leads to a concrete model for the evolution of the planetary system as being induced by the quantum evolution of the dark matter. Only a stepwise breaking of the rotational symmetry and angular momentum Bohr rules plus Newton's equation (or geodesic equation) are needed, and gravitational Schroedinger equation holds true only inside flux quanta for the dark matter.

a) During pre-planetary period dark matter formed a quantum coherent state on the (Z^0) magnetic flux quanta (spherical shells or flux tubes). This made the flux quantum effectively a single rigid body with rotational degrees of freedom corresponding to a sphere or circle (full SO(3) or SO(2) symmetry).

b) In the case of spherical shells associated with inner planets the SO(3)–> SO(2) symmetry breaking led to the generation of a flux tube with the inclination determined by m and j and a further symmetry breaking, kind of an astral traffic jam inside the flux tube, generated a planet moving inside flux tube. The semiclassical interpretation of the angular momentum algebra predicts the inclinations of the inner planets. The predicted (real) inclinations are 6 (7) resp. 2.6 (3.4) degrees for Mercury resp. Venus). The predicted (real)inclination of the Earth's spin axis is 24 (23.5) degrees.

c) The v_0–> v_0/5 transition necessary to understand the radii of the outer planets can be understood as resulting from the splitting of magnetic flux tube to five flux tubes representing Earth and outer planets. The flux tube has a shape of a disk with a hole glued to the Earth's spherical flux shell.

d) A remnant of the dark matter is still in a macroscopic quantum state at the flux quanta. It couples to photons as a quantum coherent state but the coupling is extremely small due to the gigantic value of hbar_gr scaling alpha by hbar/hbar_gr: hence the darkness.

6. Connection between dark matter and living matter?

What is amazing that the period T =hbar_gr/E associated with n=1 orbit in the case of Sun is 24 hours within experimental accuracy for v_0. This and other rather amazing coincidences between basic bio-rhythms and the periods associated with the states of orbits in solar system suggest that the frequencies defined by the energy levels of the gravitational Schroedinger equation might entrain with various biological frequencies such as the cyclotron frequencies associated with the magnetic flux tubes.

These findings encourage to take with some seriousness the TGD based quantum model of living matter involving macroscopic quantum coherence in even astrophysical length scales (at space-time sheets representing topological field quanta of various fields with frequencies in ELF and ULF range) and flow of matter between different space-time sheets as basic mechanism of quantum control and metabolism. It would be quantal dark matter at topological field quanta which makes visible matter living.

For more details see either the article "Gravitational Schrödinger equation as a quantum model for the formation of astrophysical structures and dark matter?" at http://www.physics.helsinki.fi/~matpitka/articles/nottale.pdf or the chapter "TGD and Astrophysics" at http://www.physics.helsinki.fi/~matpitka/padtgd.html#astro".

20. **Arun**
December 19, 2004

http://www.metaresearch.org/publications/books/SeeingRed-Arp.asp

Quote:

Here are some brief quotes outlining what Arp has learned from these exchanges.

"When presented with two possibilities, scientists tend choose the wrong one." "

The stronger the evidence, the more attitudes harden."

“The game here is to lump all the previous observations into one ‘hypothesis’ and then claim there is no second, confirming observation.”

“No matter how many times something has been observed, it cannot be believed until it has been observed again.”

“If you take a highly intelligent person and give them the best possible, elite education, then you will most likely wind up with an academic who is completely impervious to reality.

“When looking at this picture no amount of advanced academic education can substitute for good judgment; in fact it would undoubtedly be an impediment.”

“Local organizing committees give in to imperialistic pressures to keep rival research off programs”

“It is the primary responsibility of a scientist to face, and resolve, discrepant observations.”

“Science is failing to self-correct. We must understand why in order to fix it.”

21. **Arun**
December 19, 2004

A Arp-Bahcall debate on anomalous redshifts occurred in 1972. What has changed since then?

22. **D R Lunsford**
December 19, 2004

OK Arun, but this is rather more important:

http://arxiv.org/abs/astro-ph/0401596

Another one, this time, with Zs from .12 to .22.

Ok, clear now everyone? The above is science, with spectrometers and eyeballs and brains.

-drl

23. **Arun**
December 19, 2004

Congrats. to Iyam for injecting some humor into this vitriolic thread.

There are a lot of hurdles to be cleared before we know whether we are seeing gravitational lensing by a dense quasi-one dimensional object (dunno why people object to the word ‘string’ 🙂). Let there be independent observations of this object; let the Hubble or Keck get some observation time. Remember that it is the astronomers, not the string theorists, who get the final say as to whether something is there. Meanwhile, the theoretical community, well symbolized by the barracuda, will come out with a burst of speculative papers.

This is the way it has always worked, string theory hasn’t changed anything.

24. **Iyam deRanjeed**
December 19, 2004

Dear Quantoken,
A colleague has pointed out to me your entries on this blog and I have to tell you that scientific plegiarism is a very serious issue! Your derivation of the CMB temperature and baryon masses look suspiciously like my cosmological work on Scalar-Hadron Interactions and Thermal Excitons (S-H.I.T.E), where I derive these numbers. I have 2 papers that I published on this while a visiting scholar at the Yonkers Institute of Technology in New York.

I derived an explicit differential equation for a time-dependant dimensionless quantity N(t)(although in my paper it is called B(t)) and get a solution in the infinite time equilibrium limit
such that N(t)–>N=4 pi exp(a/3alpha) where constant “a” is fixed by initial conditions (the Planck temperature). As the universe cools off and expands and energies fall below 100Gev the running coupling constant alpha falls from 1/128 to its present constant value of 1/137. The effective gravitational constant is then essentially “condensed” out from thermal quantum vacuum fluctuations, much like Sakharov said it should, and thats why it can be related to alpha via N. Because the solution is essentially a thermal equilibrium limit I can compute the CMB temperature and get an accurate answer within current experimental bounds.

The vacuum fluctuations also create regions of trapped quantum information called “excitons” which we experience as protons, neutrons and other baryons and hadrons, and the amount of information determines their masses since I can relate entropy S to E and get the masses from m=sqrt(E/C^{2}). When alpha is 1/128 the fluctuations are much greater at the beginning of the universe and the regions of trapped information are therefore heavier and within their own horizons, so they are actually microscopic quantum black holes with a Bekenstein entropy (equal to their von neumann entropy). But these can decay via Hawking radiation and contribute to the CMB. Only as
N–>N=4pi exp(a/3alpha)=const=1/137, as the universe cools, do the trapped regions become much lighter and stable so that they appear as massive particles like protons.

Although there are differences in my model the similarities are too much of a coincidence and you will not get credit for computing the CMB temperature, since I clearly did it first. I would expect that you would at least quote my work rather than shamefully present it as your own. Anyone visiting your blog will be made aware of this. The advantage here is that I am in print for all to see.
Yours
Iyam deRanjeed
India

December 19, 2004

Lubos

For not lack of trying to understand, I appreciate the work you are doing to bring comprehension to this subject. I am always revising, to understand the theoretical positions people adopt.

According to T-duality, universes with small scale factors are equivalent to ones with large scale factors. No such symmetry is present in Einstein’s equations; ***it emerges from the unification that string theory embodies, with the dilaton playing a central role***by

Gabriele Veneziano

regards,

26. **Lubos Motl**
December 19, 2004

Those who are more interested in physics than the “Gentlemen”‘s inability to learn even the very basics of this subject (and their political statements) – I am not sure whether anyone like that attends this blog – should read my article about it

http://motls.blogspot.com/2004/12/astronomers-prove-string-theory.html

and the articles linked in it.

27. **Lubos Motl**
December 19, 2004

An idiot posted a nonsense above my message, so it may be safer to post my message once again:

It’s a waste of time. I will just keep on returning to these dangerous places to emphasize that the owner of this blog and most of the contributors on this blog are scientifically illiterate morons. They have no idea what they are talking about, and they have no respect to the basic rules of scientific integrity.

28. **Quantoken**
December 19, 2004

December 19, 2004

Damn, another typo. I guess I really don’t type well on a keyboard when do it in a hurry:

t0 = time for light to go across the classical electron radius
t0 = C/(classical electron radius)
t0 = 2.817940325×10^-24 seconds

The middle line was wrong although the numerical value is correct. Waht I meant to say is:
t0 = (classical electron radius)/C

Quantoken

31. **Quantoken**
December 19, 2004

Chris:

Thanks.

And, peter, thanks for providing a place where I can discuss my thoughts, even just a small glimpse of my theory.

Indeed I have been a bit too lazy and havn’t even got a web site set up to discuss my theory fully. I will do it as soon as I find some time dealing with the chore of getting the typesetting right.

In the future, here is my BLOG:

http://quantoken.blogspot.com

There is nothing there yet at this moment. When time comes I will disclose the full details of how I achieve those amazing results of computating the CMB temperature, solar constant, proton and neutron mass, etc, all from one consistent theory.

I am not going to deal with Lubos any more. I thought he was a smart guy having got that ln3 result. But since he is not willing to admit mistakes like another guy who got ln3 wrong did, he is just too stubburned to be persuaded. I do hope he has a calculator and punch in numbers to try to verify my calculation, trying to pick my any possible arithmatic mistakes. Here is the source of oficial physical constants:

http://physics.nist.gov/cuu/Constants/index.html

I will try to post less on Peper’s blog if I can control myself a bit. He is a nice and tolerate guy. No surprise that he is a mathematician!

Quantoken

32. **Chris Oakley**
December 19, 2004

Peter –

Please don't – I'm enjoying it.

Quantoken –

Repeating your theories in the comments section of physics blogs will get you nowhere. Collect your thoughts on a web site & if people see fit, they will visit it.

Lubos –

The image of knowing an aeroplane is going in the wrong direction without necessarily being able to operate the controls is very apt. I have talked to laymen who have read "The Elegant Universe" & come away with the impression that the whole thing is going nowhere without any prompting by me. It's not good enough to be able to sell your ideas to fellow believers. Ultimately you have to sell your ideas to the rest of the world as well & behaving like a spoiled brat is not going to help your case.

33. **Quantoken**
December 19, 2004

Regarding the CMB discovery, that's the whole point I want to make. They discovered CMB and explain it as the remains of Big Bang and hence a supportting evidence for Big Bang, and they obtained the Nobel. If they discovered the CMB and explain it as star radiations, then that trivializes their discovery and there is no way they can get a Nobel out of it, even if it is the same discovery.

It's the whole secret how you cook your data. As I have shown, without dispute, that CMB is indeed just star radiations: I obtained the absolutely correct CMB temperature that matches oberved value exactly. No one else have obtained such a precise calculation of CMB. I got it out of the simple assumption of star radiation.

Actually Sir Eddington did similar calculation and obtained 3K, a very precise number, far before CMB discovery. BigBangers can't even hope to get 3K correct today. I got all digits correct!

BTW, Lubos, are you making physical threats to me? Science can not develop if physical threats like this exists. Scientists must be able to express any idea free of fear of threats, AND free of fear of FUNDING. Unfortunately the later part is lacking.

I am putting up a BLOG of my own and I guarantee no one will be censored there. Not even you, Lubos.

Quantoken

34. **Peter**
December 19, 2004

I enjoy the spectacle of vigorous scientific debate as much as the next person, but calling for physical violence (by the US military or anyone else) against one's intellectual opponents is beyond the pale. I'll be deleting any future comments by anyone that do this.

35. **Quantoken**
December 19, 2004

I missed something in the middle due to typo. It should be

sqrt(beta) = ((2/3)*(1/alpha) + (3/2)*ln(PI))/ln (sqrt(2/PI)*(Tau/(PI*t0)))

Not
sqrt(beta) = ln (Tu/sqrt(PI))/ln((Tau/(PI*t0))*sqrt(2/PI))

The starting formula and the numerical results are all correct:

sqrt(beta) = ln (Tu/sqrt(PI))/ln((Tau/(PI*t0))*sqrt(2/PI))

36. **Quantoken**
December 19, 2004

Lubos:

Go away. Your "explaination" of what I wrote is simply erase my words on your blog. "Explanation" by censorship is not an explanation and I am not interested in dialoging with a censorship dictator.

I am not commenting on you more and you should not comment on me more either. Is that fair enough?

Now my derivation of the exact neutron mass. So that you don't bullshit more on me. I am not going to give any reasoning. Just the formula. Any one can calculate and get the same result:

Theoretical Proton mass:
Mp = Me*(1/alpha)*(ln(2*(1+3*5!+7!))/ln2)
Mp = Me*137.03599911*(ln(10802)/ln(2))
Mp = 9.1093825×10^-31 kg * 1836.146836
Mp = 1.672626404×10^-27 kg

Theoretical Neutron Mass:
Mn = Mp + Me*beta
sqrt(beta) = ln (Tu/sqrt(PI))/ln((Tau/(PI*t0))*sqrt(2/PI))
Tu is age of the universe expressed in My Natural Unit Set, where the unit of time
t0 = time for light to go across the classical electron radius
t0 = C/(classical electron radius)
t0 = 2.817940325×10^-24 seconds

Age of universe
Tu = PI * N
with
N = PI * exp (2/(3*alpha))
So:

sqrt(beta) = ((2/3)*(1/alpha))/ln (sqrt(2/PI)*(Tau/(PI*t0)))

Tau is the free Neutron mean lifetime, 885.7 seconds.
You get:
sqrt(beta) = 93.07442757(31)/58.4372(9)
beta = 2.53677(9)
The brackets above means the possible discrepancy of the last few digits.

So:
Mn = Mp + beta*Me
Mn = 1.672626404×10^-27 + 2.31084(7)x10^-30
Mn = 1.67492724(7)x10^-27 kg

The above is my calculation result. The official value is:
Mn = 1.67492728(29)x10^-27 kg
(see http://physics.nist.gov/cgi-bin/cuu/Value?mn|search_for=neutron+mass)

My result matches up to the ninth digit and is completely within the experimental margin of error.

My computation is elegant all the way and there is absolutely no adjustable parameter, no fractional number, no expansion series. Only one additon occured to calculate neutron mass from proton mass. I obtained both the correct proton mass and the correct neutron mass. Can you say a theory that achieves 9 digits accuracy this way, is crackpot?

I can not disclose my reasoning behind because the kind of Lubos will probably erase my messages and then write up a string paper to publish and claim to have calculated neutron mass.

Quantoken

37. **Lubos Motl**
December 19, 2004

It's just totally incredible what all of you imagine science is.

Concerning "bird shits on the telescope" – there were some shits indeed, but even without the shits the signal survived. This is why Kapitsa, Penzias, and Wilson made the biggest discovery in cosmology in the last 50 years, and were awarded by the 1978 Nobel prize for their discovery of the microwave background.

You will probably never understand what science is. Science requires absolute integrity. Science cannot be done under threats. I insist that if a complete moron with 0 knowledge about physics tries to rape physics and force the scientists to publish whatever he wants, then this moron should be eliminated by the government's bodies if the government has any control over the security situation in the country.

It is also a very personal responsibility of every individual scientists to resist all pressures, threats, and blackmailings that are intended to twist his or her honest scientific investigation.

Every scientist with healthy enough muscles should give a proper thrashing to terrorists like Chris Oakley who are openly trying to destroy the very basic principles of unbiased scientific research.

38. **Lubos Motl**
December 19, 2004

Dear Quantoken,

I've already explained the reality about all the stupidities that you wrote, and your latest rant does not contain anything new that has not been explained yet.

Of course that I think that Oakley's comments about funding of these amazing projects are horrible. It's an approach of a totally uniformed terrorist. People like Oakley should be dealt with by the US soldiers with the gun – and I am sort of ashamed to waste my time with such immoral idiots.

Sincerely Yours
Lubos

39. **Quantoken**
December 19, 2004

Chris said: "I would love to be the person who cuts the grants of scientists who resort to bullshit explanations whenever they see anything slightly out of the ordinary."

Chris, unfortunately you can not do it even if you have that power. That's the most people there are in the fields. The culture is cultivated by "publish or perish." You would want to provide bullshit explanations than trivial, common sense explanations or nothing at all, if you want something published. Claiming "My telescope does not work perfectly because a bird shit on it" does not get your paper published. Claiming "this peck of dust is not peck of dust but something explainable by superstring" will guarantee publication. You can't cut them all.

One big exception I must make is for mathematicians. They do not have the burden of observation and proving their result by experiments. All they ever do is the most strict mathematical reasoning. So there is absolutely no room to be bullshiting in the field of mathematics.

So mathematicians are the most honest people on the earth. That's why we do not see a single politician came from a mathematics background.

Quantoken

40. **Quantoken**
December 19, 2004

Lubos:

Looks like Chris's comment of "cut funds" really hurt your feeling more than the language of "crackpot", right? Talking is cheap, but funding is not. "Publish or perish".

Regardly your ln3 result. Are you sure you are the only surviver? You are not, you are just still breathing. The other guy has been proven to be wrong, and you got the same answer as the wrong guy got. If you have the SAME wrong answer, how come he were wrong and you were correct. It's just no body has bothered to check your mistaken yet. That's worse than being found to have made a mistake: You know your answer is wrong but you do not know how you made that mistake.

Regarding your comment of seeing the picture of the paper to believe these are two identical images, not one. My comment is smart people do NOT always believe what they see. They have brains, they subject everything they see, hear, or touch to logic reasoning, filtering all the information, before deciding which part is to be believed, and which part is not. If your brain does not have that filtering or processing power and simply take everything published as granted, then it serves no better purpose than a paper recycling bin.

You say they hide the coordinate of that particular object so no one else can see it before they collect more data. But then they claim the phenomena is so common place that within 16 square arcseconds, a visual area just a size of one galaxy at 10 billion light years awy, they could find 11 pairs. Then any one can look at any part of the sky and find plenty of this sort of things.

The center of such "two" images being so close, even closer than the radius of a typical galaxy, the object itself. Even if you think you see two separate but identical images, it could be easily explain away by a few hundred different artifacts I can think of.

The simplest and easiest explaination is they are indeed just one slightly distorted image, wrongly interpretted as two images.

For example, do you have an idea how weak the light would be if it comes from a galaxy 10 billion light years away? Radius of the universe is only 14 billion light years. Do you know how many photons they would be able to collect, during a course of several hours observation?

You probably don't know the stuff, being working in such a narrow field. Astronomical observation is not taking point and shot photos. To get anything at all, you have to aim your telescope exactly towards the same object for several hours to collect a few photons to form an image. On the earth, that means you have to rotate your telescope all the time in a very precise way to keep it targeted.

If some how it is not targetting very precisely, during the whole course of several hours, like it is off just a little bit, 2 arcseconds, then the photos would not focus on exactly the same spot, but will form a slightly distorted image.

2 arcseconds is not much. All it take, is probably a fly by bird shitting on the telescope and the tiny extra weight bends the telescope so slightly. Or a truck drive by to dent the ground surface ever so slightly.

Even without bird shits or drive by trucks, an earth surface based telescope would have to deal with the fact that star lights were bend by the atmosphere. During different part of the day the injection angle is different and the bending will be different. Different weather condition or atmosphere composition also may cause the bending to be slightly different and it is hard to model it and compensate it, on top of compensating for the rotation of the earth.

On top of all these, you have the "atmospheric seeing". The lights are distorted due to random thermo movements of the molecules in the atmosphere. This seeing makes it hard to obtain anything better than 1 arcsecond resolution even under even most optimal observational condition. So 2 arcseconds is reall not that much!!!

I have done scientific experiments so sensitive that I absolutely have to conduct it under the ground, after 2:00am, and I must not make the slighted muscle movement even to type on a computer keyboard. It's damn too easy to introduce artifacts in observational data nowadays. Being a theoretician you probably know nothing more than your blackboard.

Quantoken

41. **Lubo? Motl**
December 19, 2004

Fortunately, the people in the agencies are not idiots like you, Chris. On the contrary, some of them know much about physics. Chris, I know that you would like to be powerful, much like Peter (well, and many others for that matter, too). But one can't get too powerful if it is too obvious that he or she is a complete idiot.

If the images are confirmed identical and identially strong and undistorted, a huge cosmic string's gravitational lensing is the only acceptable explanation. I am sure that the most important people in the agencies can understand why it is so.

42. **Chris Oakley**
December 19, 2004

I would love to be the person who cuts the grants of scientists who resort to bullshit explanations whenever they see anything slightly out of the ordinary.

43. **Lubos Motl**
December 18, 2004

Peter Woit obviously has not understood the basic points about gravitational lensing yet.

For generic, point-like sources of gravitational lensing, one obtains several images that are highly distorted and that have very different intensities.

Who wants to get a feeling why it's so can play with the following simulation applet:

http://www.iam.ubc.ca/%7Enewbury/lenses/lensdemo/demo.html

It's of course the case of the other lensed object, too – the two images are NOT identical. Moreover, it is known which object is causing the lensing.

CSL-1 is special among all lensings in having two IDENTICAL images – the spectra are equal with 99.999 percent confidence level or so. This occurs for lensing by cosmic strings, but not by pointlike objects.

44. **Lubos Motl**
December 18, 2004

Concerning the last paragraph.

Peter obviously cannot or does not want to understand that in the case that the images of CSL-1 turn out to be identical indeed (and not just two similar "twin" independent galaxies), then it is just guaranteed that it is either a big coincidence (poinlike particle lensing fine-tuned to give unusually similarly strong images), or a cosmic string.

If the other possibilities are excluded, then OF COURSE that conclusion will be “a string has been observed” because only the cosmic strings naturally produce identical images via lensing. The open question will then be “what kind of string have we seen”. But yes, if Peter is afraid that these strings will either be a support for string theory (fundamental strings themselves) or Grand Unification (that Peter Woit also hates) or a similar theory at the same scale, then he is very correct to be afraid, because the scale simply works this way.

If the deficit angle is between 10^-7 and 10^-6, then the tension of the string is at the GUT scale (which is near the string scale in the more-or-less conventional models), and it is naturally a GUT object, or a string theory object.

It’s certainly not guaranteed that these “anomalies” will survive and be interpreted in this exciting way, but if it happens to be so, then only a complete idiot will be able to oppose the statement “a string has been observed”. Already today, Peter Woit is obviously getting ready for playing this role. 😉

45. **Lubos Motl**
December 18, 2004

Peter, could not you reduce your insults, at least against other people than me?

What do you mean by “What professional astronomers think of this”? Is not Sazhin a professional astronomer? The professional astronomers, such as Mikhail Sazhin,

http://xray.sai.msu.ru/~sazhin/

think exactly the same thing as everyone else who understands what’s going on. It’s a potentially very important observation (let me talk about CSL-1 now), and it is either a weird coincidence of lensing by a pointlike object that happens to create two identical images – which is very unusual – or it is a pair of 2 different galaxies that look almost identical, or it is evidence for a cosmic string seen in the telescopes.

If you ask a professional astronomer which kind of cosmic string it is, he will tell you his theories but he will also add that he does not understand the stuff enough, and you should ask professional particle physicists or string theorists.

46. **Lubos Motl**
December 18, 2004

Sorry, but I will continue to be excited about exciting things, and angry about outrageous things, because this is one of the motors that drive science and not only science. If you deliberately want to be a bitter cynic, it’s YOUR problem.

47. **Chris Oakley**
December 18, 2004

Lubos –

I do not see how anyone can conduct science in the kind of emotionally-charged atmosphere that you seem to want to carry around with you.

It is not just about being clever. I’m sure that you are cleverer than I am and – who knows – you may be cleverer than Peter. Science is not just about that, it is about exercising judgement. If in the cold light of day, after you have thought about something a lot it appears to be especially good or especially bad, then you are duty bound to follow where that leads. And in my case, the direction is not towards yet more levels of abstraction. I seems likely, therefore, that I will continue to be the the bitter, cynical old sod that you describe.

48. **Lubos Motl**
December 18, 2004

Chris Oakley, you may be looking for unique exact predictions or whatever, but what you’re looking for is absolutely irrelevant for the question how Nature works.

If there happens to be a cosmic superstring – macroscopic fundamental string, for example – 10,000 light years from the Sun, then it will become a fact of Nature and we will have to live with it – and scientists will have to give a proper explanation. If this turns out to be the case, it will be absolutely obvious that no one could have predicted this string in advance.

We have not mastered the most subtle details of string theory and therefore we can’t still calculate every detail of reality accurately and unambiguously, nevertheless string theory is making so many bold and relatively specific qualitative predictions that most of you, the bitter critics, are – politely speaking – shitting into your pants in awe (so much that you are forced to move some of this stuff on the internet).

In the real history of physics, there have never been so many truly new predictions done in advance, before they’re actually measured, as in the case of string theory. Most of previous major breakthroughs in physics started by observations that were later interpreted in a new theory. Theories of relativity are, in some sense, exceptions, and string theorists are following this example.

We would be much happier if the gap between the theorists – which are much ahead today – and the experimenters and their experimentalists shrink. It’s YOU who does not want it, and therefore you’re scared by every possible new experiment that could give us some hints about the truth.

Let me emphasize once again that cynicism of sourballs like you, Chris Oakley, has no consequences for physics whatsoever. You’re just annoying and obnoxious, but your contributions to science are exactly zero. If you think that it is easy to make reliable and unique new predictions of phenomena beyond the Standard Model, try to compete with us.

The problem is that you could not make even 0.0001% of what the average particle physicist or string theorist does. The only thing you are able to do is to spread bitter remarks and stupidities.

49. **Chris Oakley**
December 18, 2004

“Most people would think that someone who runs around saying they have a wondrous TOE that predicts amazing new things, but they’re not sure whether the amazing new things happen at the Planck scale or the scale of a galaxy, would have to be almost by definition a crackpot”

I think, Lubos, that you’re missing the point here, perhaps deliberately.

Peter and a large number of others, including myself, are looking for a specific predictions which can be tested with specific experiments. If you cannot advance any, then what you do does not deserve the label “physics”.

50. **Robert**
December 18, 2004

Calm down, calm down. In the UK this soothing turn of phrase will be forever associated (thanks to the comic Harry Enfield)with feuding Liverpudlians (natives of Liverpool, for non-UK readers). Somehow, it seems only too appropriate that it should be deployed in this context. Get a grip guys.

51. **Lubos Motl**
December 18, 2004

Peter. Sure that string theory does predict strings. It’s not my problem with your language: it’s apparently your problem with the basics of the field of science called physics. You seem to be ignorant about several absolutely basic features of physics and cosmology.

Could not you do something for me – e.g. try to learn at least the basics from Tom Kibble?

http://arxiv.org/abs/astro-ph/0410073

He’s not a string theorist, so you should be capable to read his article. Of course, reading an article like that requires that you won’t stop once the first word “string” appears in the article. If you always stop reading an article once a word “string” appears in a review or another article, you will remain ignorant about physics until your death, do you know?

Virtually every model coming from string theory predicts that long-lived macroscopic strings may exist in the Universe – usually many different types of a string. The real question is whether such massive objects have actually been created in the history of the Universe and whether they can be seen.

Some models of inflation and cosmology based on string theory say “yes”, some models say “no”. Some models that say “yes” have been ruled out, some models that say “yes” are still alive.

It’s not just string theory. A theory with a spontaneously broken U(1) always predicts cosmic strings – the monodromy around the cosmic string corresponds to the Higgs field rotating around the circle of minima. Cosmology and causality guarantees that if such a spontaneously broken U(1) exists, then there should be strings as big as the horizon radius – not just the size of the galaxy. Of course, observations can then be used to make various bounds on the existence of such objects.

Once again. I find it amazing how little you know about very basic questions such as the conditions sufficient for the existence of cosmic strings.

You even wrote: “Most people would think that someone who runs around saying they have a wondrous TOE that predicts amazing new things, but they’re not sure whether the amazing new things happen at the Planck scale or the scale of a galaxy, would have to be almost by definition a crackpot.”

Are you joking, or are you also this incredibly under-educated in physics? Strings in string theory simply ARE, and they can have any size. Small strings are light, big strings are heavy. It is a question of dynamics and initial conditions whether some particular strings are large or small. The distance of a planet from the Sun can also be large or small. The distance is a degree of freedom, much like the position of a point on a string (and therefore its size). Is this basic concept of physics REALLY so difficult for you?

Obviously, my trivial explanation of the strings’ size that was initially addressed to Quantarzan or what’s the name of the moron can also be directed to you because you seem to be equally ignorant about this absolutely basic question as the crackpot.

OK, let me start again. Have you heard of a harmonic oscillator? It is a system with a position (x) and a momentum (p). You can visualize momentum to be the velocity of a ball attached to a spring, multiplied by its mass.

According to classical physics, the energy of this harmonic oscillator is any positive number. According to quantum mechanics, it is (N+1/2)hf, where h is Planck’s constant and “f” is a typical frequency of the oscillator, and N is a non-negative integer. For small N, quantum mechanics is very important and you get quantized energy. For large N, this variable is effectively continuous and one can think about the oscillator in classical terms.

A string is a collection of many harmonic oscillators (plus the center-of-mass degrees of freedom, which are analogous to pointlike particles) – a string is an infinite-dimensional harmonic oscillator. The low-lying states of the string are the elementary particles, but there are also high-energy, long strings that can be approximated by classical physics. They’re the same strings. Strings are real, not just some fictitious objects, and of course they can become large if one creates them (having enough energy).

I wish you better luck, Peter, with your learning of physics 101 issues because your ignorance is truly breath-taking.

52. **Peter**
December 18, 2004

Hi Lubos,

You still seem to have a language problem with the English verb “to predict”. So string theory doesn’t just “PREDICT” Planck scale strings, it also “PREDICTS” strings with scales the size of a galaxy?

Most people would think that someone who runs around saying they have a wondrous TOE that predicts amazing new things, but they’re not sure whether the amazing new things happen at the Planck scale or the scale of a galaxy, would have to be almost by definition a crackpot.

53. **Lubos Motl**
December 18, 2004

Dear Quantoken,

the quantum of area announced in the ridiculous article by Baez was not 4.sqrt(3) but 4.ln(3) times the Planck area. The calculation of the asymptotic quasinormal modes in my paper – and another paper of Andy Neitzke and myself – is the only thing that survived.

The asymptotic quasinormal modes of black holes have nothing to do with area quantization. Moreover, if one computes other black holes different from the Schwarzschild, one obtains a wrong result, different from 4.log(3).

Moreover, the heuristic “calculation” of the area quantum in loop quantum gravity has been showed incorrect – even if one would believe that there is something correct about loop quantum gravity itself (the a priori probability of this is about 0.0000001%). See e.g.

http://arxiv.org/abs/gr-qc/0407051
http://arxiv.org/abs/gr-qc/0407052
http://arxiv.org/abs/gr-qc/0411035

There are no logarithms of integers conjectured for area quantization anymore.

If you have "calculated" the mass of the proton and you don't use QCD or string theory, then you may be absolutely sure that you are a complete crackpot.

Best
Lubos

54. **Lubos Motl**
December 18, 2004

Hi Peter,

I think that it is fair that this crackpot Quantoken has similar ideas about physics as you, does not he? 😉 Just teasing you.

Let me now pretend that I think that it makes sense to discuss physics with people like "Quantoken" – to prove how extremely polite I am. 😉

Dear Quantoken,

you totally misunderstood the whole issue. Sazhin et al. are not string theorists. They are astronomers, and they think that they have observed something amazing (I repeat: amazing, not "desperate"), namely a huge cosmic string hundreds astronomical units in size or bigger.

Regardless of the type of that string, one would need an explanation if the observation is confirmed. String theory obviously offers several explanations – from the ordinary ones (cosmic strings from spontaneously broken gauge group) to the super-exciting ones, namely the fundamental superstrings grown to a macroscopic size.

To some extent, various particular stringy models PREDICT(ed) the existence of cosmic strings created after inflation, and this could very well be an experimental confirmation of these predictions. Polchinski estimate the a priori probability that such cosmic superstrings may exist to be 10 percent.

But the theoretical explanation is a different level of the story than just the possibly exciting observation.

Yes, if you open the papers by Sazhin et al., you will see the specific pictures of the pair of galaxies – they are like two circles in the digit "8" and almost touch each other. You can still distinguish that these are 2 objects. The theory that there is one image only – without lensing – is safely ruled out.

If you looked at the papers with the explicit pictures, you could have avoided writing complete stupidities on my blog, your blog, and Peter Woit's blog. You know, I am putting the links to the papers at arxiv.org because I expect the average reader to open these papers. By this sentence I want to say that you are much much worse than what I expect to be the average reader.

I think that even the average people who happen to visit your blog or Peter's blog are much more skillful than you, and they will be able to open the Postscript or PDF files with the papers by Sazhin et al.:

http://arxiv.org/abs/astro-ph/0302547
http://arxiv.org/abs/astro-ph/0406516

Consequently, they will be able to see the pictures with the pair of images, and see how stupid you must be if you were not able to open the arXiv web page and rule out your silly theory yourself.

Best
Lubos

55. **Quantoken**
December 18, 2004

Regarding the "cosmic string" Lubos meantioned. It merely shows how desperate super string theoriticians are in trying to find some observational evidence, any thing, that may remotely justify their stuff. When you have that kind of desperation, you tend to OVER-INTERPRET your data.

Lubos said: "The team has observed a pair of galaxies 10 billion light years away and gravitational lensing is supposed to be the origin. The angular separation of the pair is roughly 2 arc-seconds."

Note the two key numbers, 10 billion (10^10) light years distance and 2 arcseconds (9.7×10^-6 radian angle) angular separation. At that distance and that angular separation, if these are two galaxies their center barely separated by 9.7×10^4 light years.

A typical galaxy like our galaxy, has a diameter of 2×10^5 light years. If what they observed are two images of a typical size galaxy, they barely separate half of their diameters.

i.e, what they observe is instead one concrete image from the two half of the same galaxy, but be mis-interpretted as two images. It's that simple.

The distance from the center of one half of the galaxy to the other half happen to be about 1×10^5 light years, which is the angular "separation" they reported.

How desperate they have become? They reported that with an area of the sky merely 16 square arc seconds (4 arcseconds x 4 arcseconds) they found 11 pairs of such identical galaxy images. They must have counted each individual photons received as individual images 🙂

56. **plato**
December 18, 2004

Sometimes the synthesis of ideas need to be brought together, to help people see how the issue is further developed and spoken too, by Lubos and others.

I hope the essence of the following statement highlighted is understood. I don't have any theories, but what I am piecing together from information, that has been out there for sometime. I think in this context as more of a service to those less developed in these views.

Warped Space Creates Gravitational Lensing

57. **Quantoken**
December 18, 2004

To Matti and Lubos:
Matti:
Your theory looks interesting. But have you made any prediction or calculation which matches any observation data. Any theory that does not make a prediction that is verifiable by observational data, is not science.

Lubos:
I know you are one of the guys who used different approaches to arrive at a quantum of area which is 4*PI*SQRT(3), or whatever times sqyare root 3. That was at one time very exciting because it seem quite unusual that two completely different approaches reached the same result.

However, as meantioned on Baez's web site, some one found one of your guys' calculation to be wrong and missing something, after correcting that mistake, the answer came up to be something else. If one of your were wrong, both of you have got to be wrong, because you both got the same wrong answer!!! Any comment on that one?

I guess a lot of people don't realize that when dealing with the microscopic world where continuous space and time loses meaning, so does the very notion of space and time themselves. Therefore the concept of field or topology loses meaning because you no longer have a spacetime background. A new physics must be established on brand new concepts that do not rely on the notion of space and time.

That's where I have a success theory. I have calculated the correct radius, age, mass/energy and Hawking entropy of the universe, I derived the correct baryon density and the exact CMB temperature which matches observational data well within observational margin of error. I obtained the correct solar radiation constant based on the same calculation, again it matches observational data to within observational margin of error.

I derived the precise mass of protons, which I shown on this blog, and which is accurate for the first 7 digits, the discrepancy against experimental value, although more than the experimental margin of error, can be explained away if the proton has an extremely long delay half life (many orders of magnitude more than 10^33 years).

Further, I derived the precise neutron mass based on my calculation of none-decaying proton mass, and the known free neutron decay mean lifetime. The result matches the standard experimental value exactly to the first 9 digits, to well within the experimental error!

You can't say my theory is wrong if I can derive a result accurate to 9 or 10 digits and matches the most precise experimental value exactly.

Since Peter is not interested, I am going to Lubos's web site, and show exactly how I obtained the precise neutron mass, from my theoretical frame work. So every one can verify it.

I do not have a web site detailing everything yet. I hope to do so pretty soon.

Quantoken

58. **Matti Pitkanen**
December 18, 2004

It is amusing to see how the ideology "every good idea becomes part of string theory sooner or later", and if possible, without any reference to the person who discovered the idea originally. In my case this creative record keeping is easy since after the second super string revolution it became impossible to get anything related to TGD to ArXiv.org and the attempts to publish anything non-stringy in so called respected journals is waste of time. Before continuing, I want to make clear that I am not a bitter crackpot: see the link from the Mathematics Subject Classification Table of American Mathematical Society to TGD. The ethos of mathematicians seems to be different than the ethos of theoretical physicists.

Concerning cosmic strings, I developed for more than a decade ago a model of galaxy formation based on TGD counterparts of cosmic strings [2]. These cosmic strings are 4-dimensional surfaces X^2xY^2 in M^4xCP_2, X^2 a minimal surfac (string orbit) in M^4 and a Y^2 geodesic sphere in CP_2. For all practical purposes they look like strings. These objects carry magnetic monopole flux (the homologically non-trivial 2-sphere of CP_2 carries one unit of topological magnetic charge). String tension is about 10^(-7)/G and thus much lower than the string tension of super strings (I just wonder how M theorists manage to get the string tension correctly). The order of magnitude is determined by CP_2 radius, whose value is fixed by p-adic mass calculations from electron mass.

The value of the predicted string tension is consistent with the constant velocity spectrum of stars in galactic halo [2]. The most elegant explanation for the velocity spectrum is in
terms of gravitational field created by a very long cosmic string going through the galactic nucleus and containing a sequence of smaller galactic cosmic strings around it: somewhat like pearls in a necklace. The force created by the long string behaves as 1/rho and thus yields constant rotational velocity spectrum and free motion parallel to string. Galactic visible matter could result as decay products of galactic cosmic strings. Also the yet undecayed portions of cosmic strings in the galactic plane could contribute to dark matter and even yield the mass distribution M(R) propto R predicting constant velocity spectrum as I proposed in the original version of the model. The jets orthogonal to galactic plane usually assigned to a galactic black hole would move along long cosmic strings. Also the jets associated with super-novae are assigned with magnetic flux tube structures in the TGD based model for gamma ray bursts [4].

Cosmic strings are actually a limiting case of magnetic flux tube like structures at the limit when M^4 projection of flux tube becomes 1-dimensional. The fractal hierarchy of cosmic strings and magnetic flux tube structures forms the basic of TGD based cosmology and explains the formation of structures in all length scales including even formation of stars and planets. Fractal hierarchy of cosmologies inside cosmologies is predicted [3]. The very early cosmology is cosmic string dominated and singularity free in the sense that the density of gravitational mass goes to zero like 1/a^2 rather than 1/a^4 as in radiation dominated early cosmologies. The TGD counterpart of the inflationary cosmology is a period during which 3-space is flat: the only free parameter of Robertson-Walker metric corresponding to the critical cosmology is its duration so that the theory is extremely predictive (basically by the imbeddability to M^4xCP_2 requirement)[3].

Dark matter can be identified as ordinary matter residing at the space-time time sheets corresponding to magnetic flux tubes. It can leak to "our space-time sheet" and become visible in some circumstances: the formation of solar corona is excellent candidate for this phenomenon in astrophysical length scale [4]. The flow of matter between different space-time sheets plays a key role in TGD inspired quantum model of biology. Dark energy corresponds to the magnetic energy of the string like structures [3]. p-Adic length scale hypothesis resolves the cosmological constant problem: cosmological constant is inversely proportional to the square of the p-adic length scale L(k) of the space-time sheet and for space-time sheets with size scale determined by the age of the Universe it has the required order of magnitude [3]. Cosmological constant characterizes the density of gravitational mass of string like objects and magnetic flux tubes at given space-time sheets. The negative pressure can be understood in terms of 1-dimensionality of these objects.

TGD explains also the observation of objects with different red shifts along the same line of sight mentioned by D. R. Lunsford(http://arxiv.org/abs/astro-ph/0203466). The explanation is in terms of light captured inside a cylindrical space-time sheet having outer boundary through which light does not escape. The light from a distant object can rotate N times around before it is detected and a sequence of red shifted snapshots about the evolution of the object results. Some day this phenomenon will perhaps provide a powerful diagnostic tool allowing to get information about evolution of astrophysical objects.

I am eagerly waiting the moment when string theorists discover TGD inspired cosmology and represent it as a prediction of M-theory. Quantum gravitational holography might be seen as the first example of this creative record keeping. The geometry of infinite-dimensional configuration space of 3-surfaces, which I formulated fifteen years ago, relies on the assumption that space-time surfaces are absolute minima of so called Kaehler action. This means that the knowledge of 3-surface X^3 dictates corresponding space-time surface as a kind of generalized Bohr orbit with Bohr rules fixing the initial velocities when positions are given (there are delicacies involved due to the failure of the strict determinism which are of fundamental importance).

The coding of 4-D classical physics by 3-D surfaces is nothing but an abstract formulation of quantum gravitational holography, and follows from the requirement of general coordinate invariance alone: Diff^4 symmetry can be realized only if there is a unique X^4(X^3) associated with given X^3 and Diff^4 acts on it. Recently I have developed the concept to a much detailed form in which data at 2-dimensional sub-manifolds of 3-surface code all that is relevant for the configuration space geometry and quantum state construction.

I encourage M-theorists to visit my home page: it is a treasure trove of ideas and detailed models and the policy of arXiv.org
guarantees that everything can be taken freely! For instance, p-adic mass calculations might be very interesting stuff [5]. p-Adic mass calculations predict besides elementary particle
masses also CKM matrix and hadron masses from very general number theoretical considerations using minor empirical input. The essentially new element is the possibility of quarks to appear as fractally scaled up variants with mass scale coming as powers of sqrt(2): this occurs for quarks even inside light hadrons and explains the large mass differences of light hadrons. There is empirical evidence that also neutrinos can appear as different scaled up variants.

It seems as a potentially very exciting stuff.

60. **Quantoken**
December 17, 2004

Lubos said:

"Chris W., it's not just you, there are many other people who don't know how to derive THINGS from string theory."

That statement is not just absolutely correct, its inverse form is also absolutely correct too, if THINGS means observables in the physical world. No one has derived anything from string theory that has anything to do with the real physical world, YET.

you also said: "It is certainly a well-established insight that the same fundamental strings, those that normally shrink to a supertiny size, also exist in the macroscopic form."

Could you clarify a bit what do you mean "supertiny size"? I think you mean the Planck Scale size. As the 4 normal dimentions we know all lose continuity and hence no longer exist as continuous dimention under Planck Scale, how come the other 6 unknown dimentions continue to enjoy continuity under that small scale, and hence not be treated as just a zero point?

Further "The tiny strings that constitute the particles are *really* just small versions of strings that can also be large if you have enough mass/energy."

Smaller size scales are associated with bigger energy, and bigger size scales are associated with smaller energy. That we know. We were told that due to the present of how huge energy, the other 6 dimentions all curved up into small strings. So I would expect a huge energy to be released, instead of being required, to spring the small strings into larger sizes.

Whatever you want to say about the 120 orders of magnitude discrepancy problem? As the universe presumably continue to expand, shall this disprepancy continue to increase in the future?

Quantoken

Book Review: The Quantum Quark

December 20, 2004
Categories: Book Reviews

Over the last couple weeks I've been reading several popular or semi-popular books about particle physics. I thought I'd make a few comments about them here.

The first one is called The Quantum Quark by Andrew Watson. It covers the Standard Model and its history, concentrating on quantum chromodynamics, the theory of the strong interaction. By limiting itself in this way, it is able to go into a much deeper, more detailed study of the theory than would otherwise be possible in a popular book. While avoiding the use of equations and trying to stick to as accessible a level as possible, the author manages to discuss a wide range of aspects of QCD not treated in any other book of this kind. These topics include a detailed description of jet phenomena in perturbative QCD, the behavior of quark structure functions (including their still mysterious spin dependence), the delta I=1/2 rule for non-leptonic weak decays, and many others.

The book contains several amusing stories I hadn't heard before, including the origin of the term "penguin diagram" to refer to a certain class of Feynman diagrams. Supposedly John Ellis and Melissa Franklin were playing darts one evening at CERN in 1977, and a bet was made that would require Ellis to somehow insert the word "penguin" in his next research paper if he lost. He did lose, but was having a lot of trouble figuring out how he would do this. Finally, "the answer came to him when one evening, leaving CERN, he dropped by to visit some friends where he smoked an illegal substance" (the only time he ever did that, I'm sure..). While working on his paper later that night "in a moment of revelation he saw that the diagrams looked like penguins". I'd always wondered why these diagrams had been given that name, they never looked very much like penguins to me. But then again I never tried looking at them under the same conditions as Ellis.

Witten makes an unusual appearance here, as Watson discusses Witten's Ph.D. thesis, the topic of which was the use of asymptotic freedom to study the photon structure function using deep-inelastic photon-photon scattering.

   DMS et. al.,

   I agree that large portions of Zwiebach's string theory book is at a level similar to David Griffiths' "Introduction to Elementary Particles" book. My main complaint about Zwiebach's book is that it mainly uses light cone quantization methods, and there is hardly any emphasis on other more elegant ways like conformal field theory and/or BRST. Also not much is mentioned of the superstring and supersymmetry. It seems like most of the book is largely looking at the bosonic string as a pedagogical exercise.

   On the surface, it would be a bit hard to justify subjects like supersymmetry and conformal field theory to a person who knows nothing about things such as the Klein-Gordon and Dirac equations. Also things like the path integral would seem like a mysterious object which came in "out of the blue", to somebody who has only seen basic Lagrangian-Hamiltonian dynamics and the Schrodinger equation previously in undergraduate courses on classical and quantum mechanics respectively.

   I suppose if a student has seen the raising and lower operator formalism in the harmonic oscillator and angular momentum problems from a first course in quantum mechanics, supersymmetry could possibly be presented first in the form of SUSY quantum mechanics. On the first day of class, the path integral could in principle be presented in the context of the quantum harmonic oscillator problem.

   Griffiths' particle physics book covers the basic ideas of the Klein-Gordon and Dirac equations. Arguably if students have already seen the plane wave and harmonic oscillator solutions to the Schrodinger equation along with the "ad hoc" spinor description of electrons in most undergrad quantum mechanics textbooks, the Klein-Gordon and Dirac equations shouldn't be that much more of a stretch.

   Offhand I have not been able to think of an easy non-obscure way to present conformal field theory, to undergrads who have only seen basic quantum mechanics. Presenting other methods like BRST to undergrads, would be even harder to justify offhand.

   It seems like the idea of teaching string theory to undergrads has the same pedagogical hurdles as teaching quantum field theory to undergrads. I would guess that a year-long or two semester course sequence would be required to include the superstring at the undergraduate level. Offhand I don't see it being feasible for a one semester undergraduate course covering the superstring, without doing the course at breakneck speed.

   It would be interesting to see what Lubos would do, if he ever decides to teach an undergrad course on string theory at Harvard.

2. **DMS**
   December 23, 2004

   JC

   Actually, Barton's Zweibach's book on string theory (aimed at undergrads) String Theory: A Fiest Course (Cambridge Univ Press 2004) is quite a nice book.

   Even if you think string theory is not what it is cracked up to be (as I do), you might still get a pretty good flavor of the field, including string theory on particle physics.

   I would say it is very clearly written, and should be understandable by good undergraduates since he goes through a lot of the background material quite nicely. It is at "Griffiths' level", only better IMHO.

   The other thing, that Zweibach mentions in the Preface, is that it enables physics undergrads to get a more mature understanding of the role of mathematics and symmetries in physics, and the physics covered in undergard curriculum. I agree.

3. **JC**
   December 22, 2004

   On a slightly different note, what would really impress me would be a book on quantum field theory that is as easy and painless to read as David Griffiths' "Introduction to Elementary Particles".

   Or for that matter, a string theory book that is as easy and painless to read as Griffiths' particle physics book would also be quite impressive. So far I have not come across any string theory books which are easy and painless to read. If Lubos Motl or anybody else wants a challenge, it would be to write a string theory book which is as easy and painless to read like Griffiths' particle physics book, for which even a good freshman undergrad physics student would be able to read easily.

Towards the end of my time in high school and during the summer before my freshman year of college (on the days when I didn't go out partying), I slowly slogged my way through Feynman's "Theory of Fundamental Processes" and "Quantum Electrodynamics" books, along with other books like Close's "An Introduction to Quarks and Partons", and Commin's "Weak Interactions", not knowing any better. (These books just happened to be at a local university library and I came across them by chance at the time). Besides reading the descriptive parts, I attempted to work out the calculations myself in a somewhat mindless blind manner following the "Feynman rules" as if they were a "recipe". (One can imagine how "blind" and haphazard it would have been for somebody who only knew high school level physics and calculus). Nevertheless I somehow was able to reproduce most of the correct answers in the books, but was still baffled about why these "Feynman rules" were correct in the first place. I found out later the "rules" were from quantum field theory, and I attempted to read several field theory books at the library like Schweber's "Introduction to Relativistic Quantum Field Theory" and Bjorken & Drell's two books "Relativistic Quantum Mechanics" and "Relativistic Quantum Fields". I pretty much got lost very quickly when I attempted to read through Bjorken & Drell's "Relativistic Quantum Fields" and the later chapters of Schweber's book which attempted to explain how the Feynman rules came from the quantum field theory formalism. (Bjorken & Drell's "Relativistic Quantum Mechanics" was a bit easier to digest after mindless working out similar sorts of calculations previously).

At the time I wished books like Griffiths' "Introduction to Elementary Particles" existed.

4. **Steve M**
December 22, 2004

One book I really liked was
"The Key to the Universe" by Nigel Calder. Written in 1978 there was also a bbc series accompanying it. I really liked the way this book was written and presented. It had lots of feynman-like diagrams, and plenty of coloured diagrams when the chapters on the strong forces and quarks came along. It focuses mostly on the standard model and the things that happened up to 1978.
I remember reading it in high school. I got a copy recently from a second hand book store. It is a bit dated now since a lot has happened since 1978 but still well worth a read. I still think one of the best layperson books on particle physics written.

5. **JC**
December 22, 2004

Many years ago I really liked the book "Introduction to Elementary Particles" by David Griffiths, for its easy readability. It was a lot easier to read than any other particle physics or quantum field theory books I've come across over the years. I don't know if it would be a good introduction to particle physics for a non-physicist.

If I had to choose a book for non-physicists, I really liked "The God Particle" by Leon Lederman. I always thought Lederman was a humorous speaker whenever he did a colloquium.

6.
December 22, 2004

There is a book similar in flavor by 't Hooft. The one noticeable thing about 'tHooft's book is the constant mentioning the contributions of some Dutch scientists.

't Hooft, of course, has the reputation of being (perhaps) the guy who did the most during his graduate studies (YM renormalizability, Y-M beta-function) than any other physicist in modern times. Seems like there was some tension between him and his advisor (Veltman) for some time; hopefully the Nobel Prize has dissipated that.

7. **Peter**
December 22, 2004

The Veltman book is also a good introduction to the standard model. It has a lot of interesting short profiles of various physicists, often with Veltman's typically provocative comments.

8. **RT**
December 22, 2004

How does Veltman's 'Facts and mysteries in elementary particle physics' stand compared with these others? If nothing else its penultimate sentence celebrates the title of this blog; no prizes for guessing the topic under discussion.

9. **Peter**
December 21, 2004

I saw the Shumm book in the store and only looked at it for a few minutes. Conceptually I very much agree with its point of view, which emphasizes the beauty of the structure of symmetries that determines the standard model. But I still like the Crease and Mann book better, by emphasizing the history and personalities involved it can be read with enjoyment by people with all sorts of backgrounds.

10. **xiggie**
December 21, 2004

Have you any comment on Deep Down Things by Bruce Shumm?

11. **Peter**
December 21, 2004

The Crease and Mann book is by far the best popular book I know of about particle physics. Can't recommend it too highly.

12. **DMS**
December 21, 2004

Interesting reading; I should take a look. I also liked a much older book on particle physics for the lay person: The Second Creation, by Crease and Mann. That has interesting stories, philosophical discussion by particle physicists (Georgi, Weinberg, etc), and crude idea about renormalization, and the remarkable triumph of Yang-Mills theories. I think it conveyed quite nicely what Coleman would say about the triumphs of QFT— ? made the spectator gasp with awe and laugh with joy.?

13. **Chris Oakley**
December 21, 2004

I *had* heard the "penguin diagram" story. When I was a graduate student in Oxford (1981-1984) John Ellis would occasionally appear. I cannot rule out the possibility of substance abuse, as he looked (& probably still looks) like an ageing hippy. There was a bit of role reversal going on here: unless they *had* to dress smartly, the faculty would mostly be in jeans and sweatshirts & there would be more jackets being worn by students than faculty (I for one never liked wearing jeans, although I would draw the line at the unnecessary wearing of ties).

I think that John Ellis and some of the faculty: in particular my supervisor Graham Ross & Chris Llewellyn Smith always saw themselves as the rebels, however much they pulled the strings (no pun intended).

14. **Amitabha**
December 21, 2004

The story is given with some sources and a picture on p.12 of

Book Review: Out Of This World

December 20, 2004
Categories: Book Reviews

The second popular physics book I've read recently is infinitely sillier than Watson's book on QCD. It's called Out Of This World by Stephen Webb. Its subtitle "Colliding Universes, Branes, Strings, and Other Wild Ideas of Modern Physics" gives some idea of the author's viewpoint, and indicates this is something to buy if you just can't wait for this spring's forthcoming books by Lisa Randall and Lenny Susskind.

The book is about what you would expect, promoting the glories of extra dimensions, branes, M-theory, etc. I only noticed one part of one paragraph where the author mentioned that there was no experimental evidence for any of this. On the other hand, there are dozens of poorly reproduced pictures of string theorists in their offices, which should make their parents proud. The author devotes only one page to loop quantum gravity, with the excuse that he doesn't want to say much about it because it is just a theory of quantum gravity, not a TOE. This doesn't really explain why he then goes on to devote chapters to other string, brane, extra dimension, etc. ideas that aren't really TOE's either.

The whole thing is written in a breathless "Gee, isn't this just so kewl!" style. It's the kind of thing John Horgan refers to as "science fiction in mathematical form", except it's lousy science fiction and lousy mathematics.

There's another very similar new book out, entitled The Great Beyond by Paul Halpern. Here the subtitle is "Higher Dimensions, Parallel Universes and the Extraordinary Search for a Theory of Everything", from which you can guess what will be in it. The author was a grad student at Stony Brook during the 80s, so knows many of the people who worked on supergravity during that period. I didn't have the heart to spend more time with the book than a few minutes flipping through it in the bookstore.

   -drl

2. **plato**
   December 22, 2004

   Links to url's

   One of the ways in which I look at links supplied without having to use search engines, was to look at how a web page is set up.

   right click mouse, and view source.

   In Thomas's case below this link should show as:

   http://insti.physics.sunysb.edu/~siegel/parodies/

   I have seen enough to know some are more advance in using this medium. If Peter used more pictures for instance in the mathematics he espouses he would be limited becuase of the width of his comment area.

   For him, I calculated this width to be about 360. If he stays to this width, he will not have a problem, although this must be specified beside his image url"" width=360 height=?. This depends on the percentage of the "original picture" to coordinate this width and height. A simple calculation on proportional size based on the picture seen would help.

   Hope this helps others as well. With advancements of html in these blogs one will have to learn new methods for sure, but as long as the comments area is specified, then this will control your viewing capabilties.

3. **Thomas Larsson**
   December 22, 2004

   Speaking of Stony Brook, one may want to look at the html and pdf files at

   insti.physics.sunysb.edu/~siegel/parodies/

   However, Halpern?s book is not there.

4. **plato**
   December 22, 2004

   I hate to interject myself in this new found peace:)

   I sort of had a question about math minds and physics people. Can they ever get it together?

   Maybe there's hope?:)

5. **Lubos Motl**
   December 22, 2004

   I've seen it, too. It's not so bad – the photographic quality of black and white pictures simply always looks like that if you use this technology of printing. Actually a book with a hundred of figures is pretty attractive.

   CERN comes close – who's CERN? Is it those guys who are building the accelerator 10 times smaller than mine? 😉

6. **Peter**

December 21, 2004

I checked the photo credits, 17 are credited to you (more than any other source, only CERN comes close).

7. **Lubos Motl**
December 21, 2004

I can't argue now because I have simply not seen the book yet – and it is not even guaranteed that those pictures of mine were used. At any rate, it does not seem too important.

8. **Peter**
December 21, 2004

Hi Lubos,

Sorry I didn't check the photo credits, I should have known you were somehow involved in this.

The pictures are mostly much too dark, so hard to see well. In any case, while we may argue about the beauty of string theory, in the case of most string theorists, I don't think there's much to argue about…

9. **Lubos Motl**
December 21, 2004

Too bad to hear that the pictures are poorly reproduced – many of them are my pictures.

10. **D R Lunsford**
December 21, 2004

AR – more like a theory of anything (TOA), because I can write down a KK theory for anything coming from a Lagrangian (hence having a canonical energy tensor) that can be made generally covariant – and that's everything of interest.

This simple fact, already known to Pauli ages ago, dooms the entire stringer approach from the start. KK theory is sham dynamics.

-drl

11. **Alejandro Rivero**
December 21, 2004

Well, any Kaluza-Klein theory aspires to be a TOE, doesn't it?

12.
December 20, 2004

why do you torture yourself with these sort of books?

Strominger Interview

December 22, 2004
Categories: Uncategorized

There's an interview with Andy Strominger in the Calcutta newspaper The Telegraph. Strominger was presumably in India for the string theory conference there this past week.

The thing I found interesting about the interview was how skeptical the interviewer was, repeatedly asking about whether string theory might not be wrong. Perhaps at least some members of the media are starting to get a clue.

   January 1, 2005

   Mr. "" said:
   "Discreteness of space and time happens at much larger scale that corresponds to scale of elementary particles" Then it would be accessible experimentally and would have shown up already because we can probe these scales."

   I am discussing mistake in Lubos paper in respect to the currently established science. NOT in respect to my theory. So I really do not deviate from that topic and discuss my theory further. But since you meantioned it, you forced me to explain it one more time.

   The answer is, Mr. "", don't you see logical inconsistency in your sentence: Basically you are saying: If there is a NATURAL limitation of the smallest possible size approximately equal to electron radius, then we already have the technology to break that natural limitation, and probe some thing much smaller already!!?!

   If indeed that is the natural limitation of the smallest possible size, then, certainly, no human technology could even possibly break that limitation.

   You thought you have break that limitation and probing some thing smaller, only because you have accelerated a particle to extremely high momentum. And calculation of de Broglie's wavelength gives you a size smaller than that limitation already. But the matter is even the de Broglie's wavelength formula breaks down near that limitation. That limit is in-accessible as much as light speed is un-breakable.

   Mr. "" also said:
   "And for the very last time–there are NO derivatives against position and time at all at the Planck scale in the Motl paper! It is a perturbative analysis of a classical black hole, the motivation being that the log Immirzi parameter in question can be derived from the other end…via a quasinormal mode analysis in classical general relativity. If you don't agree with this paper then submit a comment or rebuttal to the journal it was published in. Otherwise your opinions dont mean a damn thing to anyone anywhere."

   Have you read the actual Motl paper? The very first equation, whatever you call it, takes derivatives against x (the first term) and time (the third term):
   http://www.arxiv.org/abs/gr-qc/0212096
   And frequency omega corresponds to a mass/energy of a black hole. We know a black hole has a mass at least one Planck Mass or more. So he was talking about derivatives below Planck Scale limit.

   Quantoken

2. **JC**
   December 31, 2004

   I agree with Chris Oakley on this one. Lubos I can handle without any problems. Quantoken is becoming too much to handle.

3. **Randy**
   December 31, 2004

   Anderson defends western science and then it would
   seem is also fond of the Santa Fe Institute. That seems strange as I do not understand why the umbrella term 'Complexity' programme at Santa Fe is credible and ST is not. A generalisation of these new age programmes (ST, Complexity, experimental mathematics) has the common property of elevating the digital computer's role in modern science.

   http://www.physics.hku.hk/~tboyce/ss/topics/anderson.html

4.
   December 31, 2004

It is a perturbative analysis of a classical black hole, the motivation being that the log Immirzi parameter in question can be derived from the other end…via a quasinormal mode analysis in classical general relativity. If you don't agree with this paper then submit a comment or rebuttal to the journal it was published in. Otherwise your opinions dont mean a damn thing to anyone anywhere.

   I agree with Chris. Let him discuss his ideas on his own blog. Trouble is that no-one, not even other crackpots, will waste any time reading it. Thats why he is here.

5. **plato**
   December 31, 2004

   Today I am writing a article for those less inclined to understand the overall perspective that can be formed into a intelligent framework for consideration.

   The post(**The Sphere is Not So Round**) should materialize later, if people want to have a look at it. I also wrote it in response to living review that was offered.

   The link paragraph below hopefully helps to orientate one first, to better conmprehend my article today, and answers, the living review article.

At the energy scales characteristic of the universe's earliest moments, one can no longer approximate matter and energy using an ideal gas formulation; instead, one must use quantum field theory, and at the highest of energies, one must invoke a theory of quantum gravity, such as string theory. Cosmology is thus the pre-eminent arena in which our theories of the ultra-small will flex their muscles as we trace their role in the evolution of the universe.

At such small scales, how would mini-blackholes ever make sense?:)If gravity can work on such large scales, then how would would you interpret gravity at such small scales? One would need to know, what would drive these, at both the cosmological and quantum scales?

Is there any similarities here?

6. **Chris Oakley**
   December 31, 2004

   Peter,

   The half-wit Quantoken is spoiling my enjoyment of your otherwise excellent web log. How about a new year's resolution to ban him?

7. **Quantoken**
   December 31, 2004

   RT:
   The argument of ITO is irrelevant because we are discussing whether Lubos's paper was wrong or not. Lubos did not use ITO in his paper.

   He was fundamentally wrong when he wrote equations involving derivatives against position and time at Planck Scale, where every one can agree continuous space time no longer exist.

   Quantoken

8. **Quantoken**
   December 31, 2004

   Mr. "" said:

   "Q wrote" most people agree that at the Planck scale continious space and time don't exist"
   This deduction/conclusion COMES PURELY FROM quantum gravity, string theory and noncommutative geometry, all of which you have repeatedly stated you don't believe in and which "secretly inject G" (your words). Different approaches to QG all seem to converge on this conclusion that the Planck length is the lower bound or the cutoff and that space and time becomes "foamlike". But you can't condemn these theories as being wrong, as you have done, and then use their main conclusion (or one of them) to support another argument.

   Again your logic seem to work the reverse way. The notion of Plank Scale did not came from and was not derived from Quantum Gravity, String Theory or Nonecommutative Geometry. The concept of Planck Scale was first proposed far earlier than any of these three. You simply stealed that existing notion and then claimed it to be yours and you derived them from your theory.

   It's not even a correct statement that you say I do not believe in those three. There is nothing to even believe in or not believe in! "Quantum Gravity" is a theory that people have been looking for and have not found yet. "String Theory" is a broad research direction on which people hope to finally propose a physics theory, again it's not found yet. They say there are 10^123 kinds of different String theories but they have so far not found a single one, yet.

   Until you can present me string theory in one self-consistent integral piece, instead of just a few corners and parts, don't even ask the question whether I believe it or not.

   Now, I do disagree with the notion of Planck Scale. I believe the discreteness of space and time happen at a much larger scale, one that corresponds to the scale of elementary particles.

   Logically that does NOT prevent me from agreeing with the notion that at Planck Scale time and space are discrete. Because if time and space has become discrete at large scale, then they certainly are even more discrete at the smaller Planck Scale. So there is no inconsistency in my logic.

   No one sees to disagree that at Planck Scale we do not have continuous space and time. So if any one discusses differential equations where derivatives against position or time are involved, then he/she is fundamentally wrong.

   Some food for thought: Assuming there are two spacetime-coordinates very close to each other. They are of the closest distance possible yet at different spacetime location. Now, how does the two observers at the two locations conclude they are at slightly different location, instead of exactly identical location? If you can understand this question, you will begin to understand QUITAR, and know why Planck Scale is wrong.

   Quantoken

9. **RT**
   December 31, 2004

   A stochastic Ito approach to (quantum) gravity is discussed by Hu and Vedagner

   http://www.livingreviews.org/lrr-2004-3

10.
    December 30, 2004

    Q wrote" most people agree that at the Planck scale continious space and time don't exist"
    This deduction/conclusion comes purely from quantum gravity, string theory and noncommutative geometry, all of which you have repeatedly stated you don't believe in and which "secretly inject G" (your words). Different approaches to QG all seem to converge on this conclusion that the Planck length is the lower bound or the cutoff and that space and time becomes "foamlike". But you can't condemn these theories as being wrong, as you have done, and then use their main conclusion (or one of them) to support another argument. For a noncontinious/random process, like fluctuations in spactime you could use Ito calculas definitions of the derivative like you do for Brownian motion and stochastic analysis. (I dont know if anyone has applied this though in quantum gravity/geometry).

11. **Quantoken**
    December 30, 2004

    Dr. Lunsford said:

"Whatever Witten wants to think of himself, or what anyone thinks of him, is irrelevant. To be in his position of authority, and to allow and encourage the endless drain of talent and useless sqaundering of scarce resources represented by string theory, is behavior that amounts to scientific crime. His name doesn't belong in the same paragraph as Einstein's."

"crime" is too heavy a word to use, Mr. Lunsford. Witten is not in control. He is a victim of the system himself. Really whoever want to spend his/her own lifetime on whatever subject is really one's own choosing and no one else is responsible for it.

LC said: "If the string folks turn out to be wrong in the end, they'll eventually disappear except for a few fanatics. As far as I'm concerned, people are going to do and say whatever they want irrespective of how legitimate or silly it is."

Wrong LC. I do not see how you are going to prove string theory wrong. It's neither right nor wrong. It's just useless. It's a mathematician's toy that some people just love to play with. Toys are not as useful as tools but they are neither right nor wrong. The only way string folks will disappear would be when they are bored of their toys.

Right or wrong does not make certain things go away. An example is palm reading or astrology. As long as there is business, they will continue to exist for a long time. Once there is no longer any business, they would disappear over night.

That's the ultimate universal truth Darwin discovered. Survival of the fittest. In the science community, fitting is measured by the ability of getting continued funding grant. Under the system, the ones who survive are the ones who can get funding, they may or may not be on the right track of scientific discovery, but as long as there is funding, they survive.

It is much easier to get funding for super string research. For one reason this is a majority group. For another, it does not take much to feed a string theoretician, all they need is a black board and a computer. And even a computer may be overkill, many of them probably mainly just use the computer for type-writting. If I am the one who grant fundings I would figure, what the heck, it's just a very small slice of the pork barrel. So even if they are wrong, not much money could be wasted.

12. **quantoken**
December 30, 2004

Thanks Peter for providing that link. I knew that living review site but have not got a chance to read everything there yet. Will comment after I study that material. Mean while, it is still wrong to push known QM to Planck Scale or below.

Most people agree that once you reach Planck Scale, familiar concepts like continuous spacetime etc. no longer exist. So how could you still have a legitimate differential equation which differentiate against position and time, and which hence depend on the assumption of continuous space and time for its legitimacy in physics. You can't!

I do not know how your logic works, talking about derivative like dF/dx is simply wrong at Planck Scale where there is no continuous x. Any one care to dispute that?

Quantoken

13. **plato**
December 29, 2004

Peter said:*The best historical analogy is to his predecessor at the IAS, Einstein, who initially had good reasons to hope for a unified theory using extensions of Riemannian geometry. Einstein also made the mistake of pursuing an idea long after he should have realized it didn't work.*

How else, would you show gravitational collapse(turn things inside/out)?

Cosmologically, you say this area, is much like strings? You don't like the math structures in string and M theory? You don't like blackholes and mini blackholes?:)

We know GR works well in cosmological areas, so the leading geometrical principals are consistent and lead to where?:) So is there such a thing as gravity?:)Further, geometrical and topological considerations?

Is there no proof for gravity(?), so like strings, this should be avoided?

P.S. Statistically, *I think,* sound of music beats out, clock ticking and Money of Pink?:)

14. **Steve M**
December 29, 2004

Rubbish JC! Geoffrey Chew is the man! And Saturday Night Fever still ranks as one of the best selling albums of all time…but when the Floyd come back with "Dark Side of the Moon II" and then III" they will blow "Fever" out of the water!
🙂

15. **JC**
December 29, 2004

DR Lunsford,

If the string folks turn out to be wrong in the end, they'll eventually disappear except for a few fanatics. As far as I'm concerned, people are going to do and say whatever they want irrespective of how legitimate or silly it is.

A silly example of this would be the folks who today still believe in the analytic S-matrix bootstrap stuff. Other less illuminating examples would be the people who still think late 1970's "disco" music still rules the world, and/or the aging hippies who still think "acid rock" will once again rule the world.

Actually Q, the first equation Lubos writes in his paper is the differential equation for the radial perturbations of a Schwarzchild black hole with a Regge-Wheeler potential. It is a Schrodinger-like equation! Even if he calls it a "schrodinger equation" anyone with a basic physics education knows what he means. The phi(r) in his first equation describes the radial perturbations! He then analyses quasinormal modes ANALOGOUS to quasistationary states in QM whose frequency is permitted to be complex. He is studying the asymptotic real parts of the quasi-normal frequencies. Quasinormal modes are PHYSICALLY well defined as well as mathematially well defined. The BH wants to settle down to a static spherical configuration just like a bell wants to stop ringing. This black hole perturbation equation has also been known for along time: J A Wheeler and T Regge, Phys. Rev. 108, 1063 (157). Schrodinger-like equations appear in many problems with spherical symmetry. The classical heat and diffusion equations are "Schrodinger-like" equations. The Schrodinger equation is just a heat equation in imaginary time
Thats why "heat kernels" are discussed in QM and QFT contexts.

JC –

In other epochs there were fads, but these fads were not followed at the expense of other ideas, did not corrupt the very idea of science, and were not bolstered by a credulous public, an ignorant military-industrial government, and a power-hungry core group of theorists. It was not fashionable to bash Einstein and Dirac, and now even Feynman, for not being faddists, or for following their own paths.

I've been reading Feynman's lectures on gravitation. I can't tell you how wonderful it is to see Feynman, who was not regarded as a relativist in particular, show his total mastery of the subject and to discuss it with a tangible physicality – one can almost feel the tension in spacetime represented by curvature, when Feynman describes it. And yet it is OK for the stringers to "excuse" the poor blighter for not "getting it", to cast off his comments as the signs of approaching senility. Likewise Dirac – his little book on GR tells the story without BS, without hubris, and without ridiculous, boxed up, 2-tracked, egg-crated hyperbole prefaced by smart-assed, inappropriate quotes and goofy cartoons – but that sad man was, were are to believe, "misguided" because he thought of QFT as a horribly broken disaster that needed urgent repair. And Einstein – the man who invented 20th century physics – this pitiful lost soul spent his last years "pursuing a chimera", we are to believe.

How can anyone who cares a fig about science read these things and not blow his top?

As far as I'm concerned, physics, if not the entire Western tradition in science, has lost its soul. The torch is being passed to the East. The kings are dead – long live the mandarins.

Peter –

Whatever Witten wants to think of himself, or what anyone thinks of him, is irrelevant. To be in his position of authority, and to allow and encourage the endless drain of talent and useless sqaundering of scarce resources represented by string theory, is behavior that amounts to scientific crime. His name doesn't belong in the same paragraph as Einstein's.

-drl

19. **JC**
December 29, 2004

If for no other reason, folks mind as well work out the consequences of string theory just to see what it produces. As long as there's ways of getting funding for string theory research, that is going to happen anyways. It may be a different story if there's little to no funding sources for string theory research.

Since string theory doesn't have many other major competitors with a large number of researchers, many of the best graduate students will be attracted to it. (In the late 1970's the same sort of grad student "profile" seemed to have been attracted to supergravity). Whether it's animal behavior in general, herd-like behavior seems to be a dominant human trait.

21. **Quantoken**
December 29, 2004

I completely agree with Peter's 3 points observation of Witten. He is an absolute genius and his intelligence really deserves some respect.

But the more so, the more it makes him a pity. Look at the picture that a genius that do not come often on this planet walking and getting lost on a wrong road that is decorated with all beautiful flowers, but lead to no where, and at the end he would have wasted his intelligent lifetime, with little achieved and soo to be forgotten once the correct theory has been recognized. Don't you want to say pity?

All other criticisms against Superstring Theory can at most be described as "skeptical". Because no one know for absolutely sure whether it is right or wrong. They can only make a probability judgement. For me, there is no ambiguity, I know for a fact it is wrong, because I know for a fact what is the correct road.

Mr. Dr. Lunsford said:

"On the other hand you have the real crackpots like this Q, who think that physics amounts to dicking around with physical constants. No wonder the Bon-Motls of the world are so entrenched."

I am sorry. I did not "dick around with physical constants". I showed you the relationship between alpha and G. This relationship does not come from numerology coincidences.

It's true there are bunches of crackpots playing numerology. But the relationship I pointed out are DERIVED from the fundamental principle of quantum information conservation. I have not shown any one exactly how they are derived, for obvious reasons I do not want any one to take credit for it. My caculation of universe "age", CMB temperature, baryon density, Pioneer anormality acceleration, etc. are all derived from the same principle. They are not numerology conincidences.

You can call Paul Dirac a crackpot when he played numerology with G, without explaining why the relationship holds. But I have found out the "why" and have derived it rigorously from the quantum information conservation principle. So it's not numerology, but real science.

"quantum information conservation" is one of the fundamental principles of my QUITAR theory. It has solid observational support.

I would not want to discuss QUITAR any more on Peter's blog. But I have to do it this time since you attacked me first. Again I am not going to elaborate or go to details.

23. **Peter**
December 29, 2004

A few comments about Witten, since I think my point of view about him is slightly different than most people's.

1. Yes, he's a genius. It's simply an awe-inspiring and humbling experience to read many of his QFT papers. Some of his string theory papers are also extremely impressive, even if one believes their motivation to be misguided.

2. He's a physicist, not a mathematician. What he really cares most deeply about is making progress on understanding fundamental physics. His accomplishments towards this have been modest, probably not enough to get him a Nobel prize. But you have to keep in mind that, since 1973, no one else has made any really significant progress in this area. The standard model is just too good, and no one has yet had a successful idea about how to go beyond it.

3. His problem isn't too little physical intuition. He decided to pursue aggressively the quite physical idea of string theory unification, based on a plausible hope in 1984 that this might work out. The reasons for believing in this were physical, not mathematical. His great failure has been an inability to recognize that, while initially plausible, this idea really doesn't work. The best historical analogy is to his predecessor at the IAS, Einstein, who initially had good reasons to hope for a unified theory using extensions of Riemannian geometry. Einstein also made the mistake of pursuing an idea long after he should have realized it didn't work.

Mr "" said: "The "establishment camp"? That must be the thousands of …thats why technology works…"

You are playing word games with me again. You know full well who I refer to using the "establishment camp" when I say "for 20 years". They have nothing to do with today's technology that we use daily, that are developed by scientists and engineers working on real problems relevant to this world. Your camp doesn't.

You whole post did not contain a single clause disputing the physics issues I argued. The only thing you meantioned relevant to Lubos's paper is that you say Lubos wasn't using QM Schrodinger Equation.

http://www.arxiv.org/abs/gr-qc/0212096

You are wrong. The very first equation (1) Lubos wrote in his paper is Schrodinger Equation. And in the very first sentence right after that equation, Lubos called it the "Schrodinger Equation". You must have came from another planet where Schrodinger Equation means something differently. Or your brain must be re-wired in such a weird way that you are no longer speaking English in its regular meaning.

Physics is a science about our observations of this universe, not about mathematics we think about in our minds. That's a physics 101.

Quantoken

Exactly, you can define your so called quasi normal state MATHEMATICALLY any way you want, as long as your math is self-consistent. But it's not physics. In math, any thing self-consistent is correct and OK. But physics is more than just self-consistent. You can derive a set of self-consistent "physics" laws in a presumed 1 dimentional universe mathematically but it's not physics.

> I see almost no evidence of physical intuitive genius in Witten.

We know. But that's not Witten's fault. He is the one who has most deeply thought on quantum field theory.

29. **D R Lunsford**
December 29, 2004

To {anonymous lurker} –

When in school I spent countless hours poring over the journal stacks, going back into the 1800s. In this way I got a complete overview of the actual evolution of physics as it appeared in the journals. In this time I came across a large number of physicists, both famous and obscure. One of the obscure ones I'll mention off hand was a fellow named Jan Weysenhoff, a young Pole who died fighting the Nazis in the Warsaw uprising. Any single ONE of his physics papers is infinitely more interesting that ALL of Witten's physics output based on strings. There simply IS no physics content in string theory – it's a math game that does not in any way correspond to what is real. Therefore, in my mind, as a physicist, Witten is a complete bust – I find his work no more or less interesting than that of Hardy. If I had infinite time I might attempt to appreciate him from the mathematician's standpoint, as Peter does. I'm assured by Peter that Witten is a great mathematician – and I have no reason to doubt it. But, again, Weyl was a greater one, and what HE wrote regarding physics was interesting AS PHYSICS ITSELF, because Weyl not only had a Jupiter-sized brain, he had a powerful and nearly faultless intuition. I see almost no evidence of physical intuitive genius in Witten.

30. **DMS**
December 29, 2004

Well, Witten is a very good mathematical physicist. His papers are very clear and fun to read. But, in terms of impact (no I don't mean citations) he is by *NO MEANS* an Einstein (actually, John Schwarz likes to compare him to Newton, not mere Einstein) when it comes to physics, who actually did things which shaped the course of fundamental physics. And he is by no means the greatest mathematician, by *ANY* strech to imagination. There are plenty of other 20th century mathematicians who are also outstanding, and they would all be easily humbled by someone like Gauss who tackled several mathematical disciplines with ease (In contrast, all of Witten's beautiful work follows from QFT).

Witten, THE pied piper of the ST camp, has been making grandiose claims about string theory for two decades now. What has string theory to show for in terms of physics??

As Anderson correctly notes "The position is called "naive reductionism" and is typified by Witten's curious remark that "every exciting discovery in physics follows from string theory".
String theorists like to boast a lot."

Oh, but it is Witten saying it, so it must be true.

31.
December 29, 2004

Now, here is somebody calling Witten pitiful.

Reminds me of the well known phenomenon that beginners tend to disproportionally overestimate their total understanding of physics. As proven by others on this blog, too.

Learning nowadays is a humbling experience.

Like that guy who recently asked: 'How can ST have a classical limit when it makes no predictions?'

Answer: Sit down and try to understand what you are talking about and – in particular – what you are criticizing.

32. **D R Lunsford**
December 29, 2004

JC –

I don't know what else to call it, and in fact it has in common with literary criticism that what you say is less important than to whom you say it, and with how much bravado and flair. See l'affaire Bogdanoff for an example, complete with breathless groupies.

On the other hand you have the real crackpots like this Q, who think that physics amounts to dicking around with physical constants. No wonder the Bon-Motls of the world are so entrenched.

I watched three interviews last night in turn – Seiberg, Witten, and (what relief!) Dyson. Witten in particular is a total mystery to me. Here is a person with a staggering intellect, completely incapable of doing real physics. Compared to Dyson he seemed rather shallow and pitiful, despite his Jupiter-sized brain. He was more than willing for the interviewer (Ira Flato of NPR) to call him the "next Einstein". What a laugh.

"The establishment camp have been playing word games in a confusing way. For 20 years you have found nothing physically significant but invent a bunch of terminologies that no-one knows what you are talking about. You have forgotton the basics and need to take physics 101"

The "establishment camp"? That must be the thousands of dedicated and hard-working physicists, engineers and scientists who have slogged their way through very difficult and demanding degree courses, sitting hundreds of exams, sitting in 4-5 hours of lectures a day and doing thousands of tutorial problems. Then went through the gruelling process of going through graduate school, learning to do research and then defending a phd thesis against very intense scrutiny. Then had to get their papers peer-reviewed and published. That is…those that actually did the work and all the hard study! Not all of them end up doing theoretical stuff you can't prove like string theory or cosmology–many, the majority, use their knowledge in applied physics and engineering to create and extend all the technology we have today. It is not perfect by any means but is the best way there is and it gets there in the end.

Thats why science works; thats why technology works. If the universe could be understood using only "physics 101" and if all the physics-based technology that exists could be created using only "physics 101" then you simply would'nt need to be educated beyond high-school level physics and maths. The "establishment camp" also deduced and "established" all the physics basics you are so very fond of so why should you believe them at one level but not at the other? Also, you can't condemn the "establishment camp" on the one hand and them on the other expect them to accept "your theory" and the arrogant way you present it.

The terminologies and technical jargon are usually straightforward and obvious to anyone who has done the work or who has at least done a good degree course. Terms like "quasinormal modes" for example ARE the basics! They have a precise mathematical definition. You don't just guess what the term might mean! Also, you don't need a black hole either to study them–just hit a bell with a hammer! This sort of math will turn up in engineering too so that suspension bridges and skyscrapers don't collapse and so on. It is not just some made-up abstract concept.

Even if the very theoretical-type physics is in a bit of a purgatory there have been many other advances these past 20 years in applied areas like condensed matter theory, superconductors, laser physics, quantum electronics and quantum optics, computing and a whole host of other areas. Physics as done by the "establishment camp" actually works! But they are still using the same quantum theory and physics concepts that underlines the more abstract and arcane areas like string theory that can't yet be proven.

You totally and completely misunderstood what the Motl paper was all about and the more you go on about it the more you show your ignorance.
He was'nt using a "wavefunction" or the QM Schrodinger equation. He was doing a classical analysis of black hole perturbations. Perturbation analysis of black holes and stars is a well-established area of astrophysics especially in establishing the stability of stars. I am sure there are people around this blog who would like to get one up on Lubos if he had made a mistake but I don't see anyone rushing to support your rebuttal because even vehemenently anti-string people can see you are talking BS. Besides, this thread is about the Strominger interview in India–why are you hijacking it with all this stuff? Put it on your own blog.

34.
December 29, 2004

quasi normal modes were invented by relativists back in the 60s or 70s, they have a precise mathematical definition, if you want to say something meaningful, you don't go around guessing what the term may mean, you make the effort and understand that precise mathematical definition. For that you may need to calm down first…

"Postmodern" physics sounds like a cross between "new age" silliness with Beavis and Butthead. In many ways, "postmodern physics" sounds remarkably similar to economic forecasting.

"The only function of economic forecasting is to make astrology look respectable."
… (quote by economist John K. Galbraith).

36. **Quantoken**
December 29, 2004

Mr. "":

I know damped oscillation in English terms and in physics terms. But I do not know whatever a twisted alternative interpretation of terminology you may have in your camp.

Keep in mind wavefunctions in QM are different from classical definition of waves. It's a "probability wave". The phases in wavefunctions have NO physical significance. You can offset the Omega by a positive or negative number and it makes no difference. i.e., where is the zero point of energy is un-defined and can be set arbitrarily. That's a fundamental reason why QM is incompatible with GR, because GR requires an absolute reference point for zero energy.

Those are basic textbook stuff so dare you not question it. Once again, recite it exactly after me:

The phase in QM wavefunctions has no physical meaning!!!!!!

So, dare you NOT call the Omega in wavefunction using the term "oscillation"!!! An oscillation would have a physically significant phase and a physically significant frequency. But the wavefunction in QM has neither. Depending on how you arbitrarily define where the zero energy point is, the "frequence" could be offset by any arbitrary positive or negative number.

How could you call something that does not have a meaningful frequency "oscillation"? Calling such thing "oscillation" is really abusing the English language and twist the meaning of the terminology beyond recognition, and brings nothing good but logical chaos.

The wavefunction in QM is interpretted as a "probability wave". As such, the only thing that has physical meaning is the module of the wave function, i.e., the wave function multiplied by its complex conjugate. Integration of this module over all space must give a total probability of exactly 100%. That's the normalization condition of a valid QM wavefunction.

It is allowed that it transitions from one normal state to another. Such transition could show up as an imaginary term in Omega. Maybe that's what you call quasi-normal state. But such terminology is confusing, too. Such state transition itself is not a state, but merely a mix of two states.

In any case, the English prefix quasi- would mean something that's close, or something that transforms gradually and slowly. "Quasi-normal state" would have meant a state that is close to a normal state but undergoes a slow transition to another state.

In Lubos's paper, his imaginary part of Omega would be correspond to the order of Planck Mass scale. So the transition, or "damp", would happen in a time even shorter than the Planck Time. Calling such a quick transition "Quasi" whatever, is really abusing the English language.

Furthermore, any process that happens in a time shorter than Planck Time is simply none-physical. Because continuous time ceases to exist below Planck Time scale.

I do realize that probably the whole establishment camp is indeed playing the word games in such a confusing way. That only shows how crazy things have become. For 20 years you have found nothing physically significant but just invented a bunch of terminologies that no one knows what you are talking about. You have forgotten the basics and need to take physics 101 again.

37. **D R Lunsford**
December 28, 2004

He may be annoying and rude, but at least he's trying to think about things (without being willing to do any real work, it's true). I'm watching a TV show with Witten at this moment, who is reciting the string litany like a naive schoolboy mouthing his catechism. There is plenty of foolishness going around these postmodern days, among the great and the grotesque alike.

-drl

38.
December 28, 2004

No he has'nt heard of damped oscillations…and it is very clear from the stupidities he wrote that he does not understand black hole perturbation theory at all; nor does he understand what a quasi-normal mode actually is, and why by it's very nature it deals with complex frequencies; nor does he understand that schrodinger-type equations can arise in other areas of physics.

39.
December 28, 2004

Partial differential equations of the Schroedinger type are very common in classical physics, e.g the heat equation. They don't have to do anything with quantum mechanics, for example one can study the classical dynamics of a perturbed black hole. The black hole is stable- any perturbation thereof will lead to damped oscillations, which lead to the notion of quasi-normal modes. Those are complex by their very definition.

40.
December 28, 2004

Quantoken – ever heard of damped oscillations?

41. **quantoken**
December 28, 2004

Correction. I think I remembered the formula wrong. The units do not work out. The correct formula is:

V = sqrt(gravity*height)

I did say that "Further, if he even take a hot tub bath and swimmed in a swimming pool, he should have know that the wave propagate SLOWER in SHALLOW waters."

That's exactly correct that at deeper water the wave propagates faster, and when it reaches the coast it slows down. That's why the later and faster waves would push earlier but slower waves, and they pile up to create high tides that is unseen in the deep oceans.

Mr. "" said:

"You don't assume G either-G is directly related to the inverse string tension alpha'.
No-one "secretly injected G". You can get the Einstein equations out without assuming anything about G or even the Planck scale."

That's the whole point. That's exactly where you secretly injects the assumption of gravity. The "string tension alpha" has got to be inverse proportion to the size of the string. The smaller the string is, the higher the tension will be. You arbitrarily set the string size to be about Planck Length, that's where you introduced the G into the string tension, because Planck Length depends on G!!!

Tell me why strings HAVE to be of the size of Planck Length, not more and not less. Please give me a reason which does not contain the assumption of gravity. You can't.

The situation of Einstein is different. He never claimed to have "derived gravity". All he did is "describe" the gravity (in a way better than Newton). Since he simply answered the question of "how gravity works", but not the question "why there should be gravity", he is not responsible to explain where he got his G.

For string theoreticians, since you claim you have derived gravity, you have to show how you derived gravity, without prior knowing the existence of gravity. By secretly injecting G using the Planck Length, you are really not deriving gravity but simply play magic and "create" things that was never created on the stage.

Now, about Lubos's mistake in his famous paper deriving the 4*ln(3) "quantum of area". I now know he simply does not have the minimum level of basic physics training that one would expect for an assistant professor of any school, least to say Havard University.

This is reflected on his recent comments on his Blog, regarding Tsunami waves and large asteroid hitting earth. His physics instinctions do not seem to give him the ability to make judgements when an "Astronomy educator" gave an answer which is generally correct for very small asteroids but wrong for big ones. (the astronomy educator said stony ones would melt but metallic ones would not.)

Nor did he seem to instinctly realize that the propagation speed of ocean waves does not depend on frequence, wavelength or amplitude, but instead depends merely on the depth of water. The formula is roughly V = sqrt(density*gravity/height). It's actually a high school physics problem that any one can do a rough calculation.

Even if he does not know the exact formula, he should have the instinction from common sense accumulated from life experience. If you throw a big stone or a small stone into a small pond, the wave propagate at the same speed. So it's independent on amplitude, contrary to Lubos's claim. If you tap the water slowly or in rapid pace, it makes no different in the propagation either, so it is also independent on wavelength or frequence. One with basic physics training knows a phase speed dependence on frequency means dispersion, and we clearly do not see dispersion in water waves. Further, if he even take a hot tub bath and swimmed in a swimming pool, he should have know that the wave propagate slower in shallow waters. It's amazing that a physics Ph.D. would lack such basic physics instinctions, after receiving the basic physics training.

This lack of physics instinction is also reflected in his 4*ln(3) paper, which leads to a fatal mistake, which made his paper complete nonsense. Any one who studied the basic quantum mechanics and knows Schrodinger Equation should know, without having to look into textbook, that in the wavefunctions, the X (position) exponent coefficient can be an imaginary number, meaning it is a none confined and propagating wave. Or it can be a negative real coefficient, meaning the possibility of finding the particle at remote distance decreases exponentially, and hence it is a confined state.

Now the T (time) exponent coefficient, in exp(i*omega*T), The frequencey omega can be either positive or negative, meaning positive or negative energy, since energy = hbar*omega. But omega could never be an imaginary number or contain an imaginary part. The only exception is when you have slow transition between two states, then you may have an omega containing an imaginary part. Or, you can have an imaginary part but let that part approaches zero, just for the convenience of math calculation.

The reasons you can not have a frequence that contain an imaginary part, are two. One: The energy can be either positive or negative, but never imaginary. Two: more important, the wave function is a probability wave. At any given time T, you integrate the module of the wavefunction over the whole space, and it should give you exactly 100% probability of finding the particle. Once you introduce an imaginary part into omega, then the probability integration becomes time dependent and is not always 100%, which is not allowed.

That's where Lubos made his big mistake. He introduced an imaginary part into the frequence Omega, thought it is OK mathematically. But that is simply not allowed in physics.

Further, how silly he is, he called that Omega with an imaginary part some sort of "damped oscillation", "quickly brings the black hole into a SPHERICAL SHAPE". I can't help laughing when reading that. That omega in Schrodinger Equation has nothing to do with oscillation, and it certainly does not "damp". "damped oscillation" would mean the oscillation would eventually come to a complete stop. What does that mean in quantum mechanics? It's total nonsense.

Lubos does not have the "order of magnitude" instinction either. He should have realized that when talking about the black hole, the smallest mass M involved would be at least Planck Mass, in most cases it will be several times or many times more. Correspondingly the omega correspond to a time scale much shorter than the Planck Time. If it is a sort of "damped oscillation", obviously it will damp out to complete stop in a time much shorter than the Planck Time. We know time is really meaningless when the "time interval" is smaller than Planck Scale. What hell of a relaxation process was Lubos taking about?

Actually one really should not use classical quantum mechanics methods like Schrodinger Equation to study singular blackholes the size of a few Planck Mass. The mass is too high and the corresponding frequency corresponds to a time scale even shorter than Planck Time. We know at Planck Scale both GR and QM would cease to be workable because space and time is no longer continuous. One really should not push what we know at a larger scale to the limit of Planck Scale.

I am sorry to say, I expected better from an assistant professor at Havard University. Those people are supported by tax payers like me and the public do deserve to see what their tax dollars are worth.

Lubos's paper is at:

http://www.arxiv.org/abs/gr-qc/0212096

December 27, 2004

The motion of the simplest bosonic string is goverened by the generalised nonlinear sigma model action. The requirement that the theory be free of Weyl anomalies (to lowest order) leads to the renormalisation group beta functions governing the physics on the world sheet. The resulting field equations are exactly those that can be derived from an Einstein-Hilbert action (coupled to a scalar, the dilaton, and an antisymmetric tensor field, the axion). GR emerges without really looking for it. You can't avoid it.

You don't assume G either-G is directly related to the inverse string tension alpha'.
No-one "secretly injected G". You can get the Einstein equations out without assuming anything about G or even the Planck scale. Even if you don't believe in string theory as a TOE it is the only theory that makes any kind of sense as a potential quantum theory of gravity. No a-priori assumptions at all are made about what the low-energy effective theory should be like, yet you recover it; the Hilbert space appears to contain black-hole like objects, what T Banks calls "asymptotic darkness",and you get some sort of sensible result for graviton-graviton scattering. Even when you take a basic relativistic string and quantise it the spectrum automatically contains a massless spin-2 mode.
When he realised this Witten called this "the biggest intellectual thrill of his life".
These facts put it head and shoulders above all other candidate quantum theories of gravity. It does'nt neccesarily mean string theory is correct but makes it look a whole lot righter and natural than any alternative theory of quantum gravity that you can come up with. LQG can't reproduce Einstein gravity in the large scale limit even though it begins with GR.

I eagerly await the comic relief "explanation" of the "mistake" of the Motl paper even though the reviewer is clearly way out of his technical depth.

December 27, 2004

Chris said:

"Repeatedly posting a crank theory after being repeatedly asked to desist. I think I now understand why Quantoken has been banned from other physics discussion groups."

Why I was "banned" on http://www.physicsforums.com had absolutely nothing to do with repeatition. I posted there a total of exactly 3 messages, which were actually three parts of the same article since I have to partition it to limit the size of each message. There was no repeatition.

I was not even sure whether I was banned or there was a technical problem. Repeated email inquiries asking what happened to my account and why never gets any response or explanation. So I have to assume I was banned and it must be for political reasons inconvenient for the message board host to explain.

Further, I am not "repeatedly posting my theory." Upon Peter's request, I have stopped talking about the physics details of my theory and what it is based on and what its predictions are.

Currently the only time I ever "talk" about my theory, is simply a reference to its name and its existence. I never elaborate. Are you saying I shall refrain from even meantioning the name GUITAR, the same strict way ancient Egyptian King condemned that the name "Moses" shall not be uttered from any month of any person, or the punishment shall be death? That would be worse a cersorship than the middle age, at which time they at least allowed Galileo to publish his book.

If any PhysicsForums host is reading this message, I demand an explanation to what happened to my account. If you indeed banned me, it's OK. But at least an explanation needs to be given to me why and what happened, and what it takes to remove the ban. Ny repeated inquiries falled into deaf ears.

Quantoken

P.S. I am not forgetting about pointing out Lubos's fatal errors in his well known 4*ln(3) paper yet. I just have not got the time to write it yet. Once I get a little bit time I will turn around and post it here. Mean while I still want to give Lubos a little bit time to find his own mistake, so he wouldn't lose too much face when it's eventually disclosed.

45. **Chris Oakley**
December 27, 2004

"… My theory, the GUITAR theory, is the only theory capable of deriving gravity in this fashion. I derived the G from first principle using nothing but just known parameters of one electron, including the fine structure constant alpha and the electron mass …"

Repeatedly posting a crank theory after being repeatedly asked to desist. I think I now understand why Quantoken has been banned from other physics discussion groups.

Returning to the main topic, "the only realistic possible unified theory of all the fundamental forces" is an oft-repeated selling point for superstring theory. However, if I understand Arun's comments correctly then although the spin 2 particle is incorporated, this does not necessarily mean that we reproduce gravity in the required way. It is a bit like saying of a lump of quartz, "There's no reason why this should not be the most advanced microprocessor yet manufactured – it's just that we haven't quite done it yet."

46. **Quantoken**
December 27, 2004

Sorry Arun, I did not intentionally quote your words out of context. I saw it that way in Chris's original message and did not realize it was only portion of your original sentence.

Regarding background dependence/independence. It is true that super string theory violates the GR's background independence principle. But that can not be interpret as evidence that they did not secretly inject gravity in the first place to derive the result of "predicted the existence of gravity." They can pick and choose just part of GR as their input.

The fact remains that they assumed the existance of gravity in the first place (by merely using Planck Length) in their theory. So how could they later claim they derived gravity?

They surely have not derived the GR, at least the GR we known from Einstein. How could a theory start with background dependence, and end up with a background independent result?

Neither the super string camp nor the LQG camp is very honest in that both secrectly injected gravity by using Planck Length in the first place, and both later claim they derived gravity.

You can bet your money that when you see a magician "created" (or "derived", for that matter) something on the stage, it must be something previously brought to the stage before the performance, even though you may not know the detail how the magic works.

Quantoken

47. **Arun**
December 27, 2004

Since what I wrote was:

"I guess the SuperStringers' attitude would be – we know that General Relativity is correct, because it emerges out of string theory"

I don't know what all the arguments are about. The string theorist would almost certainly say that General Relativity was not an input into string theory; that in fact, starting the study of string propagation on a fixed background space-time goes against the spirit of General Relativity, and is one argument that LQGers use against string theory.

48. **Quantoken**
December 27, 2004

Chris asked:
"we know that General Relativity is correct, because it emerges out of string theory"

Is this true? How can a theory that makes no predictions have a classical limit?

I say: the statement in quotations is incorrect because it states an incorrect causal relationship. It's the other way around. GR emerged PRIOR to string theory. The correctness of GR has nothing to do with string theory. GR is what it is, regardless whether string theory is right or not.

On the opposite, the correctness of string theory has to depend on GR. That is to say, since GR is so far believed to be correct, the string theory MUST derive GR as a necessary but not sufficient condition to be a correct theory. That is to say, if string theory can not lead to GR, it is then definitely wrong. But if string theory does lead to GR, it still may not be sufficient to say it is correct.

Now, to explain what it means string theory predicted GR in layman's term. It is indeed true that you will get GR out of string theory. It is also true LQG also leads to GR. Actually it is true that ANY theory that works on discrete space-time at Planck Scale, would necessarily leads to GR.

Because GR was a secret input parameter to those theories in the first place. Certainly you will get GR at the printout end if you have entered GR on the input end in the first place.

To put it this way, string theory suggests there exists such little tiny stringy ringy thingym in addition to the regular 3 space dimention and 1 time dimention. That little ringy is only one Planck length in size. Thouse little rings would necessarily have some effect of curving the regular 4-D spacetime in large scales. And that is what we call gravity.

But because the rings are small, the gravity is also weak. The smaller the rings are, the weaker the gravity will be. Needless to say, if the rings are infinitely small, then gravity will be zero. Let's say the gravity effect strenth will be roughly proportional to the area of those rings. That happen to be about one Planck Area, which is roughly the square of Planck Length, i.e., G*hbar/C^3. So gravity is exactly proportional to G.

Surprise! Surprise?!

You see where GR is secretly punched into the keyboard in the first place to get the GR output? To obtain the correct gravity, string theoreticians have to make their stringy ringy's not too small and not too big. And the size just have to be about one Planck Length. And the definition of Planck Length happen to contain a G. And the G, of course, came from GR in the first place.

I really do not think that can be called "predicted gravity" if you secrectly entered G in the first place.

To really predict GR, you have to start with absolutely no knowledge of G and at the end you have to be able to derive G out of your theory. It should NOT be allowed that you secretly enter a known G into your formula some where in the middle.

My theory, the GUITAR theory, is the only theory capable of deriving gravity in this fashion. I derived the G from first principle using nothing but just known parameters of one electron, including the fine structure constant alpha and the electron mass.

Next time you see a theory working on Planck Scale to start with, and claim to have derived GR at the end. You know they are cheating since G was enter secretly using Planck Scale.

If any stringy theoretician has a different opinion, then I want to ask, Do you have a legitimate reason you have to make your stringy thingy no bigger and no smaller than one Planck Length, other than just to cheat the computation and get the correct GR output?

Quantoken

December 26, 2004

we know that General Relativity is correct, because it emerges out of string theory"

I was taken back by this as well.:)

I see Arun is answering, but the conceptual framework just does not seem to be clicking for some:) I have been incubating this for a couple of days and will be posting tomorrow, respective of the positions, Peter and Lubos have exemplified about the knowledge base that allows further developement by competent indivuduals in their respective areas. I'll be more specific then.

Just let me say that the quantum harmonic oscillator, if thought of as, in referrence to the holographical point on the brane, the relevance of Gr would have found value to me in the quoted statement above. I'll be more specific to this as well tomorrow.

Some might pre-empt me here if they wanted too, and expand on that point:)If both Peter and Lubos have a basis from which to speak, then what would happen if such manifestation of this thinking expanded into our world?:) How would we see the new concepts show theselves in the physics as some fractorial representation(Ramanujan) that would suit the common people?

I 'll answer this as well:)

50. **Arun**
December 26, 2004

Chris O.,

If one studies the propagation of strings in a background space-time metric then one finds a consistency requirement that the metric must follow the Einstein equations in vacuum (R_{mu,nu} = 0) at the one-string-loop level. There are stringy corrections at the 2-loop level, which are not relevant in ordinary conditions.

String theory is capable of subsuming our current theories, and also describing the limits of applicability of current theories. The problem is that where its predictions are firm (10 dimensions or stringy corrections to GR) they are inaccessible experimentally; and where its predictions are (potentially) accessible (e.g., low energy Super Symmetry) they are not necessary; i.e., if low energy SUSY is not found, then that does not invalidate string theory, because almost certainly string theory can accomodate not having low energy SUSY.

The to-us-experimentally-accessible-universe is not uniquely determined by string theory; and there perhaps is no experimental finding in our current capabilities that can rule out string theory.

51. **Chris Oakley**
December 26, 2004

"we know that General Relativity is correct, because it emerges out of string theory"

Is this true? How can a theory that makes no predictions have a classical limit?

52. **Arun**
December 26, 2004

Chris W.:

The point is well taken about how exactly theories are subsumed into other theories – how the wider theory explains the successes of the lesser theory and specifies under what conditions the lesser theory fails.

But if you ask your friendly neighborhood string theorist, and it seems inconceivable to them that string theory could be extendible in a similar way. I've already quoted to that effect. Perhaps it has to do with the converse of something else you wrote: "Any such theory that has empirical content also has the potential of being contradicted by observations."

To take up your example of the anomalous acceleration detected by Pioneer, I guess the SuperStringers' attitude would be – we know that General Relativity is correct, because it emerges out of string theory, so these experimentalists who propose spending hundreds of millions of dollars on a spacecraft experiment are stupid hacks who should not be paid to be scientists.

Maybe I'm being unjust.

53. **Quantoken**
December 25, 2004

Lubos erased my post on his blog which declared a fatal fraud in a paper he published, claiming that I do not understand mathematics enough to be able to find his mistakes and that I am not going to say what it is.

The fact is he could not find his own mistake even after I gave him a hint. Of course I am going to point out exactly what his mistake is, I said I will disclose it after Christmas. And of course Lubos is the one who does not know math. Do you have any idea what is elliptic curve, Montgomery multiplication, CRT, etc in mathematics? Don't know, do you?

Doesn't matter. Mathematics matters only where it matters to the actual physics. Your mistake in the paper, Lubos, is NOT trivial math or computation error. Your mistake is you used the wrong math in the wrong physics.

Would you tell me what is the value of Hawking Entropy or the Schiwaltzchild radius of one single hydrogen atom? Or would you tell me what is the temperature of the electron that circles the proton in a hydrogen atom?

Being an idiot like Lubos is, he will go right away and copy the formulas from textbook and plug in numbers to calculate. I am sure he will double check his math to make sure he did the calculation right. But still he will give you the wrong answer!!!

The point is the physics is no longer right when you push the physics/math formulas beyong where they should be used. You really can't calculate the Hawking Entropy of a hydrogen atom using that a quarter Planck Area formula. Because the hydrogen atom is too light to form even the smallest possible blackhole. And in a blackhole of any size, there could not possibly be any atom. You can't use another formula to calculate Hawking Entropy of a hydrogen atom either. The concept of Hawking Entropy simply do not apply to hydrogen atoms.

Now, I have given you enough hint why you made a fatal mistake in your original paper. Go figure. I will tell you after Christmas, if you can't figure out by then.

Quantoken

54. **Quantoken**
December 25, 2004

Ah ha, Wow!

Lubos was totally wrong in his ARXIV paper deriving the quantum of area 4*ln(3). See his paper:

http://www.arxiv.org/abs/gr-qc/0212096

The whole thing was wrong for a very simple reason. That's a mistake that he really should not have made if he has the least of physics instincts. At least I never expected a guy who was a Harvard assistant professor make such a mistake. The paper is 25 pages long but it took me no more than 5 minutes to find where he made a fatal mistake.

Now, Lubos, go find a spider hole first. Because once I tell you the mistake you made, you would be so ashamed of yourself, that you want to dig yourself a hole to hide in.

Had you shown a little bit respect to me before. I wouldn't have choosen to disclose your mistake publicly, and would instead email you in private. Or at least post it in your Blog only.

Oh well. Too late, you are going to be really embarrased this time. To give you a chance to save face. I will give you a hint first, see if you can find your own mistake before I tell you.
The hint is: what is the numerical value like of frequence Omega that you are talking about in your paper?

I will tell you where you made a fatal mistake in your paper, after Christmas.

Mean while, every one, Merry Christmas!

Quantoken

55. **Chris W.**
December 24, 2004

Arun,

I'm sorry for not responding more promptly to your comment. First of all, let me quote your main points:

> *The idea is, I suppose, that we can only show that a physical theory corresponds to reality to a certain precision within a certain domain. We can never rule out the possibility of a theory with wider validity, just as Newtonian gravity was replaced by and subsumed within General Relativity. So proof of a theory is not possible.*
>
> *But the Theory of Everything (or at least Superstring Theory) is different. It either applies to the real world entirely and wholly, or not at all. And here is what a professional physicist, Lubos Motl, wrote on his blog : "I am always a bit puzzled by Andy's [Strominger] statements that string theory is "just another step" – what sort of other step that goes "beyond" string theory but does not invalidate it is Andy thinking about?"*

I would amend your first remark to the following: "We can never be sure that all testable consequences of a theory will be confirmed by observation; proof of a theory is not possible. Our past experience gives us reason to *hope*, however, that a theory that conflicts with observation will eventually be subsumed within a theory of wider validity *that explains these failures, and specifies the conditions under which the failures will occur*."

More precisely, both the successes and failures of a theory are observations—empirical facts about the results of tests of the theory. Such facts call for explanations. We don't want to dismiss the success of classical celestial mechanics (for example) as meaningless or inexplicable. Indeed, part of the problem that Einstein set himself was understanding such successes, once he realized that he must reconsider the intertwined foundations of Newton's mechanics and Galileo's relativity principle in order to reconcile them with Maxwell's electrodynamics.

Many physicists and philosophers of the 19th century were ready to believe that Newton's mechanics and theory of gravitation constituted a "theory of everything", with electrodynamics relegated to the status of a continuum mechanics of the mechanical ether. The necessity of subsuming 19th century physics into a deeper and broader framework only became clear in retrospect, as did the crucial roles of the speed of light and the quantum of action, and the irrelevance of the classical idea of an ether.

So in response to your second point, nothing is fundamentally changed by considering a theory as a candidate for a "theory of everything", ie, a theory that is *presumed* to constitute a shared basis and explanation for everything we have observed about the universe, including the successes of any previous theories. Any such theory that has empirical content also has the potential of being contradicted by observations. Of course, one can try to interpret the theory so as to evade the contradictions, but one always does so at risk of destroying its empirical (as opposed to formal or mathematical) content. The most profound discrepancies are those that leave one unable to offer any scientifically defensible explanation within the framework of the theory. Either we accept them and admit that the theory fails to be both all-encompassing and scientific, or we set about undermining the theory's scientific status in order to preserve its metaphysical authority. (This is not to say that metaphysics can or should be avoided under all circumstances, which is itself a pernicious attitude.)

—-
It is worth reviewing the efforts of John D. Anderson, Slava Turyshev, and their collaborators to characterize the Pioneer spacecraft trajectory anomalies as a reminder of what a fundamental discrepancy with theory might look like, and how much effort is involved in eliminating auxiliary hypotheses that might explain it. (Anderson, Turyshev, and Michael Nieto are now advocating a new mission to the outer solar system designed specifically to investigate this problem. The Pioneer spacecraft have ceased communicating; Pioneer 10's last contact was in January 2003.)

56. **Matti Pitkanen**
December 24, 2004

I am afraid that string theory involves so many
wrong assumptions that there is no hope of making
progress by deforming algebraically a little bit. It would be better to take a more philosophical attitude, and look carefully for the strengths and weaknesses of string theory and how to possibly cure them. Here are some opinions about what "going beyond string theory" might mean.

1. Wrong realization of super-conformal invariance

Appropriately generalized super-conformal invariance is very probably something shared by any future theory. Personally I see the realization of conformal invariance at two-dimensional string world sheets un-necessarily restrictive and as the fatal flaw of the string theory.

The way out of dimension 2 is based on simple observation: light-like 3-surfaces of Minkowski space (or any 4-D space with Minkowskian metric signature) allow generalized conformal invariance by their metric 2-dimensionality and the dimension 4 for space-time becomes unique.

Also generalized symplectic structure is possible for light-like 3-surfaces, and the group of isometries for light-like surface consists of combinations of conformal transformations and compensating local scalings in light-like direction and is thus infinite-dimensional. Thus light-like 3-surfaces are really incredibly beautiful structures and I find difficult to understand why string theorists refuse to take them seriously. Also a new view about super-conformal symmetry emerges and no space-time super-symmetry (sparticles) is predicted.

2. Spontaneous compactification and Kaluza-Klein
philosophy as the second fatal mistake

Personally I experience spontaneous compactification and Kaluza-Klein approach as something absolutely ugly. To me it is a purely ad hoc attempt to extend the explanatory power of
string model beyond its natural limits. The accompanying ad hoc assumption is that of space-time super-symmetry.

Instead of trying to make 4-dimensional classical world to 11- or 2-dimensional, I would prefer to start from a real problem of general relativity. In general relativity the basic conservation laws due to the isometries of Minkowski space are lost, and one can ask how to combine the good aspects of special and general relativities. This is achieved by identifying space-time as 4-D surface of some higher-D space of form H=M^4xS, M^4 Minkowski space. Poincare invariance lifted to H. S can be fixed to S=CP_2 by requiring standard model symmetries.

In this framework the higher-D space cannot be nor need to be dynamical since the dynamics is at the level of space-time surface, and the horrors of landscape are avoided.

3. Infinite-dimensional existence is unique

M-theory has led to inflation of all kinds of deformations and variants of finite-dimensional geometry. There is however a different direction that could be followed in the attempts to generalize the notion of geometry.

Taking the uniqueness of physical existence as a guideline, one ends up with the notion of infinite-dimensional geometry. Already loop space Kaehler geometry is unique as Dan Freed showed in his thesis. The requirement that Riemann connection does not lead outside the tangent space forces infinite-dimensional isometry group and makes Kaehler metric of loop space unique. There is still a problem: although Ricci tensor is finite, curvature scalar is infinite, a clear symptom that basic objects cannot be 1-dimensional.

The space of 3-surfaces in M^4xCP_2, which possesses a maximal group of isometries, is the TGD inspired guess for the world of classical worlds as the unique arena of quantum dynamics. This space would be a union of infinite dimensional symmetric spaces with vanishing Einstein tensor labelled by zero modes having interpretation as classical, non-quantum fluctuating degrees of freedom characterizing the space and size of 3-surface. This formal analog for landscape is in key role in TGD based quantum measurement theory.

M^4xCP_2 is a very promising candidate for imbedding space. The canonical transformations of VxCP_2, V light cone boundary, act as isometries of this space and super-conformal invariance in generalized sense appears naturally in the construction of the configuration space geometry.

Configuration space gamma matrices in fact have identification as fermionic generators of super conformal algebra so that both fermionic statistics and super-symmetry have purely geometric interpretation. An important deviation from string models is that super-generators do not correspond to Majorana spinors (this leads to dimension D=10 or 11 in string models) but carry quark and lepton numbers.

4. Tangent spaces of space-time and imbedding space as number field like structures

H=M^4xCP_2 is the only option allowed by Particle Data Table and the construction of configuration space geometry favors strongly this choice. One might however argue that the preferred role of M^4xCP_2 should have some deeper, perhaps number theoretic, explanation.

The dimensions 4 and 8 for space-time surface and imbedding space of course bring in mind quaternions and octonions, and CP_2 labels the quaternionic sub-algebras of octonions just like CP_1 labels the complex sub-algebras of quaternions. The first guess is that space-time could perhaps be thought of as being surface for which tangent space corresponds to quaternionic, or more generally associative, sub-space of octonions at every point so that classical dynamics would reduce to number theory. The problems relate to the Euclidian signature of the metric. Also the non-commutativity and non associativity are questionable features.

Perhaps a better guess is that the tangent space of space-time corresponds to H_4, the algebra and “almost number field” of 4-D hyper-complex numbers. The tangent space of imbedding space could in turn be regarded as the space H_8 of 8-dimensional hyper-complex numbers.

Quite generally, hyper-complex numbers have dimension 2^n which is the same as the dimension of Clifford algebras spanned by gamma matrices, and the natural requirement is that units allow a representation in the Clifford algebra of the space in question.

a) For H_2 the commuting units are 1, e1 with e1^2=1.

b) The commuting units of H_4 are 1, e1, e2 and the product e1e2, all of them having squares equal to 1.

c) For H_8 the units are 1,e1,e2,e3 and their products. One can decompose H_8 number to two parts h= h_1+e_3h_2, where h_1 are H_4 coordinates, the “real” and “imaginary” parts of h.

The number-theoretic norm of hyper-complex number h in H_m, m=2^n, is expressible as the product of all m conjugates of h and is the m:th power of Minkowski length squared of m momentum. Lorentz group leaves the norm invariant. The failure of number field property manifests itself as the existence light-like hyper-complex numbers having no inverse and forming an ideal of H_m. Remarkably, the spectrum of momentum squared is integer valued in the restriction to hyper-complex integers: nothing but the stringy mass squared spectrum.

From the p-adic viewpoint the hyper-complex primes are of obvious interest, and the construction of infinite primes generalizing the notion of finite hyper-complex prime is especially interesting since the correspondence of infinite primes with the states of super symmetric arithmetic quantum field theory becomes very concrete.

5. M4xCP_2 as a unique 8-D hyper-complex manifold which is a homogenous space?

Hyper-Kaehler manifolds generalize the notion of complex manifold to the quaternionic manifold. This means that tangent space allows the representation of quaternionic units 1, I_1,I_2,I_3 as metric and antisymmetric covariantly constant tensors defining symplectic and Kahler forms.

In hyper-complex case similar idea works. The basic idea is that the generating units e_i are representable as contractions of covariantly constant antisymmetric tensors with sigma matrices, which commute and have squares equal to unit matrix. The 2-forms associated with generating units define what can be regarded as a generalized symplectic structure.

M^2 is the simplest hyper complex manifold and e_1 corresponds in light-like coordinates u=t+z, v=t-z to antisymmetric tensor with a non vanishing component E^1_uv=1. The square of the contraction with Sigma_uv gives unit matrix in Clifford algebra. E_uv defines a Minkowskian analog of symplectic structure since its square is metric (rather than -1 times metric).

In case of M^4 the coordinates u=t+z,v=t-z,x,y corresponding to the decomposition M^4=M^2xE_2 to longitudinal and transverse degrees of freedom are preferred. The appropriate generalization of these coordinates to what I call Hamilton-Jacobi coordinates play a key role in the construction of solutions of field equations in TGD framework.

The units e_1, and e_2 correspond to antisymmetric tensors E^1 and e^2 with non vanishing components E^1_uv=1, E^2_xy=i. iE^2_xy defines symplectic and Kaehler structure in E^2. The contractions of E^i with sigma matrices obviously commute. Note that the flatness of M^4 is absolutely essential prerequisite for having two covariantly constant 2-forms. e_1e_2 is represented as a production of contractions of E_1 and E_2 with sigma matrices.

In the case of M^4xCP_2 one additional covariantly constant 2-form E_3 is needed and CP_2 Kaehler form defines it. M^4 coordinates correspond to the real part of H_8 coordinate and CP_2 coordinates to its imaginary part. Of course, more general choices of coordinates obtained by applying generalized canonical transformations leaving the forms E_i invariant.

The conjecture is that symmetric space property plus the existence of hyper-complex structure select M^4xCP_2 as a unique candidate for H. Obviously, the existence of symplectic structure in the generalized sense is essential for the existence of hyper-complex structure. For instance, the replacement of CP_2 with symmetric space S^2xS^2 would bring in *two* additional symplectic forms whereas S^4 does not possess any Kahler form. Does the hierarchy of hyper complex manifolds contain other manifolds than M^2, M^4, M^4xCP_2, M^4xCP_2xCP_4, M^4xCP_2xCP_4xCP_8,… is an interesting question.

6. Number theoretical classical dynamics

Despite the fact that hyper-complex numbers are not a field, the notion of analyticity generalizes and leads to the idea that the classical dynamics of TOE could reduce to 4-D hyper-complex analyticity condition. Indeed, in string model the solutions of 2-D d'Alembert equation can be expressed as hyper-complex analytic functions of a hyper-complex variable assigned to the string world sheet with Minkowskian signature of metric.

A very attractive idea is that space-time surfaces correspond to surfaces of H=M^4xCP_2 for which the "imaginary" part of hyper-complex valued analytic function (possibly satisfying some additional constraints such as being polynomial) vanishes:

Im[f(h_1+e3h_2)]=0.

By implicit function theorem this gives 4-D hyper-complex number h_2 as an analytic function of h_1:

h_2= f(h_1).

This is an attractive candidate for a purely number theoretical realization variational principle, which should in TGD framework has absolute minimization of Kahler action as counterpart. The challenge is to prove this.

Lubos said:

"When Einstein started to propose his EPR paradoxes, he was sure that quantum mechanics had to be giving wrong predictions for these experiments. It's not just a matter of philosophy. He believed that the quantum entanglement was impossible, and using the current terminology, he would definitely agree that Bell's inequalities must be satisfied in reality."

Einstein was wrong in his judgements about quantum mechanics. But he was right on the profound philosophical believe that the physical world is fundamentally deterministic. Quantum mechanics is certainly a very successful theory in making predictions. But few people believe it is a final theory due to the difficulty of reconciling the difference between philosophy and the quantum mechanical picture. That's why, even in 2004, people are still debating about EPR paradox and struggle to try to understand what experiments like Alan Aspect's really tell us about reality.

It's far from being settled even today. Nobody can boast to understand EPR completely. If you think you know, it only shows you have learned the formulations of physics but really don't understand it.

Now about the famous Bohr – Einstein debate about that gedanken light box experiment. I do not why no body has pointed it out so far. The fact is both of these two great men had made serious mistakes in their great debate.

Bohr had made a big mistake in a fraud in his arguments, which used Einstein's General Relativity to prove that the uncertainty principle
still holds. And Einstein, astonished that his very GR theory was used against him, did not realize that Bohr made a fraudulent usage of his theory in his arguments.

Actually if Bohr had been right in his reasoning, he would have had discovered a way directly linking GR with the QM uncertainty principle. We wouldn't be still struggling so hard trying to associate GR with QM today.

Bohr's mistake being he confused the two delta T's. One being the deterministic and predictable time dilation due to GR effect. The other delta T being the actual uncertainty of time, which is random and un-predictable. The two delta T are totally different and unrelated. But Bohr tried successfully in confusing Einstein by using the same terminology to describe these two different delta T.

At the end of day, the uncertainty principle still holds, and Bohr could have defeated Einstein using another simplier and correct argument, by considering that photons have wavelengths related to their energy. So it is impossible to release a photon of certain energy, if the shuttle is opened for too short a time.

Future limitations of string theory.

Arun, we exchanged a few sentences with Andy S. about it today – well, there were some more material topics, too. When you ask Andy what kind of the new steps "beyond" string theory one can imagine, he says "I don't know".

It's of course partly a matter of terminology – what you consider string theory. Is M-theory still string theory or not? I think that if you accept the terminology that string theory contains things as different as M-theory, then there are only two possibilities. String theory will be proved completely wrong, irrelevant for the real world, or it will be correct and the progress will only be within string theory itself.

There is a difference from relativity and quantum mechanics. You know, the Newtonian mechanics contained three independent units, let's call them meter, kilogram, second. All other quantities have units that are products of powers of these basic units.

For example velocity is in meters per second. Special relativity showed that length and time are really related, and Newton's physics only holds for velocities much smaller than the speed of light. You set c=1 in relativity.

Similarly, quantum mechanics uses hbar, and things only look classical if the typical quantities of the same dimension as hbar (like action, angular momentum) are much greater than one. Naturally in quantum mechanics you set hbar=1, and you end up with one independent unit.

Now you're in hbar=c=1 units of quantum field theory, and everything is in powers of a GeV, so to say. If you now include quantum gravity, it also sets G=1, and says that the previous physics only worked at distances much greater than L_{planck} etc. But in these quantum gravity units, all observables are dimensionless, and there is really no other inequality that you can violate to go beyond the reach of validity of the previous theory.

String theory itself tells us exactly what sort of deformations you can do with its backgrounds and what sort of deformations you can't. There just does not seem to be any way to deform "away" from string theory. It must be exactly what it is.

61. **Lubos Motl**
December 23, 2004

Nope, quantoken, you were probably skipping your classes of history of physics.

When I write that Einstein did not believe quantum mechanics, it means that Einstein did not believe quantum mechanics. Your attempts to look for errors in my sentences are counterproductive. You should better look at the serious errors with YOUR thinking.

When Einstein started to propose his EPR paradoxes, he was sure that quantum mechanics had to be giving wrong predictions for these experiments. It's not just a matter of philosophy. He believed that the quantum entanglement was impossible, and using the current terminology, he would definitely agree that Bell's inequalities must be satisfied in reality.

He tried to invent dozens of possible contradictions in quantum mechanics, and all of these attempts of Einstein were wrong. (Well, one of them was also helpful in the understanding of QM, but not in the way Einstein anticipated.) Every time an experiment showed that Einstein was wrong, he invented another possible problem.

Moreover, in the last 30 years of his life, he really ignored the new discoveries in physics – like in nuclear physics. When he was constructing his unified field theory (until his death in 1955), it was always just a unified field theory of electromagnetism and gravity because he never considered any of the details of the emerging quantum field theories seriously.

Your comment that you don't believe in any limitation of determinism even in 2004 does not surprise me a single bit. I've already learned the level of your knowledge and understanding of physics in more detail than what is necessary.

December 23, 2004

Arun,

> *It either applies to the real world entirely and wholly, or not at all. And here is what a professional physicist, Lubos Motl, wrote on his blog : "I am always a bit puzzled by Andy's [Strominger] statements that string theory is "just another step" – what sort of other step that goes "beyond" string theory but does not invalidate it is Andy thinking about?"*

I can't speak for Lubos, and as a commoner, the thinking of the journalist would fall comparatively to my domain?:) So if the confusion rests, it would rest in the lack of interpretation that is derived from the roads leading too? We acknowledge the planck Epoch? The timing in Steven Weinberg's model of the First three minutes?

The conceptual difference as we now look at this model I wonder indeed how such thinking has been altered.We had to assume that this universe is cyclical in nature? So where do strings fit in? Gabriele Veneziano made this point clear.:)

> *It might be that the laws change absolutely with time; that gravity for instance varies with time and that this inverse square law has a strength which depends on how long it is since the beginning of time. In other words, it's possible that in the future we'll have more understanding of everything and physics may be completed by some kind of statement of how things started which are external to the laws of physics.*

Richard Feynman

If such a inquistive naure is not acknowledged then how would we move beyond the boundaries which we like to hold to in the physics of approach. You needed to have these frameworks which would motivate exploration of concepts and then bring back for us, new roads for consideration. Would one quickly dispell Smolins Three road attempt at comprehension?

Nima and others dimensionally have challenged these current views:)

63. **Arun**
December 23, 2004

Chris W. asks "Why in 2004 are we talking about proving physical theories?" in his criticism of Pathik Guha's newspaper report.

The idea is, I suppose, that we can only show that a physical theory corresponds to reality to a certain precision within a certain domain. We can never rule out the possibility of a theory with wider validity, just as Newtonian gravity was replaced by and subsumed within General Relativity. So proof of a theory is not possible.

But the Theory of Everything (or at least Superstring Theory) is different. It either applies to the real world entirely and wholly, or not at all. And here is what a professional physicist, Lubos Motl, wrote on his blog : "I am always a bit puzzled by Andy's [Strominger] statements that string theory is "just another step" – what sort of other step that goes "beyond" string theory but does not invalidate it is Andy thinking about?"

If you disagree, then certainly a newspaper reporter has more excuse to be confused than a physicist. 🙂

64. **Quantoken**
December 23, 2004

Mr. M-* said:

"Einstein did not believe quantum mechanics, even though he was a genius. There were fortunately many others who did. Feynman did not believe string theory, but there were others who did. You don't need to go far – Gell-Mann was the guy who created the strong Caltech's string theory group."

Why said Einstein did not believe in quantum mechanics. He certainly believed in the formulations of quantum mechanics and their ability to predict experimental results correctly. He just did not agree with the way how quantum mechanics was interpreted, philosophically. He believed in a deterministic picture of the world. Such belief is reflected by a phrase he said often: "God does not need to toss a dice." He thought that quantum mechanics is incomplete and must be deriveable from a better theory that is deterministic.

I believe in the same. Actually I already see what that deterministic better theory is. The physical world can be completely deterministic, but yet still none-predictable, because we observers are part of the universe and we can not obtain the whole information of the whole universe to be able to predict things completely deterministically. The job of acquiring and processing that amount of information would require one whole universe to do.

There are two kinds of believes. The kind of "seeing is believing". Which is scientific beliefs. And the kind of "accepting is believing", like believe in God or Budha. Talking about string theoreticians believing in string theory, without seeing any experimental support. That is "believing with no seeing", which I think can be classified into the religious beliefs.

Such a belief look even more like religious belief. Just like you never know whether there is soul and whether there is a God, until the very moment you die, and by then it is too late for you to change your religious belief. Many of the die hard string theoreticians also probably never will know for sure whether they were right or wrong, until they have spent their whole lifes, and probably until they go to heaven and meet Einstein there, and got the answer from him. But by then it's too later to change their beliefs.

65. **plato**
December 23, 2004

Santos,

Even Richard Feynman was not sure. When I complete posting on, The Gravity for Instance Varies with Time, you will understand what I am saying in regards to dimension and what even Richard Feynman did not realize.

Einstein limitations, were his views of what did not exist yet, and his refusal to accept quantum mechanics. We know different now, as Lubos mentions, as you now know, in context of what you quote from that Canto book.

You have to bring yourself up to speed on the subject?:)

66. **Chris W.**
December 22, 2004

Pathik Guha's piece struck me as a fairly sophomoric effort (and poorly edited to boot). Why in 2004 are we still talking about "proving" physical theories? Robert Geroch, in his beautiful little book **General Relativity from A to B** (1981), remarks early on that he can't imagine what would constitute a proof of a physical theory. Guha's careless formulation does nothing to clarify the issues now at stake in fundamental physics.

One of those issues (as Feynman said) is testability and avoidance of "immunizing strategems" when confronting the results or even the possibility of empirical tests. More specifically, in quantum gravity a central problem is how to meaningfully and consistently define observables, when spacetime structure is not only dynamical but quite possibly only an approximation to some deeper structure. From Raphael Bousso (hep-th/0412197, Introduction):

> One problem with quantum gravity is that we don?t know what the theory should compute. In particle physics, the most precise observable is the S-matrix. But this quantity seems ill-suited to cosmology, where the observer is not outside the system, initial states cannot be set up, and experiments cannot be arbitrarily repeated to gain statistically significant results.
>
> This ignorance is not especially unusual or embarrassing. It is rarely clear at the outset what a theory should compute. For example, the insight that gravity is a theory of a symmetric, diffeomorphism-invariant tensor field in itself already constituted a significant part of the development of general relativity. But once a theory is in its final form, the observables should be apparent.
>
> If string theory is the correct quantum theory of gravity, then whatever it computes presumably are the observables. But string theory—perhaps because it is *not* in its final form—has so far sidestepped the problem of cosmological observables. It defines quantum gravity for certain classes of geometries characterized by asymptotic conditions, such as asymptotically flat or Anti-de Sitter spacetimes. In these geometries an S-matrix happens to make sense, and string theory computes its matrix elements. (In the case of AdS, it computes boundary correlators, which are a close analogue of the S-matrix.)
>
> However, we have yet to learn how to apply string theory to cosmology or to an observer inside a black hole, with the same level of rigor as in Anti-de Sitter space. Hence, it would be premature to conclude that the S-matrix will remain the only well-defined object. It is too early to know what, if anything, string

> theory has to say about cosmological observables.
>
> Fortunately, classical and quantum properties of cosmological solutions impose significant constraints on possible observables, and may even hint at some of the principles on which a theory computing them must be based. De Sitter space is a case in point. Semi-classical analysis has provided overwhelming evidence that *no* exact observables exist in eternal de Sitter space—at least, none that correspond to experiments that can be performed by an observer inside the universe. This is related to the presence of a cosmological event horizon in de Sitter space, which limits the accessible information and emits pernicious thermal radiation.

Of course, as Daniel Friedan has discussed in detail, string theory has difficulties with large distance physics in general, not just cosmology.

67. **Mubos Lotl**
December 22, 2004

“To move forward, Strominger argues, the string theorists should work on the problems that they are able to make a progress on. For example, he says, they should concentrate on explaining why the dark energy that is enhancing the cosmic expansion rate is so small. ?We aren?t producing ideas on that,? he observes”

Excellent! So who at Harvard is following this good advice?

68. **Dave Bacon**
December 22, 2004

Lubos: “(violated the copyrights)”

Come on Lubos, you really believe quoting a small passage of a book with a reference is a violation of copyright law?

I use all these petty little inccorect statements by string theorists such as yourself as yet more proof that string theory is wrong (that’s a joke, in case you’re flaming powers are firing up.)

69. **Arun**
December 22, 2004

Another Pathik Guha article:
http://www.telegraphindia.com/1041018/asp/knowhow/story_3871254.asp

While it is mostly about Trieste ICTP, here is a relevant excerpt:

The audience bursts into laughter as Prof. Alvarez-Gaume, while discussing the string theory (experts? concept of a single idea to explain all physical phenomena), flashes a surrealist painting on the screen. It shows a castle on top of a huge piece of rock hanging in thin air! ?I want to convey the idea that the string theory has a rock-solid base,? he comments, highlighting critics? arguments that the theory is merely a mathematical artifact and has not been corroborated by experiments yet.

70. **Doug**
December 22, 2004

Sorry,
I forgot to include my name in the previous post. My name is Doug, and I contribute here from time to time.

71.
December 22, 2004

Has the principle of impotence, used so widely and successfully by the proponents of quantum mechanics, come back to haunt them?

“There are three major problems,” explains Strominger. “One is the problem of finding a theory that in principle can unify all the forces and particles in Nature. The second one is consistently putting together quantum mechanics and Einstein?s General Relativity. The third problem is the mathematical explanation of the black hole attribute that we computed. String theory has mathematically solved all the three problems. We don?t know if Nature avails herself of the solutions provided by string theory. But, on principle, string theory is capable of resolving all three of the riddles. Loop quantum gravity hasn?t solved any one of the three problems.”

If string theory can solve these problems “in principle,” is that any less compelling than quantum mechanics’ ability to solve chemical problems “in principle?” Larson wrote, years ago, that adherents to quantum mechanics were employing the same “principle of impotence” in regards to chemical problems:

“The physicists who are attempting to apply the latest quantum concepts to the problem have been singularly unsuccessful, if we appraise their results by any realistic standards. Some very broad claims on their behalf are often made by overenthusiastic supporters, the following from G. G. Hall being a typical example: ‘Quantum mechanics… gives the solution, in principle, to almost every chemical problem,’ but the true significance of such statements becomes apparent when Hall goes on to say, ‘Very unfortunately, however, there is an enormous gap between this solution in principle and the practical calculation of the properties of any specific molecule.'”

What amazes me is that so few recognize that, mathematical complexity not withstanding, solutions need to be able to deliver the goods or they are NOT solutions. But even worse, now we are talking about “in principle” solutions to problems that are in themselves in principle “solutions.” Quantum mechanics is a “solution” to the Bohr model of the nuclear atom, that has become the “solution” to the behavior of high-energy debris in accelerator collisions. Of course, such “solutions” have to be given 19 or 20 parameters from observation first, and some “reasonable” limit chosen to cast it in, but given these and a few, more subtle, “adjustments,” it can deliver the goods all right, just check out the standard model.

Well, at least it can if you ignore gravity, that is. We need a “solution” to our quantum mechanics “solution” that is a “solution” to our gravitational “solution,” as well. How inconvenient that the fabric of our “space-time solution” won’t accommodate the vacuum fluctuations of our “virtual sea solution.” If it did, perhaps we wouldn’t need a “solution” to our two, most spectacular, “solutions.”

It should occur to us that perhaps we have more fundamental problems than unifying the forces of the nuclear atom, or reconciling GR and QM, or explaining hypothetical black hole attributes. Perhaps the problem is that we have overlooked the fundamental definition of force as a PROPERTY of motion. Perhaps, the reason we can’t get there from here is because of our focus on forces and the assumption that forces can exist autonomously, without underlying motions!

Maybe we ought to go back to the beginning and ask ourselves, “What is motion?” If we did this, we would find ourselves confronted with another basic question, “What are space and time?” Now, Gross says that they are emergent, and Witten says that they are doomed, but what do we care what string theorists say anyway? Let them go back to the comfort and joy of basking in the beauty of mathematics.

We all know the answer to this basic question and have known since childhood: space and time are the reciprocal aspects of motion, nothing else. Common sense tells us that combining space and time in a continuum may be something that we can think about, and it may even be fun to see what happens since now we know that motion affects time as well as space (now that's a shocker!), but, come on, let's face it, Nature is not likely to be out making up such an ungainly expedient.

We know that radiation and energy are discrete. We know that motion affects time as well as space. These things we know, so it's not much of a jump to suppose that motion, that is, the only known relationship of space and time, is discrete as well. If motion is discrete, then it follows that its two, reciprocal, aspects are discrete too, and there you have it – we are off and running with a whole new concept that offers us an incredible new approach.

For instance, since we've learned that the speed of propagation of radiation relative to matter is constant, we can take that as a pretty good indication that the reason is that it's the unit speed of motion: one unit of discrete space per unit of discrete time = a velocity of c. Wow, check out the symmetry in that baby, would ya? Wonder what happens when there are more units of space than time, or more units of time than space in that otherwise perfectly symmetrical equation of motion? What else might be lurking in there? Matter must be related to this basic motion, huh? Maybe magnetic and electric properties of matter are too, ya think?

Well, to tell you the truth, there is incredible promise in this approach, including, but not limited to, particle masses, charges, and physical constants of all kinds, but we now return you to the continuing saga of legacy physics: the motion of strings in a quantum world where the curves of space don't bother us, and its fluctuations happily evolve in time.

72.
December 22, 2004

Hey Santo,

I don't quite agree. Feynman kind of realized that he may have been doing a silly mistake. This is what the second part of his answer is all about. I don't quite understand how "more" can you be aware of your doing a mistake. If he knew exactly and clearly that his viewpoint were mistaken, then he would have changed his viewpoint, would not he? 😉

I am happy that you (violated the copyrights) and cited Feynman accurately because his authentic quote is much better than my variation of it. But the content is the same.

If he realized his mistake just one piece more than what he displayed, he would have understood why string theory is the right approach.

Happy holidays,
lubos

73. **Santo D'Agostino**
December 22, 2004

Lubos,

I posted my comment because I did not wish readers to get the mistaken impression that Feynman thought himself making a silly mistake in criticizing string theory. In fact the full interview shows that he emphatically believed that string theory is crazy.

Of course, I agree that one man's opinion proves nothing, and no one is suggesting that one should treat the opinions of anyone, even a great man, as God-like. However, I do strongly believe that when one is quoting someone briefly, one must do one's best to be accurate. But perhaps I should not hold people so strongly to task in an informal setting such as this, as I would in a more formal setting such as in a published article or book.

Wishing you all the best,
Santo

74.
December 22, 2004

Yes but Lubos did you even address Feynman's point about not calculating anything?

75. **Lubos Motl**
December 22, 2004

Santo Agostino, you're missing the point.

Of course that the silly people often do not think about themselves that they are silly. But it's irrelevant what they think about themselves.

Feynman's genius is that he realized very well that even the other great physicists, such as Einstein, say a lot of things when they're old – things that look stupid to others.

He knew well that the old men are too conservative and unable to follow the new stuff too carefully. Knowing this fact about biology is helpful, but it's not enough to follow the new developments in physics – and Feynman is an example.

You know, I am one of the biggest fans of Feynman in the world, as my choice of the e-mail address shows much like other things. But looking to the old Feynman as some sort of God whose opinion about very complicated things matters even if there is no actual science behind it – that would be silly.

Einstein did not believe quantum mechanics, even though he was a genius. There were fortunately many others who did. Feynman did not believe string theory, but there were others who did. You don't need to go far – Gell-Mann was the guy who created the strong Caltech's string theory group.

Best
Lubos

76. **Santo D'Agostino**
December 22, 2004

L. Motl's "quote" of Feynman makes it sound as if Feynman thought himself silly, but that's not the sense I get from reading the exact quote (from Superstrings: A Theory of Everything?, edited by Davies and Brown, page 193; I presume this is the source that L. Motl is "quoting"):

"I have noticed when I was younger, that lots of old men in the field couldn't understand new ideas very well, and resisted them with one method or another, and that they were very foolish in saying these ideas were wrong — such as Einstein not being able to take quantum mechanics. I'm an old man now, and these are new ideas, and they look crazy to me, and they look like they're on the wrong track. Now I know that other old men have been very foolish in saying things like this, and, therefore, I would be very foolish to say this is nonsense. I am going to be very foolish, because I do feel strongly that this is nonsense! I can't help it, even though I know the danger in such a point of view. So perhaps I could entertain future historians by saying I think all this superstring stuff is crazy and is in the wrong direction."

When asked what it is that he didn't like about string theory, he replied:

"I don't like that they're not calculating anything. I don't like that they don't check their ideas. I don't like that for anything that disagrees with an experiment, they cook up an explanation — a fix-up to say 'Well, it still might be true.' …"

He is very emphatic throughout the entire interview, and his full comments are worth reading.

77. **DMS**
December 22, 2004

Actually, I am a bit surprised, as in India journalists tend to be very deferential to physicists/mathematicians (they are VERY RUDE to politicians, unlike US media, I might add!). Atiyah remarked: "I have never received the kind of audience that I have in India. I feel like a pop star."

http://cities.expressindia.com/fullstory.php?newsid=67555

Perhaps the journalist has a good physics background.

78. **Fabio Lanzoni**
December 22, 2004

"Though the experts, not particularly fond of hypes, don?t like the name that much.."

Since when are string theory experts not particularly fond of hype? They seem to spend a good deal of their time cultivating it.

It's no accident this interview came from an Indian paper: this kind of skeptical journalism is not in fashion in the US. It can lead to people asking the wrong questions and upsetting advertisers.

79. **Lubos Motl**
December 22, 2004

This Pathik Guha (journalist) is a pretty self-confident guy. 😉 Andy Strominger explains him that string theory has no competitors. Of course that Andy Strominger knows what he's saying, and his sentence also implies "the enterprise called loop quantum gravity is not a competitor of string theory". Pathik Guha nevertheless says "Strominger may be not quite right". 😉

We like the comment of Feynman very much. "I know that it's silly, that all good physicists who become old suddenly start to say all these ridiculous things about science. We know that Einstein did the same thing with quantum mechanics. I know that I am going to repeat the same silly mistake (with string theory), but I just can't help myself." 🙂

80. **plato**
December 22, 2004

A question

What's better—

This-

*Although there?s no direct evidence that string theory is correct, Strominger points out, "**we?ve a number of signposts that it?s on the right track.**" What are they? String theory, Strominger explains, has shown beautiful connections with various branches of mathematics.*

http://www.telegraphindia.com/1041220/asp/knowhow/story_4152318.asp

—or this?

*Although there?s no direct evidence that string theory is correct, Strominger points out, "**we?ve a number of signposts that it?s on the right track.**" What are they? String theory, Strominger explains, has shown beautiful connections with various branches of mathematics.*

In reference to content. So math doesn't matter?:)This would put mathematics in a really awkward position?

   Humor was once defined, in a early historical way. That now, humour might be envisioned as some aether requirement preceding mathematical recognition?:) Is it, just a good gauss(I mean guess)?

3. **Peter**
   December 24, 2004

   When I first set this up, comments were oldest first, but someone complained that they should be newest first, so I changed it. I think I'll leave it the way it is for now. At some point I'll move the weblog to newer software, then I'll see about maybe changing the ordering.

4. **dave**
   December 24, 2004

   Peter,

   You should make the comments such that when someone reads them, the first comment is at the top, and the last at the bottom.

5.
   December 23, 2004

   There are three types of mathematicians: those who know how to count and those who don't.

6. **Fabien Besnard**
   December 23, 2004

   The Wiener anecdote reminds me of another one about physicists this time, namely Pierre and Marie Curie. The Curie were one day eating their lunch, while discussing very intensely about some physics problem. Then, their very devoted maid, who had cooked the meal, asked them if the steack was good. "So it is a steack we had ? That may be." said Pierre. Apparently Marie was not more aware of what she ate.
   This one is likely to be true, since it is their daughter Eve who wrote about this anecdote.
   A lot less funny, the legendary absent-mindedness of Pierre seems to have costed him his life when he crossed the street without watching.

   PS : the anecdote is probably more funny from a french point of view, since it is very unlikely that a french pays no attention to what he is eating !

7.
   December 22, 2004

   Why did the flight to Warsaw crash?

   Because all the Poles were in the left half-plane.

   (Irrelevant context omitted)

8. **Lubos Motl**
   December 22, 2004

   Haha, very good jokes.

9. **plato**
   December 22, 2004

   What Is Real?

   The abundance of joking questions involving plays on mathematical terminology, as well as the jokes involving the stereotype of the mathematician,suggest that mathematicians like to play. The delight in playfulness would seem to run counter to the stereotype of the humorless pedant who is concerned only with precision, but there is no necessary contradiction. A predilection for fantasy…..

whoa now…are you saying mathematician's actually have humour?:)Imagine Lewis Carroll, and the stories he could tell. I think this man would rate higher in the folklore of the mathematicians?:)

Maybe because mathematcians are getting older, they like to pass off physics, with mathematical myths?:)

On Crackpotism and Other Things

December 31, 2004
Categories: Uncategorized

I haven't posted anything new here in a while, with the holidays and trying to get over a bad cold keeping me otherwise occupied. Partly because of this the comments section has been to some degree taken over by people who want to discuss things I have no interest in. I'll try and put up something new soon (comments on Penrose's new book), but I did want to make some remarks about the problem of crackpotism in theoretical physics, something which is especially a problem for open forums on the internet like the comment section here.

When I first started studying particle physics during the 1970s, it was pretty clear to me how to tell the difference between serious people and crackpots. The Standard Model had just recently been formulated and it had started to accumulate an impressive amount of experimental evidence in its favor. So, at least in particle theory, serious people were doing one of a small number of things. The more phenomenologically inclined were analyzing the new experimental results to see if they further validated the Standard Model, or suggesting new experiments that would test different parts of the model. More mathematically inclined sorts were trying to understand the rich structure of the model, trying to get a better grasp of its aspects that were still poorly understood. People inclined to speculation were working on ambitious extensions of the model, hoping to find something compelling that would both explain some of the model's parameters and make new, testable predictions.

So, to my mind, crackpots were those claiming to have new ideas about particle physics, but refusing to really engage in some way with the Standard Model quantum field theory. There were plenty of them around, including S-matrix die-hards like Fritjof Capra, those who wanted to go on about what happened before the big bang and how that explained all properties of particles, and a wide variety of people with their own private TOE that completely ignored the Standard Model. All you had to do was learn to ignore such people.

During the last 20 years, distinguishing crackpots has become a lot tougher, and it has gotten much more difficult recently. Famous professors from the best research institutions in the world go on about the properties of the universe being determined by colliding branes, or by an anthropically determined point in a multiverse, or any number of similar ideas. The dominant idea in the whole field makes nothing like what would normally be considered a testable scientific prediction, and those pursuing it don't seem too bothered by the increasing evidence that this situation will never change. Personally I haven't much changed my criterion for crackpotism in particle physics: if someone is not engaging in a deep way with the Standard Model and/or the kind of mathematical structures it involves, they're probably a crackpot.

When I first wrote a critical article about string theory and made it public about four years ago, I got quite a lot of reaction. Almost all of it was gratifyingly positive, but I ended up hearing from quite a few people who were convinced that since I didn't like string theory, surely I would like their alternative. These alternatives spanned a wide range, from very serious work to complete crackpotism, including all shades of in-between. The one thing that caused me to worry that there might be something wrong with my criticisms of string theory was the nature of a small number of my supporters. Some of these people still write to me regularly, and my e-mail is full of crazier things than what appears in the comments on the weblog. It's embarassing to get cc'd on an e-mail to a long list of very prominent physicists by someone who is quoting my criticisms of string theory to back up their own even sillier ideas.

I've gotten very good at hitting the delete key or, in extreme cases, using procmail to automatically filter this stuff out of my inbox. I suggest similar tactics in reading the comment section here. The first line of defense against people who you think are not making any sense is just to ignore them. Do not give in to the temptation to point out to them that they are not making sense, because all this will accomplish is to clutter things up as they respond to your response to them.

I'm not about to start just deleting comments that I think are of a crackpot nature, partly because it is now hard to set up a clear criterion for what is crackpotism (should I delete Lenny Susskind's comments if he decides to write in some day?). But to the extent that the volume of off-topic comments starts to overwhelm those that are interesting and related to the postings, I will have to take some sort of action. If you are posting large numbers of comments, mostly far off the topic at hand, please stop doing it now. If you are responding to such off-topic comments, please stop doing that too, don't encourage them!

Comments

1. **D R Lunsford**
   January 7, 2005

   Do non-crackpots invite you to give seminars and generally let you present your case, or do they tend to suppress your views?

   Oh heavens no, in both cases. I've talked about it in not too much detail in the usual public places, sent it to a few people who I thought might be interested, but the proper way to do it is to put it on arxiv. I don't know why they blacklisted it – all I know is, it got sponsored, got put up, and then vanished – never got any explanation. I would like for the thing to be on arxiv just on general principles, but now that it's actually been peer-reviewed and published, it's not a big issue to me any more. (In any case the publisher now owns the copyright.)

   I do enjoy talking physics though. That's what you really miss being an outsider.

Of course if you want to derive matter from the manifold, it can't be 4D. This is so simple that it's easy to overlook.*

   Well, if you are a "crackpot" then, you are in some pretty good company. Do non-crackpots invite you to give seminars and generally let you present your case, or do they tend to suppress your views?

   Weyl wrote:

   The question of the ultimate foundations and the ultimate meaning of mathematics remains open; we do not know in what direction it will find its final solution or even whether a final objective answer can be expected at all. "Mathematizing" may well be a creative activity of man, like language or music, of primary originality, whose historical decisions defy complete objective rationalization.

   So, again, it's a question of the meaning of mathematics. I believe that the non-crackpots should consider their own, canonical, forms in this light, and admit that they have no special claim to the one and only “correct,” creative, mathematized solution. The problems they face may eventually yield to the considerations of higher and higher abstractions, but most wise men seem to sense that they will not.

I believe that the importance of maintaining a connection with correct physical concepts is key in all this “creative activity.” For instance, your observation that “if you want to derive matter from the manifold, it can’t be 4D,” might make perfect sense in the context of creative mathematics, but we should always ask ourselves, whether in regard to your recourse to six dimensions, or to Witten’s recourse to ten dimensions: “can this make sense in a physical way?”

Clearly, no one has ever detected a unit of space, in any form, whether 3D, 4D, 6D or 10D. These dimensions of space are mathematical creations and nothing else, as far as the non-crackpots have been able to determine. Then, is it such a “crackpot” idea to take this physical observation at face value, and admit that there is no such thing as space, and stop continuing to give something that doesn’t exist properties that our mathematics need, such as “viscosity” (earlier generations), “warpage” (today), or “smooth tension” (tomorrow). We have filled it with fluctuating fields, made it a virtual sea of particles, and now want to roll it into tiny pieces and even say it’s a maze of glued together tetrahedrons!

Isn’t it clear that the true “crackpot” here, is the one who thinks that we can just freely invent dimensions of something that clearly doesn’t exist? Isn’t it the one who insists on giving space properties so that he/she can continue “mathematizing,” and indulging in the “creative activity of man,” as Weyl puts it? Present company excluded of course.

I realize that this “crackpot” point of view is like a voice crying in the wilderness, not likely to be heard today, but I want it on record that, like Diogenes, someone needs to hold the lamp in our faces: Honestly, where’s the space guys? Minkowski was right, when he predicted the ultimate union of space and time, but we have only unified space and time in the most unusual and unnatural way. Today, as the complexity of our perplexity grows, Witten predicts that space and time, as independent entities, are doomed, and Gross says that they are “emergent.” Well, I hope so, since they never existed as such anyway, except in our “mathematizing” activities.

The only way that space and time can be unified that makes any physical sense at all is as the reciprocal aspects of motion, as we clearly see in the simple equation of motion, v = ds/dt.

Think about it, it’s not hard to see. Can we measure either space or time without the other? No, we cannot. I defy anybody to do it. To measure space, we need time, and to measure time, we need space. Why is this so? It is so, because 3D geometry is a result of motion’s three degrees of freedom: ds/dt can take three, and only three, mutually orthogonal directions physically, and I defy the whole world to prove otherwise.

We may be able to easily format space in an endless number of ways to form manifolds, strings, or branes within our mathematical creations to our heart’s content, but we can’t move an object, or draw a figure, in more than three, mutually orthogonal, directions, no matter how hard we try. This physical fact ought to temper our “creative activity” of “mathematizing” in regards to investigating nature, but it won’t, and why is that? Because we are non-crackpots by social definition and we get paid so much for playing the role. But if we will only look in the mirror, we will have to conclude: “we have met the “crackpot,” and he is us!”

   Whether or not I’m a crackpot (I could not care less), the idea was really Riemann’s, Clifford’s, Mach’s, Einstein’s and Weyl’s. The odd thing was, Weyl came so close to getting it right, then, being a mathematician, insisted that his theory explain why spacetime is 4D, which was *not* part of the original program. Of course if you want to derive matter from the manifold, it can’t be 4D. This is so simple that it’s easy to overlook.

   I always found the interest in KK theory curiously misplaced, sicne that theory actually succeeds in its original form, but the success is hollow because the unification is non-dynamical.

   drl,

   You lost me on that one, it’s too abstract for me. It’s beside the point too, because I’m not defending Hestenes’ treatment of spacetime, but only attempting to show how a mathematical model can work under certain circumstances even when the physical intrepretation is wrong or even non-sensical.

   This intrigues me though:

   The GR program was to derive matter and spacetime on a common ground. This never really happened because Tmn was posited on the right in analogy with (backgroundful) electrodynamics. This leads to the energy and scaling problem of GR which leads to its confounding the quantizers. Solve the matter problem and the rest should take care of itself.

   I am not skillful enough to understand your paper, but I have never heard of this idea before. Are you considered a “crackpot” for this approach? Why did they blacklist your paper?

5. **Momentus**
   January 6, 2005

   “If it disagrees with experiment, it is wrong.”
   I was googling on this phrase,because I have a simple experiment, which I cannot get to behave ‘right’. I also have not found any one who can tell me what the expected experimental result should be.
   The experiment is to hang a spinning wheel(Gyro) from a long cord.It does not Rotate (precess)about the c of g.
   My study of this observed fact has revealed a new force. Now that is crackpot, by definition.

   So most learned and erudite scholars, please what should the suspended mass do? Where have I gone astray?

6. **D R Lunsford**

   Doug –

   The standard answer is that a change of basis casts the Dirac eqn in the form

   (y_mu d_mu – m y_5) psi = 0

   You could now start from this eqn and get the “real” one in the same way. So matter-antimatter is encoded in m – under spacetime parity m -> -m and matter antimatter.

This isn't mystical – you could have started with -m and have -m -> +m. You have to treat y_5 correctly to have this symmetry, and it seems to me Hestenes doesn't do that. That's why he gets a "thorn" in his eqn, an explicit appearence of y_2.

January 5, 2005

Oops,

Was in a hurry. Meant to say:

I wouldn't argue the idea that the role of antimatter is NOT crucial. Also, spacetime parity may not be as important as space/time parity in another context, but I'd have to explain that.

drl wrote:

His [Hestenes'] reformulation does violence to spacetime parity, so I don't have much faith in it.

But there is the issue of "hidden" changes of basis. I'm "looking through a glass darkly" here and quickly getting in over my head, but I wouldn't agrue that the idea that the role of antimatter is crucial, only that the mathematical abstractions seem to take on a life of their own.

Here is a paper that rings true for me, although I don't understand it all:

Parra Serra's paper

And here is a quote that rings true to me as well:

I sometimes wonder if obession with the ineffable realm of abstraction is a sort of drug addiction that is clouding the collective judgment. drl

And finally, this one:

God has chosen the world that is the most perfect, that is to say,
the one that is at the same time the simplest in hypotheses and the
richest in phenomena.
— Gottfried Von Liebniz

Nevertheless, Hestenes writes that, by reformulating the mathematics of the Dirac equation, he can show that "the zbw is a ubiquitous phenomena with manifestations in every application of quantum mechanics, even in the nonrelativistic domain."

His reformulation does violence to spacetime parity, so I don't have much faith in it.

"Similarly with GR – the problematic aspects are artifacts of approximation." – I don't see how this follows. The incompatibility of a background free theory like GR with a background dependent theory like QFT cannot be attributed to "artifacts of approximation," can it?

Sure it can – the GR program was to derive matter and spacetime on a common ground. This never really happened because Tmn was posited on the right in analogy with (backgroundful) electrodynamics. This leads to the energy and scaling problem of GR which leads to its confounding the quantizers. Solve the matter problem and the rest should take care of itself. I have a proposal if you're interested.

drl wrote

Well, this is also true for example of the Pauli spin theory. Only the Dirac theory showed how right Pauli really was. Pauli's was actually the harder problem, and within the Dirac theory, he was totally justified, as an approximation.

But what this really indicates is that the mathematical interpretation must be related to the physical concept employed. If it were not so, we would stop with the mathematical formulation. We don't, because we want to understand a physical model, not just a mathematical one. Hence, there is still a lot of dissatisfaction in the non-crackpot community because of the metaphorical interpretation of spin: we want to know what it really means.

This has led to many attempts to show that it really is generated by some kind of rotation. Hestenes regards Schroedinger's zitterbewegung (zbw) model for such motion especially noteworthy because "it is grounded in an analysis of solutions to the Dirac equation." However, zbw doesn't result in anything real. Nevertheless, Hestenes writes that, by reformulating the mathematics of the Dirac equation, he can show that "the zbw is a ubiquitous phenomena with manifestations in every application of quantum mechanics, even in the nonrelativistic domain."

So, here we see, once again, that the mathematics can work, even when there is an incorrect interpretation of the meaning of the mathematics, or even when there is a non-sensical and metaphorical interpretation, but when a correct interpretation of the mathematics accompanies a solution, great advances result.
(see http://modelingnts.la.asu.edu/pdf/ZBW_I_QM.pdf)

BTW, part of Pauli's "harder problem," was never really solved by Dirac's formulation: quantum mechanics still cannot account for the structure of the periodic table accurately.

Similarly with GR – the problematic aspects are artifacts of approximation.

I don't see how this follows. The incompatibility of a background free theory like GR with a background dependent theory like QFT cannot be attributed to "artifacts of approximation," can it?

Doug wrote:

However, there's a possibility that, for some reason, the level on which "GR is undeniably correct," is not a physical level, but a mathematical level. In other words, it could be that it is an interpretation of physical concepts that works mathematically, but is physically wrong.

Well, this is also true for example of the Pauli spin theory. Only the Dirac theory showed how right Pauli really was. Pauli's was actually the harder problem, and within the Dirac theory, he was totally justified, as an approximation.

Similarly with GR – the problematic aspects are artifacts of approximation.

For instance, Einstein's theories are based on Maxwell's equations, which show that the law of conservation leads, not only to symmetry, but to electromagnetic waves that travel at the same speed in all directions, at the speed of light. There does not appear to be an error in these equations, yet the physical concept at the time included the idea of an all pervasive aether. Contrary to popular belief, Einstein didn't eliminate the aether concept, he just modified and renamed it.

It turns out that SR is *not* based on Maxwell's theory, but that the latter exhibits relativistic behavior in an essential way, because light goes at the fundamental speed C. In fact SR doesn't need any specific field theory at all to hold it up – it's just group theory and projective geometry (Klein's program, light cone = ideal domain). And so Einstein *really did* eliminate the aether (for a while, in my reducible, lambda days, I believed as you do 🙂 He eliminated it by refining the idea of space and time in such a way that propagation becomes a primitive fact, like ponderability, that doesn't require factitious causes.

Here's an idea, let's go down to the basement and rummage through the dusty trunks of history. Who's afraid of the dark? Us "crackpots" aren't, because we have nothing to lose.

Indeed! But watch for spiders.

drl,

I whole heartedly agree with this:

Nevertheless, my own opinion is that some things in science just can't be ignored or you aren't doing science, which is not a series of wacky revolutions.

Yet, many times that is exactly what is countenanced in non-crackpot science, and in a glaring fashion to boot. One example is Ivor Catt's anomaly. You would think that science has progressed way beyond elementary concepts such as those Oliver Heaviside wrestled with in stringing the Atlantic with telegraph cables. However, like the old farmer said, "It's not what I didn't know that done me in, it's what I knowed that weren't so!"
