Both reviews give a reasonable description of what the book is about, and take the first part of the book to task for being hard going, worrying that the reader may give up before getting to the less technical later parts. Seife writes "the level of detail is inconsistent" and Fraser describes "a level of detail that is unpredictable", and this is true enough. It was a conscious decision to put together history, some basic explanations of math and particle physics, together with some explanations of the rather arcane joint successes of math and physics in recent years, all in as compact form as possible. There is a warning in the text that almost everyone is going to find parts of this hard to follow and should judiciously skip ahead. My goal was to write something that almost everyone would get something out of, from people new to the subject to those with quite a bit of technical knowledge. Undoubtedly this was an overly-ambitious idea, but on the whole I've been pleased so far to hear that people with a wide range of backgrounds seem to enjoy the book.

Because I cover so much ground in so few pages, many technical terms and ideas don't get properly explained. Both Seife and Fraser fault me for not explaining "synchrotron radiation", which is true enough, although I use the term in context to describe X-rays produced when electrons are accelerated in a synchrotron. Seife says that I don't define "eigenstate", although I do give a one-sentence definition immediately after first using the term. It's true though that anyone who hasn't taken a linear algebra course will probably just find this baffling.

Fraser complains about inaccuracies in the book, and he has found two of them: I describe Rutherford's discovery of the nucleus as taking place at Cambridge when it was really Manchester, and while this experiment is first properly described as involving the scattering of alpha particles, at a later point in the book it is inaccurately referred to as involving scattering electrons. Some of his other complaints seem to me unfounded. I don't say that Isabelle was canceled before planning was underway for the SSC, and I don't understand why he claims there was no "competing collider" at CERN (the reference was to the SpS, being used as a p-pbar collider starting in 1981).

I've just written up an errata page for the book, which includes the two errors mentioned by Fraser. It can be found here.

Update: John Horgan's review of Not Even Wrong that appeared in Prospect is available at his web-site.

Sabine Hossenfelder has the first review of Lee Smolin's The Trouble With Physics, together with an interview with Smolin. Lubos responds to this by explaining that Sabine is a woman, thus intellectually inferior, and prone to engage in "female physics".

Comments

1. **L. Riofrio**
   August 2, 2006

   I sympathise with your difficulty in getting things published. Keep at it; I look forward to reading your book. The best way to bury a bad idea is to come up with something better.

2. **Johan Couder**
   August 3, 2006

   I have to agree – your book is indeed "hard going" at times. In spite of having 'some' mathematical background I probably wouldn't have struggled through if as an interested "layman" I hadn't already read so many popular books on quantum physics, relativity and string theory before.
   But I'm glad I did. I kept buying the latest 'popular' books on string theory afraid as I was of missing out on the "Big Revolution" in theoretical physics. If anything your book made me realize string theory may very well not be the "Holy Grail" its proponents purport it to be.
   It also saddens me some string theorists do not seem to have the 'grandeur' of at least "agreeing to disagree". I'm glad though your colleague Brian Greene doesn't seem to be one of them, because I do admire him as a science popularizer (and as a scientist of course).
   I'll never reach the heights of your mathematical understanding (not by far) , but at least you didn't give me the feeling of being a complete moron. It obviously took a lot of courage to do what you did, and I (and many others I'm sure) thank you for that.

3. **Tommaso Dorigo**
   August 3, 2006

   Hi Peter,

   I think a varying level of detail is a very good idea. I enjoyed the book back to back, and the fact that the level was not always the same was stimulating to me, rather than the other way round. I did not skip pages, even if in a couple of instances I was having trouble understanding the details.

   So this kind of criticism is unfounded IMO.

   T.

4. **Hmm**
   August 4, 2006

   Johan,

   It didn't take any "courage" for Peter to do what he did. He isn't a physicist, nor even a professional resarcher of any sort. He has absolutely nothing to lose spouting his trivial ideas, and lots to gain–media coverage and recognition he could never have gotten from doing research. So it didn't take any courage–no one even noticed him enough to even care what he thought or said before, and nothing has changed in this regard.

   Peter–I've said it before. Enjoy your 15 minutes. You've taken a pretty pathetic and classless road to try and make a name for yourself, but I guess it takes the sting out of never having enough talent to be kept around in physics. However you should know that there are lots of serious and brilliant people actually struggling to make progress, who both understand your trivial points as well as hundreds of more interesting ones. You are pompous and arrogant with nothing to back it up intellectually; its lucky for you that we live in a general age of mediocrity in this society, which is the only reason you get any coverage at all.

We are all also STILL waiting for your research ideas, where are they???? Will we EVER see them??? Well it was tough going for you when you were younger, and its not going to get any easier….I'd get cracking if I were you.

5. **Marty Tysanner**
   August 4, 2006

   Peter,

   Could you please do all of us a favor and delete the above post by "Hmm"? He appears to be nothing more than a puerile, loud-mouthed, air-headed troll who has never initiated nor contributed any useful discussion here. His "contributions" are no more than noise, certainly nothing worthy of a response by you nor anyone else. I am posting something only because I am sick of seeing his meaningless drivel.

   More generally, I really, really wish you would initiate an uncompromising policy where *any* post that contains a significant personal attack on you or any other poster would be automatically be deleted without further explanation. Something like a simple line just above the comment entry area like "*Posts containing ad hominem attacks will be mercilessly deleted*" would provide adequate warning. You may feel an obligation to allow others to personally attack you so as to avoid an image of censorship, but in my view that is only appropriate as long as the attacks are restricted to ideas or appropriateness of material, as opposed to purely personal attacks like the one above. Allowing trashy comments like those by Hmm and others of his ilk (e.g., "Michael") cheapens your blog and gives it too much of an unmoderated Usenet flavor.

6. **Walt**
   August 4, 2006

   Hmm: You're helping to kill string theory. Seriously, anyone who's on the outside of the discussion (and that includes most physicists) who sees these arguments between you and Peter will side with Peter every time. Refuting bad ideas is as much a part of science as developing good ones. Peter has put forth a scientific argument against string theory; that's part of science. Your whining about the hurt feelings of all the hard workers out there is not.

7. **Hmm**
   August 4, 2006

   Marty,

   I apologize–seeing Johan call Peter "courageous" pushed me over the edge. I really do have an exceedingly low opinion of what Peter is engaged in, but I agree that it was wrong to respond as I did, not to mention a waste of time.

   So apologies Peter, and please feel free to delete my comments as Marty suggested. I will avoid leaving comments here in the future.

8. **Hmm**
   August 4, 2006

   OK one last comment in response to Walt: yes, obviously refuting bad arguments is part of science. But Peter has not "put forth a scientific argument". He hasn't said a *single* thing that isn't trivially obvious to everyone in the field; indeed most practicioners (and I'm not talking about Kaku or Greene) have much more insight into the problems of string theory, and at a deeper level, both physically and mathematically. But they also know of many remarkable aspects of the theory that are extremely compelling. The subject is a work in progress, and no one has claimed that the answer is right around the corner. That is why what Peter does is so annoying–he takes the "outsider against the establishment" line when nothing he says is news to anyone inside the subject, pretending he knows what the outcome of all the confusions is going to be, say involving the landscape, when they are very much up in the air, subjects of ongoing research. All he does is boo the people from the sidelines without offering anything positive, and not even giving anything negative that isn't universally known. And its a little galling when his specific proposals for "alternatives" are so amazingly naive, as you might expect from someone with no real experience in doing original research.

9. **Arun**
   August 5, 2006

   Stripped of the ad hominem remarks, all that Hmm is saying is – trust the string theorists, what makes string theory compelling cannot be explained to mere mortals, only the problems with string theory can.

10. **Ummm**
    August 5, 2006

    "…yes, obviously refuting bad arguments is part of science. But Peter has not "put forth a scientific argument". He hasn't said a *single* thing that isn't trivially obvious to everyone in the field…" – Hmm

    If it is so trivially obvious that stringy stuff has got into a worse situation over the past 20 years, then why get so angry about it?

11. **woit**
    August 5, 2006

    About Hmm,

    I wish string theory proponents would get their story straight. Half the time I'm someone who doesn't know what I'm talking about, so shouldn't be listened to because I've got it all wrong, the other half of the time, the problem is that I'm saying things that are obviously true to all trained string theorists, so I shouldn't be listened to because I'm boring.

    Marty,

    In the future I'll take up Hmm's offer to delete his comments. While he promises to stop posting here, from past experience he doesn't seem to believe in keeping his promises.

    I do want to avoid deleting comments from string theorists, no matter how offensive, because I've been accused by them of deleting comments I disagree with. One correspondent wrote to tell me that a string theorist had told him that the reason one doesn't see sensible responses to criticism of string theory on my blog is that I delete these.

    Unfortunately Hmm and Lubos are not alone in their behavior and attitudes in the string theory community. The recent behavior of Susskind shows that this kind of thing is more widespread, involving some very prominent people.

12. **LDM**
    August 5, 2006

It didn't take any "courage" for Peter to do what he did. -Hmm

One might ask exactly how much courage does it take to work in a discipline, like string theory, where it seems nothing can ever be tested by experiment — and hence there is never a risk of loss of scientific reputation, or ego, by any of your ideas being proved wrong in the lab.

13. **Thomas Larsson**
August 6, 2006

If anything your book made me realize string theory may very well not be the "Holy Grail" its proponents purport it to be.

"Holy Grail" = non-existent thing which generations of our best and brightest wasted their lives searching for.

14. **Thomas Mulligan**
August 7, 2006

I think the comments of Dr. Lubos and "Hmm" should be retained; they serve to illuminate the very real insecurities present in the string theory community. I do not doubt the noble motivations of string theorists, but even the most objective scientists cannot help but attach an unwarranted affinity to concepts they've spent careers studying. Most confront foundational problems with polite resistance; the two mentioned above appear to employ only ad hominem attack: the first refuge of an insecure intellect is insult.

The work Dr. Woit does here is as important to the advancement of physical theory as anything you'll find on arXiv; every scientist has a duty to ensure that our accepted theories are empirically adequate, regardless of whether or not that requires an attack on orthodoxy. If string theory becomes a genuine, potent scientific theory, it will be as a result of Dr. Woit's criticism and not despite it.

15. **D R Lunsford**
August 7, 2006

Thomas,

I agree about Peter, but I don't agree about the noble motivations of string theorists. I suppose I use a different definition of nobility, such as could be justly applied to Pauli, Dirac, etc. among other people who respected the truth. But it's just my opinion.

-drl

16. **nigel cook**
August 7, 2006

The widely agreed principle maintaining string theory is:

We are right because **everyone else is wrong.**

By and large the public agree – ie stringy hype works – because the public can't get to see any alternatives clearly; this is due to the stringy hype and censorship of physics by group think stringers. If the public could see all the alternatives, the status of physics would be reduced from a professional objective group enterprize into what would appear chaos. So they have to censor out the alternatives, or physics is finished as a respectable discipline a far as they are concerned.

17. **Peter Orland**
August 7, 2006

Most of the comments on this blog concern the value of string theory as opposed to other approaches to quantum gravity and unification. It surprises me that no one seems to have suggested that part of the controversy isn't the solution but the problem.

NO theory of everything is going to do any better than string theory has. What does Loop Quantum Gravity predict? Or dynamical triangulations?
The difficulty is that any serious attempt to deal with the Planck scale can't confront the world in the TeV range. Any approach to these specific problems needs hype to make the public think it is of overriding
importance.

There are challenging unsolved problems which have nothing do with black holes and Planck scale unification. The culture of the field these days is,
unfortunately, that little else is of interest. When I was a student, most of the students were obsessed by such problems, but eventually faculty brought them back down to earth by showing them other things to do.

I am not disputing that quantum gravity and unification are important problems. They are, and I like to think about them too. But there are other interesting problems of physics which are also challenging and have a better chance of being tested experimentally. I don't think it will take any less brain-power to solve High-Tc
superconductivity, quark confinement or turbulence than to solve quantum gravity. Dark matter and dark energy may have nothing to do with Planck scale physics. Many of the people (like me) who do work in one or more these other areas are as smart as they come (unlike me).

In practice, some string theorists do look at things like AdS/CFT, which
may not be relevant experimentally, but has definitely advanced our field theoretic knowledge, and will probably do so for some time. I also am sympathetic to, but more dubious about AdS/QCD, which seems
to be another strong-coupling approach (we have been able to do strong-coupling calculations since Wilson's '74 paper. No one has
convinced me AdS/QCD is any better). This, however, is the minority
of string theorists.

Part of our job as scientists is to be scholars. That means we have to be
knowledgable about many things. We can argue all we like about which quantum gravity theory is best, or if we instead should go back to the drawing board. I can (and do) participate in such discussions with colleagues. But shouldn't we also think about other issues?

There was some famous quote about Academia being so vicious because
the stakes were so small. I am not finding this joke funny these days.

18. **Who**
August 7, 2006

In Peter Orland's second paragraph
http://www.math.columbia.edu/~woit/wordpress/?p=439#comment-14267 the question

What does Loop Quantum Gravity predict?
is asked rhetorically, as if the expected answer were "nothing". In some people's view it is not a rhetorical question.

There are a bunch of non-string QG approaches (often referred to under the heading of LQG because it's a familiar term) that predict various things which are testable. This has permitted or will permit some proposed models to be falsified. There are also some "generic" predictions shared by a broad class of QGs. This is discussed in http://arxiv.org/abs/hep-th/0605052

The above link is to a draft chapter of a forthcoming book
Approaches to Quantum Gravity – toward a new understanding of space, time, and matter, edited by D. Oriti, to be published by Cambridge University Press.

Another contribution to the same book has bearing on testable QG predictions. It is the draft chapter by Shahn Majid
http://arxiv.org/abs/hep-th/0604130

In his chapter, Majid says:
This is also the first noncommutative spacetime model with a genuine physical prediction[1], namely a variable speed of light (VSL). The NASA GLAST satellite to be launched in 2007 may among other things be able to test this prediction through a statistical analysis of gamma-ray bursts even in the worst case that we might expect for the parameter λ ~ 10-44 s (the Planck timescale).

19. **anon**
August 7, 2006

"NO theory of everything is going to do any better than string theory has… any serious attempt to deal with the Planck scale can't confront the world in the TeV range."

Just because strings have failed miserably, doesn't prove it is impossible for others. "Not Even Wrong (N.E.W.)" gives indirect tests such as getting the vacuum energy in supersymmetry (unification energy) to agree with empirical observaton.

String theory is apparently way out by an astronomical factor of 10^113 (N.E.W. page 179). Another empirical check is that according to unification theories you should be able to predict the way one fundamental force varies with collision energy, given measurements on how the other forces vary as a function of energy. This is a test since data are accurate withi about 3%. String theory fails here too (N.E.W. page 177) where the value of the SU(3) force predicted by SUSY using SU(2) and U(1) forces is higher than experimental data by 10-15%.

So there are a few indirect tests possible and it is conceivable that some other theory could make progress by correct agreement with these data where strings/SUSY can't. Another option is some theory which is so radical it may predict masses (Tony Smith being one example) and be checked experimentally that way.

20. **Peter Orland**
August 7, 2006

Who and anon,

It wasn't my purpose to put anyone on the defensive. That said, I don't find your arguments concerning expermental predictions any more convincing than the string theorists's.

If you love LQG or another approach (or even decide you want to work on strings!), do it with my blessing. I am just complaining that so many in our field think all life exists at the Planck scale.

21. **Who**
August 7, 2006

At least one important version of LQG risks falsification next year by astronomical observation—in my view the most promising spinfoam approach actually—if energy-dependence of the speed of light is not observed in gammaray bursts.

P.O. : *It wasn't my purpose to put anyone on the defensive. That said, I don't find your arguments concerning expermental predictions any more convincing than the string theorists's.*

…I am just complaining that so many in our field think all life exists at the Planck scale.

Be happy then. 🙂 You did not put anyone on the defensive, but merely showed your lack of familiarity with the subject! No one needs to provide arguments to "convince" you of QG testability, since one simply has to point to cases where non-string QG models **have already** been constrained or are **at risk of refutation** by having their predictions falsified empirically.

If it distresses you that so many have their attention focused at Planck scale, then here is some news to cheer you up—we aren't stuck down at Planck scale: non-string QG phenomenology has ample scope at the scale of practical near-term observation.

22. **Haelfix**
August 7, 2006

The Planck satellite could in principle pick up QG signatures, and its somewhat of an on going debate in the string theory community if it has the resolution to see Stringy effects or not.

So while its not a falsifiable prediction, if it does see something it would be wonderful for the entire field. If it doesnt, well it could mean a few things.

OTOH, With further theoretical refinement it could potentially be upgraded to falsifiable lvls, so keep that in mind. I believe people at Columbia are actually working on this as we speak, so perhaps Peter can ask his colleagues in the physics department what they think.

23. **Bee**
August 7, 2006

Hi Peter,

thanks for the link. I didn't comment very much on the 'physical' content of the book. I kind of expect that Lubos will take care of that… would be good if you had the time to write a sensible review on Lee's book as well. I'd really be interested in your opinion.

Btw, did you receive an offer from Lee's publisher to send you a copy of the book? I got a rather weird comment saying that she 'of course' did not ask you. No idea what that's supposed to mean.

Best, B.

24. **Michael Edwards**
August 7, 2006

Bee,

Just wanted you to know that some readers of your review got (and enjoyed) the Bigfoot / Big Five joke (and the big game icons) even if a certain person at Harvard didn't. "Female physics" my (big) foot.

Cheers,
– Michael

25. **Peter Woit**
August 7, 2006

Hi Bee,

Supposedly a copy of Lee's book is in the mail and I should see it soon. Of course I'll write something about it here after I've read it. I've heard from Lee quite a bit about the book, going back to when he first started working on it. No idea what his publisher's comment was about, perhaps they're a bit competitive with another publisher… But I think both Lee and I see the appearance of the two books around the same time as a good thing rather than a competition. Our points of view are in many ways complementary and the fact that we reach similar conclusions about string theory from different starting points reinforces what we each have to say.

Haelfix,

For the latest on possible imprints in the CMB, see Brian's talk at Strings 2006

http://strings06.itp.ac.cn/talk-files/bgreene.pdf

As far as I know, no one has ever made the claim that this can potentially falsify string theory. The size of effects coming from Planck scale physics is debatable, and depends on the string scale, which is not known. It has to be at large enough distances for you to have a chance to see something. I think you have to be quite an optimist to believe that they're going to be visible in the Planck satellite data. But it certainly would be very remarkable if such effects are seen. One thing to keep in mind is that these calculations typically don't actually involve string theory, more things like assuming that there is a minimal length, and QFT modes below that length are cutoff. So, these calculations are sometimes described as "string-inspired".

26. **Peter Orland**
August 9, 2006

Hi Peter,

You have just reiterated my point about no theory of quantum gravity being falsifiable. Finding a minimal length (a UV cut-off) proves everybody right and nobody wrong. If such a length isn't detected by
the observations, I won't be surprised if everyone finds a way to wiggle out of it and say "I knew it all the time".

Again, I appeal to those of you hotly debating Planck-scale issues to spend time thinking about at theoretical physics at distances above 10^-33 cm. If that isn't your main interest, try to make it your hobby.

Regards,
Peter O.

Nobel Prize Winning Orgiasts

August 2, 2006
Categories: Uncategorized

DealBreaker, which is described as "an online business tabloid and Wall Street gossip blog", has a story about supposed Jeffrey Epstein parties "in which Nobel prize winners and various wealthy folks were all surrounded by young, 'nude eastern european girls, frolicking with them, and then proceeding into one big orgy party.'" The story refers hopefully to the idea that this might have something to do with the physics symposium in St. Thomas funded and organized by Epstein that was mentioned here.

Update: When I wrote this blog posting last night, it was purely based on the posting at DealBreaker, which appeared to be a silly fantasy, based I assumed on some highly exaggerated version of something that happened involving consenting adults at an Epstein party. The idea of Gross-Wilczek-'t Hooft-Hawking participating in an orgy at the conference Epstein sponsored was obviously a joke, although perhaps a bit of a tasteless one. I was completely unaware of the serious accusations against Epstein and of the fact that charges have been filed against him involving his sexual behavior. Given this context which I didn't know about, the joke isn't funny.

Epstein has been exceptionally generous to the math and physics community over the years. He's entitled to the presumption of innocence and I don't think this blog is an appropriate place for discussion of his case. So I'm shutting off further comments on this posting.

Comments

1. **Chris Oakley**
   August 3, 2006

   Peter, this is one link I wish you had not provided.

   Firstly, I find that the image of Stephen Hawking being pleasured by a bevy of Eastern European beauties is one that I do not wish to contemplate.

   Secondly, the best I ever managed to do on the junket count – which was when I worked as a quant in the City of London – was a visit to a roped-off area at Royal Ascot paid for by a broker. It was awkward as we felt morally obliged to demonstrate (financially) macho credentials by placing large bets. Luckily one of my horses came in, otherwise it would have been expensive for me, too. A nice day out, but no hired help other than the driver, who was singularly unattractive, and a man.

2. **D R Lunsford**

   Would this be a good time to bring up the social habits of ancient greek mathematicial philosophers?

6. **Jeremy**
   August 3, 2006

   I would be happy to arrange even better parties for female physicists.

7. **Cynthia**
   August 3, 2006

   Peter,

   Extremely tasteless of you to create a post on this tabloid trash! Simply put, you appear to be trapped on one side of the mountain with zero classical energy. Perhaps quantum tunneling is the only way you can safely make it back to the other side…Good luck…

   Best wishes,
   Cynthia

8. **LostHisMarbles**
   August 3, 2006

   `nude eastern european girls' what's wrong with nude western european girls? Why bother to watch soap operas when one can tune in here? Why wasn't I invited?

9. **Jeremy**
   August 3, 2006

   LostHisMarbles: As one of the more popular theories go, the collapse of the Soviet Union was not due to an inability to keep up with the expensive technological innovation and economic power of the United States, but rather because they had long, cold winters, plentiful vodka, and some of the hottest women on the planet. Why fight a cold war?

10. **Jean-Paul**
August 3, 2006

Louise — there were also women scientists there — you can see Lisa Randall in Larry Krauss' photo gallery
http://www.phys.cwru.edu/events/grav_gallery.php
Why all these bright people need somebody to pay for their Carribean vacation? They can't afford it? What a filth…

11. **anon**
August 3, 2006

Stephen Hawking is a definite suspect. He has lapdances in Peter Stringfellow's nightclub, London, in 2003 and although most media tried to censor the news it leaked out. The Scotsman newspaper even reports the teenage lady's name:

"In July [2003] the Lucasian professor for Mathematics at Cambridge University and author of A Brief History of Time spent five hours at Peter Stringfellow's lapdance club, the Cabaret of Angels, enjoying the gyrations of a 19-year-old dancer called 'Tiger'."

– http://thescotsman.scotsman.com/s2.cfm?id=1080412003

The BBC website naturally reports that the experience was beneficial to Professor Hawking's health:

"… I heard a rumour that Man City have just signed the lapdance-loving Professor, Stephen Hawking …"

– http://www.bbc.co.uk/ouch/news/btn/timhoward.shtml

12. **Tommaso Dorigo**
August 3, 2006

Hey all,

first, please don't complain if Peter throws in some trivia about physicists in here. I, for one, couldn't help laughing out loud while reading the post and the comments that ensued.

Second, what's wrong with an orgy ? An orgy never, or very seldom, kills anybody. Come on. You straight thinkers go and deal with more pressing issues, such as corpses of children hit by bombs in Lebanon. These kinds of outraged reactions to anything that has to do with sex (a healthy activity in general, and like many other healthy activities at times misused) are ridiculous and only tag narrowmindedness and bigotry.

And personally, if I was confined in a wheelchair and decided that my life was still worth living, I would have no shame in contemplating the body of a young dancer on my lap if the chance arose. Give me a break.

Cheers,
T.

13. **LostHisMarbles**
August 3, 2006

Is a party in the Carribean cool if the girls are hot?

14. **Visitor**
August 3, 2006

It might turn out to be not as funny as it seems; a posting on Angry Physics lead me to Motl's post on his blog about it, http://motls.blogspot.com/2006/08/jeffrey-epstein-arrested.html and that lead to this link to the Harvard Crimson: http://www.thecrimson.com/article.aspx?ref=514049 . Motl says Epstein has been arrested but the Crimson might be confusing "getting arrested" and "being indicted" – their reportage is not exactly clear on this point.

15. **deloprator2000**
August 3, 2006

Hopefully Mr. Epstein checked that the "nude eastern european girls" were clean. I could just imagine t'Gooft and Stephen Hawking checking into an STD clinc, I wonder if his computer has the words for "it burns when I pee".

16. **LostHisMarbles**
August 3, 2006

It makes you wonder if `nude western european girls' might not have been a better choice.

17. **justin**
August 3, 2006

This is really despicable. Peter, spreading these kind of debauched unsubstantiated rumors is very hurtful. Even the suggestion that someone as thoughtful and respectful as t'Hooft would engage in this kind of activity is infuriating.

18. **Chris Oakley**
August 3, 2006

Proposal for career advancement for Louise:

• Send resume, etc. to Stephen Hawking. Make you include photographs, e.g. the one posted on 3rd August blog entry.
• Upon arrival in Cambridge attempt to get said Lucasian Professor of Mathematics into compromising situation (shouldn't be hard, on the basis of current evidence).
• Use opportunity to tamper with his speech synthesizer, to enable remote control from mobile phone.
• At public lecture given by said Lucasian Professor, make him announce arrival of most brilliant cosmologist ever, i.e. self, and the necessity of bestowing unlimited academic honours, etc.

19. **Aaron Sheldon**
August 3, 2006

So let me get this straight, an unknown predator can stock childern and your reaction would be shock and horror. But a billionaire preys on childern and its a good source for some B-sheet humor?

You ever see the consenquences of this kind of predatory behaviour first hand Peter?

This is nearly as low as Lubos.

It would be best to apologize and possibly remove this post.

20. **D R Lunsford**

Yet More Links

August 7, 2006
Categories: Uncategorized

A pretty random collection of interesting things I've noticed recently:

The Mathematical Institute at Oxford has a newsletter, and from the latest issue I learned that Quillen is retiring and that they're planning construction of a new building. There are quite a few other articles worth reading in the newsletter, including one about George Mackey.

There's a long interview with Lawrence Krauss on the web-site of the Cleveland Plain Dealer.

Jennifer Ouellette at Cocktail Party Physics has a nice posting about Sonya Kovalevsky.

The International Congress on Mathematical Physics (ICMP) is taking place in Rio this week, and here's the program. Victor Rivelles is blogging from the conference, and says that talks will be put online after the conference. I agree with his comments about Witten here.

Tommaso Dorigo has some excellent recent postings about new results from the Tevatron on the top quark mass and the search for the Higgs. It looks like the Tevatron's best bet for finding the Higgs (or for ruling it out in some mass range above the range already ruled out by LEP) will be if it's around 160 GeV.

Also from Fermilab, there are new results from MINOS on neutrino oscillations. Sometime soon MiniBoone is supposed to be "opening the box" on their blind analysis of the data and reporting results. Anyone know when?

Comments

1. **LostHisMarbles**
   August 8, 2006

   One needs more posts about top quarks mass (+decay modes, CKM matrix els?), Higgs searches, etc, although I suppose that's not really the brief of this blog. I'm not bothered by what anyone thinks of Witten. (I've met him. He's a nice guy. I had nothing to say to him and he had nothing to say to me and that was the end of our non-collaboration.)

   FWIW does anyone know what has become of the pentaquark?

2. **Brett**
   August 8, 2006

   The pentaquark does not appear to exist. Higher statistics measurements in pretty much all the channels where something was originally observed do not show its presence.

3. **D R Lunsford**
   August 8, 2006

   LHM, you know that story of Feynman and Dirac? as best I remember, when they met, Dirac was still in an eigenstate of taciturnity and Feynman in one of speechless Dirac worship*, so they didn't have much to say to each other:

   Feynman: "That was a beautiful equation!"

   Dirac: "It was a long time ago. Are you trying to get an equation?"

   Feynman: "I'm working on mesons. It is hard."

   Dirac: "One must try."

   -drl

   *Pauli – "There is no God, and Dirac is his prophet."

4. **LostHisMarbles**
   August 8, 2006

   First meeting between RPF and PAMD.

   F: I am Feynman (extends hand)

   D: I am Dirac (extends hand)

   pause

   F: (awed voice) It must have felt good to have invented that equation.

   D: But that was a long time ago. (Pause) What are you working on?

   F: Mesons.

   D: Are you trying to discover an equation for them?

   F: It is very hard.

   D: But one must try.

5. **G Jungman**
   August 8, 2006

   I disagree with the Rivelles characterization of mathematical physics as something that would have “no prediction that has been experimentaly verified yet”. How about the proof of the stability of matter? Or how about rigorous work on Navier-Stokes or in statistical mechanics? Let’s not smear mathematical physics by comparing it to string theory.

6. **Tommaso Dorigo**
   August 8, 2006

   Hi Peter,

   thanks for the link! You should do that more often, I got 200 visitors from your site today 🙂

   LostHisMarbles: I will try to post more about the most recent stuff going on with top quarks at the Tevatron in the future. There are some nice things coming up real soon in fact.

   Cheers all,
   T.

7. **LostHisMarbles**
   August 9, 2006

   Tommaso’s post about the Higgs searches contains a revealing statement ~ each one of the solid and dashed curves represents years of analysis. That’s precisely the problem. It takes YEARS of painstaking effort in expt HEP, to nail down the most basic parameters for a theory proposed 30 years ago, and meantime no expt evidence for anything beyond SM has surfaced. Theoretical HEP just can’t wait that long. There’s just no expt guide as to what lies beyond the SM (as opposed to the 1950’s when every new accelerator produced puzzles faster than theory could absorb.) One can speak of dark matter and dark energy etc (from cosmology), but these concepts are not amenable to precise lab measurements. Even if one makes hypotheses there’s no way to do a controlled expt to test the ideas. One can blame string theory for all sorts of ills, but the crisis (if I may call it that) is nobody’s fault.

   The real problem is to lose the commitment to press ahead with expt HEP (the ILC or muon collider or VLHC etc). One can say that ST is Not Even Wrong, but it is far worse to Not Even Try.

8. **QWERTY**
   August 9, 2006

   KOVALEVSKAYA WAS AMAZING, HER WORK ON THE EQUATIONS FOR A SPINNING TOP USING ELLIPTIC FUNCTIONS DEFINATELY DESERVES THE BORDINS PRIZE. I STARTED LEARNING ABOUT INTEGRIBLE SYSTEM BECAUSE OF THIS.

   IS IT TRUE THAT WEIERSTRASS WAS HOPELESSLY IN LOVE WITH HER? WHAT ABOUT MITTAG-LEFFLER?

   ALSO IN THE PAPER SHE SUBMITTED FOR THAT THERE IS A FAMOUS QUOATATION WHICH IS TRANSLATED AS
   “SAY WHAT YOU KNOW, DO WHAT YOU MUST, COME WHAT MAY”
   BUT DOES ANY BODY (HAHAHA THIS WAS MY JOKE) KNOW WHAT IT SAY IN THE ORINGAL FRENCH?

9. **Walt**
   August 9, 2006

   It always seemed to me that Kovalaskaya was the first person to discover that partial differential equations have characteristic directions, but I’ve never seen a definitive statement that this is so.

10. **Christine Dantas**
    August 11, 2006

    Dear Peter Woit,

    Sorry if this has been already posted:

    A ‘Landscape’ Too Far? Science 11 August 2006: Vol. 313. no. 5788, pp. 750 – 753.

    Christine

11. **Christine Dantas**
    August 11, 2006

    There is also this one:

    You are made of space-time.

    Christine

12. **John A**
    August 11, 2006

    Apologies Peter,

    I’ve no idea where to express this, but I feel I must express my emotions somewhere.

    You’ll remember that I expressed my (mild) criticisms about string theory on Lubos’ blog, only to have them deleted and Lubos asking me on Climate Audit not to “nuke” his blog with my comments.

    Well, speaking of nuking, Lubos allows this comment on his blog with nary a word of rebuke let alone deletion. I can only feel that Lubos is quite, quite mad and not merely a reactionary ideologue. Of course comparing Silvio Berlusconi, Italy’s most corrupt politician of the last twenty years, with Jesus Christ makes me wonder how shakey is Lubos’ grip on reality.

13. **Peter Woit**
August 11, 2006

John,

Lubos is nuts, and his commenters are mostly even crazier. The only reason he isn’t completely ignored by the entire world is that he’s the most prominent proponent of string theory on the web, and for some people, some how, this causes them to ignore his crackpotism and lunacy.

14. **John A**
August 12, 2006

Peter,

Thanks for that. I don’t want to derail your weblog with all things Lubos, so we’ll leave it at that. I’ve vented and got it out of my system.

Topology Board Resigns

August 10, 2006
Categories: Uncategorized

One of the most prestigious journals in mathematics is called Topology. It is based at Oxford, its first issue was in 1962 and it has published many of the most important papers in the the field of topology. Since 1994 it has been published by Elsevier, and many mathematicians have been concerned over the high price that Elsevier has been charging for the journal ($1665/year). Today the entire editorial board of the journal resigned, effective the end of the year. In their resignation letter, they stated:

…the Editors have been concerned about the price of Topology since Elsevier gained control of the journal in 1994. We believe that the price, in combination with Elsevier's policies for pricing mathematics journals more generally, has had a significant and damaging effect on Topology's reputation in the mathematical research community, and that this is likely to become increasingly serious and difficult, indeed impossible, to reverse in the the future.

A few years ago a group of editors from another Elsevier journal in the area of topology, Topology and its Applications, also resigned, for similar reasons. They founded the new journal Algebraic and Geometric Topology, a free online journal (that also has an annual printed volume). One of this group was my Columbia colleague Joan Birman, who wrote an article for the AMS Notices about the issues involved.

Berkeley topologist Rob Kirby, back in 1997, wrote a letter to Elsevier that also discusses these issues. John Baez has a web-page about this that he has just updated to include information about the Topology situation, including a copy of the resignation letter.

Comments

1. **LostHisMarbles**
   August 11, 2006

   Dear Resigning Editors,
   By all means start a new (free) online journal. But be prepared to bear the burden of administration by yourselves.

   LHM

2. **MathPhys**
   August 11, 2006

   If all parties involved are minimally smart, with minimal common sense, the administration of an online journal is minimal. A typical academic, teaching a typical calculus class for engineers, with a web page and all, has comparable admin work on his hands.

3. **fritz**
   August 11, 2006

   there is another quite interesting piece of info about elsevier,
   they are involved in arms trade. take a look at that:

   http://www.physics.carleton.ca/~logan/elsevier/

4. **LostHisMarbles**
   August 11, 2006

   I am not convinced that the administration of an online journal is minimal. Physical Review Special Topics is online-only and free (no page submission charges and no subscription fees), but it is part of a larger umbrella organization (in this case APS journals). An online journal is much more than maintaining a web page and some servers.

   But — give it a shot! ~ "Online Topology" why not? And certainly divorce the journal from arms sales.

   BTW many companies (e.g. Boeing) make both civilian and military products. Many universities (e.g. MIT) have contributed heavily to defense research. The military industrial complex reaches far and wide. Microwave ovens are one of their products. So are bell-bottoms.

5. **Kyle**
   August 11, 2006

   I'd love it if this resulted in (or was the result of) a growing trend away from Elsevier. It isn't necessary that something be free; merely reasonably priced would be an improvement.

6. **DMS**
   August 11, 2006

   I think it is about time. Some mathematics journals are highly overpriced.

   I must say one extremely positive contribution of string theory has been the arxiv, which has now been embraced by the rest of physics, and to a smaller extent other fields like mathematics. It is about time the mathematicians are as enthusiastic about it; many significant papers in mathematics are still not freely available. Perelman, and a recent long proof by Morgan and Tian are notable example. I doubt Perelman's institution can afford the subscription of many math journals.

   In particle physics, the highly rated JHEP is a recent online journal that started out free. My understanding is that the subscription rate is not high(in fact, free for developing countries…)..

7. **Chris Grant**
   August 11, 2006

   On bang-for-the-buck metrics like cost per page or cost per citation or cost per recent citation, Elsevier math journals are priced in line with the journals of other commercial publishers like Springer and Wiley (and substantially cheaper than Taylor & Francis).

8. **John Baez**

August 11, 2006

LostHisMarbles writes:

But — give it a shot! ~ "Online Topology" why not?

There's no need for the former editors of Topology to start a new free online journal. A bunch of former editors of Topology that resigned several years ago have already started two such journals: Geometry and Topology, and Algebraic and Geometric Topology!

These journals are quite successful, and they're endorsed by SPARC, the Scholarly Publishing and Academic Resource Coalition. This is an alliance battling the dysfunctionality of the current system where journals are run by big conglomerates like Reed-Elsevier, with academics doing most of the work and earning practically none of the money.

So, the editors of Topology that just resigned can join their old friends and help edit these new journals.

9. **Dick Thompson**
August 11, 2006

This is a fascinating social dynamic at work One of the mainstays of the "Gutenberg Galaxy" was its total incorporation as the atmosphere of the intelligensia. What does everybody think the foreseeable social consequences will be from this accelerated flight from the dead trees and their marketplace? More isolation from the hurly-burly that includes ambitious soap salesmen? But availability to anyone who can learn about it?

10. **Bob McNees**
August 11, 2006

When I was a grad student we had an informal rule: don't submit to Elsevier journals. This was part of a boycott that I was told a lot of groups quietly took part in. The reason was that the journals were overpriced. Almost embarrasingly so. I was lucky enough to attend a school that could afford them, but many universities outside the US can't. I don't really know if those informal boycotts had any impact. I doubt it. But I got in the habit of not submitting there, and I know a lot of people who do the same thing. Maybe, as events like these become better publicized, Elsevier will take notice and change their practices. I doubt that, too.

I think there are useful parallels with the way the recording industry works. For a long time the need for distribution insured that the middle man who could get content from the artists to the consumer had a place in the business model. Self-distribution was cost prohibitive, so artists didn't really have a choice.

We've already begun to see the breakdown of this model in the academic publishing industry, at least at the level of journals, as free peer-reviewed journals come online and gain credibility. In High Energy Theory, I think JHEP is regarded as highly as Nuclear Physics B, if not more so. And, as DMS says, there's the arXiv. It seems like suicide for companies like Elsevier to keep trying to squeeze income out of their outdated and unfair business model. But if they choose to do that instead of adapting, they deserve what they get,

11. **LostHisMarbles**
August 11, 2006

I was thinking that there is a parallel with what is happening in the music/film/recording industry.

John Baez mentions on his website (among other things) ~ publish in free online journals or **start your own**. The most obvious pitfall here is quality control. In the good old days, there were a (relatively) few prestigious journals, but of course subscriptions have become ever more expensive. One naturally searches for an alternative. But if anyone can start a journal, who is to validate the quality? Baez also points out (in a reply to a post by myself here) that there are organizations like SPARC. So — it falls to the mathematical community to organize its own (free) journals and maintain what amounts to an accreditation board for quality control.

I read much praise for the arXiv, but I note also that PW has had a long-running battle with it. The arXiv is useful, but is by its nature of uneven quality.

My guess is that eventually the responsiblity of maintaining these online journals will cause the task to be delegated to a few poeple (not unlike a democratic govt which chooses to use elected representatives), effectively a new species of publisher. We shall see how the dynamic of online publishing plays out.

It seems we are living out the ancient Chinese curse "may you live in interesting times".

12. **Moshe**
August 11, 2006

I think one should not care what Elsevier and others are doing, and have a campaign to change their business practices. Even if they had no profit margin at all, their journals would still be too expensive!

That business model – the print journal- is antiquated and has to go. The new business model- peer-reviewed refereed journals run and published online by acedemics- is much better (also cheaper). Given the clear advantages, I'd be surprised if there still are any print journals left, say 10-20 years from now.

As for the administrative duties, the point is that even in the Elsevier journals most of them are done by us (referees and editors), additional tasks (once the journal is up and running) are fairly minimal, since lots of things can be automated when they are done online.

13. **Jean-Paul**
August 11, 2006

I am not so sure about bright prospects of online publishing. There must be good reasons why paper survived several millenia. Online journals will have to face tough challenges when the evolution of operating systems accelerates. It is quite possible that a software engineer won't like "The Large N Limit of superconformal…" and sends it to a trash bin.
Furthermore, at least in HET, the quality of online journals is lower than the traditional ones. JHEP's quality is much below Nuclear Physics or Physics Letters. The refereeing process needs not only academics but also professional editors.
I was always wondering when looking at some JHEP papers: is there anybody there who corrects English grammar? When I referee a paper, I don't fix spelling error or rewrite franglaise.

14. **ObsessiveMathsFreak**
August 11, 2006

I'm a fairly recent graduate student. I've grown up with the internet and in a culture of easy access to information. I was initially very surprised and to be frank, offended when I learned of the current staus quo of artifical barriers in science imposed by publishers. Are you people mad? Why do you sign away your copyrights?

I don't subscribe to a single print journal, and every paper I have is electronic. In addition, aside from what my university has electronic access to, I don't have access to electronic journals either. I'm not alone amoung my age-peers, or even those a little older. People who've grown up with the internet would find this situation bemusing if it wasn't such an obstacle.

I don't consider myself at any great disadvantage. When I initially went to the (considerable) trouble of trying to obtain the complete list in a bibliography, I found that most of the papers weren't of much use to me anyway. Papers under a publishers lock and key really just aren't worth the time or effort you put into getting them. Especially the time.

The way I look at it, if you want a publisher to cut off access to your paper, that's fine. Just don't expect me to read it, much less cite it. I'm not going to jump through hoops for your sake, and I don't expect my university library to waste money doing so either.

15. **John Sidles**
    August 11, 2006

    See Donald Knuth's commentary:

    http://www-cs-faculty.stanford.edu/~knuth/joalet.pdf

16. **SteveM**
    August 11, 2006

    Elsevier are a bunch of gangsters. They also have a vast archive of important material going backs decades that is locked up and now costs a fortune to access. Total ripoff and downright criminal. This material collectively belongs to the scientific community–not them! I needed some old Physics Reports articles from the 70s and 80s and ended up going to the original authors to try and get copies. I succeeded: they were sympathetic and felt that their old articles should be easily available for free or low cost, but it was still a hassle. If Elsevier go under it will be great day.

17. **Michael Edwards**
    August 11, 2006

    In my opinion the only justification for the continued existence of publishers – as distinct from editors – is to support retail distribution of physical media. I really like the retail model; I like having two excellent new bookstores (one indy, one relatively benign chain) and two excellent used bookstores within walking distance. Ditto recorded music, video, newspapers and magazines. And out in the real world the way editors get paid is by publishers, who amortize off the cost over the market life of the media; it's a rare author who will personally finance the cost of turning a manuscript into something that someone else will want to read more than once. So when I want a book or a CD, I shell out.

    But I can't exactly go to the bookstore and browse the latest copies of Phys Rev and JAMS. And from what I hear their publishers don't finance editorial costs, academia collectively does (with the help of its government paymasters). So I don't care whether paper journals continue to exist, as long as the Library of Congress archives the online repositories and at least one nonprofit per continent will monitor the citation patterns and bind important-looking papers together for the benefit of libraries in internet-poor countries.

    Modern journals are such a mountain of crud anyway that literature searches have to be done via something like citebase, and I expect the PDF to be a click away. Of course, it's good to interact directly with individuals from time to time and ask them what papers they personally consider important and/or well written. But why do I need a filtering service that's anonymous to me, the journal reader, when I have the citation history at my fingertips? Most of us prefilter new papers by authorship (and to a lesser degree institutional affiliation) anyway, so we don't need journal acceptance as a criterion.

    Now what was it that anonymously refereed journals were for in the first place? Oh yes, to keep the quality up and the cronyism down, so that readers are occasionally exposed to new authors with something original to say. There may be fields in which the journals are still serving that function, even Elsevier's – for instance, Am J Otolaryngology looks to be justly top in its field, although I haven't actually read many articles out of it because I have to pay $30 a pop or shlep up to the University – but mathematical physics doesn't seem to be one of them.

    If I ever write something that I think belongs in the primary literature, I'll go around pounding on doors until I find a prominent researcher who's willing to endorse it as a coauthor and upload it to the arXiv. That's effectively how the system works now, and since I have no aptitude or desire for an academic career, sharing the credit will cost me nothing.

    Cheers,
    – Michael

18. **Chris Grant**
    August 11, 2006

    SteveM:

    According to WorldCat there are 460 libraries that subscribe to _Physics Reports_. Couldn't you just go to the library nearest you and photocopy the articles you want? Afraid that Elsevier's goons would kneecap you on the way?

19. **Brett**
    August 11, 2006

    The prices of some journals are ridiculous, but there isn't that much one can do about the situation. Nuclear Physics B is an important example. This is a very prestigious journal; the only ones in particle physics that are thought of more highly are Physical Review Letters, Physical Review D, and Physics Letters B. JHEP is a respected journal, but it is not in the same league–impact factors notwithstanding. This is not a commentary on the actual quality of what these journals publish, but rather on how they are perceived based on past history–and in the age of electronic publication, the past quality of a journal is actually much more important than the present.

    Nobody reads the print versions of journals any more, and many libraries have dropped the print versions entirely. (Nobody can sit in the library and leaf through Physical Review Letters any more, since the last time I checked, there wasn't a reasonable way to get a paper copy of only this journal.) The bound volumes get sent away to storage, since people can read years' worth of articles from any computer on campus. But with an electronic subscription, there is no backup if the subscription is later cancelled. You lose access to everything, so even if Nuclear Physics B stopped publishing good papers tomorrow, it would still be worth the $15,000 per year (or whatever it is now) to use the online archives.

    Moreover, to ask a young researcher not to publish in Nuclear Physics B is simply unfair. An established physicist may have the luxury of picking and choosing, but for somebody without tenure, choice of journal can be crucial. If you want to publish a longish paper in high energy theory, your meaningful choices are quite limited. If you can't get it into Physical Review D, the Nuclear Physics B is where you have to try next. Anything else is a big step down, and publishing in most lesser journals won't mean anything it all to a hiring or promotion committee.

20. **AnotherObsessiveMathsFreak**
August 11, 2006

Computer Science Theory literature history has had at least 2 similar drives:

1. Journal of Algorithms Resignation in Dec. 2003: [*John Sidles*' link] Prof. Knuth's commentary was after his resignation from the board.

2. Forty Editorial Board Members Resign from Kluwer's 'The Machine Learning Journal' in Oct 2001.

21. **ObsessiveMathsFreak**
August 11, 2006

> Couldn't you just go to the library nearest you and photocopy the articles you want?

That's illegal. It might sound harmless, but it is illegal in the same way that downloading an mp3 is illegal. Why should I have to break the law to get my hands on a paper?

> Afraid that Elsevier's goons would kneecap you on the way?

Aren't you? Elsevier will take their cue from the software and entertainment industries. Expect ever more stringent terms and conditions on inter-library loans in the future, as well as some strongarming of your local institution.

22. **Eugene Stefanovich**
August 11, 2006

ObsessiveMathsFreak:

The way I look at it, if you want a publisher to cut off access to your paper, that's fine. Just don't expect me to read it, much less cite it. I'm not going to jump through hoops for your sake, and I don't expect my university library to waste money doing so either.

With this attitude you only impair your own ability to do research, that's all. Access to journals is absolutely essential to scientific work. In my studies I had many instances when I found crucial pieces of information and insight in obscure and hard-to-find publications. I think it is very important to have access to a good library. If your library is not so rich, you can always use interlibrary loan. In old times people used to write each other postcards with reprint requests…

I totally agree that in the Internet age there is no excuse for scientists to pay huge money to the printing industry. They can manage the online publication process themselves. Peer review, editing, etc. is not that difficult and expensive to arrange. Expensive journals are doomed.

23. **Eugene Stefanovich**
August 11, 2006

Couldn't you just go to the library nearest you and photocopy the articles you want?

That's illegal. It might sound harmless, but it is illegal in the same way that downloading an mp3 is illegal. Why should I have to break the law to get my hands on a paper?

Making one copy of an article for your own scientific research is perfectly legal. The copyright law encourages you to do that.

24. **Michael Edwards**
August 11, 2006

Er, no. The 1976 US copyright law codified the judicially created "fair use" doctrine as an equitable defense against prosecution for copyright violation. The Berne Convention doesn't go nearly as far, and most jurisdictions around the world have much weaker "fair use" provisions (if any). "Making one copy of an article for your own scientific research" is by no means automatically fair use, and relying on the historical non-prosecution habits of academic publishers is a risky proposition even in the US. You might also read up on contributory infringement, for which libraries and even authors who encourage such a practice may be liable. Best to stick to e-prints.

Cheers,
– Michael

25. **SteveM**
August 11, 2006

Chris,
At the time, living out in the country, the nearest library with the journal was just way too far away. Besides, as Obsessivemathsfreak points out the photocopying and loan conditions have gotton more stringent anyway, and since I had graduated with a doctorate I would then have had to rejoin the library at quite a cost. Just all a big hassle when I feel I should be able to access and download old material via the internet at reasonable cost. Incidently, if you want to pay for an obscure old paper from Elsevier via credit card , and you are temporarily not affiliated with any institution, it will cost you anything from $70-$100.

26. **Former string theorist**
August 11, 2006

As managing editor for a moderatley priced journal, I would like to point out that the value added in the editorial process for a well-run journal is significant. Diligent work by referees and editors (working without compensation) often greatly improves the content of the papers, and a careful copyediting process helps these results to be communicated much more efficiently. It is true that a great many journals from commercial publishers are overpriced, and the tactics used by some publishers are indeed disreputable, but for a more reasonably priced journal, which can basically only sell to libraries, the profit margin is much less than you might imagine. I support the ideas behind free online journals, but traditional refereed journals have much more to offer than simply an officially sanctioned citation list.

27. **Chris Grant**
August 11, 2006

Michael wrote: "*Making one copy of an article for your own scientific research" is by no means automatically fair use*"

And it is by no means automatically violation of fair use. Practically nothing in the law is automatic.

and relying on the historical non-prosecution habits of academic publishers is a risky proposition even in the US.

Oh, Puh-leze. There's less chance of an academic researcher in the U.S. being found guilty of copyright violation for photocopying an article from a journal for him to refer to in his research than of you being struck by lightning. Feel free to stay in your Faraday cage if you wish, but don't be disappointed if the rest of us don't join you.

28. **Michael Edwards**
    August 11, 2006

    Like I wrote, "publishers – as distinct from editors". In disciplines in which there is no functioning market economy, where people write and referee and edit at their granting agency's expense, the rational choice of "publisher" is a laser printer under my desk.

    If you want to publish a journal, run it like The Economist – snappy, well written and edited, topical, priced for home subscription with Internet archive access thrown in – and cross-subsidize it from a research arm that sells in-depth analysis in book form at a price that the market will bear. That's how Springer used to be run, and that's why a working mathematician's bookcase is liberally sprinkled with gold.

    For better or for worse, publishing is just as subject to Gresham's Law as any other industry. Fiat currency and gold don't circulate interchangeably for long.

    Cheers,
    – Michael

29. **John Sidles**
    August 11, 2006

    No one has yet mentioned PLOS–these biologists and medical researchers are well-organized:

30. **Michael Edwards**
    August 11, 2006

    (This is off topic for Peter's blog, so I'll provide a reference and some analysis and leave it at that.)

    If you have the patience to read beyond the verdict into the judicial reasoning process, I recommend CCH Canadian Ltd. v. Law Society of Upper Canada, [2004]: http://www.canlii.org/ca/cas/scc/2004/2004scc13.html

    Canada has the most explicit and liberal statutory exception to copyright infringement for library research of any country I know of. The library's custom photocopying service didn't push its luck: according to the decision, "The Access Policy states that the Great Library will typically honour requests for a copy of one case, one article or one statutory reference." The library provides self-service photocopying facilities only subject to a disclaimer of responsibility for the legality of the users' actions.

    Yet this is a Supreme Court of Canada decision, which means that it wasn't settled by any lesser court to the satisfaction of its appellate reviewers. And it stops far short of a blanket authorization of the making of personal copies or the encouragement of such activities on the part of others.

    I live in the US, which has less liberal laws, a less liberal judiciary, and a system of public investment largely based on the fantasy that "intellectual property" is traded in capital markets rather than labor and services The trend towards judicial intolerance of contributory infringement is writ large in the Napster wars. I do not recommend to others that they photocopy copyright material without the publisher's permissions and would not advise librarians and authors to do so either.

    Cheers,
    – Michael

    Gresham's Law at work:

    http://www.msp.warwick.ac.uk/gt/gtp-subscription.html

32. **Chris Grant**
    August 11, 2006

    Many U.S. academic researchers have access to Lexis through their school libraries. In a few minutes you can look up numerous law review articles on Fair Use as it pertains to photocopying of an article from a journal by an academic researcher. You won't find a single one among that takes a position anywhere near Michael Edwards' uebercautiousness.

33. **Peter Woit**
    August 11, 2006

    Michael and others,

    Please do try to stick to the topic. Fair use is really a completely different issue, and it should be discussed not here, but on blogs run by people who know something about this.

34. **Georg**
    August 11, 2006

    No idea about the situation in the U.S., but in many countries (I know Germany, Canada and the UK, but I'm sure it can't be too different elsewhere) there is a contract between some agency set up by publishers' and writers' unions on the one hand, and libraries and/or photocopier manufacturers on the other, which specifically licenses the copying of (only) individual articles or chapters from library books and journals for non-commercial purposes. The libraries and/or photocopier manufacturers pay a flat fee, and the library users are on legally safe ground, as long as they obey the restrictions of the license, which is usually posted next to each photocopier.

35. **Michael Edwards**
    August 11, 2006

    Peter, I couldn't agree with you more.

Former string theorist, how do you keep yourself occupied mathematically now? Can you tell us about some contemporary mathematical physics that you consider promising?

36. **woit**
August 11, 2006

Uh, Michael, you seem to be missing my point about not using this forum to start up discussions unrelated to the postings…

37. **Michael Edwards**
August 11, 2006

Sorry, Peter. Wasn't clear to me that alternatives to string theory weren't on topic. I'll shut up now.

38. **John Baez**
August 12, 2006

Jean-Paul writes:

I am not so sure about bright prospects of online publishing. There must be good reasons why paper survived several millennia.

Yes: there weren't computers, and scribes kept recopying papyri as the old ones decayed. The oldest known bit of Euclid's Elements is a [page from an ancient garbage dump in the Egyptian town of Oxyrhynchus](). The oldest surviving *complete* copy dates back to only 888 AD. So, the business of needing to work to keep data available is not new; it's just speeding up.

39. **Juan R.**
August 12, 2006

1) The situation is science appears to me poor than in math.

2) Offer and demand, laws of market! Nobody really obligates to editors of the journals to subscribe publication of the journal with a commercial publisher, or not? If tomorrow we become editor of a journal we am not obligated to choose Elsevier as publisher. Would we? Still more surprising would be after publishing our journal via Elsevier we blame it by its prices.

3) About free.

Some journals are claimed free over (expensive economic publishers) but those free journals are being really supported via donations, societies fees, author or institutional charges, and others. SPARC requires fees to membership…

E.g. Baez [says]():

"Unsurprisingly, the response from publishers was chilly. As a result, the Public Library of Science is starting its own [free journals]() in biology and medicine, with the help of a 9 million dollar grant from the Gordon and Betty Moore Foundation."

The Plos journals are free to readers but are not to authors. Authors (or their institutions) are required to pay a fee for publication. For instance until $2500 for publishing on PloS biology. Some time ago, it was shown that model was not suitable for high-level journals even if many academicians claimed the contrary and signed a well-known letter. If I remember correctly some computations done suggested us that a similar model applied to Science journal would require of the order of $50,000 per article to authors. Moreover, a bit of common-sense and a bit of economic study suggested that PloS was not economically suitable. PloS people (i.e. academicians) blammed against publishers but reality was there and "academicians" were wrong in their economic analysis. PloS is [economicaly unsustainable]() except, maybe, as experiment. The increase of PloS fees has been of a 66% in only two years.

4) Baez suggestions.

1. Don't publish in overpriced journals.

Except often publishing in overpriced journals offer advantages in terms of C.V. publicity and career promotion.

2. Don't do free work for overpriced journals (like refereeing and editing).

And why do free work in other cases?

3. Put your articles on the arXiv before publishing them.

Except if publishing guidelines of journal you target impede this or if your field of interest is not supported by arxiv and others…

4. Only publish in journals that let you keep your articles on the arXiv.

I.e. in some cases you are claiming "do not publish". Arxiv-like model does not work for chemistry for instance; look fiasco of CPS.

5. Support free journals by publishing in them, refereeing for them, editing them… even starting your own!

Except that free journal are an academic version of the ".com" fiasco of some time ago. Before or after economic issues arise and most of the so-called free journals will disappear in a future as most of .com did. Then the problems of non continuity of information (one of reasons for classical printed academic journals) will arise.

6. Help make sure free journals and the arXiv stay free.

Well, this is idilic. Arxiv-like model failed in chemistry and in other fields.

5) MathPhys.

I do not know how many online journals you are managed/edited, but I would aknowledge you more information on how "the administration of an online journal is minimal. A typical academic, teaching a typical calculus class for engineers, with a web page and all, has comparable admin work on his hands." Since i know nobody being able to do that you are claiming.

6) DMS said:

"I must say one extremely positive contribution of string theory has been the arxiv, which has now been embraced by the rest of physics, and to a smaller extent other fields like mathematics."

Ehh!

7) About Journal's overprices

Hum, is only Elsevier overpriced?

If I want buy a 2006 6-pages article from a first-quality journal of chemistry managed by ACS I may pay around $33.

If I want buy a 1988 18-pages article on PRD

I may pay $23 to APS.

I would pay $30 to Nature for recent a single-page Essay on strings by Witten.

Etc.

8) About printed vs online

Moshe says that online journals are cheaper. Yes, but how many are? Eliminating color (is very expensive) is printing in paper so expensive? When i worked in a chemical Bulletin here in official Galicia society for chemists, i discovered that paper printing was not so expensive as i imagined and we worked a small 1000 copies bulletin (for 10000 was cheaper still the cost per page, since there is a fixed cost for printing anything from 1 to infinite copies).

Moreover, the no so large economic advantage of online journals over printed ones will disappear with the semantic web and full online academic articles. Today "online" journals are only pdf versions of printed ones, try to offer xml mathematics, text, and graphics and database files (e.g. chemistry or cristalographic data) into your online version… and we will sew how many online journals survive in near future.

Note: several online journals guided by academicians (e.g. some cited at this blog) are clearly of very low quality from a publisher's (and author) view.

9) SteveM said:

"Elsevier are a bunch of gangsters. They also have a vast archive of important material going backs decades that is locked up and now costs a fortune to access. Total ripoff and downright criminal. This material collectively belongs to the scientific community–not them! I needed some old Physics Reports articles from the 70s and 80s and ended up going to the original authors to try and get copies. I succeeded: they were sympathetic and felt that their old articles should be easily available for free or low cost, but it was still a hassle. If Elsevier go under it will be great day."

Read my comments about APS (American Physical Society) in point 7) above. Are APS gansters also because overpricing very old papers (even from 40s)?

Moreover, would we call ganster to a Nobel laureate giving talks to very very high cost? And that about professors. If H Psy = E Psy belongs to scientific community why do profesor earn money each time they explain the Schrodinger equation to their students?

Why would a publisher offer free or low cost to old articles but professor can earn lot of money for explaining (specially in summer courses) the very old F = ma to 15-year students? Just a thought!

10) Brett said,

"Nobody reads the print versions of journals any more, and many libraries have dropped the print versions entirely."

Then I am nobody. Also whne I go to the library to search literature and I see some academicians reading print versions they may be nobody.

Juan R.

40. **anon**
August 12, 2006

So Book 2 of Euclid's Elements ended up on an ancient garbage dump. Many of the theorems in it are tedious and boring …

41. **ObsessiveMathsFreak**
August 12, 2006

> With this attitude you only impair your own ability to do research, that's all. Access to journals is absolutely essential to scientific work.

Not really. Trying to get a hold of such journals would be a far greater impairment to my work. I honestly cannot see what is in these journals that is so essential and cannot be found elsewhere. 95% of what is in most journals is of little use to me, and I cannot justify the expense, both in time and resources, in obtaining the remaining 5%.

Here's a fact most people would agree with. The majority of scientific articles are poorly written and unelucidating, regardless of their actual content. For the most part, I'm paying for something someone has thrown out the door to notch up another mark on their publication/citation quota, not for a succint, well composed and presented exposition of the author's work. The Bogdonov's paper was not an anomaly, it was an inevitability.

Faced with this, if I can't get my hands on a paper that may or may not be of any use to me, I'll spend my time doing something more productive. Like research.

42. **anonymous**
August 13, 2006

does anybody know if there are potential legal problems in publishing articles on NPB+arXiv or PRD+arXiv?

43. **xxx**
August 13, 2006

maybe Peter allows me to point out a slighly different problem: I would like to keep in my laptop a copy of books about Quantum Field Theory, etc. The problem is that

one can only buy printed versions of these books.
One can download versions of main books for free from the web (it is easy, indicating that they are quite diffused): these versions are illegal and inefficient (no hyperlinks, etc), but they are the only electronic versions available on the market.

So I wonder why it is impossible to buy textbooks in electronic form: because publishers are stupid, or due to some better reason?

44. **John A**
August 13, 2006

You'd think that if an entire editorial board of topologists resigns, they send the resignation written on a Moebius strip stuffed in a Klein bottle….or something

45. **Chris Oakley**
August 14, 2006

> You'd think that if an entire editorial board of topologists resigns, they send the resignation written on a Moebius strip stuffed in a Klein bottle….or something

How do you know that this "entire editorial board" is not just one person following a closed timelike line?

46. **John A**
August 15, 2006

You got me Chris – unless of course there are an infinite set of Universes….

47. **h**
August 16, 2006

"I read much praise for the arXiv, but I note also that PW has had a long-running battle with it."

This is probably just in physics. Mathematics is much less political. I'm a young mathematician, and my viewpoint is that there's no life outside the arxiv. We have a pretty good library here, but I go there only like twice a year; the digital revolution is already here and there's much more to come… Also, there are already many retrodigitalization projects, and most of them are free (numdam.org is an excellent example). Google is scanning ALL the books ever written, etc…

"There must be good reasons why paper survived several millenia"

Yeah, as John Baez said it, there was no internet for several millenia 🙂 The only reason for the existence of printed journals today is inertia (and the greediness of the publishing companies). Quality control is an issue – I agree with 'Former string theorist' that the value added in the editorial process is significant -, so journals are important, but the media is not.

"That's illegal. It might sound harmless, but it is illegal in the same way that downloading an mp3 is illegal. Why should I have to break the law to get my hands on a paper?"

You must live in a different world 🙂 Photocopying a paper IS harmless (and probably legal too, considering that there's a flat copyright fee included in the price of the copy machines, in the price of the ink, and maybe even in the price of the paper; same for the harddisks, blank cds, etc). Also, stupid law is not here to comply with… I'm breaking the law several times in basically every minute of my life. I have like 100 scanned math books on my harddisk, and it would cost my ANNUAL income to buy them (yeah there's life outside the US) so I wouldn't buy them anyway; thus I'm not causing any harm to anybody (and yes, I have some original math books too, and I bought them when I was much more poorer)

A Counterexample to the Hodge Conjecture?

August 11, 2006
Categories: Uncategorized

A paper appeared last night on the arXiv by K.H. Kim and F.W. Roush entitled Counterexample to the Hodge Conjecture. The authors claim to construct an example using K3 surfaces for which the Hodge conjecture is false. If they're right about this, this would be very shocking, and I would guess that most experts will be very skeptical about the result. Most likely someone soon will find a problem with the argument, but if not there will be a lot of excitement.

The Hodge conjecture is one of the Clay Millenium prize problems, so if this paper is right, the authors may very well be entitled to $1 million. For more about what the Hodge conjecture says, see the slides or video of a popular lecture by Dan Freed, or the official statement of the problem due to Pierre Deligne.

Update: The authors have withdrawn their claim to have disproven the Hodge conjecture, acknowledging problems with their argument beginning in section 5 of the paper.

   August 11, 2006

   Nobody posted this breaking news to slashdot yet.

2. **mustang**
   August 12, 2006

   ya like slashdot care.

3. **Harry Walton**
   August 12, 2006

   Hello,

   A plea for help:

   For a long time now I've tried to view the videos on the Clay Millenium Prize website.

   I consistently get an error message from Real Player – the same thing happens with the Hodge Conjecture link you've provided here.

   I watch plenty of other video web feeds with no problem.

   I've emailed the Clay site – but no response.

   Is this a known problem or is it just a problem for me?

4. **nonblogger**
   August 12, 2006

   These two authors got a paper a few years ago in Ann. Math. where they disproved a fairly old conjecture in Dynamical Systems.
   http://www.arxiv.org/abs/math.DS/9907095

   So at least their new paper does deserve to be studied carefully.

5. **ObsessiveMathsFreak**
   August 12, 2006

   I don't see exactly why it would be so shocking. A lot of these conjectures seem to be held in far too high a regard. It seems a bit paradoxical that something someones was "unable" to prove should be named after them.

   It's like the Riemann Hypothesis. There could be some sort of fractal set of transcendental complex numbers with zeros somewhere in the (0,1) strip and we might never know. So if someone finally proves the danm thing false, why the surprise? The fact that you were unable to prove it true should be taken as a hint.

6. **D. Eppstein**
   August 12, 2006

   Harry: I am also unable to view the Freed video. RealPlayer tells me that it can't access the video data at the address given in the ram file.

7. **Johan Richter**
   August 12, 2006

   From the rules of the Clay Institute:

   "In the case of the P versus NP problem and the Navier-Stokes problem, the SAB will consider the award of the Millennium Prize for deciding the question in either direction. In the case of the other problems if a counterexample is proposed, the SAB will consider this counterexample after publication and the same two-year waiting period as for a proposed solution will apply. If, in the opinion of the SAB, the counterexample effectively resolves the problem then the SAB may recommend the award of the Prize. If the counterexample shows that the original problem survives after reformulation or elimination of some special case, then the SAB may recommend that a small prize be awarded to the author. The money for this prize will not be taken from the Millennium Prize Problem fund, but from other CMI funds. "

   Would the present paper effectively resolve the problem if correct?

8. **Davis**
   August 12, 2006

> If the counterexample shows that the original problem survives after reformulation…

The counterexample comes from taking certain products of varieties; as such, I wouldn't be surprised if this allowed for some sort of reformulation excluding such examples. That's assuming their argument is correct, of course.

9. **Thomas Mulligan**
   August 13, 2006

   If their proof is sound, it's a good year for mathematics: first Poincare, now Hodge. I agree with "ObsessiveMathsFreak" about the undue confidence people put in their assumed truth of these conjectures; history has demonstrated (Hilbert's Fourteenth, Euler's conjecture, etc.) that assumed elegance should not be used as warrant for believing a conjecture to be true. Furthermore, since the Hodge conjecture is so deeply buried in abstract, complicated, specialized mathematics, it's hard to believe our intuitions would be of any utility at all. . . .

10. **Scott Aaronson**
    August 13, 2006

    So if someone finally proves the danm thing false, why the surprise? The fact that you were unable to prove it true should be taken as a hint.

    Well, there's an empirical argument: in all the areas I'm familiar with, there have been far more conjectures that stayed open for years and were finally proved, than conjectures that stayed open for years and were finally disproved. Of course the latter often get a disproportionate amount of attention.

    Incidentally, does anyone know if there's a reasonably elementary statement that's equivalent to the Hodge conjecture? I read the links from this post and a few other articles, and I still don't understand what's being asked.

11. **jb**
    August 14, 2006

    I know many experts were not at all convinced the HC had to be true, unlike with, say, the Riemann Hypothesis.

    As for equivalent elementary statements, I'm not aware of any.

12. **Kea**
    August 14, 2006

    Peter

    How many Millenium problems are there left?

13. **Yatima**
    August 14, 2006

    I would guess 7:

    http://www.claymath.org/millennium/

    Remember…remember… how many positive and negative proofs there have been for P = NP ?

    (Peter – Great Book by the way; unfortunately my mathematical ability has suffered somewhat by years in ICT)

14. **Walt**
    August 14, 2006

    Kea: 5, assuming this holds up.

    Yatima: I assume you mean 6 (it seems pretty likely now that Poincare is settled).

    Scott: I don't think there is a more elementary formulation. Algebraic geometry has been around long enough that it's become incredibly technical.

    ObsessiveMathsFreak: The Hodge conjecture is unusual in that there is so little supporting evidence. The other conjectures, such as the Riemann hypothesis, have more supporting evidence. For example, it's numerically easy to compute zeroes of the zeta function, and the 2 billion that have been found all lie along the critical line.

15. **Andrew**
    August 14, 2006

    Actually, their paper doesn't look correct. They're talking about something well-known called the Kuga-Satake-Deligne correspondence, which is implied by the Hodge conjecture. The entire paper is poorly written, doesn't seem to even try to prove the theorems they state, it looks like they completely misinterpreted the actual statement of the correspondence. All of the correct parts of the paper are lifted almost verbatim from van Geemen's paper "Kuga-Satake Varieties and the Hodge Conjecture." One of them is a computer scientist, so it looks like some amateurs are just trying to have a good time proving some famous conjectures.

16. **werdna**
    August 14, 2006

    Who is the computer scientist, and how do you know that? Theoretical computer science can be highly mathematical, and some CS people are excellent mathematicians. In fact, the P=NP problem came from CS.

17. **not a Hodge Conjecture expert**
    August 14, 2006

    Scott,

    The Hodge Conjecture is widely considered to be the most difficult millennium problem to explain to the general public, but a watered down (probably inaccurate, definitely less general) elementary statement, understandable to most mathematicians and fancy theoretical physicists, might go something like this:

    On a complex algebraic variety, every homology class that could reasonably contain a subvariety does contain a subvariety.

The “could reasonably contain” part mostly refers to an obvious obstruction: The homology class of a complex subvariety must be Poincare dual to a differential form of type (p,p).

I’m not sure why the Hodge Conjecture is rarely dumbed down in this way. I think it’s because algebraic geometers don’t realize that no one else understands algebraic geometry.

18. **Davis**
August 14, 2006

werdna:

> some CS people are excellent mathematicians…

True, but very few CS people are good *algebraic geometers*. Algebraic geometry is a notoriously difficult field to jump into, and has only a handful of intersections with CS stuff (that I’m aware of).

not a Hodge Conjecture expert:

> I think it’s because algebraic geometers don’t realize that no one else understands algebraic geometry.

I think algebraic geometers just sort of gave up on developing explanations accessible to folks outside the field (which is unfortunate, in my opinion). These days it can be challenging to explain cutting-edge AG to other algebraic geometers, nevermind non-AGers.

19. **Scott Aaronson**
August 14, 2006

On a complex algebraic variety, every homology class that could reasonably contain a subvariety does contain a subvariety.

So, to translate into my doofus computer-scientist terms: We have a solution set, S, of some system of polynomial equations over the complex numbers. We’re interested in what sorts of subsets T of S can also arise as the solution set of a system of polynomial equations. In particular, what are the possible ways that T can embed into S topologically? How can T wrap around the holes of S, and so on? The Hodge conjecture basically says that T can embed into S in “every way that it reasonably could.”

Is that completely off-base? (I don’t doubt that the conjecture is more general, but I’d be happy to understand *any* nontrivial special case…)

20. **Walt**
August 14, 2006

It’s sort of dual to what you describe. Let’s say S has a hole. The Hodge conjecture answers the question, when is there a T that wraps around that hole?

21. **Lolo**
August 15, 2006

That’s strange to me what non-algebraic geometers think about algebraic geometry : Hodge conjecture is from far one of the easiest conjecture in algebraic geometry to state (and, apart from its deepness, I think this is one of the reasons why it was chosed for the millenium problems, so that non-algebraic geometers can understand its statement). It is very “concrete” compared to other conjectures in algebraic geometry and can be understood by any graduate strudent in algebraic geometry begining his PHD.

By “concrete” I mean : it deals with smooth projective algebraic varieties over C and their cohomology. Thus you can think of them as smooth complex manifolds and for the cohomology you can think of it as singular/De Rham cohomology. There’s no étale/cristalline/syntomic/motivic cohomology in this statement and it does not need the theory of schemes or algebraic stacks or stuff like that to be stated since you deal with smooth projective varieties over C, you can use your differential geometry intuition.

22. **Walt**
August 15, 2006

Lolo: What you say is false, unless you mean by “starting his Ph.D.” someone who’s already had two years of graduate work, including lots of differential geometry. I actually find schemes easier to understand than complex analytic varieties, but that’s probably just me.

23. **not a Hodge Conjecture expert**
August 15, 2006

Lolo, with apologies, I take back my unnecessarily snarky remark about algebraic geometers. According to the official Clay statement, the Hodge Conjecture states:

“On a projective non-singular algebraic variety over C, any Hodge class is a rational linear combination of classes cl(Z) of algebraic cycles,”

where a Hodge class is a rational homology class of type (p,p), and an algebraic cycle is just an algebraic subvariety.

This description is actually quite simple and really not that fancy. So I will make a different snarky remark: Algebraic geometers have intimidated the rest of us so much that we immediately assume that we can’t possibly know what they’re talking about, even when we can. 😉

More seriously, I guess the problem is that a lot of people know what (projective) varieties (over C) are, and a lot of people know what homology is, but many of these people don’t know enough complex geometry to understand the (p,p) part, I guess?

24. **Lolo**
August 16, 2006

I agree on your last remark : the difficulty is to define what means (p,p) in the conjecture.

But I agree with you on your remark before : for me it’s easier now to understand scheme theory….but it took me let’s say something like 4 years before I can say that; to understand the definition of a scheme and basic properties takes you a few months, but to be able to work with and manipulate them as if you had ever been living with took me a long time, which was not the case for differential manifolds where just after you’ve seen the definition your intuition is avaible (just because you’ve passed the preceding 4 years to work on differential calculus on open subsets of R and after R^n as an undergraduate, if you had done the same work
in commutative algebra and functors theory then scheme theory would be immediatly accessible to your intuition).

25. **Algebraic Geometry Joe**

August 16, 2006

I've also taken a look at this paper, and I can confirm that it is garbage. It looks like the Hodge conjecture still stands. The paper is full of mistakes and the authors don't really know what they're writing about. It's a shame that this made it onto the arxiv.

26. **Danny**
August 17, 2006

I agree that it looks like the authors don't know what they're talking about, but nothing in the paper is really new except the computer calculation and a statement about incompatible cup product structures. Otherwise it's a poorly written survey of other people's work. It's well known that the Hodge conjecture implies the Kuga-Satake-Deligne correspondence, and the relationship between this and the clifford algebra stuff in the paper. I don't think that the authors don't know much Hodge theory, but maybe these computer scientists just found something numerical implied by the Hodge conjecture and wrote a program to find a counterexample.

27. **Bromskloss**
August 17, 2006

Yep, I too have problems with the video. I use Media Player Classic.

28. **Speculator**
August 17, 2006

"Algebraic Geometry Joe" and "Danny":

Could you please indicate what did you found wrong in the preprint?

Since you state that "it is full of mistakes" this shouldn't be difficult.

For your information Kim and Roush are not "computer scientists". They did disprove a few years ago Williams conjecture in Symbolic Dynamics, the main outstanding problem in the field (published in Annals of Math in 1999). Their publication list exhibits a long track of "problem solving".

Maybe it is just that Algebraic Geometers are not that good at finding counterexamples?

29. **Algebraic Geometry Joe**
August 17, 2006

I should have been more precise in my critisism. Certainly, it is possible that the Hodge conjecture has been disproved. However, the paper is badly written – there are many examples of this. Finding problems in the logic of the paper is very difficult when it makes little sense except to those who wrote it.

Here's one possible problem, though: Proposition 5.1 assumes the existance of a small deformation of a k3 surface with a transcendental lattice of constant rank. I was under the impression that this is impossible. For example math.AG/0011258.

Having said this, whoever is clever enough to disprove the Hodge conjecture is also clever enough to write a paper that I find confusing. It'll be interesting to see what consensus appears.

30. **Speculator**
August 17, 2006

This sounds different from "…it is garabage…full of mistakes…".

Don't worry, there are such deformations.…just take the constant one…

Notice also that A=>B is still true if A is an empty condition…

31. **Clark**
August 18, 2006

I have to agree with "Algebraic Geometry Joe." It's at best very poorly written. Section 5 in particular (on which everything depends) doesn't make much sense to me.

But perhaps a more irritating problem with the paper is that in the proofs of the main results, the authors refer to propositions not contained within the paper, e.g., to "7.1," despite the fact that their paper only has 6 sections. There are at least 3 examples of this.

Certainly a more legible account would be helpful…

32. **Davis**
August 18, 2006

> Certainly a more legible account would be helpful…

Agreed. I tried to read it last night, and it's not clearly written at all. And the authors really need to learn to use LaTeX's theorem and proof environments.

33. **DA**
August 20, 2006

Hi Peter, You might remember me, we were Postdocs together
on West Coast years ago, I was the only algebraic geometer at the
time.…

I just thought I'd jump in to this discussion with a few comments. It would accurate to say Hodge suggested (rather than conjectured) various things in his 1950 ICM talk. Some of these thing are known to be false (e.g. a counter example to the Hodge conjecture for integer coefficients was found early on by Atiyah-Hirzebruch, later Grothendieck found a counterexample to the general Hodge conjecture in its original formulation).

So I wouldn't be altogether suprised if the Hodge conjecture in its present form were to fail also. But, unfortunately, this preprint seems pretty unclear in various places. For example, as people have pointed out here, prop 5.1 looks suspect. The statement itself is ambiguous, and the proof seems bogus. I don't want to dismiss this paper outright (they may be on to something), but this kind of thing doesn't inspire a lot of confidence.

34. **woit**
    August 20, 2006

    Hi DA,

    Of course I remember you, thanks a lot for the comment.

    I've also heard privately from other experts the same evaluation: prop. 5.1 may or may not be true, but the proof given doesn't work.

35. **hack**
    August 24, 2006

    What? They withdrew their paper just because one of the arguments is wrong? Culture shock.

String Phenomenology and the Landscape

August 11, 2006
Categories: Uncategorized

Science magazine this week has an article about the anthropic string theory landscape controversy, entitled A 'Landscape" Too Far, by Tom Siegfried. The only theorist quoted as opposing anthropic landscape arguments as not science is David Gross, although experimentalist Burton Richter's talk at SUSY 2006, and letter to the Times ("I can't understand why they don't take up something else — macrame, for example") are also quoted. Gross says that anthropic explanations are not science but "fun parlor games", that "they're not science in the usual sense of making predictions that can be tested to better and better precision over the years."

Quoted as strongly in favor of the anthropic landscape are Susskind, Linde and Polchinski (there's an extensive side article about Polchinski's conversion experience to the anthropic ideology). Sean Carroll and Frank Wilczek promote the idea of the multiverse as a new Copernican revolution, and Clifford Johnson defends anthropic landscape studies with:

It would be nice if we could explore some of those unpalatable ideas just in case that's the way nature chooses to go.

Clifford has a posting about this on his blog, where he has more to say about this. He seems to have decided to deal with the very uncomfortable position that the evidence and rules of logic put string theorists in by advocating ignoring logic, quoting Moshe Roszali approvingly about the desirability of being able to hold contradictory viewpoints simultaneously.

The Science article does get a very little bit into the crucial question that determines whether landscape studies are science or not: is there experimental evidence that can test the hypothesis? Andrei Linde objects to people who say this subject is not science with:

It's not an easy job to do, so if you don't want to do it, then don't do it. But don't say it's not science.

It's true that the anthropic landscape is incredibly complicated and difficult to do anything with, but I don't see how that fact is any kind of argument in favor of it being a science. Linde does claim that gravitational waves can be use to "verify anthropic predictions about the nature of spacetime curvature." I don't know exactly what that's about, presumably something to do with possible effects in the CMB due to our universe being born out of a bubble nucleation. If anyone knows of any precise "anthropic prediction" of this kind, I'd be interested to hear it. But, in any case, whether or not you can by observation see whether the universe arose in this way, I don't think Linde answers at all the objection that the string theory anthropic landscape is inherently unpredictive and thus not legitimate science.

The Science article also includes a heavily overhyped statement about the experimental support for inflation, describing the WMAP results as having "provided strong support for inflation's predictions."

For a much more serious discussion of whether the string theory landscape, anthropic or not, is inherently unpredictive, you can watch the video of a talk given yesterday at the KITP by Wati Taylor on String Vacua and the Quest for Predictions. This was the inaugural talk for the semester-long program on string theory phenomenology that will be taking place in Santa Barbara. The blurb for the program is a masterpiece of hype, telling us that string theory has "the potential to predict properties of superpartners that might be found at the Tevatron or LHC and provide new experimental tests and probes of the theory", something that I don't think any serious person actually believes these days.

Taylor's talk was quite remarkable, very explicitly going over exactly how bad the current situation is for efforts to get any prediction at all out of string theory. There was a lot of discussion with the audience, and much nervous laughter. Unfortunately I found some of Gross's comments hard to hear. Taylor explained that after spending ten years himself working on trying to better understand what string theory is (he worked in string field theory), he doesn't see any realistic prospects for significant progress on this problem during the next ten years. He listed the basic problems as the lack of a non-perturbative definition in anything but special, non-physical backgrounds, the inability to do even perturbative calculations in the kind of Ramond-Ramond backgrounds that people are using to stabilize moduli, and the lack of any definition of string theory when supersymmetry is broken by a positive CC, and thus the background is deSitter.

Discussing the landscape, he said that there was no evidence for a dynamical principle that would select the vacuum, with no hint at all of how such a thing would work, and that there is no known mechanism that would destabilize the known conjectured constructions of vacua. He goes on to ask "what can we do even if we don't know what we're talking about?"

He introduced his own current philosophy, which is that unless some dramatic new breakthrough comes along in string theory (which he didn't seem optimistic about), the only idea for getting a prediction out of string theory that is still conceivable is to look for strong correlations among standard model parameters in the landscape. He didn't even bother to mention the fashionable idea of a couple years ago that one could make predictions using statistics of vacua, that idea seems to be completely dead. He noted that as time goes on, people keep finding more and more constructions of vacua, and it now seems clear that there are so many of these that one can't use their hoped-for discrete nature to make predictions.

According to Taylor, the only possible hope for getting a prediction out of string theory is if one can show that, for all string vacua, there is some strong correlation between values of the low energy field theory parameters. If it turns out that (for example), for all string vacua the number of generations is always 3 when there is an SU(3) factor in the gauge group, then knowing about SU(3) predicts the number of generations. There's no known reason why anything like this should be true, and it sounds like pure wishful thinking to me, but I guess Taylor's point of view is that string theorists should be working harder on understanding the details of the landscape in the hope of finding such a thing, because it is the only hope for getting a prediction out of the theory, and thus justifying it as a science.

Taylor acknowledges that the state of affairs is that one can't do at all realistic calculations along these lines, but he has been doing some unrealistic ones with Michael Douglas. They've been looking for correlations between the size of the gauge group and the number of chiral generations in intersecting brane models. These are quite unrealistic, with no supersymmetry breaking and unstabilized moduli. In any case, their result is negative: even in this simplified, unrealistic context, they find no sizable correlations.

Given this start, it will be interesting to see how the participants manage to get through the semester without getting so depressed about prospects for string theory that they abandon it and go on to something else. One new feature of the program is that a wiki has been set up to allow for communication and discussion between the participants.

Comments

   August 11, 2006

   Peter, you are a moron with the intellect of an amoeba. The Anthropic Principle does make some sharp predictions.

   Okay, I admit, the most general statement is a tad of an exaggeration:
   "Why should we believe the universe is anthropic? Because if it weren't anthropic, we would not exist".

   But consider a slightly less general version:

“Why do String Theorist believe the universe is anthropic? Because if it weren’t anthropic, they would not exist.”

2. **Kea**
August 11, 2006

…and the lack of any definition of string theory when supersymmetry is broken by a positive CC, and thus the background is deSitter…

de Sitter…which is, er, cough, in agreement with Riofrio’s analysis of, for instance, the type IA supernovae data, and also with a simple interpretation of certain interesting background independent QG models for which we understand the derivation of classical gravity.

3. **Kea**

August 11, 2006

> de Sitter…which is, er, cough, in agreement with Riofrio’s analysis of, for instance, the type IA supernovae data, and also with a simple interpretation of certain interesting background independent QG models for which we understand the derivation of classical gravity.

Can you please provide a reference to a “background independent QG model” for which

A) we understand the derivation of classical gravity, by which I assume you mean the existence of a semiclassical limit

and

B) which leads to the appearance of de Sitter space?

I honestly don’t know what’s being referred to here, which is why I’m asking.

6. **Kea**
August 11, 2006

This paper is a good gateway into the literature on BF theory and its variants, in the context of de Sitter gravity.

7. **Anon**
August 11, 2006

I think Kea is talking about the Kodama State.

You can read all about why that’s nonsense in http://arxiv.org/abs/gr-qc/0306083 .

But perhaps she is talking about something else. Kea?

8. **Rickkkkkkk**
August 11, 2006

Man oh man, I’m so lucky to have spent almost no time at all to be this ignorant, if I had gone to school for 10 years or spent my career just to know the same amount of nothing at all, I’d be in even worse shape

9. **Lee Smolin**
August 12, 2006

Unfortunately it appers there is still misinformation circulating about the Kodama state in the Ashtekar formulation, which, not for the first time, has to be answered here. This is a subtle issue, still unresolved, which people who have not studied the actual literature often get wrong because their reasoning is based on incorrect analogies with Yang-Mills theory. There are also interesting recent developments.

-First, there can be no objection to its use as a semiclassical state as it IS the WKB state for (A)dS, as described in hep-th/0209079 and papers referenced there. This is the first way in which the situation in Yang-Mills and gravity are not analogous.

-There is an open issue of whether the Kodama state in the Ashtekar representation is normalizable as an exact wavefunction in the physical inner product. (One reason is that it is only an exacxt solution in one ordering of the Hamiltonian constraint, whicih may not be the physically correct ordering. If so, there are corrections which have not been so far computed to the exact wavefunctional. Witten’s paper is related to this, but does not resolve it, as it concerns a different theory-Yang-Mills. Witten’s objection does not apply directly to the Ashtekar formulation for reasons discussed in hep-th/030114 and it also does not apply to its use in expansions around BF theory I mention below developed in hep-th/0501191.

-The issue is resolved in cosmological reductions in which the vacuum energy is related to a physical degree of freedom so one can make a wavepacket in the cosmological constant. This resolves the problem in that context, as shown with Alexander and Malecki in hep-th/0309045.

-The question can be investigated in the linearized case and we did so with Freidel in hep-th/0310224. The Euclidean linearized Kodama state is delta functional normalizable. The Lorentzian one has unstable modes. These may be unphysical or they may just reflect an instability of deSitter spacetime.

-The Kodama state also appears in a different, recently introduced approach, in which GR is constructed by an expanding around an SO(5) BF theory, in hep-th/0501191 .That BF theory has a single bulk solution classically, which is (A)dS and a single bulk quantum state, which is related to Kodama. This may resolve the old issues about the Kodama state because it is a sensible state of BF (Indeed it’s the only bulk state of BF theory, work on this is in progress.

-There is also a recent proposal by Randono that extends the Kodama state to a space of physical states, which he argues are normalizable. See gr-qc/0504010 and papers in preparation by him about this.

Thanks,

Lee

I am not talking about *the* Kodama state. Note the emphasis.

11. **Kea**
August 12, 2006

Sorry, Lee, I just saw your post.

12. **Sean Carroll**
August 12, 2006

Really? I'm promoting the idea of the multiverse as a new Copernican revolution? That's news to me (although I don't have a subscription, so I can't read the article). Of course, I have been known to say that we have no reason to believe that the universe we don't see looks just like the universe we do see, out the edges of infinity — but that's pretty trivially true, I hope nobody would disagree with it. If that's a "Copernican Revolution," then so be it.

13. **Chris Oakley**
August 12, 2006

> Look on the bright side, Peter. Statistical analysis of the Landscape prepares PhD students for a career on Wall St.

Not really. Wall Street interviewers will in general find an applicant with a Ph.D. in a highly speculative subject less appealing than one with a Ph.D. in a hard science or mathematics.

14. **MathPhys**
August 12, 2006

But future stringy PhD's will know a lot more about data analysis, inference, sampling theory, etc, than PhD's who worked on, let's say, lattice gauge theory.

15. **woit**
August 12, 2006

Hi Sean, here's part of the section quoting you and Wilczek:

But, he says, the idea that the known universe is only a small part of something much bigger should not come as so much of a schock. "Again and again in the history of cosmology, we've been shown that the little pieces we've been looking at are not the whole story," Carroll says. At the time of the Copernican revolution, the supposed whole universe was just the solar system. But the sun eventually was revealed to be just one star in a vast galaxy, and in the 20th century, that galaxy became just one speck in space among billions and billions of others.

As Wilczek observes, the string landscape and the multiverse merely suggest that the same story is happening again. "This is going one step further," he says. "We should be used to it by now."

16. **Juan R.**
August 12, 2006

Sean Carroll said:

"Of course, I have been known to say that we have no reason to believe that the universe we don't see looks just like the universe we do see, out the edges of infinity — but that's pretty trivially true, I hope nobody would disagree with it. If that's a "Copernican Revolution," then so be it."

Well, may be "pretty trivially true" also that the universe we do not see belong to metaphysics.

Even there exist doubts that the study of the part of universe we can see (so-called observable universe) can be considered Science since not all of scientific method applies therein; e.g. crucial distinction between observation and experimentation.

String theorists, certain loop theorists and rest of fans would be valiant by recognizing that Landscape and those "novel" ideas (idea of a multiverse is not characteristics of 20th century, of course) and "revolutions" are just pure nonsense (of interest for philosophers and film makers of course) from a purely scientific point of view.

In the case of string theory, the anthropic attitude is just the proof that string theory is a fiasco as scientific discipline (how was pointed by several Nobel laureates: e.g. P.W. Anderson)

Juan R.

Center for CANONICAL |SCIENCE)

17. **Sean Carroll**
August 12, 2006

Okay, I'll happily stand by that quoted statement. I don't really think it's controversial.

18. **Matthew**
August 12, 2006

But future stringy PhD's will know a lot more about data analysis, inference, sampling theory, etc, than PhD's who worked on, let's say, lattice gauge theory.

Lattice gauge theory teaches you lots of those sorts of skills. Given that the primary tool is monte-carlo simulation. It's pretty good prep for "Wall street"

19. **ObsessiveMathsFreak**
August 12, 2006

> Okay, I'll happily stand by that quoted statement. I don't really think it's controversial.

You might not think so, but the reality is, you guys are starting to sound like the guy from timecube.com. This isn't ad hominim. You really are.

When Copernicus proposed the heliocentric model he did so only after years and years of careful observation and data aquisition. Kepler law's proposed his laws only after years of analysis of Brahe's data, which itself took decades to gather. The Cophenhagen interpretation was not simply thrown together from mathematical equations. It too was only reached after decades of experimental data that supported it. And finally the standard model was only proposed and accepted after countless meticulous and detailed experiments gathered vast amounts of cold hard data.

In light of this, when people deriving results from mathematical equations, using pertubation theory I might add, start declaring that a multiverse landscape exists and start making anthropic arguments about "why we are here", and all with no data of any kind whatsoever, it means you sound like the guy at timecube.com.

Science **is** the experiment. If you haven't got an experiment, you've just got a few mathematical symbols on paper. I'm a mathematician, but I know that without experimental confirmation, my equations and relations, no matter how beautiful, are just that. Equations and relations of mathematical constructs. And in light of this, without experiment, I would not be inclinded to go around making predictions about multiverses, landscapes or timecubes.

Get some data, then get back to us.

20. **D R Lunsford**
August 12, 2006

I can't help but see parallels with this nonsense and the twin monsters of postmodernism and neoconservatism. One should read John Dean's book "Conservatives without Conscience" – the arguments can be taken over directly and applied to "leading" (or should I say "fuehring") academics and their relation to science, rather than politics. The key point is the utter compulsion, among a large number of people, to follow – to be a follower of somebody, *anybody* who can assuage their fear. I consider string theory, the multiverse, etc. to be profoundly conservative ideas in a bizarre sense – because they seem to hearken back to an innocent time when Aristotle and the Pope decided how the world really worked. (Comparing the multiverse to the Copernican worldview is not only utter nonsense, it is just plain contemptible.)

-drl

21. **Who**
August 12, 2006

"Again and again in the history of cosmology, we've been shown that the little pieces we've been looking at are not the whole story," Carroll says.

22. **nigel cook**
August 12, 2006

"The Copenhagen interpretation was not simply thrown together from mathematical equations. It too was only reached after decades of experimental data that supported it. And finally the standard model was only proposed and accepted after countless meticulous and detailed experiments gathered vast amounts of cold hard data." – Obsessive Maths Freak

But the Copenhagen interpretation is an ad hoc philosophy not a mathematical prediction technique, and it doesn't make unique predictions that have been tested, so you can't lump it with the Standard Model that does make predictions, has been tested.

There is an industry within physics run by full time science fiction writers who do mathematical philosophy of physics part time, and after about 1916 that was what Bohr did. OK, he did some useful applied nuclear physics theory such as determining u235 is the fssioning nuclide in natural uranium, but he just sprouted content-less, ad hoc, abjectly speculative philosophy when writing about the nature of reality and the future of theoretical physics. He claimed the Copenhagen Interpretation in 1927 solved everything completely for all time by separating and so outlawing any progress understanding of how classical and quantum electrodynamics can be reconciled:

'… the view of the status of quantum mechanics which Bohr and Heisenberg defended – was, quite simply, that quantum mechanics was the last, the final, the never-to-be-surpassed revolution in physics … physics has reached the end of the road.' – Sir Karl Popper, Quantum Theory and the Schism in Physics, Rowman and Littlefield, NJ, 1982, p6.

'… the Heisenberg formulae can be most naturally interpreted as statistical scatter relations [between virtual particles in the quantum foam vacuum and real electrons, etc.], as I proposed [in the 1934 book 'The Logic of Scientific Discovery']. … There is, therefore, no reason whatever to accept either Heisenberg's or Bohr's subjectivist interpretation …' – Sir Karl R. Popper, Objective Knowledge, Oxford University Press, 1979, p. 303.

23. **andy**
August 12, 2006

When I was at Oxford Rudi Peierls told me [words perhaps slightly disremembered] "we theorists need experimental results. Otherwise we're only speculating."

There was more, over coffee and chocolate cake at Brown's, but that's the gist.

Pity that this lesson has been forgotten.

A.

24. **Chris W.**
August 12, 2006

Andy,

Indeed. Unlike Rudolph Peierls, some prominent (and not so prominent) members of the last two generations of theorists don't really give a shit. Knowing theory, and producing more theory for their students to master, is all they seem to care about. It's kind of like a defense contractor who produces some massive system that doesn't work, and then gets the government to write yet another contract to fix it, and so on…

Analogies with out-of-control software development projects seem most apposite.

There is one kind of theoretical activity that is absolutely essential, with or without experimental results, and that is careful and penetrating examination of *problem formulations*. To the extent that's happening at all these days, it's happening at the margins, and is being mostly ignored as mere "philosophy".

(Pardon the bile in these remarks. I'm a bit cranky right now.)

25. **Who**
August 12, 2006

(Pardon the bile in these remarks. I'm a bit cranky right now.)
You didn't sound cranky or bilious, Chris: the preceding post sounded reasonable to me—-comparisons seemed apt, fair and so on.

we wouldn't necessarily agree on other issues but what you say here strikes me as uncontroversial. "out of control software development project" says it well.

26. **Kea**
August 14, 2006

32. **L. Riofrio**
August 15, 2006

Kea and Chris, right on. Einstein said that the definition of insanity is trying something repeatedly and expecting a different result. We are seeing growing acceptance of approaches (LQG, Kodama states, and my little Type Ia contribution) with testable Results to satisfy MathFreak. The Copernican revolution was preceded by cosmologies held together by epicycles and imaginary energies. This is a very exciting time to be in science.

33. **Chris Oakley**
August 15, 2006

Hi Danny,

I do my best. Resorting to cheap humour is, as you will have seen, my usual strategy when I have nothing useful to say on the topic. The APL gibberish, though, comes from the heart having had to decode the incomprehensible scripts that the New York office used to write for valuing exotic interest-rate derivatives when I worked for UBS.

34. **John Rennie**
August 16, 2006

You seem very negative about Wati Taylor's talk, but it seems to me to be a valid program to pursue. If no correlations can be found then this is worth knowing, and worth the effort.

35. **Rickkkk**
August 17, 2006

Quote "It's true that nobody has any good idea of how to test string theory, but who's to say someone won't wake up tomorrow morning and think of one? The reason so many people keep working on it is that, whatever its flaws, the theory is still more promising than any other approach we have."

I'm so sick of seeing this type of logic that I believe anti-nausea medication will soon be in order. Sean happens to be the one saying it here, but my anger isn't directed toward him. It's more toward the "only game in town" people.

If the only game in town is crap, and the -best- explanation is crap, so what? Spending your time on crap because it's the best crap there is doesn't remove the fact that you're working on crap.

I'd propose that it's better to be doing nothing, than wasting one's time working feverishly on something wrong or not even wrong.

When I see this "if you've got a better explanation let's see it" rebuttal it seems to be begging for the answer "ANY explanation is better" especially a clearly wrong one. A vacuous, unpredictive body of complexity is clearly much worse than ANY other explanation. The aether, the book of Genesis, etc. are all better explanations than string theory….and this is the beauty of this blog….because at least they're wrong, which is much more than the yarners have going

36. **Rickkkk**
August 17, 2006

Addenda, I think it's best summed by this analogy I've thought of.

Even THE MOST complex and contrived search for food in an empty room is a bad thing. No matter how elegant or theatric or difficult the methods employed, even giving up and starving from the get-go is a better approach. Leaving the room and searching elsewhere is of course the brightest thing to do.

So "what's your better explanation?" It'd be almost impossible to find a worse one, even the spaghetti monster is better.

37. **Peter Woit**
August 17, 2006

John,

I think Taylor gives a reasonably accurate description of the state of affairs as regards the possibility of ever predicting anything using string theory. He argues that the only hope at this point is to find this kind of correlations, but acknowledges that realistic calculations are impossible (you can only calculate in special cases, in an unrealistic approximation, and are trying to say something about all string theory vacua when you only know about a set of measure zero of them).

If the only hope for your theory having even a very small amount of predictivity is a very unlikely one, and you have no way of ever even checking this very unlikely possibility, why don't you give up and do something else?

38. **Who**
August 17, 2006

which include a recent posting from N.E.W.

39. **Michael Edwards**
August 17, 2006

Trying to calculate things in string theory is like looking for your keys under the streetlamp in front of your house, even though you know perfectly well you dropped them on the next block where it's pitch dark. This is not always as stupid as it sounds. If you are accustomed to finding things exclusively by sight, then you need to train your sense of touch before you stand any chance of finding your keys by feeling around where you dropped them. Perhaps you should spend some time feeling around under the light so that you can distinguish an actual dropped object from the surrounding landscape.

QFT as it stands today is a keychain dropped in the dark – a morass of heuristic prescriptions developed one by one to relate a string of symbols we call a "model" to calculations that match the experiments we know how to set up. Most of the major advances in the state of the theory have simplified the model at the expense of an added heuristic. (The examples I have in mind, roughly in historical order: Lorentz invariance, canonical quantization, the spin-statistics theorem, adiabatic coupling at infinity, Wick rotation, Ward identities, dimensional regularization, CPT invariance, gauge invariance, renormalizability, BRST invariance. Some of these are rigorous mathematics in their own right, but in the QFT context they function as heuristics for the selection of acceptable models and their elaboration into computable integrals.)

It does not seem to be widely recognized that the BRST _transformation_ is a different sort of theoretical advance. Viewed from a geometric perspective, it relates several of these heuristics (canonical quantization, Ward identities, gauge invariance, renormalizability, BRST invariance) to one another, and connects all of them to the intrinsic geometry of fiber bundles. It comes tantalizingly close to explaining why the entire framework of "second quantization" works as a method of perturbative expansion, almost irrespective of the chosen model — as long as that model is expressible as a BRST invariant Lagrangian density. And more concretely, it explains why the Faddeev-Popov gauge fixing procedure results in (some) anomaly-free QCD calculations.

Unfortunately, this leaves quite a bit of unfinished business: the apparent flatness and Minkowski signature of the metric, the presence of Dirac fermions and the nature of the Grassmann algebra they inhabit, the Wick rotation prescription for propagators, the nature and empirical values of dimensionless coupling constants at Planck scale, and the origin of mass and its relationship to broken C, P, and T symmetries. This last is the only one that seems to be remotely within the reach of experiment. But the current state of QFT is that these bits of "unfinished business" are every bit as much part of the _model_ as the mix of gauge groups and representations.

To demand under such circumstances that mathematical physicists focus exclusively on making falsifiable predictions is to misunderstand the role of theory in scientific advance. It so happens that the last couple of theoretical advances in QFT showed up in phenomenology largely as relationships between the measured values of coupling constants and angles. The next one probably will not; in fact, it may not show up in phenomenology at all, if its principal contribution is to relate (say) Wick rotation to the fact that only left-handed fermions carry representations of the electroweak SU(2).

Nobel prizes may be reserved for “visible” progress (if Nature cooperates on schedule), but it is only fair to say that work on the foundations is science too. It is rarely realized except in hindsight that this sort of “non-falsifiable” advance can reshape the landscape of plausible models, ruling some out and suggesting others that could not have arisen under the previous framework of heuristics. Quantitative predictions may have to await the next theoretical advance after that – say, obtaining three families of SU(3) triplets and singlets as an effective theory for one SL(3,R) triplet+singlet, obtained in turn as the centralizer of the discrete time reversal symmetry within GL(4,R).

What does this have to do with string theory, you ask? There is no reason whatsoever to think that the universe we live in has a compact S^1 dimension, any more than there is a reason to think that magnets are made of little arrows with their tails nailed to a lattice and springs between their tips. But many important phenomena general to phase transitions in statistical mechanics are more tractable in the Ising model than elsewhere, shedding light on which approximation techniques and other heuristics will be needed to obtain valid results for more realistic models. As I understand it, string theory began as an effort to train mathematical physicists’ cohomological sense of touch, in the light of the (relatively) tractable mathematics surrounding the streetlamp of diffeomorphisms on S^1.

Even ten years ago, one could still reasonably hope for similar insight into QFT from studying the Nambu string action. Perhaps this hope is now extinguished in many observers, and in some ostensible practitioners it seems to have been replaced by the bravado born of despair. Yet even if string theory has produced little that I would call insight, some string theorists have – or at least some of those known to the public almost exclusively as string theorists. Obviously I have in mind Ed Witten here, one or two of whose contributions I understand well enough to call a genuine insight into what a keychain in the dark would feel like. A working physicist could probably name others.

Doubtless the “community” of string theorists includes a fair number of charlatans, thugs, and complacent riders on the academic gravy train. Perhaps the proportion of dubious characters is even higher than elsewhere in this imperfect world of ours. If so, and if the careerists crowd out or drive out those who march to a different drummer, and if you care about whether physics transcends the standard model in our lifetimes, then you ought to be outraged. Not because string theory can’t predict the mass of the Higgs boson, but because it’s time to admit that the landscape under this particular streetlight isn’t telling us much about what keychains do and don’t feel like.

Cheers,
– Michael

40. **John Rennie**
August 18, 2006

Peter,

It seems to me that the real criticisms of String Theory come down to it’s unfair(?) level of funding. If money were no issue few of us would worry what the String Theorists got up to in their corner. Suppose you’re the one holding the purse strings. Surely you’d put some of the money into String related research (though probably not at the current levels) and you’d need to decide where to focus the effort. Here you have Wati Taylor pursuing a program to decide in concrete terms whether further investment in landscape research is justified. That seems to me an excellent idea and one that I’d pay for, even if I suspect I already know the answer. Isn’t this sort of research badly needed in String Theory?

It would be interesting to see if any other areas of ST research could be addressed in a similar way i.e. rather than pursue details take a step back and ask some basic questions about the feasibility of the approach. We industrial scientists are pretty good at spotting where research programs are going to cost our shareholders too much, even though they might ultimately be successful. This doesn’t seem to happen in academia. Of course even in industry we fund some blue sky work because it doesn’t cost too much and occasionally something intersting happens.

John Rennie

41. **Peter Woit**
August 18, 2006

John,

The problem with string theory is not specifically the level of government research funding. It’s more that a young researcher interested in mathematical approaches to particle theory basically will find it extremely difficult to get a job and have a research career unless they decide to do string theory. This has more to do with the hiring decisions being made by theory groups than grant funding.

Taylor is not pursuing a program designed to decide where to focus effort. He’s put forward an argument that shows that what other people are doing can’t work, that the only remaining possibility he can think of doesn’t work either, but he intends to continue with it anyway. I don’t understand why this should be encouraged.

The Unraveling of String Theory

August 14, 2006
Categories: Not Even Wrong: The Book

This week's Time magazine has as article by Michael Lemonick about the controversy over string theory entitled [The Unraveling of String Theory](). It mentions my book and Lee Smolin's, and there's a quote from Sean Caroll. There's the usual hysterical reaction from Lubos Motl: [Time Magazine: Physics is a Sin]().

Lemonick more or less gets the story right, describing the reaction of string theory critics to the landscape as:

It was bad enough, they say, when string theorists treated nonbelievers as though they were a little slow-witted. Now, it seems, at least some superstring advocates are ready to abandon the essential definition of science itself on the basis that string theory is too important to be hampered by old-fashioned notions of experimental proof.

Lemonick describes both Smolin and me as having worked on string theory. Smolin has done original research on the subject, but I certainly haven't. I don't agree at all with Sean Carroll that the problem is that not enough string theorists "take the goal of connecting to experiment more seriously". Many of them take it very seriously, but the fact that it is a failed idea that doesn't work is what has forced them into the landscape nonsense and other complicated, unworkable schemes.

The quote from me is a little bit out of context. I was making the point that physicists necessarily often start out with speculative ideas that are "not even wrong", in the sense that they are so poorly understood that one can't tell where they will lead, and that this is very much legitimate science. On the other hand, once a theory is well enough understood to see that you can't use it to make predictions, if you keep pursuing it, you're not doing science anymore.

Update: Tomorrow on [Science Friday]() Ira Flatow will have Brian Greene and Lee Smolin on to discuss string theory. The September issues of Scientific American and Discover magazines have book reviews of Smolin's book and mine. The Discover review is by [Tim Folger]() and entitled [Tangled Up In Strings](); it begins:

In the mood for some no-holds-barred gossip or a nasty screed? Then start browsing the physics blogosphere, where some exceedingly smart people are spending an inordinate amount of time belittling one another. Alas, even this magazine has come under attack. The cause of all the commotion? Some nervy upstarts are questioning the validity of string theory, which is to physics what Wal-Mart is to retail: the biggest thing around, dominant for more than 20 years now. And woe unto anyone who doubts the orthodoxy….

The Scientific American review is by [George Johnson]() and entitled The Inelegant Universe. Johnson notes one of his pieces for the New York Times six years ago carries what he now sees as an embarassing headline: "Physicists Finally Find a Way to Test Superstring Theory" (in his defense, this kind of headline is still appearing in over-hyped articles about string theory to this day). I've been a bit surprised at how friendly a reception Smolin's book and mine have been getting so far from science writers. I think one reason for this is that many of them have repeatedly over the last twenty years written articles about string theory that repeat a lot of the hype promising imminent success in producing predictions. They've now been burned too many times and are very open to listening to the critics.

Comments

1. **Eric Dennis**
   August 14, 2006

   A new informal fallacy:

   Take a position P on some controversial issue. Infer an obvious absurdity A by combining P with other propositions made by an opponent, even though you are aware your opponent believes ~P. Conclude that your opponent is asserting A and is, therefore, an incompetent fool whose arguments may be safely ignored.

   This fallacy might be called "Lubosing the Question." Or perhaps "Affirming the Lubos."

2. **Dick Thompson**
   August 14, 2006

   How about "The law of the excluded Lubos"

3. **A Friend**
   August 14, 2006

   Peter,

   I question your commitment to science – and academic scholarship in general. You have the good fortune to be a staff member of a well-funded and recognized institution of higher-learning, yet you *waste* your whole damn time trying to argue about stuff that is – in the final analysis – unarguable from a scientific point of view. String theory this! String theory that! … WHO CARES!! Everyone with some objective thinking capacity knows that string theory is still in its infancy – if you consider it to be a valid program in fundamental physics at all. That being said, it would *seem* you have nothing original to contribute other than what you have been arguing for the past ump-teen months… that string theory is not "genuine science"; yeah! we get it! Now do you want to spend your time repeating the same old broken record again and again!… or have you spent that position of academic priviledge trying to persue worthwhile research?

   … if so, what?…

   It would seem – and I say this as a friend, not an opponent – that you really don't have much to contribute constructively to the academic landscape, and hence your real *research* agenda is to spend all your time trying to convince people like Lubos that he is wrong… What a waste of time and energy!

   Your Friend

4. **LostHisMarbles**
   August 14, 2006

   Just to be pedantic: " … both Smolin and I …"

   What is timescale (and manpower/personpower scale) on which one expects to see results?

   Expt HEP hasn't produced anything beyond the SM in 30 years. (The b, t quarks, W, Z bosons, tau lepton + neutrino all fit into SM.) The pentaquark wasn't really beyond SM but didn't pan out. Expt HEP consumes vastly more millions that all of ST (perhaps more in 1 year than all of ST in 30 years … even including the cost of Caribbean orgies with nude eastern European girls). Is it then not even wrong, time to try something else? Because basically that is the way expt HEP is heading … funding for ILC is by no means guaranteed. Attempts to develop new acceleration technologies haven't gone beyond tabletop models as of yet. What to do?

Complain about ST if it makes you feel better, but ST isn't the problem.

5. **Chris Oakley**
August 14, 2006

Peter,

I forgot to say – congratulations on getting a mention in *Time* magazine!

I am not sure I approve of a magazine being named after a dependent variable, but it is at least a dimension that is known to exist.

6. **Who**
August 14, 2006

Marbles, you appear to begrudge funds to experimental HEP because for 30 years its results fit the SM. That counts as a confirmation of the SM. Presumably 30 years ago people did not KNOW that the Standard Model was so good that it would turn out to fit everything they could observe at accelerators for the next few decades.

It's clear the experimentalists acquired information by their work, while for 30 years most of the theoreticians explored multidimensional blind alleys. I think this is primarily because the string majority has not focused on major nagging problems such as the positive cosmological constant, dark matter, and gravity without prior metric. On the contrary, it drained attention from persistent central questions.

Progress in these core areas (assimilating the positive CC, dark matter, geometry without prior metric) has instead been made by a relatively small number of non-string theorists, who have now reached the stage of making testable predictions.

I have to say the quote from Sean Carroll was a laugh—what he said at the end of the Time magazine article:
The reason so many people keep working on it is that, whatever its flaws, the theory is still more promising than any other approach we have."

Marbles you suggest saying
"…Lemonick describes both Smolin and I…"
which would be ungrammatical. To your proposed correction "pedantic" is an injustice to pedants.

7. **a**
August 14, 2006

I am happy that censorship could not prevent you from bringing our problems to a wide audience. But please make it clear that only about 1/3 of high energy physicists are string theorists: otherwise wrong messages like
Peter Woit = string theorist
in some future might become
physics = string theory = shit.

8. **LostHisMarbles**
August 14, 2006

I don't begrudge funding for expt HEP but I also don't begrudge funding for ST. 30 years ago nobody knew what HEP would produce (expt or theory). When one says the last 30 years have been a confirmation of the SM, that's the point — it takes years for expt to validate any theory.

By the early 1980's the SM had been put together and the W and Z discovered, the big buzzword was "unification". A falsifibale prediction of proton decay was made, tested, falsified. The most obvious logical direction for the theory to take had failed. And so people searched for other ideas.

The fact remains that today, funding for expt HEP is increasingly hard to come by. Even RHIC (an already built machine, admittedly nuclear phys not officially HEP), has uncertain funding. And over 30 years the majority of theory (i.e. ST) has gone down blind alleys. It's easy to blame ST, but I expect the problems of HEP theory to persist until accelerators produce data beyond SM.

Dark matter? How does one perform controlled expts with dark matter? (How does it behave as a function of pressure and temperature? How to do such an expt?) If you have falsifiable predictions, then set up an expt and do it. Don't blame ST.

9. **Who**
August 14, 2006

The "dark matter problem" is to understand galaxy rotation curves and similiar related things about gravity. A pragmatic empirical approach to it would be to do the experiment which Bekenstein proposed a recent paper in Physical Review D.

http://arxiv.org/abs/astro-ph/0602266
Phys.Rev. D73 (2006) 103513

Marbles your reaction illustrates one source of the difficulty in theoretical physics.

Dark matter? How does one perform controlled expts with dark matter? (How does it behave as a function of pressure and temperature? How to do such an expt?) If you have falsifiable predictions, then set up an expt and do it…

OK Marbles, here is the experiment. Bekenstein has proposed it and it could be set up with available (Lisa Pathfinder) components. But if you try to *matterize* galaxy rotation curves–in a kind of reflex reaction–then I think you take us back into the cul-de-sac.

10. **MathPhys**
August 14, 2006

1/3 of all theoretical high energy physicists are string theorists? Is that an accurate estimate?

11. **AnonyMoose**
August 14, 2006

Peter, the discouraging replies above are unfortunate, but never mind your naysayers! I think you are doing a great job.

Eric, I am not sure what you mean because I can not assess the sarcasm or lack thereof in your post. I am fairly sure that this *new* informal fallacy is not so new, I think you are referring to the strawman fallacy. Anyways I can not tell whether you are attributing this to Dr. Woit or to Lubos. Same with Dick Thompson. I don't mean to nitpick but some of us could use clarifications.

As for the critics, you who calls her/him self Peter's friend. I think Peter Woit is committed to the scientific pursuit. You might think it a waste of time and energy to attack string theory, but then you might believe string theory to be a fringe position. Unfortunately, though string theorists may be in the minority, they are a large minority, and very vocal for that matter. Dr. Woit is merely struggling to remove this metaphysical dogma from legitimate science. And LostHisMarbles, who says there is any one problem? The HEP might not give us further success, but I would not consider it a complete waste. The HEP gave us more than string theory.

And finally, Chris, Who, thank you for encouraging Dr. Woit in his quest. *Time* Magazine. At least that dimension exists! But maybe we're not so sure of that! I mean time might not be manifested geometrically (as a dimension) after all, given that some theories of quantum gravity use 4-D spacetime as a mathematical model for a dynamic 3-D universe. (The theory of relativity may need to be changed according to the data to quantize gravity.) Maybe this is ontological speculation, but we will never know until further revolutions in physics. And we will have no revolutions in physics without proper experimentation.

12. **CapitalistImperialistPig**
August 15, 2006

Scientific American has a George Johnson review of your book and Lee's in the September issue.

Congratulations!

13. **a**
August 15, 2006

MathPhys: my estimate 1/3 for the fraction of string theorists has one digit of accuracy. Do you think that 1/3 is too low or too high? It might be higher among US theorists, but my definition of "high energy physics" also includes japanese experimentalists, european phenomenologists…

14. **Nick**
August 15, 2006

The article is on the front page of digg.com _link_

15. **D R Lunsford**
August 15, 2006

Chris,

You can go to time.com or space.com for free, but you need an ID and password to get into spacetime.com – I smell a rat.

16. **Chris Oakley**
August 15, 2006

Maybe God has reserved it until we learn to understand relativity better.

17. **Comm.Math.Phys. Santa Claus**
August 15, 2006

Hi Everyone,

Merry Christmas! (albeit somewhat early). Go to Springer's "Comm. in Mathematical Physics" website:

http://www.springerlink.com/content/1432-0916/

and enjoy free downloading for 30-consecutive days!… starting today!

Ho ho ho… now to return to the North Pole and package all those gifts for children everywhere! Ho ho ho…

18. **LostHisMarbles**
August 15, 2006

Submit a proposed experiment to run on LISA Pathfinder, to validate Bekenstein idea.

Decades ago, expt HEP validated current theory (or discriminated between competing theories), and simultaneously produced new puzzles, e.g. in 1950s there were precision tests of renormalized QED and also discovery of strange particles, parity violation (tau-theta puzzle). In 1960s there was the finding of the predicted Omega-, also unpredicted discovery of CP violation. And so on. But now for many years there is only a validation of SM, but no discovery of new data beyond SM from the accelerators. As for the cosmological stuff, propose expts to test ideas like Bekenstein's and get on with it. Never mind what the ST camp does.

What is happening in HEP today is an accident of circumstance. Don't blame ST for any of it.

Mother Nature is fickle. La Donna e Mobile.

19. **Sailor Moon**
August 15, 2006

I hope that professors in hep-th like teaching; the public is catching on, and hep-th will be defunded, just like hep-ex.

20. **LostHisMarbles**
August 15, 2006

HEP-ex (I include RHIC) is suffering from defunding because it is expensive and does not produce "instant gratification" or visible profit ~ basically no new exciting discoveries for many years (and the legacy of Manhattan project has worn off). It's not the same as getting lost in mysticism/mumbo-jumbo a la ST. But even so:

a) I do not begrudge the funding of ST

b) If there are worthy problems like dark energy, and ideas like Bekenstein and MOND, and devices like LISA Pathfinder which might be able to test the ideas, then propose an expt. Never mind ST.
c) The problems of HEP-ex (or HEP) are not caused by ST.

21. **Sailor Moon**
    August 15, 2006

    Mr. Marbles:

    The situation in hep-th is caused by the problem in hep-ex, not the other way around.

    The Superconducting Super Collider was canceled in 1993 because Congress saw a poor “bang-per-buck” ratio for investments in accelerators. High energy particle physics based on accelerators is being shut down across the US; research is migrating to the EU and and China. The US ~might~ get a linear collider in 2018.

    Yes, exciting things are happening in experimental neutrino physics, but the theory for that was done 20-30 years ago. We know that matrix elements off the diagonal aren’t zero… People have speculated that that might be the case for years.

    You might not begrudge the money that goes to ST, but remember that string theorists have to convince ~somebody~ to pay the bills. They’re highly productive at filling up pages in the Physical Review, but do they have anything useful to say about the universe we live in? Or rather, would those dollars accomplish more if we spent them on nanotechology, bioinformatics, or any of the other glamour fields that are an increasing priority at today’s research University.

22. **LostHisMarbles**
    August 15, 2006

    Sailor Moon: Indeed the problems of hep-th derive from those of hep-ex. I have said so from the beginning.
    It is an accident of circumstance in hep-ex that no new physics beyond SM has been found for 30 years. But ST is not to blame for that.

    So ST fills up pages in Phys Rev and takes funding. It is always a matter of value judgement as to where the money could be better spent. Nanotechnology etc can survive just fine on their own merits. You think ST should be defunded? Others think hep-ex should be defunded (as was the case with the SSC). Hep-ex deserves its funding, but it is a hard case to make without fresh discoveries, (as I say, an accident of circumstance). Who decides what is worthy to pursue?

    Do NOT make the fundamental mistake of thinking that if ST is defunded, that the money will go to “more deserving” fields. When the SSC was cancelled, some condensed matter people thought that the money would go to their field. It did not. Instead there was a general cutback in science funding. Basically, “if hep-ex can tolerate an $8B cut, then other fields of physics (science?) can also learn to make a sacrifice.”

    Funding is not a zero-sum game. The research money can simply disappear.

23. **Sailor Moon**
    August 15, 2006

    Yes, research money can disappear. And it very well may.

    The long term economic situation in the US is not good. US government, corporations and households have been able to spend beyond their means because the dollar is the international standard currency; the US can print dollars and trade them for oil, dvd players and sneakers. The picture won’t be pretty when boomers leave the workforce.

    Yes, what the US spends for the Iraq War in a year could pay for decades of science, but it’s not clear that basic science gives as good a return on investment as it once did. Before the 20th century, people had no idea what matter was, what life was, or how the brain works.

    There certainly are things to learn, but there may never be scientific breakthroughs as profound as relativity, quantum electrodynamics, or the discovery of the double helix. Scientists can fill journals from here until the end of civilization, but that doesn’t mean that funding agencies will care.

24. **LostHisMarbles**
    August 15, 2006

    Sailor Moon, I will have to leave it to PW to figure out the fundamental point of your post. I really have lost all my marbles.

    I merely make the point that defunding ST will not improve matters for other branches of hep-th. ST may be mysticism/dogma/etc, not science as one would like to define it, but that is neither here nor there. Researchers in other fields (CC, dark energy, etc) will have to make the case for funding on their own merits.

25. **D R Lunsford**
    August 15, 2006

    S&M,

    That’s what they said in the 1890s about the incomprehensible data of spectroscopy. I think big progress is right around the corner. In fact I know it is.

    -drl

26. **LostHisMarbles**
    August 15, 2006

    I do hope that big progress is right around the corner. I put it to you all that the way to find it is to go out and explore. Make models, formulate hypotheses, propose expts and carry them out. And **do this all on your own merits**. If ST contributes nothing to the effort, leave it be.

27. **John A**
    August 15, 2006

    Chris Oakley:

    > I am not sure I approve of a magazine being named after a dependent variable, but it is at least a dimension that is known to exist.

    …except in the realm of the quantum where the magazine de-materializes.

Yes. I am a geek.

28. **Antonio G Zenteno**
August 15, 2006

Sorry for changing the theme but it is very sad for me to notice the recent attack to this blog. Some minutes ago this blog was transformed with the typical sense of humor of this residual combination of irony with stupidity that many hackers have. In other circumstances this attacks are very less than superficial stupid games. But this blog is also a very notorious example of free-speech that is so fundamental for this communication system to survive.

So i need to say that i am in complete disagreement with this ugly way of showing the deep trash of our society that can not support the minimal requirement of left the people opinions alive even if you does not agree with them.

AGZ

29. **Ponderer of Things**
August 15, 2006

Hmm… Not a good week for Lubos.

The same issue of Times that declares String Theory "not even wrong" (hmm, I wonder where they got that quote? Is Pauli that known among Times reporters? 🙂) also featured a cover story titled "Who needs Harvard?"

Double-whammy for poor Lubos…

30. **D R Lunsford**
August 15, 2006

PoT,

Yes, I also saw that, and was reminded of the decline of the NY Times itself.

-drl

31. **Kea**
August 15, 2006

Peter

I wasn't joking.

32. **woit**
August 15, 2006

Kea,
Please stick to the topic of the posting.

Antonio,
I suspect you followed Lubos's link to this blog. The blog is fine, his link sends it through a site that translates it to "jive".

Ponderer + DRL,

Time magazine is not at all the same thing as the Times, either London or NY.

33. **Ponderer of Things**
August 15, 2006

Oops, I meant to say "Time", not sure why I said Times.
I have magazine sitting right in front of me, sorry for confusing you, DRL.

So, if a similar article is also featured in "Space" magazine, how many dimensions do string theorists have left? Is it 10-4=6 or 11-4=7?
🙂

34. **Antonio G Zenteno**
August 15, 2006

Peter,

Yes, this was the case. So my position and the interlocutor of my message are completely clear.

Thanks

35. **Kea**
August 15, 2006

Is it 10 – 4 = 6 or 11 – 4 = 7?

The 6 comes from the dimensionality (over R) of the complex moduli of the 6-punctured sphere.

36. **D R Lunsford**
August 15, 2006

Peter,

Yes that is true, I read the thing about Harvard in Time Magazine and was immediately reminded of the decline of the New York Times as a force for democracy, just as Harvard had been for truth (veritas). That Harvard would run off Glashow and hire Motl says everything. He's the Jayson Blair of matter.

-drl

37. **z3**
August 15, 2006

Scientific American Sept issue carries George Johnson's sympathetic review of Lee's and Peter's upcoming books. The review is titled "the Inelegant Universe", and made me laugh with its comparison of string theory papers to the robotic essay generator at http://www.elsewhere.org/pomo, which randomly produces a different paper every time you reload.

George now finds his own headline from the late 90s – "Physicists Finally Find a Way to Test Superstring Theory" – to be embarrassing. There is also a Burton Richter mention, as well as Hawking's quote from Beijing.

38. **Heinz Neumaier**
August 16, 2006

The ancient greeks said that a man is a man when he shows four virtues: justice, courage, measure and wisdom. In this discussion, justice is to say that what cannot be checked is not science; courage is to say this out loud despite the critics, measure is not to denigrate the opponents more than (or even as much as) they do with you, and wisdom is not to be led to embrace other issues. In contrast to many of his opponents, Peter is not only right, he is also a great man. And he is an example to others.

Peter, go on! What you do is needed in this world.

Heinz

39. **Jonathan Vos Post**
August 16, 2006

Perhaps the fraction of Physicists indulging in String Theory is 1 / pi?

Or maybe 1 / d where d is the number of actual spacial dimensions? In that case, if they are right, the percentage of them decreases…

Congratulations in any case for the Time Magazine mention. All I've ever had there was a Letter to the Editor.

40. **JoAnne**
August 16, 2006

In two years, we will have 1-2 inverse femptobarns of LHC data. In 3 years we will have 10-20 inverse femptobarns. I predict that at that point, nobody will be talking about string theory anymore. As pointed out above, we have been deprived of data at the TeV scale for a decade now (due to the untimely and unfortunate demise of the SSC) and this has hurt us all tremondously.

If the worst case scenario plays out, and the LHC discovers nothing, then that is the end of particle physics as we know it. And that includes string theory. They may think they are immune, but they are not – they will fall due to lack of funding with the rest of us.

41. **String Theorist**
August 16, 2006

JoAnne is mostly correct, but tenure is tenure, and we will write the history of theoretical physics, because nobody is better qualified to understand it than us.

42. **D R Lunsford**
August 16, 2006

JoAnne said:

If the worst case scenario plays out, and the LHC discovers nothing, then that is the end of particle physics as we know it.

I completely disagree with this pessimism. This is the mindset that created the monster of string theory to begin with. One never knows when a new idea will show up. The key point is to get a theoretrical explanation of electroweak symmetry breaking. Quantum gravity is a side issue in comparison. This explanation is not at hand, and an accelerator around the girdle of the Earth would not provide it. It has to come from someone's head. Prediction: The Higgs will not be found. That will be the great result of LHC that will set people thinking again. The answer will come out of neutrino physics.

My worry is that the data will be cooked by unscrupulous theory groups or simply misunderstood, as happened recently with WMAP 3 and Cooperstock-Tieu, respectively. The real damage done by string theory is the corrosive effect it has on scientific integrity in general.

We need more historians and fewer geniuses.

-drl

43. **Kea**
August 16, 2006

Prediction: The Higgs will not be found.

You can say that again! Can you repost those neutrino masses, Peter? I wasn't joking.

44. **LostHisMarbles**
August 16, 2006

I think the only particle to date which was misunderstood is the muon. But possibly the data could be "cooked". Find a bump, proclaim the Higgs. Does anyone recall the zeta 8.3 GeV ~ circa 1985? It was found by the Crystal Ball collaboration, promptly proclaimed to be the Higgs (the mass of 8.3 GeV didn't bother anyone) — I think some people claimed it was supersymmetry — and it was then undiscovered in a second high statistics run and never seen again.

I hope the LHC finds three bumps, the Higgs of the SM (boring), the Higgs of supersymmetry (hah!), and the Higgs scratch-your-head "who ordered that"?

45. **D R Lunsford**
August 16, 2006

LHM,

You have a way with words 🙂

Remember the magnetic monopole? 1984 I think..I was a rosy-cheeked deluded youngster and was sure it was real 🙂

Do you do online discussions anywhere? I'd like to hear your rationale for supersymmetry.

-drl

46. **King Ray**
August 16, 2006

As for string theorists, how many years do they have to wander in the wilderness before they realize they're lost? Looks like about 40…

47. **LostHisMarbles**
August 16, 2006

DRL- thanks for the compliment 🙂

Callan-Rubakov monopole ~ 1984 as I recall, catalysis of fusion (?) based on SU(2) group, but the effect does not exist in SU(5), wich was the GUT of the time.

I have no rationale for supersymmetry. I merely threw that in to be a troublemaker. I should point out that eminent physicists like Glashow (not an ST person) expounded total nonsense about the zeta. See

http://www.slac.stanford.edu/spires/find/hep/www?fin+j+PHLTA,B145,302
doi:10.1016/0370-2693(84)90359-9

Georgi et al suggested it as the lightest of a three-Higgs doublet no less
http://adsabs.harvard.edu/abs/1985NuPhB.253..205S
doi:10.1016/0550-3213(85)90527-9

I am sorry to disappoint you, but I do not do online discussions. I was looking for a reference to the "not even wrong" quote by Pauli, I stumbled across this blog, and though I realize it may be ego-deflating to PW, the fact that I am foolish enough to post anything here merely indicates that I have nothing better to do.

I suppose I disagree fundamentally with much of the philosophy expounded here. I have no great faith in ST, but I do not begrudge the funding of ST. I couldn't care less about the unravelling of any strings. The following statements may sound contradictory, but they are not mutually exclusive

a) ST diverts scarce funds from other branches of hep-th
b) Defunding ST will not make extra dollars available to non-ST research.

If anyone has worthy ideas and testable predictions, suggestions for expts, you will have to procure the funding on your own merits.

48. **Chris Oakley**
August 16, 2006

LHM,

If you think that the continuing belief that the universe must be 10-dimensional, supersymmetric and stringy does not hamper alternative ideas about the way the universe might possibly work, then you are quite wrong. This lunatic and chronic belief has up till now made it impossible for non-believers to get a word in edgeways. And if dissenters are totally ignored, then what chance do they have of getting academic jobs?

49. **LostHisMarbles**
August 16, 2006

The non-believers will have to succeed on their own merits.

50. **Thomas Larsson**
August 16, 2006

LHM, funding envy is not really at the heart of string theory critique, nor is proposing a better alternative necessary (although I have one 🙂) . Criticizing string theory is really a moral imperative. This was best formulated by string theory ex-star Dan Friedan: "recognizing failure is an essential part of the scientific ethos". If string theorists don't recognize that their theory has failed, others will. This is inevitable and long overdue.

51. **L. Riofrio**
August 16, 2006

Chris, Kea and DRL are right. Without elaboration, may I say that there are more fruitful avenues of research than are currently being funded.

52. **LostHisMarbles**
August 16, 2006

TL – Moral imperative? … if you say so.
"… nor is proposing a better alternative necessary … " — oh dear. Surely proposing a better alternative is the whole point? So what if ST is doing a bad job? Can you do a better job?

Groups or cults or whatever, which attempt to stifle debate and drown out alternatives have historically never succeeded. The truth always wins out. But that truth will some in the form of expt data. One theory never wins over another simply because it is prettier. It wins because it does a better job of explaining data. QFT didn't win out over S-matrix theory in the 1960's (or early 1970's) because of some intellectual theoretical debate. QFT (by which I mean the quark model, QCD and ElectroWeak) won out because of expt events, most especially charmonium. QFT explained the expt findings of the day, and furthermore made predictions about charmed bound states (which turned out tio be correct). Alternatives could not match this success.

There simply needs to be data (new puzzles, not merely confirmations of SM) from the LHC. Theoretical critiques of ST will go nowhere.

If you believe there is already data (e.g. cosmological), then put together an expt proposal to validate your non-ST ideas.

53. **John A**
August 16, 2006

Dear Antonio,

Unfortunately the Reference Frame has also been hacked by cockneys.

It's shockin' wha' 'appens on the Internets, guv…

54. **Thomas Larsson**
August 17, 2006

So what if ST is doing a bad job? Can you do a better job?

hep-th/0411028

Modulo some serious flaws (corrections in progress), the essential proposal is to replace QFT by QJT (J for jet), i.e. to expand all fields in a Taylor series prior to quantization. By doing so, one introduces a new datum: the expansion point. This is an essential modification, because it allows us to write down new gauge and diff anomalies, which lead to the higher-dimensional generalizations of Kac-Moody and Virasoro algebras.

There simply needs to be data (new puzzles, not merely confirmations of SM) from the LHC.

What if the ultimate theory of nature is essentially the SM coupled to GR, but treated within the framework of QJT rather than QFT?

55. **Tony Smith**
August 17, 2006

Thomas Larsson referred to hep-th/0411028 and said "… the essential proposal is to replace QFT by QJT (J for jet) …",
but
hep-th/0411028 did not refer to any of the extensive work of Gennady Sardanashvily on jet bundle physics, such as
math-ph/0203040 entitled Ten lectures on jet manifolds in classical and quantum field theory
as well as many further papers (some more recent) that can be found by searching arXiv for Sardanashvily as author. Would such works be helpful in Thomas Larsson's program?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

56. **Rickkkk**
August 17, 2006

Ludbos' post is even more ironic than usual.

"simply can't have any respect for because of their complete lack of intellectual integrity"

Unsurprisingly, Luddite Moron absolutely fails to grasp the actual meaning of intellectual integrity itself. The absolute epitomy of intellectual integrity is questioning something(especially something as foul as String Theory) I would challenge anyone to give a better characterization of what -defines- intellectual integrity. The irony here should be obvious, while decrying an act of intellectual integrity as its opposite, Ludbboose himself is the poster boy for failed integrity.

So to set the record straight: Integrity is ad hominem attacks on detractors(which as a sideline, grow more desperate as these detractors become the majority) and challenging an non-explanation like String Theory is the cardinal sin of science?

Caboose Motl is certainly the last car on a train that's heading out of town rapidly. Everyone smile and wave 🙂

57. **LostHisMarbles**
August 17, 2006

TL – pursue your ideas to fruition (perhaps in collaboration – follow up on Tony Smith post – work by Gennady Sardanashvily), figure out some testable consequence, e.g. for cosmology or HEP beyond EW scale, and find an expt collaborator/submit an expt proposal to validate it. You have to do this on your own. The ST camp doesn't owe you anything (such as a time slot at a conference). Ultimately your ideas have to survive on their own merits. Good luck.

Rickkk ~ If it makes you happy to write "Luddite Moron" and "Caboose Motl" good for you. You will ultimately go nowhere.

58. **George Lehtola**
August 17, 2006

Personally, I just like to hear the views of all writers and for this I am glad to have this Blog to raed.

59. **MoveOnOrStayBehind**
August 17, 2006

Well, there are writers, and there are scientists. Which ones do you prefer?

60. **Jonathan Vos Post**
August 17, 2006

MoveOnOrStayBehind Says:

August 17th, 2006 at 3:10 pm
Well, there are writers, and there are scientists. Which ones do you prefer?

With all due respect, there have MANY first rate scientists who were (or are) also first rate writers.

Consider, to pick just a few at random, Pascal, Darwin, Galileo, Oliver Sacks, Roald Hoffmann, Gregory Benford…

61. **Tony Smith**
August 17, 2006

Lost His Marbles, said, with respect to Thomas Larsson's NON-superstring approach to theoretical high energy physics:
"… figure out some testable consequence … and … submit an expt proposal to validate it … on your own …".

That is both true and reasonable.

Lost His Marbles went on to say:
"… The ST camp doesn't owe you anything (such as a time slot at a conference). …".

In a fair and considerate world, that would also be true and reasonable,
BUT
as Peter quoted Tim Folger saying in Discover magazine:
"… [super]string theory … is to physics what Wal-Mart is to retail:
the biggest thing around, dominant for more than 20 years now.
And woe unto anyone who doubts the [superstring] orthodoxy …",
so
our real world is "not considerate or fair"*,
and
LHM's second statement quoted above is true but NOT reasonable.

In short,
the ST camp is so dominant a monopoly in high energy physics theory,
that
it DOES owe to alternative approaches fair treatment (such as time slots in conferences,
rights to post to the Cornell arXiv, etc).

The penalty to superstringers for their abuse of their monopoly position will be a place in history alongside the inquisitors of Giordano Bruno.
Bruno's inquisitors were doubtless pleased with themselves for seeing Bruno dead,
but ideas don't die so easily,
and
to slightly paraphrase LHM:
"… ideas WILL survive on their own merits …".

If I were in the superstring establishment, I would be very thankful for Peter,
because
Peter is offering them a graceful exit from a position of great risk of a humiliating place in human history.

A graceful exit is possible because Peter is NOT pushing any particular alternative approach,
so the superstring establishment would not have to anoint a successor monopoly approach, but
only would have to admit that they have had their exclusive turn,
and now it is time to be inclusive of other approaches.

Following Peter would not even require anybody to give up their organizational positions of power, only to allow freedom of thought.

It would be sad indeed if the inevitable fall of the superstring establishment led,
not to the blooming of a thousand flowers,
but to a successor oppressor.

Would the Loop Quantum Gravity guys be any less oppressive about alternative approaches if they were to become a successor monopoly ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

*"not considerate or fair " is a quote from Batman Begins (Ras al Ghul).

62. **Thomas Larsson**
August 18, 2006

LHM – it is true that string theorists don't owe me anything, but neither do I owe anything to them (except perhaps a four-year postdoc to Lars Brink, but that was many years ago). If you don't like my marketing strategy, that's your problem.

As a physicist, I find it very significant that **all** natural string theory predictions – SUSY, extra-dimensions, 496 gauge bosons, new long-range forces (unstabilized moduli), a non-positive cc, etc. – are in apparent disagreement with experiments, and I find it deeply dishonest that this fact has been systematically deemphasized for 20 years. If string theorists had told the public about these problems, rather than going on about how beautiful M-not-a-theory is, maybe they would have gained more sympathy.

However, at the end of the day it does not matter. Theories that don't produce predictions (and correct ones) will flounder, just as companies that don't show profit will. It is neither mine nor Peter's fault that the cc is positive, that the proton refuses to decay, that the Tevatron and precision experiments show no signs of SUSY or extra-dimensions, etc. It is just Nature's way of telling us that it does not like string theory.

63. **John Rogers**
August 18, 2006

By the way, Walmart just sold all the stores it had in Germany: it did not make any profit in any of the years it was active there. Is this a sign of things to come?

64. **Som**
August 18, 2006

I believe that the whole issue of the anthropic principle is not irreconcilable with meaningful physics if you take the point of view propounded by some people (like Vafa, Verlinde and others in the context of Ads2*S2 universes), that the universe that we see is actually a collapsed state of the "universal" Wheeler-DeWitt wave-function.

From this point of view it is quite conceivable that the multiverse is like a super-Fock space spanned by axes, represented by different universes with differing parameters. However I have to say that I don't see a compelling need for the multiverse to be an exclusive product of string theory but that's another matter. What I would like to point out is that given this viewpoint one can inculcate a more ambivalent attitude towards the anthropic principle than that it is usually accorded.

65. **LostHisMarbles**
August 18, 2006

Tony Smith – I agree with much of what you say. I hope Thomas Larsson paid attention.

TL – if I don't like your marketing strategy "that's my problem"?? It doesn't matter in the slightest what I think. It's *your* ideas, you have to make of them what you will. See comments by Tony above.

66. **LostHisMarbles**
August 18, 2006

There was a Goddess Zeta Monopole from Infinity,
From her three breasts flowed Milk, Wine and SuperSymmetry,
One zap of lightning from her Trident of Incredulity,
Could reduce the most hardened non-believer to abject impotency,
She was not to be trifled with, that Goddess from Infinity.
.

I composed this for drl, but pw can toss this out if he wants to. It's not Shakespeare by a long shot.

67. **Tony Smith**
August 18, 2006

John Rogers said
"… Walmart just sold all the stores it had in Germany … Is this a sign of things to come? …".

It is NOT a "sign" that a dominant monopoly is crumbling.

Germany already had, BEFORE Walmart went there, established deep-discount chains such as Aldi,
so
failure of Walmart in Germany actually shows the POWER of entrenched monopolists (such as Aldi in Germany and superstringers in high energy physics theory).

Note that Aldi is trying to crack the Walmart monopoly in the USA, but seems to be having no more success than Walmart did in Germany.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

68. **Chris Oakley**
August 18, 2006

gorblimey guv it's a fair cop

77. **Reality**
August 18, 2006

What is it with you 'non-stringers"? Are you saddened that others are grasping concepts that you are unable to? Here's a simple question.

"Does 'YOUR MODEL' explain everything"?

Of course it doesn't.

Well, like it or not, 'SUPER STRING' DOES explain everything.

Nothing you can say will change this reality.

When you go to 'disprove' ANYTHING, you are fighting a loosing battle. Especially with yourself. Others are merely laughing at you, while some are saddened for you because you simply cannot accept this reality.

It is no wonder with such 'closed minds' that festering attitudes of rediculousness abound.

No one has a need to remove science from this model. It is merely that 'a few' of the concepts 'REQUIRED' to further understanding on this theory require your mind to be able to grasp things that it was previously unable to grasp.

You poor jealous goofs don't have a clue when it comes to reality. To say that something is false "REQUIRES FAR MORE, THE NEED OF A SCIENTIFIC EXPERIMENT, THAN THE RESULTS OF THE 'EFFECT' OF THIS THING YOU CANNOT SEE'

So, until you 'HAVE THAT PROOF', please do all of us who "HAVE SUFFICIENT PROOF" a favor, and STFU. Besides, unless you can 'back your attitude up' with a 'sustainable argument against reality', you're merely pissing in the wind. And believe me, most everyone is ;aughing at you while you do so.

78. **J.F. Moore**
August 18, 2006

I eagerly await the inevitable rebuttal to all of this (or pointed interview) from Professor Harold Hi— I mean Professor Michio Kaku. Unfortunately, it might be on AM radio at 0200. We might get lucky though and see a "controversy in physics matchup" on a cable news show.

79. **King Ray**
August 18, 2006

String theory is obviously wrong. It fails to meet the criteria of beauty and simplicity. It is a Ptolemaic theory; it is more complicated than the standard model and GR. A unified theory is supposed to be simpler than the theories it reduces to, not orders of magnitude more complicated.

80. **John Gonsowski**
August 18, 2006

Reality, take your amazing mind over to PBS and watch Brian Greene tell the general public that string theory could all be wrong. Combining "it could all be wrong" with 20 years and a monopoly is really bad. Too many eggs all in one too wrong basket for too long.

81. **KH Yarbles**
August 18, 2006

Ask yourselves how/why ST became a monopoly in the first place. QFT and the SM were dominant in the late 1970s – early 80s. Why blame ST? Why did QFT not remain dominant?

82. **Yatima**
August 19, 2006

Reality says:

"Well, like it or not, 'SUPER STRING' DOES explain everything."

This amazingly and weirdly sounds like something out of "The Incredibles":

"SYNDROME: You sly dog! You got me monologuing. I can't believe it. It's cool, huh? Zero-point energy. I save the best inventions for myself. Am I good enough now? Who's super now? I'm Syndrome! Your nemesis and…"

Sorry for this post, I'm off to do productive system administration now. (Bows)

83. **Thomas Larsson**
August 19, 2006

LHM – Maybe I misunderstood you. It seemed like you were first saying that I wasn't allowed to criticize the string theory hype because I lacked original ideas, and when I showed that I indeed had original ideas, string theorists have no reason to listen anyway. Quite an effective strategy for keeping string theory the only game in town 🙂

However, beauty has nothing to do with it, just inevitability. The multi-dimensional Virasoro algebra is important to quantum gravity for the same reason that the usual Virasoro algebra is important to string theory – it is the correct quantum form of the correct constraint algebra. That's why I decided to discover it, many years ago.

84. **KH Yarbles**
August 19, 2006

TL (and anyone else for that matter) –
Nobody was obliged to listen to S-matrix theory in the 60's, nor was anyone forbidden to criticize it. Nobody was obliged to listen to QFT either, or forbidden to criticize it. Julian Schwinger did, for example, opt out of both, and invented source theory.

"If you can't join 'em, beat 'em"
– JS, dedication in Source Theory books

Nobody is obligated to believe ST, or anything else, nor is anyone forbidden to criticize ST, or anything else, nor is any ST person required to listen to any non-ST person.

If you have ideas, they must survive on their own merits. This the ideas do by proving their worth by explaining phenomena (to a better extent than rival ideas).

How did ST become a monopoly anyway? Other camps (QFT) had a fair chance to be heard.

85. **Open Source**
August 19, 2006

"How did ST become a monopoly anyway? Other camps (QFT) had a fair chance to be heard."

But string theorists are wiling to lie, cheat, and steal.

To hype, and hype, and lie, and hype, and lie.

Nice guys finish last.

86. **KH Yarbles**
August 19, 2006

" … lie, cheat, and steal."

The scientific community at large is not obligated to believe any of ST. Historically the scientific community has shown itself to be effective at sorting out good ideas from bad. The truth wins out, despite religioius persecution, prejudice against "Jewish science" and other nonsense.

It does no good to merely proclaim "I have a (better) idea". The idea has to demonstrate its worth.

"Nice guys finish last." Don't whine.

87. **Open Source**
August 19, 2006

Technically speaking, any theory would be as good as string theory because string theory predicts everything and nothing.

Ergo the government should give equal funds to every theory.

Why should other theories have to prove themselves when string theory does not?

"Human–all too human," is what String Theorists are.

Their vast yearning to be on Nova Star Trek specials has blinded them to their mendacious mediocrity, and it has brought out the very worst from their small, cowardly, conformist, group-think minds.

I wish String Theory had at least one postulate we could talk about, but the postmodern joke lackas even that.

88. **Open Source**
August 19, 2006

KH Yarbles Says: "It does no good to merely proclaim "I have a (better) idea". The idea has to demonstrate its worth."

Does that mean that NSF should immediately stop funding String Theory which has failed to prove its worth for over thirty years?

Let's write a letter to the NSF, and KH Yarble, the defender of all that is Right, and True, and Worth Something can be the first to sign it.

That way, funding can go towards better theories which are rooted in logic and reason, such a MDT.

89. **Tony Smith**
August 19, 2006

KH Yarbles asked:
"… QFT and the SM were dominant in the late 1970s – early 80s.
… Why did QFT not remain dominant?
… how/why [did] ST bec[o]me a monopoly in the first place …" ?

Perhaps the existence of a monopoly in theoretical high energy physics is a reflection of the sociology/psychology of the USA high energy physics community.

Raoul Bott made an observation about the Princeton IAS under Oppenheimer:
"… Oppenheimer had taken over, and he was very dominant in the physics community. He had a seminar that every physicist went to.

We mathematicians always thought they ran off like sheep,
for we would pick and choose our seminars! …".

Consider some excerpts from other entries in this blog over the past year or so:

"… ObsessiveMathsFreak Says:
When you were young, you assummed that scientists were a magnamous, logical and rational bunch. You had great faith in their ability to be imparital and to discern the truth through the application of scientific rigour. You also thought they had great integrity and were above petty actions as they aspired to the greater goal that was The Truth.
Then you grow up … see that scientists are just as human as everyone else, pettiness included.
It's still very disappointing though. …".

"… D R Lunsford Says:
It all sounds like groupthink … Groupthink seems to be at the bottom of much of our (USA) current dysfunction. …".

"… Dumb Biologist Says:
… it seems …[superstring theorists]… have forged ahead so far away from attainable real-world checks and benchmarks that the system of peer review is all they've got, or perhaps will have, for a very, very long time.
How could the tyranny of groupthink not prevail in such an environment?
It's functionally equivalent to a church.
Very sad. …".

In short,
the USA high energy physics community acts like a herd of sheep,
with more importance placed on being a member of the herd than on exploring new territory.

I fear that, unless that collective mind-set it changed,
if LHC fails to see supersymmetry and so puts the final nail in the coffin of conventional supersymmetry,
the herd will just follow the most then-charismatic shepherd
(Lee Smolin seems to be trying to fill that role, using his Loop Quantum Gravity program)
and continue in its dysfunctional group-think ways.
To use the church analogy, think of the Roman Catholic church being replaced in England by the Church of England.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Although I have a physics model that in my opinion substantially contradicts
(by calculating particle masses, force strengths, Dark Energy : Dark Matter : Ordinary Matter ratio, etc)
the assertion in a comment in this blog entry by Reality: "… What is it with you 'non-stringers"? … Here's a simple question. "Does 'YOUR MODEL' explain everything"? Of course it doesn't. …",
I would be very unhappy if my model were to be used as a monopoly that suppressed other approaches.
My view is that a thousand flowers should bloom, and that all important institutions (university departments, laboratories, institutes, etc) should encourage active investigation of ALL the blossoms,
by rewarding grad students, post-docs, etc., for work on whatever they find interesting.
If a studied model turns out to be wrong, then the work showing it to be wrong should not be considered a worthless negative result, but a useful contribution (like weeding a garden) to advancing physics by cultivation,
and such negative results should be just as important as positive ones in getting publications, Ph.D.'s, post-doc jobs, and faculty appointments.

PPS – Although the above is written about theoretical high energy physics, experimenters in high energy theory are not immune, with their groupthink problems being due to a combination of
necessary large collaborations
and
unnecessary insistence on a single consensus viewpoint with respect to results of data analysis.

90. **Who**
August 19, 2006

Tony your fears seem a bit exaggerated, non-string QG is a bunch of different approaches. You say
***I fear that, unless that collective mind-set it changed, if LHC fails to see supersymmetry and so puts the final nail in the coffin of conventional supersymmetry, the herd will just follow the most then-charismatic shepherd (Lee Smolin seems to be trying to fill that role, using his Loop Quantum Gravity program) and continue in its dysfunctional group-think ways*.**

There is no monolithic LQG program. Check out the contents of Oriti's book ("Approaches to QG" Cambridge 2006?) a lot of which is already on arxiv. It is an association of separate initiatives. What I see John Baez students and former students doing is way different from what I see Laurent Freidel and collaborators doing. At present, neither of those approaches makes contact with what Lee Smolin has been pursuing recently (which itself is not conventional LQG either.)

Research funding policy is different from specific programs. Your PS sounds rather much like what Smolin has been proposing as a policy direction in fundamental theory research funding—support proven talent and independence, by individual rather than by program. That is an investment strategy at policy level, not an "LQG program" and it does not require a charismatic research tzar to implement. Both your PS and Smolin's essays on the subject are directed against groupthink.

91. **KH Yarbles**
August 19, 2006

OS –

It's Dr Yarbles to you.

"… That way, funding can go towards better theories which are rooted in logic and reason, such a MDT. "

This repeats a fallacy which persists with many people. NSF does not have a pot of money which will be redirected elsewhere, if ST is defunded. There will be no money for MST if money for ST is cut. In fact, NSF has been defunding HEP for many years now, and the trend shows no sign of abating, e.g. the cut of RSVP (Rare Symmetry Violating Processes) at BNL.

" … KH Yarble[s], the defender of all that is Right, and True, and Worth Something … "

a) I owe drl a debt of gratitude here, which I am not sure I can repay. But see below …..
b) I cannot even defend the chastity of a Goddess, and CO may have strong words about even that.

TL proposes non-SM ideas which he claims to be better than ST. A paper on arXiv is a good first step, but it is by no means the last. It is necessary but not sufficient. Make a falsifiable prediction and put together an expt team to test it.

Tony Smith writes much that is sensible. See also sensible reply by Who. What can a fool like I add?

Back in the early 80's, QFT + SM was utterly dominant. The prevailing attitude was that the next step was unification of the strong, weak and EM interactions into one gauge group (GUT), the smallest candidate of which was SU(5). The immediate predicted consequence of GUT SU(5) was proton decay. This was a clear cut falsifiable prediction, but unfortunately
a) the prediction failed
b) QFT had no backup Plan B. It simply fell into disarray.

Equally unfortunately — and this is nobody's fault — expt HEP simply did not turn up anything beyond SM, and after 30 years there is still nothing beyond SM from the particle accelerators. QFT relied on working closely with hep-ex, and there has been no food for QFT.

`Who' is correct to note that non-ST (e.g. LQG) is not monolithic. ST's source if strength is arguably simply that it is monolithic.

What is my answer? … Hep-th will languish until there is some new non-SM data from the accelerators. It is nobody's fault. Rail against ST if it makes you feel better.

92. **KH Yarbles**
August 19, 2006

There was a Goddess from Infinity,
She was the final authority on g-string theory,
There were those who said it was all not even wrong,
Alas and alack, their yarbles were insufficiently strong,
She reigned supreme, that Goddess from Infinity.

93. **Open Source**
August 19, 2006

YOU'RE MISSING THE POINT!!

NSF damages physics by a factor of 1,000 for every dollar it spends on string theory.

NSF influences billions of dollars of cashflow with its millions of dollars.

Brian Greene's Hocus Pocus Diddly-Docus has set physics back a hundred years, as it has fostered a fan-boy star-trek atmosphere which has exiled physicicists who deal in reality, logic, and reason.

96. **Rickkkk**
August 19, 2006

Quote: "Technically speaking, any theory would be as good as string theory because string theory predicts everything and nothing."

This is a point that I was making in a previous post, a point that isn't made enough it seems.

The typical rebuttal, demonstrated many times in this post, is "DO YOU HAVE A BETTER MODEL?"

97. **KH Yarbles**
August 19, 2006

No-one has ever accused me of ever getting the point. There is a leverage factor of 1000 for every dollar spent by NSF? Fine… I have no idea. NSF damages physics by the dollars it spends on ST? … I also have no idea. Complain if you want to.

98. **KH Yarbles**
August 19, 2006

CO – I'll take that as a compliment.

99. **Rickkkk**
August 19, 2006

Darnit, I pushed enter too soon.

Anyhow, that rebuttal isn't adequate. As the quote says(correctly) there are NO worse models, theories, or even speculations worse than string theory. This isn't just angry slander or hyperbole, analytically speaking if there is a definition of a PERFECT, albeit perfectly bad theory, it is string theory. It is the model of avoiding predictions by predicting everything. It is absolute PERFECTION in its “badness”

I want to reemphasize, I am not being sarcastic here or even inflating the truth. I am genuinely impressed by the vacuousness of the yarn.

So, yes, I have a better model, my brother has a better model, my grandmother has a better model.

No model is better than string theory? Indeed…”no model” would be better or at the very worst, equivalent.

August 19, 2006

The comment section has degenerated into nearly pure noise, bad jokes and pointless bickering, so I’m turning off comments on this posting. Unless you’ve got something informed and substantive to say about the topic of the posting, please resist the urge to write here. I’ve recently had complaints from several physicists that they don’t want to comment here because of the huge amount of noise and nonsense. I feel the same way myself. This is seriously damaging what I’m trying to do here.

Aaron Bergman Review of Not Even Wrong

August 19, 2006
Categories: Not Even Wrong: The Book

Aaron Bergman has written up a review of my book and posted it over at the String Coffee Table. It's quite sensible and makes reasonable points, so I'm very glad he wrote it. Here are a few comments of my own about the points raised in the review. I don't have time to discuss everything in it right now, but if someone feels that I'm not addressing an important point of Aaron's let me know.

It's true that the book isn't "even-handed" in the sense of repeating many of the arguments made for string theory. One reason for this is that I assumed that essentially all my readers would have read at least something like one of Brian Greene's books. I originally intended my book as something that would be published by a university press and be aimed at people with some background in the subject. The fact that it ended up being published by a trade publisher wasn't my first choice, and the wide attention it is getting from people who know little about physics is a surprise to me, something I wasn't counting on.

Instead of repeating many of the what seem to me highly over-hyped claims made for string theory and spending a lot of time explaining exactly how and why they're over-hyped, I decided to just write down as accurately as possible how I see things. The black hole entropy calculations are an example of what I mean. I do mention these, but I think Aaron's description of them as a "holy grail" vastly overestimates their signficance. It's also true that string theorists still have not been able to do calculations for the case of physical 4-dimensional black holes. A truly honest description of the situation would require a detailed examination of exactly what has been calculated, and what remains still not understood. This is a highly technical business, not easy to extract from the often hype-filled literature, and I just didn't think that even if I put the effort into doing this well, it would work as part of the book. Similar comments apply to the AdS/CFT story, where sorting through the hype and clearly distinguishing exactly what has been achieved and what hasn't would be even more difficult.

People can compare what I have to say to what string theorists have to say, and see that there's a different point of view on many things. If they have some expertise, they can look into these more deeply and decide for themselves. Aaron describes the book as "tendentious", but I think it's much more scrupulously accurate in its descriptions, honest and even-handed than any of the many books promoting string theory, essentially all of which contain vast amounts of misleading hype designed to give the reader an inaccurately optimistic view of the theory.

About the CC and supersymmetry: I re-read that section after Lubos's review complained about it, and it was not clearly written. But the argument that I'm not giving SUSY credit for being wrong by 10^{60} instead of 10^{120} doesn't make sense to me. Both are obviously in the same category of being completely off-base in a very fundamental way. The situation with SUSY is actually worse than non-SUSY, because in a non-SUSY theory the vacuum energy is not something that you can calculate even in principle. In a SUSY theory (before you turn on gravity), it's the order parameter for supersymmetry-breaking, so has to have a scale of at least 100s of GeV to explain the lack of superpartners. Your theory of quantum gravity is supposed to ultimately explain the CC, and, for doing this, supersymmetry not only doesn't improve the situation, it introduces a huge new problem you have to find some way around.

About the section on mathematics, and that I'm being petty about denying credit to string theory. Again, I think what I write is far more honest that just about anything string theorists have to say about the relation of string theory and mathematics, much of which is based on alotting to string theory purely QFT results.

About S-matrix theory, Chew, Capra. I think the lesson of what happened with S-matrix theory is an incredibly important one, and suspect that someday history will repeat itself. Before asymptotically free theories, people were convinced they had a good argument that QFT couldn't be fundamental, just as many people are now convinced that problems with quantizing gravity imply that QFT can't be fundamental. The arguments from Chew and Capra about getting rid of symmetry arguments and QFT in favor of the bootstrap are all too similar to things one hears these days from some string theorists. As for the denial of reality by Chew and Capra, post-QCD, there is no analog yet in the case of string theory. But, if someone finds a better way of quantizing gravity and getting unification, I'm willing to bet that, just like in the case of S-matrix theory, most theorists will move on, but some will refuse to ever give up on string theory and deny reality. We'll see what happens. Eastern religions are a lot less popular in the US these days than they were in the 70s, so I don't think there will be a new "The Tao of Physics". But, already, if you take a look at Susskind's "The Cosmic Landscape", it holds up as science no better that Capra's book.

About describing string theory as a cult with Witten as its guru. I believe Joao Magueijo in his book explicitly does this, and I can think immediately of three well-respected physicists or mathematicians who have, unprompted, used this description in conversations with me. Based on my experience, I'm pretty sure that if you sample non-string theorist physicists, you're going to find many people who would describe the behavior of string theorists as "cult-like". This behavior is described by Lee Smolin as "groupthink" and he has a lot to say about it. I wrote that I don't think it's useful to describe string theory as a religious cult, because the phenomena are significantly different, but I would characterize the behavior of some string theorists in recent years as "cult-like". Some people exhibit a disconnect from the reality of the problems of the theory that is much like the way members of a cult behave in face of evidence contrary to their beliefs. Lubos is an extreme case, but there's lots of others, of varying degrees. Describing Witten as the field's "guru" I think is actually uncontroversial. There's nothing wrong with having "gurus", as long as you realize they are sometimes wrong. People who have demonstrated great amounts of knowledge and wisdom deserve to be listened to very seriously, but no one is ever right about everything.

About the Bogdanovs. The main reason I wrote about the Bogdanov story, (besides for its entertainment value), is that I think it shows conclusively that in quantum gravity in general, many people have lost the ability or willingness to recognize non-sense for what it is. Sure, this is not specifically a string theory problem, but it's also not a problem specific to non-string theorists doing quantum gravity. This was swept under the rug at the time, and attributed to a few lazy referees, rather than dealt with as a serious problem that needs to be addressed if the field is not going to drown under an increasing tide of crap, and I think this was a big mistake, with the tide rising since then. I don't apologize at all for writing about it in the book. As for the inclusion of the e-mail describing the reaction of the string group at Harvard, I don't know its author, but I was assured by its recipient that it was legitimately from someone who was visiting there at the time. One member of the string theory group at Harvard is Lubos, and he has repeatedly defended the work of the Bogdanovs on his blog as legitimate science, no worse than much else of what is published in this field.

About Hagelin. Again, I wrote about him in the context of a chapter examining the difficulties involved in deciding what is science and what isn't. More specifically, how do you tell who's a crackpot and who isn't? There are plenty of people out there whose ideas about physics are uniformly incoherent and easy to dismiss, but there are also cases like Hagelin, who combines excellent research credentials with crackpot ideas about science. How do you decide who is a crackpot and who isn't? What about Lubos, what about Susskind? Many string theorists seem to hold the opinion that I'm one. Lacking the normal sort of discipline that comes from confrontation with experiment, a scientific field is in a very tricky state, and needs to be careful to enforce high standards of what makes sense and what doesn't, and not let pseudo-science take over. Aaron notes that most of the audience at the Toronto panel discussion voted against the anthropic landscape, but he doesn't mention that anthropism seemed to be a majority opinion amont the panelists, who are the ones who hold power. This is an extremely dangerous situation for this field. I don't think the possibility that some readers of my book are going to get the impression that most string theorists are not doing science is anywhere near as much of a problem as the fact that quite a few powerful ones definitely aren't anymore.

About comments on this blog. Please avoid adding to the noise level by posting non-substantive or off-topic comments, engaging in repetitive arguments that go nowhere, promoting your own ideas that have nothing to do with the posting, or generally making comments that have nothing new to say that hasn't been said many times here already.

Comments

1. **Jonathan Vos Post**
   August 19, 2006

I think that there is an ongoing subthread about comparisons, along several axes, of science, mathematics, and writing for mainstream (i.e. nonscientist) audiences. You yourself comment above: "… it ended up being published by a trade publisher wasn't my first choice, and the wide attention it is getting from people who know little about physics is a surprise to me…"

Similarly, the full-page attention of Time Magzine shows a wider audience than this blog might directly reach. I am NOT going off on my own experiences as a scientist/author here, but do think that there is a wider context to be considered with authors such as thos scientists,such as Fred Hoyle, Carl Sagan, Robert F. Forward, and Marvin Minsky, who became science fiction writers themselves.

The question that one must ask is: "Whom am I trying to reach? String Theorsist who mostly resent this message, but might conceivably to turned around to dissenters; ant-string theorists, with whom I'm preaching to the choir; or a wider audience of humans interested in science and its social impact, although not themselves practicing in the field?"

Perhaps you've already answered that question on this blog. If so, I apologize for missing it.

2. **Lubos Motl**
   August 19, 2006

   Peter, if you thought that such a book could be published by a university press, then you have really lost a contact with reality. Do you understand that the university presses are meant to publish serious scientific work that can be used for years instead of opinionated piles of emotional rubbish written by people who don't understand what they're talking about at the technical level and who are searching for the 15 minutes of their fame?

   Everyone who has learned how to work with the theory knows how to extract the content of papers about black holes, AdS/CFT, or anything else – and ignore "hype". Peter Woit only looks for unscientific themes that he can twist and use for his undemanding readers. He doesn't find much of them in the research papers, so he adds. 80% of this blog and the book is irrational obnoxious whining and 20% is stuff that is only added to create an illusion that his production is not pure whining. No one is interested in these 20% and the value of the 80% is just in the controversy that they create.

   Witten is a guru because he's the most achieved theoretical and mathematical physicist alive. But it is only Peter Woit who builds a religion on this. He argues that Witten was and is the right reason to accept string theory. Some people want to be led but it is ridiculous to say that the guru system is a rule. Witten also has (respectful) competitors and they're not the only ones who view science very differently. Many other people went through a similar development as Witten but independently.

   But even if people were led by Witten, that would be no disaster because Witten is rather bright. I think that many people could improve the quality of their opinions by a few orders of magnitude if they switched from their idiosyncratic rubbish to parroting of Edward Witten; most of these people who are subjects of the previous sentence are not string theorists. I don't like parroting but in the case of Peter Woit, this would be among my first recommendations. Imagine that he could become a spokesman for Witten instead of writing all this junk.

   The sections about the role of supersymmetry for evaluating the vacuum energy are, once again, completely wrong, much like the rest of the book as I described on 17 pages of errata.

   The main reason why I respect Profs. Bogdanovs from the University of Belgrade more than Peter Woit is their creativity combined with a desire to follow the standards of scientific discoveries, isntead of trying to revise science and cripple it by new kinds of social engineering and irrational emotional moods which is what Peter Woit and Lee Smolin openly want and systematically fight for.

   What the Bogdanov brothers have written arguably makes no full sense to any of us but their work proves that they have spent a lot of effort and time to learn the relevant things and they have rather original ideas. I have been impressed by them given their previous, seemingly unrelated profession. Their ideas about quantum groups suggest that they might really know them better than I do – and I've tested them to learn that their mastery of the group SO(4) and its non-compact forms dramatically exceeds Peter Woit's abilities in the same subfield. 😉

   It is sad that Peter Woit is so jealous that I rate him below the Bogdanov brothers, but this is simply how the reality looks like. They are also more achieved scientists than he is according to superficial social criteria. Guess whose contribution to science is negative and whose contribution to science is at least non-negative. 😉

   Also, if Peter Woit were willing and able to focus on the actual science, I am sure that the frequency with which my name would occur would definitely be lower than it is.

   Magueijo's book is similar crap as Woit's book.

   Woit's arguments that our no-go theorems about QFT behind gravity can fail because other theorems in the past have failed is cute but worthless until someone actually finds a loophole in which they can fail. But this is not how Woit would like science to look like. He prefers to falsify theories by collecting 50 angry crackpots who doom a theory without a glimpse of a rational scientific argument.

   I am sure that most of us including the Bogdanov brothers know that this is not how ideas and theories in physics can be rejected, which is why it is rather legitimate to count Peter Woit as a crackpot regardless of the fact that he would prefer, together with his brainless readers, to choose this title for Lenny Susskind, one of the most original physicists of our time.

3. **bob**
   August 20, 2006

   Thank you, Lubos, for that enlightening discussion.

   Peter, I think you have identified something important when you mention how difficult it is to distinguish between crackpots and non-crackpots. It's all too easy for a physicist to pretend that he knows nonsense when he sees it, and behave dismissively of whatever he doesn't understand. As long as he sees others behave dismissively of the same thing, he is probably safe, and this is where groupthink becomes amplified by immaturity. In an area where nobody understands anything, such as quantum gravity, the ones who behave dismissively at least appear to know something, and those who follow the dismissive ones become string theorists.

   But, as interesting as the sociology might be, there is still the practical question of how to distinguish crackpots from non-crackpots. John Baez's Crackpot Index, and the dozen or so other documents which claim to provide guidance on this subject are whimsical. They are dismissive and sneering, displaying immaturity and leaving the reader with the message that it is clear and obvious what is nonsense and what is not, and that those who cannot distinguish between nonsense and sense are the fools, deserving of ridicule.

   This behavior is no doubt very amusing for the children in the physics schoolyard, but there must be practical way of determining what is sense and what is nonsense, and it must never be to look at who is doing more ridiculing, John Baez or Lubos or whoever, and suppose that whatever they ridicule is nonsense. Whoever follows that strategy is only pretending to be a physicist, and is in fact too immature to think for themselves, but all ridicule online is performed as an act of theatre before these pretenders. So what is the alternative?

4. **Open Source**

August 20, 2006

Lubos says,

“Do you understand that the university presses are meant to publish serious scientific work that can be used for years instead of opinionated piles of emotional rubbish written by people who don’t understand what they’re talking about at the technical level and who are searching for the 15 minutes of their fame?”

Is that why Brian Greene’s books and Kaku’s books on String Theory are published by non-university presses?

Einstein and Bohr and Newton and Feynman and Dirac all exhibited vast humility because they were physicists who valued Truth above all else.

We ought to follow their lead.

http://revver.com/video/48391/21022

5. **bob**
August 20, 2006

And I think we need something more specific than a vague commitment to high standards and scientific integrity and other affirmations which are little more than promises to be good, and which carry little weight because in each case, the crackpot believes himself to have more integrity than his critics, and can claim with full honesty that he, as far as he understands, is making perfect sense.

What we need is an objective standard, which specifies exactly what criteria an informal argument must satisfy in order to be considered “valid”. Mathematical proofs already have clear standards, but physics has an overlap with philosophy (“at the fundamental level”) and has experimental data and its incrediby-poorly-agreed-upon notion of what constitutes a theory of physics. The objective standard for valid informal arguments must not be “No stupid pseudoscience”, which would be no better than simply declaring oneself to have high standards. The standard should include distinguishing premises from conclusions, and not appealing to any oracles, such as common sense, or what the community believes, in order to justify labelling something as a conclusion instead of a premise.

6. **anon**
August 20, 2006

‘There are plenty of people out there whose ideas about physics are uniformly incoherent and easy to dismiss, but there are also cases like Hagelin, who combines excellent research credentials with crackpot ideas about science. How do you decide who is a crackpot and who isn’t? What about Lubos, what about Susskind?’ -Woit

‘… Woit … prefers to falsify theories by collecting 50 angry crackpots who doom a theory without a glimpse of a rational scientific argument. I am sure that most of us including the Bogdanov brothers know that this is not how ideas and theories in physics can be rejected, which is why it is rather legitimate to count Peter Woit as a crackpot regardless of the fact that he would prefer, together with his brainless readers, to choose this title for Lenny Susskind, one of the most original physicists of our time.’ – Motl

I think Woit should try to find the time and the patience to explain gently and kindly to Motl that physics is ultimately based on facts, and stringy stuff isn’t. (I’ve tried, but lack sufficient tact to succeed.)

Stringy Bogdanov published a paper in peer-reviewed IoP Classical and Quantum Gravity, which later retracted its endorsement for the paper because it had no rational argument.

Bogdanov didn’t have a PhD, but was awarded one for getting his paper in CQG and virtual copy in another journal. He still has the PhD…

7. **Yatima**
August 20, 2006

Lubos Motl says: “Peter, if you thought that such a book could be published by a university press, then you have really lost a contact with reality. Do you understand that the university presses are meant to publish serious scientific work that can be used for years.”

My goodness. Such Vitriol. Counterexample? One swift grab into the bookstack behind my back produces “Superstrings: A Theory of Everything” by Cambridge University Press, first published 1988 (paperback, Canto edition, printed 1995), which is basically a set of Interviews made for BBC Radio 3. For ‘less scientific’ you would have to get one of the numerous hardcover books on consciousness studies by reputed UPs…

(The book has interviews with John Schwarz, Ed Witten, Michael Green, David Gross, John Ellis, Abdus Salam, Sheldon Glashow, Steven Weinberg and “old man” Feynman: “They are not checking the ideas hard enough against experiment because of the difficulty in caclulating anything. That means they are up in the air and I don’t have to pay much attention!”)

8. **Lubos Motl**
August 20, 2006

Dear Yatima,

the book “Superstrings…” is made of “mere” interviews, but they’re interviews with 8 super top physicists of that era. This is why the book has a scientific value as a book about history and sociology of science because it rigorously answers what the relevant people – heroes of physics – think at the time of publication.

Not Even Wrong is not a valuable book about sociology of science because it only captures bitterness of a particular nobody that won’t be interesting for scholars in the future in any way. Even today, he’s mostly interesting for similar nobodies, most of whom are anonymous like the confused “poster” above Yatima.

Best
Lubos

9. **boreds**
August 20, 2006

“The main reason I wrote about the Bogdanov story, (besides for its entertainment value), is that I think it shows conclusively that in quantum gravity in general, many people have lost the ability or willingness to recognize non-sense for what it is.”

I’m reiterating what AB said in his review, but I don’t think this is a justifiable statement. Who are the many theoretical physicists who don’t have the ability to recognise bogdanov for nonsense? Whoever reviewed the papers had presumably lost the *willingness* to recognise it, but in any case that’s still not `many’ people.

Don't think you are help your argument by conflating your other objections about string theory with this story!

10. **anon**
August 20, 2006

Dear Lubos,

your confusion about Feynman and stringy stuff was predicted and explained by Feynman:

'… I do feel strongly that this [string theory] is nonsense! … I think all this superstring stuff is crazy and is in the wrong direction. … I don't like it that they're not calculating anything. … why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations in these string theories – absolutely none! …' – Feynman in Davies & Brown, 'Superstrings' 1988, at pages 194-195

Feynman said, in his 1964 Cornell lectures (broadcast on BBC2 in 1965 and published in his book Character of Physical Law, pp. 171-3):

'The inexperienced, and crackpots, and people like that, make guesses that are simple, but [with extensive knowledge of the actual facts rather than speculation] you can immediately see that they are wrong, so that does not count. … There will be a degeneration of ideas, just like the degeneration that great explorers feel is occurring when tourists begin moving in on a territory.'

Sheldon 'string theory has failed in its primary goal' Glashow – http://www.pbs.org/wgbh/nova/elegant/view-glashow.html

'Sheldon Glashow has strong opinions about string theory. Like how it has failed in its primary goal of incorporating gravity into the standard model of elementary particles. How its inability to be experimentally tested makes it ''permanently safe'' from either proof or falsification.'

Hope you are now less confused.

Kind regards,
anon.

11. **John Rogers**
August 20, 2006

As a infrequent reader, I am appalled by the discussion. There is one person (Woit) saying that there are no experimental predictions from string theory, and another (Motl) who says that there are two: black hole entropy and AdS/CFT. For any scientist, it is clear that neither of the two candidates are predictions about experiments. Why does Motl, who is clearly a bright guy, deny this?

The things which are open to prediction in physics are clear: the fine structure constant, the particle mass ratios, the other coupling strengths (and a few more). None of this is "predcitable" so far. The question is simple: will string theory achieve the predictions?

12. **not-a-fool-arogant**
August 20, 2006

Lubos,
I am sure PW will be remembered long time after you will be forgotten. If not for scientific achivements, then at least for saying loud and clear: the king is (most likely) nacked.

13. **bob**
August 20, 2006

boreds says:
Who are the many theoretical physicists who don't have the ability to recognise bogdanov for nonsense?

I remember the time. Before John Baez and Ark Jadzyck started interrogating the Bogdanovs. Nobody was willing to say that it was nonsense, because nobody was sure that it was, and anybody who loudly proclaimed in full view of the public that it was nonsense would soon be humiliated in full view of the public if it turned out not to be nonsense. And nobody was really sure, from just reading the papers, whether or not the Bogdanovs were thinking about anything coherent.

So, I would say that everybody who was aware of it at the time, was unsure about whether it was nonsense or not. If it wasn't nonsense, it was certainly written in such an awkward way that it was unintelligible perhaps to everybody but the authors. And where is the boundary between those who don't even know what they are saying, and those who are confused but think they have discovered something, and they may even be less confused than us, but still not right.

So, Mr. boreds, and Peter, the unfortunate situation is that you can't just stamp your feet and demand that everybody be immediately able to distinguish between nonsense and genuine science. You have to specify a unique objective procedure which we can always use to analyse something and then say whether it's nonsense. Perhaps you would claim that you know nonsense when you see it. Should we then bring everything to you, to ask you for help distinguishing sense from nonsense? What will you say of string theory, and, if it is nonsense, how will you convince the string theorists that your nonsense-detecting powers never fail? Will you reveal the procedure for identifying nonsense?

14. **Rickkkk**
August 20, 2006

I actually think Lubos is right about much of what he says in his first comment. Peter certainly isn't doing any science and shouldn't complain about the noise-level that accompanies discussing sociology and politics of science rather than actual science. Without having read the book I can assent that Peter resorts to sometimes emotional "salespitching" rather than hard facts.

However, I'd say that this is understandable, defensible, and certainly not something String Theorists are above. No, as Aaron says and Peter would surely admit, his and Lee's books are not even-handed, but when taken in the context of other popular science books(especially string-hypers) they do begin to introduce some even-handedness into the whole debate.

Popularizers of String Theory have seldom been even-handed in their description of the situation, and it's certainly due time for some uneven rebuttals, for balance if for nothing else.

As a footnote, pretending to have more dignity than an opponent will only assure your loss. If you're not willing to stoop to their level then you lose, in any competition. The non-stringers actually need cheerleaders, as the stringers have certainly brought theirs out. I'm considering becoming the non-stringer Lubos, I'm certainly more comfortable with the language and have had enough human contact to make sensical insults. For some reason, Idiom is the hardest thing to grasp when learning English and it shows when Lubos decides to foam at the mouth and invents horrible insults.

All the same, good “post” Lubos.

15. **Anon**
August 20, 2006

” I think Woit should try to find the time and the patience to explain gently and kindly to Motl that physics is ultimately based on facts, and stringy stuff isn’t. (I’ve tried, but lack sufficient tact to succeed.)

Stringy Bogdanov published a paper in peer-reviewed IoP Classical and Quantum Gravity, which later retracted its endorsement for the paper because it had no rational argument.

Bogdanov didn’t have a PhD, but was awarded one for getting his paper in CQG and virtual copy in another journal. He still has the PhD…”

First, G.Bogdanov passed his thesis in 1999 and the papers were only published in 2001/2002. It clearly invalids any causality link.

But what I am saying, though (as some mathematician did on WP) is that “a handful of blogs reactions and a smattering of fora publications do not mean that a rumor turns suddenly into a fact (which is the problem with wow-gee-whiz reporting). Nonetheless, it is wrong to report CQG’s first email as if it was pretty much the only factual one. No matter how many people like the dramatic, exciting story of the mythical Bogdanoff non sense, including lazy physicists, there is no hard or direct evidence of such a non sense”.

Regarding CQG, its so called “statement” was presented by Baez as an “official document” issued by CQG editorial board around november 1st 2002. However its real source has never been clearly establlished and it was never confirmed by CQG’s editorial board. Instead, on november 11,2002, CQG published an official statement whose content was indeed quite different.

Here is a link towards an article of the bulletin of the “Physics-Astronomy-Mathematics division of SLA” http://www.sla.org/division/dpam/pam-bulletin/vol30/no3/physics.html

One finds, in reference n° 13 of the references quoted by the author :
http://listserv.nd.edu/cgi-bin/wa?A1=ind0211&L=pamnet#11

One can see the original and official text issued by Andrew Wray and H. Nicolaï of CGQ on November 11 2002, in response to the charges of hoax :
http://listserv.nd.edu/cgi-bin/wa
A2=ind0211&L=pamnet&T=0&F=&S=&P=3647

As you can see, the authenticity of the so called “official statement” which circulated on SPR and elsewhere was never established . The official text that was clearly released in the public domain sounds quite different but was never known (because it was kept more or less under the carpet by some physicists whose interest was to promote the “negative” version of Nov.1 instead.

Here is the integral version of November 11. As you can see, it reads quite different from the previous version : http://listserv.nd.edu/cgi-bin/wa?A2=ind0211&L=pamnet&T=0&F=&S=&P=3647

“Date: Mon, 11 Nov 2002 10:38:46 +0000
Reply-To: andrew.wray@iop.org

From: Andrew Wray
Subject: Classical and Quantum Gravity
Comments: To: SLAPAM-L@lists.yale.edu
Content-Type: text/plain; charset=”us-ascii”

I’m writing on behalf of the Institute of Physics in response to a recent discussion on this list re the following paper:

‘Topological field theory of the initial singularity of spacetime’ by G Bogdanov and I Bogdanov, Class. Quantum Grav. 18 4341-4372 (2001)

As you might expect, a number of our readers have contacted us about this and it has been widely discussed online.

Our position is this: Classical and Quantum Gravity endeavours to publish original research of the highest calibre on gravitational physics. It is one of the highest standard journals in its field and makes continuous effort to maintain and improve the quality of research communication. In common with many journals, we consult among a worldwide pool of over 1,000 referees asking two independent experts to review each paper. A third referee is selected if the first two disagree. 45% of submitted articles are rejected and almost all accepted articles are revised before publication. The paper ‘Topological field theory of the initial singularity of spacetime’ by G Bogdanov and I Bogdanov made it through this review process and was therefore published in the normal way.

At present, there are no plans to withdraw the article. Rather, the journal publishes refereed Comments and Replies by readers and authors as a means to comment on and correct mistakes in published material.

We have passed this information on to the community and ask that if your colleagues enquire about this, you forward this e-mail on to them.

Thank you for your help with this matter.

Regards,

Dr Andrew Wray

16. **Lubos Motl**
August 20, 2006

Dear anon,

I agree 100% with Feynman's comments about the crackpots, and I have written the very same things many times. See e.g.

http://motls.blogspot.com/2005/08/common-crackpots-errors.html

where the section about the "Inability to falsify a conjecture by a comparison with the most elementary data" is closest to Feynman's comments.

Concerning Feynman's misunderstanding of string theory, he was just too old and others did the same errors when they were old – like Einstein with quantum mechanics.

Feynman, however, exceeded all these other guys because he already realized that the reason why he was saying such a nonsense was that he was already too old and a bit senile and slow.

Glashow is a great guy and I certainly share very many points how physics should be approached with him (together with the date of birth that we also share with Heisenberg) but what he has been mostly saying about string theory is, while charming, technically wrong, too.

This is a typical example of the breathtaking hypocricy and inconsistency of the "Not Even Wrong" community. Peter Woit criticizes others for being members of a religious cult led by a guru – but his readers and sometimes Woit himself permanently flood the internet with sociological pseudoarguments based on some irrational quotes of well-known physicists.

It does not matter that they're famous. What they're saying is nonsense as everyone who knows these things at the technical level can check which is why these pronouncements don't have much effect. But at least, they're famous and they have earned a lot of credit in the physics community that they can freely spend by saying bullshit about string theory. Glashow could write hundreds of Woitian articles against current physics and he would still have positive account balance. On the other hand, Peter Woit has no credit. Trash is the only thing he contributes.

Best
Lubos

17. **anon**
August 20, 2006

'Feynman, however, exceeded all these other guys because he already realized that the reason why he was saying such a nonsense was that he was already too old and a bit senile and slow.' – Lubos

Dear Lubos,

Feynman was still sensible enough the same year to expose (1) the o-ring failure cause of the Challenger disaster cause, and more to the point, (2) the role of GROUPTHINK in causing scientific tragedy when false hype about low risks occur, see http://www.ralentz.com/old/space/feynman-report.html

String tragedy is the same; wishful thinking and suppression of dissent on pseudo-scientific grounds (just as well NASA didn't reject Feynman as senile).

Bests,
anon.

18. **Jeremy**
August 20, 2006

How is what Glashow says wrong?

19. **TheGraduate**
August 20, 2006

I think it is fair to say that what is being discussed here is the sociology of science rather than science itself. However, it seems to me that this is precisely the domain of the issue that Peter wishes to address.

I think the issue can be summarized as whether fewer resources should be allocated to string theory or not. There is no way to address this question that removes the human element. I do not think the scientific method can be used to definitively settle such a question. We must therefore look to some other investigative method.

Individuals can be subject to biases but even if they were not, it is usually unreasonable in most contexts for one individual to allow another to decide for him or her simply because the decider claims to be more knowledgeable. There should in most cases be good reasons to defer.

Usually, one asks for objective, real world criteria or neutral third parties and other resources of this nature.

Peter alleges that the string theory community is dysfunctional. The string theory community is free to ignore him. However, I think it is time to acknowledge that without a neutral third party or recourse to the sort of neutral and general criteria that could be applied to any field of science, it will be difficult to move forward.

I think for example the argument that very intelligent people support string theory is an OK argument for an individual to make when trying to convince himself but it is a horrible argument to use when arguing with a heterogenous group of scholars.

20. **Jimbo**
August 20, 2006

When it comes to Glashow, Lubos' comments are clearly, N.E.W.

If Feynman was "senile" in the few years prior to his death, I'll choose senility anyday, compared to LM's babbling rants, as string's principal cheerleader. One wonders if this time next year, when prelim evidence starts to accumulate from the LHC, if he'll be
nearly as vitriolic ?
Lenny's book was really a `shot across the bow' for theoretical physics & science, as it put all on notice that when it comes to the 3-centuries old scientific method, "We must all hang together, or else we shall all hang separately" – B.Franklin
There can be no capitulation to the stringers, without experimental predix followed by expt. proof.

21. **Aaron Bergman**
August 20, 2006

(Beware the Bogdanov sock puppets….)

Anyways, as for

> I remember the time. Before John Baez and Ark Jadzyck started interrogating the Bogdanovs. Nobody was willing to say that it was nonsense, because nobody was sure that it was, and anybody who loudly proclaimed in full view of the public that it was nonsense would soon be humiliated in full view of the public if it turned out not to be nonsense. And nobody was really sure, from just reading the papers, whether or not the Bogdanovs were thinking about anything coherent.

this just isn't true. I was willing to say it. Jacques was willing to say it. John Baez was willing to suggest that it was a hoax after reading it. This is all archived on the internet.

22. **Lubos Motl**
August 20, 2006

Dear anon,

sorry to say but looking at an O-ring, while impressive, is not enough to judge a theory at the Planck scale. It was a cute old Feynman but a different Feynman that one who discovered the Feynman diagrams, and he realized it very well.

If there is a great example of groupthink, then it is the groupthink – or more precisely group-non-think – of the community on this particular blog.

Anyone who says something that this mob doesn't like – i.e. everyone who says something that makes sense – is immediately under coherent fire of this uniform clan of people whose brains are turned off most of the time.

When I talk about Glashow saying nonsense about string theory, I primarily mean the silly comments that string theory is divorced from experiments.

http://www.pbs.org/wgbh/nova/elegant/view-glashow.html

Everyone who knows what string theory does in phenomenology knows that it is a nonsense. Buy the new phenomenology book of Michael Dine when it's out. You will see that string theory is the only framework to think about virtually all possible experimental observations in the future at a deeper level than the level "look, we see something": supersymmetry, axions, dark matter, details of grand unification, small black holes, and so forth, and so forth.

It is clear that many string theorists are more mathematically oriented, but it is a completely logical and correct approach in an era when we simply don't have too many new experiments that could directly lead us. I think that Glashow misunderstands this point, too.

String theory has been gaining importance exactly because it uses strategies that turned out to be most useful for progress in theoretical physics. Even if nothing else than the "details" about the possible braneworld scenarios, AdS/CFT correspondence, mirror symmetry, and a few other mathematical and phenomenological things were the only results in the last 15 years, string theory would clearly beat any other subfield of high-energy physics in this era.

Various discrete gravity people only achieved complete mess that is not interesting for anything. Pure phenomenologists didn't have almost any new ideas – at least no new good ideas that would be unrelated to string theory – either. String theory is the way to go because it gives us both deep mathematics as well as completely realistic new phenomena that are interesting and we would hardly discover them without the beacon of string theory.

That's why it's been naturally growing and it is bad if someone misunderstands how the evaluation of ideas work in the free market of ideas. All the Sean Carrolls and others who try to dictate how much mathematical reasoning vs. how much experimental dreams should be included in theorists' research show that they completely misunderstand that the theorists must use whatever is the best guide at a given moment, and there can't be any verse of the Bible that would define what the best path is forever. They just don't understand science.

Best
Lubos

23. **Lubos Motl**
August 20, 2006

Dear TheGraduate,

indeed, Peter Woit tries to address – and to cripple – the sociology of science. But he has no credentials to do something like that and the scientists generally don't think that there should be sociological committees that would manipulate with science in the way that Woit dreams about in his perverse dreams.

Woit's opinions are both completely flawed as well as unsupported by any scientific credentials, so there is indeed no reason why a serious publisher should print this kind of material as science or as social science.

Dear Aaron,

Baez's statement that Bogdanovs' papers were a hoax was a lie, and it was a very malicious lie. I would personally guess that the real reason why Baez wanted to damage the brothers was that they are more successful in many respects than he is. If the same paper were written by two anti-war janitors, I am sure that Baez would never criticize the authors.

I am still unconvinced that we are so sure that there is nothing interesting about their ideas. What all of you are showing is groupthink. All of you are heroes in saying that you know for sure that the work has no sense whatsoever – simply because you are hiding behind others and if all of you are wrong, the individual wrong people will be forgotten. The same groupthink as the groupthink of the left-wing blogosphere that is "sure" about a wide variety of things, for example that the differences between abilities of various groups have a social origin, not a biological one.

It is an irrational political movement. The anti-Bogdanov hysteria is another example of it. There are hundreds of papers a year submitted to the arXiv and journals that make as much sense as Bogdanovs' papers or less but they are not subjects of this hysteria. All of this hysteria is rotten. And Peter Woit is the last one who has the moral right to criticize the Bogdanov brothers because what he has written about science in the past we remember is much more transparent crap.

Best
Lubos

24. **woit**
August 20, 2006

Aaron is right about the Bogdanov history, many people (including myself) immediately upon reading their papers agreed that they were full of nonsense, and expressed this opinion in public forums. Especially anyone with any expertise in TQFTs could see that the statements the Bogdanovs were making about them were incorrect.

The alternate editor's note pointed out by one commenter is quite interesting. I would very much like to know what the true story is about this. There seem to be two very different versions of this note, the first one claiming there was a problem with the paper, the second denying this. Which is right? If anyone knows the true story here, please let me know.

bob,

Distinguishing sense from nonsense is sometimes easy, but often not. The mechanisms for doing this are well-understood: scholarship and rational discussion. In the case of the Bogdanovs, there are many places where scholars have rationally gone through what they wrote and explained what is wrong with it. John Baez especially did a careful job of this.

In the case of string theory, there's a disturbing level of refusal to engage in this process. The most extreme example around is Lubos, who chooses not scholarly debate, but ideological ranting unmoored from logic and evidence.

As for Lubos, I'm of two minds about his comments. On the one hand, they're perfect examples of the problems with how some string theorists are conducting research in their field. The Harvard string theory group anointed him as their choice for the best young person in the field, and, from all the evidence I have, continues to support him, so he's not some random person who has lost his marbles. On the other hand, he generates reams of idiocy, encouraging other people to respond to it, and this is likely to keep reasonable people from participating in the comment section here. It's also true that he has banned me from commenting on his blog.

So, I'm just not sure what to do…

25. **Chris Oakley**
August 20, 2006

Not directly relevant, but …
Science collides with a Big Bang, by Jonathan Leake.
This is an article in today's *Australian* about cosmology, focusing on disagreements between Neil Turok and Alan Guth. To quote the last paragraph:

> The academic world is often thought to be one of reasoned debate rather than vitriol.†
> What is driving the heated emotions? Peter Woit, an advanced maths lecturer at Columbia University, in New York, believes he has an explanation for the present fury: the physicists are simply getting bored.

————–
† Who thinks that? (No-one I know). What planet is *he* on? (Maybe one of the newly-classified ones).

26. **Aaron Bergman**
August 20, 2006

It's very easy to put forth vague ideas like "the signature of spacetime might fluctuate". To publish a paper, you need to actually calculate something or somehow put some scaffolding around the idea. The problem with the Bogdanov's papers is that almost every technical statement in their papers is either unoriginal or nonsensical. The papers should have never been published.

27. **woit**
August 20, 2006

Chris,

I talked to Leake on the phone the other day, and don't recall saying that this had anything to do with being "bored". What I did say was that scientists often behave less than rationally, but under usual circumstances, experimental results often adjudicate arguments among theorists. The lack of any experimental results relevant to string theory is one cause of the heated controversy there. I pretty much refused to comment on controversies in cosmology since I'm not especially well informed about them. If he'd replaced "bored" by "frustrated", it would have been a more accurate characterization of what I said to him.

28. **Santo D'Agostino**
August 20, 2006

One of Lubos's problems is with the English language. Consider his comment:

"Feynman, however, exceeded all these other guys because he already realized that the reason why he was saying such a nonsense was that he was already too old and a bit senile and slow."

There is a rather large difference between admitting that there is a chance, however small, that one could be wrong, and realizing that one is senile. Lubos does not seem to understand this difference; perhaps he does and is purposely misrepresenting, but I am willing to give him the benefit of the doubt. One hopes that once he becomes more familiar with English idioms he re-reads the Feynman interview with greater understanding.

The same misunderstanding of English, however, cannot forgive Lubos's posting of comments on the Not Even Wrong manuscript at the Amazon web site, and passing them off as a review of the book. (His later posting of a long list of errata on his own web site proved that the comments were indeed about the manuscript.) He mentioned in his "review" that his comments were about a "different edition," when there was only one edition available. Even someone whose first language is not English should realize that these actions are unscholarly. In this case they are also despicable.

29. **Chris Oakley**
August 20, 2006

Hi Peter,

My limited experience of journalists tells me that you were lucky that he wrote something that was even close to what you told him on the phone.
I was reassured when I tracked down an article about the elopement of my great^3 grandparents that the journalist in question had managed to mis-spell *both* their names.

BTW: Please don't ban Lubos. He's the best entertainment on the internet.

30. **David**
August 20, 2006

Dear Lubos,
You say often that ideas should stand or fall on the basis of evidence not on who proposed them. If you believe this, why do you attack people on the basis of credentials or what is, in your opinion, lack of scientific success rather than hard facts? BTW, speaking of hard facts, we are still waiting for your reply on your famous things that have been "more or less rigourously proved wrong" from your 17 page critique of NEW. Here's an opportunity for you to explain why the book is wrong. Further, statistics is a good subject if you're really interested in science. Check out the people part of the Stanford Stat Dept website for papers that provide some great reading.
David

31. **Lubos Motl**
August 20, 2006

Dear Aaron,

I tend to agree with you even though I don't think it is completely trivial to ask questions like "can the signature fluctuate?" I don't remember anyone else asked it before them. What's your answer, by the way? This is about causality in quantum gravity. Of course, the question is only meaningful if one believes that the metric tensor is a good variable even for fluctuations of order 100% which it probably isn't because you need the rest of string theory in this regime. 😉

Whether or not the papers are published depends on the referees but do you believe me that they were far from the only paper that could be labeled as unsuitable for publishing by many physicists? I am ready to list examples because it is just wrong if everyone thinks that it is desirable to attack Bogdanovs all the time while no one would dare to say something similar about similar papers.

Why is there so much hysteria about it? They were just trying to add another paper about very difficult questions that was expected not to break the mysteries given their being outsiders. They were not trying to argue that all of physics is wrong or something like that which is what some of their colleagues try.

Best
Lubos

32. **Aaron Bergman**
August 20, 2006

There are plenty of crap papers on the ArXiv as everyone knows (although I'd say that there's more outright nonsense in these papers than anything I've seen in a long time). The reason why the Bogdanov's got so much attention was mostly because of the initial rumor that it was an intentional hoax, but also because the papers got past the refereeing process.

33. **Rickkkk**
August 20, 2006

Peter, I think Leake was simply extrapolating that no experimental results leads to boredom. I think it's a correct statement, but perhaps not quite concise. Metaphorically speaking, the lack of experiments have allowed these arguments to flourish in a way that idle hands cause problems. It's subtle, but a still accurate metaphor.

34. **Chris Oakley**
August 20, 2006

> The reason why the Bogdanov's got so much attention was mostly because of the initial rumor that it was an intentional hoax, but also because the papers got past the refereeing process.

I think that you will find that their having a prime-time science TV show also had something to do with it.

35. **Peter Woit**
August 20, 2006

Santos and David,

It's bad enough having this comment section cluttered with people who want to discuss Lubos's current nonsense, please don't try and carry on older arguments with him here.

36. **anon**
August 20, 2006

Dear Lubos,

'You will see that string theory is the only framework to think about virtually all possible experimental observations in the future at a deeper level than the level "look, we see something": supersymmetry, axions, dark matter, details of grand unification, small black holes, and so forth, and so forth.'

Sure, stringy stuff is a good framework for planning sci-fi, but it isn't making unique checkable predictions that could falsify it when tested. The nearest you come is with the soft scattering spectra, but even if that is real, it could just have another cause. The best experimental checks on string theory will be open to other interpretations, because it is so vague. String theorists are careful to kick in new alternative ideas like Smolin's while they are still infants, before they can grow into a viable threat to stringy stuff.

Many claimed stringy predictions, such as large 0.1 mm-sized extra dimensions, are just not falsifiable. If the strings aren't found, maybe you just rule out that sub-version of string theory or else blame the sensitivity of the experimentalists. You dismiss such critics as Feynman and Glashow as senile or crackpot, while asserting uncheckable, speculative, empty frameworks instead of building on facts!

As for the Bogdanov's, the tale is that there were two brothers, one of which was failed his PhD examination and was told to get peer-reviewed stringy papers published before he received the degree. After publication, he was awarded the PhD. This story is almost as fantastic as string theory itself, so maybe it's just half-truths/lies. I've abused Woit's hospitality enough so had better end here.

Kind regards,
anon.

37. **Jeremy**

August 20, 2006

Peter,

Do nothing. I have been moderating online discussions for years. Getting rid of people who say something in opposition, something which is different, or even something which is "merely" hurtful, is rarely a solution.

From my outside perspective, Dr. Motl doesn't detract as much from discussion as much as you may think he does (except in not allowing you to speak on his own web site). While his comments could stand to be respectful, the dozen or so I've read so far tend to be on topic as regards the posts in which they respond to, though they all share the disrespectful quality. Also see one of my initial emails to you as regards a person's lifetime work being challenged.

As to the charge of being tendentious, I am only about halfway through the book right now, but I've read nary a statement so far which matches the word. There is certainly the strong point of physicists vis a vis mathematicians, and the title would indicate a large lean towards being against String Theory.

That a book about the point of view that resources, time and energy should be allocated more towards other endeavours is tendentious is, well, patently obvious. I don't think Mr. Bergman has made a case for your description of events and explanations being heavily slanted (I would certainly expect there to be some slant). I will, of course, reserve judgement in that respect until I have completed the book.

Dr. Motl,

Thank you for your response on Glashow.

38. **bob**
August 20, 2006

Peter said:
Distinguishing sense from nonsense is sometimes easy, but often not. The mechanisms for doing this are well-understood: scholarship and rational discussion.

Of course, but these are not objective criteria; they are just labels which anybody can apply to himself and deny to his enemies. Lubos can write what he writes and then say that it's scholarly and rational, and you can disagree and say that what you are saying is rational and that what he says is incoherent. Everybody can then take sides, insulting one another, and claiming that it is clear and easy for everyone to see which side is right, when both sides are lying about this. It is not easy; it is very difficult, and objective criteria are needed, and "scholarship and rational discussion" are very good indeed if you have specified a procedure for distinguishing between rational scholarly argument and incoherent nonsense.

But there is no such procedure, or at least nobody has specified one. So instead the situation is that an honest person looks at either side where the people say "The arguments of the other side are nonsense, and this is clear for everyone to see, and anyone who doesn't see it is stupid". Neither you nor Lubos can point to any objective standard which could be used to make the decision, though you will both claim that objective standards exist which your opponent fails to meet, but neither of you can specify them.

39. **Arun**
August 20, 2006

Aaron's review does address "the only game in town" and amends it to the "best game in town", and gives two cogent arguments from physics (blackholes and AdS/CFT) why it is interesting and also from the math. point of view. He does say he doesn't have any good idea as to where a better game might come from, and believes and hopes the next Einstein will make his breakthrough regardless of the system of academic research in place.

I do think the discussion needs to proceed from that point – can we make the "better game" less prone to accident? I certainly don't mean that good ideas can be produced on demand. But supposing some one does come up with a good idea, how do we make sure it doesn't perish unheard? It seems obvious to me that there are more hospitable and there are less hospitable environments for good new ideas; do we have have any way of improving the environment?

40. **David**
August 20, 2006

Sorry.

41. **Tony Smith**
August 20, 2006

Arun asked "… supposing some one does come up with a good idea, how do we make sure it doesn't perish unheard?
It seems obvious to me that there are more hospitable and there are less hospitable environments for good new ideas;
do we have have any way of improving the environment? …".

My ideas about that (which I have stated before in other comments and elsewhere, so my apologies for redundancy) are:

No consensus-monopoly view should be allowed to suppress alternative approaches.
A thousand flowers should bloom,
and all important institutions (university departments, laboratories, institutes, etc) should encourage active investigation of ALL the blossoms,
by rewarding grad students, post-docs, etc., for work on whatever they find interesting.
If a studied model turns out to be wrong, then the work showing it to be wrong should not be considered a worthless negative result, but a useful contribution (like weeding a garden) to advancing physics by cultivation,
and such negative results should be just as important as positive ones in getting publications, Ph.D.'s, post-doc jobs, and faculty appointments.

A big problem in implementing such an environment is that it would do away with closed good-ol-boy dominant-paradigm networks in which good-ol-boy A gives postdoc jobs, etc, to grad students etc of good-ol-boy B and all the good-ol-boys (and their grad students etc) always enjoy big barbecues in which all the HEP-theory pork is spread around among the Members of the Club.

Such Pork Clubs are very hard to get rid of in any human community, whether it be Congress or HEP or anything else. Even if a "Reformer" comes along and defeats the "Entrenched Machine", most of the time the "Reformer" just becomes a new "Emperor" (which is why Beethoven's Symphony 3 was not named for Napoleon).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Even Beethoven had difficulty getting great new ideas accepted by the establishment.
According to some CD liner notes by Constantin Floros:

"… When the news was brought to him that one of his [late string] quartets, played by Schuppanzigh, had met with a poor reception, he [Beethoven] said laconically: "One day it will please them." …".

42. **Peter Shor**
August 21, 2006

You say that

> Aaron notes that most of the audience at the Toronto panel discussion voted against the anthropic landscape, but he doesn't mention that anthropism seemed to be a majority opinion amont the panelists, who are the ones who hold power. This is an extremely dangerous situation for this field.

Is antropism the majority view among the string theorists that hold power, or just the loud ones? Because it seems to me that there are a few very loud, somewhat crackpot, string theorists, who have discovered that spouting lots of speculative nonsensical stuff brings them publicity. There are also a number of fairly sane string theorists who have relatively little to say right now because the field is only making very slow progress at the moment. And for some reason, the sane string theorists are too polite or too afraid to say anything negative about the loud ones. The sad part would be if, in the current climate, spouting loud, interesting-sounding, nonsense is a good way to advance ones career.

43. **Peter Woit**
August 21, 2006

Peter,

Besides certain loud ones (Susskind), the anthropic landscape is promoted by quite a few less loud but very prominent theorists. Examples include Harvard's Nima Arkani-Hamed, as well as Joe Polchinski, Michael Douglas, Shamit Kachru. I'm sure there are lots of theorists who are not happy with the anthropic landscape, but at this point I think most of them accept the idea of the landscape, if not the anthropic part. Most remarkably, the only string theorist I know of who seems willing to publicly criticize anthropism is David Gross.

44. **ksh95**
August 21, 2006

Bob commented:

> Neither you nor Lubos can point to any objective standard which could be used to make the decision, though you will both claim that objective standards exist which your opponent fails to meet, but neither of you can specify them.

The standard is and always has been clear: in the absense of experimental evidence the group that can accumulate the most power becomes correct.

45. **TheGraduate**
August 21, 2006

I have been reading this blog for a year and a half now. As someone who is considering grad school in a year, I guess I am probably part of the target audience of the recent books about string theory … in that, they have and continue to have an influence on the things I think about studying. They also have an influence on what I say to other people who are thinking about what field they want to go into.

I am mostly neutral at this point. I still think string theory might be enjoyable for purely mathematical reasons even if the physics thing doesn't work out but am not one for believing things that have no experimental foundation. My faith in the 'unreasonable effectiveness' of mathematics is not that strong.

Peter

I was wondering to what extent do you believe the 'cult-like' behavior had to do with external monetary pressures and public exposure. Are people unaware of possible deficiencies in their arguments or simply unwilling to admit this in public due to the loss of prestige, power etc? The former would be irrational while the latter is quite rational.

To my mind, the idea that theory needs to be supported by evidence seems pretty straightforward. Is there something about the culture of theoretical physics that I am missing?

I would also be curious to know whether people think that US national politics plays a role in this. I have noticed that for instance, at least in the case of Lubos, he is very concerned about 'anti-science' attitudes. Is this kind of concern common in the string theory community?

You see this kind of concern repeated often in national politics from contraversies with evolution, to AIDS, to global warming. Is string theory just part of a larger trend of rocky relationships between science and the public and issues concerning the nature of evidence?

46. **Shamit Kachru**
August 21, 2006

Hello:

Since I occasionally see responses by active scientists here, I am writing for their benefit:

You will see many views attributed to prominent particle and string theorists in this blog. (Or Motl's blog, or other blogs of similar ilk; there are now several). In many cases that I am aware of, these attributions range from outright lies (in more than one case, statements that I never made have been attributed to me), to vast oversimplifications or quotations taken out of context, on issues of significant complexity. In the blog discussions of the "landscape," I am sure from personal knowledge that many brief summaries of the views of leading theorists (put forth by active bloggers) have ranged from misleading to simply incorrect as representations of the person's actual opinion. Usually these incorrect summaries of the opinions of others, have served as launching points for polemics (which are a peculiar but common feature of several of the popular blogs).

Most of the subjects under active investigation in particle/string theory, are not best discussed in blog-level sound bites. This is not unique to particle/string theory, of course. So for any active scientists out there, don't think what you read here in any way represents the views and activities of your particle theorist colleagues: ask them directly yourselves, to get a better picture.

Since blogs can be a tremendous time sink, most of us (certainly me) do not usually respond even to those threads that pretend to directly address the goals and merits or flaws of our work. For that reason I certainly won't make more appearances here; it just seemed possibly useful to inform (remind?) everyone of the obvious comments above.

Shamit Kachru

47. **John Baez**
August 21, 2006

Peter writes:

The alternate editor's note pointed out by one commenter is quite interesting. I would very much like to know what the true story is about this. There seem to be two very different versions of this note, the first one claiming there was a problem with the paper, the second denying this. Which is right? If anyone knows the true story here, please let me know.

Check out the Wikipedia article on the Bogdanov affair – and also the discussion page for that article.

According to the article, the editors of Classical and Quantum Gravity issued a note by email saying:

Regrettably, despite the best efforts, the refereeing process cannot be 100% effective. Thus the paper […] made it through the review process even though, in retrospect, it does not meet the standards expected of articles in this journal. The paper was discussed extensively at the annual Editorial Board meeting […] and there was general agreement that it should not have been published. Since then several steps have been taken to further improve the peer review process in order to improve the quality assessment on articles submitted to the journal and reduce the likelihood that this could happen again.

If you're curious about this emailed note, ask Greg Kuperberg.

According to Wikipedia,

Later, the editor-in-chief of the journal issued a slightly different statement on behalf of the Institute of Physics, which owns the journal, in which he insisted on the fact that their usual peer-review procedures had been followed, but no longer commented on the value of the paper. In particular the sentences "[…] it does not meet the standards expected of articles in this journal" and "The paper was discussed extensively at the annual Editorial Board meeting […] and there was general agreement that it should not have been published" were removed."

In the discussion page, you'll see that lots of mysterious people – or maybe just one or two, using lots of pseudonyms – tried to change this Wikipedia article. Just like the fellow who posted here, these people tried to downplay the original note. The folks at Wikipedia eventually blocked these changes, deciding they were caused by "sock puppets": the Bogdanov brothers in disguise. This seems likely, both because it's they did the same thing to Jacques Distler, and because: who else would bother?

So, Peter, I guess the Bogdanovs are reading your blog and posting to it. Congratulations!

48. **woit**
August 21, 2006

John,

I've been the recipient of fake e-mails from the Bogdanovs, so did check that the source of this comment wasn't the same as that of one of those. Looking at the Wikipedia discussion, I see that this has become much more complicated, presumably involving lots of different addresses. The source of this comment is a Paris internet connection, but I have no idea whether it's from the Bogdanovs or someone else.

The information in the comment is accurate as far as I can tell. Personally, I was unaware that CQG had changed it's statement from the one Kuperberg distributed, which acknowledged a failure in the refereeing system, to the later one, which did not acknowledge this. Actually, I find this kind of appalling.

49. **woit**
August 21, 2006

TheGraduate,

I don't think the controversy over string theory has anything to do with the political fights going on in the US over science. Lubos's description of any criticism of string theory as "anti-science" is just ridiculous, part of attempt to attack in over-the-top manner anyone who disagrees with him about the subject.

The political fights about science have to do with the Bush administration's embrace of the religious right and its attitudes, and physics pretty much has nothing to do with this. I don't think the religious right has any opinion one way or another about string theory, and the Bush administration has recently made physics research one of its top priorities for higher funding.

As to why string theorists so often refuse to acknowledge problems with the subject, I won't speculate about their motivations for doing this. However I will say that I think it is a big mistake, both for scientific reasons, as well as non-scientific ones. They're seriously damaging their own credibility and that of the field as a whole.

50. **woit**
August 21, 2006

About Shamit Kachru's comment,

I'd like to point out that I make a very serious effort here to be as accurate as possible, although I'm sure I don't always succeed. When discussing someone's views, if possible I try and quote their own words, completely and in context. In the case of the Landscape, I've at times been so appalled by what I see going on that I've expressed myself in excessive ways that were not wise.

Presumably he's responding to my characterization of him as a proponent of the anthropic landscape point of view, and suggesting this is less than accurate. This characterization is based on some of his talks, and of the following quote from his colleague Susskind (see page 351-2 of his book):

"At Stanford University – my home – there is pretty near unanimity on the issue, at least among the theoretical physicists: the Landscape exists. We need to become explorers and learn to navigate and to map it Shamit Kachru and Eva Silverstein, both in their early thirties, are two of the world's young leaders. Both are busy constructing the Landscape's mountains, valleys and ledges. Indeed, if I were to attribute to anybody the title of the Modern Rube Goldberg, it would be to Shamit. Don't get me wrong; I don't mean to say that he makes bad machines. On the contrary – Shamit has brilliantly used the complicated machine parts of String Theory better than anyone to design models of the Landscape. And the Anthropic Principle? It goes with the territory. It's part of the working assumption of all my close colleagues at Stanford, young and old."

Susskind presumably has extensively discussed this with Kachru. If his characterization of Kachru's views is inaccurate, Kachru's problem is not with blog postings like mine, but with a published book of his senior colleague. A blog might actually be an excellent place to set the record straight if Susskind's published version is incorrect.

Kachru is quite right that some of these issues are complicated and discussions of them have sometimes invoked oversimplified or incorrect descriptions of his views or those of other people. But I don't think he's right that this medium is inappropriate for serious discussions of these issues. He and anyone else who wants to carefully explain their views on the issues discussed here is strongly encouraged to do so. I'll happily post here anything of this kind that he or anyone else who feels similarly is willing to write.

51. **Peter Shor**
August 22, 2006

I am certainly drastically oversimplifying things here, but if I am to believe Shamit Kachru and Peter Woit, not only are the loud string theorists spouting nonsense, but some of them are also claiming that everybody agrees with their nonsense. And as I said,

> for some reason, the sane string theorists are too polite or too afraid to say anything negative about the loud ones.

52. **TheGraduate**
August 22, 2006

Dr Kachru:

In business, management and even law, there is often the issue of how to allocate resources to views proposed by different experts with sharply contrasting points of view.

Assuming that one is not going to read every bit of everyone's work before deciding, what does one rely on:

1. Credentials

2. A documented track record of successes

3. The relative amount of support for the differing points of view among those in the know

My only window on this contraversy are these blogs, the magazines and talking to other people that enjoy the occasional read of 'Scientific American' or 'New Scientist'.

My best guess is that to the casual, neutral observer whose first opinion on string theory is primarily derived from the Nova special and seeing Brian Greene at their school (as I definitely did) … I would say that for that sort of person, the recent contraversy about string theory seems pretty plausible.

I think to the general neutral party, the idea that one would need evidence to support a particular point of view is pretty uncontraversial and this line of reasoning would make sense to an engineer, a lawyer or even a banker.

I think it has become fashionable with the magazines to play up the contraversy as this is the sort of thing that sells magazines: Time, Scientific American etc

I would actually really appreciate if a few people from the string community seriously debated Dr Woit. From my observations of the blog, Dr Woit seems very earnest about allowing fair debate.

Normally, I would say this sort of debate is the internal business of the scientific field involved but at least since the Nova special, many issues of string theory have become public interest.

53. **DMS**
August 22, 2006

I too would hope Shamit Kachru would post a long detailed reply somewhere. A blog posting is an ideal place, in my opinion.

I would suggest that it is a HUGE mistake for prominent string theorists to ignore criticism from Peter Woit and others and dismissing opinions of outsiders as 'crackpots'. Maybe some get satisfaction by "High-Five-ing" insults of Peter and Lee by some string theorists, but it is not helping change the perception of string theory or string theorists among outsiders.

For all the criticism of string theory by Peter(sometimes unfair, I think), it is INFINITELY BETTER than what a prominent string theorist did by writing popular books on "Cosmic Landscape and the Illusion of Intelligent Design". It won't be long before the "illusion" part is dropped in the popular perception of the subject. Perceptions matter.

It does not help when patently false/exaggerated statements are made to promote the subject. Please stick to the remarkable results that have been of great interest to mathematicians; that is impressive by itself. And admit failure of string theory in uniquely predicting physics beyond the standard model(obviously, compatibility with anything coming out of the LHC is not the same as a prediction).

Ultimately, credibility of physicists, and ultimately science is at stake. Scientific thinking is under assault, but not from Peter. Look further AND closer….

54. **Juan R.**
August 22, 2006

Lubos Motl Said:

> Witten is a guru because he's the most achieved theoretical and mathematical physicist alive. But it is only Peter Woit who builds a religion on this.

Well, Sylvester James Gates, Jr. (the Jim Gates of the superstring site) states in a NOVA interview:

> String theory is often criticized as having had no experimental input or output, so the analogy to a religion has been noted by a number of people. In a sense that's right; it is kind of a church to which I belong. We have our own popes and House of Cardinals.

I agree with Jim Gates.

Juan R.

Center for CANONICAL |SCIENCE)

55. **anonymous**
August 22, 2006

Dear Peter,

I don’t know much about Shamit Kachru’s views on the issue, but I don’t see how the Susskind quote implies that he is a proponent of the anthropic approach.

56. **woit**
August 22, 2006

anonymous,

“the Anthropic Principle? It goes with the territory. It’s part of the working assumption of all my close colleagues at Stanford, young and old.”

the quote pretty explicitly claims that the Anthropic Principle is Kachru’s working assumption in his Landscape research. Presumably he’s a proponent of his own research and its assumptions. Undoubtedly, as he says, his views about this are more complicated. But I wasn’t purporting to give an accurate and full description of his views, just listing him among others who are propounding a research program that invokes the Anthropic Principle, and Susskind clearly identifies him as part of this group.

57. **TheGraduate**
August 22, 2006

Most of responses I have so far heard to Peter’s criticisms by people who state that they are string theorists are often angry and of the “I will not dignify this with a response” variety.

I had gradually been coming to the conclusion that Dr. Motl is some kind of crazy person. As far as I can tell. I have observed him having fights with several people on string theory and several other things. I am astounded that he teaches at Harvard. I assume he is tremendously knowledgeable on what he has been hired to teach about. However, he seems very bad at everyday causal reasoning … in my opinion.

I was also disappointed in the episode where Susskind says “There’s another fellow who has his own theory, I won’t tell you who his name is or what his theory is, but he writes lots and lots of theories and his theories go glub, glub, glub to the bottom of the sea before he even gets a chance to put them out there.” … with consequent fall in my opinion for both him and Stanford … Anyway, I digress.

I am somewhat curious about whether this sort of disdain extends not just to the ‘stupid’ physicists but if it also extends to the ‘stupid’ public. After all, I assume the point of the many attempts to popularize the subject was to bring the public into their otherwise insular world. And of course, quite a few of their endeavours require public good will and support and most importantly public money.

58. **Chris Oakley**
August 22, 2006

> I had gradually been coming to the conclusion that Dr. Motl is some kind of crazy person.

Just as a matter of interest … how long has it taken you to get to this realisation?

59. **J.F. Moore**
August 22, 2006

Although I’ve been looking forward to the American release of your book, Peter, I must admit I was worried that it might bog down on the details at the expense of giving a nice sweeping view for the lay reader (or a scientist in a totally different field like me). Your comments indicate that I have nothing to worry about and make me anticipate it even more. Also, I think it is great that a trade firm that might push hard (who knows?) to the mass market is publishing your book. I look forward to seeing you on Oprah as the monthly book selectee (joking).

60. **Peter Woit**
August 22, 2006

J.F. Moore,

General advice to readers of the book is that there are certain sections, especially in the earlier chapters, that are aimed at a more specialized audience, but the book is written so that if you skip ahead you should still be able to follow what is going on.

By the way, I just got a big carton of books delivered to my office, and it looks to me like the thing is available for sale on Amazon.

61. **tweet-tweet**
August 22, 2006

Lubos,

You’ve published your own criticism of loop quantum gravity, on wiki as “objections to loop quantum gravity” for which lee smolin and others have written their rebuttals (you called tweet-tweet’s facted-based responses to your list of objections “vandalism” on wiki)

so how is Peter’s book any different from what you did for wiki? Esp since popular books on string theory, such as michio kaku’s and briane greene’s, make almost no mention of the problems string theory has? as a scientific emprical theory, string theory does have problems you must admit.

you strongly object to lqg as doing science, yet you object to people who object to string theory as science.

62. **Who**
August 22, 2006

Hello tweet,
It was also my impression that the original “objections to loop quantum gravity” in the wiki article contained inaccurate assertions, thanks for trying to correct them! I believe that section was eventually removed from the wiki LQG article, was it not?

To get back to the Aaron Bergman review, I think it has misleading statements on page 5 which could be corrected. This is a key section where he presents a justification for continued string research, perhaps THE most often used justification—that requires giving a false impression of progress achieved in non-string QG, so as to make the “game in town” point.

I will quote the review and bold some places where I think what Aaron says is questionable, as may be seen by consulting recent papers on arxiv such as

http://arxiv.org/abs/gr-qc/0604044
Graviton propagator in loop quantum gravity
http://arxiv.org/abs/gr-qc/0604016
Hidden Quantum Gravity in 3d Feynman diagrams

"One exception is the collection of ideas generally termed Loop Quantum Gravity (LQG)… It is a radically new class of theories that has as yet been **unable to make any contact with the major results of the usual style of quantum theory**. In contrast to string theory, the theory of quantum gravity so produced has **not been able to demonstrate even the attraction known to Newton** hundreds of years ago… "

thanks.

63. **Anon**
August 22, 2006

Having read both of those papers, I think Bergman's statement remains (for the present) completely accurate.

But I guess a critical discussion of those papers would be "off-topic" as far as Peter is concerned.

64. **Peter Woit**
August 22, 2006

Anon,

Yes, please, I don't think any light would be shed here by going over that same argument again. It is certainly worth pointing out though that many people working on LQG would disagree with Aaron's characterization of the subject. But another venue moderated by someone else would be the place to discuss this.

65. **YBM**
August 23, 2006

Peter, could you post here (or send me by e-mail) the IP address of this likely sock puppet ? I could easily checked if it's Igor/Grichka or not.

BTW, It is clear from Lubos' comment that he didn't even try to check the actual content of the Bogdanov's papers, neither did he checked all the distateful parts of this affair (falsifications, sock puppets, treats, misquotes – even he is one of their victim), he merely instrumentalizes this affair against you because you happen to have pointed out their blunders. This conduct of him backfired on his face. I do not think that someone able to support crackpots in order to attack one of his collegue deserve any respect.

66. **Peter Woit**
August 23, 2006

YBM,

Thanks for looking into this, it does appear that this comment came from one of the Bogdanovs. Thanks also for the news of their forthcoming book: Voyage vers l'Instant Zero.

http://ybmessager.free.fr/epiphysique/forums/phpBB2/viewtopic.php?t=183

67. **YBM**
August 23, 2006

In case some of this blog readers would like to comment on the specific issue of the Bogdanovs affair, which is quite off-topic here : the forum accepts posts in english.

68. **tweet-tweet**
August 23, 2006

hello who,
yes lubos article is not in wiki, but is in the lqg talkback. it does not pass wiki's npov.

anon, perhaps the physics forum is the place to discuss the two papers?

69. **anonymous**
August 23, 2006

Dear Peter,

You say,

—
"the Anthropic Principle? It goes with the territory. It's part of the working assumption of all my close colleagues at Stanford, young and old."

the quote pretty explicitly claims that the Anthropic Principle is Kachru's working assumption in his Landscape research.
—

I still don't think it is fair to base the claim that Kachru promotes the anthropic approach on this quote by Susskind, so I guess we just disagree on this issue.

70. **YBM**
August 24, 2006

Motl> "Profs. Bogdanovs from the University of Belgrade…"

1. The Bogdanovs brothers have never been professors
2. There is no link between them and the University of Belgrade, they got their Ph. D. from University of *Bourgogne*, in France (Dijon)
3. The Bogdanovs have never been members of any laboratory or university since they've got their Ph. D (the lab they've been in Bourgogne has even been dismissed right after that !)

Motl really took time to examine what he’s talking about. Anyway he’ve admitted having the same views on science as a whole as the B. Does he mean that misquoting people, forging thesis reports and falsifying documents are standard behaviour ?

Some Links

August 20, 2006
Categories: Uncategorized

Lee Smolin's forthcoming book "The Trouble With Physics" has a web-site.

There's a new group blog focusing on n-categories, The n-Category Cafe, which will be run by John Baez, David Corfield and Urs Schreiber. It looks like Urs will basically be moving operations from The String Theory Coffee Table to this new blog.

The August issue of Symmetry is out. Lots and lots of articles about the LHC.

For the past week and a half Fermilab has been hosting a summer school on physics at Hadron Colliders. The talks are available here, and many are quite interesting. For example, history buffs should look at the talks on the top discovery by Tollefson and Varnes, and there's a nice survey talk by Chris Hill in which he emphasizes the role of symmetries. Hill notes that unification of couplings in the MSSM doesn't quite work, off by 3 sigma in the prediction of the strong coupling constant. He describes supersymmetry as "our best operational hypothesis" but believes that "It (probably) won't be the MSSM!!!".

The Telegraph seems to have tracked down Perelman and has an article about him entitled World's top maths genius jobless and living with mother. It claims that Perelman is not going to the ICM, where it is assumed he will be awarded the Fields medal, because he can't afford the trip. It also claims that in 2003 he was not re-elected to the Steklov institute and forced to leave. I find lots of things in the article hard to believe, remarkable if they're true.

The rumor is that this week's New Yorker, on the newstands tomorrow, will have a long article by Sylvia Nasar (author of the Nash biography, "A Beautiful Mind") about the Poincare Conjecture and Perelman's proof.

Last month the IHES held a conference on motives. Many lectures and references are now available here.

The IHES web-site also has a preprint of a new survey article by Pierre Cartier entitled A primer on Hopf algebras.

This summer's Park City program was on the topic of Low Dimensional Topology. Some lecture notes are available here. These include notes taken by Gabriel Drummond-Cole, who also has lots of other notes from interesting talks and lecture courses.

Update: The New Yorker article, by Sylvia Nasar and David Gruber, is called "Manifold Destiny" and is in this week's issue, but not available on-line.

The ICM is starting tomorrow, with video of talks available here. There seem to be four lecture slots scheduled for lectures by Fields Medalists, I'm deeply embarassed that I still haven't heard reliable rumors about who they all are. There have been solid rumors identifying Tao and Perelman, of the less solid ones retailed here, Bhargava sounds to me the most plausible. I guess we'll know soon….

Update: The New Yorker article is now available on-line.

Comments

1. **anonymous**
   August 20, 2006

   Some of the morning lectures at the IHES school have been recorded on video, and that includes the lectures of Kontsevich. Perhaps one could get hold of them if there's an interest.

2. **Who**
   August 20, 2006

   wasn't the title "A Beautiful Mind"?

3. **QWERTY**
   August 20, 2006

   IT SOUNDS LIKE PERELMAN DOES WANTS TO GET THE FIELDS MEDAL. SURELY THE ICM WILL PAY FOR THE TRAVEL EXPENSES OF FIELDS MEDALISTS? I HOPE HE DOES NOT GO CRAZY LIKE GROTHENDIECK

4. **An interested reader**
   August 20, 2006

   Yes it was called a beautiful mind.

   I enjoyed your book, now I want to enjoy the controversy: wouldn't it be a good idea to group the links to all the reviews of Not Even Wrong that you know of, to help interested readers?

5. **woit**
   August 20, 2006

   Thanks Who, I thought there was something wrong with that when I wrote it, but was in a hurry. Fixed now.

   Interested reader,

   Putting together a page with links to all the reviews I know about is on my to do list, should get to it soon.

6. **Chris W.**
   August 20, 2006

   The book: *A Beautiful Mind* (ISBN 0743224574)

   The New Yorker's table of contents for 8/21 shows no sign of an article by Sylvia Nasar.

7. **woit**
August 21, 2006

Chris W.

That's last week's issue, this week's will have a cover date of 8/28.

8. **Mnev**
August 21, 2006

Yes, Sylvia Nasar was here in SPb in june.

9. **Who**
August 21, 2006

Yes, Sylvia Nasar was here in SPb in june.

wow. excuse my naive enthusiasm. She was already onto the story, the editors at NYorker had probably already OK'd the idea and she was already in Saint Petersburg doing the research. In June.

Let's hope for the best, as a piece of writing.

Mnev congratulations on being a fellowcitizen of so many outstanding poets and mathematicians, men and women alike. SPb = great town

10. **Mnev**
August 21, 2006

Thanks. I agree. Nobody knows strings here.

11. **Who**
August 21, 2006

Nobody knows strings here.

This is fortunate.
They have the chance to invent something quite different.

12. **Chris Oakley**
August 21, 2006

Review of anti-science books in *Scientific American*:

13. **Who**
August 21, 2006

The anti-science writer who reviewed the anti-science books is George Johnson who has a picture of his gravestone
http://sciwrite.org/glj/gravestone.jpg
posted on his website
http://sciwrite.org/glj/

thx Chris

14. **TheGraduate**
August 21, 2006

The review in Scientific American says "10500 perfectly good M theories" which I immediately thought was a manageable number but It's actually 10^500 right?

Also, the article in the New Yorker seems to be called "Manifold Destiny: Who really solved the Poncairé Conjecture?" by Sylvia Nasar and David Gruber.

15. **ObsessiveMathsFreak**
August 21, 2006

> The Telegraph seems to have tracked down Perelman and has an article about him entitled World's top maths genius jobless and living with mother.

Once again, Perelman has raised the bar for mathematicians everywhere.

16. **Who**
August 21, 2006

[b]Once again, Perelman has raised the bar for mathematicians everywhere.[/b]
This is without question the silliest thing that has ever been said in Peter Woit's blog since its inception. We must be careful!
Let us make a serious effort to get on topic, whatever the topic is, so that Peter does not shut down the thread!

17. **DMS**
August 21, 2006

Actually, [Erdos](#)was also remarkably similar to Perelman in one sense; he had no money or interest in material wealth. Erdos had no home(lived out of a suitcase) or money, and survived on the goodwill of fellow mathematicians(particularly R Graham). He was also rather uninterested in fame. He should have received the Fields with Selberg or the elementary proof of the Prime Number theorem(among many other things).

But then again, history will view Erdos as being a far greater mathematician than Selberg…

I hope the mathematical community makes sure that Perelman has money and equipment(i.e, pen, paper, laptop, internet access) to support himself and his mathematical work.

18. **anon**
August 21, 2006

Sabine has confirmed the first application of string at the Backreaction blog:

http://backreaction.blogspot.com/2006/08/bumpy-white-string.html

I apologise to Lubos Motl. String does inspire useful technological innovations, despite being useless in science.

Perelman and Tao are Field medalists, but who are the other two?

22. **Thomas Larsson**
August 22, 2006

[Hill] describes supersymmetry as "our best operational hypothesis" but believes that "It (probably) won't be the MSSM!!!".

Does this mean that there is growing consensus that the MSSM is wrong? If so, what does it mean for SUSY as a solution to the hierarchy problem, which was the main reason for believing in SUSY in the first place?

Prof. Manjul Bhargava

Ph.D. Princeton University 2001
Dissertation: Higher Composition Laws
Advisor: Andrew Wiles

Manjul Bhargava: An Artist of Music and Math

Music, Math… "One of my favorite activities is listening to Indian classical music, a most wonderful and multidimensional form of music which unfortunately still has not fully yet made its way to the West. I also enjoy playing the tabla, the most common of the Indian percussion instruments…"

What a relief. Imagine if he played stringed instruments, theoretically…

24. **ICM News**
August 22, 2006

The 2006 Fields Medalists are:

1) Andrei Okounkov (Princeton University),
CITATION: "For his contributions bridging probability, representation theory and algebraic geometry",

2) Grigori Perelman (formerly of Steklov Institute of Mathematics, St. Petersburg)
CITATION: "For his contributions to geometry and his revolutionary insights into the analytical and geometric structure of the Ricci flow",

3) Terence Tao (University of California, Los Angeles),
CITATION: "For his contributions to partial differential equations, combinatorics, harmonic analysis and additive number theory", and

4) Wendelin Werner (Université de Paris-Sud, Orsay),
CITATION: "For his contributions to the development of stochastic Loewner evolution, the geometry of two-dimensional Brownian motion, and conformal field theory".

2006 Nevanlinna Prize goes to Jon Kleinberg (Cornell University).

The first awardee of the Gauss Prize is Kiyoshi Itô (formerly of University of Kyoto, now retired).

Well done all!

Four Are Given Highest Honor in Mathematics
Courtesy of International Congress for Mathematicians

http://www.nytimes.com/2006/08/22/science/22cnd-math.html?ex=1313899200&en=897c1543a33626bc&ei=5088&partner=rssnyt&emc=rss

Terence Tao, a native of Australia, is one of the youngest Fields Medal winners ever at age 31.

Grigory Perelman is the most prominent of the medalists, not only because the Poincaré conjecture had ranked among the most heralded unsolved math problems, but also because of his reclusive personality.
Courtesy of International Congress for Mathematicians

Wendelin Werner, top, works on problems at the intersection of mathematics and physics. Andrei Okounkov, bottom, was honored "for his contributions bridging probability, representation theory and algebraic geometry."

But Dr. Perelman refused to accept the medal, as he has other honors, and he did not attend the ceremonies at the International Congress of Mathematicians in Madrid.

Sir John Ball, president of the International Mathematical Union, which is holding the conference, told The Associated Press that he did not think Dr. Perelman's decision to turn down the award was intended as a snub. "I am sure he did not mean it that way," he said.

The Fields Medal, often described as mathematics' equivalent to the Nobel Prize, is given every four years, and several can be awarded at once. Three other professors of mathematics were awarded Fields Medals this year: Andrei Okounkov of Princeton; Terence Tao of University of California, Los Angeles; and Wendelin Werner of the University of Paris-Sud in Orsay.

Dr. Perelman, 40, is known not only for his work on the Poincaré conjecture, among the most heralded unsolved math problems, but also because he has declined previous mathematical prizes and has turned down job offers from Princeton, Stanford and other universities. He has said he wants no part of $1 million that the Clay Mathematics Institute in Cambridge, Mass. has offered for the first published proof of the conjecture.

Beginning in 2002, Dr. Perelman, then at the Steklov Institute of Mathematics of the Russian Academy of Sciences in St. Petersburg, published a series of papers on the Internet and gave lectures at several American universities describing how he had overcome a roadblock in the proof of the Poincaré conjecture.

The conjecture, devised by Henri Poincaré in 1904, essentially says that the only shape that has no holes and fits within a finite space is a sphere. That is certainly true looking at two-dimensional surfaces in the everyday three-dimensional world, but the conjecture says the same is true for three-dimensional surfaces embedded in four dimensions.

Dr. Perelman solved a difficult problem that other mathematicians had encountered when trying to prove the conjecture, using a technique called Ricci flow that smoothes out bumps in a surface and transforms it into a simpler form.

Dr. Okounkov, born in 1969 in Moscow, was recognized for work that tied together different fields of mathematics that had seemed unrelated. "This is the striking feature of Okounkovs's work, finding unexpected links," said Enrico Arbarello, a professor of geometry at the University of Rome in Italy.

Dr. Okounkov's work has found use in describing the changing surfaces of melting crystals. The boundary between melted and non-melted is created randomly, but the random process inevitably produces a border in the shape of a heart.

Dr. Tao, a native of Australia and one of the youngest Fields Medal winners ever at age 31, has worked in several different fields, producing significant advances in the understanding of prime numbers, techniques that might lead to simplifying the equations of Einstein's theory of general relativity and the equations of quantum mechanics that describe how light bounces around in a fiber optic cable.

Dr. Werner, born in Germany in 1968, has also worked at the intersection of mathematics and physics, describing phenomena like percolation and shapes produced by the random paths of Brownian motion.

The medal was conceived by John Charles Fields, a Canadian mathematician, "in recognition of work already done and as an encouragement for further achievements on the part of the recipient."

Since 1936, when the medal was first awarded, judges have interpreted the terms of Dr. Fields's trust fund to mean that the award should usually be limited to mathematicians 40 years old or younger.

    August 22, 2006

    "Jobless and living with mother" …. the non Russian journalist (Nadejda probably is innocent) is not really giving us an accurate picture here.

    To put this in perspective for the western readers…

    Living with parents in the Former Soviet Union (FSU) is fairly normal and even if he had a regular job, living at home would still not be a big deal.

    Second…After Perestroika, the government gave the citzens their apartments (some younger FSU citizens are not aware of this fact, it would seem) …so it is very possible his mother has no mortage expense. Walking or taking the subway (metro) is normal mode of transportation, so no car payment either…Medical care is very good, and inexpensive — so no medical bills to speak of as in the west.

    Granted the Russian pension is not much, but the economics is not quite the same as in the west.

    Therefore, for Perelman to live at home, with his mother, does not in any way compare, or have the same stigma, as a similar situation in the west.

27. **TheGraduate**
    August 23, 2006

    I just read the article in the New Yorker. Who knew the situation was this dramatic?

    The most important idea in the article seems to be the argument that Dr Shing-Tung Yau of Calabi-Yau fame is stealing people's credit. I don't know if that is true but that seems to be the definitive verdict of the article.

    In case, the implications of the article were too subtle, they have supplemented with a full page graphic of Yau stealing the Fields Medal from Perelman's chest.

    It is a well written essay. I do not know in what repects Gruber contributed but I enjoy Nasar's writing. I can not say whether the reporting is accurate or not. I did think in passing that they had not defined a manifold but I assume most mathematical readers would be familiar with this term.

    Perelman is definitely portrayed in a positive light: more or less normal except for being extremely hard working, honest, open and humble and of course, mathematically brilliant.

The details about Yau seem almost tangential. The angle of Yau seems to have been inserted by the author's themselves rather than emerging naturally from the interview with Perelman. Perelman himself, as represented in the text, expresses indifference to what Yau may or may not have done.

28. **gunpowder&noodles**
August 24, 2006

"The most important idea in the article seems to be the argument that Dr Shing-Tung Yau of Calabi-Yau fame is stealing people's credit. "

What a shocking revelation. I'm sure nobody ever dreamed of such a thing before. STY's reputation for being self-effacing is famous throughout the length and breadth of Nagorno-Karabakh.

29. **GeomGeek**
August 24, 2006

"The details about Yau seem almost tangential. The angle of Yau seems to have been inserted by the author's themselves rather than emerging naturally from the interview with Perelman. Perelman himself, as represented in the text, expresses indifference to what Yau may or may not have done."

sure, especially the bit about Yau giving three days to the editors of the AJM to comment on the Cao-Zhu paper without showing the paper

not to mention the story with the 105%

30. **TheGraduate**
August 24, 2006

There is also an article in Notices that I had not seen before but it touches on similar issues to the New Yorker article .

"Conjectures No More? Consensus Forming on the Proof of the Poincaré and Geometrization Conjectures" by Allyn Jackson

http://www.google.com/search?hl=en&lr=&q=perelman+notices&btnG=Search
(It's the first link.)

It says in part "Some of the news articles were translated into English and posted on the Web. In those articles, the achievements of Cao and Zhu, both of whom are Chinese, are emphasized, while the achievements of Perelman are mentioned in a less prominent way. In one story from the Xinhua news agency, which appeared on June 21, 2006, the name of Perelman does not even appear."

It also says that "Yau said that he was misquoted in some of the media accounts and does not endorse what is said there."

They also provide a link to a website to some slides purportedly used by Yau in a lecture. They don't say what they want you to look at but I found the following quote.

"In Perelman's work, many key ideas of the proofs are sketched or outlined, but complete details of the proofs are often missing. The recent paper of Cao-Zhu which was submitted to The Asian Journal of Mathematics in 2005 gives the first complete and detailed account of the proof of the Poincaré conjecture and the gemetriziation [sic] conjecture. They substituted several arguments of Perelman by new approaches based on their studies." — Yau

31. **MathChina**
August 25, 2006

This email has been sent to Ms. Nasar and the Now Yorker.
———————————————————————

Dear Ms. Nasar:

As a mathematician who was born in China, I am deeply offended by your article with Mr. Gruber in the recent issue of the New Yorker. Your narrative plays to the stereotype that mathematicians of Chinese heritage are "technical" but not "original".

(1) In the first sentence of your article, you identified Professor Yau as "the Chinese mathematician". In fact: Yau is a U. S. citizen. To make my point simple: Don't you agree that it oddly emphasizes your cultural heritage if you are called "the Bavarian journalist and
writer"? (I noticed that you were listed as an American journalist and writer born in Bavaria in the Wikipedia.)

(2) In your narrative of the works that led to Yau's Fields medal, you misrepresented the facts and downplayed the originality of Yau's contribution," 'He was not so much thinking up some original way of looking at a subject but solving extremely hard technical problems that at the time only he could solve, by sheer intellect and force of will,' Phillip Griffiths, a geometer and a former director of the Institute for Advanced Study, said".

(3) Even in your narrative of Chern, there is no mention of any of his original work or idea.

(4) In Yau's seminar, "[e]ach student was assigned a recently published proof and asked to reconstruct it, fixing any errors and filling in gaps". As for the controversy surrounding
Givental's work, "[o]ccasionally, the difference between a mathematical gap and a gap in exposition can be hard to discern. On at least one occasion, Yau and his students [Bong
Lian and Kefeng Liu] have seemed to confuse the two, making claims of originality that other mathematicians
believe are unwarranted." You were adamant that Professor Givental's work is complete and correct. A simple search in MathSciNet's review of Givental's paper should have given you a different perspective.

(5) In your narrative of Professor Tian's reaction to Yau's allegations, you again emphasized Tian's Chinese heritage: "I [Tian] have deep roots in Chinese culture. A teacher is a teacher. There is respect. It is very hard for me to think of anything to do."

(6) "Yau's entrepreneurial drive extended to collaborations with colleagues and students, and, in addition to conducting his own research, he began organizing seminars. He frequently allied
himself with brilliantly inventive mathematicians, including Richard Schoen and William Meeks." Yau has many students from China; some of them are now professors in top universities in this
country. Of course, none of them are supposed to be "inventive", not even "Yau's most successful student" Tian. I also question the connotation of "entrepreneurial".

(7) It is now clear that you are determined to prove your point. "Mathematicians familiar with Perelman's proof disputed the idea that Zhu and Cao had contributed

significant new approaches to the Poincaré. 'Perelman already did it and what he did was complete and correct,' John Morgan said. 'I don't see that they did anything different.'" " 'It is not clear to me what new contribution did they [Cao and Zhu] make,' he [Perelman] said. 'Apparently, Zhu did not quite understand the argument and reworked it.'"

I could have listed a lot more; but I think these are sufficient to illustrate my point. Here is a challenge to you, Ms. Nasar: List the sentences in your long article that associate Chinese/Chinese-American mathematicians with "originality" and likewise those that separate them from "technicality".

I have enjoyed tremendously reading your beautifully written "A beautiful mind". It was a moving and inspirational story. I am now then truly disappointed and horrified by this article of yours in the New Yorker, a magazine that is supposed to represent the best of intelligentsia. Personal vendettas lead us nowhere. Your article is hugely biased. It is a disservice to the mathematical community as a whole; it irreparably and unnecessarily damages Yau's reputation; it does not help Tian; and most importantly, it plays to the false and harmful stereotypes of mathematicians of certain cultures.

One internet chatter, apparently a mathematician/student of Chinese origin, reported that one of his colleagues placed the cartoon in your article on the office door. The chatter stated that he felt "ashamed" when passing by the colleague's office.

For all the harms that have occurred, I believe, at the minimum, a public apology from you and the New Yorker to all is warranted.

Sincerely yours,

A mathematician born in China

32. **gunpowder&noodles**
    August 25, 2006

    This email has been sent to Nasar and the NEW Yorker:

    Dear Ms Nasar: thank you for finally exposing the truth about this truly shameful and disgusting episode. At last Perelman will get all of the credit that is his due, in no small measure due to your public airing of the appalling efforts on the part of certain people to prove their superiority by means of every dirty trick in the book.

33. **Lau**
    August 26, 2006

    Dr. Nasar, your article is fair and unbiased. No need to apologize to idiots like that. They are mad because you are famous and is an authority in journalism and what you say has some type of impact! I, as a Chinese, feel that you are brave enough to challenge such an authority in mathematics who does not treat other fairly and attacks his rivals unnecessarily. THANK YOU!!! You are an unbiased person!! The righteous Chinese scientists salute to you!

34. **CalabiYauManifold**
    August 26, 2006

    "TheGraduate Says:
    August 23rd, 2006 at 12:30 pm

    I just read the article in the New Yorker. Who knew the situation was this dramatic?

    The most important idea in the article seems to be the argument that Dr Shing-Tung Yau of Calabi-Yau fame is stealing people's credit. I don't know if that is true but that seems to be the definitive verdict of the article.

    In case, the implications of the article were too subtle, they have supplemented with a full page graphic of Yau stealing the Fields Medal from Perelman's chest.

    It is a well written essay. I do not know in what repects Gruber contributed but I enjoy Nasar's writing. I can not say whether the reporting is accurate or not. I did think in passing that they had not defined a manifold but I assume most mathematical readers would be familiar with this term.

    Perelman is definitely portrayed in a positive light: more or less normal except for being extremely hard working, honest, open and humble and of course, mathematically brilliant.

    The details about Yau seem almost tangential. The angle of Yau seems to have been inserted by the author's themselves rather than emerging naturally from the interview with Perelman. Perelman himself, as represented in the text, expresses indifference to what Yau may or may not have done. "

    The mentioned work by French mathematician is done by Aubin, it is not enough strong to be extended to solve Calabi conjecture. Yau's result is totally original and has opened a new field for many others.

    This article is truely beautifully written, but I'm suspicious that it is too one-sided. I'm interested to know the whole truth behind it.

35. **TheGraduate**
    August 26, 2006

    Some people had been saying that the article was meant to show Yau as a bad guy but I think the title might give more of a clue as to what the authors were intending.

    They entitled the piece 'Manifold Destiny' which is a play on words and refers to the doctrine of 'Manifest Destiny' ie US expansionism.

    I suspect the authors were meaning to talk about Chinese expansionism. I think this makes more sense because the audience of the New Yorker would probably find something like that more interesting than petty squabbles in mathematics.

    I think they emphasized Yau as Chinese because in their view, he is using the mathematical achievement as another way to give China recognition on the global stage.

36. **Ng**
    August 26, 2006

    If you want to know the whole truth, you have to ask S.S. Chern and his students who know Yau well as well as all the experts in the field to speak fairly and unbaisedly!!! Which is impossible.

37. **MathLover**

August 27, 2006

No dubt that Perelman has some admirable personalities. He is a hero of his own. Do we need a villain in contrast in this drama? I think the New Yorker's article is manipulative. The authors logic goes like:

1. Perelman is a hero
2. Hamilton and Yau are too slow in their own program and are unwilling to learn from Perelman
3. Yau is a bad guy trying to steal the credit from Perelman for his own students

The article may convey point 1 to a more general public and the writting is beautiful there. But I don't buy their points 2 and 3. As for 2, the math community as a whole has been relectant to declare Perelman's victory and slow to learn from Perelman. They only officially confirm Perelman's solution of Poincare conjecture at this ICM. No final verdict about Thurston's geometrization conjecture yet. Moreover, no significant new results come out of Perelman's ideas from other mathematicians. I hope the 3 manuscripts will change the situation.

As for Yau's part I suspect the authors description is leant towards his opponents. The quotes of other math professors are unbelievably uni-directional: destructive to Yau. There must be a master plan behind this game. The controversy between Yau and Tian is another drama worth. Yau against his own student, because he feels obligated to fight corruption in academic world of China.

[Note: I've deleted the last part of this comment, which was a personal attack on Tian]

38. **woit**
August 27, 2006

MathLover,

I've deleted quite a few personal attacks on Yau that were posted here, some from the same person using different names. I've also deleted the last part of your comment, which is a personal attack on Tian.

Please, do not try and use this blog to carry on the Tian-Yau warfare. I think this is an extremely bad thing for mathematics, and I want no part of it.

39. **MathLover**
August 27, 2006

Peter,

I respect your decision to delete last part of my post. Thanks a lot for maintaining this blog. What I wanted to add is that we living outside of China have certain obligations to promote universally valid civil values to China, including fight against corruption. Yau has exposed himself in the fore-front of fighting corruptions in academic world of China. He doesn't deserve such mud slinging from the New Yorker article on his back from the free world! I'm the same opinion that the authors have over done their spin, see Jeremy's post:
http://www.math.columbia.edu/~woit/wordpress/?p=448#comment-15143

40. **Columbia Chemist**
September 1, 2006

Dear Peter:

I have been following this blog since late June after the many news report in China about he Cao-Zhu paper, because I wanted to get some insight from the mathematicians abroad. I'm not in mathematics, but I have been inerested in history and sociology of science for years. For your information, I got my Ph.D in chemisry from Columbia, and now I'm a chemistry professor at Beijing.

Here I'd like to share with you of some first-hand information about the Chinese coverage of the Yau press conference on June 3, 2006, and the controversial over it.

My wife is the reporter at the Sciencetime at Beijing who was one of the few reporters at the press conference given by Professor S. T. Yau on June 3, 2006. She has all the original materials including the press release given to them by Professor Yau on June 3, and the recording of the press conference.

If people read those reports on the ScienceTimes, he would agree that the reports by my wife and her colleagues at the ScienceTimes have been the most truthful, fair and authorative on the whole affair so far. If these articles have been availabe in English, many controversy can be easily clarified. Unfortunaely, these reports have generally not been picked up by most people. (Bad news travels fast.)

Since we learned the New Yorker Magazine (I used to be a subscriber of the NYM when I was a New Yorker) article by Sylvia Nasar and David Gruber, my wife and I were both stunned by the untrutful accounts of many of the events. The account in the NYM article about the media coverage in China only picked up some obviously controversial reports, but never really did serious research on the whole thing. I have to say it is absolutely bad jounalism, and is an indication of lack of professionalism.

Here are some things I may help to clarify.

1. About the contrversy around the credit for solving the Ponicare Conjecture.

The Xinhua News Agency first reported on June 4 that Professor Yang Le told the reporter a division of 50%+25%+30% credit between Hmilton, Perelman and Chinese Scienctits. The news is here:
http://news3.xinhuanet.com/newscenter/2006-06/04/content_4644722.htm (in Chinese)

However, on June 9, the same reporter of the Xinhua News Agency
wrote another news in which Yang Le specificly emphasized that he was not an expert in the field to make such judgment and that he was against any attempt to make such judgment. The news is here:
http://beijing.icm2002.org.cn/mcmweb/Three_Said.htw (in Chinese)

Why there were such two completely opposite reports by the same reporter from the Xinhua?

The truth is that before the first news was wrote, Professor Yang Le was not interviewed by the reporter. And after Professor Yang Le's protest about report to the XinHua reporter, the Xinhua reporter offered in order not to retract the first report he was willing to make a real interview with him in exchange. Believe or not, such unprofessional practice sounds strange, but it does really happen in China. I do not know how such strange number was reached at the beginning, but the truth was that Professor Yang Le was not intviewed by the Xinhua reporter before the interview for the second report.

Unfortunately, this second report has never been noticed. It is fine for ordinary people not to notice it, but it is not acceptable for anybody who is trying to do investigative journalism.

From the recording of the press conference, where 8 reporters from five Chinese media, including the reporter from the XinHua News agency, were pesented, some reporter asked Professor Yau whether Cao-Zhu's paper can claim all the credit, and Professor Yau specificly said that Hamilton and Perelman's contributions were the most important, Cao-Zhu's paper just presented the complete proof and closed the case, and the proof of the Poincare Conjecture was a group effort. There was no mentioning of the division of credit in the press conference. Professor Yang Le was not present at the press conference.

After the press coference, my wife and one of her colleague at the Sciencetimes had an exclusive interview face to face with Professor Yang Le in the same day. There was no such mentioning of percentage in that interview.

When first saw the controversial about the strange 105% number, I myself had the impression that I had read it also from my wife's report in he Sciencetimes. I even joked her for not being able to make the percentage correct. My wife was angry at me for the wrong impression and she asked me to read all the reports in the Sciencetimes and to find whether there was such report of the moronic percentage. The truth is that there was no such report found in their reports, and also no such thing in the recordings as wellas in the first-hand notes she had, including in the press conference, the inteview with Professr Yang Le on June 3, 2006, and another exclusive interview of the Siencetimes with Professor Yau on June 2 of 2006.

I then spent some time a few days ago on the inernet to do my own research on the 30% credit story. Such research should have been done by Ms. Nasar and her associates. I have to say after going through all this materials, I learned how wrong and the New Yorker article was.

I have aways been telling my wife how unprofessional many of the reporters in China are, and how unfortunate that I have to live with this fact. But I have never expected that people like Professor Nasar can be so unprofessinal in writng the article in the New Yorker magazine.

My wife was a fan of Nasar's book on Nash, A Beautiul Mind. She has been proud of being assciated with Columbia (where I got my Ph.D), for the prestigious Journalism School and or having Mrs. Naser as her idol. As a real scientist myself and somebody who had read books on the game theory in my teens, I told her years ago that I actually did not like very much the book and the movie. She did not understand why.

Now she finally understand me.

I wondered why Mrs. Nasar did not even try to get any first-hand account of many of the events in China by contacting her peer journalists before formulating her case. How can people trust her other stories? Was she writng an investigating report or a fiction?

2. Mrs. Nasar and Professor Yang Le

My wife told me that Mrs. Nasar actually met Professor YangLe at the String Theory Conference at Beijing in late June. There was even news photos caught them in the same picture. Professor YangLe said that they briefly chattd or greeted each other there. But Mrs. Nasar never confirmd the 30% percentage story with him.

This is truly the strangest thing for any investigating reporting.

3. About the news coverage in China on the Poincare Conjecture.

Undoubtedly there alwas have serious problms in these reports. As I mentioned above, these problem can only be attributed to the status of lack of professionalism of the reporers, especially in science reporting.

However, for obvious reasons, I do not want to blame the reporters for this situation in China. To understand all these, probably Mrs. Nasar can spend more time in China and try to write an real investigative report on it.

For whatever origin of this situation, to use such unreliable sources of media reports in China before making serious investigtin and to make wild accusations against Professor S. T. Yau is totally untrustworthy and misleading.

4. What I leaned about Professor S. T. Yau?

I have heard many people gossiping about Professor S. T. Yau's personality before. As a chemist, I had no interest in it. I'd rather pay more attention to the personaities of the people in my own field than in mathematics. After listening to hours of the recordings of him, I have to say that it is definitely not possible that he is the villain as depicted in the New Yorker Magazine. I have to say that he fits perfectly as a great person and a great scientist. These people who have been wildly attacking him are far from the truth and are definitly making a fool of themselves.

I believe that people who care will get the truth of the story eventually. I'm glad that this blog is a place which has provided a excellent platform for discussing it.

In the end, I'd like to suggest people to use their commonsense and to try to find of the facts before making their own judgment on this matter. Finding out the truth is not so difficult. It is unfortunate that some people never try.

Sincerely yours,

Columbia Chemist

41. **cl**
September 1, 2006

I have read both news items provided by the post. I found the post to be misleading. The description of the first is correct. But in the second one, published on June. 9th. what Prof. Yang Le said is that assigning percentage is not "completely accurate, I don't agree with that, either. However, Chinese scientists did make outstanding contributions." He never said that he is not an expert in the field to make judgement, instead, he said, "My research eare is complex analysis, but I know Yau, Cao and Zhu very well." He went on to say that that the contribution from U.S., Russia and China are "all extremely important, without any of them, the thoery won't be complete". Finally, he conclude that " in the process of resoling the conjecture, Prof. Yau provided ideas and advice, other people(include Hamilton, Perelman, Cao and Zhu) used Yau's important results, along with other imporatnt theoy in geometric analysis, a field Yau established, to make the breakthrough.

Another fact not being mentioned by either the New Yorker and Columbia Chemist is that, on June. 7th, the ministry of Education of China, sent an official congratulatory letter to Zhu's university for resolving Poincare conjecture. It represents the official position of the Chinese government, not just "lack of profesionism of reporters."

I also like to mention that in an 08/18 article on ScienceTimes, its journalist recalled that they obtained a press release on June 03, cleared stated that R. Hamilton obtained "outstanding and fundamental" results, Perelman provides "key ideas", but Cao and Zhu "completely resolve" the Poincare conjecture.

Unlike Ms. Nasar, I am a Chinese mathematician, so I understand Chinese very well. I also lived in mainland China for more than twenty years, so I understand the meaning and process behind a congratulatory letter from the ministry of education. I admire Yau's achievement in mathematics immensely. He is one of the greatest methematician of this centry. I consult his book and papers very frequently in my research. But on this matter, I do believe that what he did is wrong. As a great scientist, for whom seeking truth should be one's life time devotion, he should apologize.

Fact will not mislead people. Partial fact will.

People used to think that the Xinhua News Agency is the official news agency of the Chinese government, and so its news release must be some kind of official statement. Now people can know the process of how its reports were made, so people can be careful when reading the news.

I also found in one newspaper here there was an exclusive conversation between Professor Yau and the reporter. However, there was no such exclusive interview, and the report was a collage of information gethered from other media reports.

One important fact is that I do not see where is the "official position of the Chinese government" on Cao-Zhu's paper. I knew of the so-called congratulatory letter to Zhu's University from the departmrent of the education from the media reports. Such congratulations letters have been sent to different people all the time in China.

cl should have mentioned that not only the Department of Education, but also the Chinese Academy of Sciences (CAS), and the Academy of Mathematics and Systen Sciences under CAS all sent brief congratulation letters to Zhongshan University the same time. All the letters started with the sentence: "We are all glad to hear that ….".

See here, http://www.cunews.edu.cn/html2006/hndq/hndqxw/151610461.htm

Such things usually happen when these agencies learned the news of a high profile paper is published. I have to say that this practice is silly, and the content can not be taken as any official statement. Seriously, such congratulation letters just like the letters one would receive when his family has a new born son. Why not cl try to get all this kind of letters for things in different disciplines together and show them to the internetional colleagues?

I think my simple intention is to provide facts on the following, and to show why people should not use the inconsistent news reportings to make strong judgment, especially for the investigative report in the New Yorker magazine.

1. Whether Professor Yang Le said anything about the moronic percentage which had been attributed to him?

2. What did Professor Yau actually do or say in his own words?

I do not see anything wrong when somebody so heavily involved claim some credit for it. Whether it is excessive is the issue and also a matter of opinion. Being a scientist myself and a reader of Robert Merton's works, I do not see what Professor Yau had done was very inappropriate, given the facts clarified and the unknown factors fairly weighted. Certainly this does not mean I endorse everything done or said by Professor Yau. I have no interest in it.

If cl can let usknow when was the last time he actually listened to Professor Yau's own words, his comments may carry some weight. Otherwise, being a mathematician and also Chinese does not actually help with anything when speculations are drawn from partial words in secondary sources.

As to what matter Professor Yau should appologize for, I do not see the point from cl's posting.

I'm sorry that I will not post here again, unless somebody wants to verify facts I know with me here. Otherwise, it would be funny to see a Chemist frequently running in the Math world.

Let me repeat:
Fact will not mislead people. Partial fact will.

Best regards,

43. **cl**
September 2, 2006

Reply to Columbia Chemist's post,

I never posted here before, the only reason I did is that I felt the second news item in your post was mistranslated and permutated. So , in the first paragraph, I just provided correct translation. The two items also led me to the SceinceTimes report in which the original press release, which you mentioned also, was quoted, then I provide a translation in third paragraph. As for the congratulatory letters from the ministry of education, they are not sent to many people all the time. last year, or maybe two years ago, Prof. Wang Xiaoyun from Shangdong University obtained very important results in cryptography, this is probably the most important achievement in mathematics in China during the last two decades, it is widely reported by both Chinease and international media, she never got any congratulatory letters from the ministry of education. I personally never heard Prof. Yau talking about Poincare conjecture. so, I can not comment on what he says.

September 5, 2006

To all the people who are fighting for Tian and Yau, or who want to share the truth,
It will be nice to show your respect to this place, please bring the Tian-Yau fight or related materials to other related places.
Do it properly and you will be appreciated by the readers of this blog.

45. **MathLover**
September 5, 2006

I'm also tired reading too many comments that do not shed light on the true background. We will see in the future and in the other place what arguements between Tian's and Yau's fans (including one from mine) really hold.

Here is a very interesting interview Atiyah gave in the realm of ICM2006 preparation bulletin (3rd July 2006):

http://www.icm2006.org/press/bulletins/bulletin08/#2

-Quote:

Q: After Perelman's work, can the Poincare conjecture be considered proven?

A: The work of Perelman on the famous Poincare conjecture is widely admired. But in mathematical questions of this complexity final judgement is suspended until the complete proof has been written down, scrutinized by the mathematical community and accepted. That stage has not yet come.

Quote end-

If we are honest, we have to ask ourself, Is Poincare conjecture a theorem now?

I don't know what Atiyah thinks now. It's truly a strange (and maybe even controversial) math history and remarkable ICM for me, the world around Poincare's conjecture changed in just 2 months.

Thanks for Peter to maintain this post open.

46. **jeremy**
September 8, 2006

MathLover,

If you ask Atiyah the same question now, he, as any other responsible mathematicians, will probably give you the same answer.

The world, as far as Poincare conjecture is concerned, has not changed at all, even with the recent media storm. After all the dust settled, the mathematics community will have to do exactly what Atiyah said in his interview. Otherwise, mathematics as we know it will no longer exist. I personally have faith that the final conclusion of a mathematical problem will only be given by the mathematics community, not by the media.

However, from what has happened in the last two months, we have learnt a great deal about mathematicians. These guys can behave exactly like politicians. Their skill of personal attacking and backstabbing is certainly no worse than the ordinary politicians. They probably played politics and media better than the politicians from their own district. I have to congratulate them for that.

47. **sk**
September 13, 2006

1. In Perelman's second famous preprint, he said that another paper with the proof of Theorem 7.4 would be given, but it is still not available. There are two versions of Perelman's Theorem 7.4. One is the strong version with only two conditions, which no proof is available except for Perelman's "sketch". The other is a weak version with an additional condition, which might be too weak to apply according to Kleiner & Lott. Actually, Kleiner-Lott and Cao-Zhu did not prove it, they circumvented it.

What would Perelman reply if he met some experts and they asked for the proof? Note that in April 2003, nobody could fully digest his first two articles. After his return, he posted his third paper devoted entirely to the Poincare Conjecture.

2. Many people, including an article in "Notices", criticized the abstract of the Cao-Zhu paper. However, people who read Orwell's "1984" should know that the phrase "it is the crowning achievement of the Party" is quite common in communist countries. The purpose is to express highest admiration to the Party. In their paper, Cao-Zhu did the same to the Hamilton-Perelman Theory.

2006 Fields Medal Winners

August 22, 2006
Categories: Uncategorized

The winners of the 2006 Fields Medals are Terence Tao and Grigori Perelman (as widely predicted), also Andrei Okounkov, and Wendelin Werner. For some more information, see the press releases at the ICM site.

Okounkov's mathematical work has been in the area of representation theory and its links to combinatorics. His work in mathematical physics is well-known, relating random partitions and the statistical mechanics of certain crystals to Gromov-Witten and Seiberg-Witten theory (counting holomorphic curves and instantons). For some nice expository papers of his about this, see here, here, and here.

Wendelin Werner I know little about, his work involves 2d random walks and is related to CFT. There has been a lot of activity recently in this field, and there's a related program going on this semester at the KITP. A friend wrote to me this morning to speculate that this is the same Wendelin Werner who at age 12 appeared in the film "La Passante du Sans-Souci".

Update: Luca Trevisan is blogging from the conference.

Today the arXiv servers contain the message " arXiv.org servers are currently under very heavy load due to demand for Grisha Perelman's papers, published only as arXiv.org e-prints, which are available below."

Comments

1. **Harry**
   August 22, 2006

   Do we know if G. Perelman has accepted the prize ?

2. **Jeremy**
   August 22, 2006

   apparently not.

3. **bharath**
   August 22, 2006

   It appears Grigori has chosen not to accept the medal. He has also declined Clay prizes and position offers form Princeton, Stanford. He surely has his own reasons.

   Definitely an interesting development.

4. **Peter Shor**
   August 22, 2006

   Gregory F. Lawler, Oded Schramm and Wendelin Werner received the George Polya Prize for the work on stochastic Loewner evolution (SLE), and Schramm and Werner both individually received the Loève in probability theory (in 2003 and 2005, respectively; I believe Lawler was too old for the Polya prize). Does this mean Oded Schramm is already favored for a Fields Medal down the road?

   By the way, stochastic Loewner evolution was a great advance in probability theory and statistical physics: it let people prove a whole bunch of interesting conjectures that had previously been unproven, including some related to conformal field theory.

5. **q2**
   August 22, 2006

   The slides from the Laudatios about the Medallists' work may now be found by clicking on "Prizes" in the left frame here. (couldn't seem to get a direct link to work…)

   Regarding Schramm, he was actually already too old for a Fields this year, having been born in 1961 according to the citation for his 2003 Poincare Prize. In the interview on the page Peter W. linked to, Werner mentioned that he felt like the medal was for all three of Lawler, Schramm, and himself, even though the other two were over the age limit.

6. **kantor**
   August 22, 2006

   Yes he is the passant du sans souci and also a beautifully nice guy helping probability to be associated not only with markets !

7. **Thomas Larsson**
   August 22, 2006

   My understanding of Werner's field SLE (Stochastic (or Schramm) Loewner Evolution) and its relation to CFT is as follows:

   Various spin models in statphys are related to graphical problems, when you make a graphical (high-temperature) expansion of the partition function. E.g., percolation is described by the q-state Potts model in the limit q -> 1, and self-avoiding walks (SAWs) by the N-vector model when N -> 0. E.g., the partition function of the Potts model is sum_G q^c u^L, where the sum runs over graphs G, c is the number of clusters, L the number of links, and u is related to temperature. Note that in the graphical formulation, q and N don't need to be integers.

   Spin models at criticality are described by conformally invariant QFTs. In particular in 2D, the nice ones are the minimal models, with central charge c = 1 – 6/m(m+1) and anomalous dimension h = (pm – q(m+1))/6m(m+1). The central charge is related to the parameters q and N above; q = 2, N = 1 and c = 1/2 is the Ising model, whereas geometrical models typically correspond to the c -> 0 limit. Moreover, critical exponents correspond to anomalous dimensions on the CFT side and to fractal dimensions on the geometrical side, as D = 2 – 2h. In particular, when c -> 0 and p and q integer or half-integers (there is a reason why you need half-integers too, but I don't remember), we have D = (100 – n^2)/48, n integer. This formula covers many well-known fractals, such as the percolation cluster (D = 91/48), the percolation hull (D = 7/4), the SAW (D = 4/3), and the red links (D = 3/4).

Whereas the relation between geometrical phase transitions and CFT was intensely studied by physicists in the 1980s, many things remained conjectural. E.g., conformality was only assumed (and supported numerically), never rigorously proven. Some ten years ago, percolation was becoming studied by mathematicians coming from stochastic processes (Werner, Schramm, Loewner, Smirnov come to mind). Here you regard the e.g. the boundary of the percolation cluster as a stochastic process, a modified form of Brownian motion depending on a parameter kappa, called rapidity and closely related to the central charge; c = 0 is kappa = 6.

Within SLE you can rigorously prove formulas written down by physicists 20 years ago. There is obviously a close connection between SLE and CFT, which has been investigated by a number of people, e.g. John Cardy, and I think that this is more or less a bijection. These theories also share the same glaring limitation, namely the restriction to 2D.

8. **urs**
August 22, 2006

Another discussion of SLE can be found here.

9. **axion**
August 23, 2006

It's a bit rough on Tao and the others — Perelman's achievement completely and utterly dwarfs theirs.

10. **comentator**
August 23, 2006

Until a press release or formal comunication from Perelman regarding the award of the Fields medal is seen, it can be safely said that he accepted the Fields medal. and so far there is none.

11. **zerocold**
August 23, 2006

Hi, ok my comments on this post was wrong
http://www.math.columbia.edu/~woit/wordpress/?p=350
Tao has win the Medal.
Congratualions to him and to this blog for the correct forecasting.
zerocold

12. **Zelah**
August 23, 2006

Also, I would like to add my congratulations to

Kiyoshi Itô, winner of the Gauss prize for applied mathematics! I predicted this last year! Finally the bias against applied work has been lifted.

Finally, it is interesting that nobody on this site is particularly interested in Andrei Okounkov!

13. **MathPhys**
August 23, 2006

This a string theory discussion site, and Okounkov's work (connecting strings to algebraic combinatorics) will probably end up being one of the more lasting aspects of string theory.

Here is an article by S Nasar on Perelman from The New Yorker

http://www.newyorker.com/fact/content/articles/060828fa_fact2

14. **Seth**
August 23, 2006

To axion:

Do you really imagine it's so rough being aknowleged as one of the best mathematicians in the world, but still having someone better than you?

Judging from the physicists I know, even smart people are usually satisfied with being "merely" very good at what they do.

15. **Peter Woit**
August 23, 2006

zerocold,

My suspicion is that someone blabbed to Lubos about Tao at an early stage in the process, long before Tao was notified that he had won. So, when he answered your e-mail asking him about this, he was answering truthfully.

16. **D R Lunsford**
August 23, 2006

What a magnificent article!

-r

17. **TheGraduate**
August 23, 2006

D R Lunsford said "What a magnificent article!"

Could you elaborate?

18. **Responder to axion**

August 23, 2006

I find the claim that the achievements of Perelman dwarf those of the other Fields medalists highly questionable. Tao's diverse accomplishments in p.d.e.s, harminic analysis, number theory, combinatorics are awesome – for example see his web page or, when they are posted on the ICM site (not yet – I just looked), Fefferman's laudation and Tao's lecture.

19. **comentator**
August 23, 2006

Christine Dantas blog has a nice article from the BBC News about the declining of the Fields medal by Perelman. Citing that the president of the IMU John Ball, travelled to St.Petersburg to talk with Perelman to know the reasons of his declining to accept the Medal. So; I guess this makes it official the declining of the Medal by Perelman.

20. **GeomGeek**
August 24, 2006

Sylvia Nasar's article is beautifully written, well-researched and clearly explains Perelman's choice.
Much better than the millions of uninformed papers describing the reclusive borscht-eating weirdo of St Petersburg.
It's funny how it has been the talk of all maths common rooms for years that some famous chinese mathematicians are ridiculously bullish, but things don't seem to have improved much (though this seems to be just one example of an attitude with which Perelman refuses to have anything to do).
After reading Sylvia Nasar's paper I wish Perelman made a public statement to accompany his refusal.

21. **woit**
August 24, 2006

Please, personal attacks on anyone involved in the Poincare story have no place here and will be deleted.

22. **tg**
August 24, 2006

I read Nasar's article, and indeed I learned gossip that I wasn't aware of, even though I know some of the people involved. It was entertaining.

That being said, I think it plays to the stereotype that
Chinese mathematicians are "technical" but not profound
(I speak mainly of her description of Yau's Fields medal
achievements), and moreover "bullish" (to borrow from
GeomGeek above).

What's wrong with describing the truth about ill conduct?
Nothing, per se — but in the interest of balance, I wonder how many other (influential) mathematicians act similarly, albeit in less famous instances; e.g., protecting the work/unrealistic promotion of one's students (say unfairly
at the cost of others), or undue influence of hiring committees and journals?

On the one hand, Luca Trevisan writes a useful blog of the ICM activities, where she says "John Ball starts his speech by explaining how…work is appreciated solely based on its merits, not on the way it is promoted." (Come on…) On the other hand, we have Nasar's description of Yau's behaviour, juxtaposed prominently with his heritage.

The reader of this blog could easily come away with the impression of the benevolence of mathematicians save a certain subset. I don't think that paints a fair picture at all. With fame/power/influence, academics of any stripe can and sometimes do take advantage of their position. Newton did it to Leibniz, and as an example, it isn't first, last, or uncommon.

23. **TruthSeeker**
August 24, 2006

You're right, tg, for saying that bad behavior is not uncommon in academia. This is unfortunate because scientists and scholars are supposed to be distinguished from politicians in that they ought to have a tremendous respect for truth — not half or one-sided truth — but the whole truth.

24. **Peter Woit**
August 24, 2006

tg,

I don't think the article was promoting the idea that Chinese mathematicians are "technical" rather than profound, and in any case Chern and many others provide excellent counterexamples. However, what is going on in China as the country becomes much more prosperous and influential, quickly developing a new and large mathematics research community, definitely seems to be part of the story here.

25. **q2**
August 24, 2006

tg,

You say the article plays to a stereotype of the bullishness of Chinese mathematicians…well, there's a plural there, and the reader of the article does indeed encounter more than one Chinese mathematician. Do you think Nasar and Gruber portray Tian that way, for example? I sure didn't come off with that impression.

While it's surely true that prominent academics in any field sometimes use their influence in non-even-handed ways, some senior mathematicians that I've talked to (both before and after his sallies in the Chinese media back in June) have indicated that Yau's persistent efforts to disparage the work and integrity of certain other researchers goes well beyond anything that they've seen from anyone else. I think that that aspect of Yau's personality is an important bit of context for understanding the present situation, and when I read the article I was relieved that Nasar and Gruber felt no obligation to hide it.

26. **Chris W.**
August 24, 2006

From the New Yorker's press release on the 8/28 issue:

> Nasar and Gruber write that the prospect of being awarded a Fields Medal, math's most prestigious prize, matters little to Perelman, who says that he plans to

refuse the award. “It was completely irrelevant for me,” he tells the writers. “Everybody understood that if the proof is correct then no other recognition is needed.” Perelman declares that he has retired from the mathematics community and no longer considers himself a professional mathematician: **“As long as I was not conspicuous, I had a choice. Either to make some ugly thing”—a fuss about the math community’s lack of integrity—“or, if I didn’t do this kind of thing, to be treated as a pet. Now, when I become a very conspicuous person, I cannot stay a pet and say nothing. That is why I had to quit.”**

27. **MathPhys**
August 24, 2006

In this particular food fight, Tian’s optimal game plan to play saintly, and watch as Yau self-destructs.

28. **tg**
August 24, 2006

Dear q2,

Certainly, Yau’s personality/behavior is (in)famous. As I said previously, I see nothing wrong with exposing the truth. However, I also asked for context, since that clearly affects how we absorb the said truth (e.g., “hearing only one side of the story…” blah blah).

In this case, Nasar and Gruber could easily have included a sentence or two from a neutral authority to the effect of “in math, as in academia more generally, there are always priority fights and bad behaviour, from all kinds….Yau is today’s unfortunate example”. I believe they deserved to, because they so closely tie Yau with the Chinese –a point they insisted on emphasizing, which is incidental to Perelman’s plight.

I believe they know the stereotype, and in general, it makes for a more entertaining article to exploit the reader’s reaction “oh yeah, there they go again…”. Indeed, as you say, there’s a plurality of Chinese involved in the story. However, my impression was that none were portrayed as bucking that stereotype. Some (Tian) were merely portrayed neutrally.

For example, with regards to the “technical” sentiment (and in response to Woit’s remarks), Nasar and Gruber do not say “Chern was among the most original and inventive geometers in history”. To the layman reader (being a Newyorker article), Chern’s only role is to give birth to Yau.

Finally, yes, the senior people you speak to, find Yau’s actions extremal. However, are his actions portrayed as they are, and he made a singularity of, in part because he’s Chinese? I think so.

29. **q2**
August 24, 2006

Finally, yes, the senior people you speak to, find Yau’s actions extremal. However, are his actions portrayed as they are, and he made a singularity of, in part because he’s Chinese? I think so.

I don’t buy this, because I really can’t think of either:

(a) Any other living pure mathematician of any ethnicity who has shown Yau’s penchant for engaging in (and enlisting the media in, e.g. in his interview about Tian last year) ugly, highly public turf wars; or
(b) Any other Chinese mathematician whose reputation for bad behavior among senior people at all resembles Yau’s.

If Nasar and Gruber had portrayed Yau’s antics as somehow common among mathematicians, in my opinion it would have been a serious misrepresentation of the current culture of pure mathematics. You’re going to have to come up with a much more recent example than Newton-Leibniz to convince me otherwise.

30. **tg**
August 24, 2006

Dear q2,

I hear what you are saying. I claim that Yau’s behaviour is not really that different than what many academics in math (and elsewhere) do. I don’t think that’s a serious misrepresentation. It just turns out that in most cases, the setting is not nearly as famous as a battle of Fields medallists, concerning a (truly) important open problem, or within a popularly known area such as string theory.

If I mentioned people I thought that were essentially no better than Yau in some given area of pure mathematics, chances are many would never know about it, nor really care to talk about it. Most topics in pure math just aren’t that well connected, unfortunately.

You know that I can hardly start naming names. But generally, e.g., it is not uncommon that I see good jobs going to certain people, or papers being accepted to important journals under objectively odd circumstances — while at the same time other qualified people or papers are shut out. These phenomena are often euphemistically called “white noise” or “randomness” in the system. Politics is involved; why deny this?

This is not an indictment of our field. I just wish Yau’s behaviour would be cast in this context.

31. **TheGraduate**
August 24, 2006

“In any dispute the intensity of feeling is inversely proportional to the value of the stakes at issue — that is why academic politics are so bitter.” — Wallace S. Sayre

Nothing so ephemeral as acknowledgement.

32. **Thomas Larsson**
August 25, 2006

Yesterday a review of conformal random geometry, which is Werner’s field, appeared on the arxiv: math-ph/0608053. It is written by Bertrand Duplantier, who for the past 20 years has been the leader of this field, having used CFT methods to compute more fractal dimensions than you want to know about.

33. **TTT**
August 25, 2006

I understand it would take tremendous personal courage and the purity of heart, so the hope is slim, but what would you think of if – for the sake of Science and the future of the field – Yau stood up, apologized to Perelman (regardless of who’s wrong in this situation), and invited him back to Mathematics?

In that case there won't be any losers… otherwise, we all lose.

Are deeds like this possible in modern research?

34. **Peter Woit**
August 25, 2006

TTT,

I don't think Perelman actually cares one way another about Yau. He's been quite consistent in his life that he wants nothing to do with the standard reward system of academia and questions of who gets recognized for what. Unfortunately, the New Yorker article didn't really explain what he's up to now: what was the problem at Steklov? is he still thinking about math? The reaction of some mathematicians I've talked to about the article is that the authors missed a chance to find out what they would really like to know: what is the guy working on now?

35. **TTT**
August 25, 2006

So people do believe he decided to secretly stay in Math?

In that case they are in trouble, because:

A person who can live on milk, bread, and butter, who is free from the pressure of find/keep-a-position-publish-publish-publish-or-die system, and who doesn't care whether some intermediate result would be named after him, has a huge advantage over the rest of them. Unlike many who want to put any reasonably interesting idea out their as soon as possible for all the world to see, he can continue working on whatever he wants without attracting ANY attention and without giving away ANY precious clues.

How long did he stay in the US doing postdocs? 4-5 years? Let's say he saved $200,000 during that time. In Russia, he can live on that with no financial worry for the rest of his life.

At the rate of 8 years per millennium problem, he will solve all of them by 2050.

A rather original way of doing research which, experience shows, happens to be extremely effective,…….. provided you are a genius, of course. Any geniuses out there who wanna try that too?:)

36. **MathPhys**
August 25, 2006

I don't know what happened between Perelman and the Steklov, but I imagined it was time to renew his affiliation and someone asked him to fill in some routine form, just like everyone else, and Perelman characteristically said something like

"If you want me here, you will not ask me to fill in a form, and if you ask me to fill in a form, you don't want me here",

and things escalated and the mole became a mountain and he eventually lost his job. I wouldn't be surprised if that's how it happened. He seems to be that kind of person.

37. **werdna**
August 25, 2006

MathPhys wrote:

"If you want me here, you will not ask me to fill in a form, and if you ask me to fill in a form, you don't want me here."

The second half of this statement is just the contrapositive of the first half. Now, would the very-terse Perelman need to repeat himself unnecessarily? 🙂

38. **MathPhys**
August 25, 2006

He's quoted in The NewYorker as saying things like that:

When a member of a hiring committee at Stanford asked him for a C.V. to include with requests for letters of recommendation, Perelman balked. "If they know my work, they don't need my C.V.," he said. "If they need my C.V., they don't know my work."

39. **Graham**
August 26, 2006

Zelah said:

> Also, I would like to add my congratulations to Kiyoshi Itô, winner of the Gauss prize for applied mathematics! I predicted this last year! Finally the bias against applied work has been lifted.

In fact, Hans Foellmer, who gave the Gauss Prize address honoring Ito, mentioned your comment as "a posting on the internet". Congratulations, you're famous.

40. **Mark Yasuda**
August 26, 2006

A historical quote that many might feel is applicable to Yau (as depcited in the New Yorker article):

"This excessive impudence is unbelievable in a man who has sufficient personal merit not to have need of appropriating the discoveries of others."

For those who don't recognize it, it's an English translation of a comment made by Legendre in 1820 regarding Gauss. Gauss, in some well-known instances during his life, chose to minimize the contributions of others or claim at least partial priority based upon his unpublished work. In Gauss' case, the claims all appear to be justified, but they do come across as self-serving and had detrimental effects in certain cases (e.g. J. Bolyai).

41. **MathLover**
August 27, 2006

Perelman has won my respect once again after my reading of New Yorker's article. What puzzles me is why the math community is so slow to declare his victory, and even more important, so slow to produce new results from Perelman's genius ideas. In ICM 2006 they only declared the Poincare conjecture been solved. What about Thurston's geometrization conjecture? Manuscript by Morgan and Tian treats only Poincare conjecture. Cao and Zhu do have a complete treatment of geometrization conjecture, this is also where they claim they don't fully understand Perelman's arguments (in contrary to Morgan-Tian) and substitute their own results (weaker than Perelman's assertions). As a layman, I enjoy reading Cao-Zhu's treatise more than other two.

Perelman's quit is regretable, but we shall respect his choice for whatever reason. I hope he will come back. It's a pitty that he no long has personal impact to math, unlike great Alexander Grothendieck who changed half math world before left. I have learned recently that Grothendieck's father was deported and murdered at Nazi concentration camp Auschwitz. (His mother was German.) Grothendieck himself has rejected awards on his pacifist stance, or saying something like he has enough for living from his pension. Truly admirable person!

42. **MathPhys**
August 27, 2006

Grothendieck also had wives and children that he totally abandoned.

43. **MathLover**
August 27, 2006

To MathPhys,

Is he insane?

44. **MathPhys**
August 27, 2006

I read some of his (Grothendieck's) autobiographical notes a while ago (I'm not so sure if what I read is formally part of "Récoltes et Semailles", or not).
There he describes how during meditation he sees visions and talks with the angels. Does that make him insane? I don't know, but he surely lives in a world of his own.

45. **tg**
August 27, 2006

Dear MathLover,

Re: "and even more important, so slow to produce new results from Perelman's genius ideas."

Some reasons I can think of:

(1) Few people (professional mathematicians) understand consequences/deeper aspects of his work (beyond the Poincare conjecture).

(2) Those that do (Lott, Yau, Cao et al) were busy just trying to get his arguments to be believed (otherwise why bother with the next step if it's all wrong?).

(3) The feeling that Perelman's work has "killed" the field, so new graduate students and others are loath to bother continuing on.

(4) Work _is_ being done. Math takes time, man.

46. **jeremy**
August 27, 2006

Peter,

I am a little disappointed by your response to TTT. Not by your comments, of course, but by the reactions of your mathematician friends to the New Yorker article. Are they really so concerned about "what is the guy working on now"? Do they have worry at all about "what is the guy living on now"? Are they interested at all in finding out if Perelman needs any help? I truly hope that the mathematics community will at least try to find out the answer to the question that you raised "what was the problem at Steklov?", and provide help when Perelman needs.

Sylvia Nasar and David Gruber went to St. Petersburg, not to find the answer on the well-being of Perelman, but to find the answer from Perelman on the question of who should get credit for the proof of Poincare conjecture. They are more interested in the "who should get credit for what" controversy surrounding the proof of Poincare conjucture, and how they can write and sell a story. They found, of course, the wrong person to answer their questions. But they certainly have all the materials to write a good story.

The materials that they have gathered are so good that many of the science writers could only dream of. There is Poincare conjecture, one of the toughest mathematical problems in the universe. Solving this problem will not only lead one to Fields medal but also to the million-dollar prize given by the Clay Institute. There are the non-inventive Chinese mathematician (Yau), who not only steals other peoples work but also want to be the king of geometry and to take credit from everybody else's work; the friendless Russian Jew and mathematical genius (Perelman), who proved the Poincare conjecture but rejected the Fields medal. The credit for his work is now in danger of being stolen; and the unremarkable American playboy mathematician (Hamilton), who needs constant push by Yau but still cannot get the job done. There is also a list of very much involved mathematicians whose names are associated with many of the well know universities.

Anyone who read Sylvia Nasar's previous book on mathematicians, A Beautiful Mind, will acknowledge that Nasar is an excellent writer, and will also find that this time she is having even better materials to write about mathematicians. She has a Chinese villain, a Russian genius. The potential for portrait of sex, money and Fields medal, all mixed up with an even tougher mathematical problem, not to mention the fuss and controversy about "who should get credit for what". With a little spin, or even without spin, Sylvia Nasar and David Gruber could have written a fascinating and believable tale. The problem is that there is that controversy and some spins are necessary. Spin, however, is a different form of art, an art form that is often mastered by political speechwriters. As storywriters, Nasar and Gruber are obviously not experts on spinning. They have over done their spin.

To spin properly, one must first get the facts right, and then spins the facts to his/her favor. Spin over zealously without the facts can have dire consequences. One example is Bush administration's spin on the Iraq's WMD, we all know that we are now in a mess in Iraq.

There are too many over zealous spins to count in the Nasar-Gruber article. Here I list a few and point out their not so pleasant implications.

A large part of the Nasar-Gruber article is devoted to Yau, he is described as a Chinese mathematician who wants to solve the Poincare conjecture for China. He was also anxious to become the next famous Chinese mathematician after Chern. The fact is, both Chern and Yau are Americans. When Chern was awarded the National Medal of Science in 1975 and Yau was awarded the same medal in 1997, each of them was cited as one of the best American mathematicians at the time. Referring Yau and Chern as Chinese mathematicians is as ridiculous as referring Nasar as a Middle Eastern writer. To make their story, Naser-Gruber have used false information about one of the main characters in the story. In an article that partially committed to reveal the dishonesty of Yau, they committed some dishonest acts of their own. What a spin!

Anyone reads New York Times and books beyond mathematics would know that China is a communist country. It has one of the worst human rights record in the world according to the latest UN human rights report. In a communist country, power belongs only to the communist party. It controls every aspect of people's life, including mathematics. As for today, a New York Times researcher is still in prison in China. To reach the power structure in that country, you have to be a member of the communist party. To have power, you would have to be a powerful party member. Nasar-Gruber have us believe, through Joseph Kohn, that "Yau's not jealous of Tian's mathematics, but he's jealous of his power back in China." But, do Nasar-Gruber also try to tell us that Tian is a powerful member of that repressive and corrupted communist party, and some of Yau's accusation of Tian's corruption may be accurate? We do not know the truth. But to spin so hard that brings doubt to their own arguments is a bad example of spin.

I was hoping that the New Yorker article could have told us more about Perelman's current situation, especially after reading the article published by Telegraph.co.uk. There is not much about Perelman that we haven't read before in the Nasar-Gruber article, then again Nasar-Gruber were writing about the "battle over who solved" Poincare conjecture. What we are supposed to learn from the article is about the battle, not about Perelman. But in one of the occasions that Perelman talked to them, they leave us the impression that Perelman was contradicting himself. According to Nasar-Gruber, "Perelman repeatedly said that he had retired from the mathematics community and no longer considered himself a professional mathematician." Yet when asked about Cao-Zhu' paper, which had just been published, Perelman knew the paper well, and did not see "what new contribution did they make". That is good news. It shows that Perelman still goes to library and read the current issues of mathematical journals. Moreover, Perelman also knew that it was "Zhu did not quite understand the argument and reworked it." Without reading the paper, Perelman would not have known that his proof was reworked. Without involving in the mathematics community, he would not have known that, in the Cao-Zhu paper, it was Zhu, not Chao, who has reworked his proof. Zhu is probably the one who reworked Perelman's proof, but this is not obvious even for people who are involved in the mathematics community. Perelman, as we all know by now, has no need to contradict himself. He probably did not even care about Cao-Zhu' paper, for he has already done the proofs three years ago. The only possibility for the contradiction is that, to spin about the "battle", Nasar-Gruber needed not only to ask the question, but also needed an answer. The answer described in the story might very well indicate that they made up this part of story. Again, we do not know the truth. But this time Nasar-Gruber manage to bring doubts on themselves.

I cannot remember who said this "writers never lie, they just make up stories."

It is unfortunate that the mathematics community was incapable of and incompetent in determining the completeness of Perelman's proofs of the conjectures. It has to rely on storywriters to help them to fight a "battle". After all the Washington style of dirt digging, mud slinging and spitting in the faces, is it time to go back to check the proofs again?

47. **woit**
August 27, 2006

Jeremy,

I think most mathematicians aren't concerned about whether Perelman has enough to live on, since they are well aware that he has turned down many offers that could provide him with more money if that's what he needs. The most recent is the Fields, which carried some money with it. The mathematicians at many institutions (including my own), have contacted him with offers to pay him very well to come visit, give lectures, and discuss mathematics. He has turned all these down, mostly not even bothering to respond to them. This is his choice as to how to arrange his life, and it has worked for him so far. Working this way by himself he figured out how to make more progress on mathematics than anyone else in recent years.

As I wrote, it is a shame that Nasar-Gruber didn't explain what the problem with the Steklov was, maybe that was something other mathematicians could intervene to help with, maybe not.

As for the comments about the "corrupt communist party member" Tian, please don't again post this kind of personal attack here. When you do it, you don't exactly help your case in complaining about the article's unfair personal attacks on Yau.

48. **Eli Rabett**
August 27, 2006

In a situation such a Perelman's (or Yau's) you don't get the complete picture from one article in the New Yorker, because to write such an article means that the authors have a story to tell, with a beginning, middle, end and moral. Think of the Nasar-Gruber article as a data point. The unpacking of Perelman's results will be another.

49. **Jack.Li**
August 28, 2006

Woit,

I don't think Jeremy was trying to say that. Please go back to read his lines.

On the other hand, coming from China, I also feel Jeremy has somewhat unwittingly exaggerated the role of "communism" in China's scientific research. The reality is, in science, as long as you are truly good (researchwise, not playing politics), you will be profoundly respected.

But the problem with the current China is, after virtually only 20 years' of reform and openning to the outside world (recall how the Cultural Revolution completely destroyed science and scientific spirit), China has not been able to produce many truly outstanding world-class researchers. During such a period of transition, you can imagine why some people are playing politics to gain funding and prestige. **Compared with Pelerman, they are shameful.**

On the other hand, Yau has been a courageous fighter in China to attack all the major corruptions in China's academia. **In China, if you want get things done, it is better to take the top-down approach (not bottom-up).** It has been said that even the Chinese Premier is now paying attention to Yau's words on how to stop all the acadmic corruptions and unfair playing rules (esp to young native Chinese researchers).

Just share some random thoughts with all the new friends here….

50. **yd**
August 28, 2006

The Fields 2006 citation for Perelman says that:
"his results provide a way of resolving … the Poincare
Conjecture and the Thurston Geometrization Conjecture."
and that the math community is still checking his work and
no one has found serious problems in the work.

Is this the same as unequivocally declaring that

the two Conjectures have been resolved by Perelman and
that there are no problems in the work?

Or, is this a best-case compromise IMU can possibly make
between not recognizing his work in 2006 2-3 years after
Perelman's posting and 100% recognizing it now but with a small
chance of having to deal with a serious problem or
gap someone may find in the work some time down the road?

Can someone shed some light?

Thanks,

51. **A.J.**
August 29, 2006

tg wrote:

(3) The feeling that Perelman's work has "killed" the field, so new graduate students and others are loath to bother continuing on.

I'm not sure this is true. As MathLover pointed out, there's probably quite a lot that can be done with Perelman's techniques. Geometrization can probably help us understand 3d TQFT and knot theory, for example. The problem is that these techniques are really hard to use. That's why it took several years for the ideas to be accepted as true (although I seem to recall Hamilton saying a few years ago that the ideas were probably correct), that's why the full proofs are hundreds of pages long, and it's why we haven't seen the same rush of theorem proving that came after Seiberg-Witten.

52. **ordinaryamerican**
August 29, 2006

Chern and Yau are Chinese mathematicians. Over one billion Chinese understand this obvious fact. Both were born,raised and educated-excluding Yau's Berkely years- in China and Hong Kong.

Yau clearly wants his accomplishments to seen as a great of achievement for the Chinese people. Americans of European descent are not interchangeable with one billion Chinese living in China.

I would rather have my tax dollars spent on developing home-grown mathematical talent(like my own three daughters)

53. **ordinaryamerican**
August 29, 2006

One last thing. Peter, thank you for this website. You are performing a great civic duty for the general public.

Lubos hasn't pulished a scentific paper in nearly three years. There is something very weird going on over at the Harvard physics departement. Or maybe Lubos is working on something very top secret.

54. **tg**
August 29, 2006

Dear ordinaryamerican,

You say:
"Americans of European descent are not interchangeable with one
^^^^^^^^^
billion Chinese living in China."

Thank you for proving my point; I presume you enjoyed Nasar and Gruber's article.

55. **tg**
August 29, 2006

Dear A.J.,

""(3) The feeling that Perelman's work has "killed" the field, so new graduate students and others are loath to bother continuing on."

I'm not sure this is true. As MathLover pointed out, there's probably quite a lot that can be done with Perelman's techniques."

I should have called my "reasons" for why more isn't being done by "general/plausible reasons". Sure, I believe a lot can be done — but how convincing is the situation to an incoming grad student, with there being so much math available to be done?

"Geometrization can probably help us understand 3d TQFT and knot theory, for example."

This sounds nice to me!

56. **Peter Woit**
August 29, 2006

ordinaryamerican,

Please take the nationalism and racism elsewhere. I'll delete anymore of it that people try and introduce here, but I have to admit you do give credence to those commenters worrying that anti-Chinese prejudice is an issue.

57. **?**
August 29, 2006

Hoping to be on-topic, I would like to ask: before that the Poincare conjecture was proofed, somebody doubted about its validity, or it is one of these statements that physicists consider true for obvious intuitive reasons?

58. **Peter Woit**
August 29, 2006

There's no "obvious intuitive reason" for the Poincare conjecture to be true, and because it was so hard to prove, their certainly had been mathematicians who speculated that there could be a counterexample and looked for it.

59. **TheGraduate**
August 29, 2006

Peter,

Would you say or have you heard other mathematicians speculate on whether there is something specially about 3 dimensions that made it the last and most difficult case to solve the Poincare conjecture in?

60. **Peter Woit**
August 29, 2006

TheGraduate,

The standard explanation is that in higher dimensions there's so many ways to move things around that things simplify. The conjecture was proved in dimension 5 and above during the sixties. dimensions 1 or 2 are easy, because there's not that much that can happen. The worst cases are dimensions 3 and 4, because there's enough room for a lot of complicated things to happen, but not enough to move things around and simplify.

I don't know of a particular reason why 3 should be worse than 4. Actually, the "smooth Poincare conjecture" still remains unsolved in 4 dimensions, this says that there is only one "smooth structure" on the four-sphere.

61. **Who**
August 29, 2006

Graduate,

You asked Peter
Would you say or have you heard other mathematicians speculate on whether there is something specially about 3 dimensions that made it the last and most difficult case to solve the Poincare conjecture in?

I can tell you one special thing about 3D that you can think about while waiting for an authoritative answer. This is just something that comes to mind about 3D that might not actually address your question. A fun thing though.

You can tie knots in 3D.

whereas in 2D it is hard to tie knots, and in more than 3D the knots tend to come untied and turn out not to be knots.

62. **TheGraduate**
August 29, 2006

Thanks for the answers Peter and Who.

A few months ago, I had been reading an overview of past fields medal work by Michael Monastyrsky and I was struck by the following:

"From the time of Cayley, the following division algebras were known: real numbers, complex numbers, quaternions, and Cayley numbers … A natural question to ask is: Are there other division algebras? The negative answer was obtained only in the 1960s and proved to be closely related to the following topological question: find all spheres on which the number of independent, continuous vector fields is equal to its dimension. There are only three such: S1, S3, S7."

I can't even begin to claim I understand all the ideas in that quote, but… it seemed to suggest something special about these sorts of spaces: reals, complex numbers etc that have proven so useful in physics.

63. **q2**
August 29, 2006

To expand on Peter's explanation of why higher dimensions have been easier for the purposes of the Poincare conjecture, the point is that an important tool in the higher-dimensional case (both for Poincare and for related results, like the h-cobordism theorem) is something called the "Whitney trick," which is used to ensure that if two transverse submanifolds P and Q of complementary dimension in a simply-connected manifold have homological intersection number zero (which ordinarily just ensures that their intersection points come in oppositely-signed pairs) then one can isotope them to not intersect at all. To perform the trick, given any algebraically-cancelling pair x,y of intersection points between P and Q one needs to find an *embedded* 2-dimensional "Whitney disk" with the left half of its boundary being a path in P from x to y and the right half of its boundary being a path in Q from x to y. By simply-connectedness, one can always find a map of a disc into the manifold with the right boundary conditions–and if the dimension of the manifold is at least 5 then after a little jiggling the disc will become embedded and so the Whitney trick works. If the dimension is three or four, the disc can be jiggled to be immersed, but it will tend to intersect itself and thus not be embedded.

The failure of embeddedness isn't as bad in dimension four, since genericaly all the self-intersections are single points. Because of this, Andrew Casson had the bright idea of using a complicated kind of infinite-dimensional handlebody now called a Casson handle as a replacement for a Whitney disc; Michael Freedman's big technical result was that a Casson handle is homeomorphic to a standard handle, and this enabled him to prove that all the 5-or-higher-dimensional techniques for the h-cobordism theorem and Poincare still work in dimension 4 if one is willing to work up to homeomorphism rather than diffeomorphism. My understanding is that at the time he thought that if only one were cleverer one could extend his result to the smooth category, but within a year it became clear that that wasn't the case: although we still don't know whether the smooth Poincare conjecture is true in dimension 4, we do know via Donaldson's results that the h-cobordism theorem does fail in that dimension–so Freedman's technical result was actually as good as one could hope for.

In three dimensions a prospective Whitney disc would intersect itself in a one-dimensional submanifold, so there's nothing analogous to Casson handles that one could try to use. In that regard, it's fair to say that the proof of Poincare in dimension four is very much in the spirit of that in higher dimensions–although showing that the ideas from the higher-dimensional case actually extended to dimension four required hard, Fields-medal-deserving work. The proof in the three-dimensional case uses a completely different approach.

64. **q2 appreciator**

August 29, 2006

q2, this was wonderfully informative, thank you very much.

65. **TheGraduate**
August 29, 2006

Thanks q2. I don't quite understand all the terms but it's good to at least know what the relevant ideas and mathematical objects involved would be.

66. **dt**
August 30, 2006

I just read the Nasar article last night. As a lover of geometry, and as a Chinese woman, it left me sad and disgusted and angry. All the more so because I knew the New Yorker was running a story about Perelman, and I had so looked forward to reading it — it's not every day that I get to read about math in the New Yorker! I had expected a detailed biography of Perelman, with detours into the world of modern mathematicians and their work, a sketch of the historical background to the Poincare conjecture, a depiction of the working life of mathematicians in the 21st century. ….I don't know how one explains the pursuit of abstract mathematics to a lay audience, but I was greatly looking forward to the attempt.

Instead, as I read on and on, I could not believe how she was turning this beautiful story, this "landmark not just of mathematics, but of human thought" into a petty, racist soap opera.

Her descriptions of Yau as a washed-up uncreative techno nerd, and her implication that the Chinese are trying to improperly take credit, were painful to me. It seemed like such an exaggeration and distortion of Yau's motives, work, and personality, and in a more anodyne but nevertheless insidious fashion, of Perelman's motives, work, and personality (basically, he's given the personality of a paranoid sheep). The subsequent comments of mathematicians quoted in the article indeed prove without a doubt that she was distorting their comments re Yau. Yet, even with all her deceptions, she couldn't hide the fact that Yau *had* with his sharp mathemactical nose identified a critical problem and the right approach, as demonstrated by how hard he was encouraging Hamilton to follow up on his Ricci flow method.

This is a great story and Perelman is a true hero. Unfortunately, even though Sylvia Naser has a good command of English and rhetoric, she clearly doesn't love math or have any inkling of its walk-on-air beauty, to do justice to the story. Otherwise, I'm sure she would have been able to communicate a shred of that beauty in her long-winded article.

By the way, the quote about the 50/25/30 breakdown in credit made at a speech in China, which Naser turns her nose at ("Even mathematicians can sometimes forget how to add") was obviously an ironic joke by Yau, a self-deprecatory laugh at the unseemliness of China taking a percentage of the credit in this case, and indeed, the futility of ever apportioning credit exactly (yet it is completely understandable that China, a developing country, would want to celebrate its small but impressive contrbution to this discovery and it is touching of Yau to cheerlead this effort; I for one am proud that Chinese mathematicians living and working in China and publishing in Asian journals are able to do world-class mathematics). It might also be a geometry joke, since geometry is all about getting rid of numbers and not having to use coordinates.

Grigory Perelman got it exactly right when he said "journalists should have better taste."

67. **MathPhys**
August 30, 2006

dt,

Please calm down.

From everything I've read, the 50/25/30 breakdown was not intended as a joke. Someone made a silly mistake. That's all.

Further, S T yau is very well known to be notoriously competitive. There are many, many stories circulating about him to this effect since many years.

On the other hand, we all know of (born and bred in the) US scientists who are at least as competitive as Yau, so this not a particularly Chinese characteristic.

68. **tg**
August 30, 2006

Dear dt,

I support your finely written comment.

69. **geometer**
August 30, 2006

At a recent ICM interview Cao said that Yau never talked about "50/25/30 breakdown", and does not agree to any such breakdown.
(I think this is in ICM daily news of August 29).
Now this is interesting because the quote in Nasar's paper (from a press conference at the math institute in Beijing) is very precise and clear. I am sure someone must have the whole press conference on tape. I wonder who is lying here?

70. **TheGraduate**
August 30, 2006

dt:

I am glad you and other Chinese had chosen to share your opinions here.

I thought perhaps Nasar and Gruber were looking at things through the prism of American foreign policy. Through that prism, the rise of China would be potentially threatening.

One of the reasons that I do not think it rises to the level of racism is that I do not think they would have reacted to a similar situation with a Japanese person in the same way. I think this is because Japan is a strong partner of the US.

For me also, the article was not what I had expected it would be.

One question I did have for you or any other Chinese speakers that might care to comment: quite a few people who have identified themselves as Chinese have said things along the lines of Yau being brave or noble or caring etc. I was curious about what these comments were based on. Are these based on assumptions or are they based on things you know about Yau that non-Chinese speakers would not know?

For instance, How did you come to this conclusion: “obviously an ironic joke by Yau, a self-deprecatory laugh at the unseemliness of China taking a percentage of the credit in this case, and indeed, the futility of ever apportioning credit exactly”?

71. **TheGraduate**
August 30, 2006

geometer:

72. **geometer**
August 30, 2006

page 2 of http://www.icm2006.org/dailynews/dailynews29.pdf

73. **tg**
August 30, 2006

Dear TheGraduate,

You said:

“One of the reasons that I do not think it rises to the level of racism is that I do not think they would have reacted to a similar situation with a Japanese person in the same way. I think this is because Japan is a strong partner of the US.”

The notion that Japanese and Chinese are not treated the same does not mean to me that there is no racism involved!

You also asked:

“Where did you hear/see the interview? Can you provide a link or reference to the source?”

Look at http://www.icm2006.org/dailynews/

I actually had some problems reading the files. But I did notice an interview with Cao who asserts that Perelman’s work was clearly the central (final) step in Poincare. Interesting Cao also seems to suggest that Yau has said the same to Nasar during her research into her biased, anti-China article. But this never seems to appear in her write up.

It should also be noted that even with regards to Nasar’s “A beautiful mind”, I’ve heard that a number of mathematicians have been angered by how she’s twisted/exploited their words to achieve effect. I ignored that feature of her journalism until recently, since the text was so nicely written.

So while previously, I believed what she said was true, but not given proper context — I now how reason to suspect that what she’s said in her article includes crucial falsehoods.

In retrospect I’m embarrassed as follows. As a mathematician, I so rarely see my field portrayed in media — so when it does happen, I’m quick to read/see it and enjoy it. I think I’ll be more discerning in the future.

74. **TheGraduate**
August 30, 2006

tg:

Another reason I do not consider race as the dominant factor is that if Yau had been born and raised in America then they probably would also not treat that situation the same way. Do you perhaps mean some form of discrimination besides race-based discrimination?

I don’t think there is any reason to be embarassed for mathematics. Everyday people care more about politics than they do about computations. This kind of controversy will probably be more attractive to young people as it shows mathematics matters and also it shows mathematians as strong, socially aware characters in the form of Yau. It also shows Perelman as a detached guru-type … which is probably also appealing for some young people. Something for everyone …

I had a brief conversation with Nasar when she signed my copy of “A beautiful mind”. She was pretty friendly. I don’t think she is a saint though. It was always fairly obvious to me that she wasn’t a pushover. She gathered a lot of information on Nash for a long time against his will. She documented a lot of things on Nash that he probably didn’t want in print.

75. **TheGraduate**
August 30, 2006

tg and geometer:

Also, thanks to you both for the link to the interview.

76. **Deane**
August 30, 2006

There are way too many half-truths, and extrapolations here for my taste. I’m surprised that Peter is not deleting more of this stuff.

The (mis)allocation of credit appeared in the Chinese press but is attributed not to Yau but to a Chinese mathematician named Yang Le, who as far as I know has no particular expertise in Ricci flow or the Poincare Conjecture.

77. **tg**
August 30, 2006

Dear TheGraduate,

You raise an interesting point about how Yau would be treated if hypothetically he were born and raised American. I’m honestly not sure, based on my own experience.

Perhaps a reasonable thought experiment would be to wonder how likely the Newyorker would run such a piece if it so happened that Yau was an American, born in another country X, and his activities were closely tied to being of X ethnicity, for various values of X. Again, I recommend reading the September notices of the AMS (available online) for another perspective on this and related issues (with regards to more "mortal" mathematicians).

78. **TheGraduate**
August 30, 2006

tg:

Do you mean the article "An Invisible Minority: Asian Americans in Mathematics" ? I have read that article.

79. **tg**
August 30, 2006

"Do you mean the article "An Invisible Minority: Asian Americans in Mathematics" ? I have read that article."

Yep. Although I suppose here is not the place to discuss it — as much as I'd like to.

80. **geometer**
August 30, 2006

tg:

according to Nasar's article Yang was indeed talking about allocation of credit, but Yau was standing next to him and confirmed what Yang said. And in any case, if Yau thought this allocation of credit was entirely unappropriate he could've distrubuted a statement (eg post it on the Beijing Math Inst site) to that effect, clarifying his position. He did not do that at the time, and the phrase about "50/25/30 breakdown" went arount the world.

BTW, speaking about "invisible minority". This article in the Notices hinges on the difference between Asians and Asian Americans. This may be a valid point as far as students/postdocs are concerned but for faculty it makes no sense. The absolute majority of tenured math faculty are citizens or permanent residents, so they are already Asian Americans, no matter where they were raised or educated.

81. **tg**
August 30, 2006

Dear geometer,

You might have wanted to direct your comment about Yang's remarks to Deane. I've only spoken about Cao's remarks at the IMU; I haven't thought to raise the issue about Yang, although it sounds interesting. In any case, as I've said before, whether Yau said these things or not is not relevant to my argument. My complaint is unfair focus on this man and his relationship to the Chinese. I'm sure that if Nasar wanted to, she could research any one she wanted and make a case that that person is scum of the earth.

You said:
"BTW, speaking about "invisible minority". This article in the Notices hinges on the difference between Asians and Asian Americans. This may be a valid point as far as students/postdocs are concerned but for faculty it makes no sense. The absolute majority of tenured math faculty are citizens or permanent residents, so they are already Asian Americans, no matter where they were raised or educated."

I'm not sure I fully understand your remark about the "invisible minority". There are plenty of non-American asians (e.g., mainland Chinese) who graduate from math PhD programs. They certainly have barriers too — but it's surprising to me how _few_ Asian Americans (given the advantages of citizenship and language) do so. I think it's this suprising fact that is what the author wants to focus on. The article is mainly about barriers to a tenure track position, I agree — but I still think it is relevant to faculty.

82. **HI**
August 30, 2006

I didn't think the article of Nasar and Gruber was necessarily disrespectful to Chinese, but what is clear from reading the comments here is that there are people who are eager to make a connection between the aggressive behavior of certain Chinese mathematicians with their nationality. As an Asian, though not Chinese, I am not happy to see those comments.

The fact is that it is not uncommon for successful scientists and mathematicians to have reputation of being aggressive or even nasty. I guess John Nash, who was the subject of Nasar's book is an example. But you don't see anyone who associates John Nash's personality with his heritage. How about Jim Watson? Carlo Rubia? It seems the connection is only made when the scientists/mathematicians are of certain ethnicities.

83. **geometer**
August 30, 2006

tg: Sorry for misplacing my post to Deane. Now you say: "My complaint is unfair focus on this man and his relationship to the Chinese. "

Okay, I don't think Yau-Tian fights and Chinese math politics are relevant to Nasar's story, but surely Yau (not anyone else!!) the one who singlehandedly created the controversity on the "who proved the Poincare Conj" issue and this is what the Nasar's article is mainly about. According to Yau's survey at arxiv (see last page) the Perel'man's argument is not written in complete detail, and Cao-Zhu papers give a first complete and detailed account, and that Cao-Zhu contribute original ideas not present in Perel'man's proof. This feels very different from what Hamilton, Morgan-Tian, Kleiner-Lott are saying. They do say that Perel'man's proofs are concise but they never doubt their completeness. In fact, in his ICM talk Hamilton said "the Perel'man proof is correct and complete", and Morgan-Tian, Kleiner-Lott give all credit to Perel'man, they said that no substantially new ideas were needed. To me it sounds like Cao-Zhu could not follow Perel'man's argument and found it easier to prove it differently. This is okay and happens all the time in math. However, when this happens people say "this is another, perhaps easier proof", and they get credit for the new proof, not the new result. (Even though Morgan in his ICM interview said he could not see what was so new and different in Cao-Zhu paper). Now you might say that this is a free country and Yau could express his opinion on any topic including Perel'man's proof, even though other experts say otherwise. Well, if Yau were nobody, people would not worry what he says. The trouble is that because (as I think) Yau is the most influential person in geometric analysis, what he says matters, and when he does something unethical, it hurts the geometry community. So this story is indeed about Yau. If he did not do what he did, there would be no controversity. And Nasar merely aired the controversity to the general public; most of what she wrote about Perel'man's story is no news to me, and I did not like Yau's survey the first day I saw it, and I was upset when I heard the "50/20/35 breakdown". Both events happened way before I read Nasar's paper.

84. **tg**
August 30, 2006

Dear HI,

“But you don’t see anyone who associates John Nash’s personality with his heritage.”

Absolutely correct, and that’s my point, don’t you see?

85. **TheGraduate**
August 30, 2006

HI:

Who here is eager to make a connection between Chinese mathematicians and their ethnicity?

If one were to crudely split the different comments into two groups, All I see are some people that say that the article is outright anti-Chinese and other people saying they didn’t think it was as negative as all that.

Most people are explicitly or implicitly saying that racism and nationalism are bad for mathematics.

Only outlier is ‘ordinaryamerican’ who had some stupid things to say but PW clearly put him in his place.

tg:

I think Asians are unrepresented at the faculty level in comparison to the number of Asians that are present at the graduate student level. I actually had this opinion before I ever set eyes on the September issue of Notices.

I don’t know why that is but I guess the September notices is the beginning of an explanation.

I think one important point that the article makes is that there is a lot of variety in Asia: South Korea, India, Vietnam, Japan etc

86. **tg**
August 30, 2006

Dear geometer,

Based on what I know, I can see why one could be upset about this priority fight. As I’ve been saying all along, even if I grant every fact that you cite (and I’m mostly inclined to), then I still have an issue with the article (and moreover the caricature that accompanies it).

Nasar and Gruber could have written about the controversy of correctness, saying that even a Fields medallist (Yau) was sufficiently unsure — in contrast to his learned colleagues (Morgan, Lott et al); math is about proofs, and sometimes what is a proof is debatable and in this case has caused heated discussion; Yau although raised in China is an American, having been trained in the US and considered among America’s best mathematicians, etc etc. Even keep most of the quotes that are there, but downplaying the whole China connection.

In that case, it would be clear that Yau-Chinese is not the connection, but rather Yau the scientist is. I’d have no problem with such a (boring) article. Nasar and Gruber cleverly and subtlely went just beyond the line.

Nasar is a crafty and skilled writer. She’s no dummy. I’ll assume the same for Gruber. They know Americans have a fear/distaste for China and their expansion. They know incorporating China into this would play well, and she exploited it. But, in my opinion, all people of Chinese descent are detrimentally affected by this approach — a small cost for her paycheck.

87. **tg**
August 30, 2006

Dear TheGraduate,

You say:
“I think Asians are unrepresented at the faculty level in comparison to the number of Asians that are present at the graduate student level. I actually had this opinion before I ever set eyes on the September issue of Notices.”

…and the number of graduate students are underrepresented in comparison to the number of undergraduates. I also agree with you about the point concerning many different “asian ethnicities”.

88. **geometer**
August 30, 2006

tg: okay, I see where you are coming from and mostly agree with what you are saying. I might add that what I disliked about Nasar’s paper is that it portaites Yau as no longer so great a mathematician whose best days are long gone, which is why he is playing politics. I think, Yau is truly great, but I also think some of the things he does hurt our field, and I wish he could stop (or be stopped).

89. **TheGraduate**
August 30, 2006

tg:

I guess what I am hearing from you is that you think that Nasar and Gruber should have avoided the China vs America issue. So I ask you, why? You say ‘all people of Chinese descent are detrimentally affected ‘ and so I ask you, how so?

Are you saying, there should be no articles about China? China is a country with 1.3 billion people. It is kind of hard to ignore.

Are you saying there should be no articles about the rise in Chinese power on the global stage. (Again, a billion people and hard to ignore.)

Are you saying there should be no articles in America where people express concern about the rise in power of China? (Given that the US is commited to go to war against China if it invades Taiwan, that might be wishful thinking.)

Anyway, the Chinese government is investing a lot in getting better quality schools and keeping better quality researchers in China … everybody knows this.

Actually while I'm on the subject of under representation … Asians are also under represented in US politics … I think if this situation was corrected the US would have a lot easier time dealing with China.

90. **tg**
August 30, 2006

Dear TheGraduate,

You ask:
"I guess what I am hearing from you is that you think that Nasar and Gruber should have avoided the China vs America issue. So I ask you, why? You say 'all people of Chinese descent are detrimentally affected ' and so I ask you, how so?"

Your questions are very valid. However, I have already said and repeated all that I really have to say multiple times. I guess all I have to say at this point is that reasonable people can come to differing opinions about the same issue!

91. **TheGraduate**
August 30, 2006

tg:

Okay. Fair enough. Basically I think that if this kind of stuff affects American-born people of Chinese descent then that has to do with the prejudice of the people that are affecting their lives.

The internment of the Japanese-Americans wasn't wrong because it was wrong to go to war with Japan or to bring up going to war with Japan or even to bring up the rising power of Japan. It was wrong because they were American citizens just like any other American citizens and deserved to be treated as such.

92. **Russian**
August 30, 2006

As a person of Russian decent and a lover of trigonometry with a limited exposure to the world of advanced mathematical studies, I observe with a surprise and discontent the tidal wave of negative reaction of Chinese geometry lovers to the article of Nasar and Gruber.

I do not know what criteria Mr. Woit is using to characterize someone's writing as racist and homophobic views, but I am amused at shear amount or futile discussion about number of Chinese PhD students and whining about being underrepresented, etc, etc, etc.

Nasar and Gruber, in my opinion, made several good points:
a. Some people can not accept the fact they exhausted their scientific potential and are trying to influence the scientific community thru maneuvers looking legitimate. Is not it the reason that many talented people in science world and academia leave being tired of politics, chase for higher place in hierarchy based not on talent but ability to develop connections, build coalitions?

b. It is Yau who turned the solution of the math problem into the matter of Chinese pride, no more, no less. I read in disgust the announcement of Xinhua News Agency English edition stating that Chinese scientists resolved a century-old Poincare conjecture. If Xinhua lied (not for the first time) it was responsibility of Chinese scientists to establish the truth.

c. I was especially disappointed with Yau taking lower road on a loner like Perelman. Perelman clearly has distaste for everything that is not related to the core value of every science, namely contribution to the favorite research field without consideration for success, monetary compensation, vanity, recognition, etc. Not so for Dr. Yau; not being able to contribute any significant work for the last twenty years, he it trying to reach fame utilizing thirst of the Chinese government for good publicity.

While it would not fair to characterize all Chinese based on dirty politics of Dr. Yau, it won't be inconsiderate to note that none of the Chinese geometry lovers were dare to criticize Dr. Yau. Is it something about introverted nature of Chinese culture that critique is accepted if only comes from inside and only from people within the community of certain statue or authority?

I have great respect for Chinese history and people, but that does not mean I have to agree with superficial speculations of Chinese
geometry lovers. I will tell them, it is not quantity that matters, it is quality. I will tell them, if you can not be at the front, let it go, let others go ahead with their ideas.

93. **werdna**
August 30, 2006

To Russian:

How do you know that "none of the Chinese geometry lovers were dare to criticize Dr. Yau"?

There has certainly been plenty of criticism of him on this forum, many of it from Tian supporters, I am sure. (Just ask Peter, who must be tired of deleting all those personal attack posts.) None of them is a "Chinese geometry lover"?

And please do not stereotype Chinese geometry lovers. The vast majority of them are busy doing mathematics and do not post here.

94. **TheGraduate**
August 30, 2006

I guess this issue is raising a lot of nationalism. China and America are geopolitical rivals. There is not much than can be done about that except maybe for Americans to try to understand China better and for Chinese to try to understand America better. I think those people who have connections both to China and America can probably make a big difference in this. Such people are more likely to be able to see what things people from both countries will find honorable and desireable.

95. **Peter Woit**
August 30, 2006

Russian,

There have been plenty of comments here from Chinese people critical of Yau, and I deleted many such others that were far more hostile.

Everyone,

Please stop with the discussion of nationalism/racism, etc. It's not going anywhere, has only a little to do with this story, people are just repeating themselves, and it hasn't been very enlightening. There's a reason I try and avoid discussing my opinions about political matters here: I find virtually all political discussion on blogs to be a complete waste of time. Most people love to argue their political opinions, very few pay much attention to what others have to say. You end up after a while with pure noise, and participating in it just wastes time and energy. So, please, if you want to discuss the Poincare story, fine, but try and stick to the facts and the mathematics, avoiding personal attacks on Yau, Tian, or anyone else, and you better have something really new and really interesting to say if it's on the nationalism/racism issue (and it should be related to Poincare).

96. **outsider**
August 30, 2006

I am not a professional mathematician, but it seems to me that a number of people here have an entrenched grudge against Yau and that some of these people also form their opinions based on the New Yorker for their "facts" and mathematics.
The critics of Yau here ascribe him certain vague disposition and views that he apparently holds. But it is not clear that this kind of attribution originates from the critics themselves, including the New Yorker, or Yau really holds them (please see the interview given by Cao for the ICM). What we then tend to have is basically a series of personal attack on his character, often based on hearsays and second-hand gossips. Whatever the nature of Yau's personal character, surely his critics are not saying that they are saints themselves? Not checking facts or distorting them and then proceed to attack the person's character is utterly deplorable. The best way to have a go at Yau is to do better maths than him, period.

I have a different take on the Poincare Conjecture.
In the press reports that I have read from China, Yau has often maintained that the Cao-Zhu paper was the finishing step of the works of Hamilton and Perelman. Likewise in the Cao-Zhu paper, they explicitly referred to the paramount importance of Hamilton and Perelman. All these are conveniently ignored by some people.

As an outsider looking at mathematics in history, there is nothing wrong with assigning percentages in the debate on Poincare. We may disagree with the allocation, but it is a reminder that major advances in mathematics are often built on the cumulative endeavor of many others. John Morgan, in his ICM talk, indicated that in the currency of the mathematics community, Perelman should be accorded with the Poincare proof. However, according to him, Perelman would not have done it without Hamilton and "vital" contribution from Yau. History will judge the allocation.
Perelman spoke of honesty in the New Yorker. But why does he not have the honesty of acknowledging the works of Cao, Zhu, Morgan, Tian and others in providing the rigor and details for his program? He provided sketches on some of his proofs and over the last 3 to 4 years has not prepared or able to produce rigorous proofs for his program (why Steklov could not help out?). I hope that I am not wrong in saying that sketches can not be regarded as proofs for the requirements of mathematics as a science. I think the works of those authors have given the ICM the added confidence to award Perelman the Fields medal and the mathematics community to accept Poincare has indeed been proved.

97. **MathPhys**
August 30, 2006

To me, Perel'man's behavior is due to reasons that have nothing to do with mathematics or with the math community. I think he reflects his feelings towards other issues on the math community, by not completing or publishing his proof, by declining to accept prizes, etc, etc.

98. **another outsider**
August 31, 2006

the fact that 3 different groups completed the Perelman program in roughly the same time suggests that it is routine work. I do not see any point in assigning more merit to the group that could publish a full proof a bit faster than others.

99. **Stevem**
August 31, 2006

"To me, Perelman's behavior is due to reasons that have nothing to do with mathematics or the mathematics community"

It is possible Perelman is having a "mid-life crisis" or has even had a nervous breakdown after years of very intense mental work on this problem. Events or personal/professional issues at the Steklov perhaps pushed him over the edge. Speculation of course but it would not surprise me if that indeed is the case.

100. **Russian**
August 31, 2006

Dear Peter,

Please do not be afraid of noise: unless it is "white noise" (I wonder why it is called 'white' and if there were political motives involved when giving the name), a noise signal carries useful information; and in the cosmological sense may carry information about other civilizations.

Also, I do not have any intension to criticize your blog policing policies; you can delete mine on any occurrence you want. Not being able to judge what you have deleted, I can judge what you left.

I have read an eclectic collection of essays from self-pitying geometry lovers, further called "polishers". These underappreciated, under-recognized and under-promoted people, some already with advanced degrees, some with such degrees in sight who are spending their lives polishing steps of the scientific ladder the giants are climbing by every day, and watching genius like Perelman running up the ladder in cheap and dirty boots.

After all, what a misfit this Perelman is. Even Steklov does not like him, not to mention the great news agency Xinhua. Frankly, he does not deserve to solve any important problems because:

1. He did not work with Yau on that problem, and what is even worse, does not care what Yau thinks or does
2. Instead of submitting for peer review 3,000 pages of polished proofs he published his solution on a website
3. He did not go to Marshall Putin and Russian news agencies for the purpose self-aggrandizement
4. He survives on milk and bread in lieu of green tea and rice
5. He is a weird guy in the middle of mid-life crisis struggling with mental disorders and long beard
6. He refused to accept Fields award while thousands upon thousands of "polishers" are ready to die for a glimpse of it.

Peter, unfortunately you can not avoid unavoidable. There are scientific giants in this world and there are pygmies. There are stars and dwarfs, supernovas and black holes. Some are jealous of others and their jealousy spills over in their writing. It is OK.

101. **Deane**
August 31, 2006

I for one am very grateful to all of the "polishers", including Morgan-Tian, Kleiner-Lott, Cao-Zhu as well as Ben Chow and his co-authors, who have devoted an enormous amount of effort to writing what are essentially expository books and papers. Although some of them may have embarked on their efforts hoping to find substantial gaps that they could fill and claim some credit, all of them completed their work knowing full well that they were performing a service to the community that would add very little to their own resumes.

I am also extremely grateful to Perelman for his brilliant contributions to mathematics and for delivering them to the community in a manner that has led to the most and best publicity that mathematics has ever had. I am saddened by Perelman's decision to withdraw from the mathematical community.

I am grateful to Yau for far too many things to list here but in particular for helping to create more drama in the Perelman-Poincare story and accentuating the publicity.

I am grateful to Overbye, Nasar, and Gruber for entertaining and well written stories that introduced the world to real mathematics and real mathematicians. Without them, there's no way Stephen Colbert would have ever done a piece on the Fields Medal and Poincare conjecture.

Have some of these people done things that I am dismayed by? You bet. But if I want to express any of them publicly, I will attach my name to what I write. I am disgusted by anonymous postings, both here and elsewhere, attacking one person or another. They are all acts of cowards and therefore not worthy of the slightest attention.

Deane Yang
Professor of Mathematics
Polytechnic University

102. **Deane**
August 31, 2006

Two more:

I am very grateful to John Ball, the IMU, and the local organizers of the ICM 2006 for an exceptionally well run ICM 2006 (based on reports I've gotten. I wasn't there) and a masterful job of publicizing the ICM and Fields Medals.

I am very grateful to Yau and David Gu for the graphics they provided for Overbye's article in the Times. Especially the rabbit, which generated such a strong reaction from many readers, including Stephen Colbert.

All in all, it's been a very memorable summer for mathematics. The challenge is figuring how to proceed from here.

103. **TheGraduate**
August 31, 2006

Anonymity has a long history in democracy. Benjamin Franklin used several pseudonyms. http://www.pbs.org/benfranklin/l3_wit_name.html

I mostly appreciate everyone that bothers to post especially if they are willing to respond fairly to challenges to their point of view and they avoid ad hominem … without a good faith basis between the conversationalists, there is really no point to discussing anything.

However, I sympathize with Peter because I bet he's probably often held responsible for a lot of what is on here.

I think that this case of Nasar and Gruber is very interesting and relevant contrast to string theory case. There are some superficial similarities … media attention, academic controversy …

The media seems to love this stuff lately. For instance, the retraction of papers that happened recently at Columbia. It seemed like some sort of minor dispute between a Professor and his former graduate student and yet it had international coverage.

104. **yd**
August 31, 2006

The New Yorker is reading every letter to the editor as proof that Manifold Destiny has really boosted the sales of the magazine.
Nasar is happily collecting her royalties. Perelman is quietly working on
the remaining 6 Conjectures while other mathematicians are
arguing on the internet. True mathematicians should go
back to work now.

BTW, does anyone know where to find the information on the
reaction from the math world when Beautiful Mind was published?

105. **ks**
September 1, 2006

> Instead, as I read on and on, I could not believe how she was turning this beautiful story, this "landmark not just of mathematics, but of human thought" into a petty, racist soap opera.

Maybe it would be helpfull to overcome this narcistic identification with everything that is chinese? I think this is a very dangerous attitude which reminds me somewhat in the nervous wilhelmian paranoia reigning in pre WWI Germany – a nation which had once been some european "tiger state" with empire ambitions.

The article is kind of a moral tale about use and misuse of power in the scientific community and about the dedication and drives of opposite characters within. It is written as some kind of tragedy involving two very strong main characters – one might guess that "Woit vs Lubos" would be a nice theme for a comedy. The contemporary western culture is absurd, not tragic.

The only aspect which is originally chinese in this play and which has to be attributed to its culture is Tians devotion to his teacher Yau.

PS. Writing a detailed biography of Perelman is likely pointless and would become the real soap ("why is he living at his mothers flat…") Perelman seems to try to live the life of a russian saint. So its about losing some properties of personality and not being obsessed with it.

106. **woit**
September 1, 2006

This topic seems to generate bad behavior here, including people thinking it is a good idea to post comments under multiple pseudonyms or other people's names. Since the signal to noise ratio is about zero, I'm also shutting off comments here.

U.S. Publication of Not Even Wrong

August 22, 2006
Categories: Not Even Wrong: The Book

Today a heavy box with copies of the U.S. version of Not Even Wrong arrived at my office, and I'm quite pleased the thing is finally being published in this country. It appears that Amazon has it in stock (see [here]()), the very old publication date they still have listed as "September 30" is incorrect. Presumably it should soon be available at fine book-sellers everywhere…

Update: Lubos has posted his usual slanderous review of the book on the Amazon site, and then presumably logged in from many different places to vote for his own review. Now it seems I get just one star instead of the two I got in the UK, since it seems I have "abandoned any integrity". As usual, he's very big on intellectual integrity. He lists as the first "embarassing error" in the book the Gev instead of Tev typo that was in the British edition, although he is well aware that, thanks to him, the typo was fixed for the US edition, which is the one he's reviewing. He's also paranoid and delusional, accusing me of "using various tricks to erase all inconvenient reviews".

Update: I've updated the NEW errata page to include the US edition, and also started a reviews and press coverage page.

Update: Since Lubos's review of NEW on Amazon has been deleted, he is now offering $20 to anyone who posts a one-star review of "the book with the black satanic cover", and manages to get Amazon to leave it there for at least two weeks. Yet another example of string theorist's belief in the "market-place of ideas", I guess.

Comments

1. **Kasper Olsen**
   August 22, 2006

   😉

2. **c.w.**
   August 22, 2006

   congrats, peter! i finished the U.K. version a few weeks ago and loaned it to a friend who had just watched the 3-part NOVA series.

3. **Ron Avitzur**
   August 22, 2006

   Congratulations!

4. **David**
   August 23, 2006

   Congratulations. I really enjoyed the UK edition. Well done.

5. **D R Lunsford**
   August 23, 2006

   Congratulations, Peter! I well remember reading your original paper "String theory: an evaluation" while at work back in 2001. I was literally dancing in the aisles that someone finally got it and had the balls to speak up. Well done.

   -r

6. **comentator**
   August 23, 2006

   Congratulations!!

7. **Shan Gao**
   August 23, 2006

   A very intriguing book! It should be also read and understood by the string theorists. Congratulations!!
   By the way, I will soon publish a new book Quanum Motion, which may also imply that string theory is incomplete, or even wrong. See my research website http://www.quantummotion.org/.

8. **King Ray**
   August 23, 2006

   Peter, congratulations! I've had it preordered on Amazon for months, so hopefully it will arrive soon. Keep up the good fight. The string may really hit the fan now, with all the publicity the US printing will bring in the media. Brace yourself!

9. **ksh95**
   August 23, 2006

   Screw it, I'll contribute to the Buy-Peter-A-porsche fund.

10. **TheGraduate**
    August 23, 2006

    Congratulations. Hope to see it in Barnes and Noble or Borders some time soon.

11. **Christopher**
    August 23, 2006

I've received my copy of your book. Looks good. Congrats.

12. **Jody Trout**
August 23, 2006

Congratulations, Peter!

I received notification from Amazon today that my copy is in the mail. I look forward to reading it! Keep up the good work.

Cheers,
Jody

13. **nigel**
August 23, 2006

Congratulations. I bought the British version and I like the fact that it is not varnished with any hype or speculation. When are you going to write a textbook? Now you have media attention, I hope you get contracts for other books lined up and get non-returnable advances. Try to get a contract to either edit an encyclopedia of non-biased QFT research, or to edit a journal. Unless you do something like that, it probably won't ever happen, or else will be a flop.

14. **Rickkkkkkk**
August 23, 2006

Good deal and congratulations

15. **Who**
August 23, 2006

I just checked Amazon's physics best sellers list and the book was #5

(just above Brian Greene "Elegant Universe" which was #7)

They update hourly, so if you look now it might be different

http://www.amazon.com/gp/bestsellers/books/14545/ref=pd_ts_b_ldr/102-4540543-7840144

This best seller list is what you get by narrowing
Books > Science > Physics.
It is still pretty broad.

On the same list where N.E.W. is #5, I saw "Warped Passages" as #31, and "Fabric of the Cosmos" #39 and "Road to Reality" #44.
However many of the other titles were textbooks.

16. **Tommaso Dorigo**
August 24, 2006

Well done Peter!

I am glad there is a US version, I also will be most happy to go to my usual Borders and thump my fist at the information desk if I don't find your book on the shelves… Just for the sake of it. Of course it'd be much better if they had it on a bookstand on top of a pile in front of the entrance…

Cheers
T.

17. **Vicky**
August 24, 2006

My copy is on the way. My birthday is next week and I have taken the day off from work, so I will probably spend a bit of the day reading. I will post a review on Amazon once I have finished the book.

Congratulations!

18. **Who**
August 24, 2006

As of 1 PM eastern today, the Woit and Smolin books were #14 and #15 on the Amazon physics bestsellers list.

19. **TheGraduate**
August 24, 2006

Who said:

"As of 1 PM eastern today, the Woit and Smolin books were #14 and #15 on the Amazon physics bestsellers list."

I casual reading of the list suggests that they are being pushed down the list by textbook sales. A large number of the books that are higher on the list are textbooks.

20. **Alain-Paul**
August 25, 2006

How about a frensh-transleted version?

I can read english, it's just for the comfort.

Alain-Paul.

21. **D R Lunsford**

August 25, 2006

I would be willing to do the translating.

-r

22. **woit**
August 25, 2006

Alain-Paul,

I haven't heard anything recently, but Dunod has bought the French rights to the book and I believe that they have hired a translator, but don't know what the state of that is.

23. **Alain-Paul**
August 25, 2006

O.K. for the response.

If the edition Dunod has bought the french right, i think the project is on its way.

Great!

p.s. Sorry for some mispelling of the previous message (even in the mail !).

Alain-Paul.

24. **Tony Smith**
August 25, 2006

Peter, will you be doing any book-signing and/or talk-show tours for the USA edition?
How about CSPAN TV, which often does serious books?
If you do, please post your schedule.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

25. **nigel cook**
August 26, 2006

Professor Lubos Motl has reviewed N.E.W. yet again on Amazon. Amazon had to delete his previous reviews of N.E.W. which falsely claimed that string theory is based on evidence similar to that which evolution is based on. He really is a character. I know that at least two readers complained to Amazon that he was making inaccurate and irrelevant propaganda for string theory disguised as a book review. He now complains of N.E.W.'s 'embarassing errors'. (Is embarrassing generally spelt as embarassing by most Americans, or only by Czech-born string theorists?)

26. **Who**
August 26, 2006

nigel,
double R is correct and usual, but plenty of Americans (not just the person you mentioned) misspell it with a single R.

27. **Who**
August 26, 2006

I hope someone besides myself is interested in how sales are going as indicated by the Amazon "general physics" bestseller list.
Earlier I referred to the raw "physics" list, but that has a lot of specialized textbooks among which books for wide audience are scattered, so narrowing it down to what Amazon calls "general physics" is helpful

http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

I will give rankings of some other wide audience books for perspective. As of 10 AM eastern Saturday 26 August the "general physics" bestseller list included:

Elegant Universe #5
Brief History of Time #9
Trouble with Physics #12
Not Even Wrong #13
Warped Passages #18
Road to Reality #21
Cosmic Landscape (Susskind's book) #76

28. **D R Lunsford**
August 26, 2006

Motl's review is the usual sophistry. I reported him to Amazon.

-r

29. **Lubos makes me puke!**
August 26, 2006

Nigel- I believe he is still "Assistant" Professor Lubos Motl. I hope he is still a long way from a full professor or Harvard has gone down the tubes.

30. **chand**
August 26, 2006

Concerning translations, maybe Lubos would be interested in helping to translate Peter's book in Czech? Apparently, he did a good job with Brian's "The Elegant Universe"…

31. **be careful**
August 26, 2006

Lubos might notice that you wrote Gev and Tev instead of GeV and TeV!!!

32. **Visitor**
August 26, 2006

Lubos Motl – bringing the spirit of Leninism to theoretical physics.

33. **TheGraduate**
August 26, 2006

"It would be very foolish to throw away the right answer on the basis that it doesn't conform to some criteria for what is or isn't science" — Leonard Susskind

Apparently IDers are very fond of this quote. I was watching book tv (C-SPAN2) today and one of the pro-ID authors of 'Traipsing into Evolution" repeated this quote.

A search of the quote on the internet finds other IDers equating ID and string theory and claiming a double standard and that legal challenges to ID should apply to string theory.

34. **dan**
August 27, 2006

Peter,

would you mind a wiki entry, along with summary of your arguments against string theory?

do you think lubos' string theory rebuttals to your criticisms to be substantive?

35. **Thomas Larsson**
August 27, 2006

The only substantive critique in Lubos' latest post is apparently that the US edition of NEW has a satanic black cover. Hard to argue about that.

A few posts before, Lubos speculates that God is an American citizen. With that definition of God, it makes sense to claim that string/M-theory is the language in which God wrote the world. The world doesn't seem to care much, though.

36. **Alphonse Warakomski**
August 27, 2006

Reading the popular literature on string theory has often left me with two ideas that the theory is nothing but mathematical masturbation and that physics under string theory has become the new metaphyics. Thanks for the expose, I read most of it last night after buying it yesterday.

37. **D R Lunsford**
August 27, 2006

Lubos' slander has now been removed from the review list

-drl

38. **John Rennie**
August 27, 2006

I see Motl's review has been removed (before I got a chance to read it). I'm not sure this is a good thing as it feels like censorship to me. If it was obvious to Amazon that his review was a rant it should be obvious to Amazon's customers too.

39. **stupid**
August 27, 2006

'If it was obvious to Amazon that his review was a rant it should be obvious to Amazon's customers too.'

Maybe that's exactly why they reported it, and why Amazon deleted it? If you want to see Lubos' stringy propaganda, take a look at his blog, but try keep a sick-bag handy.

40. **John C**
August 27, 2006

Shame that Motl's review was removed from Amazon, it was great reading. One phrase that stuck out in my mind was the one where he said something like "anyone interested in seriously pursuing theoretical physics should not read this book as they will get confused". Does he really have such a lowly opinion of the next generation of theoretical physicists and their ability to think and discriminate for themselves? Or did he unintentionally reveal that "String school" is really about indoctrination, and not about discovery?

41. **Peter Woit**
August 27, 2006

John Rennie,

I'm in general very much in favor of promoting Lubos and his views, to the extent that I've suggested to several science journalists that they should do a story on him. As far as I know, none of them have taken my advice. However, Amazon has an interest in not allowing its reviews sections to be used for obviously dishonest personal attacks, so they were quite justified in removing his.

The review that was deleted was the same one that was up on the amazon.uk site for a couple months before they decided to delete it. It's also still up on the amazon.ca site, where it's the only review, and may be responsible for the fact that the book seems to be selling much less well through that site. Lubos has made it clear that he is willing to stoop to just about any level of dishonesty to keep people from reading what I have to say about string theory. In the case of the UK review, he knew that only giving the book one star would make it likely that his review would be deleted, so he gave it two stars. In the case of the US review, he couldn't help himself and used just one star, which led to the quicker deletion there.

42. **Peter Woit**
August 27, 2006

Tony,

Right now there are a few places I'm tentatively scheduled to appear and talk about the book: Oct. 6 at the Cafe Scientifique in DC, Nov. 6 at the Princeton U-Store, Nov. 16 at the University of Minnesota, and some time in the winter at the NY Academy of Sciences (with Lee Smolin). When these are firmed up, I'll try and make up a web-page with more details.

43. **Peter Woit**
August 27, 2006

dan,

Not sure what you mean by a "wiki entry". There are already things on Wikipedia about me, about string theory, and about the criticisms of string theory, although I haven't looked at any of these recently.

No, I don't think Lubos's criticisms are substantive. When he first put them up on amazon.uk, I wrote something about them, see

http://www.math.columbia.edu/~woit/wordpress/?p=401

44. **Frank B**
August 27, 2006

A couple of specific comments on the book (UK ed):

1. On page 111 higher dim theories are traced back to Kaluza 1919. It is fairly well known that G Nordström (1881-1923) published a 5 dim unification of EM and gravitation (scalar version) already in 1914 (Phys Z). A brief summary in modern notation is given by F Ravndal (Scalar gravitation and extra dimensions, Proc. of the Gunnar Nordström Symposium on theoretical physics, eds., C Cronström & C Montonen, Helsinki, 2003: 151-164.)

2. On p 61 it is claimed that QED is a "complete theory". In what sense is it complete? If *complete*, should QED eg predict bound states for the H-atom?

3. On p 191 it is claimed that "if a theory is non-renormalizable it is inherently incapable of ever reliably calculating anything". Fermi-theory did make some successful predictions though non-ren. Indeed, within effective-field theory approaches it is known that renormalizability is not a necessairy requirement for extracting measurable quantities below some energy scale. One question is whether quantum-gravity as an effective field theory will ever bottom out in the form of a renormalizable theory — if not, there might still be a fully sensible (non-perturbative) theory.

A message of the book is that people should concentrate on symmetries and their representations, which sounds good, but it is a vague suggestion that hardly lures people away from ST or anything else. Anyway, NEW is a smooth read; 1st part informative, second part more about opinions than ideas.

Regards FB

45. **woit**
August 27, 2006

Frank,

Thanks for the comments.

1. Yes, I'm a bit weak on the history of extra dimensions, should have mentioned Nordstrom. In the book I do point out that my history was often incomplete, concentrating on explaining the origins of the names associated to ideas.

2. The sentence in question just says that QED was "complete" in 1929, by which all I meant was that the fields and Hamiltonian were known.

3. Yes, the discussion of renormalizability is an oversimplification. Various people have complained that I didn't explain the effective field theory point of view on non-renormalizable interactions. Maybe I should have, but the book already contains a lot of indigestible material for most people, this would have added a bunch more to try and write something accurate and that would be accessible to people who don't already know this story.

Explaining the details of what I have in mind about representation theory would really not be possible in this kind of book. And, the last thing I wanted to do was write something hyping some very speculative ideas.

46. **Dan**
August 27, 2006

Hello Peter,

There's a brief paragraph of criticisms of string in wiki, which talks about the landscape and lack of experimental prediction. There's a lot it doesn't mention such as SUSY-breaking.

I am curious as to whether you think Strings should continue to funded & research, at least at present levels if not more, should LHC discover evidence of SUSY particles or extradimensions or both. — obviously, should LHC fail to find such particles then the answer would be no. Also, there is research observation of dark matter, which could be an axion particle which is predicted by string theory. Axions, SUSY particles may be indications string theory is the right path?

47. **You**
August 27, 2006

"I'm in general very much in favor of promoting Lubos and his views, to the extent that I've suggested to several science journalists that they should do a story on him. As far as I know, none of them have taken my advice."

Here’s an old article on Lubos,
http://www.nytimes.com/2001/05/01/science/01ARCH.html?ex=1156824000&en=b187905670e458eb&ei=5070

48. **Thomas Larsson**
August 28, 2006

I am curious as to whether you think Strings should continue to funded & research, at least at present levels if not more, should LHC discover evidence of SUSY particles or extradimensions or both. — obviously, should LHC fail to find such particles then the answer would be no.

This is interesting. Do string theorists in general think that string theory funding should be reduced if no evidence of SUSY or extradimensions are found at the LHC?

49. **woit**
August 28, 2006

Dan,
Axions have nothing in particular to do with string theory, and observation of them wouldn’t necessarily tell us anything about string theory.

If the LHC finds new physics, whether it be supersymmetry, extra dimensions or whatever, lot of people will be jumping into whatever area it is, and there will be plenty of funding for this. String theorists will have to make the case that string theory has something to say about this new physics. Whether they can do this plausibly depends on what the LHC finds…

50. **Peter Orland**
August 28, 2006

Frank B asks,

On p 61 it is claimed that QED is a “complete theory”. In what sense is it complete? If *complete*, should QED eg predict bound states for the H-atom?

The answer is YES. Without a potential-energy approximation scheme, this is hard. Such a scheme exists, however, and works well (in relativistic physics, potential energies are a fiction). For example, the Lamb shift is predicted by QED. Bound state eigenvalues and eigenfunctions are
analytically calculable.

This is so despite the likelihood that QED is probably a free field
theory with no cut-off.

51. **Peter Orland**
August 28, 2006

P.S. I didn’t mean real QED is free. I only meant that a cut-off is
necessary at some high energy scale.

52. **Who**
August 28, 2006

Update: … now offering $20 to anyone who posts a one-star review of “the book with the black satanic cover”, and manages to get Amazon to leave it there for at least two weeks. … the “market-place of ideas”, I guess.

this book fits that description
http://www.amazon.com/gp/product/list/0375708111/ref=pd_ts_b_3/102-4540543-7840144?ie=UTF8&n=14560&s=books

53. **dan**
August 29, 2006

Would you object to string theory if it claims to be a branch of mathematics, rather than a branch of science? Would you object of string theorists re-name themselves string mathematicians?

Briane Green’s position is that since axions, SUSY, and extradimensions are fundamental predictions of string theory, that if they are discovered, continued research in strings would be justified.

Dan,
Axions have nothing in particular to do with string theory, and observation of them wouldn’t necessarily tell us anything about string theory.

If the LHC finds new physics, whether it be supersymmetry, extra dimensions or whatever, lot of people will be jumping into whatever area it is, and there will be plenty of funding for this. String theorists will have to make the case that string theory has something to say about this new physics. Whether they can do this plausibly depends on what the LHC finds…

54. **Peter Woit**
August 29, 2006

dan,

Yes, I would object if string theory claimed to be a branch of mathematics. Most of what string theorists do has little to do with research mathematics, i.e. creating new mathematics. The landscape is not mathematics, for instance. There certainly are parts of string theory that have led to new mathematics, and some of that kind of research is part of mathematics. There already are quite a few people who work on it in math departments.

55. **dan**
August 29, 2006

Do you think if experimental research were to come to have some precise values for string theory, such as the precise scale of SUSY-breaking, that knowing these hard facts could help string theory be more predictive?

Yes, I would object if string theory claimed to be a branch of mathematics. Most of what string theorists do has little to do with research mathematics, i.e. creating new mathematics. The landscape is not mathematics, for instance. There certainly are parts of string theory that have led to new mathematics, and some of that kind of research is part of mathematics. There already are quite a few people who work on it in math departments.

56. **Peter Woit**
August 29, 2006

dan,

String theory really says nothing about supersymmetry breaking, which is one of the main reasons it is not predictive. Knowing the scale of SUSY breaking wouldn't help. People often assume it is just high enough that superpartners will be seen at the LHC but not the Tevatron. This assumption in no way helps to get any predictions out of string theory.

57. **Who**
August 30, 2006

I noticed this morning that a well-known ranter had posted a derogatory ** review of The Trouble with Physics which was not taken down when I looked in some 4 hours later but by then TwP and NEW were #3 and #5 on the amazon Physics bestseller list
http://www.amazon.com/gp/bestsellers/books/14545/ref=pd_ts_b_ldr/102-4540543-7840144

and they were #2 and #4 on the amazon General Physics bestseller list
http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

(which has more wide audience books and fewer specialized textbooks and manuals)

this is the first time I have seen both books so high in the bestseller listing and it caused me to wonder if the heavy-breathing crank-telephone call style ** review saying how bad TwP is–could that have actually had an effect and helped trigger a burst of orders for the books? Most likely just a random fluctuation, but still it was strange to see sales climb sharply right after, in effect, receiving crackpot hate-mail.

58. **Frank B**
August 30, 2006

Peter Orland,

1. indeed, I understood's Woit's "a complete theory" as suggesting a notion of a complete theory (no *gaps*). But, how do you get the H-atom from QED as a perturbative theory whose content is given by the Feynman rules? To my knowledge no one has extracted non-trivial non-perturbative solutions from QED, but I may be wrong of course. My point would be that for QED we know how to successfully *cheat* (eg insert bound states), but for strange theories like ST we do not have good clues for cheating, more exacting math may in fact just lead further astray (when not guided by physical insight)..

Woit,

2. on p 266 it is said that QM "loses much of its mystery" when one works in the language of group theory. What *mystery* gets resolved this way? The main *mystery* commonly associated w/ QM is that of the measurement problem (*wave collapse*) — how is this defused talking groups?

3. On p 55 it is claimed that spin is "inherently a quantum mechanical notion". However, is not spin a feature of SU(2), and thus it does not depend on QM as such? One can also introduce (*uninterpreted*) spin variables in classical mechanics/field theory.. Indeed, the classical/quantum distinction is somewhat blurred from the formal point of view since Schrödinger QM can formally be described as a classical field theory (*canonical QM*). This sort of *blurring* is of interest, I think, when one tries to think about what quantum gravity might mean (is *quantization* well defined?).

Finally a comment on *ostracizing* ST from physcs and math — Is there a problem slotting it in mathematical physics then? To me it seems that much ST-related stuff de facto appears in math phys type journals.

Regards FB

59. **Peter Woit**
August 30, 2006

Frank B,

What I had in mind as a "mystery" of QM, was why observables are no longer c-numbers as in classical physics, but are given by self-adjoint operators acting on a Hilbert space. This is what you get when you have a unitary rep of a Lie algebra, and it is in this sense that representation theory explains something mysterious about QM.

Classically, angular momentum has to do with SO(3) symmetry, but is a continuous variable, and you don't see the difference between SO(3) and its double cover SU(2). Discrete spin quantum numbers are a purely quantum phenomenon, and there you do see the difference.

60. **D R Lunsford**
September 1, 2006

Peter, you may find this interesting:

http://www.physics.gatech.edu/people/faculty/finkelstein/Emptiness031215.pdf

This is very original thinking about the nature of QM and its relation to relativity.

-drl

61. **Peter Orland**
September 5, 2006

Frank B Says:
August 30th, 2006 at 4:41 pm

1. indeed, I understood's Woit's "a complete theory" as suggesting a notion of a complete theory (no *gaps*). But, how do you get the H-atom from QED as a perturbative theory whose content is given by the Feynman rules? To my knowledge no one has extracted non-trivial non-perturbative solutions from QED, but I may be wrong of course. My point would be that for QED we know how to successfully *cheat* (eg insert bound states), but for strange theories like ST we do not have good clues for cheating, more exacting math may in fact just lead further astray (when not guided by physical insight)..

Frank,

Feynman rules are not the entire story of field theory, and certainly not QED. Bound states in quantum field theory cannot be obtained systematically inm perturbation theory. In principle, they can be obtained by the Dyson-Schwinger equations (a set of exact integral equations for Green's functions). In practice, the DS equations are
often impossible to solve without some approximation. For QED, such an approximation exists, which is the Bethe-Salpeter equation, which reduces in turn to the Schroedinger bound-state equation.
For more a more complex theory, like QCD, there are proposals, which in my opinion are dead wrong (the approximation, not the DS equations).

So, once again, yes, QED in principle gives all the masses of bound states of atoms, positronium, etc. The caveat to all this is that there must be a cut-off somewhere in the ultraviolet, or the theory is trivial.

62. **Frank B**
September 6, 2006

I am not intending to press these points, but they are related to the bigger issues of what one means with *intrinsic quantum mechanical* and *complete theory*, so I add some further (not very deep ..) comments.

1. Since group representation theory is applied to so called classical mechanics (CM) too (representations on phase space via symplectic/canonical transformations) it is not clear how group representations as such (even involving spin) distinguish between CM and QM. Unitary transformations contain symplectic transformations, and in this respect QM is (formally) a special form of CM. The relation between state, observable and probability is in this view the distinguishing (interpretative) feature. One reason why this issue may be more than of formal interest is that quantum gravity may require a deeper characterization of what it means to be *quantum*.

2. I am aware that one can get approximations from QED that are interpreted e.g. as the Schrödinger equation for electron in the H-atom (relativistic case unsettled?), but there may be disputes about exactly what assumptions are made along the road (I know only the broad outlines). Another point is that in order to be *approximations* we should be able to give their error bounds, otherwise the approximations are based on faith. However, and this is the main point, in physics it is common to work with incomplete or even inconsistent theories (such as classical electrodynamics + charges) successfully when we have learned their domain of applicability. In this way physics differs from *pure mathematics* (which immediately reminds one of the Einstein quote: "As far as the laws of mathematics refer to reality, they are not certain; and as far as they are certain, they do not refer to reality"). Physics needs not just experiments, but genuine physical insight (such as the principle of equivalence) in order to evolve. To me the book by Woit has brougth up this issue (which is not restricted to string theory): Do mathematical *speculations* replace physical insight? Has the development of theoretical physics reached a stage where [in lack of new experiments/or because of a possible *desert* — of course, one should not forget the exciting findings in astronomy/cosmology, no desert there] the only remaining lead (whatever it is worth) is in mathematical constructs? On this history may teach us some lessons but it does not foretell.

63. **Who**
September 8, 2006

a propos the main topic—US publication of N.E.W.
the book continues to sell really well, judging from the amazon general physics bestseller list

As of today Friday 8 September at 1:20 PM pacific, its standing and those of several other wide-audience books for comparison were:

#1 TwP
#2 NEW
#7 Elegant Universe (Greene)
#8 Road to Reality (Penrose)
#13 Brief History of Time (Hawking)
#38 Warped Passages: Unraveling the Mysteries of the Universe's Hidden Dimensions (Randall)
#40 The Cosmic Landscape: String Theory and the Illusion of Intelligent Design (Susskind)
#88 Parallel Worlds: A Journey Through Creation, Higher Dimensions, and the Future of the Cosmos (Kaku)

the top two (TwP and NEW) were also #2 and #3 on the entire PHYSICS bestseller list, number one being a book about the effect of music on the brain.

The complete physics list contains books on specialized subjects as well as "general" physics books—so it has a wider range than the general physics list. General physics best sellers, besides the usual Greene and Hawking fare, tend to be first-year college textbooks.

so it looks like the US publication is going along successfully, the Woit and Smolin books may not be selling like hotcakes but they are selling like Freshman Physics textbooks. And in September, the start of the Fall semester, that can't be too bad.

A Castle For Mathematicians

August 24, 2006
Categories: Uncategorized

The American Institute of Mathematics was founded in 1994, with financing from John Fry, the Silicon Valley businessman responsible for Fry's Electronics. The Fry's store in Palo Alto is quite remarkable, containing everything a Silicon Valley geek might need, with a huge selection of potato chips and computer chips. In recent years, AIM has been running a wide variety of workshops, at a temporary location called the AIM Research Conference Center (ARCC), which is basically in back of the Palo Alto store.

Last month, the City Council of Morgan Hill approved plans for construction next to a golf course of a huge castle that will provide a permanent home for the ARCC (for a news story about this, see here). It will be modeled on the Alhambra in Spain, occupy 167,000 square feet, contain a "gourmet-industrial kitchen with master chefs from a San Francisco seafood restaurant and a Napa Valley resort", and much else besides. Fry himself is closely involved in the design of the castle, which is rumored to cost over $50 million, and planned to be ready for occupancy in 2009. More details about this are here, and there's even a video of what the castle will look like.

Comments

1. **David**
   August 24, 2006

   AIM is an interesting organization that sponsors quite interesting workshops, all of which (including those past) are described on their website (AIMath.org), many with references. Many of these workshops are of interest to some types of scientists as well as mathematicians. As an example, they just had one on Low Eigenvalues of Schroedinger and Laplace Operators.

2. **andy.s**
   August 25, 2006

   aaahh crud. I was hoping they would get the Winchester Mystery House.

3. **Stefan**
   August 25, 2006

   Great link, but I wonder what differentiates AIM from AMS?

4. **csrster**
   August 25, 2006

   Tasteful.

5. **anon**
   August 25, 2006

   Very nice video, except that the turrets are square shaped, whereas cylindrical designs are much better at resisting bombardment since impact impulses get arched over a much larger area in an attack on a cylinder than on a flat wall, which reduces damage.

6. **anonymous**
   August 25, 2006

   They should have based it on Uraniborg, Tycho Brahe's castle/research institute.

7. **anon**
   August 25, 2006

   (I meant of course that the turrets are 'rectilinear', not 'square'. Must always use correct terminology!)

8. **ObsessiveMathsFreak**
   August 25, 2006

   This certainly won't do much to improve the Ivory Tower sterotype of mathematicians.

9. **Dick Thompson**
   August 25, 2006

   Competition for the Institute for Advanced Studies? I hope is has lots of little cafe's tucked away in overlooked nooks. Since Fry seems to have a communal model of doing math versus the IAS lonely genius model, he might want to encourage what has worked before in that mode.

10. **Thomas Love**
    August 25, 2006

    The cafes are necessary since, as Erdos put it: "Mathematicians are machines for turning coffee into theorems". After deriving results in private, the lonely genius must communicate his/her results to the community. Besides, community is necessary to provide stimulation.

11. **A.J.**
    August 25, 2006

    The trouble with turning coffee into theorems is that it increases entropy: we can't turn unwanted theorems back into coffee.

12. **hack**
    August 25, 2006

    How much good mathematics has been accomplished while looking out over a golf course?

13. **Doug Natelson**
August 25, 2006

How much good mathematics has been accomplished while looking out over a golf course?

Well, since the grad college at Princeton overlooks a golf course, I'd guess there's a pretty good chance that much of John Nash's early work was done in that environment.

14. **Chris**
August 25, 2006

AJ said, "The trouble with turning coffee into theorems is that it increases entropy: we can't turn unwanted theorems back into coffee."

That is what comathematicians are for!

15. **TTT**

*****

All those movies about nutty genius mathematicians, and, way important, the TV show NUMB3RS. Mathematicians are hot!

17. **Jonathan Vos Post**
August 26, 2006

Numb3rs is a hit because of good writing, good directing, good acting, and their Math Advisor, Dr. Gary Lorden, Executive Director of Mathematics, in Caltech's Physics, Astronomy, and Mathematics division.
http://www.math.caltech.edu/people/lorden.html
He is a noted expert in Statistics; I took advanced probability from him; he's written letters of recommendation for me. The Chairman of Math is the great Barry Simon, I.B.M. Professor of Mathematics and Theoretical Physics. http://www.math.caltech.edu/people/simon.html
In all our wide-ranging discussions, String Theory has never come up. Although Caltech has major String Theorists (as I've posted before, including undergrad classes) it remains a small part of a much larger physics, astronomy, and math effort, and does not seem (to me) to affect the mainstream of research and teaching.

18. **Carl**
August 27, 2006

The most amazing thing about Fry's are the architecture and decor. The second most amazing thing is the range of electronics sold there. So are they going to sell Peter's new book?

I bought Not Even Wrong($21.56) and Smolin's new book($20.80) at Barnes and Noble. They didn't have them in stock, but could mail them to me when available. Since the order ($47.34) was over $25, the shipping was free. Years ago B&N started a card program that requires you to pay $25 per year to join. I have avoided shopping there ever since. They still have the program, but I held my nose and paid my money.

If Peter comes up here to Seattle on a book signing I'll get him to sign it. I am a bit ashamed to admit that I once got a professor of physics, Gregory Benford to sign a science fiction book of his that had been remaindered. But I was a cheap physics grad student at the university at the time.

And I started a blog. I had to do this in order to thank a grad student for publicly more or less endorsing my theory of the quarks and leptons. Not that I claim to understand her comments on M theory. Maybe after reading Peter's book I will.

19. **TheGraduate**
August 27, 2006

To Carl:

To be fair the Barnes and Noble, you don't have to get the card if you don't want it. But you get 10 percent off every purchase if you do.

Of course you would need to buy more than 250 dollars of books per year for this to be worth it.

20. **Pyracantha**
August 27, 2006

Rosebud….

21. **Carl**
August 27, 2006

Regarding Barnes & Noble's $25 per year, I buy maybe 300 books per year. I easily spent $1000 a year there; the card would be a bargain for me. But it seems to me that what they really did was to raise all their prices about 5% and issued the card in the hope of crowding out the competition. I think that that is monopolistic and I won't have any part in it.

Some people don't like the privacy issues, but I carry cards for all the local supermarkets in my otherwise thin wallet. There's plenty of room in there for a free B&N card. In the meantime, I find the selection of books at other bookstores quite satisfactory. If I were Peter, I would refuse to sign books at B&N stores.

The Trouble With Physics

August 28, 2006
Categories: Book Reviews, Not Even Wrong: The Book

I've just finished reading Lee Smolin's new book The Trouble With Physics, which should be released and available for sale very soon. It's a great book, covering some of the same ground as mine, but with significant differences.

This won't be a usual sort of review, since I'll mainly concentrate on discussing the parts of Smolin's book that I found most interesting, and my perspective here is kind of unique, having spent a lot of time writing about many of the same subjects that he covers. I will offer some capsule consumer advice: if you have any interest at all in what is going on these days in fundamental physics, you should buy and read both books. If you really are on a tight budget, and your main interest is in the relation of mathematics and physics, you should get mine. If your main interest is in quantum gravity or the foundations of quantum mechanics, you should get Smolin's. His is more appropriate for someone with little background in this area, mine contains some significantly more demanding material which requires some expertise to appreciate.

What most fascinated me about Smolin's book is the personal story behind it. He was a graduate student at Harvard during the same years that I was an undergraduate there, and describes well that place and time. The standard model had just been formulated a few years earlier, and experimental confirmation was pouring in. Many of the people responsible for the standard model were there at Harvard, and there was more than a bit of justifiable pride and arrogance. Smolin was of a philosophical bent, and initially put off:

The atmosphere was not philosophical; it was harsh and aggressive, dominated by people who were brash, cocky, confident, and in some cases insulting to people who disagreed with them.

He studied the philosophy of science and was very struck by Paul Feyerabend's *Against Method* (there are also has some amusing tales of later personal encounters with Feyerabend). Feyerabend's philosophy of science has been described as "anarchistic"; he sees no one "scientific method", but science as a very human activity, in which all sorts of different tactics are used to make progress towards better understanding. Smolin recognized that much as he would prefer a more deeply philosophical approach, it was the much more pragmatic tactics of people like Coleman, Glashow and Weinberg, who wouldn't be caught dead talking about the nature of space and time, or foundational problems of quantum mechanics, that was what was really having success.

Smolin begins his book by explaining what he (and I) see as the most important fact about the past thirty years of theoretical particle physics research. We're in a historically unprecedented situation, with virtually no progress being made on the fundamental problems of particle physics for a very long time, despite huge efforts. In his description, the field has "hit a wall"; I like to describe it as a victim of its own success. The standard model is just too good. It's too hard to find an experimental result that disagrees with it, and too hard to come up with theoretical advances that will address some of the things it leaves unexplained. Smolin sees the source of the problem in the field's insistence on sticking with a way of doing science which worked until 30 years ago, but now has become dysfunctional, with string theory only a symptom of the underlying problem. He writes:

I have mentored several talented young people through crises very similar to my own. But I cannot tell them what I told my younger self – that the dominant style was so dramatically successful that it must be respected and accomodated. Now I have to agree with my younger colleagues that the dominant style is not succeeding.

Elsewhere he writes:

My hypothesis is that what's wrong with string theory is the fact that it was developed using the elementary-particle-physics style of research, which is ill-suited to the discovery of new theoretical frameworks… This competitive, fashion-driven style worked when it was fueled by experimental discoveries but failed when there was nothing driving fashion but the views and tastes of a few prominent individuals.

Smolin was a student of Stanley Deser's, and during his graduate student years supergravity was a field that was just taking off. He describes getting to know Peter van Nieuwenhuizen and Martin Rocek and being offered a chance to get into the field at the ground floor, one he passed up because he couldn't believe that the kind of lengthy algebraic calculations they were doing could give real insight:

It was like being offered one of the first jobs at Microsoft or Google. Rocek, van Niewuwenhuizen, and many of those I met through them have made brilliant careers out of supersymmetry and supergravity. I'm sure that from their point of view, I acted like a fool and blew a brilliant opportunity.

Smolin didn't join the Stony Brook supergravity group, but found that he could make a place for himself in the physics community working on quantum gravity, but using particle physicist's methods:

… an easy opportunity opened up while I was a graduate student, which was to attack the problem of quantum gravity using recent methods developed to study the standard model. So I dould pretend to be a normal-science kind of physicist and train as a particle physicist. I then took what I learned and applied it to quantum gravity.

Smolin ended up with a post-doc at the new ITP in Santa Barbara, which luckily was running a program on quantum gravity that year. His career tactic almost didn't pay off:

One day, as we were waiting for the results of our applications, a friend came by to tell me that I was unlikely to get any jobs, because it was impossible to compare me with other people. If I wanted a career, I had to stop working on my own ideas and work on what other people were doing, because only then could they rank me against my peers.

The most powerful parts of the book are the chapters entitled *How Do You Fight Sociology?*, and *How Science Really Works*. They give a detailed and clear diagnosis of the problematic way string theory research is being conducted, and decisions are being made about who deserves a job. Smolin has an insider's point of view, particularly because he himself worked on string theory:

… during the years I worked on string theory, I cared very much what the leaders of the community thought of my work. Just like an adolescent, I wanted to be accepted by those who were the most influential in my little circle. If I didn't actually take their advice and devote my life to the theory, it's only because I have a stubborn streak that usually wins out in these situations. For me, this is not an issue of "us" versus "them," or a struggle between two communities for dominance. These are very personal problems which I have been contending with internally for as long as I have been a scientist.

So I sympathize strongly with the plight of string theorists, who want both to be good scientists and to have the approval of the powerful people in their field. I understand the difficulty of thinking clearly and independently when acceptance in your community requires belief in a complicated set of ideas that you don't know how to prove yourself. This is a trap it took me years to think my way out of.

Smolin gives many examples of the "groupthink" behavior of the string theory community, while characterizing string theorists as "almost all more open-minded and self-critical and less dogmatic than they are *en masse*." He describes string theorists as:

… supremely confident both of the truth of string theory and of their superiority over those unable or unwilling to do it. To many string theorists, especially the young ones with no memory of physics before their time, it is incomprehensible that a talented physicist, given the chance, would choose to be anything but a string theorist.

…Anyone who hangs out with string theorists encounters this kind of supreme confidence regularly. No matter what the problem under discussion, the one option that never

comes up (unless introduced by an outsider) is that the theory might simply be wrong. If the discussion veers to the fact that string theory predicts a landscape and hence makes no predictions, some string theorists will rhapsodize about changing the definition of science.

Some string theorists prefer to believe that string theory is too arcane to be understood by human beings, rather than consider the possibility that it might just be wrong.

Smolin finds in the string theory community a sense of entitlement and disdain for anyone who works on alternatives to the theory, with major string theory conferences never inviting people who work on alternatives to speak. An editor from Cambridge University Press told him that one string theorist said he would never consider publishing with the press because it had put out a book on LQG (I see why their publishing my book was out of the question…). At string theory conferences Smolin would be asked "what are you doing here?" or told "It's so nice to see you here! We've been worried about you." Some friends explained to him that if he wanted to be considered part of the string theory community he had to work not just on string theory, but on the particular string theory problems that were fashionable at the moment.

One problem for physicists trying to get tenured positions that Smolin mentions is that most universities now require letters from 10-15 people evaluating their work, with a small number of negative evaluations sufficient to sink their chances. If you're working on something other than a mainstream topic, finding 10-15 people who can comment knowledgeably on your work can be impossible. He describes string theorists as mostly submitting the same two or three research proposals. This narrow concentration on a small number of problems is defended by some senior theorists as a "disciplined" approach, one that will more surely lead to progress than encouraging people to pursue a variety of different research directions.

Very recently, Smolin sees things changing:

Until last year I had hardly ever encountered an expression of doubt from a string theorist. Now I sometimes hear from young people that there is a "crisis" in string theory. "We have lost our leaders," some of them will say. "Before this, it was always clear what the hot direction was, what people should be working on. Now there's no real guidance," or (to each other, nervously) "Is it true that Witten is no longer doing string theory?"

One can quantify this new situation by noting that there have been virtually no heavily cited new papers during the past few years, except perhaps for the KKLT one that is part of the landscape story.

Smolin notes that many string theorists (including himself) have often been ill-informed about the exact state of knowledge concerning crucial conjectures about string theory. One example he discusses in detail is that of the finiteness of multi-loop string amplitudes. The state of the subject is that one knows how to precisely formulate them and can show lack of divergences only up to two loops (this is due to the work of d'Hoker and Phong). At higher genus d'Hoker and Phong have a conjectural definition, but have not yet been able to show that divergences cancel. Few string theorists seem to be aware of this, and some of them react with great hostility and shower with insults anyone who mentions this issue (as I've done here on this blog).

There's much else of interest in Smolin's book, including a lot of material about what he sees as promising ideas in quantum gravity, discussion of research on the foundations of quantum mechanics, and a chapter on "seers", people doing original work on foundations. These include 't Hooft, Penrose, and many others less well-known.

While I agree with just about all of what Smolin has to say about string theory, my own background is different and I see promise in very different lines of research than he does. I'm much more skeptical than him about our ability to get useful experimental data on quantum gravity, and see questions about quantum mechanics rather differently. My prejudice is that, lacking experimental guidance, the thing to do is to try and better understand the mathematical structures underlying the standard model. In the past, better physical models have gone hand in hand with deeper mathematics, and I'll bet this will continue to be true in the future. Quantum mechanics has deep connections to representation theory, a part of mathematics that unifies many different subfields. It seems likely to me that a better understanding of quantum mechanics will come from better understanding representation theory and its connections to physics.

There's a lot of other sorts of material in the book that I haven't discussed, and I strongly recommend that people read the whole thing. It's very, very good, and anyone interested enough to follow this blog will find it highly rewarding.

Comments

1. **Aaron Bergman**
   August 28, 2006

   Well, if I had a free copy….

   Anyways, regarding

   Anyone who hangs out with string theorists encounters this kind of supreme confidence regularly. No matter what the problem under discussion, the one option that never comes up (unless introduced by an outsider) is that the theory might simply be wrong.

   I can't say I know every young person in the field, but I've talked to a fair fraction, and I have to say that with a few notable exceptions, I don't see that sort of dogmaticism anywhere. Saying that string theory might be wrong isn't a particularly interesting observation, so I can see why it doesn't come up, but I've rarely met someone who doesn't think that string theory could be the wrong theory of quantum gravity.

2. **Jimbo**
   August 28, 2006

   Peter paraphrases Smolin as saying, "being offered a chance to get into the field(SUGRA) at the ground floor, one he passed up because he couldn't believe that the kind of lengthy algebraic calculations they were doing could give real insight"…

   Einstein would agree whole-heartedly with Smolin's reluctance, and this goes to the heart of the problem in theoretical physics in my opinion. In the absence of experimental evidence for SUSY and/or a driving paradigm, string theorists have chosen to hack their way thru the jungle with a `mathematics machete', obscuring any hope of real physical insight, and venturing off into the surreal world of mathematical physics, which with few exceptions, has seldom yielded any deeper insight into nature's secrets.
   Now, we are paying dearly for this obsession with math, with no end in sight. Only the LHC can level the playing field, as the recent astro-observations of Dark Matter did with the alt.theories of DM, MOND & TeVeS, which are now history.

3. **Stefan**
   August 28, 2006

   "My prejudice is that, lacking experimental guidance, the thing to do is to try and better understand the mathematical structures underlying the standard model."

   I agree with you 100%!! So, may you kindly do the undergrads a favour and tell us what those specific topics are.

   Stefan

4. **Kea**
August 28, 2006

Well, I must say that this is very entertaining.

5. **nigel**
August 28, 2006

Stefan, see http://www.math.columbia.edu/~woit/repthy.html for general background course on relevant maths and see http://arxiv.org/abs/hep-th/0206135 for some specific physical ideas explaining the Standard Model tentatively using such ideas. At top of page 51, the Standard Model particles are obtained with electroweak symmetry properties. This should be impressive if you are interested in the links between Standard Model and advanced mathematics without resorting to extra dimensions.

The taste in ideas for extreme abstraction in particle physics is set by symmetry principles more recently, and laws of nature further in the past. This is not the same approach that you use if you are dealing with relatively simple phenomena where you might try to guess a full mechanism and write down the relevant basic equations straight off, and then solve those equations.

If you take nuclear physics, where you have the shell model and the liquid drop model of the nucleus, you can use visual analogies to help formulate a model that makes checkable predictions, which are semi-classical. But with particle physics, it looks more promising to search for symmetry principles and other abstract laws than to guess a sem-classical model.

I mean, suppose you were crazy and guessed that the particle is like a piece of string, and then you found that to get it to work just as an ad hoc model you needed to make make it extra dimensional string, and then you still failed to predict anything with it for 20 years? How embarrassing!

6. **wkrn**
August 28, 2006

From your semi-review I do not understand what is the main point of the book (I do not have it).
In my opinion The Trouble with Quantum Gravity is that it is disconnected from experiments: sociological difficulties are not the problem, but a consequence of it.

The Trouble with High Energy Physics is different: experiments have not told us what we hoped, and we are waiting for the verdict from LHC. So, better to discuss after LHC.

7. **TheGraduate**
August 28, 2006

Peter:

How likely do you think it is that the LHC might actually contradict string theory and end its dominance?

8. **TheGraduate**
August 28, 2006

Peter:

I had one more question. What kind of impact has string theory had on modern mathematics? I have lately been becoming more and more impressed with the number of branches of mathematics that have been impacted by string theory.

9. **Fabien Besnard**
August 28, 2006

Thanks for this review, this all seems very interesting.

A sidenote : Feyerabend emphasized on the sociological aspect of science, but more : he saw scientific truth as a sociological phenomenon. In this respect the situation in today's physics clearly disproves Feyerabend's views since string theory is by no way acknowledged as a scientific truth, despite the sociological dominance of string theorists.

A question : does anyone know about another historical example of the "groupthink" Smolin describes ? I can think of the "N-rays" affair but it did not went that far, no lasted for so long.

10. **D R Lunsford**
August 28, 2006

Thanks for that Peter, I look forward to this book. I get impatient with Smolin because he's such a nice guy, and it seems to me what physics needs is some "tough love" and a few bitch slaps now and then – but it's obvious he is a sincere researcher and representative of all that's good in science.

For contrast, one should poke over to Motl's blog and read the page upon page of incoherent, basless ranting there. It's mind boggling.

-drl

11. **D R Lunsford**
August 28, 2006

RE the effects of sociology in physics, check this out:

http://www.theaustralian.news.com.au/story/0,20867,20192903-2703,00.html

I've long understood that the problem is not just string theory.

-drl

12. **Peter Woit**
August 28, 2006

Graduate,

The LHC can't contradict string theory, since string theory predicts nothing about what it will see. If the LHC sees something new and exciting, most theorists will be trying to figure that out, paying less attention to string theory.

The question of the impact on math of string theory is complicated. I did write something about this in my book, although that only scratched the surface. One complication is that much of the most important math that has come out of string theory research is really results from 2d QFT calculations.

13. **Stefan**
August 28, 2006

Nigel,

Thanks for the links. I'm having a look through the Rep Thry paper; seems quite interesting. Do you know of any (introductory) texts you think are worth studying to get up to speed in this area?

Peter,

If you recall our discussions some time before, i.e. on gauge fields and Dirac operators, I have been combing through Amazon.com for relevant introductory texts. The best ones I could find were:

"An Introduction to Dirac Operators on Manifolds" — Jan Cnops

and

"Operator Methods in Quantum Mechanics" — Martin Schechter

If you have any added suggestions please let me know.

Among the ideas you place forward, studying "geometric quantization" holds, atleast from my neophyte vantage point, (potentially) fundamental insights into QM and QFT, and may even (with the passage of time and careful consideration) displace string theory as the most important approach to fundamental physics research… I do think IT'S THAT IMPORTANT!
I also wonder if von Neumann's QM work would be helpful to study here? Do you also feel Jouko Mickelsson's work is important enough for the afore-mentioned programme to warrant careful study? [No offence intended to the author, but the book's cost is WAY too high for your average student to afford… unless it's worth all my three months' summer savings. ;-)]

Thanks.

Stefan

14. **Michael Bacon**
August 28, 2006

Here is a link to an NPR "debate" between Smolin and Greene:

http://www.npr.org/templates/story/story.php?storyId=5670911

Smolin's new book was the "trigger" for this piece.

15. **TheGraduate**
August 28, 2006

Peter,

I will definitely be looking for your book in the book store and I will investigate what you have to say about the connection between mathematics and string theory in more detail.

I have been becoming more and more surprised at what little evidence there is for the validity of string theory.

Are they really basing all this on mathematical and historical coincidences?

It sounds a bit limp to say that a line of reasoning is good because a particular model has nice properties you had not expected it to have. Is this really the extent of their reasoning?

16. **Thomas Larsson**
August 28, 2006

Stefan, if you want to have an idea what's in Jouko's book, have a look at his papers from anno dazumal, e.g. this, this, this, this, and this.

However, note that there might be some problems, see e.g. this and this.

17. **Thomas Larsson**
August 28, 2006

Sorry, missed a double quote. The links should be
this,
this,
this,
this,
this,
this, and
this.

18. **SFB**

August 28, 2006

We should be calling it STRINGTHEOLOGY.

19. **tg**
August 28, 2006

I'd like to thank Michael Bacon for the link to the Smolin-Greene interview. Having listened to the interview now, I'd like to post my thoughts on it as a layman to the subject whose academic life has only been tangentially touched by string theory. I, like many other mathematicians (I presume) have no vested interest in whether strings are bogus or not — I'd just like to know some arguments in both directions, just for my general scientific edification.

Frankly, Michael Greene was far more polished (understandably, he's had practice) and presented a more compelling point of view on general grounds. Smolin, in my opinion, was at times longwinded in his presentation, which hurt his debate.

Smolin has a difficult task to begin with. People, and scientists aren't really interested in unclear claims about what doesn't work, or "negative campaigning". Smolin stresses the lack of experiments. Greene says things take time. (What's wrong with that?) Moreover Greene asserts the mathematical consistency of things, which not knowing the specifics, sounds like reasonable evidence. These are things, Greene says, keep people inspired.

Smolin asserts that string people are holding back non-string people. He seems embarassed to make this claim directly, but rather hints at it in various ways. Greene counters that his _own_ graduate students sometimes work on non-string physics. Personally, I don't find it surprising that one field in a subject looks down at other fields, or consumes resources. It's annoying to be on the wrong side of the tracks, I know, but a priori, I have to admit this doesn't mean to me that the ideas in the field per se are faulty.

So I summarize that string theory is an with high degree of mathematical consistency but which clearly needs experimentation. Its difficult math and difficult physics, so therefore time is necessary to come to an appropriate conclusion.

Is there something I'm missing? I'd be glad to be better informed on this debate…

20. **Peter Woit**
August 28, 2006

TheGraduate and tg,

Both my books and Smolin's contain very detailed answers to your questions, I don't want to try and rewrite a lot of this here. As for the Smolin-Greene radio show, it's really not possible to sensibly debate these issues in a few minute long radio program for the general public. About all you can get off in that time are quick sound bites which will be highly misleading in one way or another. The quick answer to tg's summary is that:

1. string theory does not have a high degree of mathematical consistency, actually no one knows exactly what the theory is.

2. the problem with string theory is not that it needs experimentation. The problem is that it can't predict anything, at any energy, including being unable to retrodict things being studied in current particle physics experiments.

3. the theory is more than 30 years old, has been intensively studied for 22 years, with the result that it now looks a lot less likely you can get physics out of it than people thought 22 years ago. The problem is not that progress is slow, it is that progress is negative.

21. **Peter Woit**
August 28, 2006

Stefan,

I don't know the books you mention. One nice short introductory text on representation theory is Graeme Segal's lectures in Carter, Segal, McDonald, Lectures on Lie groups and Lie algebras.
Unfortunately I don't know a really good introduction to geometric quantization, in its relation to representation theory. There is a recent book by Kirillov, called "Lectures on the orbit method", which may be the closest thing.

22. **JPL**
August 28, 2006

Hi Aaron:

Saying that string theory might be wrong isn't a particularly interesting observation, so I can see why it doesn't come up, but I've rarely met someone who doesn't think that string theory could be the wrong theory of quantum gravity.

This observation of yours, however, sounds particularly interesting! If it never comes up how can you be so sure that you never met anyone who thinks it is an impossibility, I mean, that String Theory could simply be wrong? Telepathy? Groupthink? Pray let us know…

23. **Doug**
August 28, 2006

The title of the book refers to what's wrong with physics. The failure to recognize string theory's shortcomings, because of its dominance, no matter how disturbing to skeptics, and no matter how unfair to competitors, is only a small part of the story of what's wrong with physics.

On the Science Friday show, Smolin was just getting into the real problem, when Flato cut him off to take a call from a lady suggesting that what is needed is "thinking out of the box," but before that he was addressing Green's statement about the consistent calculations.

As Green explained how that extensive testing the consistency in the calculations of string theory, and its consistency with the established concepts of past physics, shows that the "theory comes through with flying colors every step of the way and keeps us thinking that things are at least headed in the right direction," Flato turned to Smolin and asked, "Well, Lee, what would be wrong with that, if things are working like that?"

Smolin said:

> If you really put quantum mechanics together with the description of space, then we know, from general considerations, that the notion of space should disappear. Just like the notion of the trajectory of a particle disappears in quantum mechanics, …the same thing should happen to space and the geometry of space.

I’m sure he was referring to background independence here, but he didn’t get to explain it very well, just that string theory doesn’t address this very directly, while other approaches do.

My question is, Peter, does he explains this well in the book, and does your work address this problem?

24. **Peter Woit**
August 28, 2006

Doug,

There’s a lot in Smolin’s book about the issue of background independence, not much in mine. In general I’m mostly writing about particle physics, Smolin is much more concerned with quantum gravity, and he certainly writes well and clearly. I don’t have any particular wisdom on this subject myself.

And please, if you want to discuss your favorite ideas about quantum gravity, don’t do it here.

25. **TheGraduate**
August 28, 2006

Peter,

I understand your reluctance to summarize complex arguments that you’ve already put years into expressing better elsewhere and I do promise that I will read your account in full when I get the opportunity.

At the moment though, I am a bit curious about whether the pro-string theory argument can summarized into the phrase: “The mathematical coincidences are too surprising to be chance.”

Could you say whether this is very, very roughly the crux of the pro-string theory argument?

26. **woit**
August 28, 2006

TheGraduate,

The pro-string theory argument for unification is mainly that the theory provides a quantum theory of gravity.

The argument about mathematical coincidences is more that an argument that calculations show that things are happening in string theory for reasons that are not understood. This is just an argument that there is something going on in string theory that is not yet understood. That’s an argument for further research into the theory, but not an argument that it is going to give you a useful unified theory.

27. **dan**
August 28, 2006

““Is it true that Witten is no longer doing string theory?”

well is it true?

have you or lee read lubos top 12 results from string theory?
http://motls.blogspot.com/2006/06/top-twelve-results-of-string-theory.html

28. **anonymous**
August 28, 2006

TheGraduate,

some mathemacians indeed say that string theory is an activity which produced some very beatiful and important mathematical ideas, which justifies this activity. Whether you want to call that activity ‘physics’ is another matter…

29. **Aaron Bergman**
August 28, 2006

This observation of yours, however, sounds particularly interesting! If it never comes up how can you be so sure that you never met anyone who thinks it is an impossibility, I mean, that String Theory could simply be wrong? Telepathy? Groupthink? Pray let us know…

Conversations in social situations rather than in researchy situations.

30. **JC**
August 28, 2006

I wouldn’t be surprised to see another “string theory” style sociological phenomena popping up decades later in particle physics, if string theory falls by the wayside in the near future. Seems like these sorts of things happen frequently enough every few generations or so.

31. **TheGraduate**
August 28, 2006

Peter,

Ah okay I think I see now. And I think I’ve read elsewhere that you definitely don’t agree that it provides a quantum theory of gravity.

Anonymous,

I guess I figure they are saying they have a degree in physics and they get paid by physics departments and therefore they are doing physics … probably a good enough argument 99% of the time

32. **David**
August 28, 2006

Stefan,
I really liked Schechter's book. You may be interested in some more recent work that follow's Schechter's. All of this can be downloaded from the following websites:
Barry Simon, Math Dept, Caltech
Gerald Teschl, Math Faculty, U of Vienna (both research articles and Lecture Notes [actually book preprints]),
Susanne Teschl, U. of Applied Sciences,Technikum Wien (thesis).
You can find all of these by using Google with the person's name.
Best,
David

33. **Egbert**
August 28, 2006

My copy of NEW just arrived today. At the back it says the URL of your blog is
http://www.math.columbia.edu/~woit/worelpress

Apart from that it looks good.

About the supreme confidence of string theorists – from the experience that I've had, it seems that there really are some amazing things that string theory has done. Counting rational curves is a good example; AdS/CFT and the dualities are impressive too, and it sure looks like it has something to do with quantum gravity, getting the entropy A/4 right for at least some black holes, and having Einstein's equation in it and so on. These things are, quite frankly, too amazing to be just a coincidence.

The problem is that these things have been interpreted as evidence that string theory is the one true theory of the universe, but in fact it is evidence that there is some underlying self-consistent mathematical structure, which may or may not be a theory about physics. All of the signs seem to point towards the conclusion that it is not a theory about physics, but is rather a mathematical structure which relates 2d CFT to various gauge theories in various manifolds.

Still, though, the string theorists, like Ed Witten, like to oversimplify and say that they think string theory has produced too many fascinating insights to be "wrong".

34. **ark**
August 28, 2006

To Dan and Anonymous
I am one of those whose work was selected into top 12 results in string theory (e.g. read #6 in this list) mentioned by Dan and, indeed, I have to say that, for instance, work by Grisha Perelman would never be completed (most likely) should he in his 3 Fields medal winning papers not use some basic string-theoretic results obtained in 80ties. This fact alone is sufficient for justification of string theory existence. But, surely, I can mention many other things, e.g. read my hep-th/0608117 and references therein. Clearly, sooner or later the dust will precipitate and there will be a lots of good bits and pieces of work for grabs by everybody who likes to work more than to talk.

35. **D R Lunsford**
August 28, 2006

Peter, why did you delete my comments?

-drl

36. **woit**
August 28, 2006

drl,

Because they had nothing to do with the posting, which is a review of Lee's book. I'm tired of explaining this to people, but this is not sci.physics, it's not a place for people to discuss their favorite ideas about physics. I don't have the time, energy or interest to moderate something like that.

I'm pretty annoyed about this comment section today anyway, I've been spending a huge amount of time deleting comments from idiots who want to denounce Yau or Tian, using endlessly changing pseudonyms. I really, really don't have time for this these days.

Egbert,
I noticed that typo and told the publisher about it. I've also set up my web-site so it responds properly to the incorrect URL.

37. **D R Lunsford**
August 29, 2006

Peter, I agree with you about that, but my comments were to the point and on topic, or so I thought. Relax, you are on target and have nothing to fear.

-drl

38. **hongbao zhang**
August 29, 2006

Peter,
Have you a free electronic copy of it? If you have, could you send it to me? We want to translate this great and intriguing book into Chinese so that more young guys in China could read it.:)

Thanks in advance.:)

My email: hongbaozhang969@hotmail.com

39. **MathPhys**
August 29, 2006

tg,

Do you know what the problem with string theory is? It's Edward Witten. If you think Michael Green is polished, you should listen to Witten.

When Witten speaks, he's extremely convincing. It's very difficult to refute an argument that he makes. It's very difficult to resist following in his footsteps.

Is that a good thing or a bad thing? Should non string theorists argue that having Witten on string theory's side gives the latter an unfair advantage? I think they should.

40. **Thomas Larsson**
August 29, 2006

Stefan and Peter,
When Stefan referred to Jouko Mickelsson's work and a way to expensive book, I assumed that he meant Current algebras and groups, which AFAIK is the only book he has written. Since I have read (although perhaps not understood) both the book and the papers I linked to, I can claim that there is considerable overlap.

41. **nitin**
August 29, 2006

Hello Peter

Your short review sure got me very interested in Smolin's latest book! I have ordered both his and yours, and I am eagerly waiting to read them. hehe.. It's very likely that I will be among a very few from my country, Mauritius, to read them (maybe Sanjaye Ramgoolam, a "string theorist" countrymate, at Queen Mary, will read one or both of them). Last time I tried convincing a friend about Physics, I ended up giving him Penrose's "A Road to Reality" as birthday present!

Cheers.

42. **tg**
August 29, 2006

Dear MathPhys,

"If you think Michael Green is polished, you should listen to Witten."

In fact, I have heard him speak (live) — but I can hardly compare. One was a technical talk to a group of mathematical string theory people, and the other was a popular talk.

43. **Peter Woit**
August 29, 2006

hongbao zhang,

Sorry, but I don't even have an electronic form of the book, and couldn't distribute it for free if I did. Anyone interested in acquiring the rights to publish a translation in another language needs to contact the people at Jonathan Cape, my deal with them was that they hold world-wide rights to publish the book.

Mathphys + tg,

The Science Friday show involved Brian Greene, not Michael Green. Brian is a lot better at this than Michael, I would think.

44. **Michael Bacon**
August 29, 2006

My take was that Smolin did well given the format. In any event, it was refreshing to listen to them discuss the issues in a civil way. Lubos would do well to draw the appropriate lessons.

45. **Gina**
August 30, 2006

Peter, is it possible to state the main (say, 10-15) points for the "case against string theory" with 4-5 sentences on each?

This will be very helpful. Please consider doing it.

It will be useful to

a) separate the stricktly scientific points from more sociological and philosophical points

b) to separate points that say that (*)"string theory is not (yet) successful" from those saying that (**) "this and that aspects of the theory are fishy" from those saying that (***) "string theory is not the right direction for dealing with "final theory/grand unification", from those saying that (***) "the whole endeavor of final theory/grand unification is misguided".

c) To hint if physics requires more back-tracking or it is just string theory that is problematic.

Thanks!

46. **a**
August 30, 2006

dear Gina, I think that the main scientific problem is: since we cannot directly probe quantum gravity, a useful theory of quantum gravity must predict something at the lower energies where we can do experiments. Strings allow something like 10^500 different possibilities: this seems practically equivalent to allowing everything and predicting nothing.

47. **nigel**
August 30, 2006

Stefan,

I hope Peter will produce an introductory textbook on Representation Theory and Particle Physics.

Gina,

Your idea would I fear produce a list of string theory claims with the same boring label 'uncheckable speculation' beside each.

‘Extraordinary claims require extraordinary evidence.’ – Carl Sagan.

You can see plenty of extraordinary claims in string theory (it solves almost all the big problems of unification, quantum gravity, the nature of particles, black holes). You don’t see any stringy evidence, let alone extraordinary evidence, and nobody expects to find much.

The string theory failure has some weak precedents in science: check the detailed history in peer-reviewed physics journals on the “Vortex Atom” and “Aether” (both the subjects of intricate mathematical speculation and wild claims of ad hoc success from mathematical physicists including Kelvin and Maxwell, who both died firmly believing flawed theories).

However, string theory is more dangerous. At least Kelvin and Maxwell’s ideas could later be checked by experiment. String theory deliberately speculates about practically uncheckable phenomena (Planck scale unification, etc) so remaining safe from experimental refutation, so becoming a religion:

‘Whatever ceases to ascend, fails to preserve itself and enters upon its inevitable path of decay. It decays … by reason of the failure of the new forms to fertilise the perceptive achievements which constitute its past history.’ – Alfred North Whitehead, F.R.S., Sc.D., Religion in the Making, Cambridge University Press, 1927, p. 144.

48. **RA**
August 30, 2006

“We’re in a historically unprecedented situation, with virtually no progress being made on the fundamental problems of particle physics for a very long time, despite huge efforts.”

That’s a convenient and shaky rewriting of history upon which to build your foundation.

‘Extraordinary claims require extraordinary evidence.’ – Carl Sagan.

That goes both ways.

49. **Peter Woit**
August 30, 2006

Gina,

At this point, I’m way too busy, and writing another explanation of what the problems are with string theory isn’t at all something I want to spend time on. The article I wrote back in 2001 is still a good short version of the argument, all it is missing is a discussion of how things have gotten much, much worse for string theory since then, because of the landscape.

The issues involved here are pretty complicated, and I don’t think short sound-bites, or me countering people’s “10 quick reasons why string theory is great” with “10 quick reasons why string theory doesn’t work” is going to be very enlightening. Partisans of one point of view or the other aren’t going to be convinced by this, and people who want to seriously understand the issues and make up their own minds should read both the pro-string theory point of view put forward in several books, and the other side of the story, as explained in my book and in Lee’s. I do believe that the problem is not just string theory, but more generally the idea of supersymmetric grand unification, these issues are discussed extensively in the book.

50. **Peter Woit**
August 30, 2006

Lubos,
While, unlike you, I’m not banning those who disagree with me from posting comments here, I’m not going to tolerate and will continue to delete any comments like your last one that attack people other than me.

51. **Gina**
August 30, 2006

Thanks for considering my suggestion and the comments, Peter
(and thanks nigel and a for the 2 items.)

Certainly my suggestion was not meant to replace reading your book or Smolin’s but it could be helpful for me to understand what is the essentials, e.g. while reading these books or the elegant books on the other side.

Your review on Smolin’s book (which is of the same size as what I would like to read) is very personal/philosophical almost like a gathering of two veterans on the same side of a battle but not so useful to understand the essentials.

Is the critique of string theory is similar to the critique on biologist for not understanding/finding cure for cancer? or is it stronger.
Is the idea that string rather than point particle can, in principle,
lead to a “grand theory” a-priori senseless, or just not yet successful, or reasonable-to-start-with but by now clearly a failure?
10^500 looks fishy but is 10^500 possibilities really that bad?

I think the main reason for me to be suspicious with “string bashing” is that it did not lead (yet) to interesting science: namely
to scientific papers (not popular reviews and books). Why is that?

52. **Lubos Motl**
August 30, 2006

Dear Peter,

you completely missed my point. My point was not to attack other people than you. It was, on the contrary, meant to prove that you are the #1 moron on this crackpots’ discussion forum. 😉

Best
Lubos

53. **Peter Woit**
August 30, 2006

Gina,

Again, for the short version, I recommend reading my 2001 article. Yes, 10^500 possibilities really is that bad. All indications are that it makes it completely impossible to ever extract a real prediction from the theory, which is deadly.

The situation of string theory is very different than that of cancer research, an analog would be if current cancer treatments not only didn't help at all with the disease, but made it much worse.

"string-bashing" by itself doesn't lead to interesting new science, except in the sense that encouraging people to stop working on a failed idea and look for something else to do may have a positive effect. Lee is one of the leaders of a very active research program that is working on new and different ideas, and he has published a long list of scientific articles on this. I have my own ideas about alternatives to string theory, have written much less about this. For some of what I have written see my long 2002 paper on the arXiv.

54. **Peter Woit**
August 30, 2006

Lubos,

Actually I did get that that was the point of your comment. But, sorry, if you want to write comments here about what a moron I am, you have to avoid at the same time attacking other people as morons, since I'm not going to allow that.

55. **Tom Killick**
August 30, 2006

I am not a physicist. I am an engineer. It has always seemed to me that postulating un-testable hypotheses is more the domain of religion or philosophy than of Physics. I would like to draw you attention to work being done by Charles Francis that is evolutionary, exciting and that does belong in the realm of Physics. This work claims to have bearing on dark matter, the age of the universe and more. It is also eminently testable and appears to explain currently anomalous data and makes specific predictions about future data.
I am intrigued by work being done by Charles Francis for much the same reason as you concentrate in your review of Smolin's book on the areas that most interest you, the personal story. I went to high school (in fact a very prestigious private catholic boarding school) with Charles Francis the late sixties and early seventies. I can unequivocally say that he was the most brilliant mathematician and logical thinker I have ever met. At sixteen he could produce elegant, concise and original proofs that allowed me, other classmates and his teachers to begin to understand the power and beauty of mathematical physics. I know he went on to Cambridge and Birkbeck college in London to finish a number of degrees. He is a very eccentric individual which has allowed him to focus on solving what he calls "the really important problems" for the last 40 years. His eccentricity has also isolated him from much of what I assume to be the hubris of modern physics.
His paper which in his characteristically un-self effacing way is titled

"Does a Teleconnection between Quantum States account for Missing Mass, Galaxy Ageing, Lensing Anomalies, Supernova Redshift, MOND, and Pioneer Blueshift?"

56. **Gina**
August 30, 2006

Here is my a priori take on this before reading any of these books.
———————————————————————

1. The question of quantum gravity and this grand unification is a
major intellectual/scientific challenge.

2. String theory offers understanding for this problem as well as deep and interesting insights on various issues from physics. Motl list of 12 appears to be very impressive. (And apropos Motl, I even conjecture, perhaps contrary to this example, that most string theorists are neither bullies nor male Chauvinist.) Not many other scientific theories can match such a list. String theory is the only major theory that offers such understanding for the unification problem. It also led to great mathematics.

(Well, there is some amount of over-sale, and discussions with serious faces of all this multiple universes stuff but this is not that unusual.)

3. There are serious problems with string theory concerning the possibility to draw concrete predictions that can be verified. There are also many possible string theories. (I do not share the interpretation that these limitations of the theory are fatal. And maybe we cannot hope for more.)

4. String theory is still rather tentative. It is quite possible that the
theory will fade away because of its difficulties and it is also possible that it will be replaced by a different theory which does a better job. It is possible it will prevail.

———————————————

As for the discussion, I cannot see, nigel, how string theory can be "dangerous" and I cannot see, Peter, how things can between 2001 and 2006 have gotten "much much worse" (but I can see you being much much more excited.) And "dying (like Maxwell) with a firm belief in a flawed theory", nigel, can serve as a nerd's curse
but it is not significantly more terrible than just dying. (Unless the death is caused by the theory.)

57. **Lubos Motl**
August 30, 2006

Virtually all of string theorists are nice people who never argue with anyone else, they're not chauvinists, and most of them are feminists. Most of them also think that string/M-theory are robust twin towers that are not threatened by any social effect or passionate proponents of alternative theories or proponents of no theories, and they almost always try to avoid interactions that could lead to tension which also gives them more time for serious work. Almost no string theorists drive SUV and they produce a minimum amount of carbon dioxide.

58. **Peter Woit**
August 30, 2006

Gina,

Discovering that your theory has 10^500 times more solutions to it than you thought it did really does count as "much worse". Virtually every string theorist will admit that the "landscape" is a huge problem for the theory. Things really are much worse now than they were 5 years ago.

59. **anonymous**
August 30, 2006

Hi,

I came across this weblog after Amazon automatically recommended me Peter Woit's new book. I went through it and I was amazed to see the extend that some disagreements can take and the way that people, affiliated with high profile institutions, behave when they should be models for the rest of the community and their students. Congratulations!

Personally, I find the situation rather interesting and I really hope something good will come out of this, whether it is in favour of string theory or not. I would like to make a comment, however, on the situation the way I see it. Please keep in mind that I am not a string theorist and I wouldn't even call myself a physicist in general. Nevertheless, here it is.

Let's see how long it takes for someone to get a PhD. Usually it is 4 years as an undergraduate and 5 years as a postgraduate. Most of the young people interested in string theory feel that they should start studying the subject while undergraduates. I guess that is why MIT introduces string theory classes and Zwiebach publishes books on "undergraduate" string theory. It has to do with demand, the customers have to be satisfied somehow. Blame it to the hype. In the graduate school you are forced to publish something, as if the rest of the thousands of people that form the "community", or physics as a science in general, is going to be saved by the students' publications. I may be wrong on this and it might be indeed necessary to publish as many papers as possible although I really doubt it. So, what is left? Narrow minded people, they have been doing strings or whatever all their life so you can't expect anything better, or disgusted and bored people who realize that life can be exciting without physics and go work for the industry, capitalizing their PhDs by getting nice flats and nice cars and going in nice places for their vacations.

I recall an undergraduate telling me that he wants to get his degree as soon as possible and go do a PhD in string theory without doing a masters first and that is why he chose to study for a 3 years bachelors (this senario is possible in some countries). I mean, how is that possible? Senior people are very well educated, no doubt about that, but what about the undergraduate/graduate folks? I am looking at the well known QFT book by Peskin and Schroeder sitting in my bookself right now. How long does it take for someone to read it, solve the excercises and be able to reproduce the results mentioned in it? In other words, master it? What about general relativity? Cosmology? Non relativistic quantum mechanics? Particle physics (with a phenomenological bend)? Statistical physics? Catch up with the rest of the community? Interact with people working in other fields like for example condensed matter or mathematics. Two or three years? If not, then how does someone attempt to solve a problem when he doesn't even know what the problem is in the first place? How is critical thinking going to be developed the way the educational system works?

60. **Ted Fails**
August 30, 2006

Im an amateur at this, but it seems to me that if there is already a
huge uproar over explaining the number "one" as arising naturally
in physics (ie, the CC), then how is it that anyone is comfortable with a finite number like 10^500? If this number is not infinite then
isnt it really wierd? (If it IS cardinal C, then why is it refered to as
10^500, which, by the way, is a very long way from C.)

In a unital algebra, "one" will frequently be present, but I find 10^500 a much more curious number.

Anyone please comment.

61. **ak**
August 30, 2006

tg claimed:

'So I summarize that string theory is an with high degree of mathematical consistency but which clearly needs experimentation. Its difficult math and difficult physics, so therefore time is necessary to come to an appropriate conclusion.'

I point out that the bare fact that string theory centers a discussion of dominating sociological and/or 'philosophical' character which in fact can be led largely decoupled from scientific arguments 'disproves' the above sentences. In fact there seems to be nearly a consent, even across the frontiers, about a certain lack of 'predictions' implied by string theory, while the disagreement centers mainly about the degree of this absence (which puts a claimed-to-be 'theory of everything' in a rather ironic light) and/or the 'interpretation' of this generally undenied fact ('it takes time'). I think that philosophy is fine as long as it supports or manifests the 'explaining' aspects of a mathematical formalism which shares as its necessary property 'prediction', I remember to have learned this years ago being still an undergraduate from a popular book by David Deutsch, his point was more or less that in purely logical terms a theory wouldn't need to be able to explain phenomena AS LONG as it makes the right (i.e. verifiable) predictions about them. To summarize the above discussion one can only conclude that string theory goes the opposite way, it more or less seems to suggest that prediction is fine but nothing compared to the intriguing implications suggested by the theory's 'explanation', this culminates obviously in this 'landscape' argument, where prediction is intrinsically senseless and explanation (the anthroposophic principle, the multiuniverse) puts itself into the perspective of initiating a 'new era' beyond Kopernikus, Einstein et al. I mention that one could parallelize these observations with not-quite recent arguments of german philosophers/sociologists (!) Adorno and Horkheimer whose 'Kritische Theorie' predicted and observed exactly the above discussed failure and tendency of modern rationalism and science in general to become 'mythological regression', even not as a corollary of the scientific method but as an intrinsic principle hidden in rational progress, danish philosopher Kierkegaard already observed in the 19th century that 'this century has produced more myths than any era before', I wonder what his comment would be today.
I could add that concerning my personal experience with 'modern physics' and mathematics I already doubted the mathematical rigor and consistency of 'the standard model' which was the point where I changed to mathematics, from the constant efforts of mathematicians to understand recent and non-recent concepts in 'modern physics' (only to mention the 'path integral', mirror symmetry) I can only doubt the above mentioned term of the claimed 'mathematical consistency' of string theory, even the meaning of this word combination is unclear (what does it mean: a theory which is logically consistent, should this be a particularly 'nice' feature of string theory or is ist just the most necessary condition for a mathematically formulated physical theory to become science?) and as it seems it is relatively hard to 'believe' that it is physics at all, it might be difficult and 'in some sense' consistent, but possibly neither mathematically consistent nor difficult as a physically theory, so maybe one could say it is an extremely difficult and sociologically 'consistent' metaphysical theory ?
(I apologize if this became a bit polemic.)

62. **Lee Smolin**
August 31, 2006

Dear Peter,

Thanks for the very thoughtful review. I have been distracted by some great personal blessing but see tonight that my book is available on Amazon.com and that Lubos has posted a two star review as you predicted. I am not interested in playing a game with Lubos or anyone else whose modus operandi is ad hominum attacks rather than serious engagement about ideas. (His attribution of some positive comments about my book made by Sabine Hossenfelder to the intellectual inferiority of women is for me so far beyond the pale, I really have no energy to further engage with him.)

I wrote a book which treats those with whom it disagrees with a great deal of respect and admiration. The point is not who is a member of what community or who is esteemed by whom, it is about which ideas are right about nature and which are wrong. I wrote about string theory, not to demean it, but because it was the best idea we had about unification and if it is in crisis then we have reason to reexamine our presuppositions which led us to believe in it so strongly (and I do mean us.) My book arose out of such a re-examination and its value, for me, is that it contains proposals for what are the wrong ideas that took such a promising idea to its present crisis. So I am not willing to engage with people who are not willing to recognize good faith and respond in kind. But I am of course happy to discuss with those who takes the time to read it and responds in the spirit in which it was written.

Thanks,

Lee

63. **Who**
August 31, 2006

Congratulations on the aforementioned blessing. Hope all are well:
though I and others know you only through your work, many must be wishing you joy.

64. **Gina**
August 31, 2006

Rather than attacking string theory directly a more promising way for trying to see what is wrong (if anything) with it to try to question the basics of extremely successful theories which preceded it. Peter, Lee is there some "QED bashing" in your books? (Even "QCD bashing" is already considered bad sportsmanship.)

65. **10^500**
August 31, 2006

Oversimplified answer to Ted Fails: "how 10^500 comes out?"

Strings want 6 or 7 extra dimensions, and to predict anything at low energy you must know their geography. Some complicated geography (holes and branes here and there) seems needed to try getting the complicated physics we observe. Strings tell that all of geography is dynamically fixed by vacuum expectation values of fields. There are many fields: a few fields describe the size and shape of extra dimensions, others tell the amount of each magnetic-like fluxes that can wind around each hole, etc, etc, etc. With a normal potential, each field has a few possible minima, and thousand of fields can have few^thousand minima.

10^500 is so many that, whatever we measure, string theory might have 10^100 solutions that practically look like it, altough finding them might be practically impossible.

Despite all impressive achivements, and despite Lubos Motl, this seems the end of the story.

66. **Gina**
August 31, 2006

It was a pleasant surprise that I could read Peter's 2001 paper
feeling that I understood most points Peter had made. This paper is almost disjoint (or orthogonal) to what I asked Peter. (Maybe 2-3 specific "anti string theory" claims can be extracted.) Part of the paper is a sort of philosophy of science look at particle physics and string theory of the last 3 decades geared towards "philosophy of funding of science". Philosophy of funding of science is an interesting and important subject worthy of discussions and debates but it is a separate issue to the "case against string theory" (as a scientific theory). I would still be happy and greatful to see a summary of the "case" against string theory along the lines I asked.

67. **TheGraduate**
August 31, 2006

To Gina:

(Well this is by no means authoritative but the anti-string theory case seems to be roughly as follows:)

1. String theory does not predict anything

2. There is currently no obvious way to modify it so it would predict something

3. String theory is reducing the probability that other (possibly more predictive approaches) will be tried.

All of these points can be expanded into sub-cases but I think they cover all the categories of objections.

68. **Lubos makes me puke!**
August 31, 2006

Gina- I would suggest that you visit the archives of this Blog starting with March of 2004 which has a good article about Peter and his education and qualifications. You can skim the articles and read the important articles about String theory fairly rapidly. This would help you understand that this is a very complicated problem that has arisen from virtually a idea that never had any of the empirical physical evidences that is required for the scientific method. The beauty and complexity of the mathematical calculations necessary to explore the extra dimensions of string theory lured a lot of our most brilliant and gifted students to work for many years only to find that they had invested their time unwisely. Rather than admit their mistake, some like Motl will do anything to keep this dogma a science. Something it has not been for a long time. We all owe our gratitude to Peter for making us aware of this problem.

69. **ak**
August 31, 2006

I have to admit that I still tend to get headache reading papers about particle physics whatever their background and philosophy might be, at least from my point of view they mostly tend to involve a considerable amount of mathematical sophistification but themselves completely lack the beauty and conisistency of the mathematical results and theories involved, in contrary they tend to mix up rigorous mathematical results with speculative ideas and concepts from mathematical and/or physical 'folklore', which makes ist extremely difficult for 'non-insiders' to decide what is still logically consistent deduction and what is wishful thinking or black-box deduction. I assume, and Peter seems to indicate that, that the 'problems' modern physics faced in the development since the 1970s derive as much from its desynchronization with mathematical justification of the concepts involved as with with its disconnectedness from experimental evidence. Motls list seems to reflect either intrinsic features of the theory which seem to be nearly tautological ('unity of supergravities') or concepts which are as interesting as yet poorly understood from a mathematical viewpoint (AdS/CFT/ mirror symmetry). From this point of view Peters attempt to re-view the mathematical concepts of the standard model seems to be promising; one could finally hint to an article of Berhelm Booss-Bavnbek, who judges post-war mathematics to be 'deformed' in a characteristic manner by aims of 'fictional warfare', this point of view is possibly not completely irrelevant to the discussion here (unfortunately in german):

'Symptome der militärischen Deformation: undurchdringliche Komplexität, rücksichtslose Kreativität und täuschende Vertrautheit'

http://www.uni-muenster.de/PeaCon/wuf/wf-90/9021101m.htm

70. **Gina**

August 31, 2006

Motl:

Can you please tell me (just a few sentences understandable to a laywoman) what is your opinion on the two claims:

1) That string theory cannot predict anything and will not be able to.

2) That there are over 10^500 possibilities which makes things worse.

many thanks in advance –Gina

71. **Who**
August 31, 2006

"The Trouble with Physics" (topic of thread) continues to be #1 on the Amazon general physics bestseller list
http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

at least it was 9AM to 4PM pacific time today, could of course be different at 5 PM—list changes hourly.

72. **Ming**
September 1, 2006

"My prejudice is that, lacking experimental guidance, the thing to do is to try and better understand the mathematical structures underlying the standard model."

I disagree with you 100%. The farce of string theory has shown definitively that more mathematics isn't the way forward for physics. I think the way forward is that we need to re-examine the basic foundation of the whole edifice of theoretical physics and look for the missing key pieces (of physical concepts, not mathematics) that everybody has so far overlooked. We need to question the foundation of everything and take nothing for granted. Looking for the easy half-hearted way out by using ever fancier mathematics simply won't work.

Unfortunately this kind of work is despised by most practising theoretical physicists, who're almost all of the "problem solver" variety. What we need desperately are more "seers" as Smolin described them, or "thinkers" may be a better word for it because it doesn't have the superstitious connotations of seers. If we look back at the history of theoretical physics, the most prominent advances were almost always made by thinkers and not problem solvers. Einstein being the best example of a great thinker (though he's also a darn good problem solver). Thinkers can think outside of the box (i.e. the existing formalism of theoretical physics), while problem solvers can only work within the box. The almost complete stagnation of theoretical physics for the past half century is due to an almost complete lack of quality thinkers, with all physics jobs going to the best problem solvers. As long as this extreme imbalance between thinkers and problem solvers persists in theoretical physics, I'm afraid there's no hope for true advances… IMHO

73. **Ming**
September 1, 2006

I just noticed that a recent 5-star review of Smolin's book has been deleted while Lubos' 2-star review is getting suspiciously high number of "helpful" votes. It looks like someone is actively (and desperately) "reporting" positive reviews of Smolin's book while artificially generating helpful votes for Lubos' review. I've only seen this kind of behavior from the site of another "science" book, the author of which is a total crackpot, and he is writing fake 5-star reviews for his own book while trying to report and delete all negative reviews (sad thing is he succeeded). Didn't know that string theorists/supporters can also fall so low…

74. **Eugene Stefanovich**
September 1, 2006

Ming,

I agree with you 100%. The usual paradigm:

Standard model and general relativity are great. The only thing left is to put them together.

lead us in a corner. The only way out of this corner is backward. No amout of clever problem-solving will help.

75. **ak**
September 1, 2006

I remark that it could be already 'mythological regression' to assume a GUT would actually exist. Periods of extreme idealism were quite frequent not only in science but also in philosophy or art (Hegel, Kant, Nietzsche) and Lubos gives an example of even biologists thinking of 'their' path to the universally saving GUT. The crisis of modern physics is not their lack of progress towards idealism, it is its implicit contact with the natural limitations of human (experimental) insight into nature itself (only to mention the energy scale of reasonably realizable accelerators). Possibly the non-existence of 'seers' derives from the fact that there 'is nothing to be seen' which would not go beyond the intrinsic limitations of human insight, at least derived from the standards of current technical ability. Apart from the fact that Einstein 'knew' what would have to be predicted, there in fact was experimental data (Michelson-Morley) giving at least subtle traces of the directions to choose, are there any comparable 'traces' today (Neutrino mass, dark matter?), one could doubt this. Apart from this, from a non-mathematical point of view idealism and regression were always closely connected, I only mention german idealism and its consequences for the history of the last century, it could be a characterizing property of a 'theory of everything' that it predicts in fact NOTHING, so string theory follows the 'dialectic principle' of human rationalism maybe in its purest form. I am personally quite happy about the existence of small-scale problem solving which, as a matter of exactness of the techniques involved, has from my point of view at least the potential to be of 'practical use' in human scale, that is, in human 'everyday life'. I objected a tendency in theoretical physics to substitute the reality of existence as human beings and the diversity of (even physical) reality by concepts of extreme idealizing, at the same time simplifying, potential. The current status of absence of 'predictiveness' of string theory is possibly just a corollary of the wish to include apparently uinversal 'explanation', under whose regime details as 'mathematics', 'logic', 'rationalism', 'predictiveness', in the end maybe 'science' itself seem to lose their relevance or status as guiding (and limiting) principles they acquired over the thousands of years of growth of human knowledge (at least in the 'exact sciences'). Possibly it is the moment where the exact sciences lose their insight into their own limitations where they end to exist as 'exact sciences' and turn themselves into mythology, I already said this above. For my own part, I am quite happy to consider exact sciences as 'exact' but limited and the other disciplines of human thinking (which EXIST, even to me as a mathematician) as 'inexact' but potentially unlimited, possibly the status of modern physics gives a hint towards the growing disassociation of the scientific worlds or human thinking in general, which would in the end lead again towards the concept of 'thinker': maybe it would be Einstein, knowing the history of post-war physics and societies in general, to conclude that there is a certain whisdom in preserving 'mythology' as 'mythical' and 'exact sciences' as 'exact', maybe this is what would have to be 'seen' from his perspective.

76. **Lee Smolin**
September 1, 2006

Ming,

I'm not doing anything, it is very sad to watch. I wrote two books before, there was a lot of disagreement, for example from string theory friends who told me that my idea of the landscape of theories was silly and there would soon be a principle of vacuum selection that gave unique predictions. But no one behaved badly. What is really sad is that there are many string theorists who are ethical and act and talk in good faith, if I were them I would be appalled to let me field be so represented. Besides which this kind of behavior provides strong evidence for the claim that there is something pathalogical in the sociology of the field.

Thanks,

Lee

77. **ks**
September 2, 2006

Just for the record. String theory has nothing to do with the philosophy of "german idealism". Attributing the believe in hypothetical stringy objects that are not detectable but shall be present for complicated theoretical reasons to Kants critics of pure reason or his categories of mind *a priori* or Hegels self-reflection of absolute mind and its projections into history, is hilarious. I do not even want to imagine what Nietzsche had made out of this drive into self delusion and science-as-cult beyond its empirist tradition. Maybe an appraisal of John Horgans writings as being *sound*? German idealism is close to the contemporary radical constructivist/deconstructivist philosophy, to existentialism, phenomenology etc. not to a naive believe in the objective existence of ones own intellectual phantasies.

"German idealism is close to the contemporary radical constructivist/deconstructivist philosophy, to existentialism, phenomenology etc. not to a naive believe in the objective existence of ones own intellectual phantasies."

Here is a good example to what conclusions german philosophers are lead to, in this case concering the Higgs mechanism:
http://www.dpg-tagungen.de/archive/2006/dortmund/akphil2.pdf
Unfortunatly this is in german. What is being said there is that "neither an ontological, nor an epistemological interpretation of the Higgs mechanism is tenable"; this follows fram a "critical analysis".

The link given above, "Symptome der militärischen Deformation: undurchdringliche Komplexität, rücksichtslose Kreativität und täuschende Vertrautheit'" in another beautiful example of political ideology mixed up with science.

Good that there are other parts of the world where science is moving on, although I am getting concerned about the US too, after reading the opinions in this blog here.

81. **ak**
September 2, 2006

no, there seem to be some 'misreceptions', I did not compare string theory to 'german idealism', the argument was that to believe in the existence of a GUT could be a form of idealism, there is no such thing as pure 'naive believe in the objective existence of ones own intellectual phantasies', string theory takes place on a sociological/philosophical background and I just point out that it was Einstein co-initiating the belief in the existence of a GUT. My point was that real progression in modern physics could mean to be a little bit closer to Kierkegaards criticism of Hegel (opposing his dominant position, claim of unifying logical concepts etc.) and from what I understood, Peter and Lee move a bit in this direction. By the way I don't think that 'german idealism', as a philosophical phenomenon, is very close to existentialism or deconstructivism and 'to move on or to stay behind' is exactly what this discussion is about.

82. **ak**
September 2, 2006

I have to correct myself in the sense that the point is that to rethink modern physics with the explicit aim of a GUT remains pure 'idealism' as long as there are no fundamental experimental guidelines to show what exactly a new theory should predict or explain BEYOND the capabilities of the existing models. The unexplained constantness of the speed of light in a vacuum was Einsteins starting point, maybe I am not quite informed, but I do not see that there are any compareable fundamental facts pointing beyond the existing models today. In this situation the string theorists can hardly blame non-string-theorists to develope alternative pictures, one could for instance raise the question why not anyone seems to be interested in the notion of 'symplectic spinor' or symplectic Dirac operator, from a physical point of view the symplectic Dirac equation could possibly be the starting point for a geometric theory of bosons (since it involves the 'symplectic Clifford algebra'), a not quite new paper

http://www.mathematik.hu-berlin.de/~klein/ftr.ps

shows that there is a natural notion of pseudo-differential quantisation involved over sections of a certain line subbundle of the sympletic spinor bundle, on the other hand the metaplectic representation implies the Schrödinger equation for linear hamiltonian systems on R^{2n} and is reflected in some sort of Lie derivative

http://www.mathematik.hu-berlin.de/~klein/liabl.ps

the picture is admittedly not quite coherent, but as a physicist, i could possibly just 'couple', for instance over Kaehler or Calabi-Yau manifolds, the Dirac operator over the ordinary spinor bundle with the symplectic Dirac operatior over the sympl. spinor bundle (taking tensor products and operator 'sums)' and see what 'happens', for Calabi Yau manifolds a natural notion of Maslov index would be involved and would give rise to some notion of 'quantisable' Lagrangian foliations, which would correspond to the dimension of the kernel of the square of some restriction of the symplectic part of the coupled operator etc etc, maybe a new 'TOE', who knows.

83. **ks**
September 2, 2006

> I just point out that it was Einstein co-initiating the belief in the existence of a GUT.

Actually this goal must be attributed to Newton and all his followers. Einstein and other quantum theorists of the first generation destroyed the old worldview and broke it into two incompatible parts without losing the researchers inherent destination of a complete and consistent physical explanation of the whole world. There is no point to make in the inexistence of a GUT because its existence is undecidable unless it exists. It can't be disproved by reason. We can only get stuck. Hence demystification doesn't help us because there is no other side of true reason but just a decision to make for everyone when its time to give up, which is finally subjective.

What really happened with the desire of a GUT is that it became an aspect of mass/pop-culture and its proponents rock-stars of popular science magazines ("Einsteins legacy" etc.) and books. Physicists and to a lesser degree mathematicians are our last heros the last people who truly "transgress the boundaries" which is properly mythological and part of the fascination. Besides the person Stephen Hawking it was ST that had been in the focus of the *economy of attention* of fundamental science in the last decades. String theory is both a highly esoteric and speculative branch of mathematical physics and the pop culture of the TOE. This tension makes it interesting even for visitors who are by no means "active researchers" in the sense of Distler. I'm not claiming that depressing the public about the TOE wouldn't be healthy for the theoretical physics community even if it's going to shrink to the size it had at Einsteins time.

> I have to correct myself in the sense that the point is that to rethink modern physics with the explicit aim of a GUT remains pure 'idealism' as long as there are no fundamental experimental guidelines to show what exactly a new theory should predict or explain BEYOND the capabilities of the existing models.

This is undisputable. Reason without experience is empty, experience without reason is blind, as Kant said.

Well I don't really agree. The desire for unity is completely justified, as is seeking it in geometry. All three major developments since Newton – Maxwell, Einstein, and Dirac – are based on geometry and the idea of unity, or rather as Finkelstein would say, "relativization", which amounts to simplification of the underlying Lie algebra of observables by decontraction. The problem seems to be that the current practitioners are just uncommonly bad at finding the key physical ideas, because they are too enmeshed in arcane mathematics. Klein, Courant, Weyl, all warned us this would happen.

-drl

85. **ak**
September 4, 2006

I am afraid not to understand the dialectic principle of these two points:

'The desire for unity is completely justified, as is seeking it in geometry.'

'The problem seems to be that the current practitioners are just uncommonly bad at finding the key physical ideas, because they are too enmeshed in arcane mathematics.'

The 'desire for unity' is claimed to be derivable from purely mathematical reasoning, at the same time to be 'enmeshed in arcane mathematics' is attributed to the unability of finding 'the key physical ideas'. This could hint to some key misunderstanding of string theorists reasoning, taking on one hand mathematics as a guideline for fundamental aims and on the other hand attributing subsequent experimental deficits of the theory to the unability of 'practitioners' to find the key physical ideas while being absorbed in mathematical reasoning. To resolve this one should possibly follow the contrary strategy: to take experimental facts as the origin of thinking (not taking experiments as the corollary of mathematical idealism) and to use on the other hand plain mathematics as the tool to derive a theory from this experimental starting point (I point out that my above statement about a possible 'TOE' derived from symplectic spinors was of substantial ironic character).

86. **D R Lunsford**

No one ever claimed it was derivable from "purely mathematical reasoning". Indeed the intuitionists firmly believe that such a thing does not exist, and that both math and physics are stimulated by mutual interaction. Finding the right physical idea is an irreducible activity – finding its mathematical realization is not. By "arcane" I mean – disconnected from "physical reasonableness". Certainly there are many complex mathematical structures that are eminently reasonable. The main activity of the physicist is to come up with physical ideas that are reasonable and tractable. That is what is completely missing these days.

-drl

87. **ak**
September 4, 2006

'The main activity of the physicist is to come up with physical ideas that are reasonable and tractable. That is what is completely missing these days.'

I still do not agree on the form of this conclusion. It is a myth Einstein derived Relativity from pure physical intuition, there was an experimental guiding principle which lead to concepts like 'Lorentz invariance' and Minkowski space (Michelson-morley). From THIS point, it was in fact a pure 'thought experiment' to generalize to curvature, geodesics and so on, but the experiment could in fact qualify the result of these thought experiments to be true. In the current situation of modern physics there seems to be neither a clear physical guiding principle derived from experiment nor a possible way to judge the result of a wide variety of thought experiments, so one cannot in fact blame the state of string theory to the absence of 'thinkers' producing reasonable physics. It is exactly this belief in 'new physics emerging from human brain' which lies at the esoteric origin of string theory and potentially also of related concepts.

88. **amused**
September 5, 2006

Thanks for this review Peter, I'm looking forward to reading the book
(and yours).
Smolin makes some astute observations, but it's one thing to describe the problem and another thing to find a viable solution. As Smolin points out, young peoples' job prospects in formal particle theory are determined by how they are viewed by senior influential physicists, and since most of the latter are string theorists (at least at the

leading US uni's) it puts the non-stringers at a huge disadvantage. As far as I can tell from reviews of the book and what he has written elsewhere, Smolin's solution for this seems to be some kind of "democratisation" where funding and jobs get distributed over various areas in proportion to the number of people working in them. What do you think about this? Personally I'm against it. One reason is that it just replaces preferential weighting for string theorists by preferential weighting for people working on some broader selection of areas. What if my preferred research area is not among these? Or if the representative for my area on the "committee" is not very eloquent (he neglected to develop his salesman skills through hyping of our area to the public) and therefore can't get us a decent share of the pie? Or if I suddenly find that there is something exciting in a non-represented area that I want to work on? Besides that, I do think these kind of things should be left as much as possible to "market forces". The problem is that at the moment we don't have a genuine free market; it's more like a monopoly a la Microsoft.

Anyway, if Peter will indulge me I'ld like to propose a different solution: How about just letting people work on whatever they like, without preferential weightings for any particular areas, and evaluating them solely on the basis of the progress they make? This requires of course some objective measure for evaluating "progress". We need something that can be used to evaluate and compare people across different areas. The normal thing in academia is to base this on journal publications. Problem is that people don't care much about journals in theoretical hep these days. When you write a paper you stick in on the archives, where it gets seen by the senior influential people in your field, and your stock goes up or down depending on what they think of it. Subsequent publication of the paper in a supposedly major journal is usually routine and doesn't mean much. This situation is ok for evaluating and comparing people within the same area, but how are you supposed to compare people across different areas? Although they publish in the same journals there is no way to tell the relative quality and significance of their works just from "major" journal publications, since it doesn't take much to get published. Similar things can be said about citation counts (which not only measure the significance of the paper but also the well-connectedness of the author and the size and popularity of the area in which the paper lies).

However, there remains one physics journal which is still non-trivial to publish in: Physical Review Letters. So how about using number of publications there as the evaluation measure? (The weight of each paper should of course be normalised according to number of co-authors, and with a further appropriate reduction for young people who are just going for a ride on the coattails of seniors.) While it is true that some areas of physics (e.g. condensed matter) are easier for getting published in PRL than formal particle theory, within the latter area there doesn't seem to be any biases (e.g. it is not unusual for both string theory and LQG papers get published in PRL) so it would seem to be a level playing field for all. The string theorists surely won't have any objection to this – since they are so brilliant they will surely welcome the opportunity to prove it in an objective setting. In fact I'm sure it's only their natural modesty which has prevented them from filling up the pages of PRL already. It will also give a chance to the hardcore younger stringers to finally silence those "penis envy"-afflicted cynics out there, who go around disparaging them for being mindless clones, absorbing what they are spoonfed like sponges but incapable of doing anything original and significant on their own.
(Whoops, seems like I might have slipped into string-bashing mode at the end there ;))

89. **Ron Macnaughton**
September 9, 2006

I'm a high school physics teacher who just yesteray was asked what I thought of String Theory. My student had trouble understanding what he thought was the deepest theory developed so far.

I explained how most astronomers used to believe planets moved in circles or circles on circles. Eventually Kepler showed only elliptical orbits explained the observed positions of Mars.

I gave the opinion that String Theory makes some assumptions and it might come close to explaining reality, but I didn't think it would ultimately be successful, just as epicircles went into the dustbin of science.

I said that's only a high school teacher's opinion, but many brilliant people worked on it and believed it.

I think the main problem is that String Theory doesn't seem to include General Relativity.

I find the sociology of science rather interesting. We talk about heroes who have a pure drive for understanding, but Tycho Brahe gave Kepler the Mars problem, because he thought it would be too hard for the young whipper snapper to solve. Correct theories (plate tectonics) get rejected for decades. Wikipedia still lists only string theory as a theory for quantum gravity, even though many alternatives are out there.

I read "moron" comments on this blog which I find embarrassing when I hope to inspire young people to take up science as a career.

I can't wait for my copy of both books to arrive.

90. **woit**
September 9, 2006

Hi Rob,

An important thing to explain to students about science is that it makes testable predictions that can be checked. Things like string theory are very speculative ideas that some people someday hope will become legitimate, testable science, but they're not there yet. Some of us think it never will get there, some are more optimistic.

Categories: Uncategorized

Wired has an interview with Lee Smolin.

The French internet site Arte has interviews with various physicists, including one with Carlo Rovelli. If you don't want to watch the videos, there's a text summary (in French).

Mel Schwartz died earlier this week. He won the Nobel prize in 1988 for his 1962 co-discovery of the muon neutrino at the AGS at Brookhaven. Schwartz left physics for a while and founded his own company near Stanford. He returned to Brookhaven and worked on the plans for RHIC, then came back here to Columbia where he was a professor in the physics department, so I had the pleasure of meeting him a couple times. After his retirement he moved to Idaho.

Freeman Dyson's 1951 lectures on QED have been put in TeX and posted on the arXiv.

This fall Graeme Segal will be visiting Columbia as "Eilenberg Chair", a visiting position we have that was funded by the sale of part of Sammy Eilenberg's collection of South and Southeast Asian art to the Metropolitan Museum. Segal will be giving a course on The Mathematical Structure of Quantum Field Theories, which I'm very much looking forward to.

Another course I'd like to attend, but it's too far away, would be Dan Freed's one this semester on Loop Groups and Algebraic Topology. The web-site for the course includes a reproduction of Bott's wonderful lecture notes dealing with the topology of compact Lie groups.

There's a new paper out by Thomas Thiemann summarizing the technical state of LQG. I haven't had time yet to read it, but hope to spend some time soon doing that. A good place to discuss it would be here, where Aaron Bergmann has already started, also see some comments by Robert Helling. A not so good place to discuss it would be here.

Eckhard Meinrenken has an interesting new paper entitled Lecture Notes on Pure Spinors and Moment Maps, which promises a more detailed forthcoming paper by him, Alekseev and Bursztyn.

Some recent and ongoing conferences that have talks online are at Ahrenshoop and Santa Barbara.

Comments

6. **Lubos and the Bogdanovs**
   August 31, 2006

Hi Peter

I visited a bookstore in the capital city today, and I saw a copy of the Bogdanovs' "Avant le big-bang" ("Before the Big-Bang"), recently (May 2006) published by "Le livre de poche" editions, in the french section bookshelf. Guess my surprise when I picked it up and had a look at the back! A comment by Lubos figured there. I quote:

"Les frères Bogdanov proposent quelque chose qui, d'□un point de vue spéculatif, a le potentiel pour représenter une alternative à la gravité quantique.
Professeur Lubos Motl, physicien théoricien,
Université de Harvard.",

which translates into:

"The Bogdanov brothers propose something which, from a speculative point of view, has the potential of being an alternative to quantum gravity.
Professor Lubos Motl, Theoretical Physicist,
Harvard University."

Go to this (http://www.livredepoche.com/index.html) for proof that I am not making this up.

Wow! I guess I should not be surprised by now when it comes to Lubos; only the latter can say such a thing about whatever the Bogdanovs are up to. Did he actually read this book?

I know this is not the place to post this, and I apologise if this is too much.

7. **LDM**
August 31, 2006

Thank you for posting the very nice Dyson link…

BTW, American edition of NEW, page 99 — you might be interested in knowing that Kharkov is in Ukraine, not Russia …
(though it is true most people in Kharkov might prefer the Russian lanuage to the officail Ukrainian language and Kharkov has strong ties with Russia)

8. **Thomas Love**
August 31, 2006

drl wrote: The typesetting of the Dyson lectures is an absolute prize! Thanks to Mr. Moravcsik!

Evidently he didn't read all of the typist's notes, Moravcsik did the rewriting from the first edition to the present one. The current TEX typesetting was done by David Derbes, a PhD student of Higgs.

It will be an interesting read, reading Dyson and then NEW. I ordered the package of NEW and Smolin's book from Amazon and I haven't received either.

9. **RandomSurfer**
August 31, 2006

I can't resist pointing to a link for the "eerie similarities" department. It's written by a reasercher in computer graphics, but… well, read and see for yourself: Leaving.

10. **Chris Oakley**
August 31, 2006

> Moravcsik did the rewriting from the first edition to the present one. The current TEX typesetting was done by David Derbes, a PhD student of Higgs

This gives the lie to the commonly-held belief that Ph.D. students are no good to anyone.

11. **woit**
August 31, 2006

LDM,
Thanks for pointing out that Kharkov is in the Ukraine, a fact that I wasn't aware of. The inaccuracy this caused in the book is minor. I refer there to Golfand, Likhtman, Volkov and Akulov as "Russian physicists in Moscow and Kharkov". Looking into this, while Volkov and Akulov were in Kharkov, Volkov was born and mostly educated in Leningrad, moving to Kharkov at age 26, so referring to him as Russian is not inaccurate. I don't know about Akulov, who was Volkov's student, quite likely he is Ukrainian.

12. **lostsoul**
August 31, 2006

Thanks for the Dyson link; latex is better than a hand written scrawl.
All round, you're keeping it real; and I keep coming back.

13. **nontrad**
August 31, 2006

The Dyson link, and the rest that are all QFT related, is one of the primary reasons why I continue to return to Peter's blog.

Simply put, there is a fond place in my heart / mind for all things QED!

Feynman, simply put, has been a hero of mine since at least I was 16. Sam Schweber's 'QED and the Men Who Made it' (http://www.pupress.princeton.edu/titles/5524.html) is a book that I literally poured over when I was first studying QFT… searching for inspiration for the how's and why's of that strange and wonderful place called 'quefithe'.

Dyson and Schwinger and Tomonaga, Pauli and Oppenheimer and Bethe and Wheeler and Dirac all became heros too…as a result of Schweber's book.

These notes then are a blast from the past that strike, apropos, of the leaves just now starting to change with the coming Autumn…

Scanning the notes, I am reminded of Dover's Principle of Relativity (containing the original papers 'On the electrodynamics of moving bodies', 'Mathematical aids to the formulation of generally covariant theories', 'The theory of the gravitational field' and 'Hamilton's principle and the general theory of relativity'); which I first bought in a used book store in a dog eared copy printed in 1952 that still sits on my book shelf.

The days when physics was still physics….

14. **YBM**
August 31, 2006

Dear "Lubos and the Bogdanovs", if you had a look *inside* the book, you could have read the same quote this time translated as :

"Les frères Bogdanoff proposent quelque chose qui, d'un point de vue spéculatif, a le potentiel pour être une alternative à la théorie quantique."

which translates into :

"The Bogdanov brothers propose something which, from a speculative point of view, has the potential of being an alternative to ***quantum theory****."*

Motl is falsified in the worse and more delusional "anti-String theory" book ever published in France (the cranky brothers are not proposing a "alternative to quantum theory" , but to "string theory" on the basis of bogus math and pre-graduate faulty physics), and is quite happy with that as long as he think he can use that against Woit. What a pity.

Motl couldn't (yet) be called a crackpot (at least on physics issues, anything he writes on computing on his blog is a joke), only a phycho. I guess it won't last long before he'll fall into the first category.

15. **YBM**
August 31, 2006

in case Lubos 'psycho' Motl would like to check the cover

16. **Gina**
September 1, 2006

Dear Lubos Motl:

Can you please tell me (just a few sentences understandable to a laywoman, even just a friendly link will be useful) what is your opinion on the two claims:

1) That string theory cannot predict anything and will not be able to.

2) That there are over 10^500 possibilities which makes things worse.

many thanks in advance –Gina

17. **woit**
September 1, 2006

Gina,

Lubos has his own blog at motls.blogspot.com. If you want to start a discussion with him, best if you do it there.

18. **dan**
September 1, 2006

dear anti-woit lubos,

if peter is materially wrong about something, that certainly deserves to be aired, but if peter is factually correct on his statements on string theory, then as a scientist, wouldn't you agree this kind of skepticism is to be valued?

Peter, have you seen Lubos top 12 top stringy results, and do you think that those results are sufficiently impressive so as to justify the current effort in the string theory research program?

19. **Chris Oakley**
September 1, 2006

As Peter quite rightly does not allow self-promotion here I will keep this short, but I have just added a section on the spin-statistics theorem to my on-line text book (preamble here). Intelligent feedback (by e-mail) would be appreciated.

20. **Stefan**
September 2, 2006

I came to know via an e-friend that his commentary to Lubos' post on Connes' new paper was removed. What more, he was permanently banned from posting there again.

He told me that what he wrote was neither personal in nature, nor degrading to Lubos' work or intellectual abilities (well, maybe a little), nor in any way offensive to anyone else.

His primary criticism was the following [in paraphrased form]:

Lubos, until you prove your value as a researcher (by say writing something which either: a) gets the attention of leaders in the field – say Witten or Gross or 't Hooft etc. or b) gets 500+ citations within a year of publication; or both) you will not get many to listen to your constant (and never ending…) spiel on random and (mostly, not always) off-topic issues that have nothing to do with physics…

in this case: your review of Connes' paper.

He goes on to add [in subtle language]: To critique someone like Connes' may be a bit out of your league…

I guess that probably offended Lubos' sky-high ego… and in the true spirit of scientific dialogue he banner him ever from posting again.

Wow, it's a side of Lubos he rarely reveals to anyone else…

…interesting… and intriguing I must add.

21. **Stefan**
September 2, 2006

Hi Peter,

Don’t quite understand why you blocked my previous post.

Stefan

22. **woit**
September 2, 2006

Stefan (and others),

The WordPress spam filter is idiosyncratic, often working very well, sometimes deciding to mark comments as spam for no obvious reason. When this happens, I don’t get a notification of it, but they go into a queue. I check the queue periodically, but often only once a day.

dan,

No.

Amazon Reviews

September 2, 2006
Categories: Uncategorized

I'd really much rather ignore the activities of Lubos Motl, but his unethical behavior recently has sunk to new lows, and it seems necessary to point this out and encourage others to take appropriate action.

When Lee Smolin's new book The Trouble With Physics first became available recently on Amazon, Lubos immediately posted a "two-star" review of the book, one that immediately had a large number of votes that it was "helpful", likely generated by Lubos himself. The review is thoroughly dishonest and designed to mislead anyone who might consider buying the book ("Lee reveals his intense hostility against all of modern physics", "Lee proposes a truly radical thesis that it is wrong for mathematics to play a crucial role in theoretical physics", "He also denies the difference between renormalizable field theories and the rest", "one of his rules says that the conclusions must be accepted by everyone if their author is a person of good faith", etc., etc., etc…). The dishonesty includes the use of two stars rather than one, since Lubos is well-aware that Amazon is more likely to immediately delete one-star reviews.

After a while, another review appeared, a positive 5-star review. At some point, it seems that Amazon deleted Lubos's review, perhaps because some people had, quite justifiably, clicked on the link that allows one to report a review as inappropriate. Lubos then posted on his blog a rant about this. Later on, he somehow managed to get the 5-star review deleted, and his own one reinstated (and removed his blog posting). At the present time, the only review of Smolin's book on Amazon is the dishonest one by Lubos. This situation provides yet another example of the kind of disturbing behavior of parts of the string theory community that Smolin has detailed in part of his book. Unfortunately, if people just ignore what Lubos is up to, we end up with situations like the current one at Amazon, so I encourage people to consider what action they can take to do something about this. As for Amazon, the answer to dishonest speech is honest speech, so I encourage people to post honest reviews there of the book, I've just done so (and if you want to review my book while you're at it, that's fine too…).

Lubos still has up on his blog an offer to pay people $20 for writing bad reviews of my book. I've complained to people in the Harvard physics department that this kind of professional behavior by one of its faculty members is unethical and not the sort of thing protected by academic freedom. I've also pointed out to them that Lubos regularly publicly claims that his colleagues share his views (most recently in the Amazon review where he goes on about Smolin visiting "us", and what "we" "mainstream physicists" think). While it appears that at some point an attempt was made by someone at Harvard to get him to suppress his extreme political views, I've seen no evidence whatsoever that anyone in the string theory group at Harvard has a problem with his behavior in defending string theory. This is also true of the larger string theory community, which remains almost unanimously (Aaron Bergman is the one exception I can think of) unwilling to publicly criticize Lubos's tactics. A common recent defense of string theory against its critics is that its proponents hold power because they have triumphed in the "marketplace of ideas." It's not a pretty sight to see how this triumph is being defended now that there are other voices in the marketplace.

Update: About an hour and a half after I posted this, my positive review of Smolin's book had accumulated a bunch of "helpful" votes, Lubos's a bunch of "unhelpful" ones, and, I'm guessing, a bunch of reports as "inappropriate". His review then disappeared. My sympathy goes out to whoever it is at Amazon who has to moderate this kind of controversy. Since Lubos is such a poster boy for the problems of string theory, I should say that I'd be happier if his review had not been deleted, but remained there, countered by other, more honest reviews.

Update: I see that Lubos's "one-star" review of my book is now back up (carrying the original date, why's that?) with the comment:

My review has been erased four times because the author keeps on encouraging other enemies of science on his discussion forum to report my review as inappropriate. This is not fair and is a reason why I returned to 1 star.

Well, his review is inappropriate, so I can see why people click on the link that reports this. Again, I'd prefer that it stay up there to show how string theorists behave, but that others with more honest reviews submit them also. Besides, like most authors these days, I do periodically check my Amazon sales ranking, and, as far as I can tell, when his review is there, sales improve. Go, Lubos!

Update: OK, now his review of my book has disappeared, and the one of Smolin's has reappeared. Depressing, my sales should soon head downward, but I'm glad Lee's will do better.

Update: Lubos is indefatigable, both his reviews are back, mine now says:

My review has been erased five times because the author keeps on encouraging other enemies of science on his discussion forum to report my review as inappropriate. This is not fair and is a reason why I returned to 1 star. Please don't trust the counter of helpful votes either. It is being distorted by the visitors of Peter Woit's blog who are directly controlled by the author of this book.

It seems that I "directly control" visitors here. Wow.

I'm guessing Amazon must have some sort of automated system, which apparently deletes reviews that receive a certain number of "inappropriate" votes, but allows the review to be edited slightly and resubmitted.

Update: Lubos seems to have managed to get my review of Smolin's book deleted, as well as one of the 5-star reviews of my book. I can't compete with him in terms of fanaticism, so will just have to take people's advice and ignore what he is up to in terms of manipulation of Amazon reviews. Smolin is a new father and also doubtless too busy for this. People who don't like this situation are free to try and do something about it, by writing reviews, or contacting Amazon, Lubos's employer, or the people he refers to as "us" in his review to make them aware of what is going on.

Comments

1. **Arun**
   September 2, 2006

   I really think you pay too much attention to Lubos Motl. I think once his current position with Harvard ends, his string theory "friends" will distinguish themselves by their enthusiastic lack of support for his future career. Here today, gone tomorrow – why would anyone risk any political capital in this fight anyway?

   Please don't make this to be about physicists, keep it about physics. Don't let it be said that the opposition to certain ideas arises from an underlying dislike of the people involved.

2. **Peter Woit**
   September 2, 2006

   Arun,

This isn't about dislike of Lubos, who I hear is a charming fellow, and I'm sure that's right. It's about the tactics being used by string theorists to suppress criticism. Quite a few physicists have told me that they don't dare say anything publicly critical of string theory, because of fear of what will happen to their careers if they do. One reason for this fear is the apparent support of the string theory community for Lubos and his tactics. Your own question "why would anyone risk any political capital in this fight anyway?" demonstrates the problem: if Lubos has so little support, why would anyone think they would be risking political capital in this field if they complain about his unethical behavior?

The problem isn't so much Lubos as the community he is a part of and its willingness to tolerate his behavior.

3. **Kris Krogh**
September 2, 2006

Now I see what Lubos means by his "free marketplace of ideas." One buys and sells the scientific truth with money.

4. **Anonymous Coward Michael**
September 2, 2006

Do you really think people at Harvard take you seriously enough to consider your complaints as anything more than spam? I wish you could hear the many little side remarks made by serious scientists mocking and disrespecting you in various everyday situations. You got the attention you were craving, all right, but you also paid the price for it. Congratulations, you *are* the class clown!

5. **Yatima**
September 2, 2006

M. Motl really needs to get professional help. The amazing shrillness of his commentary reminds me of posts on alt.alien.visitors or the grating sounds that one unfortunately (and increasingly) hears coming from unhealthy parts of the religious spectrum. Of course, all this is not entirely unexpected, after all, this involves Faith, in a big way. Faith cannot permit doubts. And as always, you have onlookers nodding approvingly from the sidelines while the unbeliever is being given a good and somewhat amusing trashing. Same old, really.

"Nature and Nature's laws lay hid in night; God said, Let Newton be! and all was light." … but this is said only because Newton was a really really nasty customer. He was also wrong in the end.

6. **Peter Woit**
September 2, 2006

Michael,

Thanks for the insider info on what the "serious scientists" up there in Cambridge such as yourself have to say. Always a pleasure to hear from you.

7. **anon**
September 2, 2006

"Concerning Feynman's misunderstanding of string theory, he was just too old … he was saying such a nonsense … he was already too old and a bit senile and slow…"

– http://www.math.columbia.edu/~woit/wordpress/?p=446#comment-14825 which is Dr Motl's attack on Feynman's alleged incompetence in 1988, when Feynman worked out the cause of the space shuttle explosion in 1986, as the physicist on the Special Pesidential Commision. Motl the added that discovering the O-ring failure problem was nothing compared to string theory.

So even if Feynman was around today, he would be dismissed as senile, and nobody would ask Motl for evidence or tell him to be more objective and less political. Everyone who contradicts Motl, regardless of the lack of evidence Motl has, will be dismissed as a moron, so you cannot discuss anything (unless you agree with him). This is why people don't really want to argue with Dr Motl. So authority in particle physics continues sliding into his hands.

8. **richard**
September 2, 2006

While I am not anti-string, Lubos does seem to be doing for the image of string theory what the movie "Deliverance" did for canoeing holidays.

9. **ks**
September 2, 2006

Michael, I guess Harvard takes public mind serious when it starts to considers ST to be a self delusion with high aggression potential and psychopaths as its promoters. Lubos actions are somewhat of a tragicomical attempt to correct the impression that ST is a failure by scientific standards that prevailed at least for a couple of centuries. On the other hand I believe public mind is tolerant about some artistical branch of theoretical physics that got stuck in "mathematical science fiction" (J.Horgan). No one really knows what to expect.

10. **Who**
September 2, 2006

as of today 12:15 pacific, or 3:15 PM your time, the Amazon general physics bestseller list was

#1 TwP
#2 Elegant Universe by Brian Greene
#3 NEW
#4 Douglas Giancoli college physics text
#5 a Stephen Hawking book

http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

at the moment TwP has 5 stars, perhaps because of Peter's review and the many positive votes it has received (I havent followed that, so can't say.)

11. **Anon**
September 2, 2006

Everyone else (both inside the string theory community and outside) ignores Lubos's rantings. The only person paying attention to them is Peter Woit.

Without Lubos to hold up as an exemplar of what's "wrong" with the string theorists, where would Peter ever find material for his blog?

12. **Peter Woit**
September 2, 2006

Anon,

Lenny Susskind.

13. **Anon**
September 2, 2006

What about Lenny Susskind?

Are you saying he's a lunatic like Lubos?

14. **Peter Woit**
September 2, 2006

Anon,

No, while from what I hear his reaction to my book and Lee's is not that different than Lubos's, he's not as nuts as Lubos. But he is, with a striking degree of success, devoting his energies into turning particle theory into a pseudo-science.

15. **Anon**
September 2, 2006

So, aside from the fact that he disagrees with you about the scientific status of the Landscape, is Susskind really the worst example you can come up with (besides Lubos)?

No wonder you spend all your time talking about Lubos, then.

16. **Peter Woit**
September 2, 2006

I don't think there's much worse you can do to go on a campaign to trash the whole idea of what it means to do science, so, Susskind is an impressive case.

Lots of other examples to talk about, but Motl and Susskind really are about the best, since each in his own way embodies well different things that have gone wrong with the field, and they have the backing of very influential institutions. Without them, there still would be plenty to write about: particle physics at its highest levels these days is pretty full of followers of Susskind and other varieties of Landscapologists. For arrogance, dishonesty and unethical behavior, besides Lubos there's always Jacques Distler.

It would be harder to come up with good material for this blog without Lubos and Lenny, but I think I'd manage fine.

17. **mathdude**
September 2, 2006

I have one question: How mathematical are both Lee Smolin
and Peter Woit's books?

I'm hoping they are not too layman oriented but instead make some attempt to
explain the basics in fairly clear fashion with some actual mathematical
discourse?

18. **woit**
September 2, 2006

mathdude,

Mine is significantly more mathematical than Lee Smolin's. But it is written without equations, more in the style of a book for laymen, so mathematically sophisticated people may find this annoying to deal with. It has some fairly challenging material in it, but in a form different than the way I would have written it for an audience of mathematicians.

19. **Lubos makes me puke!**
September 2, 2006

I just ordered both books. I have read most of what peter has written here and was not that interested to read the book. I did it just to say to that nut lubos Motl, that his slimy campaign against real science and scientist will never hide or destroy the truth. For those that can see and understand will stop at nothing to see it through to the light of day! I will do all I can to see to it that his attempts to slander those who try and have a open and honest discussion and find the truth in science, will in the end destroy his academic career.

20. **nigel**
September 2, 2006

mathdude,

As an example, Chapter 3 (Quantum Theory) in N.E.W. is where you begin to find a completely different – and more realistic – explanation of the fundamentals than you get in most popular books. There is an historical-context discussion of how the Hamiltonian operator works on vectors in Hilbert space or wavefunctions, Weyl's work in Lie groups such as U(1), the "unitary group of transformations of one complex variable" which is illustrated simply by an Argand diagram (Fig 3.1 in N.E.W.), SU(N), etc. It isn't a textbook, but is a vital supplement.

21. **Benni**
September 2, 2006

Peter, Lubos offer of 20$ for negative reviews of your book seems to be erased from his blog

http://motls.blogspot.com/2006/08/20-award-to-fight-against-review-fraud.html
or at least this link does not work anymore!

congratulations Benjamin

22. **Benni**
September 2, 2006

Lubos review on Smolins book got deleted
http://www.amazon.com/gp/product//0618551050

23. **John A**
September 2, 2006

I objected to Lubos' review. It is not for him to say what is science and what is not because someone objects to the fact that ST has not produced a single empirically testable claim.

24. **anon**
September 2, 2006

Dear Peter

I find your use of Lubos rather disingenuous. Lubos is not a poster boy for string theory. Rather, he is clearly a rather sad case of a brilliant and kind but disturbed and paranoid individual. You are making yourself ridiculous by taking him seriously. The community doesn't 'tolerate' his behavior, but mostly tries to ignore it like any reasonable person would, although a few people try to figure out how to help him.

Lenny is not crazy at all, but he loves to be provocative. But he is not a posterboy either.

Most string theorists are no more interesting/arrogant/crazy than the rest of us, (which may not be saying a lot) just more formal and mathematically inclined.

25. **CapitalistImperialistPig**
September 2, 2006

Motl's deranged reviews are annoying, but I agree that it is more useful to have them up than not. Lubos may not be the posterboy for String Theory, but he is the most visible combatant in the blogosphere. There are many prominent string theorists who read Motl's blog at least occasionally, and the failure of any of them to denounce his tactics is very telling. Either the Stalinist streak in String Theory is scary enough that even the most prominent dare not denounce it or they agree enough with him that they find him a useful tool.

I find it reminiscent of the power of the Ku Klux Klan in the old South. Most prominent citizens would mouth words like "the Klan goes to far" while being secretly pleased that these hoodlums were doing their dirty work.

On a completly different note, the review LM has up of Alain Connes newest paper is pretty interesting. Lubos may be nuts, but there is still a powerful mind in there somewhere.

26. **Aaron Bergman**
September 2, 2006

I find it reminiscent of the power of the Ku Klux Klan in the old South. Most prominent citizens would mouth words like "the Klan goes to far" while being secretly pleased that these hoodlums were doing their dirty work.

Oy vey.

Is this what it's going to come to? The 'failure to denounce' game? I get enough of that on political blogs.

27. **LDM**
September 2, 2006

The problem, it seems to me, is that the layperson reading Amazon reviews is not really in a position to analyze the scientific quality of any of Lubos opinions. If NEW was aimed a target audience of professional Physicists only — people who are quite capable of analyzing Lobos' statements –then Lobos' review would largely serve to discredit himself.
But, because NEW has a target audience that is non-technical, Lubos' reviews are unfortunate. Similary with the Trouble with Physics. However, no quantity of Lubos reviews can prevent serious researchers from reading these books and drawing their own conclusions. So in that sense, Lubos reviews are irrelevant and NEW and The Trouble with Physics are important contributions.

Based on what Lubos has posted here, I have a different opinion of Lubos' understanding of Physics, and "brilliant" is a ridiculous use of the word in his case.

28. **RA**
September 2, 2006

CIP,

Your comparison of Lubos to the KKK is stunningly inaccurate and would be laughable if it weren't so malicious and offensive. How could you? With that smear of a totally wrong stereotype about Southerners being racists, you've not only offended me but most other Southerners. If this is your and Peter Woit's idea of a way to promote an alternative to 'popular' physics then you're not going to be very profitable.

29. **Gina**
September 3, 2006

Lubos Motl had posted a few highly inappropriate comments on this blog, but I do not see why his review on Smolin's book and, in particular, the quotes you gave from his review are inappropriate. Perhaps Lubol's interprrtations on Smolin's views are incorrect but I do not understand, Peter, why you call them inappropriate.

30. **CapitalistImperialistPig**
September 3, 2006

RA and Aaron,

OK, Lubos is not the KKK. His lynchings are strictly verbal, and thus not reasonably comparable to real ones. That doesn't mean that they are harmless. His vicious attacks on Lee, Peter, and Christine, for example, are clearly intended to cause pain and destroy careers.

Those in power who witness such attacks and don't intervene (Polchinski, Maldacena, and the whole Harvard String mafia for for example), or actually join in, like Susskind, cannot pretend to be blameless.

31. **CapitalistImperialistPig**
September 3, 2006

RA – Also, I don't plan to lose much sleep over whether people might be offended by my calling the KKK (and those who supported it) racist.

32. **gunpowder&noodles**
September 3, 2006

On the whole, I have to say that I find it very educational to follow LM's activities. People often remark on the astonishing disjunction between the personae of people in real life and on the web, eg A. Bergman's claim that J Distler "isn't the man [PW] thinks he is". Sadly, all the evidence suggests just the reverse: that the blog persona is the real one, and the nice-guy-when-you-meet-him-in-person is just a facade which the individual finds it expedient to assume. I'm afraid that I think that when we deal with our fellow physicists remotely, we must brace ourselves to deal with the Mr Hyde rather than the Dr Jeckyll. Case in point: how many times have you heard, especially recently, jaw-dropping stories about the kinds of remarks people put into referee reports? Last year I had a paper accepted by a famed journal on the basis of a referee report which praised my work in fulsome tones, especially for one particular result. The catch was that I had not proved this result, nor claimed to. Clearly the referee had just skimmed the paper, got the impression that I was agreeing with his prejudices, and approved it on that basis alone. Now turn to LM's favourite activity these days: he tries to "review" all the papers on hepth on a given day; recently, even more astonishingly, he has tried it for gr-qc. The modus operandi was the one I have described: he reads enough to try to judge whether the author is a Good Guy or a Bad Guy in the interminable Western he directs in his head, and judges the paper accordingly. I think all young students should attend to his methods, because less transparent versions of the same thing are going to determine their professional fate. You can learn a lot from LM. Not about physics, admittedly…..

33. **Aaron Bergman**
September 3, 2006

"Intervene"?

This is silly. Lubos isn't a child. There's no big string theory boss who tells us all what to do. Frankly, I don't see why anyone should stop him. I don't like what he has to say most of the time, but he's got every right to say it.

Grow up and ignore him. And stop blaming an entire community for your inability to do so.

34. **Stefan**
September 3, 2006

I recently had an e-friend tell me the following:

He came upon Lubos' review of Connes' recent paper. He read what Lubos had to say. He then offered the following comments [paraphrased]:

Lubos, you seem to hold many (firmly-held) views on many topics (most of them off-topic in nature), but – despite your vitriolic remarks – very few will take you or your endless commentaries seriously until you prove your merit as a professional scientist. This can be done via: a) writing some paper that gets the attentions of people like, say, Witten, Gross, or 't Hooft, etc. or b) accumulating 500+ citations on a paper within a year of publication, or both. Until you achieve this you will only be viewed as a rabbler and nothing more.

And by the way, critiquing someone like Connes might be a wee-bit out of your league.

[Stefan]: Guess what happened next? He was banned from ever posting at Lubos' site again. Well, I guess the defender of free thought and critical dialogue wasn't feeling like his usual (over-)confident self…
Figures!

35. **Ebgert**
September 3, 2006

🙂 He he. I think it's great fun to see physicists fight in front of the public. Peter and Lee on the one hand say that Lubos's behavior is inappropriate and that Susskind is abandoning science, and Lubos and Susskind on the other hand engage in name calling, "glub glub glub" and crazy rants.

So the public is supposed to watch this and think that physicists are clever, respectable people who work hard and adhere to strict standards of professionalism and scientific integrity. And Peter and Lee can say "What are we supposed to do when Lubos and Susskind behave like that?", and Lubos and Susskind can say "Those people aren't even scientists; they're just crackpots who are jealous because we're right and they're wrong."

Beautiful. This is dragging the reputation of physicists everywhere into the gutter. Once physicists gained the world's respect when Einstein changed our views of space and time and then atomic physics showed the world what power truly is. Now you are all a bunch of squabbling children and the lesson the public will take from it is that nobody's right and nobody understands and astrology is just as good as the latest physics theories because the physicists themselves say so (although one bunch of physicists says it about one theory and a different group says it about a different theory).

So the physicists have brought disgrace upon themselves, like the philosophers did before them. Now follows a century when physicists can no longer behave so arrogantly and dismiss the other sciences like chemistry and biology as being beneath them. Serves you right, you arrogant assh*les.

36. **Anon**
September 3, 2006

Hi Peter,

You mentioned Lubos Motl, Lenny Susskind and Jacques Distler by name to illustrate what you dislike in the string community as well as Aaron Bergman as a positive figure. By chance (or not) these four are a subset of the people who write blogs and/or are very visible to the general public and the laymen.

In my opinion this fact alone confirms that your main points against string theory are sociological in nature and not necessarily accurate as such since the sampling is not representative (if you think otherwise, what are you arguments?)

If you would have technical points to raise you would name people writing influencial technical papers with whom you disagree. Now Lenny Susskind is certainly influencial but his landscape related ideas are in my opinion not in the string theory mainstream. I'm sure you could also name a handful of equally influencial string theorists who either ignore the landscape philosophy or expressly disagree with it. That is exactly what I mean when I say that your sample is not representative.

In addition the fact that you are fighting with "blog-people" explains why the mainstream ignores you. That is simply because blogging is not a scientific activity according to the majority of physicists and so whatever happens on blogs is not a concern to them. You are of course entitled to think that your blogging activity is a scientific activity but you should also acknowledge the fact that according to the majority it is not. Thus there is no reason to be surprised that your complains to the Harvard faculty are ignored. It is simply because people do whatever they please in their spare time, it's not the business of their collegaues.

To illustrate my point (it's just an illustration, don't take it literally please): if you find your wife (suppose you have one, I don't know) and Lubos having sex in one of the seminar rooms of Harvard you are 100% entitled to be mad at him. You may also think at first sight that the academic community of Harvard should somehow condemn this activity and you might also think that because the whole thing took place at Harvard the whole Harvard community has something to do with it. After one or two clear days you will however find (I guess) that this issue has to be dealt with exclusively by you, your wife and Lubos. That is because nobody broke any laws and the academic community has nothing to do what some of the faculty members are doing in their spare time and certainly I haven't seen signs in any classrooms that having sex is not allowed. Thus it would be foolish to demand a condemnation, public outcry, official statements against Lubos etc.

With your blog, Lubos's blog, your book, Amazon reviews, etc, etc, 99% of the things you are busy with the issue is exactly the same. This kind of stuff is not science thus people who care about their scientific integrity do not get involved in such issues on a professional basis, only as a out-of-office activity. Again, you may think that it is part of your professional activity but most don't and it would be much better for you if you grasped that point and would not fight with windmills.

Anon

37. **Ebgert**
September 3, 2006

gp&n:

You're absolutely right, people do tend to become more aggressive and nasty when they're writing on the internet, and Lubos is an extreme case (I've met him many times and he was pleasant every time, always very very very smiley). The one thing which doesn't change is that he sounds in person just as much like a party-political spokesman as he does on the internet.

But I would disagree that the aggressive internet persona is more "real" than the one we meet face to face. The facade we show to people when we meet them in person is just part of the collection of strategies we have for dealing with people and getting along with them, while satisfying our emotional needs. The aggregate of our strategies is our personality, so I think the techniques we use to avoid offending people who are standing in front of us have to count as a part of our personality, even though we might prefer not to have to use them, and when we are on the internet, the person isn't standing in front of us so we don't have the same pressing fear of causing offence.

Lubos is a wonderful case. Thanks to his internet behavior, Lubos will be remembered much more than Witten, when future historians of physics tell the story of string theory and its decade or so in the limelight. The internet is the human collective consciousness, and Lubos is there, visible and loud, while Witten is nowhere to be seen.

Also, congratulations to Peter (and Lee). Thanks to you, the string bubble has burst, like the housing bubble and the dot-com bubble before it. Your voices have been heard – the emperor has no clothes. Every scientist outside of string theory has been waiting for somebody to do this, and it is truly a joy to see Michael say that "serious scientists" don't agree with you, because he just means "string theorists". In fact, the string theorists are the only ones who don't agree with you. And they may be the only one who truly count in their own minds, and this is wonderful as well, because they will soon realise how little their opinions count in the real world.

From now on, every mention of string theory in the public media will include a comment or two from "the critics", "for balance". No more uncritical praise for string theory from the media. The tide is turning against them. The word is out – string theory has nothing to say about the real world. The only thing that can save them now, in the eyes of the media, is a prediction about the result of an experiment. But the string theorists know, even more than everybody else, that this will never happen. All of the pep-talks at conferences, "One day, we'll all be heroes!", it was all propaganda, and it may have stirred your heart, Aaron, but you can't avoid that sinking feeling in the same heart – you've wasted your life, and it's too late to stop, too painful to admit defeat.

Hahahaha! 🙂

By the way, the string bubble was on top of a physics bubble. It was the culture of arrogance and aggressiveness in particle theory that allowed a bunch of cocky cultists to take over: "We don't need no rigor; we don't need no experimental results to back up our indubitably correct guesses and hopes. We are the string theorists and the proof of our correctness is our manifest superiority over every other human mind." Well, unfortunately the culture of physics is such that people who say things like that become the "glorious leaders" of all of physics, and when they go down, the respectability of all of physics goes down with them, glub glub glub.

38. **Gina**
September 3, 2006

Stefan,
Something does not add up in what you wrote: Lubos' comments on Connes' paper were overall very positive (a bit funny to read though).

39. **Ebgert**
September 3, 2006

Anon,

You are right; it is not science, but that is beside the point. The battle is being fought in full view of the public, and it is a battle for the public opinion. It used to be the case that the public opinion was that string theory is right because the people on television and in the newspaper say so. Now the people on television and in the newspaper don't say so any more. The string theorists have lost the battle.

The fight over scientific issues, like whether the landscape exists, will take place within string theory, and the conclusion, in case you haven't been paying attention, is that the landscape does indeed exist, at least in so far as anything within string theory "exists". Lubos and the people who "disagree" with Lenny are not saying that the KKLT vacua aren't solutions of string theory. They're saying that maybe maybe maybe some as yet unknown and unpredictable something might possibly happen that will make everything OK again, so that string theory can go back to the way it was *before* Lenny pointed out the landscape.

Hahahahaha! That's like saying maybe maybe maybe somebody sometime will find some way to evade Goedel's theorem, so that all of mathematics will become provable again. That's why they're in the minority. They're the die-hard, have-faith, never-give-up-and-never-look-facts-in-the-face hardcore believers. Faith over reason. That's who the people who "disagree" with the landscape are.

The “moderate” people like Aaron try to strike a middle ground, saying that the majority of string theorists “don’t work on the landscape”. Hahahahaha! That’s like saying “Well, I know that it’s been proven that what I’m trying to do is impossible, but I don’t concern myself with what has and hasn’t been proven to be impossible.” Hahahahaha! 🙂 Keep up the good work, guys.

40. **Farrold**
September 3, 2006

As best I can tell from Amazon’s data system, the tag “crackpot” has been used 13 times on Amazon, 11 of them by Motl. Fascinating.

Meanwhile, in the Physics bestseller category this hour, the rankings run Smolin, Woit, Greene, Penrose.

http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

41. **David**
September 3, 2006

Stefan,
I learned from CIP that Lubos can only ban about 20 people at any one time. I was banned for a while but it was lifted when, I guess, he was madder at 20 other people than he was at me. This comment may free up someone else again. I don’t comment on Lubos’ own postings any more; he just deletes or refuses to discuss things in a rational manner. His treatment of Bee recently was, in my view, over the top. I do like to, sometimes, comment on what others are saying.

Peter,
As I’ve said before I got the UK edition of NEW early and I thought it was great in the sense of making me think about and appreciate some things I hadn’t thought about before. Thank you. I should be getting my copy of Lee Smolin’s book in the next few days. I look forward to a similar experience with that. WRT Motl he talks about what it means to do science and be a scientist but then ignores that in many of his posts. He knows what others should do but he doesn’t do it himself. If I was in string theory or at Harvard, I would regard him as super embarrassing. With his public postings and his record on SPIRES, I don’t see how he’ll get tenure but I’ve been wrong about that before. In any case, “This too shall pass”. In the long run, people will appreciate your behavior esp. in comparison to LM. You’re wise to leave his comments here for others to see.
Best wishes,
David

42. **Ebgert**
September 3, 2006

David,

Indeed, Lubos is a hypocrite. But if you are an American living in the McCarthy era, you can get tenure even if you spread lies saying that communists eat babies. Similarly, if you are in the Soviet Union, you can get tenure while saying that Americans eat babies. Today you can get tenure in Iran for saying that Israelis eat babies or you can get tenure in Israel for saying that Iranians eat babies. So Lubos’s statements that string theory critics eat babies will not do any harm to his career. Anybody who thinks that string theorists are more capable of a balanced judgement than Americans were during the McCarthy era is naive. Human nature has not changed for hundreds of thousands of years, let alone a single generation.

PS. Nobody eats babies.

43. **Gina**
September 3, 2006

Ebgert,

Your Godel’s theorem example goes the opposite way. There was a “foundational crisis” in mathematics based on the fear that its foundations are not provably sound. Godel’s theorem confirmed this fear but strangely this was the end of the “crisis” and mathematics continued as before. There were people like Brower that thought and taught that mathematics should be done completely differently in view of these problems but his views did not prevail. So if “landscape” to “string theory” is like “Godel’s theorem” to “mathematics” you can expect a bright future for string theory.

44. **Alejandro Rivero**
September 3, 2006

I think you people are getting a tendence to exagerate 🙂

“Human nature has not changed for hundreds of thousands of years” —> there is not evidence of language skills from human species 200 000 years ago. And remember that mithocondial Eve and Y-chromosome Adam are estimated between 80000 and 35000 years ago.

“There was a “foundational crisis” in mathematics based on the fear that its foundations are not provably sound”.@ –> actually there was some different approachs to foundations, Godel incorporated early into formalism and proved was doomed.

” Lubos’ comments on Connes’ paper were overall very positive ” —> Early comments were possitive. A longer (but not deeper) reading of the paper, done without the background of axiomatics of ncg spaces, led him to a fast dismiss.

45. **MathPhys**
September 3, 2006

Peter,

I think I’ve noticed something quite interesting taking place over the past two weeks, which I think coincides with the appearance of discussions of Smolin’s book in addition to yours.

Namely a number of people who normally won’t think at all about particle physics, approached me, and undoubtedly others, asking me if I’ve heard of or read two recent books that claim that string theory is totally wrong, particle physics is a mess, etc.

What I want to say is that I’m struck by what seems to be a sudden awareness amongst the public of what’s going on.

It seems to me that in spite of what people like Lubos and Susskind are saying on public forums, or doing on amazon, you and Smolin, rightly or wrongly, are winning the public vote.

46. **Ebgert**
September 3, 2006

Gina,

I agree with most of your points. In fact, Brouwer was correct, and mathematicians didn't pay as much attention to him as they should. Instead, they said "What's that weidro talking about? Never mind, who cares? Let's ignore him and call him a crackpot."

But mathematics lost a lot of its pomposity thank's to Goedel's theorem. They became humbled and realized that they were not talking about the Platonic ultimate truth, but rather about what results could be obtained from specific starting points using specific procedures. Al least, the logicians realized this. Perhaps it hasn't penetrated the thick skulls of many mathematicians yet (it has been less than a hundred years). Certainly we can't expect the physicists, with their little brains and their big egos, to understand the consequences for many generations. The physicists, string theorists in particular, will continue to insist that they are talking about the ultimate truth for the foreseeable future, but thanks to Lenny Susskind, we have a proof that they (the string theorists) are not.

> "Human nature has not changed for hundreds of thousands of years" —> there is not evidence of language skills from human species 200 000 years ago. And remember that mithocondial Eve and Y-chromosome Adam are estimated between 80000 and 35000 years ago.

Please see the wikipedia entry on [human evolution](). My statement stands. Humans have *not* evolved significantly since the McCarthy era; if you think otherwise you are wrong.

47. **Ebgert**
September 3, 2006

Mathphys,

Let me offer a different interpretation. The public can't remember or distinguish between Lee, Peter, Lubos or Susskind. To them, they're all "some guy". But what they can do is smell blood. And they like it. 🙂

48. **Gina**
September 3, 2006

Ebgert,

hmmm, I am glad that you agree with most of my points. You come across as being rather hostile towards physicists and mathematicians. This looks unfortunate to me. Overall, it is not dificult to create public hostility against intelectuals, scientists and various other minority and/or "elite" groups. But I do not think this is a very good path to follow and I doubt if this is what Peter or Lee intend to do in their critiques. Brower, right or wrong, was also a mathematician and he probably also had an "ego" (a term coined by yet another intelectual).

" The physicists, string theorists in particular, will continue to insist that they are talking about the ultimate truth…"

So is this what all this debate about? that physicists/string theorists/mathematicians/ will concede that they are not talking about the ultimate truth, and when they do they can continue developing their scientific disciplines as before?

49. **Ebgert**
September 3, 2006

Gina,

Do you know why Brouwer started constructivism? Or why intuistionistic logic was considered a desirable thing at all? The mathematicians who I declared to have "thick skulls" are the ones who say "No, we do not know and we do not care, and because we don't know about it, it isn't worth knowing." It is this attitude that I am hostile to, and I will continue to be hostile to it, because there is a difference between the arrogance of the ignorant and the intolerance of the educated. If those who are well-informed bow down before the ignorant and say "Ignorance is just as good as knowledge, and the ignorant are as just as qualified as the knowledgable" then the present situation will continue, with the ignorant becoming glorious leaders who can lead whole disciplines astray. I dare say that if Brouwer had been a little less tolerant towards his contemporaries then mathematics might be in a much better state than it is today.

I am not, of course, arguing that everybody should be intolerant towards everybody else. What I am saying is that there is a *clear* difference between well-formed arguments and proven theorems on the one hand and vague assertions of intellectual superiority and dismissiveness on the other hand. The two are not equally acceptable. Intolerance and hostility *should* be shown towards those who say "We have not proven what we say, but we are right because we are great and intelligent", which is the message of the string theorists. They deserve to be greeted with intolerance and hostility. Bowing down and submitting and saying "Oh, why yes, whatever you say must be right, and you must be more intelligent than me because you say so" is *not accepable* and it must *never* happen again, because it has brought (fully deserved) humiliation to physicists.

> So is this what all this debate about? that physicists/string theorists/mathematicians/ will concede that they are not talking about the ultimate truth, and when they do they can continue developing their scientific disciplines as before?

You do not understand. The mathematicians/physicists are following a certain procedure. If they think that they are discovering the ultimate truth, then they will do one thing. If they understand that they are not, then they will do another (different!) thing. Consequently they will not simply "continue developing their scientific disciplines as before". Do you not understand that there is a difference between mathematics as practiced today and constructivist mathematics, for example? Do you not think that it is even worthwhile to be aware of this difference?

You think that when somebody says: "You are doing the wrong thing because you are making a mistake. Please understand this particular point …", that is the same as saying "I want you to unthinkingly repeat this sentence, and then carrying on doing what you were doing before." There is a difference between these two things.

50. **Ebgert**
September 3, 2006

Gina,

I realize I'm blabbering on a bit much here (actually, I'm kind of enjoying swapping between blog blabbering and blabbering at an actual party, which may explain why I'm so incoherent). But the stuff about Brouwer isn't really that relevant. The point I was originally making about Goedel isn't that his theorem killed off any possibility of future progress in math, but rather that it would be foolish to spend the careers of thousands of people on the hope that somehow sometime somebody will find some way to return to the way things were before we knew about Goedel's theorem.

Lubos's argument about the landscape, and, implicitly, the thinking of the string theorists who "don't work on the landscape", is that maybe somehow things might someday return to the way they were before we knew about the landscape and the discretuum of vacua. That's why I was making the analogy. Your criticism of my analogy seems to be based on the interpretation that I was saying that Goedel's theorem killed math, so the landscape should kill string theory. I wasn't saying that.

51. **TheGraduate**
September 3, 2006

Studies in Human evolution is another area of science filled with much 'religious' fervor. It is also another branch of science that wants to provide a TOE (for all things human) and tends to try to make it's case to the public directly. It is also interestingly enough a group that makes its case by arguing that its opponents are idiots and don't deserve to be listened to or even argued with.

I have never waivered in my support for evolution as the explanation for why we are all here and yet I have never waivered in my conviction that this mode of argument is beneath 'real' scientists.

52. **Fort Knox**
September 3, 2006

Just for the record, a recently deleted blog entry about a $20 prize:

http://tinyurl.com/jmsca

53. **Gina**
September 3, 2006

Ebgert,

I see. Also while I did feel some hostility towards math physics etc. in your earlier comment I did not notice it in your later one so maybe it was not really there. From what I heard, while mathematicians regarded Goedel's Theorem as a beautiful piece of mathematics it almost did not influence they way mathematics is practiced and not so much the way mathematicians regard mathematics. In any case, any way you want to take your nice analogy it comes pro-string theory.

I also think from what I heard that while Brower ideas and constructivism had some influence in some areas of computer science, they did not have significant influence on mathematics itself. But at the time when Brower went lecturing about his ideas he was accepted almost as a hero and people where excited from the prospect of a revolution in mathematics.

Of course, I cannot say if you are right when you say that Brower was right. It looks that this is not what most mathematicians think and probably very few really know the details of constructivism. Maybe others can comment more about it.

Be that as it may be, Brower had some alternative theory. Is the anti-string movement came to the point where there is some alternative theory (even if very partial or incomplete or a little strange)?

54. **Stefan**
September 3, 2006

So, after all these posts and endless arguments–counter-arguments we (most of us atleast) seem to have arrived at a broad concensus:

Ignore that little guy from Cambridge, and move on to real discussions!

Topic 1:
Where is Connes heading with his programme?

Topic 2:
What background is necessary to work on the "Yang-Mills and Mass Gap" problem outlined by Witten and Jaffe [Clay Millenium Problems]?

55. **Alejandro Rivero**
September 3, 2006

Topic 2 amusingly should be in Woit's early training, according the wikpedia: "Peter Woit's earliest work verified Edward Witten's 1979 quantum chromodynamic formula for the eta-prime mass in terms of the second derivative of the vacuum energy.". So perhaps a blog entry will appear some day. The question of course is not about a mass sum rule, but about a proof of a gap in the mass spectrum of QCD, ie about the fact that QCD-binded objects get some mass.

Topic 1 will move this week, as Connes will take a couple hours in the Newton Institute to expand about this preprint. Connes his goal I can not tell, it is a sort of cross fertilisation between gauge theory and geometry and in principle it is one of a series of examples to clarify which is the right generalisation of (differential) geometry to algebras beyond the commutative case. Physics could benefit because the axioms seem to impose restrictions to the possible gauge groups and its representations.

In deeper layers this programme would help to understand foundamentation of QFT. For instance it is amusing that the absence of anomalies, which is a quantum requeriment, appears here as a geometric requeriment, Poincare duality. Also, there is a paralell programme running, by Connes Kreimer Moscovici and some other interested people, looking at the renormalisation group from new perspectives.

56. **Tim Swanson**
September 3, 2006

"It is being distorted by the visitors of Peter Woit's blog who are directly controlled by the author of this book."

That's why I always wear a tin-foil hat.

57. **Boaz**
September 3, 2006

anon raises an interesting question that I see cropping up here somewhat regularly. Namely: "what is the relationship between the online blogging community and the rest of the physics world?"
He (she?) says that the conflict between Peter and Lubos is irrelevant because the activities going on in the blogs are not a part of the professional activities of being a

scientist or academic. But there is clearly some overlap and this relationship is changing and being negotiated on a daily basis. If that poster is still reading, I wonder if he could comment on what he thinks a more appropriate role for blogging would be in professional scientific discourse?

58. **Bob McNees**
September 3, 2006

Peter,

It's silly to claim that the "larger string theory community" is "unwilling to publicly criticize Lubos's tactics." Most string theorists are unaware of, or don't care about, the exchanges between the two of you.

All of your exchanges with Lubos have two things in common: you and Lubos. If you don't like him, ignore him. If he goes to far then deal with it as you see fit, but don't expect someone else to do it for you.

There are lots of string theorists who read your blog. I think that most of them, like any good scientist, are genuinely interested in and open to criticism. Treating them as if they are part of some nefarious string theory conspiracy, intent on silencing a critic, will only convince them that you don't have anything worthwhile to offer.

59. **Thierry M.**
September 3, 2006

I was considering buying Woit's and Smolin's books, since I am deeply interested in theoretical physics in general and string theory in particular. I changed my mind. Reading the last post on this blog, what I see is some childish dispute about negative reviews being pushed in and taken out of Amazon.com. Who do you think cares about this? This is ridiculous. Where are the deep, noble thoughts and demeanor of people like Einstein and Bohr? Are they being replaced by ridiculous disputes and insult exchanges between angry bloggers? This is very disapointing, very sad, because I thought that blogs would bring a real progress in the exchange of ideas in physics. But this proves I was wrong. Just the opposite is happening. After all, you are no Einstein nor Bohr, a thing I should have realized from the beginning. I will now remove all physics blogs from my browser favorites. I don't want to have my mind polluted anymore by such rubbish.

60. **CapitalistImperialistPig**
September 3, 2006

String Theory is not falling into disrepute in the public mind despite the antics of Motl and Susskind, it's falling into disrepute because of them. The public may not be able to understand anything about the scientific (or, more realistically, philosophical) questions at issue, but they can tell who is wearing a black hat. When one side bullies and blusters, and the other responds with measured argument, it's obvious who the good guys are.

A bully usually has a crowd of hangers on. They don't seem to stick around long after he takes a punch, though.

61. **woit**
September 3, 2006

Woke up late today, then after a lazy morning logged in to find far too much here to deal with, and in my e-mail a link to a review of my book and Lee's by Susskind. I'll write a bit later about the Susskind review, and, just to brace you for the shock, I'll have some positive things to say about it.

I deleted a bunch of the more off-topic comments here, will try and respond briefly to a few of the others:

anon (who thinks I'm being disingenuous about Lubos):

I'm using the term "poster boy" in the sense not of someone who is representative of a problem, but an extreme, exaggerated case of a problem, as in posters of exceptionally cute and suffering children used to get people to contribute money for medical research or to alleviate poverty. Lubos is in no way representative of string theorists, but his arrogant conviction that people who disagree with him are idiots, that string theory is the only possible way forward for particle theory, that string theory has been hugely successful, etc. are exaggerated forms of attitudes that I've found to be all too prevalent among string theorists.

Anon (who thinks I don't have a representative sample),

I mentioned certain people explicitly because they are ones who publicly make their views known, thus inviting a public response. I don't think I've anywhere claimed that they are typical of string theorists. Among string theorists whose views I'm aware of, but haven't mentioned, one large group consists of perfectly reasonable people who are responsible scientists, with whom I just happen to have a scientific disagreement about the prospects for string theory. There also are a significant number of others who, in one aspect or another, exhibit Lubosian behavior. Some of these do this as anonymous commenters here and I don't know who they are. In other cases I've witnessed or have reliable first-hand accounts of such behavior, but I don't think it's appropriate to identify such people here. I'm not in any way claiming to know what fraction of the string theory community thinks what.

I don't think that your claim that Lubos's blog and his attacks on critics of string theory is, like his sexual behavior, purely part of his private life, and not part of his professional life, is in any sense supportable. I doubt he feels that way, for one thing. The whole question of what role blogs play in the professional activities of scientists is a complicated and interesting one. I see this blog as part of my professional activity, if you ask Jacques Distler, I suspect he sees his the same way (although he sees mine differently…).

As for what I think Harvard or his colleagues should do about Lubos, let me make clear that I complained to them specifically about his offer to pay people to write bad reviews of my book (and this offer seems to recently have been taken down). For the rest, all I'll say is that if one of my colleagues in my department was behaving the way he is and I was aware of it, he'd get an earful from me about what he was doing, and if he kept doing it, I would take steps to make sure that the targets of his behavior knew I did not support what he was doing.

62. **John A**
September 3, 2006

Lubos' disgraceful review of Lee Smolin's book has been removed. I wonder how long it will be before a) Lubos posts yet another review and b) Amazon gets tired of hosting him.

63. **CapitalistImperialistPig**
September 3, 2006

Aaron – *"Intervene"?*

This is silly. Lubos isn't a child. There's no big string theory boss who tells us all what to do. Frankly, I don't see why anyone should stop him. I don't like what he has to say most of the time, but he's got every right to say it.

Grow up and ignore him. And stop blaming an entire community for your inability to do so.

Lubos has every right to engage in a campaign of libel and personal vilification? I have my doubts. Since Peter has made himself a public figure in this debate, winning a libel suit might be difficult, but Lubos has been extreme enough that it might be possible. It is possible that Harvard is liable for any damages too, since they give him the platform, let him use their logo on his web site, etc.

Maybe you should check it out Peter. The publicity should be great for your book. And Harvard has really deep pockets if you win!

Is ignoring and permitting a crime itself criminal? I'm not sure, but I'm sure it isn't innocent.

64. **woit**
September 3, 2006

CIP,

I'm not the litigious sort, generally of the opinion that if one finds oneself hiring lawyers for anything other than routine paperwork, one has made a bad mistake of one kind or another. As for suing Lubos, my father was a lawyer during the early part of his career, and one piece of wisdom he imparted to his sons was "never sue anyone who doesn't have any money". On the question of my extremely wealthy alma mater, I seriously doubt that, if push came to shove, the administration there would support illegal behavior by one of its faculty members that might be tied to the institution. The fact that Lubos removed the offer that I complained to them about may be evidence for this. I kind of doubt that he did this unprompted.

65. **Aaron Bergman**
September 3, 2006

Lubos has every right to engage in a campaign of libel and personal vilification?

Libel has a very specific legal meaning. Being a dick is not included, the last I checked. I don't think much of the internet would survive if it were.

66. **woit**
September 3, 2006

Aaron,

My layman's understanding is that, legally, libel is the act of writing and publishing untrue things with reckless disregard for whether or not they are true, for the purpose of defaming someone's reputation. It appears to me that there is a good argument that Lubos's reviews of my book and Lee's on Amazon are examples that fit the definition.

I suspect though, that there is an insanity defense against libel accusations, and it appears that Lubos would have no trouble finding colleagues who would testify on his behalf.

67. **David**
September 3, 2006

The Graduate,
I don't think it's fair to compare an evolutionary biologist to LM. Remember evolution has 150 years of data supporting it, while string theory, at present, has zip. Michael Shermer's "Why Darwin Matters" clearly points out the differences.
Best Wishes.

68. **Gina**
September 3, 2006

In my opinion none of the strong sentences that Peter quoted
from Lubos' amazon critique:

"Lee reveals his intense hostility against all of modern physics", "Lee proposes a truly radical thesis that it is wrong for mathematics to play a crucial role in theoretical physics", "He also denies the difference between renormalizable field theories and the rest", "one of his rules says that the conclusions must be accepted by everyone if their author is a person of good faith"

Can be regarded as libel. (I am not a legal expert though.) As I said, I even did not find his Amazon critique inappropriate unlike some of his posting on this blog. (And some comments on him do sound like libel.)

I cannot understand the obsession with Lubos. It certainly does not support in any way the case you are trying to make, Peter. (OK maybe I can undesrtand it. Still I think it does not support the case you are trying to make and the quality of this blog.)

On the other hand, Stefan cncensus is good and his topic 2 looks like a great topic.

(I have a wonderful romantic theory though based on maximum nicyhood principle to explain why for Lubos who gave up old strings with his home, family, neighborhood and homeland for the sake of new strings in string theory, his vested interest in these string theory is unusually high which explains everything.)

69. **TheGraduate**
September 3, 2006

To David:

Please re-read my comment.

I wasn't saying either string theorists or evolutionary theorists are ultimately wrong. All I said was supercilious dismissal of those that disagree with you is a tactic that should be beneath every serious scientist … unfortunately, it's not.

70. **Benni**
September 3, 2006

peter your review of lees book was deleted

71. **King Ray**
September 3, 2006

I think that if Lubos keeps spending all his time blogging and reviewing other people's work, instead of doing research as he is being paid to do, he is going to perish academically. If he goofed off that much at a real job, he would be laid off for lack of productivity.

72. **David**
September 4, 2006

The Graduate,
Sorry, I must have been unclear. What I meant was that the biologists aren't taking the point of view you suggest but rather the ID/creationists are misrepresenting what science is and often the known facts as well. The public can often be fooled about technical issues and people in science don't know everything either. Further, misrepresentation is, in my view, what LM is often about.

73. **MathPhys**
September 4, 2006

Thierry,

I thought you left us a long time ago. I hope all is well.

74. **Arun**
September 4, 2006

I'm beginning to be confused about who represents what. Lubos is a charming fellow, we're told, though his blog output, which is all that I have available to make a judgement, doesn't reveal any hint of charm. That means Lubos's own blog does not represent himself, unless when we say "Lubos is charming" we really mean "Lubos is charming, except when he is obnoxious". If on-line activities do not represent a person, then no wonder no one cares about whether various tactics used are ethical or unethical, because they do not represent the person.

75. **Roger Schlafly**
September 4, 2006

Peter, please don't get paranoid like Lubos. You don't know whether Lubos got your review deleted. It could have been other string theorists, who may or may not have been reading his blog. With you and Lubos publicizing this deletion war, others may get into the act.

76. **Eli Rabett**
September 4, 2006

It is very simple, when Motl goes up for tenure send copies of his very best to the Harvard Corporation.

77. **Christine**
September 4, 2006

Motl's most impressive record of bad behavior is probably this one (see the comment's section), attacking a quantum gravity student in the occasion of her grandmother's death.

Peter Woit, please do forget about this tragic personage. I know this theme can be quite entertraining for many, but I think it is enough for some time already.

Best wishes,
Christine

78. **woit**
September 4, 2006

Roger,

Sure, you're right, there's no way to know. But, mysteriously, in the past, Lubo's Amazon reviews have often appeared with an almost simultaneous large number of "helpful" votes. Maybe he has a large number of people who agree with him and closely follow his activities, maybe he's pretty adept at manipulating Amazon's system.

Christine,

I pretty much do ignore what Lubos writes on his and other blogs (the example you gave of grotesque behavior is far from the only such), but the (succesful) attempt to maniupulate Amazon rankings is kind of different and seemed worth pointing out to people.

79. **David**
September 5, 2006

Christine,
While, of course, Lubos was nasty in the example you gave he can be, and often is, much worse than that. While by searching archives, you could find these worse examples (Mahndisa points one out in your example), I suggest you save yourself the time. Just watch The Reference Frame from time to time and you'll certainly see more of these. BTW I'm sure Mahndisa appreciated your comment. I also agree with Peter about the Amazon rankings. There LM is using misrepresentation and misinformation to try to keep information from as many people as possible. This is not what one expects from a Harvard Asst. Professor.
Best Wishes.

80. **Christine**
September 5, 2006

Then if this post is to be really useful for the general public, I suggest you make it appear as on of the first links when one searches google on LM.

Best wishes,
Christine

81. **D R Lunsford**
September 5, 2006

This is very interesting:

http://en.wikipedia.org/wiki/Right_Wing_Authoritarianism

One can easily see evidence of this behavior point by point in LM and his ilk's behavior (see "Significant Correlations").

BTW, a similar situation to the particle physics is beginning to develop around Big Bang, dark matter and black holes in astrophysics.

83. **Who**
September 10, 2006

BTW, a similar situation to the particle physics is beginning to develop around Big Bang, dark matter and black holes in astrophysics.

Anonymous, I don't understand what you are saying. Could you be a bit more specific?

84. **Who**
September 10, 2006

The last amazon sales rankings on this thread on 2 September over a week ago, when it looked like this:

**as of today 12:15 pacific, or 3:15 PM your time, the Amazon general physics bestseller list was

#1 TwP
#2 Elegant Universe by Brian Greene
#3 NEW
#4 Douglas Giancoli college physics text
#5 a Stephen Hawking book**

http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

As of 9:30 AM pacific this morning 10 September the lineup was roughly the same. Some titles added for comparison

#1 TwP
#2 NEW
#3 Elegant Universe (Greene)
#4 Douglas Giancoli college physics text
#7 BHoT (Hawking)
#10 RtR (Penrose)
#27 Cosmic Landscape…Illusion of Intelligent Design (Susskind)
#28 Hyperspace…Parallel Universes, Time Warps… (Kaku)
#30 Warped Passages (Randall)

http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

85. **dan**
September 11, 2006

Hello Peter and Lee,

Where would be the best place to discuss Lubos' review of your books (NEW, TROUBLE) from amazon, and your response to Lubos' criticism?

Issues to consider:
Is Lubos criticism of NEW/TRouble substantitve?
Does he offer strong counter-arguments?
Is Lubos factually correct in his criticism?
What are some counter-arguments to Lubos' claims?

For example on Smolin's & Woits book Lubos claims
"For example, he dedicates dozens of pages to speculations about the divergent amplitudes at finite orders of the perturbation theory – amplitudes that have been proven to be finite. "

Is Lubos factually 100% correct, and if so, then Smolin & Woit would be incorrect?

Another Lubos critique of Woit and Smolin

"There are also frequently repeated speculations that string theory and M-theory don't exist and many other similar "ideas", together with the most popular myth that string theory can't be experimentally tested. Neither of these things is supported by any results in the scientific literature"

Incidentally Lee, if you are reading this Lubos says

"The interactions between Lee Smolin and mainstream physicists are interesting. Lee often visits us. We smile at each other and Lee is being politely explained why his newest theories can't really work. Lee says that he understands these arguments. Then he returns to a conference or a journalist and repeats that all of his theories have been perfectly proven, while offering even more unusual theories. The newest theory says that the neutrinos are octopi swimming in the spin network. Believe me, we like him but it is not always easy to take him seriously."

Is Lubos factually correct about Lee? Has the unnamed Harvard string faculty taken the time to explain to Lee why he's wrong, and Lee ignores it?

86. **woit**
September 12, 2006

dan,

If you want to discuss Lubos's views, please do it at his blog. I won't be participating, because it would be a huge waste of time, and, in any case, I'm banned from posting any comments on his site. In the past he has deleted anything I've written there (which should give you some idea of how interested he is in discussion with anyone who disagrees with him and knows what he talking about).

As for the points you bring up, Lubos is just lying. Superstring amplitudes have not been proven to be finite above two-loops, and string theory cannot be experimentally tested. From past experience, there's no point in trying to discuss such questions with him, he's a pure ideologue with no interest in what might actually be true. I've written a posting here responding to his absurd and dishonest "review" of my book, but am not going to spend more time on this.

I definitely agree with commenters who have complained that there is too much Lubos discussion here. Please don't submit more unless there is something extremely new and interesting to be said on the subject.

Hold Fire! This Epic Vessel Has Only Just Set Sail…

September 3, 2006
Categories: Not Even Wrong: The Book

The August 25th issue of the Times Higher Education Supplement has a feature article by Leonard Susskind about my book and Lee Smolin's entitled "Hold Fire! This Epic Vessel Has Only Just Set Sail…" (unfortunately only available to subscribers). The bulk of it consists of two parts: an extended analogy designed to show what he thinks the current state of string theory is, and a long ad hominem argument about why people shouldn't listen to me and Smolin.

In Susskind's analogy, the current state of particle physics is like the 15th century European view of the world, aware that there was a large Atlantic ocean out there, but with no idea of what lay beyond it. String theorists are like ship-builders, building vessels that intrepid string theorist explorers will courageously pilot out into the risky unknown. I'm a "Chicken Little" figure, telling people that if they do this they'll fall off the end of the earth. Smolin is a builder of ships that don't float.

Susskind mostly ignores the contents of my book and Smolin's, which, in his analogy, both provide detailed analyses of the history and current state of a shipbuilding project, which, despite massive investment, has led only to a huge, overweight vessel which can't even get out of the harbor. Both of us are arguing that this project needs to be restructured and largely abandoned, and investigation of other ship designs supported and encouraged.

The part of Susskind's long ad hominem argument that attacks Smolin is just stupid, vicious, and offensive and I won't repeat it here. Given how limited the successes of string theory have been, his attacks on Smolin's work as ideas that are not working out is completely indefensible.

Susskind devotes a surprisingly long part of the article to discussing me and my career, and I have to admit that what he has to say is, while less than completely accurate, far more sympathetic than I would ever have suspected, especially given the many harsh things I've had to say about him here and elsewhere. He describes me as "one of those Princeton mavericks, who had the guts to work on other questions, in particular modern nuclear physics ", and criticizes (during the mid-eighties) "an unusual degree of hubris in Princeton, a smug, arrogant dismissal of any ideas that didn't fit the string theory agenda."

Susskind's interpretation of my early career is sympathetic, but a bit off. I actually left Princeton in the summer of 1984, just before the string theory "revolution" hit. I spent the early years of the era of string theory dominance at Stony Brook, with limited contact with what was going on in Princeton. Susskind doesn't quite directly say so, but he strongly implies that my criticisms of string theory are motivated by bitterness at not being able to have a successful career in a physics department due to the domination of string theory. What actually happened is that in 1987, after my postdoc at Stony Brook, I did find myself unemployed, and at the time wasn't too happy that string theory dominance was one of several reasons no one was much interested in hiring me. I spent a year as an unpaid visitor in the Harvard physics department and got a part-time job teaching calculus as an adjunct instructor at Tufts. During this year I had plenty to live on, but did face an uncertain future and wasn't so happy about it. People at Harvard and at Tufts were quite helpful, and in the spring I was offered an excellent job for the next year at MSRI, the math institute in Berkeley. After that I came to Columbia, and from my time at MSRI on, I have no complaints whatsoever about my career, feeling I've probably done better than I deserved, living in the places I most want to live, working with excellent colleagues under good conditions. So, as far as the embittered part of my career goes, it was pretty much limited to a short period of about a year, almost 20 years ago, during 1987 and 1988.

Susskind ends his discussion of me with something positive:

But Woit is correct to remind us how important diversity and humility are in the face of the vast sea of ignorance.

and ends his review by quoting ‘t Hooft as a sceptical critic of string theory, finishing with:

This leads ‘t Hooft to another important point: diversity of viewpoints is to be cherished, not suppressed. This is something that Woit and Smolin have properly reminded us of, and string theorists should not be allowed to forget it.

So, all in all I've quite mixed feelings about this piece. Susskind's attack on Smolin is highly reprehensible, and the way it ignores discussion of real issues, concentrating on dubious analogies and ad hominem argument, is disappointing. But, I have to admit that in his more than charitable discussion of one of his fiercest critics he shows a capability for gentlemanly behavior I wouldn't have suspected (and wish he had shown Smolin), and, in the end he recognizes and admits that Smolin and I are making an important point that string theorists need to take note of.

Update: Several people have pointed out that the same issue of the Times Higher Education Supplement also includes a quite positive review of Not Even Wrong by Philip Anderson. On the whole it's accurate, although I think Anderson neglects to mention that, lacking experimental results, I'm much more of a believer in the possibility of using mathematics to make progress in particle theory than he is. There are quotes from and discussion of the review at a new blog here.

Update: The THES in a later issue has a letter about Susskind's article, which correctly points out that answering criticisms of string theory by claiming they come from a "mid-level theoretical physicist" or a member of the "Chicken Little Society", didn't address the fact that in the same issue these criticisms were coming from an extremely distinguished theorist and Nobel Laureate (Anderson). The letter writer's reaction to Susskind's article was:

Moreover, Susskind's defence of string theory not only failed to address Anderson's key criticism of string theorists – namely that their theorising is not grounded "on the acute observation of nature" – but rather reinforced this impression.

Comments

1. **JC**
   September 3, 2006

   Peter,

   How big was string theory at Harvard around 1987-88?

   When did the string people take over Harvard's particle theory group?

2. **Ebgert**
   September 3, 2006

   > Susskind's attack on Smolin is highly represensible

   I think that's a typo.

   Is it fair to say that Susskind is attacking Smolin more than you because Smolin is offering a competitor to string theory, while you aren't?

3. **Boaz**
September 3, 2006

I haven't read the article, but I wonder if Susskind's ship metaphor comes from the following quote by V. Weisskopf (if so, its a pretty bold move to try to put string theorists into the role of the ship builders!):

There are three kinds of physicists, as we know, namely the machine builders, the experimental physicists, and the theoretical physicists. If we compare those three classes, we find that the machine builders are the most important ones, because if they were not there, we could not get to this small-scale region. If we compare this with the discovery of America, then, I would say, the machine builders correspond to the captains and ship builders who really developed the techniques at that time. The experimentalists were those fellows on the ships that sailed to the other side of the world and then jumped upon the new islands and just wrote down what they saw. The theoretical physicists are those fellows who stayed back in Madrid and told Columbus that he was going to land in India.

September 3, 2006

I ordered the two books by Woit and Smolin from B&N about a week ago. They arrived by UPS about 48 hours later. I started reading them two days ago. Very hard to put down. I highly recommend both books. The effect is to invigorate me to learn more about string theory and the alternatives.

So far my only complaint about Woit's book is that in his description of QM he suggests that it is not possible to use vectors to represent quantum states, but that spinors are required. This is commonly believed but it is not true. The density matrix representation of a quantum state can be written as a combination of scalars and vectors (i.e. multivectors of Clifford algebra) with no spinors needed. One can then split the density matrix into things that act like spinors by pre and post multiplying by a constant "vacuum" spinor.

This was what Julian Schwinger used as the foundation of QM in his classic book "Quantum Kinematics and Dynamics". While Schwinger did not write his book from a multivector point of view, the application will be obvious to any Clifford algebraist who reads it. Also David Hestenes has a geometric theory of QM that is written entirely in Clifford algebra and hence has no spinors.

Smolin's book is written towards a more general audience and is quite sympathetic to string theory. I've already got a half dozen margin notes in each and I'm not 1/3 through.

5. **Benni**
September 3, 2006

I have asked Suesskind in munich in person, if he thinks that alternatives should be considered when stringtheory is in this devastative state.
He said: "Of course. If you have any alternatives to this landscape, tell us of it."
He also said that the landscape picture is unwanted and unlikely but if stringtheory is true it might be the only thing they have.

I think this was honest.
To say that alternatives must be considered amlostly includes that he admitts stringtheory might be wrong.

6. **MathPhys**
September 3, 2006

Re Peter's outline of his career, I wish to point out to those who didn't live through the early 80's that these were very bleak years for young people looking for jobs in theoretical high energy physics, particularly if they wished to stay at major universities in the US AND were not high achieving string theorists.

I personally know of a number of PhD graduates from Harvard and Princeton from that time, at least one of whom was a student of, and strongly supported by Witten, who couldn't find positions, and eventually quit science, and these were all people who would have very easily become full professor, at good universities, within 10 years in the 60's.

What I want to say is that, it's not like Peter has failed. In fact, relatively speaking, he's one of the very few academic survivors of that era (yours truly included :-)).

7. **woit**
September 3, 2006

JC,

It's been a long time, but from what I remember there were fewer people there working on string theory than there are now, especially at the senior level.

Ebgert,

Thanks for mentioning the typo, fixed.

No idea what Susskind's motivation is. He has critical things to say about Princeton, maybe that's part of the story in some obscure way. Perhaps he sees me as the enemy of his enemy (Gross and Witten).

8. **John Baez**
September 4, 2006

JC wrote:

> How big was string theory at Harvard around 1987-88?

It was big. I was a math postdoc at Yale then, coming from a PhD at MIT, and string theory was all the rage both in physics and in math at all these schools. In math, people were excited about conformal field theory and topological quantum field theory. In physics, I seem to recall that the heterotic string had everyone all agog.

Of course, there probably weren't as many tenured string theorists in the physics department at Harvard back then as there are now – there hadn't been time for the excitment to translate into hires.

9. **Thomas Larsson**
September 4, 2006

Susskind should have credit for one thing: admitting that ST has very little or no chance of ever saying anything definite about our universe – this is the essence of the anthropic principle, isn't it? In a way, Susskind's anthropism is dual to Friedan's defection.

Admitting defeat is not easy, and perhaps the anthropic phase was psychologically inevitable. According to Stephen Hsu, Susskind now "said very clearly that string theory might be wrong, but that we could still learn from it." A few years ago, a senior string theorists contemplating that ST might be wrong would have been notable.

10. **Jason**
    September 4, 2006

    Dude, you have too much free time.

11. **alejandro riveroi**
    September 4, 2006

    does the analogy mentions archimedes?

12. **Ebgert**
    September 4, 2006

    Alejandro,

    It doesn't. You can read it online if you get a "free 14 day trial". I used to be suspicious of these things because they might want a credit card number which they start charging if you don't cancel. Many web sites will make it a difficult task to cancel the "subscription". In this case they just ask for a name and email address and then verify the email address and then give you access.

    You have to opt out of the spam, though.

13. **MathPhys**
    September 4, 2006

    String theory was big at Harvard in 1987–88, not because the older, tenured people, such as S Coleman, H Georgi and S Glashow, worked on it (they never did), but because the younger untenured (Harvard Society Fellows) types did. There were L Alvarez-Gaume, P Ginsparg and C Vafa. There were also even younger people like G Moore, and a number of others. Haravard was definitely a hotbed of string theory then.

14. **Arun**
    September 4, 2006

    String theorists are shipbuilders who believe they have proved that ships must have 26 masts.

15. **comentator**
    September 4, 2006

    good comparison to what String theorists are now brought by boaz of the famous remark by V.Weisskopf

16. **Doormat**
    September 4, 2006

    I'm surprised you didn't mention (by maybe I can't read or something) that the same issue of the Times Higher carried a review of NEW (see pages 22-23) which was *very* much in agreement with the main points of the book. Worth a read if your in the UK…

17. **King Ray**
    September 4, 2006

    Peter,

    I received both your and Lee's books from Amazon recently and haven't started reading them yet, as I am finishing up a novel. I was wondering if you had an opinion on which book would be best to read first?

18. **RA**
    September 4, 2006

    Of course, this being your blog and all I can see why you'd interpret Susskind's article as more 'favorable' to you and less so to Smolin, but I have to ask how you can see this an not an insult:

    "Woit seems to not realise (or not care) that
    this would rob the subject of all the romance of exploration and leave it
    to the dullest plodders. The brightest, bravest and boldest young
    explorers want to go where no one else has gone before. But Woit is
    correct to remind us how important diversity and humility are in the face
    of the vast sea of ignorance."

    Do you not realize that he's calling you a 'dull plodder' who needs a good dose of humility?

    Perhaps your misreading of Susskind's article is very indicative of your general ability to understand other ideas and concepts. In reading the complete article it is pretty clear that Susskind is kinder in his descriptions of Smolin than he is of you. I realize it is painful to read criticism and to try to make the best of it, but to present Susskind's appraisals as you do seems pretty dishonest, if only to yourself.

19. **Who**
    September 4, 2006

    Doormat, by whom was the recent review of NEW on pages 22-23 of the 25 August (London) Times Higher?

    So far I am reluctant to sign up for the two-week trial which Egbert suggests at
    http://www.thes.co.uk/current_edition/story.aspx?story_id=2032023

    But apparently doing so would permit one to read not only the Susskind blarney-piece but also an actual review.

It's possible that Susskind's colorful talk of others' books boosted sales of his own, which has risen abruptly and is currently #6 on amazon general physics bestseller list. A week or two ago I saw it bouncing around in the #40-#85 neighborhood.

Arun, I was laughing aloud at your comment:

String theorists are shipbuilders who believe they have proved that ships must have 26 masts.

20. **a**
September 4, 2006

Who,

It isn't funny, it's quite tragic. So a better nautical analogy is the Titanic (an unsinkable ship on its maiden voyage designed by the best people, carrying most people's blessings and endorsements, admiration and praise).

21. **TheGraduate**
September 4, 2006

(Thank you Egbert for pointing out that a 14-day subscription was enough to gain access to the article. I had not previously wanted to comment on something I had not read.)

This article had too much ad hominem for my tastes. The author often refers to credentials and not to arguments.

So for him it's a problem that "in the blogosphere everyone is an expert, everyone has an opinion and all opinions are equal." To me this is just normal democracy.

Every one of his critiques of string theory's critics had a ranking attached:

1. Journalists with "no more than high-school physics"

2. Woit who is "a computer administrator" and an "untenured mathematics instructor"

3. Smolin, the "mid-level theoretical physicist"

4. t'Hooft is the "most renowned physicist of our age" which is pretty high praise but I did think it was odd to omit that t'Hooft had won the Nobel Prize. Also his discussion of what Dr t'Hooft disagreed with suggested he wasn't really a critic.

The piece is even organized in order of increasing credentials.

I also didn't think the name calling was helpful: "Chicken-Little" and "Don Quixote"

22. **MoveOnOrStayBehind**
September 4, 2006

>String theorists are shipbuilders who believe they have proved that ships must have 26 masts.

They are those who believe that a ship must swim. Others propose to build alternative ships out of stones…despite lots of applause from the blogosphere's experts, those have not left off, and this for good reasons. The story Susskind writes is quite accurate, with regard to science as well as to the people involved.

23. **TheGraduate**
September 4, 2006

Peter,

"Loose ends and Gordian knots of the string cult" by Philip Anderson is in the same issue of Higher Education

I don't know if you've seen it before. It's pretty favourable. I would almost call it a resounding endorsement.

http://www.thes.co.uk/search/story.aspx?story_id=2032027

24. **a**
September 4, 2006

To extend the Titanic analogy, the stringy landscape (10^500 vacuua solutions) is the ice berg straight ahead.

The Captain's critics want to immediately put the ship into reverse, to slow it down (reducing hype) and reduce the risks of an embarrassing disaster. Critics also demand the full filling of all lifeboats (alternative theories) in good time.

But the Captain thinks this is unnecessary (since the ship is unsinkable) and that starting to fill lifeboats will seem like defeatism, and may cause panic problems.

The Captain on balance decides that changing course very slightly will prevent disaster, while giving the passengers a spectacular glimpse of the ice berg (landscape) in passing …

25. **A**
September 4, 2006

Susskind makes nice analogies but does not address physics: string theory turned out to predict 10^500 different things. This is why it is now seen as a metaphysical speculation; this is why people in Princeton and elsewhere initially hoped in mono-vacuism or, at least, in oli-vacuism.

26. **MathPhys**
September 4, 2006

RA,
I haven't read Susskind's article yet, but when I read the passage that you just quoted, my interpretation agrees with that of Woit rather than with yours.

27. **TheGraduate**

September 4, 2006

RA,
I have read the entire article and my interpretation is also closer to Woit than yours.

28. **Carl**
September 4, 2006

I signed up for the 14 day free trial. Arguments that are intended to be read by non specialists always descend first to claims about what "4 out of 5 dentists" believe, and then to ad hominem attacks on the expertise of the other side. The human condition is that 99.9% of what any human knows he knows only on the basis of what he has been told.

29. **nitin**
September 4, 2006

I have something written about Philip Anderson's review of NEW on my blog ;)

30. **woit**
September 4, 2006

Doormath, TheGraduate, Nitin,

Thanks for pointing out the Anderson review. I wasn't aware of it, someone had just mentioned to me the Susskind review, and I didn't notice the Anderson one. Anderson is a well-known string theory skeptic, so I'm not suprised he has positive things to say about the book. I met him when I was a student at Princeton and have corresponded with him about this topic.

RA,

You've removed that quote from context. Susskind was noting that I have positive things to say about string theory as a dual to gauge theory and a possible way of solving QCD, while claiming it doesn't work as an idea about unification. He was correctly saying that string theory wouldn't continue to get people as excited if that's all it is. He's missing the point that I'm all in favor of people pursuing ideas about unification, just not ones that don't work.

I have no doubt that he thinks some rather negative things about me, with "dull plodder" the least of it. I was in no way claiming that he's a fan…

King Ray,

Kind of depends on your background, although for most people who don't know quite a bit about the subject, Smolin's
may be a better starting place, since it explains more about the basics of string theory. One exception would be if you're a mathematician, since in that case my book should do a better job of giving you the background of the subject.

31. **Who**
September 4, 2006

that is a thoughtful blog, nitin. I just spent a while musing at it
http://commeappeleduneant.blogspot.com/

32. **King Ray**
September 4, 2006

Peter, thanks for the advice. I have sufficient math and physics background, so that is not an issue.

33. **woit**
September 4, 2006

King Ray,

OK, in that case it doesn't matter much which you start with, I think both books reinforce each other, with two different perspectives that lead to similar conclusions. Mine is shorter, but it's more dense and a few parts are a significantly more technical than Lee's, so may require more concentration to follow. Kind of depends what you're in the mood for…

34. **D R Lunsford**
September 5, 2006

I thought the Anderson review was right on the money, and was gratified to see that Peter is being taken seriously among real physicists at the highest level. Thank God this business is almost over.

I didn't detect any bias from Anderson against math, rather, against second-rate mathematicians taking over physics departments and thus displacing what might be first-class physicists. I've always felt that string theory is a sort of revenge wrought on physics by matheists who can't do the problems in Resnick and Halliday 🙂

-drl

35. **D R Lunsford**
September 5, 2006

Susskind's diatribe is filled with the usual self-congratulatory, unctuous sarcasm one finds in these people, the narcisstic self-absorption of the fey dilettante. I remember Gell-Mann giving a lecture about string theory years ago, in the late 80s, during which he managed to insult his hosts before everyones' coffee was poured (the UMd Physics and Astrophysics Dept. whom he called "half-asstrophysicists"). The article is much in that manner. And what he says about Peter is anything but gentlemanly – rather, highly condescending and completely ad-hominem. A truly repulsive read.

-drl

36. **King Ray**
September 5, 2006

Peter, thanks, I think I'll read yours first since I've been eagerly awaiting reading it for months. Don't let Lubos get you down; he's only helping your cause and proving your point.

37. **Chris W.**
September 5, 2006

The following quote seems apposite. I'll leave to the reader to determine its source:

> *If in this book harsh words are spoken about some of the greatest among the intellectual leaders of mankind, my motive is not, I hope, the wish to belittle them. It springs rather from my conviction that, if our civilization is to survive, we must break with the habit of deference to great men. Great men may make great mistakes; and as the book tries to show, some of the greatest leaders of the past supported the perennial attack on freedom and reason. Their influence, too rarely challenged, continues to mislead those on whose defence civilization depends, and to divide them. The responsibility of this tragic and possibly fatal division becomes ours if we hesitate to be outspoken in our criticism of what admittedly is a part of our intellectual heritage. By reluctance to criticize some of it, we may help to destroy it all.*

38. **MathPhys**
September 5, 2006

The Open Society and Its Enemies, Karl Popper.

PS Oh, the miracle of google.

39. **hack**
September 5, 2006

Well if we're gonna go with this mideaval shipbuilding analogy, we must cast Witten as the brilliant mathematician who realized, by gluing opposite edges together, the flat earth model becomes a torus, thereby elegantly solving the age old problem of what kept all the water in the ocean from draining over the edges. Toroidal earth theory has become all the rage in educated circles because of its mathematical elegance. Captain Susskind, who calls himself the father of torus theory because he co-invented the donut during his earlier career as a pastry chef, wants to prove the theory by sailing due north, and coming back home from the south. Lee Smolin is a heretic who thinks it's not such a good idea to send all the ships in the same direction. Lubos is Susskind's pet monkey, trained to fling dung at his enemies. There, now we have a proper analogy.

40. **LDM**
September 5, 2006

It would be interesting to know if Susskind was this way *before* string theory and his subsequent fame. If the theory is good, it can stand on its own merits and he certainly does not need to belittle its detractors. It is sufficient to point out the weakness, if any, in their arguments.

Also, NEW, page 69, there is the statement that the electromagnetic force is carried by the photon…
Of course, this is the way QFT describes it…as long as you make it clear it is the exchange of *virtual photons*, where all 4 polarizations are needed, and not real photons where only 2 are used…
Granted, the layperson probably does not care about this distinction, but a physics student pondering how it is an exchange of (virtual) particles can create an attractive force might.

41. **Peter Woit**
September 5, 2006

LDM,

There's much that is imprecise in the book. When writing something like this, at each point one has to decide whether to say something imprecise, or to tell a more accurate and more detailed version of the story. Telling the more accurate version requires writing something longer, and one has to decide if it's worth the extra demands on the attention of the reader to get it right. This is one case where going into more detail would have taken me too far afield.

It seems to me that ad hominem argument is what one resorts to when one doesn't have an argument on the facts, and I would claim this is what is going on here. If I had my facts about string theory wrong I'd have heard quite a lot about it from string theorists, their silence on this issue is significant.

42. **Anon**
September 6, 2006

Susskind was famous long before string theory became popular in 1984/85. He made important contributions to all branches of particle physics, from lattice gauge theory to …

It is a testament to the power of the internets that he is now best known as the person Peter Woit characterizes as an enemy of science.

"If I had my facts about string theory wrong I'd have heard quite a lot about it from string theorists, their silence on this issue is significant."

Maybe, aside from Lubos, the rest of them are just too polite.

43. **Peter Woit**
September 6, 2006

Anon,

Yes, maybe what I have to say about string theory is wrong and string theorists (other than Lubos), are just too polite to point this out. It's also possible that string theorists (other than Lubos) don't discuss the predictions string theory makes because they're just too modest.

44. **Anonymous Coward from UCSB**
September 6, 2006

`Yes, maybe what I have to say about string theory is wrong and string theorists (other than Lubos), are just too polite to point this out.'

OK, Peter, just this once. From your comment on the NC thread:

`As for the single bit of info here, I remember a time when string theorists were going on about no-go theorems that showed that you couldn't have string theory in deSitter space, i.e. with a positive cosmological constant. When a positive cosmological constant was found, they seem to have come up with a way of dealing with that problem. If the spatial curvature comes out positive, I'm sure they'll come up with something.'

The Maldacena-Nunez no-go theorem, hep-th/0007018, was specifically for supergravity backgrounds without branes or string corrections. In fact, it was already well-known (beginning with Becker & Becker, hep-th/9605053) that such corrections allow much more general solutions. The MN theorem was well-known at the time not to be relevant, and in fact the BB paper is the ancestor of most stabilized string vacuum constructions.

And, you have your chronology wrong: the cc was well-known when the MN paper appeared. As usual, you have chosen to misconstrue what you know in the most negative possible way.

As to why more string theorists do not post (or do so anonymously) I suggest that it is a matter of time: it is much more time-consuming to actually do research than to sit back and criticize the efforts of others.

45. **woit**
September 6, 2006

AC from SB,

"you have your chronology wrong"

I don't see where I said anything about the Maldacena-Nunez paper, that's not what I was referring to. And, by the way, the comment was largely a sarcastic joke, probably not worth trying to explain it to you though.

Thanks for showing us that all string theorists other than Lubos are not just too polite. I'm kind of missing your point though about how serious string theorists are so busy doing important research into the landscape that they can't type in their actual e-mail addresses (the one you left "woitisabozo@physics.ucsb.edu" was very clever, I guess it's right that string theorists are just smarter than the rest of us).

46. **Anonymous Coward from UCSB**
September 7, 2006

Please do tell us which no-go theorems you were referring to. And it is a pretty sad escape to claim to have been joking.

47. **amused**
September 7, 2006

Susskind's article is a blast. "Could it really be that a secret cabal of scientific priests have plotted to overthrow the rules of good scientific method and have absconded with the nation's scientific funding?" Yes they have, the bastards ;). But underneath the colourful ship-building and exploration analogies it's just the same tired old line that string theorists always take in response to critics: "Any physicist with an ounce of ambition and adventure should be directly working toward discovering a glorious Theory of Everything, and string theory is the best (or only) hope for this at present." This is supposed to justify the continued pursuit of string theory irregardless of what it requires (e.g. changing the definition of science) as well as its continued domination of the formal theory end of particle physics.

The main issue for some of us critics is not whether or not string theory is a waste of time, but whether people should have no option but to work on it if they want a career in formal hep theory. We don't have anything against people trying to construct an "epic ship" if they want to; in fact we wish them best of luck. But there is still much of interest that can and should be done in "near coast exploration" using currently developed ships; it's a mistake to just drop all of this and concentrate exclusively on building an epic vessel. We are certainly interested in the prospect of finding the New Land, but suspect that there are other ways to get to there besides sailing straight out into the ocean. E.g., by gradually and carefully pushing out the boundaries of near coast exploration it may be possible to find a series of landmasses that will allow us to get to the New Land in a series of steps. The ship-building innovations required sail from one landmass to the next might be more within our capacities than those required for an ocean-crossing "epic vessel".
(Some of us suspect that not only may it be possible to reach the New Land in this way but it will also happen sooner than by epic ship across the ocean. But we don't doubt that if and when the epic ship eventually arrives they'll trumpet it with great fanfare and proclaim themselves the true discoverers…)

In any case, isn't it sensible to allow near coast exploration to continue while the epic ship project is underway? That way, if the ship ends up ensconced in a multiverse/flotilla of floating icebergs there will still be hope of eventually reaching the New Land by other ways, even if the epic ship-builders themselves prefer to give up and simply redefine "New Land" to be an iceberg flotilla.

(As an aside, we find it most amusing when the epic ship-builders use their constructs with great pride to (attempt to) give low-resolution mappings of near coast areas in already-known regions, pretending to really care about these areas while at the same time being totally uninterested in and indifferent to breakthroughs in traditional ship building which open the possibility of exact mappings…)

48. **Peter Woit**
September 7, 2006

AC from UCSB,

Maldacena and Nunez were not the first ones to point out this problem.

Not much point in trying to explain a joke to someone who doesn't realize that it's hilarious having one of the leading figures in theoretical physics giving a series of prominent lectures about a theory of everything that is nearly infinitely complicated but only predicts the sign of one quantity (and acknowledges that there's probably a way around that, given that other ways of populating the landscape can likely be found).

49. **Anonymous Coward from UCSB**
September 7, 2006

Since you can't cite any references, and are changing the subject, I assume that you are conceding the original point: you created a fictitious chronology out of your own imagination to make string theorists look bad, when in fact the chronology was that reverse of what you claimed. String theorists were not in any sense `going on about de Sitter no go theorems' before the cc was seen.

You were right about one thing, calling you a `bozo' was inappropropriate. But `one who distorts the facts to make others look bad' is just so clumsy.

Your `joke' is no different from the vitriol that you pour on string theory every day, and insulting people and then claiming to be joking is not at all an original strategy, it is classic behavior.

I think we are finished with this subject.

50. **woit**
September 7, 2006

AC from UCSB,

The history of the no-go theorems you're talking about goes back to the mid-eighties. I'm not going to waste my time getting together references and arguing about their significance with someone who has nothing better to do than to spend his time insulting me in a cowardly fashion from behind the cloak of anonymity

You're the one who is evading the point here, that Landscape research is a really bad and depressing joke. Yes, I pour vitriol on this kind of research, it's destroying the field of particle physics. I'm far from the only one who thinks this.

As for who goes around personally insulting people, look in the mirror. The only person whose name I've invoked here is Susskind, and I am criticizing his argument, not him personally. You're unhappy that I've perhaps unfairly characterized some people's scientific arguments. Maybe I have, maybe I should have dealt more seriously with them, and explicitly stated the well-known fact that, in this case as in essentially all others, there's no such thing as a real no-go theorem in string theory, you can get whatever you want. I didn't happen to think it was worth the trouble. But you really need to learn the difference between personally criticizing someone and criticizing a scientific argument.

Yes, I think we're finished with this subject, unless you're willing to put your name and reputation behind what you have to say.

51. **A**
September 7, 2006

adding to "amused" above:

Philosophy, after trying many epic vessels, remained at the starting point.

Physics, thanks to near coast navigation, progressed even too far.

52. **Anon**
September 7, 2006

"The history of the no-go theorems you're talking about goes back to the mid-eighties. I'm not going to waste my time getting together references … "

We're all capable of using SPIRES to find the exact references. How about some names and approximate dates to get us all started?

53. **Chris W.**
September 7, 2006

Amused,

Your characterization of the situation reminds me of what is now happening to science within NASA; it is being sacrificed in favor of massive engineering boondoggles—a manned return to the moon (and establishment of a base there) and a manned expedition to Mars. These projects will probably collapse into a mess of cost overruns and missed milestones before they attain their stated objectives, but the aerospace and defense contractors involved (and the federal officials and members of Congress promoting their interests) will certainly benefit in the meantime.

[By the way, you nearly ruined a great comment by contaminating it with the pseudo-word "irregardless".]

54. **UCSB**
September 7, 2006

Hi Anon,

Let me help. The papers did indeed exist, but the precise issue is when `string theorists were going on about them', to use PW's words. They existed but in fact were so unknown that Maldacena and Nunez were not aware of them (and did not cite them) when they rediscovered and generalized their results. One paper is

RESIDUAL SUPERSYMMETRY OF COMPACTIFIED d = 10 SUPERGRAVITY.
B. de Wit, D.J. Smit (Utrecht U.) , N.D. Hari Dass (NIKHEF, Amsterdam) . NIKHEF-H-86-15, May 1986. 44pp.
Published in Nucl.Phys.B283:165,1987

This was cited a grand total of 6 times in the ten years before the dark energy was found, then 4 more in the next two years, and then 78 times when it was rediscovered after the MN paper (which itself was cited 289 times). So this clearly shows at what point string theorists were `going on about this'. By the way, MN themselves discuss the limitations on their assumptions, and cite a list of aready-existing papers that lie outside these assumptions and are not constrained by the theorem (beginning with Strominger in 1986, long before the dark energy was found). So there was no point in time at which those actually working on the construction of superstring vacua regarded these theorems as a constraint.

The other early paper was

Aspects Of Supergravity Theories.
G.W. Gibbons (Cambridge U.) . Print-85-0061 (CAMBRIDGE), Jun 1984. 53pp.
Three lectures given at GIFT Seminar on Theoretical Physics, San Feliu de Guixols, Spain, Jun 4-11, 1984.

which was even less cited and less known (it appeared only in a conference proceedings, before the days of the arxiv).

55. **woit**
September 8, 2006

I've wasted my time and found the precise reference I was thinking of when I wrote the lines that so upset AC from UCSB, they're from a paper but also correspond to what I remember hearing in a talk around this time

"This means that there is no classical way to get de Sitter space from string theory or M-theory… In fact, classical or not, I don't know any clear-cut way to get de Sitter space from string theory or M-theory. This last statement is not very surprising given the classical no go theorem. For, in view of the usual problems in stabilizing moduli, it is hard to get de Sitter space in a reliable fashion at the quantum level given that it does not arise classically".

Funny that we're told that the no go theorems were "well-known to be irrelevant", I guess this particular string theorist wasn't very well informed. It's true that he didn't claim that string theory “predicted” a non-positive CC, he’s not the sort to go on about bogus string theory “predictions”. And, by the time of this quote, the experimental evidence was in favor of a positive CC.

People who are very concerned with the issue of whether I’ve got this right still seem to insist on ignoring the main point: is Susskind’s “prediction” a bad joke or not?

56. **Anon**
September 8, 2006

“I’ve wasted my time and found the precise reference …”

And the precise reference is …?

“Funny that we’re told that the no go theorems were ‘well-known to be irrelevant'”

They weren’t well-known at the time.

And by the time they became well-known, they were already understood to be irrelevant (in the sense that there were already well-known string backgrounds that violated the assumptions of the theorems).

UCSB has the history right.

57. **Anonymous Coward from UCSB**
September 8, 2006

E. Witten, hep-th/0106109, 3 years _after_ the supernova data.
So you did distort the chronology: you stated that string theorists made a wrong prediction and then backtracked when the data came out the other way, whereas this was an honest statement of a research puzzle. And Witten was indeed out of the loop on this subject, since the first dS solutions (E. Silverstein hep-th/0106209) appeared at virtually the same time.

58. **woit**
September 8, 2006

Anon and AC from UCSB,

I think the Witten quotation speaks for itself, your statement that the no-go theorem was “well-known to be irrelevant” is simply wrong. Witten was giving talks at places like Strings 2001 saying what I quoted. He did not consider these theorems “irrelevant”, and if there’s one thing Witten rarely is, it’s “out of the loop”. Yes, it’s true that the way I stated things exaggerated the true situation. As I said, it was somewhat of a joke made in the context of responding to Susskind’s absurdity.

For the N’th time, will you or won’t you address the issue of whether or not Susskind’s argument is an absurdly bad joke? I understand very well why you would rather argue about something else, but sooner or later people in this field will have to face up to what is going on. You can devote your days (and nights) to anonymously attacking anyone who tries to point this out, but it won’t change what is happening.

59. **amused**
September 8, 2006

Chris,

Although I can well understand the temptation I think you’re being too harsh comparing string theorists to sleazy aerospace/defense contractors and congressmen. As individuals they aren’t really doing anything different from other physicists or academics in general by promoting their own area and supporting the people in it to the exclusion of others. But in this singular situation of string dominance the leaders of that field need to realise that with great power comes great responsibility. I.e. the responsibility to act in the best interests of physics. I wonder if they ever give any thought to this – it’s certainly not something they like to talk about. Do they really think it’s in the best interests of physics that the string program is pursued to the exclusion of everything else in formal hep theory?
The current protestations from string critics are nothing compared to the merciless slamming that awaits them from future historians of science if they don’t exercise their responsibility wisely.

(And as for the pseudo-word contamination, it was a quite mild contamination level by my usual standards ;))

60. **Anon**
September 8, 2006

“Yes, it’s true that the way I stated things exaggerated the true situation.”

You wanted to know why none of the string theorist bother to respond to you.

That’s why.

UCSB chose one recent example, but we could do the same with just about everything you say on this blog.

If you want them to take you seriously, then you’ll have to take them seriously, too, and not engage in this kind of deliberate distortions and obfuscations.

61. **woit**
September 8, 2006

Yet another anonymous string theorist,

“we could do the same with just about everything you say on this blog.”

Whoever you are, hiding behind anonymity, you’re completely dishonest.

Look, what is going on here is that, in a throwaway line in the comment section here, in the context of discussing the completely insane state that string theory has come to, I made a reasonable analogy to another similar issue in string theory. I wrote two sentences, both of which are completely accurate, but which could be read together as making a misleading accusation. I shouldn’t have done this. I’ve written probably a thousand pages of stuff here. Every bit of it is signed by me, and if I’m wrong about something I will admit it.

In response to this, I've gotten mostly dishonest responses from what appear to be three separate string theorists, none of whom dare put their name to what they write. AC from UCSB's claim that what I wrote was untrue because these no-go theorems were "well-known to be irrelevant" was shown to be not true by the quote from Witten.

Sure, sometimes in a comment section here I say something that is not quite right, sometimes for rhetorical effect. Anyone who wants to is welcome to correct me, but doing so in an insulting and dishonest way, hiding behind anonymity, is just kind of pathetic.

For the N+1th time, will any one of the three of you actually address the question at issue: is Susskind's "argument" a bad joke, deserving of being made fun of, or not?

62. **UCSB**
September 8, 2006

`is Susskind's "argument" a bad joke, deserving of being made fun of, or not?'

Actually, this is an interesting question, thank you for asking it. What if the curvature is measured to be positive? There is natural explanation: tunneling from nothing (Hartle-Hawking, Vilenkin) produces universes with positive spatial curvature, whereas tunneling from a higher dS state produces universes with negative spatial curvature. Either of these processes is sufficient to populate the landscape, so indeed neither observation would falsify the environmental solution to the cc problem, it would tell us something important about quantum cosmology.

The relation between these two processes has never clearly been understood by quantum cosmologists working in the effective QM-GR: every one has their own person favorite for the wavefunction. A complete theory of cosmology should explain the relation between them, most likely both occur in some form but presumably, barring an accident, one or the other is much more likely. Indeed, providing a theoretically convincing solution to this old area of controversy is a target for string theory, though observational test depends on having few enough e-foldings for the curvature still to be visible.

63. **z3**
September 8, 2006

Peter finally grudgingly admitted to an inaccuracy in an off-the-cuff, un-researched remark in a comment section — this is actually a pretty hard thing to do, especially in public view. One can respect him for that.

USBC finally calmed down and start to address physics — for a while there he was latched on to a secondary topic, attacking in full rage, and in so doing exposed the fact that he himself is not quite in full command of the history of the topic either.

Anon just extrapolated Peter's one error by 3 orders of magnitude to show that the entirety of Peter is in error. I hope he is more conservative in his main areas of study.

And we all now see how memory is not 100% reliable and why one must always research the facts before making quick strong statements.

64. **dan**
September 9, 2006

Hello Peter,

Even if string theory is unable to make predictions at any level, could you accept it as legimate scientific research as a way of explaining (but not necessarily predicting) fundamental physics, such as 3 generations of fermions?

There are many instances of a scientific theory (i.e meterology, evolutionm, n-body problem, fluid dynamics) that cannot predict (because too much is unknown or equations poorly understood or impossible to solve) but are considered scientific for other reasons.

thanks

65. **TheGraduate**
September 9, 2006

dan:

I could be wrong but I think that you can get predictions out of meteorology and mathematical analyses of the n-body problem and of fluid dynamics over a small enough time scale and in special circumstances.

Also in each case, there are actual physical systems that can be catalogued. Collection, arranging and categorization is also a scientific activity. For instance, a meteorologist can observe and classify types of clouds and the conditions under which they are known to form.

In the case of evolution, you can easily apply selection pressure to bacteria, viruses, protozoa etc and observe the affects on different allelles. eg. exposing bacteria to antibiotics and observing the shift in the population to antibiotic-resistant bacteria

66. **TheGraduate**
September 9, 2006

dan:

I think a good way to figure out if one is doing science or religion is to ask yourself whether your approach is vulnerable to the sorts of errors that religious approaches to finding truth are vulnerable. I think in the case of string theory, they certainly are.

Without accountability, the reasoning process tends to go awry.

67. **dan**
September 9, 2006

so TheGraduate Says:,
would u c string theory as a scientific theory in the sense of explanatory rather than predictive?

68. **nigel cook**
September 9, 2006

dan,

String theory probably “explains” why the science fiction of extra dimensional spacetime, superpartners, gravitons, multiple universes, and time travelling in wormholes is so popular.

There is a list of hyperspace films at http://en.wikipedia.org/wiki/Hyperspace_(science_fiction) and we owe a great debt of gratitude to Professor M. Kaku, who is the “anchor” of hyperspace, according to the first reference on that Wiki page.

Without string theory “explanation” hype, where would science fiction be today? It would still be half-plausible fictional stories based upon science. String “explanation” is not just replacing half decent religions (thanks to Susskind’s new book on the anthropic principle, landscape and intelligent design), it is also replacing decent science fiction with brilliant stringy films.

I wonder if Speilberg and others in Hollywood will become stringy defenders, joining Motl, Distler, and Susskind? 😉

69. **woit**
September 9, 2006

dan,

To have a scientific explanation of anything, you have to be able to check that the explanation is correct. That’s why you need a testable prediction. “Explanations” that can’t be checked and tested are not part of science.

All the sciences you mention make many testable predictions, meteorology is all about learning how to make better and better predictions.

70. **dan**
September 9, 2006

Nigel, I find what you say amusing.

Peter, string theorists have claimed that the fact string theory can derive BH-entropy a priori in agreement with Hawking-Berkenstein calculations, predict the spectrum of the standard model and three generations and particle masses, provide a theory of gravity in agreement with general relativity at long distances, are examples which check if the explanation are correct.

71. **woit**
September 9, 2006

dan,

This kind of discussion is pretty off-topic, and has taken place a hundred times here before.

1. The BH entropy calculations don’t apply to physical black holes, so don’t predict anything you can observe, even if you do find a black hole you can examine.

2. It’s just a complete bald-faced lie to say that string theory predicts the standard model, 3 generations and particle masses.

3. The idea that it gives GR at long distances is the strongest argument in favor of string theory. This is not a prediction, at best a postdiction (and you can argue about this..), it’s the recent people picked this theory to look at. As Lisa Randall has been known to point out: “Yes, string theory predicts GR. In 10 dimensions.”

72. **dan**
September 10, 2006

Peter,
Sorry if it’s off-topic, I should say “output is MSSM”

73. **Peter Woit**
September 10, 2006

dan,

It’s every bit as much nonsense to claim that string theory predicts the MSSM as to say that it predicts the standard model.

Noncommutative Geometry and Physics

September 5, 2006
Categories: Uncategorized

This week the Newton Institute in Cambridge is running (with funding from the Templeton Foundation) a workshop on the topic of Noncommutative Geometry and Physics: Fundamental Structure of Space and Time. The program is here, some of the talks are online here, and Paul Cook is blogging here (with truly scary pictures of a Newton Institute restroom). Thursday evening they will be having a public panel discussion, entitled The Nature of Space and Time: An Evening of Speculation.

For someone interested not in quantum gravity but in particle physics, the most interesting of these talks is doubtless that of Alain Connes, entitled Noncommutative Geometry and the standard model with neutrino mixing. He has a new paper out, with the same title, with more details promised in a forthcoming paper with Chamseddine. I've been carrying the paper around for a while now, hoping to understand exactly what he's doing, but it's rather dense and some of the calculations are involved and don't carry much of an explanation. I really wish I'd been at the talk to hear his exposition of what he's up to here.

Among the other talks at the conference I would like to have heard would be that of Samson Shatashvili, who is doing some very interesting things with 2d gauge theories. He has a new paper out (with Gerasimov) which looks quite readable, entitled Higgs Bundles, Gauge Theories and Quantum Groups.

Another conference going on that is finishing up this week is the Erice "International School of Subnuclear Physics", this year entitled The Logic of Nature, Complexity and New Physics, and dedicated to Richard Dalitz. Back during the sixties, seventies and eighties, the Erice School was an important yearly event, featuring the best theorists around giving expository lectures on the latest ideas, often including spectacularly beautiful lectures by Sidney Coleman. This year's school just looks profoundly weird, with an interesting and reasonable set of lectures on the experimental side, but the theoretical side mostly devoted to "complexity and the Landscape", featuring an opening lecture and mini-course about the Landscape by Susskind, a mini-course about the Landscape and its computational complexity (i.e. why it is hopeless to ever use it to predict anything) by Denef and Douglas, and more complexity from Zichichi, Beck, Gell-Mann and Tsallis. Many of the lectures are available here. Steve Hsu is blogging from the conference, and he reports that Susskind says the Landscape program is science since it now gives exactly one bit of information about the universe (the sign of the spatial curvature k), although he expects Andrei Linde to be able to make that bit disappear if he wants to.

Update: Urs Schreiber has an excellent discussion of the Connes program here and here.

Comments

1. **PPCook**
   September 5, 2006

   Hi Peter, thanks for the link. The conference here is very interesting, but what has been very tough is the realisation that to understand the Connes paper it does not help to hear him speak. It is, of course, a pleasure to hear him speak. And he is an excellent speaker. It's just to benefit one really must hear him speak while holding all the ideas behind the approach in your head. I think there is much promise in his approach, but it does seem to be very constructive. It seems the most important point to start learning about the Connes approach would be his paper with Chamseddine The Spectral Action Principle. Perhaps after spending years staring at the standard model one might gain the same feeling as Connes and one might feel that the starting points are intuitive, although perhaps not. One must bear in mind Alain Connes' own words when assessing his approach to physics:

   "There are two fundamental sources of 'bare' facts for the mathematician. These are, on the one hand the physical world which is the source of geometry, and on the other hand the arithmetic of numbers which is the source of number theory. Any theory concerning either of these subjects can be tested by performing experiments either in the physical world or with numbers. That is, there are some real things out there to which we can confront our understanding."

   Treating experimental data on the same footing as number theory seems to remove the need for motivating certain assumptions. The standard model just is – we have observed it, that is good enough. At the end of his talk he described string theorists who look for more than is apparent as living in "a dreamworld". I think this is understandable, but the dream is alluring. It is also very natural for scientists to seek explanations, but yet it is proper to respect experimental evidence. Nevertheless the formulation of Connes is extremely compact, and one hopes it is not just exquisite engineering.

2. **John Baez**
   September 6, 2006

   Connes surely doesn't get the right *dimensionless constants* in the Standard Model Lagrangian – if he did, folks at the Newton Institute would be drinking champagne and dancing naked in the streets. So, how does he manage to come so close yet not that far? And, what is his attitude towards these constants? Did his audience press him on this point?

3. **steve**
   September 6, 2006

   Peter,

   I never thought I'd be defending string theory, but I think your remark above is too negative.

   Lenny didn't claim victory because there is a single robust prediction from the Landscape. He's seems disturbed that most low-energy observables are unpredictable, even in an anthropic framework.

   However, it does mean the Landscape is falsifiable — if Planck measures a positive curvature it will strongly disfavor the scenario.

4. **Peter Shor**
   September 6, 2006

   John,

   It looked to me from his abstract that the dimensionless constants were parameters that Connes could put in his model, and the only actual predictions (so far) came at unification scale? I don't understand any of this, so could somebody verify whether this is right?

   Anyway, it seems to me that if the string theorists got this close (for whatever values of close he got), there clearly would be dancing in the streets.

5. **A**
   September 6, 2006

Following your link, I tried to read the Susskind lectures, but they contain a few words, almost no equations, plenty of cartoons.
My child got interested.

6. **amanda**
September 6, 2006

“However, it does mean the Landscape is falsifiable — if Planck measures a positive curvature it will strongly disfavor the scenario”

It will disfavor the *particular* scenario that LS pushes, with Coleman-de Luccia instantons. Of course, LS has the bad habit of pretending that his way of doing things is the only way — cf his repeated declarations that black hole complementarity, which is nothing but the wildest of wild speculations, is a “law of nature”!

7. **MathPhys**
September 6, 2006

amanda,

What do you mean by “black hole complementarity” more precisely?

8. **steve**
September 6, 2006

Amanda,

I’m under the impression that if there are many metastable vacua (almost all with much larger vacuum energy than our own), then it is highly likely that our universe must have originated in a tunneling (bubble nucleation) event. If so, the curvature has to be negative. It so happens that Coleman-Deluccia worked out the bubble form, but I don’t see that Lenny is making a nontrivial assumption.

Am I missing something?

9. **D R Lunsford**
September 6, 2006

Has anyone improved on Brout’s paper as an exposition for physicists?

-drl

10. **Peter Woit**
September 6, 2006

steve,

I didn’t say he was claiming victory, just that he was using this to answer certain people who argue that this is not science. It’s good to hear that he’s disturbed by not having any low-energy predictions, but the problem with the Landscape is not just at low-energy, it doesn’t give predictions at any energy.

As for the single bit of info here, I remember a time when string theorists were going on about no-go theorems that showed that you couldn’t have string theory in deSitter space, i.e. with a positive cosmological constant. When a positive cosmological constant was found, they seem to have come up with a way of dealing with that problem. If the spatial curvature comes out positive, I’m sure they’ll come up with something.

11. **urs**
September 6, 2006

John Baez said

> Connes surely doesn’t get the right dimensionless constants in the Standard Model Lagrangian – if he did, folks at the Newton Institute would be drinking champagne and dancing naked in the streets. So, how does he manage to come so close yet not that far? And, what is his attitude towards these constants? Did his audience press him on this point?

I don’t think the point of this quest for the spectral action of the standard model is to predict the standard model’s properties.

I think the main point is first of all to understand which spectral triple precisely is the one whose spectral geometry describes the standard model.

It would of course certainly be a nice side effect if some properties of the standard model were derivable this way, maybe in the sense that they might turn out to be forced to have a certain value to admit a spectral description at all.

So I think the point is that if you want to understand something deeply, you should first try to find its most elegant/powerful/compact description. And Connes rightly points out that encoding the entire standard model into a spectral triple does achieve such a description.

And we learn by that, for instance, that we observe a world of metric dimension 4 and KO-dimension 4+6 mod 8.

While not a prediction, that looks like a remarkable insight.

I am going to say more about that at the n-Café. So far there is an introductory entry.

12. **wolfgang**
September 6, 2006

I did not see much discussion on the quantization of the theory in the latest paper of Alain Connes. Is renormalization etc. already taken care of automatically in this approach (or described in another paper) ?

13. **urs**
September 6, 2006

> I did not see much discussion on the quantization of the theory in the latest paper of Alain Connes. Is renormalization etc. already taken care of automatically in this approach (or described in another paper) ?

As far as I can tell, so far this is just a way to rewrite the standard action functional in a different form.

See section 6 of Connes' latest paper for remarks on what might be expected as a "UV completion" of this spectral action.

In fact, his collaborator Chamseddine once began trying to understand if the spectral action obtained from a 1-Dirac operator could be the limit of a UV-complete one obtained from a 2-Dirac operator

14. **Alejandro Rivero**
September 6, 2006

wolfgang, one intriguing thing of Connes approach is that some details that are supposed to come from quantisation appear here as a consequence of the axions. Paricularly, Poincare duality imposes anomaly cancellation.

15. **A**
September 6, 2006

Actually the prediction of negative curvature has nothing to do with string theory: as shown by Coleman-deLuccia, a negative curvature arises from vacuum decay, for any potential studied so far. Next, anthropic arguments are used to argue that inflation maybe does not need to suppress the curvature down to unobservably small values.

16. **PPCook**
September 6, 2006

John,
No one in the audience asked about the dimensionless constants…
Best wishes,
Paul

17. **urs**
September 6, 2006

The Yukawa coupling constants are encoded in the "metric" of the internal (d_KO = 6)-dimensional space, namely in the Dirac operator associated with it. See equation (1.21) of http://arxiv.org/abs/hep-th/9606001

I talk about that here.

18. **urs**
September 6, 2006

Furthermore, apparently the bare gauge coupling is related to the volume of spacetime by equations (2.20) and (2.29) of the review. More details are here

http://golem.ph.utexas.edu/category/2006/09/connes_on_spectral_geometry_of_1.html#c004520

So, in a word, Connes does not *predict* the parameters of the standard model. What he does instead is to identify the "geometry of a non-geometric KK compactification" that does reproduce the standard model (including the dimensionless constants).

19. **steve**
September 6, 2006

A: Yes, but as I mentioned in a Landscape scenario our universe likely originated in a negative curvature bubble nucleation, so there is a definite sign prediction for k. Inflation might have flattened things out, but it would be hard to explain a positive measurement of k.

It isn't that negative k, or a nucleation origin, require string theory, but rather the converse.

20. **TheGraduate**
September 6, 2006

Hi,

I know people are in the process of figuring out what Connes' paper means but I was wondering if anybody could summarize in a sentence or two of nontechnical language what issues are in play. So far I understand the following:

1. This paper says something about the number of dimensions being equal mod 8 … and since (26 = 10) mod 8 … that says something about string theory … perhaps

2. It also makes progress in a group theoretic description of the standard model …

I apologize for my abyssmal ignorance and would greatly appreciate some breakdown.

21. **Andy Neitzke**
September 6, 2006

`What he does instead is to identify the "geometry of a non-geometric KK compactification" that does reproduce the standard model (including the dimensionless constants).'

Does he explain what theory one has to "compactify" on this nongeometric background to get the Standard Model?

22. **urs**
September 7, 2006

First of all, many thanks to "anon" for pointing out a stupidity I said. The corrected statement is here

http://golem.ph.utexas.edu/category/2006/09/connes_on_spectral_geometry_of_1.html#c004536

> Does he explain what theory one has to "compactify" on this nongeometric background to get the Standard Model?

Well, his theory is that given by the action functional which you cook up from the spectral triple.

So, given any spectral geometry, Connes considers the action functional obtained from its generalized “heat kernel expansion”.

That’s his way to formulate things. There are indications, though, that, if applied for instance to the Dirac-Ramond operator, this generalized “heat kernel expansion” reproduces precisely the effective string theory equations of motion.

That’s at least what Ali Chamseddine claims to have shown. See p. 10 of

http://arxiv.org/abs/hep-th/9701096

as well as

http://arxiv.org/abs/hep-th/9705153 .

23. **urs**
September 7, 2006

> summarize in a sentence or two of nontechnical language what issues are in play.

The idea is this:

To any given ordinary Riemannian manifold X, we may associate the Einstein-Hilbert Action. That’s gravity.

We know from Kaluza-Klein, that if X looks like Y x S^1 that gravity on X looks like gravity coupled to electromagnetism on Y.

Now, Connes comes along annd says that there is something like a “generalized” Riemannian manifold. And he provides a way to define a notion of action for that, such that for X an ordinary Riemannian manifold that action reduces to the ordinary Einstein-Hilbert action (plus correction terms of higher order).

So, he says, assume our spacetime is not an ordinary Riemannian manifold with extra forces in it, but just some generalized Riemannian manifold with only gravity.

Using his generalized notion of the Einstein-Hilbert action, we may check for each such generalized Riemannian manifold what its “gravitational” action looks like.

In a similar fashion, fermionic matter propagating on an ordinary Riemannian spin manifold (= coupled to gravity) may be generalized to fermionic matter propagating on a generalized Riemannian manifold.

So, Connes says, what I want to do is to find a generalized Riemannian manifold X of the form Y x Z, such that my generalized theory of gravity coupled to fermions on X looks like gravity coupled to our standard model on Y.

He plays around a little and finally finds Z such that this works.

24. **anon.**
September 7, 2006

urs wrote:

There are indications, though, that, if applied for instance to the Dirac-Ramond operator, this generalized “heat kernel expansion” reproduces precisely the effective string theory equations of motion.

Is this a leading-order statement in both g_string and alpha’, or are higher terms in the “heat kernel expansion” that should reproduce some or all of the corrections?

25. **urs**
September 7, 2006

> Is this a leading-order statement in both g_string and alpha’, or are higher terms in the “heat kernel expansion” that should reproduce some or all of the corrections?

Yes, Chamseddine checks leading order only.

I don’t know if the higher orders “should” agree. But if they do, we’d get a nicely coherent picture of what is going on.

Maybe to emphasize that, allow me to reformulate Connes’ approach somewhat suggestively this way:

He is considering the theory of a superparticle (*worldline* susy) in d_KO = 10 dimensions, determined by a Dirac operator D.

He takes the interactions of this superparticle to be such that the effective target space action is Tr(f(F)) + (psi,D psi).

Then he looks for compactifications

D = D_0 + D_F

such that this effective target space action agrees (to lowest order) with the standard model coupled to gravity.

That’s not precisely how Connes states it. And maybe it’s wrong. But maybe it’s right.

26. **PPCook**
September 7, 2006

I Just noticed the paper A Lorentzian version of the non-commutative geometry of the standard model of particle physics by John Barrett today (who has also spoken here at the NCGW, but not on this topic). It seems strange that, to my knowledge, it hasn’t been mentioned amongst the online discussion of the Connes paper even though it appeared on the same day as the Connes paper and in fact even a few entries earlier on the archive. The results appear at first to be identical.

27. **Chris W.**
September 7, 2006

From Connes (hep-th/0608226):

8. Acknowledgements
The detailed computations and extension of this work to the left-right model will appear in a joint work with Ali Chamseddine and Matilde Marcolli. The need to have independence between the KO-dimension and the metric dimension already emerged in the work of P Dabrowski and L., Sitarz on Podle´s quantum spheres [10]. The results of this work were announced in a talk at the Newton Institute in July 2006, and the fear of a numerical error in the above computations delayed the present publication. *It is a pleasure to acknowledge the independent preprint by John Barret (A Lorentzian version of the non-commutative geometry of the standard model of particle physics) with a similar solution of the fermion doubling problem which accelerated the present publication*.

28. **urs**
September 7, 2006

Coming back to the question on what, if anything, the spectral thing predicts, there are a couple of intersting remarks in

hep-th/9605001

(which is in general a pretty good account of the details involved).

In the introduction, the authors cite a couple of papers that argued that "most" models of Yang-Mills-Higgs type that one could write down are not obtainable by spectral action.

In the concluding section, it furthermore says that

– assuming a Higgs, the spectral stuff predicts a minimum of two generations

– including also the measured top mass then also predicts a maximum of 5 generations

– existence of the Higgs forces the electroweak sector to be chiral

– "the choice of possible gauge groups is very much restricted" it says

– finally: the huge span of fermion masses can *not* be explained.

So, there are a couple of internal consistency conditions, but the compactification metric (hence the set of dimensionless parameters) is essentially free input.

—

I have tried to expand on the superparticle point of view mentioned above:

http://golem.ph.utexas.edu/category/2006/09/connes_on_spectral_geometry_of_2.html

29. **anon.**
September 7, 2006

– existence of the Higgs forces the electroweak sector to be chiral

!

So the claim is that any time there's a spectral geometry formulation of your theory, you can only Higgs a gauge group with chiral fermions? There's no way to e.g. add a Higgs for SU(3)_color to this model?

Is there a heuristic explanation of why this should be true? It seems very strange.

30. **John Baez**
September 8, 2006

Connes writes:

> It is a pleasure to acknowledge the independent preprint by John Barret (A Lorentzian version of the non-commutative geometry of the standard model of particle physics) with a similar solution of the fermion doubling problem which accelerated the present publication.

Heh. The French never, *never* spell John Barrett's name right.

But, it's great that he scooped Connes. He'd been working on this for quite a while – he was quite excited about it when I saw him this April in Marseille, for the thesis defense of Alejandro Perez.

31. **urs**
September 8, 2006

> Is there a heuristic explanation of why this should be true?

I am not entirely sure. What I know is this:

the Higgs arises as the "internal" component of the connection, A_int.

By the general logic of the approach, this term is given by the commutator of the internal Dirac operator with an algebra element a

A_int = a [D_int ,a'] .

The algebra and its representation is such that projected on the anti-particle sector [D_int,a'] = 0, so we just get a contribution on the particle sector.

This is computed for instance on p. 26 of hep-th/960353 .

After the computation, you impose the self-adjointness condition and find that the term A_int is exactly given by a quaternion-valued function, which is to be interpreted as the Higgs.

A similar discussion must be in hep-th/9605001 somewhere, I guess.

32. **nontrad**
September 8, 2006

At the risk of disrupting the ongoing discussion, I flipped through Douglas' 08.31.06 Erice lecture on 'computational complexity and fundamental physics'.

It all seemed mostly innocuous until I arrived at the slide inwhich Douglas' began to discuss protein folding, and that made me pause.

Douglas makes some comments about evolution and the random order of amino acids in protein chains, which don't strike as anything other then a crude cartoon of the reality of proteins.
How and why such a cartoon-ish sketch of proteins appears in a talk on cosmological questions is then troubling to me since it suggests a situation of cartoons built on cartoons. Or analogies built on analogies. Or a castle made of sand.

Douglas then refers to Smolin's 'cosmological natural selection' and call's it 'bizarre', which immediately made me realize that perhaps Douglas is unaware of how his own thesis appears just as bizarre as those Douglas perceives as being bizarre. The pot calling the kettle black typically indicates bad news for someone.

Susskind's talk similarly features loops of DNA appearing more then once.

Hard to say that it isn't troubling to see what appears to be a tower of cartoons based on cartoons.

Who knows, perhaps all of these folks are super geniuses who have really figured is all out and are on the verge of a tottally complete and unified theory of everything.

I guess I'm caught up on the fact that their road to that end seems so fantastically unreasonable!

33. **cox**

Actually I am having a hard time trying to distinghish if he thanks John Barret or John Baez in the first minutes of his talk :-DDD

(between minutes 20…21 of the MP3 file. Not at the end, where Barret is clearly named)

Open Access Publishing

September 9, 2006
Categories: Uncategorized

There's a big debate within the scientific community in general about how and whether to move away from the conventional model of scientific publishing (journals supported by subscriptions paid by libraries, only available to subscribers) to a model where access to the papers in scientific journals is free to all ("Open Access"). The main problem with this is figuring out how to pay for it.

In his latest This Week's Finds, John Baez gives a link to some information about the Open Access movement. One of the main actors here is SPARC (the Scholarly Publishing and Academic Resources Coalition). There's an associated SPARC Open Access Newsletter and a blog, Open Access News.

Inside Higher Ed has a recent article about this, and last week's Science magazine also has an article. The Science article discusses a new proposal put out by a task force from CERN that can be found here. The CERN task force has gathered a lot of interesting data about the particle physics literature, counting roughly 6000 papers/year, of which about 80% are theoretical. They found that about half of the journals publishing most particle physics papers are willing to move to an open-access model, with a cost per paper of between \$1-3000. These included APS and IOP journals, but did not include Elsevier journals like Nuclear Physics B. The APS has announced a program that would make papers in its journals open access at a cost of \$975-1300 per paper, and Elsevier has announced something similar at around $3000/paper. The CERN task force proposes raising \$6-8 million/year over the next few years to start supporting the half of the journals (not including Elsevier ones) that it has identified as ready for Open Access.

What is being proposed here is basically to give up on what a lot of people have hoped would develop: a model of free journals, whose cost would be small since they would be all-electronic, small enough to be supported by universities and research grants. Instead the idea here is to keep the current journals and their publishers in place, just changing the funding mechanism from library subscriptions to something else, some form that would fund access for all. The CERN task force suggests various sources for funds over the next few years, in a transition period, but doesn't address the long term funding problem. If you fund these things out of, say, NSF grants, when Congress decides to cut the NSF budget, there's a serious danger of the plug getting pulled on a field's entire scientific literature. One popular idea is that researchers themselves should pay the cost. The problem with this is that the bulk of the literature is theory papers, mostly from people who can't afford this. When there is a mixture of journals that require authors to pay the cost and those that don't, authors abandon the ones they have to pay for. The Elsevier journals like Nuclear Physics B achieved dominance over the APS journals during the 70s when the APS journals were financed by "page charges" paid by authors, but Nuclear Physics B cost nothing to publish in.

The CERN task force doesn't seem to me to be providing a viable long-term plan for moving to the kind of open access model they are supporting. It doesn't address the fundamental problem of keeping a system where physicists hand over the scientific literature to Elsevier, then have to figure out how to buy it back. Even if a willing organization is found that will give \$3000/paper to Elsevier, what will keep Elsevier from deciding to keep publishing more papers? What if the organization in question gets tired of this and decides to stop paying?

The CERN report also contains a lot of highly debatable arguments. It claims that the current refereeing process is extremely important, valuable, and must be maintained at all costs, ignoring the fact that virtually everyone accesses papers at the arXiv, not at the journal. It's true that the refereed version in a journal may be improved and have errors fixed, but authors are generally free to replace the original preprint version by a corrected one on the arXiv. The description given in the report of the "high standards of peer review" doesn't agree with the reality of what is going on (see the Bogdanov affair). The mathematics literature still has a functional peer-reviewing system and it plays a very important role of keeping the number of incorrect proofs and unreliable results to a minimum, but the particle physics literature is very different. The report does continually make the point that the refereed journal system is crucial to the ways institutions evaluate people and decide whether to hire or promote them, but it doesn't address the issue of whether this is a good thing.

The report also tries to claim that the advent of LHC data will somehow make the refereed particle physics literature and open access to it much more important. I don't see this at all. The experimental results from the big LHC detectors will come out only after very careful vetting by the groups themselves, and I don't see how a referee is likely to have much of a useful role there. If surprising experimental results are found, there will be a frantic battle among theorists to get a preprint out that explains the new data, and everyone will be following this on the arXiv. By the time such papers get through refereeing and are published, few people will still be paying attention to them.

Update: Nature Physics also has a recent article about peer review and open access.

Comments

1. **anonymous**
   September 9, 2006

   Peter, isn't the democratic solution is to have an alternative to arXiv, i.e., to have two independent electronic servers with different referees etc?

   This existed in the CERN Document Server up until 8 October 2004, when:

   "The CERN Scientific Information Policy Board (SIPB) closed the CERN CDS EXT preprint series, thus depriving me of preserving my work by posting it on EXT, as I had done with some papers that blacklisting had barred me from posting on arXiv…" – Tony Smith, http://www.valdostamuseum.org/hamsmith/jouref2.html

   Mainstream string theory and other evidence-lacking orthodoxies survive and indeed flourish just because they acquire dictatorial power to suppress other options by force, i.e., where you have one electronic preprint server with one set of referees, and no alternative. Imagine Lubos Motl or a close friend of his in charge of arXiv, and you see why people are so cautious about attacking the mainstream. Externally-submitted CERN Doc Server papers (accepted up to 2004) now can't even be revised/updated!

2. **CapitalistImperialistPig**
   September 9, 2006

   Peter,

   The ArXiv model is orders of magnitude cheaper to run than most of the open access models cited. I doubt that peer review does a lot for physics, but couldn't it be replaced by an open commentary scheme? Authors could solicit commentary from either known or hidden reviewers. A hidden review panel could probably be managed by an almost entirely automated process. Review comments could be either provided to the author or public.

3. **MathPhys**
   September 9, 2006

   I think that nowadays when a typical mathematician or physicist does a literature search, they start by searching arXiv. When something relevant is found, they use it.

   The main criteria to verify correctness is whether the author is known, and whether the work is cited in other preprints. I doubt if being published in a printed journal is a criterion at all.

Even if the preprint is a few years old but unpublished, one thinks “Oh, maybe it was in a conference proceedings”.

4. **D. Eppstein**
September 9, 2006

I don’t know if I’m typical, and my research area is far from physics, but I usually start my literature searches with Google Scholar. ArXiv is a great resource but still does not contain most research in my area, and anyway Google indexes it well along with some other resources such as the ACM Digital Library that cover my area better.

5. **werdna**
September 9, 2006

MathPhys says:

>I think that nowadays when a typical mathematician or physicist >does a literature search, they start by searching arXiv…The main >criteria to verify correctness is whether the author is known, and >whether the work is cited in other preprints.

Actually, mathematicians do not verify correctness of results based on the reputation (or lack thereof) of the author(s). Neither do citations matter much to them either. What matters is the correctness of the proof. That’s why the peer review process serves a much more important function for math journals than for other disciplines.

6. **Scott**
September 9, 2006

Thanks, Peter! To me there’s something astounding — and in need of explanation — about the academic community’s spinelessness and timidity on this issue. “Sure, we should experiment with open-access, but *obviously* we can’t abandon the core idea of donating all our work to Elsevier and then spending a fortune to buy it back.” What is the source of this craven conservatism, among people who in other contexts are (1) trained to question things, (2) generally left-leaning and distrustful of corporations, and (3) finely attuned to the ironic and absurd? I speculated about this in a book review I wrote in April, but didn’t reach a satisfying answer. I’ll be grateful if anyone else has a conjecture.

7. **jeremy**
September 9, 2006

Actually, peer review is important for all areas of scientific research, unless you don’t want to know the correctness of the previous results that you are referring to.

8. **John Baez**
September 10, 2006

Scott writes:

> To me there’s something astounding — and in need of explanation — about the academic community’s spinelessness and timidity on this issue. […] What is the source of this craven conservatism, among people who in other contexts are (1) trained to question things, (2) generally left-leaning and distrustful of corporations, and (3) finely attuned to the ironic and absurd?

As an academic who has rebelled against the system of academics working without pay for media conglomerates who charge high prices for the resulting journals, the source of the conservatism is **obvious**.

Reed-Elsevier, Springer Science+Business Media, and other conglomerates now own many of the most prestigious journals in science. They’ve spent the last half century buying them up.

“Prestige” may seem like an abstract and subjective concept, but it plays a deadly serious role in the career of any academic. Hiring, promotions and other decisions are based on it.
If a mathematics department has a choice between hiring two candidates, otherwise equal, one of whom has published a paper in *Inventiones Mathematicae*, while another has published in *Transactions of the American Mathematical Society*, everybody knows who will get the job. Every mathematician, that is – for we all know which journal is more “prestigious”.

So, even as the university library is crying for help, struggling to pay the ever-growing costs of journals run by the big media conglomerates, the science faculty continues to publish in these journals, because their careers depend on it.

The science faculty also work as editors for these journals, typically for no pay – just for the prestige of being on the editorial board. They also work without pay refereeing articles for these journals. They write papers that appear in volumes published by the same media conglomerates, again just for the prestige of having a paper in a prestigious volume. And, they write books for presses owned by the same conglomerates.

I find *these* activities to be a bit more craven, because I haven’t seen people getting hired just because they do these things. But, just as millionaires work their ass off to become billionaires, a lot of the most prestigious scientists engage in these activities to polish their reputations to an ever finer sheen. This is especially true of people who have given up trying to do original research.

I get lots of invitations to write books and papers for various collections, because people know I can write. These days I almost always turn them down. I’ve learned a key fact: when someone gives me an *honor*, it’s usually a way to get me to do work for free. I still give lots of talks, because I get free travel out of it, and I really enjoy explaining stuff. But writing review papers for volumes published by prestigious publishers – that’s something I’ve come to really dislike.

Each time I turn such an offer down, I feel a little ache, because I know I’ll miss out on a little piece of *prestige*. For example, I could have contributed to the forthcoming “Princeton Companion to Mathematics”. I almost did – what a great opportunity! But I didn’t. I’d rather do whatever the hell I want on a given day – usually thinking about math and physics. I’m in an incredibly lucky position where I can afford to do this; it seems insane not to.

In short, to understand what’s going on, you have to realize: big companies care about profits, academics care about prestige.

9. **Scott Aaronson**
September 10, 2006

Thanks, John! I agree that prestige is part of the answer — but if it were the whole answer, then wouldn’t we expect academics to agree *in principle* that the system sucks, even as they vied to publish in the top journals? (Much like they agree in principle that global warming sucks while driving their SUVs.) Yet I have friends who get up at conferences to *defend* the system, who make arguments like “maybe if we’re nice to Elsevier they’ll give us a 5% discount…” That’s the part I don’t understand: are they trying to reduce cognitive dissonance? Or is it just inertia?

10. **jeremy**
September 10, 2006

John Baez writes:

"In short, to understand what's going on, you have to realize: big companies care about profits, academics care about prestige."

Companies, big or small, have to make profits, if only to survive. Academics, however, don't need to gain prestige by publishing in a prestigious journal, if they can make breakthroughs in their research. Recent work of Perelman on Poincare conjecture would be an excellent example.

11. **M**
September 10, 2006

I do not see any Open Access problem: having papers on arXiv plus a line on SPIRES adding "published on…." already is Open Access.

The real problem is that it is expensive, because hiring committees and libraries keep traditional journals alive.

What we would need is not arXiv + Open Access journals, but arXiv + refereeing agencies i.e. somebody who certifies the quality of papers.

This somebody should be accepted by hiring committees (that already accepted JHEP), not be managed by physicists (just like a typical journal), not spend money in re-typesetting papers (possibly unless for those few authors who have serious problems with grammatics or with LaTeX).

JHEP retypsetted everything and could not survive as a free journal, was managed by physicists and political battles sometimes distorted even the refereeing process.

12. **amused**
September 10, 2006

Following on from what John Baez wrote above, and providing one possible answer to Scott:
In theoretical hep these days, people working in the dominant area don't have much need for publishing in prestigious journals – their
standing, job prospects etc are determined by the opinions of the senior influential people in their area on the papers they put on the archives. On the other hand, for people outside the dominant area, especially those from obscure backgrounds and without the "right connections", the possibility of publishing in a prestigious journal is practically the only way to gain some visability and the possibility of a research career. I owe my own career to date, tenuous as it is, to the existence of such journals and am therefore not much inclined to say that the system sucks. More objectively, well-run "prestigious" journals have an important role to play in research communities by providing objective "quality stamps" in the midst of all the political/sociological stuff. Private publishers who have been able to maintain such journals over longer periods deserve some respect and appreciation for this, regardless of what one might think of their pricing policies.

13. **Gebar**
September 10, 2006

You need a new model –or rather an extension of the present one. This will seem utopic, of course, but it is not unfeasible.

First you have to have some kind of "committee" who will actually try to find solutions and implement them. For example, sparc. The more prestigious, the better.

Academic publication has two main players. Arxiv and the "prestigious" journals. Arxiv could and perhaps should be extended (see rumors of "censorship" of papers that do not agree with its administrators' beliefs).

Ideally, it could be extended through a partnership with a big player in the open access field. The committee could talk with Creative Commons, Internet Archive, OurMedia, Wikipedia, and Google, to provide servers and bandwidth.

Any of them would be interested, I think, in participating in such a project. Right now, I, as an individual, can publish anything I want for free in OurMedia or the Internet Archive, with the material retained there indefinitely.

The printed part covered by the "prestigious" journals is much more important. Only electronic access through solutions such as arxiv is not enough to overthrow the present paradigm and mindset. You need also printed journals with a physical presence in the libraries that will gradually "push aside" the existing exorbitantly priced ones.

For this you will need a partnership with a self-publishing company (e.g. lulu.com). The cost of self publishing a black & white 100 pages book through lulu is $6.53, plus shipping, which is extra and obviously varies by area, but is not unreasonable. So what is this $3000/paper published in a journal, when the editorial board and referees all work for free?

Amazon also has a self publishing program. It is more expensive, but again this is a matter of negotiations. Amazon undoubtedly would like to be associated with such a prestigious project, as would any company.

With such a model, you could charge libraries reasonable amounts, and be even able to pay the editorial board and the referees. And you could sell subscriptions too, again with reasonable prices.

So you set up this partnership with the self-publishing company, you get the prestigious editors and referees from the prestigious journals to work on the open access journals too, and then gradually only on the open access journals, you persist in this, and you may have something.

You just need important papers from important people to get published in your open access journals, and the rest will take care of itself. This is not so difficult. People with established reputations will not have much resistance in publishing in open access journals, and if they do, the rest will follow.

Well, I did say that it will seem utopic. However, it only seems so, it isn't. You can't do open access with the old closed bureaucratic mindset. You need to get into the project players with the new open mindset.

That said, I know it is quite improbable for something like this to actually happen. And this despite the fact that you, the academics who participate in these science blogs, plus your interested friends and acquaintances, could get together, review a number of worthy papers from arxiv, and have a printed journal out by the end of the month.

You already do this when you post in your blogs links to arxiv papers you consider important. The step from that to have these papers printed in a journal of good print quality is trivial. You could even start by publishing Pelerman's papers. You can't get more prestigious than that.

14. **Peter Erwin**
September 10, 2006

For what it's worth, paying for journal publication is somewhat the norm within astrophysics, and has been for years (pre-dating the whole "open access" dicussion). Three of the four top journals have "page charges" (slightly more than $100 per page); these are sometimes paid by authors' institutions, and sometimes by the authors out of their grants (this is a standard budget item in grant proposals, like money for attending conferences). The two US-based journals, which always have page charges[*], do not suffer relative to the British journal *Monthly Notices of the Royal Astronomical Society*, which has no page charges.

(These are in addition to institutional subscriptions.)

[*] The European journal *Astronomy and Astrophysics* has a system where "sponsoring countries" contribute yearly sums, in return for which all scientists from those countries can avoid the page charges.

15. **ObsessiveMathsFreak**
September 10, 2006

> The report also tries to claim that the advent of LHC data will somehow make the refereed particle physics literature and open access to it much more important.

What is it with all the appeals to authority of the LHC? It's not even finished, but every second argument in the theoretical physics blogosphere and beyond seems to add in that; "LHC will probably confirm/disprove/support/question this theory/argument/viewpoint".

It's only a particle accelerator, albiet an extremely big one.

16. **Gina**
September 10, 2006

While the prices of commercial journal is often too high and scientists should play a role in pushing towards lower prices, I would be very cautious to try to move to an entirely different system where everything is controlled and run by scientists and/or based on publically-financed infra-structure.

On another matter, I would like to suggest to Peter to devote a special post on the "not even wrong" blog to allow for comments, questions, reviews, critiques, and perhaps a discussion on his book "not even wrong".

17. **Sailor Moon**
September 10, 2006

And where does the funding for arXiv.org come from? The discretionary budget of a library with a frozen (shrinking if you account for inflation) budget. It competes with armies of librarians in public services, an undisciplined program of one-off digital libraries, armies of public services librarians, a content-management system implementation undertaken for political reasons, and competition with Project Euclid, an essentially for-profit effort in math publishing.

The future isn't bright.

18. **TheGraduate**
September 10, 2006

In order to have open access I think the following changes are key:

1. All professors should be paid for their work: I think that professors working for free introduces economic inefficiencies because it makes it difficult to access the true cost of printing the journal.

2. Specific institutions should offer temporary contracts to have their journals managed by the companies in the private sector and the institutions should then offer their journals to the public for free.

The competition is necessary to keep prices down. Without competition, the prices would inevitably rise. By having specific institutions offer this service, it also allows variation eg. governments, universities.

I think it is essentially impossible to offer something to the public for free without having a benefactor.

19. **Juan R.**
September 10, 2006

Academia would focus on the true issue: optimization of the publishing process, developing a solid scientific language for publishing (LaTeX is **not**) being learned by young scientists and enginners at University. Any other approach is in my opinion –and history is proving me- a waste of time. If you do not reduce publishing costs, them translating them from readers to authors (PloS approach) or to mixed grants/funds/fees approaches or to 'free' systems (e.g. ArXiV) will not work as time has proved in many ocassions:

– PloS is economically unsustainable and currently they are losing a lot of money and survives thanks to millionary funding from third philantrophy bodies.

– ArXiv model has failures with administration, peer-review and is only working for simple publication process (PDF articles served online) in theoretical disciplines. It does not work for other disciplines. ArXiv-like approach fiasco in chemistry is well-known, i.e. the fiasco of the chemical preprint server: CPS.

– About SPARC. I find interesting they omit to say the free PloS journal cited in its site relies on $13 millions philanthropic grants and that charge $2,500 to authors. A look to SPARC membership dues is also interesting.

– Etc.

There is also a myth about that electronic journals are of small cost. Well, PDF versions of printed articles are cheap but that is not all one needs. In disciplines as chemistry publishing is something more than a PDF article of a theoretical work. Moreover, the myth of low cost vanishes with full electronic journals doing use of advanced web technologies: semantic web, XML specific scientific languages for datuments, databases…

In my opinion, there is another myth on private publishers being too expensive –that myth was base of finantial failure of PLoS and related approaches-. Well I have purchased 10 pages article from 80s on APS journals (official body for physicists) at $25 and 3 pages 2006 articles on ACS (official body for chemists) journals at $25 (the online version). Both APS and ACS are **non-profit** official bodies and publishs their own journals. Still $8,3 per page for a recent article or $2,5 per page for a 20 years old article are very expensive rates. This indicates that excesive profit from private publishers is not all of the problem, is it? Note: i agree that profit rates of Elsevier, Nature, and other private publishers could be lower and journals less expensive.

Another point of disagreement is in the double attitude of academia. At the one hand, they critize expensive journals and claim for open or free approaches but when publishing most of people choses a highly respected journal (i.e. those usually at $30 per article) because their colleagues give it more prestige and posibilities for a career. Would not prestige be offered in basis to quality of works instead where they were published?

Baez said:

You are right, but in some countries (e.g. Spain) position in Academia follows strict buroucratic (stupid?) rules. You receive many points for publishing in journals of class A, and little points for journals of class B, and C. After all points are computed for the committe and you can obtain a career or not.

Gebar said:

> For this you will need a partnership with a self-publishing company (e.g. lulu.com). The cost of self publishing a black & white 100 pages book through lulu is $6.53, plus shipping, which is extra and obviously varies by area, but is not unreasonable. So what is this $3000/paper published in a journal, when the editorial board and referees all work for free?

This highlights another of myths between academics. I managed a printed bulletin for chemists some years ago -Galicia química for the official body of chemists in Galicia (Spain)- the real cost was not in printing and distribution (we optimize size and shape for printing costs and weight for minimizing distribution charges). The real cost was in administrative and meta-publishing costs. Therein today you buy a 10 pages PDF article by $30 today on a non-profit ACS journal. Elsevier for instance has developed their own XML language for its internal publishing workflow. Even reusing available standards –e.g. MathML for mathematics from W3C, character encodings from Unicode- they still were forced to develop extensions to the official MathML spec for special needs on its journals and continue working with the Elsevier matrix for encoding because Unicode does not cover all of academia publishing –this will change when STIX project for scientific and enginnering fonts was finished-.

Suggestion: The 'open' or 'free access' initiative would also address the problem of books and monographs. They are very, very expensive doing scientific data was only accesible to rich scientists (or scientists in a rich University). How could someone at some humble University pay more than 1000 euros -more than $1270- for a specialized handbook on molecular physics and quantum chemistry from Whiley?

    Nice post!

21. **LDM**
September 10, 2006

    The mathematics literature still has a functional peer-reviewing system and it plays a very important role of keeping the number of incorrect proofs and unreliable results to a minimum, but the particle physics literature is very different.

    For example, the classification of finite simple groups (alluded to in NEW by the way), completed in the 80's, required ten thousand journal pages. Some of the papers were so dense it is probable that they were read only by the author himself and the referee.

    Would anyone believe this classification if it was based on pages only in the axXiv?
Probably not.

22. **TheGraduate**
September 10, 2006

    LDM:

    It seems to me we probably shouldn't believe it if it was only read by two people. Wouldn't you agree?

23. **LDM**
September 10, 2006

    TheGraduate:

    I understand your point and it is a good one.

    For me, it is more interesting to consider if such a proof could have been done using the arXiv as a means of publication…before we get rid of the journals, let's first be aware of and have a clear understanding of what they have accomplished.

24. **TheGraduate**
September 10, 2006

    LDM:

    I don't think open access and peer reviewing are mutually exclusive. For instance, one could have a review system where reviewers have rankings and a paper derives a reliability rating from the generally esteem in which a reviewer is held.

    In order to control the reviewing process, one might require that only AMS members can review AMS approved journals or something like that.

There is really no reason that open access has to mean a completely anarchic process.

Incidentally, I think it's important to pay reviewers for their work.

25. **D R Lunsford**
September 10, 2006

I used to spend countless hours pouring over the journal stacks in my library, while an undergraduate. I spent more time in the library than in class. Every now and then I'd come across a fascinating idea that was far off the mainstream but intrinsically interesting. Such papers have no chance on the arxiv. Open access is worthless if a battery of censors with an explicit agenda circumvents it. I still think I am the only person to have an already peer-reviewed and published paper censored from the arxiv. I have three more and a fourth underway which are IMO at least interesting. I dare not send them to the arxiv. Is this openness? If so it is a strange definition.

-drl

26. **Alejandro Rivero**
September 10, 2006

but couldn't it be replaced by an open commentary scheme? Authors could solicit commentary from either known or hidden reviewers.

Hey, this is an idea. The soon to be abandoned physcomments site was accused of SPAM because for every paper in hep-th* he asked two persons to comment about. Of course every referee request from every refereed journal is SPAM according the definition "spam=unsolicited email". But it could be diffferent if the Author is asked to write, or at least to sign with his email address, his own cover letter, which in turn is to be sent to two anonymous referees who can shoose about CCing back to the author or sending directly to the journal.

>Academics, however, don't need to gain prestige by
>publishing in a prestigious journal, if they can make
>breakthroughs in their research. Recent work of Perelman on
>Poincare conjecture would be an excellent example.

The problem is that not only breakthroughs like Perelman's are important. In fact, those are rare and far apart. Incremental progress and consolidation of acquired knowledge is enormously important and, in time, is what leads to breakthroughs.

In fact, the progress that has been made in particle physics over the last 15 years is mostly incremental: a truly impressive mass of theoretical and experimental results that sets the stage for the next large breakthrough.

But the merits of incremental work are to some extent more debatable and open to subjective, and even "political," criticism. There's where the seal of approval of a leading journal enters the game.

28. **TheGraduate**
September 10, 2006

D R Lunsford:

There is always the internet. I think the issue is really not censorship at all. We are in an age where we can always find information if the author wants to make it available.

I think the issue is really information that can not be accessed.

When something is published by a journal, it obtains the seal of approval of that particular publisher. It is this seal of approval that we care about …

The price of this seal of approval is the information now can not be accessed by those of us too poor to obtain it.

I think we are in an age where it is within our grasp to overcome this disadvantage. Youtube, Wikipedia and descendants of Napster are proving this over and over everyday.

I would hope there would be a sort of large system where all papers could be found but those that had not been reviewed by a respected reviewer could be filtered out IF AND ONLY IF the searcher wanted them filtered out.

29. **Energex42**
September 10, 2006

I think a viable model can be a non-profit foundation run journal system. A donation from a famous person can get this thing started, then a break-even fee would be paid from the academic subscribers to keep it running.

30. **Scott Aaronson**
September 10, 2006

drl: Would you mind linking to the published paper of yours that was rejected from the arXiv? I think that, because of the arXiv's central role in disseminating science, the moderators ought to avoid doing anything that even *looks* like censorship, even if it means the rest of us need to scan the titles of a lot of bad or irrelevant papers. So I'd be curious to see what it is that they rejected.

The real cost was in administrative and meta-publishing costs.

That's exactly what I mean when I say that you cannot do open access with a bureaucratic mindset. You let your "partner" (Amazon, or Lulu, or whoever) handle the administrative and meta-publishing costs, because they have already in place the infrastructure to do it.

Managing your subscriptions could be as simple as logging into your journal administration account in Amazon and clicking a few buttons so that the last issue of your journal will be sent to a list of recepients, in the same way you order a book to be sent to a friend.

The subscriptions could also be sold be Amazon, as well as individual issues. I can bet you they will cost a ridiculously small fraction of these hair raising prices charged by elzevier and sparc.

Any big publishing house would jump at the opportunity to partner with a formal body of academics who want to set up such a project. However, it only makes sense to go with a company that already functions according to the open access model, so that you control the material instead of the publishing house. Else you will end up with the same situation you have today.

Here's a challenge. Propose ten important papers and get permission from their authors to be published. Anyone of you could set up an account in lulu or some other such publisher, set up the issue, and have it sent to the authors or anyone else who wants it. The price again would be ridiculous.

The only thing missing to make this viable is a respected group of people who will manage this, and a respected editorial board and group of referees, perhaps the same people who now slave away for Elzevier.

33. **John Baez**
September 11, 2006

Scott Aaronson writes:

> Thanks, John! I agree that prestige is part of the answer — but if it were the whole answer, then wouldn't we expect academics to agree *in principle* that the system sucks, even as they vied to publish in the top journals?

Hi, Scott!

That's a good question. I spend a fair amount of time trying to teach people about the the problems with the system. Academics who read my stuff usually *do* agree that this system sucks. If they're idealistic enough, they even stop publishing in evil journals. Others agree "in principle" but feel their careers can't afford that much idealism.

But the people who are being most directly injured are not the academics – it's the librarians. They're the ones who have to keep cancelling journal subscriptions or buying fewer books in order to hang onto subscriptions to the "prestigious" journals. If you talk to them, you'll find they're *livid*.

You might say the academics are being hurt by a system where they do lots of work for free while big companies make money off their labor. This is true – but I think most academics value the prestige they get from association with prestigious journals more than the money they might earn.

(There's something so nice about seeing your name on the front cover of a famous journal, right there with the bigshots in your field. It's like seeing a bronze bust of yourself. The feeling itself is worth thousands of dollars, even apart from the useful connections and influence such a position gets you.)

So, I think most academics see the problems as abstract, until their favorite journals get cancelled when the libraries can't afford them anymore – or until they notice that their libraries can't afford to buy many books anymore.

34. **John Baez**
September 11, 2006

Jeremy writes:

> John Baez writes:

Academics need prestige to survive – that's how we get jobs, and that's how we get promotions. Yes, we can get this prestige by making breakthroughs like proving the Poincare conjecture – gee, why didn't I think of doing that? But, most of us don't make such breakthroughs.

So, most academics will do whatever they can to collect scraps of prestige: giving talks at conferences, organizing conferences, serving on advisory boards, publishing in prestigious journals, publishing books at prestigious presses, etcetera.

If you want to see all these scraps of prestige lined up neatly and organized, just look at job applications. Anyone on hiring committees will know what I mean.

In short: to get an academic to do something, just dangle a bit of prestige in front of him. Companies aren't dumb: they know this.

35. **TheGraduate**
September 11, 2006

My feeling is that the publishers aren't really offering anything special when it comes to journals so economics dictates that prices have to fall. Academia is sort of a communist universe (lifetime jobs, free work) so maybe that's why it is taking so long for the journals to drop in price.

For instance, I am sure Wikipedia is affecting encyclopedia sales and Wikipedia is written by random people.

36. **Florifulgurator**

September 11, 2006

So, why not opening a prestigious free electronic journal with a prestigious editorial board like Inventiones Mathematicae, and the main server (feeding the mirrors and printers) at some prestigious institute?

I guess we need to wait for that till the old pre-internet big names have died out and leave space for 21st-century-ready internet literates…

37. **Moshe**
September 11, 2006

John, I am with Scott on this (I think), that is, I just don't get it, including the prestige part. For example if the editorial board of "Topology" that just resigned got together and established the free-access electronic journal \tilde{topology} or topology' or something, which would be now the prestigous journal? I'd like to think an academic community would look beyond brand names and such when attaching prestige to publications, for example by quantifying it using "impact index" or other such criteria.

38. **Juan R.**
September 11, 2006

Gebar,

Let me doubt that partners like Amazon or Lulu have the infrastracture to do it. I already wrote a bit about technical details above.

> Here's a challenge. Propose ten important papers and get permission from their authors to be published. Anyone of you could set up an account in lulu or some other such publisher, set up the issue, and have it sent to the authors or anyone else who wants it. The price again would be ridiculous.

Well, the true is that we talk with Google Scholar people and even they can offer just a small subset of search and indexing capability needed (e.g. nothing at level of CAS functionality). The Googlebot directly indexes PDF files and extract metadata to databases, but it is limited since work in PDF files. Yes, pdf files is everything in ArXiv but is not in other disciplines where c3d and csm files or cif
databases are needed.

It is true that high cost of journals is an issue, but i think that academicians are losing the main point. In fact, all alternatives i know to the standard model either provide just a subset of functionality (e.g. online journals managed by academicians via web server) or failed in other disciplines (e.g. fiasco of ArXiv in chemistry) or are economically not viable (e.g. academicians abandoned Elsevier because was too expensive -they claimed- and funded PloS are losing a lot of money even when soliciting $2500 fees for each article).

Juan R.

39. **Ken Muldrew**
September 11, 2006

It may be worth keeping in mind that this discussion extends beyond theoretical research. The vast majority of scientific papers communicate experimental results (vast is too small a word!). The utility of experimental results, even rather trivial, incremental results, lasts for decades (centuries, even). This is especially true in fields like biology and medicine where there are no theoretical structures that can be used to figure out what the result of some experiment ought to be. Refereeing is essential for experimental papers to ensure that enough methodological details are provided for the experiments to be repeated, as well as for technical issues. This refereeing is done by scientists, without charge, and run under the auspices of scientific societies (also run by scientists and paid for by scientists). Archiving, though, involves print journals and library subscriptions. And high quality archiving with widespread distribution is essential to the scientific enterprise.

My point is that there is more to this than just prestige; a scientist is a member of a community that has extended temporal boundaries. One can do work that extends something done by a scientist who died a century ago, but only if you know the details of what that person did so long ago. The integrity and honesty of scientific work is currently maintained through the journals and this has to be retained. For experimental work, something like the arXiv is sort of a bridge between conference talks and publications; a new phenomenon that doesn't replace the old ways but rather adds to them, like email as it relates to phone conversations and page-written letters.

I think we can solve the archiving problem through the interaction of scientific societies with librarians (and possibly the creation of some new organizations who have a passion for the integrity of information, much as those who join scientific societies have a passion for learning the nature of things). But this solution will probably take the form of a phase change, and few can afford to submit to a process that doesn't happen very quickly. For those commenters who disparage scientists for their lack of spine, it's actually a pretty big deal to lose your livelihood and your career. By the time you put maybe 10 or 12 years of university study, 4 years of post-doc, a bunch more years as a semi-faculty ghost before finally getting hired, you have quite a bit invested in your career. Getting to this point means that you have a bunch of ideas and projects that you want to get done to share with the scientific community that you belong to. It's just not very tempting to stuff it all and become a martyr to the cause at a point where it's not clear how effective your effort might be. Because if you don't keep pumping out the papers in decent journals, you're down the road.

40. **Chris W.**
September 12, 2006

Ken,

This recent Wall Street Journal article is relevant to your comment about access to experimental results, as well as the general concern with open access, although the focus here is on a shorter time horizon:

Gates Won't Fund AIDS Researchers Unless They Pool Data
(WSJ, 7/20/2006)

> There's no guarantee these particular grants, or the Gates foundation's efforts in general, will lead to a working vaccine. But since fragmented vaccine efforts have yet to protect a single human from the pandemic that rages out of control in many regions, some supporters argue it's time for a new approach. Grant recipients and outside observers were unsure whether data-sharing requirements of the grants could pose potential legal or patent conflicts with Mr. Gates's vow to respect intellectual property. Foundation officials said this week researchers would still be free to commercialize their discoveries, but they must develop access plans for people in the developing world.
>
> . . . .
>
> There are four major goals to be funded by the grants: vaccines that spark neutralizing antibodies to block initial infection by HIV; vaccines that make stronger T-cell response to kill infected cells; creation of standard criteria to measure success or failure; and a new, secure Web site for sharing all the data in real time.

“Whether in academics or industry, scientists want to protect intellectual property. … With the alliance, the shift is to say: ‘No, the large enterprise is more important than the position I keep by holding my data close,’” says Steve Self, a biostatistician at the Fred Hutchinson Cancer Research Center in Seattle, which is lead investigator of a $30.1 million grant to create new adjuvants, ingredients that boost a vaccine’s power. Dr. Self got a $10 million grant to create a secure central data repository to be named Atlas.

Enforced data sharing, Dr. Self predicted, “increases the pace of discovery enormously rather than waiting for the process of writing formal journal articles, waiting for them to be published, and [confirmed] by other labs.” As efforts funded by the Gates grants get under way, other funders must not be lulled into complacency, warns Mitchell Warren, executive director of the New York-based AIDS Vaccine Advocacy Coalition, a nonprofit community group. Activists recently have voiced concerns that the National Institutes of Health budget is flat in real terms.

September 12, 2006

Posted as a test; please feel free to delete after an hour or so.

(My last comment vanished into thin air…)

42. **Peter Woit**
September 12, 2006

Chris W.,

Your previous comment ran afoul of the WordPress automated anti-spam software. It is highly suspicious of links in comments. Maybe it also noticed that your comment is getting fairly far away from the topic of the posting…

43. **Chris W.**
September 12, 2006

Can you suggest any guidelines about including links, other than “don’t do it” or “include them at your own risk”?

44. **Peter Woit**
September 12, 2006

Chris,

Hard to say, the anti-spam feature is called “Akismet”, most of the time it does a remarkably good job, which is why I keep using it. But it does make mistakes, often hard to tell why, except that links are something that make it suspicious (much of the spam consists just of links). It seems to use some proprietary algorithm running on their server, which they don’t divulge. As far as I can tell, it also doesn’t allow any configuration choices, e.g. I can’t whitelist people

45. **Exploited**
September 13, 2006

I do not have a research position, and probably will not have one in the foreseeable future. At the same time, I continue to publish papers in very prestigious peer-reviewed journals, at the top of their range. In this research, I invest most of my waking existence not taken up by my actual paid duties, and I get paid nothing for it.

In most publishing models, the author gets paid by the publisher, or in royalties, or both. Yet I am expected to provide my work, from which the publisher derives obvious economic benefit, entirely for free. The fact that I collaborate in my own oppression, in order to be taken seriously, probably shows me for the idiot I am. Still, something is wrong with the model. It may have worked better in the past, but for people like me it fails miserably.

46. **jeremy**
September 13, 2006

John Baez writes:

“So, most academics will do whatever they can to collect scraps of prestige: giving talks at conferences, organizing conferences, serving on advisory boards, publishing in prestigious journals, publishing books at prestigious presses, etcetera.
If you want to see all these scraps of prestige lined up neatly and organized, just look at job applications. Anyone on hiring committees will know what I mean.
In short: to get an academic to do something, just dangle a bit of prestige in front of him. Companies aren’t dumb: they know this.”

The price of the prestigious, and not so prestigious, journals and the prestige sought by academics to advance their careers are two different things. One is created by the publisher, the Companies; the other is the product of the academics. All the prestige collecting activities listed above are in fact have nothing to do with the Companies. It is fair to argue about the sky rocketing journal prices, but it would be unfair to accuse the publishers for dangling “a bit of prestige in front of” academics.

It is not too difficult to find that although the Companies publish the prestigious journals, but none of the editors and the editorial board members of those journals comes from the Companies. In fact, the Companies do not even have much to say about who should be in the editorial board. It is the academics that serve as the editors of the journal choose other academics as editorial board members. It is also the decision of these people to publish or not publish a submitted paper. In many cases, it is the editors who will do things such as inviting “bigshots” writing review papers and organizing special issues for the journal to make the journal more prestigious. The survival of the academics is also decided by other academics based on the, sometime unspoken, rules by the academics. The real problem is the system. A system created by academics themselves. The Companies, at most, take advantage of the system, but who wouldn’t. We can hardly blame them.

The price of the journal, as the price of anything else, is controlled by the market. It is a problem that can, and will be, solved by the market force. (Game theory?)

47. **Stinker**
September 15, 2006

If you believe in open access, how come your book is not available for free on the web?

What’s the difference between commercial journal publishers and commerical book publishers besides that the former don’t pay authors?

48. **woit**
September 15, 2006

Stinker,

The main problem with commercial scientific journals is the high cost, which can be $1-2 per page. You can buy my book on Amazon for about $18, which is around $.06 per page (and the paperback will be cheaper). If commercial journals were charging $.06 per page, no one at all would be complaining. It's the very high costs which are causing serious problems for library budgets, causing them to have to cancel journals and not buy books, ending up with journals only being accessible at a small number of wealthy institutions.

Personally I also find books and journal articles to be quite different in that it often makes sense to read a journal article on line, or print out a copy to look at, but I neither want to have to print out, nor try and read on a computer screen, a 300 page book. For books like mine, the amount publishers charge to produce a well-made printed version seems reasonable. What is more of a problem are technical monographs that are often sold for $100 and up, raising the same kind of problems of affordability and accessiblity as journal articles.

49. **Stinker**
September 15, 2006

Sounds reasonable. I think the main difference is who bears the cost. The buyer of the book presumably wants to buy the book; the temporary instructor laid off because his university finds it more important to maintain a subscription to (insert your favorite crap Elsevier journal here) presumably does not want to maintain that subscription. Which is to say when one submits articles to commercial journals the cost is felt by someone else; when one publishes one's book on blah-blah it is only the publisher and the buyer who face any costs.

To put it still another way – a lot of the more expensive commercial journals are closer to vanity presses than a lot of folks like to admit – their quality is low, the barrier to publication is low, and the main reason for submitting to them is to pad one's CV, which as we all know is very important for the good of humanity (at least a small part of it).

50. **TheGraduate**
September 15, 2006

I think there are definitely some externalities concerning the buying and selling of journals.

The publishing company provides two services to the academic community, the actual physical journal and the prestige of association with that journal either through publishing in that journal, editing that journal or reviewing for that journal.

I think this situation is somewhat similar to the fashion industry where one both pays for the article of clothing and the prestige (or branding) or that article.

I think this situation almost certainly guarantees that the academic community is overpaying relative to the actual cost of manufacture and administration of the journal.

The prestige end of things functions like a tournament. In other words, a large number of researchers support the system, so that a few can excel by publishing in the most exclusive journals. But frankly, statistics on the number of papers published by most academics suggest that most academics don't benefit at all.

The journal end functions in a monopolist manner as one can not buy equivalent product from different producers.

In other words, all around this system is pretty horrible.

Note, the benefit to an individual academic in terms of submitting to a prestigious journal and advancing his career is paid for by the ENTIRE academic community. Isn't this madness?

I think the way to achieve low prices is pretty well explored ground. Many producers, equivalent product across producers, transparency in terms of determining costs and benefits.

51. **Ivars**
September 16, 2006

All scientific information must be free and accessible to users; It does not matter whatever model is used as long as it serves the purpose and moves in right direction of increased availability.

If it stops to serve its purpose, it will be changed or eliminated. No need to worry about the RIGHT solution. When time will come, old style publishers will dissappear, but to achieve that, competition with open access is needed.

It is very OK to start it by funding the current publishers into their own elimination. Why not?

Various Links, Latest From Kaku

September 10, 2006
Categories: Uncategorized

Seems like everyone is getting a MySpace site, first Michio Kaku, now GLAST.

There was a conference this past week in Madrid honoring Nigel Hitchin's 60th birthday. The program is here.

The latest issue of Nature has an article by Barry Mazur about recent progress on the Sato-Tate conjecture due to Mazur's Harvard colleague Richard Taylor and collaborators. My meager understanding of this result is that it involves extending the Taniyama-Shimura-Weil conjecture from the case of the two-dimensional representation of GL(2) to symmetric powers of this representation.

Mark Trodden and Christine Dantas both have well-done reviews of Alex Vilenkin's Many Worlds in One, which I wrote about here. Mark implicitly compares the book very favorably to Susskind's recent one promoting similar ideas. I kind of disagree with him about the book, feeling that, no matter how well done, promoting to the general public science consisting of highly speculative ideas that seem to be untestable is not a good idea. It's true that the multiverse cannot be simply dismissed on the grounds that one can't directly observe it, but if the idea is to be considered part of science one has to come up with some way to test it. So far no one has been able to come up with a plausible proposal for how to do so, and there are solid arguments that this is inherently impossible.

Update: A commenter points out that on his MySpace site Kaku has posted a copy of a forthcoming article by him that is supposed to appear in New Scientist. It is about the controversy over string theory, but doesn't at all deal with the criticisms of the theory contained in my book and Smolin's. It does contain a thoroughly dishonest paragraph about me, misrepresenting my position at Columbia (Kaku is well aware than I am a faculty member and teach graduate courses here, as well as administering the department computer system), and describing me as a "former particle physicist" (he's well aware I have recently written a book on the subject of particle physics and continue to conduct research on the subject; then again, many people consider him to be a "former particle physicist"). He ascribes my criticism of string theory to jealousy over having been turned down for tenured positions at prestigious universities in favor of string theorists, and misquotes something I wrote about string theory:

String theory has only a "poetic relationship" to reality.

I never have said or written anything like this. He is misrepresenting a point I made in the book that string theory is a quite complex mathematical structure that only has a very distant relationship to musical notes and vibrating physical strings:

Once one starts learning the details of ten-dimensional superstring theory, anomaly cancellation, Calabi-Yau spaces, etc., one realizes that a vibrating string and its musical notes have only a poetic relationship to the real thing at issue.

The paragraph about me is dishonest and misleading, and so is much of the rest of the article. Kaku claims that string theory is being criticized because it cannot be directly tested by observing vibrating string modes. Critics of string theory are well aware that many theories can only be indirectly tested, and the arguments we are giving are about lack of any predictions at all. He describes five "indirect tests of string theory", neglecting to mention that string theory makes no definite predictions about what the five kinds of experiments being described will actually see. In particular, his claim that "string theory makes specific, testable predictions about the physical properties of dark matter" is simply untrue.

Some of the article is devoted to criticizing "media hype", and a "spoiled society, always demanding immediate results". Given his own role over the last twenty years in over-hyping and over-promising results from string theory, this is kind of funny to read. In the end, his response to the critics is similar to that of Susskind: less than honest ad hominem attacks, misrepresentation of criticism, and insistence that any evaluation of the success or failure of string theory be postponed to the far distant future, at a time when he will no longer be around.

Update: From Stanley Deser, perhaps the shortest arXiv theory paper ever.

Comments

1. **anon**
   September 10, 2006

   I notice from your link that Michio Kaku has a new blog entry dated today here which gives the complete test of a New Scientist article of his to come out in mid-November:

   "Civil War Erupting over a "Theory of Everything"
   "By Dr. Michio Kaku

   "… The debate is so white hot that some physicists have traitorously switched sides. …

   "… It's a sign of the vitality of theoretical physics that people are so passionate about the outcome. Science flourishes with controversy. …

   "… Basically, any unified theory must:

   "1) unify gravity with the quantum theory (whose most advanced version is the Standard Model, with its bizarre collection of quarks, leptons, gluons, W-bosons, etc.)

   "2) yield finite answers. …

   "The Standard Model of particles simply emerges as the lowest vibration of the superstring. And as the string moves, it forces space-time to curl up, precisely as Einstein predicted. Hence, both theories are neatly included in string theory. And unlike all other attempts at a unified field theory, it can remove all the infinities which plague other theories.

   "But curiously, it does much more. Much, much more. …"

   Professor Kaku goes on to decribe you as "former" particle physicist, and tells the world his reaction to your case:

   "Personally, I smile when I hear this criticism. … My own personal point of view is that we live in a spoiled society, always demanding immediate results. We pop pills, push buttons, flip channels, and demand instant gratification. The media whips this up, lavishing praise when you are on the rise, and dumping on you when you are down."

The most important thing is that Kaku only tries to refute your case with a list of very “indirect tests” for string theory, without once mentioning Smolin or his work. The indirect tests could be also consistent with many other different theories, so confirmed predictions mean nothing, particularly since alternative theories are suppressed.

2. **Mark Trodden**
   September 10, 2006

   Hi Peter. I just wanted to correct you that I don’t necessarily compare the book to any specific other piece of work by anyone else. I merely comment on Vilenkin’s attitude. I haven’t actually read the other book you mention.

3. **woit**
   September 10, 2006

   Thanks Mark,

   I’ve added a note to correct this.

4. **D R Lunsford**
   September 10, 2006

   Peter – in the vernacular – you rock.

   -drl

5. **Christine Dantas**
   September 10, 2006

   Woit wrote:

   I kind of disagree with him about the book, feeling that, no matter how well done, promoting to the general public science consisting of highly speculative ideas that seem to be untestabe is not a good idea.

   You are certainly right on this. However, I have given Vilenkin some “discounts” because he, in fact, is careful at some points:

   – Page 61: “Another important question is whether or not such scalar fields really exist in nature. Unfortunately, we don’t know. There is no direct evidence for their existence”.

   – Page 91: “A physical theory can be suported by the data, but it can never be proved. On the other hand, a single well-established fact that contradicts the theory would be enough to disprove it.”

   – Pages 116-117: “Do we really have to believe all this nonsense about our clones? (…) First of all, there is always a chance that the theory of inflation is wrong. (…) Even if our universe is the product of inflation, it is conceivable that inflation is not eternal.”

   And, this one, which probably is not a consensus, but gives some sense that things might be confined anyway to the realm of internal theoretical consitency, at least for a long time to come, and these theoretical ideas could also end up as completely wrong when experimental facts come into play:

   – page 193: “(…) quantum cosmology is not about to become an observational science. The dispute between different approaches will probably be resolved by theoretical considerations, not by observational data. (…) This issue is not likely to be settled any time soon.”

   So, I tend to believe that the public for this book, namely, people interested in science, will be able to get the warning messages. But I do think that he could have been much more emphatic on the warning signs, yes.

   Christine

6. **MathPhys**
   September 10, 2006

   I want you all to stop trashing Michio Kaku. Anyone who can figure iceskate that good at the age of 59 has my support.

7. **TheGraduate**
   September 10, 2006

   Peter,

   I was curious about why you were so hard on Kaku, calling him “dishonest”. I was thinking that “former particle physicist” was much more positive than what Susskind had said.

8. **Renormalized**
   September 10, 2006

   “For ten dark years, string theorists wandered in the wilderness. Only the true believers, those willing to suffer severe deprivation and humiliation, kept the home fires burning.these dark years.”

   This reminds me of a story from the bible where another religion was born. Nothing like suffering to bring out castrametation, fortification and entrenchment.

9. **woit**
   September 10, 2006

   TheGraduate,

   It’s remarkable that both Susskind and Kaku won’t answer the criticisms of string theory in my book and instead engage in ad hominem argument. Susskind had a lot to say about me, both in a radio interview and in the Times Higher Education Supplement. Some of it was stupid and dishonest, some of it wasn’t.

   Kaku is well aware that, besides administering the department computer system, I’m a full-time faculty member in the math department at Columbia, teach graduate and undergraduate courses, and continue to engage in research in particle theory. His description was designed to try and dishonestly discredit what I have to say. I think it’s pathetic. It’s highly tempting to respond in kind by quoting what some of his colleagues have to say about him, but I’ll restrain myself.

10. **woit**
September 10, 2006

Renormalized,

He also refers to string theorists as “defenders of the faith”.

I wonder why some people think string theory has become a cult…

11. **who is Kaku?**
September 11, 2006

dear Peter, maybe you should clarify to the readers outside US: why M. Kaku is so important? SPIRES tells that he wrote a paper in 1999 and various string papers many years ago, so the answer remains unclear to me.

12. **MathPhys**
September 11, 2006

I think Kaku is great. You have to admire a man who has the guts to call himself “one of the founders of string theory” AND look up people like Witten in the eyes.

13. **Johan Couder**
September 11, 2006

I rather liked the Feynman joke

‘(Schwarz remembers meeting Richard Feynman in the elevators during these dark years. Feynman would say to him, with a smirk, “And how many dimension are we in today, John?”)’

You should definitely add this in your next edition.

14. **John Baez**
September 11, 2006

who is Kaku? asks:

> dear Peter, maybe you should clarify to the readers outside US: why M. Kaku is so important?

His importance has nothing to do with his research. Just look at his website. He’s famous as a popularizer of science – a kind of media star. He has a call-in radio show. He’s written a number of popular books – you can buy autographed copies from his website! And, he writes columns for influential papers like the Wall Street Journal. So, he affects the opinions non-physicists have about physics.

One can argue about how this matters – but I think it matters a lot. For one thing, every physicist was at one stage a non-physicist. If students hear some branch of physics is cool, they will want to enter it. For another thing, some non-physicists make policy decisions that affect physics.

15. **MathPhys**
September 11, 2006

John,
I actually agree with what you say. Someone has to the job that Kaku is doing: bringing science to the layman in a glamourous way, and he’s definitely good at it.

16. **stupid**
September 11, 2006

“PARALLEL WORLDS
A Journey Through Creation, Higher Dimensions,
and the Future of the Cosmos

“Parallel Worlds [has been] selected as a Finalist for the Samuel Johnson Book Prize for Non-Fiction…” – http://www.mkaku.org/

See? It’s “Non-Fiction”. So extra dimensions are fact.

17. **Chris Oakley**
September 11, 2006

> Parallel Worlds [has been] selected as a Finalist for the Samuel Johnson Book Prize for Non-Fiction…”

I would be prepared to nominate it for the *Humour* prize.

18. **Chris Oakley**
September 11, 2006

Oh – and by the way, Peter, Happy Birthday and keep up the good work!

19. **LDM**
September 11, 2006

Regarding the behavior of scientists who have managed to become famous (whether this fame was acquired through genius of research or self-promotion is moot)…

Once a scientist becomes famous, he/she is then in a very fortunate position to positively influence events outside of science…i.e., affect public policy.

We need only remember Feynman and the shuttle disaster…and before him, you can find Linus Pauling getting atmospheric testing banned
(a nice video on this if interested: http://video.google.com/videoplay?docid=257544512953282441&q=linus+pauling&hl=en)

I think it would be very foolish for a scientist to tarnish his/her reputation for veracity just to promote a book and make a few dollars…because once you have lost this reputation, it is very difficult to recover.

Also, Happy Birthday Peter!…life begins at N=40
(http://www.newscientist.com/article.ns?id=mg19025450.500)

20. **hack**
September 11, 2006

Everyone knows that Kaku is THE FATHER OF STRING (field) THEORY.

Anyone know how to make "field" appear in a smaller font?

21. **A Babe in the Universe**
September 11, 2006

Happy Birthday, and many more! Your criticism of strings is needed to balance hype of Kaku, Greene and others. Whip eternal Inflation Now!
After that, how about "dark energy"?

22. **Peter Woit**
September 11, 2006

I've just heard from Michio Kaku, who has had his webmaster take the article in question down, explaining to me that it was a very preliminary version of something he was writing, he had yet to check any of the facts in it, and had not intended it to be made public. My thanks to him for his gracious behavior when this was pointed out to him.

23. **werdna**
September 11, 2006

And kudos to you, Peter, for your gracious acknowledgment of your critic's proper behavior. Giving credit where credit is due (even to your "enemies") is a necessary characteristic of a good scientist.

24. **Mahndisa**
September 11, 2006

09 11 06

Happy Birthday Peter, and the links you provided on the non commutative geometries were quite useful. Thanks. As to the other stuff, sometimes I wonder if you spend too much time dealing with naysayers but perhaps the controversy can generate book sales. In any event I wish you success and more book sales!

25. **Ron Avitzur**

John Baez wrote: *some non-physicists make policy decisions that affect physics*. XKCD illustrated this recently.

26. **Stefan**
September 12, 2006

Post I:

Hi Peter,

Peter, regardless of all the neverending cocophony surrounding HEP these days, *ultimately* it will be experiments and solid research which will decide the validity of respective theories.

Can't critics (of any theory – strings, LQG, or what-not) take the intellectual moral high-ground and just post a message (similar to the one above) on their websites and *move on* to conduct research.

27. **Stefan**
September 12, 2006

Peter, your site is no longer accepting my comments. So, perhaps later.

28. **nigel**
September 12, 2006

Stefan,

Feynman and Glashow did that. They spoke out against the domination of HEP by stringy speculations, but were ignored. It did not help to create a greater diversity of research directions, because nobody listened.

Groupthink doesn't fall that easily. If Peter used this blog mainly to explain his own research in representation theory, he would just be another person with an axe to grind, or "pet theory".

Dismissing critics for promoting alternatives to string is more effective that dismissing critics for having no alternatives to string. In the former case, the critic is deemed an egotist, while in the latter case, the critic is deemed a dull plodder. Better dull plodder than egotist.

The inclusion of the Calabi-Yau manifold with its many variable parameters makes M-theory inherently insoluble and speculative. The response to such criticism is a Watergate-type cover up by a Nixon-like stringy leadership.

29. **D R Lunsford**
September 12, 2006

Happy integer T sub P, Peter – my friend the high school physics teacher ordered both the UK AND the US editions of your book for his library – and Smolin's, and to be fair, Susskind's. Here's hoping T sub P = k for large k.

-drl

30. **woit**
September 12, 2006

Stefan,

My blog software decided you were a spammer after you submitted several short comments in quick succession. Please don't do this, and please avoid submitting long comments (in one part or many) that aren't directly related to the postings here.

Yes, critics of string theory should, now that the problems with string theory are finally getting a proper airing, devote more of their time and energy to working on alternatives and explaining to others what they are. Now that my book is done and out, that certainly will be more the focus of my attention.

31. **Stefan**
September 12, 2006

Peter,

Thanks for the guidelines; I'll try not to post in succession from now on.

As for your second paragraph: yes, it's time to discuss alternatives. If you recall (?) our previous discussions, I have browsed through Amazon looking for works in Operator theory (for QM), Gauge-theory (the best ones I could find), and other areas in HEP. If you don't mind may I share the list with you to elicit your feedback? (I don't have much expertise in the areas covered).

If you should agree please send me a confirmation e-mail at my supplied address.

p.s. I know, the post is somewhat out-of-topic, but I don't have your e-mail. Please forgive… 🙁

Your friend,
Stefan

32. **dan**
September 12, 2006

I personally have read Kaku's books, and I object to how Kaku presents string theory as established fact.

From what I am reading now, it sounds like Kaku is another Lubos.

33. **MoveOnOrStayBehind**
September 12, 2006

"Can't critics (of any theory – strings, LQG, or what-not) take the intellectual moral high-ground and just post a message (similar to the one above) on their websites and *move on* to conduct research."

Right, critics and alternatives always occupy the moral high ground, just for contradicting the main stream, isn't it, no matter whether it makes sense or not (a classic german attitude).

Alas…. hmm.. there may be a little little bit of a problem…. while it is easy to convince laymen that the mainstrem needs to be abandoned just for the sake of it, the experts need to be convinced too, of any viable "alternative"… and, lets face it…. where is such a thing? The string community eagerly waits for tips and guidance as to what those alternatives were!

It's like NASA engineers being told that they should abandon their trade and rather consider alternative rockets and engines, out of old dishwashers, car motors, etc while carpenters propose to build rockets out of wood. I am sure if it came down to a vote on the internet, the mainstream rockets would be eliminated in favor of such "alternatives" everyone with zero education can have an idea about. It doesn't matter what the engineers say, as everyone on the internet is an expert and counts equal, as Lenny says so nicely. Indeed this is democracy at its finest!

34. **Peter Woit**
September 12, 2006

MoveOn,

The problem with your analogy is that NASA engineers have designed rockets that do what they are supposed to do. String theory, as an idea about unification, doesn't do what it is supposed to (explain anything about the standard model). In your analogy, string theory would be a heavily financed program to design a rocket that, after more than 20 years of effort, had only produced a sequence of more and more complicated test rockets, each performing worse than the last, with the latest versions (the anthropic landscape ones) blowing up in people's faces at launch.

String theorists should stop whining that no one is presenting them with a well-worked out alternative that can do the things string theory has failed to do, and either get to work on an idea about string theory that goes somewhere if they have one, or help look for an alternative.

35. **Eugene Stefanovich**
September 12, 2006

MoveOnOrStayBehind:

Your comparison of string theorists with NASA engineers would be correct if string theorists had at least one flying rocket. They hadn't. Isn't it a better analogy to say that string theorists are trying to build a rocket out of yarn? Then switching to old dishwashers does look as a big step forward.

36. **dan**
September 12, 2006

Incidentally Peter,
one reason I come to this weblog is that I find your comments about string theory entertaining.

"In your analogy, string theory would be a heavily financed program to design a rocket that, after more than 20 years of effort, had only produced a sequence of more and more complicated test rockets, each performing worse than the last, with the latest versions (the anthropic landscape ones) blowing up in people's faces at launch."

LOL

Incidentally, Peter, I read your book, including your anecdote about seeing Witten at the library and then disappearing, and musing he's an extra-terrestial alien with teleportation, wouldn't the quickest, easiest, most economical and most straightforward way to get string theorists to work on other research programs (such as LQG & Sundance-Bilson preon models of the standard model) would be to convince just one man, Edward Witten, to work on them? I would imagine if Edward Witten could be convinced to work on LQG, a lot of other string theorists would follow suit.

"String theorists should stop whining that no one is presenting them with a well-worked out alternative that can do the things string theory has failed to do, and either get to work on an idea about string theory that goes somewhere if they have one, or help look for an alternative. "

Where Witten goes, string theorists follow.

37. **TheGraduate**
September 12, 2006

dan,

That's an interesting point. I would be interested to read what Witten had to say about the current situation. I read that his undergraduate degree was in history. I bet he's a pretty good writer.

38. **dan**
September 12, 2006

TheGraduate,

I forget if I read that in Peter's or Lee's book (that Witten was a history major.) It amazes me I would think Witten was a super-child prodigy, math olympiad, etc. I wonder if he's like a Good Will Hunting.

I would be interested to read what Witten had to say about the current situation as well. I would be interested to read what Witten had to say about Peter Woit's NEW or Smolin's Trouble books.

One wonders whether Witten's pursuit of strings is like Einstein's pursuit of a unified field theory, and Smolin-Sundance-Fotini's preon model might be the equivalent of Tominiga-Feynman's pursuing quantum field theory.

39. **ak**
September 12, 2006

move on said:

'Indeed this is democracy at its finest! '

it seems it wouldn't be quite that simple to translate the failure of a 'TOE' to layman's terms if string theory wouldn't obviously fail on layman's grounds, one could call this a problem of perspective: for to judge rocket launchers not-launching-rockets you don't even have to see the rocket launcher.

40. **Chris Oakley**
September 12, 2006

> I would be interested to read what Witten had to say about Peter Woit's NEW

I think that we already know the answer to this: he did not want the book published as he felt it was airing the HEP theory community's dirty laundry in public.

41. **dan**
September 12, 2006

Dear Chris Oakley,

Did Edward Witten specifically state he did not want NEW published, and if so, where does he say this? And Peter, if Witten expressly did make such statements, how do you feel about that?

Curious
Dan

42. **Peter Woit**
September 12, 2006

About Witten,

As far as I know, it's not at all true that Witten opposed publication of NEW in any way. After I ran into trouble with Cambridge about publishing it, I sent Witten a copy and asked him what he thought. I don't want to quote personal communications here, or put words into his mouth, but he certainly didn't in any way tell me he didn't think it should be published. He definitely disagreed with my point of view, gave some reasons why, and wasn't offering to call up Cambridge and tell them they had to publish my book, but he also was not at all telling me that he objected to its publication in any way.

Chris's characterization does describe one of the referee reports that Cambridge got, but from the very little I was told about the referee, it definitely wasn't Witten.

43. **dan**
September 12, 2006

Dear Peter

"He definitely disagreed with my point of view, gave some reasons why"

I understand that your communication with Witten is private and personal, and that you will not inclined to share them, which is entirely understandable, but generally speaking, (not necessarily speaking about Witten) what reasons do respectable, seriously scientific string theorists who are familiar with the arguments and criticisms levelled in your book (i.e landscape, SUSY-cosmological constant, etc.,) and Lee's, continue to research string theory?

String theorists in general disagree with your viewpoint, and what are the general reasons they give, that are non-polemical rationally defensible, scientifically respectable?

44. **Peter Woit**
September 12, 2006

The most recent thing Witten has written about his views on string theory that I am aware of is from late last year, a piece in Nature:

http://www.sns.ias.edu/%7Ewitten/papers/Unravelling.pdf

I think it reflects well the views of sensible string theorists and is scientifically respectable and rationally defensible. It's not really "polemical", but it definitely takes the most optimistic possible view about string theory that can be defended and, as readers here are well aware, mine is rather different.

45. **Dan**
September 12, 2006

Well thank you Peter. Do you whether he's made any public statements about LQG?

Thanks
Dan

46. **Peter Woit**
September 12, 2006

Dan,
I don't know of any place Witten has made any public statements about LQG. At least in the past, rumors were that he wasn't very enthusiastic. No idea what he thinks now.

47. **dan**
September 12, 2006

Thanks. I think Witten's research interest is the single most influential decision into the direction of physics.

48. **woit**
September 13, 2006

dan,

Not always. For some reason, very few people are following Witten in the direction of his latest research interest, relating QFT and the geometric Langlands program.

49. **a**
September 13, 2006

in the above link, Witten writes: "And where critics have had good ideas, they have tended to be absorbed as part of string theory, whether it was black-hole entropy, the holographic principle of quantum gravity, noncommutative geometry, or twistor theory".

Did he forgot anthropism (e.g. Weinberg 1987)?

50. **stupid**
September 13, 2006

I notice that the first Google hit on the Geometric Landlands Program states prominently that it is partly funded by DARPA, the Defense Advanced Research Projects Agency:

http://www2.math.northwestern.edu/langlands/

Perhaps this military sponsorship is putting some people off following Witten?

51. **Benni**
September 13, 2006

Suesskind has told me in Munich, that "Witten hates the Landscape of String Theory because we cannot get predictions from it"

52. **Jeremy**
September 13, 2006

I find myself increasingly unhappy with Dr. Kaku the more I hear him speak in public as I get older. I knew how he was personally from a family connection and I can't mesh the personal with his large public profile.

After A Brief History of Time, one of my earliest popular physics books was Hyperspace, which I enjoyed very much as a child. However, after rereading it last year, I actually found it quite disappointing, filled with ephemera and run-through with torrid poetic descriptions.

I looked up his television appearances on YouTube about six weeks ago and just had to laugh at the situations he put himself in. From speculative fiction to futurist, his commentary was so filled with mayhap and possibility. More humour than anything else. I didn't understand why, with the kind of mind and content he's supposed to have, that's what he was coming up with.

And the "preliminary" version of his article very much got my head scratching. While obviously my opinion of him as a popularizer and scientist has changed over the last few years, I never once thought of him as mean. I can understand the need to respond to challenges, and the desire to scar opponents, and even those thoughts coming to the fore, but to actually write that down for publication and have it go online is disappointing to me.

53. **Alejandro Rivero**
September 13, 2006

De Broglie was also majored in history, wasn't it?

54. **TheGraduate**
September 13, 2006

Peter,

You said "very few people are following Witten in the direction of his latest research interest, relating QFT and the geometric Langlands program."

I was curious about the mathematical background of the string theory community. OF what does the typical mathematical education of a string theorist consist ? It seems as if they cover more ground than even most mathematicians.

55. **TheGraduate**
September 13, 2006

Let me rephrase my previous question a bit. Do most string theorists have the mathematical background to contribute to relating QFT and the geometric Langlands program?

56. **Peter Woit**
September 13, 2006

TheGraduate,

The mathematical background of string theorists varies widely, from no more than that of your average non-string theorist particle theorist to quite a lot more. But very few do have the background to work on the geometric Langlands stuff Witten is working on. To be fair, extremely few mathematicians themselves have the background necessary to follow the mathematics involved.

57. **Sebastian Thaler**
September 13, 2006

Peter-

You will probably enjoy Monday's edition of the comic strip THE FLYING MCCOYS:

http://news.yahoo.com/comics/uclickcomics/20060911/cx_fmc_uc/fmc20060911

58. **dan**
September 13, 2006

"in the above link, Witten writes: "And where critics have had good ideas, they have tended to be absorbed as part of string theory, whether it was black-hole entropy, the holographic principle of quantum gravity, noncommutative geometry, or twistor theory".

did he forget LQG or preon theory?

59. **A.J.**
September 13, 2006

Three comments in one:

One for dan,

did he forget LQG or preon theory?

I don't think Witten is unaware of the existence of these theories.

One for stupid:

People who don't like DARPA-funded projects probably should avoid using the internet.

One for Peter:

I enjoyed the book. Thanks! (I guess further commentary belongs on some other thread.)

60. **dan**
September 13, 2006

one for AJ "I don't think Witten is unaware of the existence of these theories. "

He hasn't embedded LQG or preon theory into string theory AFAIK.

I wonder if Witten's apparent ignoring of LQG/Preon theory is like Einstein's pursuit of unified field theory in a time when he ignored quantum field theory and the standard model was being formed.

Incidentally Peter, as a particle theorist, since strings is an obvious failure, how promising do you think preon models such as the Sundance model is, to explaining the standard model, possibly simplifying it, and then relating it to spin foam LQG?

http://arxiv.org/abs/hep-th/0603022

61. **A Babe in the Universe**
September 13, 2006

PW, do you think that the many universes proposed by "eternal inflation" relate to the landscape?

62. **Peter Woit**
September 13, 2006

dan,

Unlike the case of Einstein, in Witten's case there is no analog of the great advances in quantum theory and quantum field theory that Einstein was ignoring. Idea about preons, etc. are still extremely speculative, a long way from something solid.

Louise,

"Eternal inflation" is the mechanism that anthropic landscapeologists generally assume will populate the landscape.

63. **Gumbi**
September 14, 2006

Do you consider it a factual matter whether we live in an anthropically-selected landscape universe? That is, is it a question of fact whether the laws of physics which govern our universe have this nature, that there are very many or even infinitely many parallel universes, and we live in one that is compatible with our biology? Or can physicists choose the laws of physics, and if they find the landscape unpalatable or frustrating, they can choose different laws of physics for our universe to be governed by?

In other words, what if the landscape is true but unprovable, and physics as we know it has in fact reached its end? Is this possible, or can physicists prevent it from happening by their efforts and research?

64. **Peter Woit**
September 15, 2006

Gumbi,

It's true but unprovable that our universe may just be a simulation in a computer run by a higher intelligence, but speculating about this is no more science than the anthropic landscape. Until now the scientific method has done very well as a way to learn more and more about the universe in a reliable way, and I think will continue to work, although the difficulty of doing higher energy experiments does make things tougher. I certainly see no need to do what many of the landscape people are doing, abandoning the scientific method for no good reason.

65. **Jason**
September 16, 2006

Re: Trouble with Physics and Not even wrong.

I may have missed something, but I notice that unfortuntely Peter indexes Lee but Lee does not behave but reciprocally. Too bad especiallly from theorists who have in common their seeking attention outside the stringy mairnstream. How lame is that. Get it together, you guiys.

PS Not that there's anything wrong with lameness.

Yet More Links

Frank Wilczek, besides his other accomplishments, is also the star of an opera, entitled Atom and Eve. More commentary on this from Betsy Devine, and Jennifer Ouellette, as well as a report here, and a review here.

Paul Cook has a report on the Templeton-sponsored panel discussion at Cambridge on The Nature of Space and Time.

In October 2004 the French magazine Ciel et Espace published an article about the Bogdanovs entitled The Bogdanov Mystification (English version here). They sued the magzine in December 2004 for defamation. Evidently a French court has now decided the case against the Bogdanovs, fining them 2500 Euros for frivolous litigation and requiring them to pay the magazine's costs.

The Institute for Advanced Study has been famous in recent years for the emphasis of its theoretical group on string theory. They seem to be moving a bit more towards phenomenology these days, and there will be a workshop on axions there next month.

The Tevatron is performing well, recently achieving new record luminosities. You can keep track of their progress here.

LBL will soon be hosting a conference to celebrate the 50th anniversary of the Particle Data Group.

Chad Orzel has a perceptive review of Not Even Wrong at his blog, Uncertain Principles.

Update: There's a tradition among bloggers of "carnivals", collections of the more interesting recent blog postings in a certain area. The physical sciences now have one of their own, the first edition is now available, and it's called Philosophia Naturalis.

Update: Note added about the Bogdanov court case, giving claims about this by Igor Bogdanoff.

Comments

1. **hack**
   September 13, 2006

   That's too bad about the Bogdanov brothers. Did Lubos testify on their behalf?

2. **Apropos**
   September 13, 2006

   BTW I have not seen Lubos posts lately, given the turmoil with ST is that a signal that they are abandoning their trenches and running for cover?.

3. **Geon**
   September 13, 2006

   Dr.Woit,
   I respect your view on current status of hep-th but do you not think maintaining this blog(and repetitive nature of articles) and publishing books for 'general public' is just 'not good enough'? If you despise string theory, are you working on any alternate theory? As long as you spend your day 'putting links on webpages' I don't think your opinion will be given much credit.

4. **TheGraduate**
   September 14, 2006

   Geon,

   I can't speak for anybody else but I find these links excellent. I am always hearing about things I wouldn't know about otherwise.

5. **Thomas Larsson**
   September 14, 2006

   The Tevatron is performing well, recently achieving new record luminosities. You can keep track of their progress here.

   I am under the impression that 2 fb^-1 is an important limit for the Tevatron – is this not the point where a light Higgs, and thus indirectly susy, could be ruled out at 95% CL (a 5-sigma discovery would take much more, though)? With 1.9 fb^-1 and counting, Tevatron data are starting to be really interesting.

6. **Geon**
   September 14, 2006

   Sure, I have nothing against useful links. But I guess my point to Dr.Woit was that convincing 100 lamers(via non technical argument with no single equation, referring to 'personal' matter, criticising string theory and yet he himself can only 'speculate' on alternatives) is not only easy but is pointless. In that regard I strongly think doing "something" even though it may not be 'real' physics is more productive.

7. **Alejandro Rivero**
   September 14, 2006

   Geon, it is a regret than the english language does not have two different pronouns for "you" in plural and singular situation, because if it had you cound have considered if it is meaningful to ask a particular person about a global issue. And I would say yes, collectivelly we are working towards other approaches and yes, Woit (and Smolin) sort of political trenches are part of the fight.

8. **Heineken**
   September 14, 2006

   i really have nothing constructive to say, but thought i'd take a moment to talk about the misappropriation of terms from philosophy and the arts. Lubos has called

Smolin’s viewpoint “postmodern”. now i have not read Smolin’s latest, but i am familiar with some of his nontechnical works including 3 Roads to Quantum Gravity. getting to the zero dimensional point, it is string theory which strikes me as postmodern, not any other alternative approach to quantum gravity. one main idea in postmodernism is a rejection or questioning of the rational approach e.g. the scientific method (post Enlightenment hegemony).

string theory, at least to a layman like myself, has become disconnected from experiment. this hardly strikes me as rational, Enlightened, or even scientific. Lubos (the master of puppets) states that Smolin’s ideas are postmodern, yet a theory that misses the mark by 55 orders of magnitude is not?

“Radical as the fundamentals of quantum mechanics were, it’s easy to overreach when applying them in nonscientific contexts. I find the most bothersome example to be the frequently abused uncertainty principle, which is often misappropriated to speciously justify inaccuracy.” (Warped Passages, L. Randall)

philosophers and layman get blasted when they misuse terms from science, yet when it’s the other way around …

i think i’ll order a copy of Alan Sokal’s new book “Fashionable Nonsense (Pulling Your Strings Since 1984)”. i enjoyed Dawkin’s review of it, entitled “Lubos Disrobed … And It Ain’t a Pretty Sight”.

Lumo, the matrix theory has you.

9. **Geon**
September 14, 2006

What has coming up with an alternative theory got to do with political fight?? I thought we are doing physics here?

10. **TheGraduate**
September 14, 2006

Geon,

Not every argument requires an equation to be valid.

11. **Santo D'Agostino**
September 14, 2006

Geon,

Criticizing a proposed theory is an essential part of the scientific enterprise.

Heineken,

Very nice point about postmodernism, and your last line was amusing.

All the best,
Santo

12. **Geon**
September 14, 2006

Santo D’Agostino and to others(Is Dr.Woit ignoring my comments?),
I have nothing against criticism on string theory. I myself don’t yet believe in string theory too. But! I would rather be ‘deeply unsatisfied string theorist’ rather than ‘complaining non-string theorist’ for the reasons I have described above. Heineken said “a theory that misses the mark by 55 orders of magnitude ” do you really think string theorist are all happy about this? I think what drives them despite these nonsensical results are 1. There are ‘indications’ which gives them a strong feeling that ‘something’ is going on with string theory(yes it might be just some miraculous coincidences or maybe not!), 2. Simply this is the most developed work in progress we have at the moment as far as quantum gravity is concerned. I don’t know how could someone be as ‘confident’ as Dr.Motl but still it ‘does’ produce some signs which especially at this time of the century when there is hardly any experimental lead, is all we can rely on. Getting to point, string theory ‘definitely’ has worthy to be studied+alternative ‘could’ be addressed but you can still do this with your mouth shut+publicly advertising such situation to ‘general public’ is not ‘physicists’ job but that of reporters.

13. **Peter Woit**
September 14, 2006

Geon,

I’m not ignoring your comments, I was waking up, having a long breakfast, during which I was starting to read a new book that just arrived (“Dirac Operators and Representation Theory”), which looks like it should be quite helpful in relation to ideas about BRST that I’ve been working on.

Sure, I’d rather be spending time making positive progress on alternatives to string theory than criticizing string theory. But for twenty years physicists who were well aware of the problems with string theory kept their mouths shut while particle theory was taken over by people endlessly repeating the same overhyped claims for string theory, including the ones that you are echoing. I think this has done a huge amount of damage to the field, and someone needs to point this out and give an accurate picture of what is going on here. This is not something that a reporter can do, it requires someone who knows the subject. I’d much rather it be someone else, and I hope to spend more of my time working on positive alternatives, but I’m not about to shut up, no matter how much string theorists would like that to happen.

14. **Geon**
September 14, 2006

I apologise for using ths strong language there I didn’t imply that to you if you know what I mean. I certainly admire your view and I think it’s as equally valid as any other string theorists view of this nature at this stage. In some sense I think you are more ‘concerned'(in a positive way) and true ‘physicist’ in the sense that your moral is to put mother nature first. Your book did have some positive effect on me personally and gave me an opportunity to think about what made me up until recently to be brainwashed about string theory. In that process I did realise that it wasn’t really due to my deep understanding of these subjects but rather due to flash campaign presented by Dr.Greene. Now, I think I am in the state of neutral, but certainly I’m not a critic like you simply because I don’t have much knowledge yet. But certain things that I pointed out above is really addressing different ‘attitude’ taken by you and by string theorists, and I think the latter are in a way ‘trying’ whereas I get impression that you focus bit too much on publicising this situation.

15. **comentator**
September 14, 2006

It should be mentioned also the brain drain; Taking enthusiastic graduates to study ST and shutting off other areas of study for alternatives . this point has been mentioned before and is really troublesome not to mention the publications wall.

16. **King Ray**
September 14, 2006

Einstein once said in his later years words to the effect that the feeling of conviction you have that a theory is correct has absolutely no correlation with whether it is actually true or not. I think the string theorists need to understand Einstein's comment, which came from his being totally convinced he was on the right track a number of times in his search for a unified field theory, only to realize that he was going in the wrong direction. Now we know he didn't have enough information. The string theorists refuse to accept that they are on the wrong track.

17. **Loopy**
September 14, 2006

I can't wait to see tomorrow's post about Gregg Easterbrook's article on Slate.

18. **SFB**
September 14, 2006

Geon et. al.,
string theory takes an enormous amount of money away from other approaches. This happens via suported graduated students, faculty positions, grants, etc. Many of the people in charge of such money are not experts in string theory, other approaches, nor the philosophy of science. They have to make decisions based, in part, on things like the zeitgeist. Therefore, it is only fair to popularly express the many doubts about string theory, as string theorists have popularly expressed the many hopes for it.

The brian drain is secondary in my view: these people would perform calculations within *whatever* approach was most popular at the time in their careers they have to show something.

None of the string theorists have been able to approach the real problem: the foundations of quantum mechanics. They should be exploring the mathematical concequences of quant-ph/0506228. The fact that they are working on string theory is a commentary on how superficial their thinking is: string theory relies on mathematical coincidences instead of principles that must be true. Of course, workers in other approaches are guilty of this too.

I realize that it *looks* like unification is essential to string theory. But I don't see why this might not be an artifact of counting the number of parameters of the theory in a conceptually anthropomorphic way. Is the number of dimensions of the theory a free parameter? Is the number of kinds of dimensions (compact, etc.) a free parameter? Is **each** dimension to be counted as a parameter??? Until there is a theory (in the philosophy of science) that removes anthropomorphic biases and is universally applicable that gives the number of parameters (free and bound) of a physical theory I believe no argument can be made that the dimensions are not each parameters– meaning that string theory might assume just as much as the assumption of the trivial union of GR and QFT in the first place. (I could do any of this myself, given the salary of any one person paid to work on string theory.) I have not even mentioned the "landscape".

I would like to see a return to common sense (as understood within physcis). See the paper mentioned above.

19. **Chris W.**
September 15, 2006

I just skimmed [Easterbrook's piece](). With friends like him, you don't need enemies. I would suggest ignoring him.

20. **Whoman**
September 17, 2006

Peter,
Talking about Tempelton… I thought you would be interested to know that fqxi.org has announced grant winners. The two top winners are Louis Crane (A New Approach To Quantum Gravity, With Possible Applications) and Steven Giddings (Observation And Non-Locality In Quantum Gravitational Physics).

21. **Shantanu**
September 17, 2006

Peter, sorry to change topics, but I am wondering if you looked at the videos
of talks at the string phenomenology workshop at Santa Barbara ?
any particular talks look interesting or such?

22. **woit**
September 18, 2006

Whoman,

I did see that announcement, wrote a bit about it here when it came out at the end of July.

Shantanu,

I have a pretty low opinion of the whole concept of "string phenomenology", but did look at some of the talks on the KITP website. Nothing I saw there changed my mind. That field continues to produce a lot of hype and nothing close to a real prediction.

Reviews in The Economist, Slate and the Times

September 15, 2006
Categories: Not Even Wrong: The Book

This week's issue of The Economist has a review of my book and Lee Smolin's, entitled All Strung Up. It's quite positive about the point of view on string theory that Smolin and I share, and correctly identifies where we see things differently about the role of mathematics. Nothing in it that will be news to readers of this blog.

Yesterday I also saw two reviews that I don't think much of. The first is Gregg Easterbrook's piece at Slate, The Trouble With String Theory. It's a very enthusiastic review of Smolin's book, and when I started reading it my initial reaction was positive, although it did seem a bit over the top. As I read on, besides wondering "Hey, is he going to mention my book too?", I started to remember who Easterbrook is, and how stupid some of his previous writings on physics were. By the end of it, I was very glad Easterbrook had left me out of it. One sometimes depressing aspect of being on this side of the string theory controversy is seeing who some of one's allies are.

Easterbrook is best known as a sports writer writing about the NFL, but for some reason various prominent publications feature his writing on other topics. The biggest mystery of all is why places like Slate and the New Republic have him writing about science, a topic he seems to know nothing about, and be actively hostile to. For once, Lubos Motl's paranoid rantings about "anti-science" people who dislike string theory do actually have someone they legitimately apply to. This latest Easterbrook effort isn't even original, he's plagiarizing himself, writing:

Today if a professor at Princeton claims there are 11 unobservable dimensions about which he can speak with great confidence despite an utter lack of supporting evidence, that professor is praised for incredible sophistication. If another person in the same place asserted there exists one unobservable dimension, the plane of the spirit, he would be hooted down as a superstitious crank.

which isn't very different than what he was writing in the New Republic three years ago:

Ten unobservable dimensions, an infinite number of invisible parallel universes–hey, why not?

Yet if at Yale, Princeton, Stanford, or top schools, you proposed that there exists just one unobservable dimension–the plane of the spirit–and that it is real despite our inability to sense it directly, you'd be laughed out of the room.

The second new review that I don't think much of is one that I got a copy of late last night (after a party held to celebrate the US publication of my book). It will appear this Sunday in the New York Times Book Review and is the first really hostile review of the book by a science writer that I've seen. I've been very pleasantly surprised by how positive the reviews of the book have been so far, since I initially expected much more of a mix of sympathetic and hostile ones. Most science journalists have seen years and years of string theory hype go by, with no progress towards any of the promises made for the theory ever actually being fulfilled, and this has left them with a more and more skeptical attitude towards the theory. The Times reviewer, Tom Siegfried, most recently wrote a book entitled Strange Matters: Undiscovered Ideas at the Frontiers of Space and Time, and somewhat earlier a book called The Bit and the Pendulum: From Quantum Computing to M-theory. Both books feature a breathless, gee-whiz, completely credulous take on the most speculative ideas around, thoroughly mixing science fiction and fact, with little interest in distinguishing the two. At the time I was writing my book, ones like Siegfried's were models for me of the opposite of what I was trying to do, so I'm not surprised he didn't much like what I wrote.

Unlike most authors who don't have any viable way of responding to reviews they consider unfair and misleading, it's all too easy for me to do so here, so a response to the review follows.

Siegfried complains that I use technical jargon, for example by discussing "perturbation expansions". While there are certainly places in the book that have some technical material in them that most people would be best advised to skip over, this isn't one of them. To understand anything at all about the current state of string theory, you need to have some idea about what a perturbation expansion is. This is carefully explained at one point in the book. It's not clear to me what Siegfried's point is. Does he not know what a perturbation expansion is? If so he shouldn't be writing or reviewing books on this subject. Does he think that the audience for this kind of book is not capable of following such an explanation? If so, he has a profound lack of respect for the people who read these books. As far as I can tell, they cover a very wide range of backgrounds, but most of them have had a good high school or college education, and many have taken a calculus class where they have been exposed to power series expansions, and I explicitly refer to this in my explanation.

One can write a book like this by refusing to try and explain anything that can't be explained to someone with only a grade school education, but that's not what I was doing. I don't think you can honestly communicate much about the current state of particle theory and string theory if you follow this tactic. My decision was to first see which topics I wanted to try and write about, then do my best to give an honest explanation in the simplest and clearest terms that I could manage. Some topics end up being pretty accessible to everyone, others do require significant background to understand and appreciate. I think most readers of the book will learn some things from it, while not understanding everything. But they won't go away from the book being fooled into thinking they understand something that they don't.

Siegfried's review is unremittingly hostile, with virtually everything he has to say about what is in the book a misleading and less than accurate characterization. According to him I allege that people only do string theory because Witten has "mesmerized" them, mainly use quotes that reflect what people thought 20 years ago, engage in irrelevancies about masturbation, etc. This last has to do with a quote from Gell-Mann (He used to say, "physics is to mathematics as sex is to masturbation", changed his mind after 1984) that I discuss because it reflects well the attitudes of particle theorists towards mathematics, and the relation between the two subjects is one of the central concerns of the book. This discussion may be tasteless, but it is not at all irrelevant to what I was writing about.

Siegfried claims that my central accusation is that string theory makes no predictions and that I am flat-out wrong about this. He writes:

*…string theory **does** make predictions — the existence of new supersymmetry particles, for instance, and extra dimensions of space beyond the familiar three of ordinary experience. These predictions are testable: evidence for both could be produced at the Large Hadron Collider, which is scheduled to begin operating next year near Geneva. These predictions are not of the specific quantitative kind that would definitively prove string theory true or false, but their confirmation would certainly be taken as impressive support.*

The fact of the matter is that string theory makes none of the "predictions" Siegfried has been led to believe by the hype about string theory that he seems to have swallowed whole. It predicts nothing about what extra dimensions might be visible at the LHC, not even their number. Similarly, it does not predict that superpartners will be visible at the LHC or what their properties will be. His use of the term "supersymmetry particles" indicates how little familiarity he has with the subject, while still feeling quite comfortable accusing me of getting this all wrong.

Siegfried is rather more kind to Smolin's book, but also manages to mischaracterize it, insisting that Smolin is not content with favorable evidence for string theory, but is demanding some much higher standard of definitive proof. He ends by comparing both of us unfavorably to Schwarz and other 1970s string theorists, noting that they didn't complain about the dominant research program in particle theory during their day. The problem with this argument is that the dominant research program was gauge theory and the standard model which, very much unlike string theory, had a huge and increasing amount of experimental evidence backing it up. If it hadn't had this, I strongly suspect that Schwarz and many others would have also been complaining, loudly.

Update: There's a short, but very well-done, review of the book in today's Guardian. Also a mention in the Toronto Star, where science journalist Jay Ingram describes how:

A few years ago, the occasional physicist would confide in me that string theory — the idea that matter is composed of super-tiny vibrating strings — would one day be seen to *be wrong, a big mistake*.

Update: The review in the Times is here.

Update: The Boston Globe has a quite positive review of my book and Smolin's here.

Update: More coverage of this in USA Today. This piece includes a quote from John Schwarz that experiments will verify string theory in the future, and implies this will happen at the LHC. Lubos has his trademark insightful commentary.

Comments

1. **andy**
   September 15, 2006

   Does Tom Siegfried have any science education? I mean, is he confusing himself as a science journalist with an actual scientist?

2. **optimist**
   September 15, 2006

   Hello, Dr. Woit,

   This is my first time to leave some message here. Although I strongly agree with your critics about superstring theory I would be rather optimistic in different direction.

   These days I am studying AdS/CFT to learn AdS/QCD which is interesting topic these days. In doing these I realized that AdS/CFT did give theoretic predictions which were not clear from field theory sides. Even though they are just theoretical consistency I think they give very good reason to study string theory.

   Maybe understaning quantum gravity is too early for us but thanks to string theory it could be true that we happen to have unexpected tools to investigate nonpertavative regime of gauge theory.

   If people insist that they are doing "theory of everything" with accepting anthropic approach then you can criticize them and I agree you. If people see string theory as a tool for a strongly coupled guage theory then I think you should be encourge them to do it especially if they are fresh graduate students. Understanding strongly coupled guage theory is very important and useful thing, I think. Too critical mood could be harmful even to this kind of important research.

   Thanks.

3. **Who**
   September 15, 2006

   Peter, just for reference here is a link
   to a free copy of the 11 August Science magazine article by Tom Siegfried you mentioned in an earlier post.

   http://susy06.physics.uci.edu/press/susy06_science_naturalness.pdf

   He was covering the SUSY 06 conference and called the piece "A Landscape Too Far?" IIRC you gave a link to the subscribers-only version of the article but not to this copy at the official conference website.

   Readers may remember the article has a special sidebox where Joe Polchinski recounts how he used to be skeptical of the Landscape but then "got religion".

   This article shows something of how Siegfried works as a science journalist. He is evidently on chummy terms with many eminent string people and chats easily with them—obtaining seemingly valuable spontaneous quotes that enable him to tell their story in a personalized "insider" way.

   I am not approving or disapproving—especially since I havent seen his NYTBR piece about the two books. I merely remark that Siegfried is a sympathetic trusted insider science journalist who could be effective as informal spokesperson for the string community.

   He must have a fair amount invested in his access to and relation with important stringfolk. Should be an excellent person to voice the community's interests, rebut it critics, and tell its story to the public.

   Here is the KITP bio
   http://www.kitp.ucsb.edu/community/ITPBios/Siegfried.html
   His MA in journalism at U Tex Austin had a Physics minor.
   This is in answer to andy's question about science education.

4. **Thomas Love**
   September 15, 2006

   Finally finished reading NEW over lunch today. While I agree with you about the errors of string theory, there is quite a bit I disagree with you on, especially the correctness of the standard model.

   As you discovered, "The enemy of your enemy is not necessarily your friend."

   Now on to Smolin's book!

5. **Tommaso Dorigo**
   September 15, 2006

   Hi Peter,

   this continuing claim that string theory predicts supersymmetry and large extra dimensions, which the LHC will be able to find, reminds me of the following sentence from Kathy Mansfield's "The Fly": "we cling to our last pleasures as the tree clings to its last leaves".

   I think the tree will be bare soon – Give the LHC a couple of years.

   Cheers,

T.

6. **PPCook**
September 15, 2006

Hi Peter,

“Physics is to math what sex is to masturbation.”

I thought this excellent quote was due to Feynman.

Best wishes,
Paul

7. **woit**
September 15, 2006

Who,

The first entry for “Tom Siegfried” under Google is his listing as a journalism fellow at the KITP in Santa Barbara. I guess that’s where he learned about “supersymmetry particles” and all the string theory predictions for the LHC.

PPCook,

Gell-Mann does explicitly claim priority on this, although many internet sources list Feynman. It is only one of many discoveries the two of them have fought over credit for…

optimist,

I agree with you that AdS/QCD is interesting and that string theory is a promising approach to studying strongly coupled gauge theories. But I don’t think there’s the slightest danger that too few theorists are working on this subject.

8. **Carl**
September 15, 2006

Siegrfried complaining about talk of arcana such as “perturbations” misses the point. When one of my relatives asked for a recommendation, I sent them to Smolin’s book because it is written for a more general audience (and will probably sell a lot more copies).

9. **CapitalistImperialistPig**
September 16, 2006

Peter,

I think that if evidence for a sparticle was found at the LHC a lot of people, myself included, would count it as suggestive of the value string theory. Lubos is apparently confident enough of SUSY at the LHC that he has put a dime ($1000) on it. At least he puts his money where his mouth is!

Ditto if evidence for any extra dimensions, never mind how many or what size is found.

Either of these discoveries ought to point the way to new physics, but string theory would be an obvious first resort.

I’m jus sayin…

10. **Dan**
September 16, 2006

CapitalistImperialistPig I agree with what you say, if LHC finds either SUSY or extra dimensions then interest in string theory will continue to mount, and other approaches will either dry up or attempt to merge with string theory.

However, what-if,
what if LHC finds neither the higgs boson nor SUSY nor higher dimensions? What would happen to physics and string theory?

My prediction:

Non-SUSY 4D LQG will continue to languish, and interest in String theory will continue unabated.

11. **A**
September 16, 2006

if SUSY is there, LHC would see some new hadrons, new leptons, new higgses, but telling if they are SUSY would be difficult. E.g. LHC can measure some of their masses, but SUSY does not predict any mass. SUSY predicts couplings, telling that sparticles decays are too fast to be measured.

About extra dimensions at LHC: Dorigo could bet 100000$ against them, and likely no physicists would accept the bet. Extra dimensions are considered too unlikely.

12. **Nathan Myers**
September 16, 2006

Who really believes Lubos would pay if LHC results came out against him? If you do, offer to hold the money in escrow, before the experiment is performed, and see what happens.

13. **gambler**
September 16, 2006

Dudes,

Betting is *the* way to measure how firmly somebody is convinced of something. Not long ago in England people would talk about those who lacked the “courage of their convictions", where "conviction" is what you have if you're convinced of something.

Is there a web site where people can place wagers about things like sparticles? String theorists and string-theory critics could each make a lot of money, and humiliate their enemies, if only they're right. Although, maybe the string theorists would chicken out because maybe string theory is right even though supersymmetry will never be seen. Maybe string theory is wrong even if the sparticles are found, but I don't think so …. supersymmetry is one thing as a mathematical feature of a qft; it's quite another thing to say that it's a part of "the universe"; the second statement is a religious one, part of the same religion as strng theory.

Nathan is right, though. Escrow is what we need, and a Trusted Third Party. There might be legal problems if it's in the United States, but there are places in Europe and maybe in Vegas where it should be legal. I think this is something to push for – raise the stakes and then raise them further – checking for susy at LHC is the closest thing to a test of string theory we'll see in our lifetimes. Let's make it as spectacular as possible. After LHC, we'll all be fired anyway.

14. **Scott Aaronson**
September 16, 2006

Go to http://www.ideosphere.com (unfortunately, it doesn't let you bet with real money)

Robin Hanson is a major proponent of betting on scientific questions, and has lots of writings and links on the subject.

15. **PPCook**
September 16, 2006

Hi Peter,

Thanks for the information about the quotation. I didn't realise they also disputed quotations.

Best wishes,
Paul

16. **CapitalistImperialistPig**
September 16, 2006

A,

I don't know how firm the evidence is on this, but my understanding is that the lightest supersymmetric partner is supposed to be stable, as it must be if it is to account for, say, dark matter. No such discovery would "prove" string theory, but it would be a potent clue that ought to lead somewhere – maybe even to ST, which is the first place everyone would look.

Betting may give us insight in to peoples strength of conviction, but it doesn't give any into their soundness of judgement! Out of respect for Peter's policies I will avoid mentioning any of the examples that occur to me.

17. **Gina**
September 16, 2006

A week ago I wrote, especially for this blog, a critical pre-review of Peters book "not even wrong". Among other things, it contained a clever analogy between string theory as a theory of everything and mathematical logic which is the mathematical theory of everything and a critical assessment of Peter's ideas on sociology and funding of science ending with the strong statement: "As there is no such thing as a riskless risk, Woit's ideas on this front may deserve the title 'not even wrong'".

I explained why, in my opinion, Peter does not really have a "case" against string theory.

Since the pre-review was not ready in time to be included in the comments following the post I aimed at (one categorized by "not even wrong – the book"), I posted it in a later and unrelated post. There it lasted 5-6 hours before being deleted. It was read by at least two people (or entities), the "renormalizer" who suggested to delete it and Peter who deleted it. In spite of its short time under the sun I was satisfied with my effort and outcome, but in a world where some are trying to find an ever-lasting theory of everything which will reduce later physics to just filling the details, and a few are trying to prove that two decades of efforts of thousands string theorists amount to zero if not less, my short lived pre-review cannot be considered as highly ambitious nor as a success.

I thought of resubmitting my clever yet ill-fated pre-review, but now, my mood is different. Rather than reviewing the matter at hand let me make a few remarks how can, in my humble opinion, the overall nice book by Peter (after all it is justa book not a "case"), be made nicer.

Most of the chapters of the book are very good. I think this is a very good popularization of particle physics all the way to the "standard model". Popularization of science is a tricky business and deserves a whole separate discussion. There is no way to avoid some "cheating" but one should still try to be honest, useful and non-manipulative and Peter does a good job. The description of the connections with mathematics are especially good. The story about the Seiberg-Witten discovery is told very vividly. With the exception of too strong rhetorics most chapters on string theory are also well-written. I am learning a lot reading the book. Thank you, Peter!

What could make this book nicer?: I can see the temptation to include the Bogdanov brothers story (and to mention the (overplayed) Sokel's hoax), and Peter had a personal record to set for this case. But overall this story does not belong to this book. The story about the string theory guy who became a Maharishi scientist also does not belong here. The same goes for the refereeing process for Cambridge University Press. I have quite a few scientists friends, and complaining about referee reports is one of the few drawbacks in their sweet lives. Beside, they are the referees themselves! (and they also complain about the burden of refereeing.) The rhetorics against string theory, and string theorists, as Peter himself noted (p.225, l. -5) is indeed too strong. This does not add to but rather reduce the value of the book.

The concluding chapter starts with a beautiful quote from Bob Dylan's song "Absolutely sweet Marie" – "But to live outside the law, you must be honest". When I saw it I thought that this is a self reference and that Peter set a standard for himself: If you want single handedly, coming from the outside, to claim that one of the hottest scientific area of our time failed and the efforts of thousands of string theorists worthless, you better be honest about the details, presentation and even your own motives.(And overall Peter is indeed quite honest.) Peter's intention quoting Dylan was different as he referred not to himself but to string theorists — that without empirical support to their theory should be honest. It is good to remember that nobody is or can be completely honest. So in view of Dylan's quote, the laws and traditions of conducting science as well as debating science are better respected.

And Dylan's cryptic line from "Love Minus Zero/No Limit" also comes to mind:
" There's no success like failure, and failure's no success at all."

18. **TheGraduate**
September 16, 2006

Gina:

I was another entity that read your review. I think it contained a mistake of perspective that I think is also contained in your current post. In both, you consider Peter's book a popularization of string theory. As far as I understand Peter's intentions, it is not. It is an argument against string theory being the "only game in town".

On a side note, why do you keep saying how clever your review was?

19. **Peter Woit**
September 16, 2006

CIP,
One can certainly reasonably claim that the discovery of supersymmetry at the LHC would provide some encouragement to the research direction that has led people to superstring theory, but that's a far cry from claiming that superstring theory "predicts" that evidence for supersymmetry will be found at the LHC. As for superstring theory "predicting" that the LHC will see evidence for extra dimensions, that's just complete nonsense. Some of the fanatics like Jacques and Lubos are willing to put some money down on supersymmetry at the LHC (it will be interesting to see if they pay off), but I don't know anyone willing to put money down on the LHC seeing extra dimensions.

Gina,

Your earlier comment was deleted because you posted it in a completely inappropriate place. As for this one, obviously I disagree with you about the relevance of some chapters in the book to my argument. In particular, the refereeing story at Cambridge was a very unusual one, involving two referees who strongly backed publication, and two string theory partisans trying (successfully) to stop Cambridge from publishing the book, while lacking any arguments against its content. Given that one of the main reactions from string theorists to the book has been that "string theory has won legitimately in the marketplace of ideas", I think it is important to explain how this marketplace sometimes operates.

I should perhaps have made more explicit what I meant to convey with the Dylan quote. It's not specifically about me or about string theorists, but about the situation particle physics finds itself in. Lacking the discipline enforced by experiment, theorists now need to be a lot more self-critical and honest in evaluating the results of the speculative work they are engaged in.

20. **John A**
September 16, 2006

> One sometimes depressing aspect of being on this side of the string theory controversy is seeing who some of one's allies are.

It's not just a problem in theoretical physics 🙁

21. **John A**
September 16, 2006

The only big result I expect to see from the LHC is conformation of the Higgs Boson. Anything else is a bonus.

22. **A**
September 16, 2006

CIP: one difficulty in distinguishing supersymmetry from alternative theories, is that almost all of them have a stable neutral particle, because all theorists want to explain dark matter. "Dark matter at LHC" is the safest bet. If dark matter will be found, understanding why it is stable might lead to fundamental progress.

23. **Gina**
September 16, 2006

TheGraduate said: "I was another entity that read your review. I think it contained a mistake of perspective that I think is also contained in your current post. In both, you consider Peter's book a popularization of string theory. As far as I understand Peter's intentions, it is not. It is an argument against string theory being the 'only game in town' ".

The Graduate: I think I was quite accurate. The first half of the book is indeed a popularization of particle physics all the way to the "standard model". The second part contains a popularization of string theory plus an argument against it. This argument refers to string theory "stand alone" as well as to the aspect of string theory being "the only game in town".

Peter: My main (mild) critique of today was not about irrelevancy but that the items I mentioned (and a few others) reduce the quality of your book. Of course, a book may have many qualities and I am mainly referring to the quality of the book as a serious discussion and debate of science (of the kind appropriate to a university press). For example, if you refer to the string theory community as a "mafia" this statement is, of course, highly relevant, but making such a statement reduce the value of the book, at least in my opinion. I think you are wrong to consider your experience with Cambridge university press as very unusual. Many authors had similar experiences even with much less controversial (and more important) books and papers. (This is an empirical issue that, in principle, can be tested.)

I think the story of the Maharishi string theorist is irrelevant. You do discuss a little in a straight way the comparison between string theory and the occult. This is fine. But on top of it you add further insinuations and stories towards such a comparison and, again, this reduce the quality of your book. Overall, it is a nice aspect of your book that you are not "part of the story" and the few places where you add yourself to the story, e.g., the Bogdanov e-mail, seem somewhat artificial.

"… theorists now need to be a lot more self-critical and honest"

Yeah, we all need to.

24. **D R Lunsford**
September 16, 2006

It's a shame the Times has fallen so far as to not be able to field a single good science writer (Overbye included). *Are* there any good science writers?

-drl

25. **TheGraduate**
September 16, 2006

Gina,

I haven't read the book yet so my objection was a limited one. I just thought that you were critiquing a book that Peter didn't write. I know it's not the book he intended to write BUT I do not know for sure it is NOT the book he wrote. Unless, it was stated in the preface, introduction and on the dust jacket that it wasn't a popularization, I think it is perhaps a fair assumption that the average reader would consider any review of particle physics contained within the book as a popularization.

Hopefully if the book makes it to second edition, all the stuff that people are pointing out are things that are going to go into the book. It does appear from the objections I've seen people making that the book needs a little more framing so people know why certain things have been included.

I think in the pantheon of string theory books, it is obviously to be read after some of the others. It really makes no sense to read 'Not Even Wrong' if there had never been any such books as "The Elegant Universe" and "The Fabric of the Cosmos".

26. **Chris Oakley**
September 16, 2006

TheGraduate says:

> I think in the pantheon of string theory books, it is obviously to be read after some of the others. It really makes no sense to read 'Not Even Wrong' if there had never been any such books as "The Elegant Universe" and "The Fabric of the Cosmos".

The purpose of *Not Even Wrong* is to point out that something (string theory) commonly regarded as a success is actually, as a scientific theory, a failure. Popular books on the subject, such as Greene's, are only one aspect of this.

27. **woit**
September 16, 2006

Gina and the Graduate,

I did not refer to string theorists in the book as a "mafia", I said that some of the people who wrote to me did so. It is a fact that many people in the physics community feel this way and I was reporting this. It's not a word I would use to describe my own perception of string theorist's behavior.

All the things that Gina objects to are things that I was reporting that are factually accurate. I didn't do much "framing" because I think the world is a very complex place, and there are many possible lessons to be learned from phenomena like Hagelin, the Bogdanovs, or my experiences with Cambridge. I explained a bit about some of the lessons that I personally drew from these stories, but everyone can make up his or her own mind. Aaron Bergman felt that I was making unspoken implications, but that's really not the case. If I have something critical to say about anyone, I say it explicitly and clearly.

At various times while writing the book I thought that I should shade what I was saying to make it more palatable to others, for instance to ensure that referees would agree to let me publish it. In the end I decided this was a bad idea, that I should put down on paper exactly what I thought. For better or worse, that's what's in the book. It is in no way at all a political document.

28. **TheGraduate**
September 16, 2006

Peter,

Thanks for the clarification.

29. **Garrett**
September 16, 2006

I recently bet two young string theorists that superparticles wouldn't be found by the LHC.

The more reasonable of the two thought the odds would be around 50%, because much recent theory involves supersymmetry breaking at an inaccessible energy scale. So it looks (from an unenlightened viewpoint) like string theorists are aware of the threat to their models imposed by the LHC and are back peddling further away from prediction of observables superparticles.

I encourage others to take up bets like this one. Understanding and, consequently, prediction is what physics is supposed to be about. And bets are fun.

30. **dan**
September 17, 2006

Dear Peter,
It seems clear that should LHC find any SUSY, it will be a big boost for string theory, but if LHC does NOT find SUSY, do you think interest in string theory will wane, or do you think it will continue unabated?

Curious
Dan

31. **A**
September 17, 2006

let me try to answer to dan: if LHC finds nothing new, somebody will try the string-anthropic landscape, but bigger changes will happen: somebody will leave the field, somebody will move to neutrinos, cosmology, astropysics, most collider experimentalists will shift to astroparticles, laboratories such as CERN could survive studying neutrinos or flavor.

We do not need bets to make LHC results interesting.

32. **Garrett**
September 17, 2006

I'd like to see an interesting Higgs sector.
(But, err, this is getting off topic.)

33. **Thomas Larsson**
September 17, 2006

It seems clear that should LHC find any SUSY, it will be a big boost for string theory, but if LHC does NOT find SUSY, do you think interest in string theory will wane, or do you think it will continue unabated?

Dan, you have sort of given the answer yourself: [Strings should continue to funded & research, at least at present levels if not more, should LHC discover evidence of SUSY particles or extradimensions or both. — obviously, should LHC fail to find such particles then the answer would be no.].

34. **Fabien Besnard**
September 17, 2006

Speaking about bets : surely no one would accept to play a game where, if X happen you lose 1 $ and if X does not happen you don't gain anything. This is precisely the sort of game that some string theorists would like others to play : if susy or extra dim are seen at LHC, string theory wins, and other theories lose, but if they are not seen string theory doesn't lose and others do not win ! One can certainly conjecture about loss or gain of confidence, but since there is no quantitative prediction of the needed energy level to see such phenomena, this won't come any close to a Popperian falsification procedure.

35. **dan**
September 17, 2006

Hi THomas,
I was wondering if Peter agreed with what I thought — and what should happen and what Peter thinks might happen are two seperate issues, I think what SHOULD happen is that not finding SUSY at LHC SHOULD be grounds for decline interest in strings. Whether that does happen, given the dominance of string theory in academia seems unlikely.

36. **Gina**
September 17, 2006

Peter,

It is a crucial quality for a book to reflect the author's thoughts and point of view so in this respect I do not have any argument with your choices on what to include in the book, even if my taste is different.

I think that the parts of the book with non technical explanations of physics and mathematics related to the standard model and further to string theory are very good and could serve as platforms for several alternative books. It could have been (and still can be) a good platform for a scholarly discussion and critical evaluation of string theory from the point of view of history, philosophy and sociology of science which would be suitable for a university press publication.

The path that you took makes the book perfectly appealing for a commercial publisher but indeed not appropriate for a university press publication. Part of it is the rhetoric and selection of issues to discuss, and part of it is the clarity and strength of your overall argument.

Concerning the small issue of using the word "mafia". Indeed it is a quote from somebody else, but the discussion in the following sentences gives the impression that you endorse what is behind this term if not the term itself. This I find unfortunate.

37. **dan**
September 17, 2006

Hello A,
Given the cost of LHC, somwhere north of $8 Billion US $, if LHC does not find nontrivial new physics, it's hard to imagine the urge to build even more expensive colliders. In the US, the SCSC was cancelled. I do wonder, if the only new physics LHC discovers is the higgs boson, at a price tag of $8 billion, I cannot imagine that even more expensive particle accelerators will be built to achieve higher luminosities. (If LHC sees lots of new interesting and nontrivial physics, then I could see the push to build even larger, more expensive particle accelerators).

As you suggest, a null result would probably result in the shift might be to astrophysical particles and neutrinos. In the event of a null result, what I would like to see is particle physics taking non-SUSY, non-string approaches, such as preon theories.

For me, a null result would be strong experimental support for Woit's NEW thesis, that string theory is probably the wrong approach, and is taking resources away from perhaps more promosing approach. There are theoretical problems with SUSY-MSSM, and should LHC not detect SUSY, I think continued dominance of string theory at the expense of alternative approaches would be experimenally unjustified.

38. **woit**
September 17, 2006

dan,

I'm not very good at prediction of what will happen to string theory. Personally, several years ago I would never have predicted that serious scientists would keep working on string theory after they accepted the existence of the landscape.

My best guess is that string theorists will keep doing string theory no matter what unless another bandwagon starts up for them to join. This might come about because of an exciting unexpected LHC result, because Witten comes up with a promising non-string theory idea, or some other reason. If the LHC doesn't turn up supersymmetry or extra dimensions (which I think is very likely), string theorists will concentrate more on black holes and cosmology (this has already been happening). As they do this, they'll slowly lose the support of their colleagues in other physics subfields, their funding will get cut, and, to a large extent, they'll take the whole field of theoretical particle physics slowly down with them.

39. **MoveOnOrStayBehind**
September 17, 2006

"As they do this, they'll slowly lose the support of their colleagues in other physics subfields, their funding will get cut, and, to a large extent, they'll take the whole field of theoretical particle physics slowly down with them."

That's what you dream about, isn't it. But dream on.

40. **woit**
September 17, 2006

MoveOn,

No, it's not my dream, quite the opposite. It's just an extrapolation from what is already going on, which is sad and depressing to watch.

41. **Gina**
September 17, 2006

"My best guess is that string theorists will keep doing string theory no matter what unless another bandwagon starts up for them to join. This might come about because of an exciting unexpected LHC result, because Witten comes up with a promising non-string theory idea, or some other reason. If the LHC doesn't turn up supersymmetry or extra dimensions (which I think is very likely), string theorists will concentrate more on black holes and cosmology (this has already been happening). As they do this, they'll slowly lose the support of their colleagues in other physics subfields, their funding will get cut, and, to a large extent, they'll take the whole field of theoretical particle physics slowly down with them."

This is an excellent generic guess for any prominent theory:

My best guess is that X-theorists will keep doing X-theory no matter what unless another bandwagon starts up for them to join. This might come about because of an exciting unexpected EMPIRICAL result, because some prominent X-theorists comes up with a promising non X-theory idea, or some other reason.

If the EMPIRICAL support (or another exciting thing) doesn't turn up (which I think is very likely), X- theorists will concentrate more on possible application to theory Y (this has already been happening). As they do this, they'll slowly lose the support of their colleagues in other subfields of their sup-sup field , their funding will get cut, and, to a large extent, they'll take the whole sup-field slowly down with them.

42. **woit**
September 17, 2006

Gina,

Yes, but in the generic case, a real possiblity is that "X-theory will achieve one or more of its major goals, making it a solid and permanent part of science, opening up new areas to work on that build on this success". That's not at all in the cards in this case…

43. **Dan**
September 17, 2006

Since thus far there is no experimental support for proton decay, a generic feature of all known GUT models, do you think theoretical particle physics has been dragged down by GUT hopes?

Curious
Dan

44. **woit**
September 17, 2006

Dan,

Lee Smolin has an interesting anecdote about a discussion with Eddie Farhi, who told him he left particle physics after proton decay predicted by GUTs was not observed, figuring there was no way to get experimental info about unification, thus one shouldn't work on it.

Supersymmetry GUTs push the lifetime up, but even they may be in trouble with experiment soon.

Personally, GUTs always bothered me, because they don't solve the main problem of the standard model, the Higgs sector, just making it worse by having to introduce more Higgs fields to break the GUT symmetry. They do have some interesting features, e.g. all particles fitting into one SO(10) rep, and coupling constant near unification, but I think one definitely needs some quite different ideas to make anything like a GUT really work out.

45. **Renormalized**
September 17, 2006

Gina- Do you always just regurgitate what others have written? I can't see you are adding anything to any discussion you have been involved with. Your responses are more in line with a common online troll.

46. **Dan**
September 17, 2006

Dear Peter,

Thanks for responding. Sounds like Eddie Farh had the right idea. In someways GUT's foreshadow strings.

"Supersymmetry GUTs push the lifetime up, but even they may be in trouble with experiment soon."

Kamiokande proton decay and LHC together can give four scenarios regarding SUSY and GUT and string theory.

Obviously, the experimental scenario that would most favor your NEW would be LHC fails to find SUSY, proton decay is not observed and rules out all SUSY-GUT's at 99.7% confidence. You and Smolin would be "heros", although I'm unsure whether string theory will continue its dominance in academia.

If Kamiokande failure to proton decay rules out even SUSY-GUT's, would that be enough to falisfy the string theory unification project?

It would be pretty exciting if LHC discovers SUSY, but Kamiokande rules out all forms of SUSY-GUT (as the proton does not decay), or Kamiokande discovers proton decay consistent with SUSY-GUT, but LHC fails to discover SUSY.

If LHC discovers SUSY and Kamiokande discovers proton decay consistent with SUSY-GUT predicted proton lifetimes, string theory will continue its dominance as SUSY-GUT can be embedded in the string framework. Lubos and Jaques believe this will be an outcome, Lubos is willing to bet money, and I think if it is the outcome, I think their confidence in strings will have some experimental support.

In this scenario, I can't imagine either your NEW or Smolin's Trouble gaining any traction whatsoever.

47. **Yatima**
September 17, 2006

Dan says:

> You (Woit) and Smolin would be "heros"

Why should that be so? A hearty expression of frustration that turns out to be justified when the brick wall is finally reached does not a 'hero' make – and I do not think it is the authors' intention to acceed to hero status. 'Hero' would be the research group that comes up with the Next Good Thing, whatever that is.

> I think if it (SUSY + proton decay consistent with GUT) is the outcome, I think their confidence in strings will have some experimental support.

Hmm… how much experimental support would that actually be (I am unable to judge this). If you succeed in circumnavigating the earth, your conjecture that the earth is round, hollow and has big holes at the poles has some experimental support, but you still need to check those poles. Now if these are too difficult to reach, what then?

Btw. are preons still being worked on?

48. **jeremy**
September 17, 2006

Yatima write:

"Why should that be so? A hearty expression of frustration that turns out to be justified when the brick wall is finally reached does not a 'hero' make – and I do not think it is the authors' intention to acceed to hero status. 'Hero' would be the research group that comes up with the Next Good Thing, whatever that is."

To express such frustration so publicly, to challenge the status quo so vigorously, and to argue for alternatives so heartily is courageous and heroic. Who knows, the hero "that comes up with the Next Good Thing" may only become hero after being inspired by NEW.

49. **LDM**
September 17, 2006

Regarding the Siegfried review…it is pretty obvious he doesn't really understand what he is writing about…which I find irresponsible, since he must certainly realize that some people might make a decision to purchase or not based on his review.

But I suppose it is a two-edged sword, since I now would never consider buying or even recommend to anyone his upcoming book…

50. **Gina**
September 17, 2006

"That's not at all in the cards in this case…"

Wow, so you have them cards, Peter! Boy, we have a lot of questions to ask you…

51. **Gina**
September 17, 2006

"Who knows, the hero 'that comes up with the Next Good Thing' may only become hero after being inspired by NEW."

A better bet yet is that she will be a string-theorist.

52. **Gina**
September 17, 2006

And here is my own last-week review.

"NOT EVEN WRONG", by Peter Woit; A review

(Replies and comments are very much welcomed, also you ReNorm)

Peter Woit is wrong claiming that "string theory" is "not even wrong". It is questionable if the distinction between "right", "wrong" and "not even wrong" coined by Wolfgang Pauli should be taken as a serious way to classify scientific theories (and even if this is the correct translation to English of Pauli's terms). It is a nice gimmick, though, and a great name for the book. In any case, the insights and truths offered by string theory, one of the most daring intellectual endeavors of our time, may well be wrong. They may also prevail as an important and unique part of physics. We cannot tell which way string theory will go.

"Landscape", the possibility of a huge number of theories that we may never be able to choose between, may be an artifact of string theory itself, or just of string theory in its present form. But it can also be an "impossibility result" which reveal a genuine problem with our ability to describe physical reality at some scales, if we like it or not.

Whether string theory will prevail or not, it seems hard to argue that string theory contributed important insights and technical infrastructure to mathematics and to physics.

It is important (also for string theorists; at least on weekends) to be aware, that even if "string theory" is a "theory of everything", string theory is not "everything". In mathematics we see many examples of such a distinction. Mathematical logic is a "mathematical theory of everything" that was developed in order to understand the foundations of mathematics. But while mathematical logic formally includes all other mathematics, in reality it is a beautiful field which is one out of many fields of mathematics and, as a matter of fact, a rather separate field. It took many decades before important links between mathematical logic and other mathematical disciplines were found.

There is no a priori advantage or importance to the theory which study the most fundamental and general rules. (In my own mind, relevance is of key importance which is why from all sciences my own heart goes to Chemistry.) But there is no a priori disadvantage either.

Peter Woit is a scholar. Modern science and academic life do not give sufficient incentives for true scholarship and large parts of the book exhibit both genuine scholarship as well as Woit's gifted ability to present and discuss in non-technical terms complicated mathematics and physics.
Another advantage of the book is that Woit does not offer alternatives of his own to string theory. Woit does present a few nice ideas and observations that deserve to be pursued,

When it comes to string theory, Woit has concerns (some shared by string theorists), complaints (a few justified), suspicions, and unrealistic expectations (like everybody else); but Woit does not have a case.

Recommendation: For a layman wanting to read about string theory I would recommend Brian Greene's "The Elegant Universe" over Woit's new book. An intelligent reader should use plenty grains of salt to any new scientific theory and any popular book describing it. Woit's "case against string theory" may be of some interest to string theorists and other theoretical physicists. I suspect that this is the audience Woit really wants to address.

As I explained elswhere, some of the choices Woit has made as for what to include as well as some of his rhetoric are disappointing.

I am also not happy with Woit's analysis of sociology, politics and funding of science. For a scientist, trying to explore something completely new (e.g., a replacement for string theory,) is a very very risky business. Woit aims at a
system which allows scientists to take riskless risks. As there is no such thing as a riskless risk, Woit's ideas on this front may deserve the title "not even wrong".

Gina

(And thank you Ebgert for the analogy with mathematical logic.)

53. **Gina**
September 17, 2006

Gina–do you have a background or degree in physics?

54. **TheGraduate**
September 17, 2006

Gina,

One thing I've disliked about many of the reviews so far, including yours, is that they spend a lot of time arguing the string theory case for the string theorists instead of reviewing the actual book.

I just don't understand how it makes sense to review a book with a polemic about why it makes sense to continue doing some theory that the book is critiquing.

I would have thought the more sensible thing to do (in a review) is to analyze the author's main points and outline:

1. The facts that the author states which are incorrect

2. The deductions the author makes with correct facts but incorrect logic

3. Correct deductions made by the author with correct facts which are nevertheless constitute an incomplete analysis

By doing this, one gets at the quality of the author's arguments.

In that sense, my feedback to your review would be to be more specific and support your points … but that is my liberal arts education coming out …

As your opinion, I guess it's fine. There is only so much one can put into a random post on a blog. But as written, your point of view seems unsubstantiated.

55. **TheGraduate**
September 17, 2006

Gina,

I normally wouldn't have commented on your review but you did ask for commentary.

56. **woit**
September 18, 2006

Gina,

Please stop submitting repetitive and non-substantive comments here, as well as ones that show little understanding of the issues involved. I'm happy to debate people with a serious background in string theory who want to discuss the arguments in my book, but you're just wasting my time.

57. **Thomas Larsson**
September 18, 2006

will continue its dominance as SUSY-GUT can be embedded in the string framework. Lubos and Jaques believe this will be an outcome, Lubos is willing to bet money,

Of course, this also means that somebody else is willing to bet money against them – in Distler's case, somebody with inside information from the Tevatron. Also note that Motl's original bet involved the date 2006. Depending on the exact conditions and his success in renegotiating them, he may already have lost his bet in less than four months.

58. **Dan**
September 18, 2006

Dear Mr. Larsson, I've not heard of someone with inside information from TEV betting against Distler on SUSY. Could you elaborate?

Peter, when you say that string theory cannot be falsified, stringy unification theories are built on top of SUSY-GUT, which predict proton decay half-times. If the current null result from Kakimone continues, then at some point in the future SUSY-GUT's can be ruled out by experiment as SU(5) have been, hence string theory unifcation scenarios built on SUSY-GUT's would be experimentally falsified. (stringy unification scenarios is the one reason to take string theory seriously).

59. **Thomas Larsson**
September 18, 2006

Here.

Of course, nobody knows the outcome of future experiments for sure, but I would take Dorigo in 2006 a lot more seriously than Motl in 2001. Not only because he is in the loop, but also because he formulated his bet after five more years of experiments yielding null results for susy (Tevatron, SuperK, PEDM, muon g-2, …).

60. **Renormalized**
September 18, 2006

"I am also not happy with Woit's analysis of sociology, politics and funding of science. For a scientist, trying to explore something completely new (e.g., a replacement for string theory,) is a very very risky business. Woit aims at a system which allows scientists to take riskless risks. As there is no such thing as a riskless risk, Woit's ideas on this front may deserve the title "not even wrong". "

This shows a total lack of understanding or insight into what Peter has said from the beginning. He is not asking for a riskless risk (I feel dumb even copying riskless risk), He is asking for strings to be tied to reality in even the smallest way.

61. **Thomas Larsson**
September 18, 2006

If the current null result from Kakimone continues, then at some point in the future SUSY-GUT's can be ruled out by experiment as SU(5) have been, hence string theory unifcation scenarios built on SUSY-GUT's would be experimentally falsified.

Can you be more specific about when this is supposed to happen?

In hep-ph/0005095 Pati wrote on p 4:

"strongly suggests that discovery of proton decay should be around the corner. In fact, one expects that at least candidate events should be observed in the near future already at SuperK."

This was written in May 2000. Is September 2006 still in the near future from that?

62. **Steve Myers**
September 18, 2006

Peter,
I read the review in the NYTimes. Yes, sounds like the guy has an agenda & knows little math-physics. But a point I made months asgo : reading reviews, for an author, is not worth the time. Best criticism comes from editors & trusted friends in the field.
Another general point: if someone's grounds for doing or believing something is not based on reason, you can't reason them out of it.

63. **Peter Woit**
September 18, 2006

Dan,

My impression is that you can get a fairly wide range of predictions of the proton lifetime out of different supersymmetric GUT models, so unfortunately experiments won't be able to rule out the whole class of such models anytime soon.

LDM and Steve,

I'm not very interested in criticism from Siegfried, his own books are models of what I think is wrong with popular books on physics, and he seems to understand very little about this subject. His arguments in his review don't make much sense, they seem to be purely motivated by distaste for the fact that anyone would criticize the subject he has been spending his time promoting. I don't think he would see himself as being irresponsible, he clearly hates what I was doing with my book, and wants to discourage anyone from buying it.

In practice, his review completely trashes my book, but is much kinder to Smolin's. The net effect I think is that it encourages people with any interest in the subject to buy Smolin's book (which is doing extremely well since the review). As far as getting the news out to the general public about what the situation with string theory is, fine with me if Smolin ends up being much more successful at doing that than me.

64. **Alejandro Rivero**
September 18, 2006

I'd not say that Dorigo his bet is based on "inside information"; in fact his blog is one of the best efforts to pass experimental information towards a wider public community (I hope you will mostly agree; I think I am not biased by his quoting of my preprints).

What surprise me of his bet is that it is not restricted to SUSY but also to any non minimal Higgs. Still, I think that the terms of discovery put on his side of the bet the composite Higgs and 4+0 dimensional model if not new particles are needed.

65. **D R Lunsford**
September 18, 2006

Alejandro – I would accept a single bet of up to $1000 bucks that the Higgs will not be seen at all as such, rather something strange and interesting with neutrino physics (e.g. very massive majoran) that will require a retooling of the SM.

-drl

66. **A**
September 18, 2006

if somebody is interested in proton decay in supersymmetric models: it is caused by a) triplet Higgsinos and b) vectors. a) is uncertain and typically too fast, but it is easily avoided in more complicated models. b) is more precisely predicted and small, beyond the reach of Super-Kamiokande; it can be reduced only with dirty tricks. Hopefully, the next two rounds of proton decay experiments will test b) closing the issue before 2030.

67. **Quantoken Impersonator**
September 18, 2006

One criticism I have with not even wrong, which is excellent in enthusiasm and for inspiring the reader to learn more about the study of the real mathematical physics subject of quantum field theory, is this:

Woit offers no analysis of the possibility of external refutation of string theory by another theory being successful.

To understand this, consider other failed theories like phlogiston, caloric, epicycles, mechanical gear cog ether.

In each case (let's call these 'religious theories' for simplicity), the theory was incapable of falsification within itself because it made no checkable predictions per se, just as is the case for string.

But in each case the theory was eventually INDIRECTLY FALSIFIED by alternative theories being extended to do more stuff than the religious theory.

Woit rightly takes a conservative line and doesn't make grandiose claims that alternatives are likely to overthrow string anytime soon in the way that alternatives overthrew the 'religious theories' mentioned above.

Woit should however acknowledge some probability (however low it seems subjectively) that the end of string will come by some paradigm shift away from M-theory and towards phenomenological modelling, rather than through the failure of the large hadron collider and experiments.

Because string speculations swamp arXiv and provide so many contradictory "predictions" about the number of "branes" and the mechanism for the strength of gravity, not to mention the landscape of vacuum energy solutions, I'm confident that string theorists are perfectly capable of reading ANY experimental data from LHC as "evidence" for some version of string theory.

Since the "predictions" are so vague, almost any data from LHC could be read as a suggestive hint that superpartners could exist. People WANT to see confirmation + Woit and Smolin put pressure on the mainstream => the mainstream cooks up some false evidence. Easy! Critics sorted.

Woit will find it harder to say that the Emperor's clothes are threadbare convincingly (which will be the case when string celebrates evidence from LHC), than to say the Emperor is naked (the case today in 2006). You're cornering a wild beast in string theory; it will put up a frenzied fight rather than surrender.

Woit will be deemed by the media to have a vested evidence in making negative noise and being dismissive towards string, so you'll be ignored, and I fear that fiddled LHC or other "evidence" for big branes in string theory will sink all atlernatives forever. Even epicycles and phlogiston had some alleged evidence. Can't Woit survey some alternatives and write an arXiv paper objectively categorising alternatives to string according to how many facts they encompass, and how few speculations they require? (At present Motl is the only one who repeatedly claims to do this, but his scheme has only one category for alternatives: crackpot.)

68. **TheGraduate**
September 18, 2006

Finally got my copy of NEW and T w/ P at the local bookstore this morning.

69. **Yatima**
September 18, 2006

Quantoken Impersonator wrote:

> predictions per se, just as is the case for string.

Well, according to Thomas Kuhn (in 'The Structure of Scientific Revolutions') that would be the normal state of affairs. You don't need 'checkable predictions' as everything is 'explained' by your current approach.

The prevailing theory (e.g. "phlogiston") would explain any observations made and proponents would push observed anomalies to the boundary, either ignoring/cataloging them or explaining them away ("this could easily be explained by high concentrations of tightly bound phlogiston…needs more study")

After anomalies accumulate and remain unexplained, a new 'paradigm' is proposed (generally by someone with no vested interest in the prevailing paradigm). That new paradigm then has to win over the existing one. Kuhn writes: "In the sciences, the testing situation never consists simply in the comparison of a single paradigm with nature. Instead, testing occurs as part of the competition between two rival paradigms for the allegiance of the scientific community".

Kuhn refutes the existence of a Popperian falsification procedure, any prevalent paradigm having to be flexible enough to (within bounds) accomodate anomalies. Not unreasonable: If there is no competing paradigm, people will just shrug in response to an anomaly and say "we know it doesn't always work"

Now, String Theory does not seem to fight, it just assimilates. It looks like an exploration of a mathematical space with the hope that something in that space will be found that, with some specialization/parametrization is able to generate all existing observations – and then some. Unfortunately one does not know whether there is such thing at all and whether it is anywhere in the 'vicinity' of the target, M-theory ('vicinity' could actually be defined more rigorously here) Most probably though there are many many such things out there, so you want to find the one that is least generalized… I will stop now. Sorry sorry Peter.

P.S. Kuhn used 'paradigm' first, before marketeers misappropriated it, to describe achievements "sufficiently unprecedented to attract an enduring group of adherents away from competing modes of scientific activity (and) sufficiently open-ended to leave all sorts of problems for the redefined group of practiioners to resolve".

70. **TheGraduate**
September 18, 2006

What does Kuhn say about the role of needing to get tenure in the propagation of faddish scientific theories?

I've heard a lot about the physics job market being very, very tight and how only the more 'elite' physicists get academic jobs these days … I've also heard just being able to say you work on string theory carries with it a presumption of being an elite physicist …

I suppose I'm a bit surprised that there isn't more discussion of that aspect of things ie the very real possibility of putting a lot of these chaps out of work.

71. **King Ray**
September 18, 2006

I think that as Kuhn describes in his book, The Structure of Scientific Revolutions, that we are in a period between paradigms where physicists are wandering in the wilderness, doing things such as string theory. It will take a revolutionary new idea to create a new paradigm. Kuhn stated that physics and science do not advance monotonically, but in leaps and bounds when new paradigms emerge. In between paradigms, there is stagnation, like now. It's been 25 years since I read Kuhn's book, but certain points he made have really stuck with me.

72. **Chris Oakley**
September 19, 2006

> It will take a revolutionary new idea to create a new paradigm.

I am sick of hearing that a new "revolution" is required in physics. The two most important "revolutions" in physics in the last century were special relativity and quantum mechanics, and I have not even seen the results of these applied honestly and consistently.

73. **Thomas Larsson**
September 19, 2006

Alejandro, I admit that "inside information" was for rhetorical effect. However, Dorigo's post did confirm my suspicion that past experiments are tightly constraining all kinds of post-SM physics at the LHC. I agree that his site is a wonderful place to learn about experimental HEP.

Anyway, my point was that Distler's and Motl's bets are not strong evidence for SUSY, since insightful people are betting against them.

74. **Gina**
September 19, 2006

In my review there is a typo which makes one sentence ambigious , when I wrote

"Whether string theory will prevail or not, it seems hard to argue that string theory contributed important insights and technical infrastructure to mathematics and to physics."

I simply meant, of course

"Whether string theory will prevail or not, it is a fact that string theory contributed important insights and technical infrastructure to mathematics and to physics."

(To your question, Gina, I do have an academic background but not a degree in physics.)

75. **dan**
September 19, 2006

"Thomas Larsson Says:
Anyway, my point was that Distler's and Motl's bets are not strong evidence for SUSY, since insightful people are betting against them."

That's a good point.

I actually think that string theory does make "soft predictions" that can be "falsified", by soft I mean qualitative falsification not quantitative predictions. String theory, since it requires SUSY, and a SUSY theory consistent with known observation. Peter has objected to Distler and Motl's claim strings "predicts" or "outputs" MSSM (I mistakenly said SM originally) but perhaps the word "embed MSSM in the string theoretical framework" would be more accurate?

Mr. Larsson, to answer your question,
I am under the understanding that SUSY-GUT that would be consistent with current observation would be either MSSM- SUSY-GUT SU(5) or SO(10), it's my understand current observed proton half-life of 10^35 rules out 95% confidence MSSM-SUSY-GUT SU(5)

"arxiv.org/abs/hep-ph/0302272 – It is widely believed that minimal supersymmetric SU(5) GUTs have been excluded by the SuperKamiokande bound for the proton decay rate."

"arxiv.org/abs/hep-ph/0108104 "We make explicit the statement that Minimal Supersymmetric SU(5) has been excluded by the Super-Kamiokande search for the process $p \to K^{+} …

That leaves us with MSSM- SUSY-GUT SO(10), which I think can be said to be embedded in the framework of heterotic E8 type string theory (If Peter objects to the word prediction or output). MSSM- SUSY-GUT SO(10) would be the most minimal SUSY-GUT known consistent with current observations of the SM. It also predicts proton decay although I am unsure what half-life it predicts, and predicts masses for superpartners that is within reach of LHC energies.

This paper
http://arxiv.org/PS_cache/hep-ph/pdf/0004/0004266.pdf
states it is highly model dependent.

In summary: If no proton decay is ever observed + no SUSY seen at LHC energies (or future colliders) + Loretnz violation observed at GLAST + absence other string-inspired observations such as cosmic strings = falsification of SUSY GUT SO(10) = other MSSM models are unlikely to agree with experience == unlikely string theory is correct as a result of experimental and observational evidence.

76. **Peter Woit**
September 19, 2006

Dan,
As far as I know, the SO(10) SUSY gut doesn't predict masses of superpartners within reach of the LHC, it doesn't predict them at all. With current Tevatron bounds, some degree of fine-tuning is needed to make supersymmetry work, so one can worry that one has already lost the supersymmetry explanation of the hierarchy problem. If superpartners have such high mass that you can't see them at the LHC, you need a lot more fine-tuning. But then again, if you believe many string theorists these days, the hierarchy problem is resolved anthropically anyway.

77. **dan**
September 19, 2006

Dear Peter,

I probably will need to do some research, and possibly ask the usual suspects who are familiar with the relevant literature in arxiv

I thought the reason Lubos & Distler are *publically* willing to bet money is that they have reviewed the relevant literature in arxiv and unpublished, on SUSY and SO(10) SUSY GUT and believe that SO(10) SUSY GUT predicts superpartners (i.e neutralino) accessible at LHC ranges (with SO(10) SUSY GUT representing low-energy phenomenology of string theory consistent with known facts) otherwise, they stand to lose money. I suppose the bet could be extended for proton decay.

The article: "http://arxiv.org/PS_cache/hep-ph/pdf/0004/0004266.pdf" does mention fine-tuning SUSY to match observation.

It seems to me that most string theorists feel since LHC's results are still several years into the future (Distler commenting it takes time for LHC to run at spec.) I think for string theorists, it's business as usual.

78. **Christine**
September 20, 2006

Gina wrote:

[The Landscape] can also be an “impossibility result” which reveal a genuine problem with our ability to describe physical reality at some scales, if we like it or not.

For what is worth, maybe an “impossibility result” *for string theory*, like it or not.

BTW yesterday I received Smolin’s book from the assistant director of publicity and just from reading the first pages it made my day. Smolin is the voice of lucidness in a sea of… of… *hep-th nightmare* (yes, except for very few exceptions, doesn’t it look more and more like some kind of physics nightmare?? Why not rename hep-th to str-math, “string mathematics”?). If string theory proves to be correct, I’ll also be one of the first to applause the effort. (I am not particularly against string theory — or “against theories” anyway.). But while the situation is so far from success, other coherent, promissing alternatives must be encouraged. Otherwise, this is not how science must proceed. Even my 7 year old son can understand this.

It’s difficult to add something to what has already been so cleverly said elsewhere, except to acknowledge, based on individual experiences, that the sociological effect is real and damaging and somehow must be reduced as much as possible from the scientific activity.

I look forward to Woit’s book with great interest as well, and see how both books complement each other. It’s a very special moment in the history of science, and all I can hope is that I’ll be able to write a responsible review on these historical books.

Christine

79. **Gina**
September 20, 2006

Let me make a few more remarks on the discussion above.

One frustrating thing about this science business is having to keep double checking not only those matters of disagreement, but also matters of complete agreement. There was a single item in the discussion I certainly agreed with Peter about, the need of an honest and self-critical approach, and even this item, on closer examination, is not that simple.

We do not pay scientists to be just honest we pay them also to be gullible. They have to be gullible mainly regarding their own abilities and also regarding their beliefs on the foundation of the current theory they are working in, the prospects for its success, the relevance of the methods, and the overall importance.They have to be a little blind to the frustrating nature of their profession and to the overwhelming probability of a sense of missing out on their lives down the road.

To me, Peter, the signal concerning the state of string theory coming from Gross’ “never never give up” statement is not that much different from what you are saying. (I could imagine how I would feel if my personal physician, Dr Gross had told me: “The outcomes of your tests have now arrived, and I will never never never never give up on you, Gina.”) I think Gross’ massage to the young scientists is the more correct one. What I’d tell to them young (and old) brilliant guys and gals is: “Do not give up and always keep your mind open, (and get a life, and put things in proportion, and remember, it is a struggle all right, but it is not really, really, really a war.)”

So if you feel we are in a bottleneck here, wish to cut some corners, and do not have the patience to wait for the emergence of the next paradigm as beautifully explained by Yetimar (or persistence of this one), maybe it will be a good idea to follow Quant Imp’s suggesting having an arXive-quality document summarizing the alternatives. And maybe my suggestion from a few weeks ago to have a scientific short document with the main point for the “case against string theory” which will elaborate on the main problems and can get a little technical but without the maharishi, and the brothers, and summer salaries and the job market, can also be a useful idea.

“but in the generic case, a real possibility is that X-theory will achieve one or more of its major goals, making it a solid and permanent part of science, opening up new areas to work on that build on this success”

One has to be very very gullible (much beyond what is needed for a scientist) to believe that this is the case for a generic scientific theory.

“Gina, … but you’re just wasting my time”.

Well, as they say, “A scientist who is not waisting his time is waisting his time”. Anyway, I will try to improve the quality of my remarks (and reduce their frequency), and I hope they will eventually become interesting to you. But please do not delete me from these infinite cyber valleys.

80. **Yatima**
September 20, 2006

Gina, this pertains to your interests, I think.

Just now I’m burrowing through Lee Smolin’s book (in the middle of the night…hmm double special relativity? tasty!) but I will stop for now and quote from a novel by Arkadi and Boris Strugatsky (not to be confused with the Bogdanoffs) called ‘Far Rainbow’ which on the face of it is about an physical experiment going horribly wrong as the underlying governing laws are unknown (a classic, recently explored by Greg Egan) but it actually seems to echo the Great Patriotic War. Anyway, towards the end, Camille, the greatest physicist of Rainbow, is heard to say (he has worked too hard not to mention died a few times):

“The Great Logician. Logical methods demand absolute concentration. To do anything in science, day and night you have to think about one and the same thing, read about one and the same thing, talk about one and the same thing.. And where can you go from your psychic prism? Away from the inborn capacity to love… You’ve got to love, read about love, you’ve got to have green hills, music, pictures, dissatisfaction, fear, envy… You try to limit yourself – and you lose an emormous part of your happiness. And you know very well you’re losing it. So then to blot out that consciousness and put an end to the torture of ambivalence, you castrate yourself. You tear away from yourself the whole emotional half of your humanity and you leave yourself with only one reaction to the world around you – doubt. Then loneliness lies in wait for you.”

Hopefully most physicists are not so bitter. But stil, one gets what he means.

John Baez is encouraging people to join in a campaign to "save New Scientist" from itself, i.e. to get them to stop publishing so much scientific nonsense. This seems to me like a worthwhile goal; maybe if they stop writing articles about crackpots and their "electromagnetic drives", they'll also stop promoting bogus over-hyped claims from prominent theorists about cosmology, string theory, etc….

Shing-Tung Yau is fighting back against the New Yorker article "Manifold Destiny", which was very critical of him, essentially claiming he was trying to steal credit for the proof of the Poincare Conjecture from Perelman. He has hired a lawyer and set-up a web-site. The web-site includes a long letter from his lawyer to the New Yorker, making his case that the article has many inaccuracies. There will be a webcast tomorrow at noon giving his side of this story. Many other blogs and newspapers are discussing this, see here , here, here, here, and here. Unfortunately for Yau, he has strong support from Lubos Motl, who seems a tad obsessed, ranting about how the quality of the New Yorker article:

resembled the style and ethical standards of many jerks in the blogosphere, including a colleague of Sylvia Nasar at Columbia University.

People who want to engage in bashing of Yau or of his opponents are warned that they should do it elsewhere. Only comment on this here if you have something to say that is substantive and respectful of all parties involved.

Besides Yau's webcast, tomorrow you can also listen to me on the SETI Radio Network program, broadcast on Discovery Channel Radio. This will also be on their web-site, more info here.

The Harvard Crimson has an article about Nima Arkani-Hamed, who evidently made Popular Science's "Brilliant 10" list for

his research on the idea that our universe may be only one of many "multiverses" and that additional dimensions may exist.

(many "multiverses"???) Arkani Hamed promotes the anthropic landscape and split supersymmetry as a test for it:

He recently proposed a model for new physics, called split supersymmetry—which theorizes that half of all particles in the universe have partner particles. He said that if the results of the LHC experiment reveal split supersymmetry, "it would be a tremendous push in the direction of a multiverse."

"Right now a lot of people are on the fence," about the theory of a multiverse, Arkani-Hamed said. "I think if the LHC sees split super symmetry it's over."

Also on the multiverse front, Gibbons and Turok have a new paper out on The Measure Problem in Cosmology. They claim to have a way of determining a measure on the "multiverse". Only problem is that with their measure, the probability of having inflation work out the way it is supposed to is about e^{-180}.

Update: Another radio appearance today, on the program This Week in Science.

Update: To view today's webcast, go to www.premierewebcast.com, get your software working, and enter room 150144. I'll be skipping this myself, partly because I'll be in a faculty meeting.

Update: If you want to read a lot of incredibly ill-informed and worthless comments on the Yau story, there's always Slashdot.

1. **Me**
   September 19, 2006

   «John Baez is encouraging people to join in a campaign to ?save New Scientist? from itself, i.e. to get them to stop publishing so much scientific nonsense.»

   Last time I read New scientist was arround 1994. Back then I was still in high-school and even so I recognized it mostly (not all) as vapid at best, deceitful at worst.

   Apparently it has gotten worse.

   «The writer of this article, Justin Mullins, seems aware that conservation of momentum is violated, but then churns out a lot of meaningless double-talk about ?reference frames? which he seems to think demonstrates that relativity somehow comes to the rescue:»

2. **Peter Orland**
   September 19, 2006

   New Scientist is too far gone to save. If I were to get a paper cut from an issue, I would immediately seek a tetanus shot.

   What worries me more is the fate of Scientific American. Scientific American inspired generations of people to become scientists and engineers. Though it is still miles above New Scientist, its quality has significantly declined.

3. **Peter Orland**
   September 19, 2006

   It seems pointless for people to take sides in the Yau vs. Perelman
   fight. With so much attention focused on the debate, the truth will
   win out, no matter who champions either side. What a silly waste of time. The people who will (and should) decide the issue is the mathematical establishment. The papers are there, with dated submissions, in black and white – so where is the debate?

   The argument does not seem to even be a matter of intellectual courage, since neither side needs defenders from the sidelines. It is
   courageous to take an unpopular position out of conviction, not to argue who deserves more credit.

4. **Thomas Love**
   September 19, 2006

   The campaign to save new scientist from itself is much like your campaign to save science from itself.

As far as string theorists go: Just give them enough string and they will hang themselves.

5. **Dick Thompson**
September 19, 2006

I don't think the campaign to save New Scientist will go anywhere. Reed Elsevier is surely not going to change their ways unless profits fall, which is not likely to happen.

On Yau, it's just sad to see this man, to whom math and physics are so indebted, embroiled in a he said, she said scandal at this point in his life.

6. **nigel**
September 19, 2006

New Scientist's success in popularizing physics in the UK is demonstrated by hard, factual statistics:

"Physics has declined in popularity among pupils at school and students at university, research suggests.

"A-level entries have fallen from 55,728 in 1982 to 28,119 in 2005, according to researchers at Buckingham University." – http://news.bbc.co.uk/1/hi/education/4782969.stm

Cause for real celebration by New Scientist! I wrote an opinion leader in Electronics World saying that stringy hype is destroying British physics years ago, but the only responses were from moronic crackpots who claimed the decline in interest in physics was due to TV or computers or anything but stringy stuff. Nobody cares.

7. **Johan**
September 19, 2006

New Scientist is published by Reed Elsevier?! In that case, I don't particularly care what happens to it.

8. **werdna**
September 19, 2006

Peter Orland,

Just to clarify one thing: The so-called "Yau vs. Perelman fight" does not exist at all. Yau, in his attorney's letter, calls it a "fictitious battle." Cao and Hamilton also testified publicly that there was never a controversy surrounding questions of credit, etc. (As it turned out, the 50-25-30% quote was made up by a third-world reporter!) The only people who decided to make it a problem were the irresponsible authors/"fact-checkers" of that NYer article. As we now know, that piece apparently contains a lot of fiction.

There is a so-called "Tian-Yau affair," however, but it is a different matter entirely and should best be left to the two parties involved to sort out.

9. **MathPhys**
September 19, 2006

I read the various commentaries that followed The New York article, and I'm shocked by how Nasar seems to have enticed then misinterpreted every single academic that she interviewed.

I still have to read one academic that was quoted in her article come out and say "Hell, yeah, that's my opinion. What will you do, Yau? Not invite me to your birthday party?"

10. **gunpowder&noodles**
September 19, 2006

Regarding Gibbons and Turok: Lubos had a posting about this paper which reveals something about his way of thinking. Basically he thought that they were criticizing inflation, which is The Establishment. He even went so far as to say that the GT paper should not be published, and should not even have been posted on the arxiv, because it criticizes an Established Theory.

He doesn't like *any* criticism of The Establishment, and that is the sole reason for his support of Yau. See? It all hangs together. Sort of.

Regarding Yau: To many people, I think the most shocking thing in the original Nasar article was the allegation about how he rammed through the paper in the Asian JM. I note that this crucial episode is not mentioned in the long letter. Why? I think we all know the answer, and we all know what it implies.

11. **Peter Orland**
September 19, 2006

To MathPhys,

Perhaps I mischaracterized the matter as a fight. Yau's talk at the meeting in China, however, certainly seemed like a shot across the bow. Usually when a breakthrough occurs, attention should be (and usually is) focused on the research articles where the breakthrough happened. I don't work in the field, but the breakthrough in this case seems to be Perelman's, from what I can tell.

Incidently, I have not read the New Yorker article yet, but now I am very curious to know why some people are very upset about it.

12. **Peter Orland**
September 19, 2006

Oops, I meant werdna, not MathPhys. Please excuse me.

13. **Roy**
September 20, 2006

Werdna,
Slightly off topic– but I was curious what you meant by the following– "(As it turned out, the 50-25-30% quote was made up by a third-world reporter!)"

Why is the adjective "third world" important?

14. **werdna**

September 20, 2006

I think that if people have an objection to anything Yau might have said or done, they should personally write him at his Harvard address using their real identity and give the professor a chance to reply to it.

It pains me to see such a hardworking and accomplished mathematician who's contributed so much to the field to be dragged through the mud by an outsider like Nasar. He does not deserve it. And neither did those people who have been deliberately misquoted in the article. The judging of all relevant works, including who contributed how much to what part of the PC, should be left entirely to the mathematical community. And this community likes to take its time to rigorously go through everything to ensure correctness and fairness. This is something that certain writers/researchers/journalists could learn from.

15. **MathPhys**
September 20, 2006

To gunpowder&noodles,

The episode in Nasar's article regarding the publication of Cao and Zhu's paper is not mentioned in Yau's lawyers' letters because it has nothing, and I repeat nothing, to do with this entire sad story.

As werdna said earlier, the Yau-Tian conflict has nothing to do anything else.

16. **jeremy**
September 20, 2006

Peter,

First time listen to your radio interview (This Week in Science). The messages are certainly there, but if you can make the sentence shorter and not stop in the middle of it, it will sound much better. Still, very well done.

In the letter of Yau's lawyer, it mentioned the relationship between Phillip Griffiths and Nasar. What is the relationship? Wife, girlfriend or mistress?

17. **werdna**
September 20, 2006

Roy,

You've asked a fair question. I added that adjective to suggest that the authors should have known better than to rely solely on a source of information that might not be completely reliable, given that journalism standards were generally considered lower in developing countries. I certainly did not mean to suggest that reporters there were less honest than those in wealthier nations. There are many factors (such as educational level, likelihood of being sued, job pressures, etc.) that may cause or force some reporters to be sloppier than others. But again, that is the general impression.

18. **Chris Oakley**
September 20, 2006

Re: This Week in Science podcast.

Helpful note for those wanting to listen to Peter and not the less hot broadcaster's notes about his Hawaii vacation: start the audio exactly 30 minutes after the beginning.

19. **Thomas Larsson**
September 20, 2006

"I think if the LHC sees split super symmetry it's over."

???

If the LHC sees sparticles, it would prove nonsplit SUSY, wouldn't it? What is the signature for split SUSY, and how can it be distinguished from no SUSY?

20. **geometer**
September 20, 2006

werdna,

1) I personally think that this is a free country and people can say whatever they want without providing their names, but you seem to follow a different standard (and I respect that). So if you wish to critisize Nasar you should write to her using your real identity, so she has a chance to respond to the accusations.

2) I welcome Yau's letter (the more information the better), and I am especially glad the quote of credit distribution seems to be false (as it was ugly). The way I see it Yau knew the "50/25/30 quote" went arount the world like fire, and he knew it was reported by Xinhua, which is a news agency millions of people pay attention to (I am sure New Yorker has much smaller audience). So if Yau wanted to rectify the situation he could've posted/distribute a correction saying that "Xinhua report was incorrect, and here is what really happened". Yau did not do that. Now some people might think that "Xinhua report" benefited Yau's case (and it did, at least initially), and this is why he did not compain.

21. **comentator**
September 20, 2006

I found very interesting the words by Perelman in an interview after he talked with J.Ball in St. Petersburg. "It seems that Cao did not understood my arguments and he rewrote them, but everything is there".

Now at this point is hard to say who contributed what; But a good indicator will be the Clay prize, since they will be hearing from the people who actually has been working on Perelman's papers and I guess only one or at most two persons will receive it, being Perelman one of them of course.

22. **mathjunkie**
September 20, 2006

I don't believe the New Yorker's report on Yau!

Parts of the report are hard to be proved.

23. **MathLover**
September 20, 2006

geometer,

About your point 2, it's actually the case. The counsel's letter clearly states that the misquoted deputy director Yang Lo refused the idea of share of credit. Unfortunately only the first Xinhua news goes through the world, not the second one. But those facts were available to Nasar. Nasar was even warned by Yau that there were opponents to his fight against corruptions in Chinese universities / higher education system. Those opponents have obviously their fingers in the press.

BTW, we all support free speach and free press, but not free slandering. Every one is responsible for his / her own words. I don't see werdna using any other standard here.

The counsel's letter really shed light on this subject. It's clear, Nasar's article damaged the math community severely. Hints point to conspiracy that those who have an interest to against Yau are at work. Nasar may become involved knowingly or unknowingly.

24. **TheGraduate**
September 20, 2006

Yau should be doing the webcast in approximately 11 minutes.

25. **geometer**
September 20, 2006

MathLover,

Unfortunately I cannot read Chinese, but I did run the Yang Lo's intervew through the web translator and could not see any clear claim that the previous news was incorrect. In fact, the whole Yang Lo's interview was a celebration of "Cao-Zhu success", and it implied, as far as I could see, that their effort was no less significant that Hamilton's or Perelman's (which is false in my professional opinion).

I agree that "The counsel's letter really shed light on this subject", but I see no damage to the math community. On the contrary I think we shall all gain at the end because of this extra publicity.

26. **werdna**
September 20, 2006

geometer,

There are anonymous commentators who post responsibly, and then there are those who hide behind a cover to hurl personal attacks and baseless accusations at others. The postings of the latter usually get deleted – at least in this forum anyway. As has been pointed out, free speech does not mean free slandering.

Personally, I would not write to Nasar myself. Those who have been misquoted by her had made repeated requests to correct inaccuracies and distortions in the past, but their attempts were unsuccessful. If the messages of these victims were ignored, what good would my letter to her do? Do you think she would even respond?

As for your other point, I believe MathLover has addressed it satisfactorily. Note that the June 4th Chinese news report was quickly rescinded on June 9th.

27. **Curious Bystander**
September 20, 2006

There were interesting comments signed by "Anon at
http://motls.blogspot.com/2006/09/shing-tung-yau-goes-after-shoddy.html
They are now partially removed?!

Lubos objected that my first post here didn't address the individual points of the letter, so I'll try to do a bit of that presently. This may be boring, but hey, our host asked for it.

The letter does not provide 12 pages of evidence of libel–it provides a few pages of evidence that Nasar was less-than-ideally fair, along with a whole lot of petty bitterness and innuendo. A general issue that I would mention first is that, as I indicated earlier, I think that Nasar probably got the impression by talking to a lot of people that Yau wasn't trustworthy. Whether or not that's a correct impression is not something that I feel competent to judge, but if she had that impression then I do not believe that Yau saying, "I told you X and you didn't print it" or "You didn't let me give my version of X" is actionable, because a journalist is free to judge whether or not certain statements and sources are credible.

The specific objections don't start until page 3. We see a long list of sentences beginning with "You gave [Yau] no chance to respond to…" As I indicate above, all these can be explained by Nasar growing to distrust Yau over the course of researching the article. If there is a law stating that journalists are obliged to solicit and reproduce all of their subjects' opinions on everything they discuss in an article (even when they distrust the source in question), I'd be interested in seeing it. Nasar may be guilty of jumping to conclusions or being somewhat unfair here, but I seriously doubt that she's guilty of libel.

Page 4 first complains about the subtitle and the picture–as I said I think the picture is rather problematic, but again it's not clear to me that Nasar is responsible for it. There's then a complaint about the famous 50-25-30 distribution of credit that the Chinese state media reported in early June (mysteriously, this seems to have disappeared from the online stories). Nasar and Gruber quoted from a press conference, attributing the distribution to Yang Le and giving a quote from Yau (which Yau now says was fabricated–by a Chinese reporter, not by Nasar) which seems to endorse it. Now Yau is quoting an e-mail that he sent to the fact checker to the effect that "I did not say it and people put that into my mouth." Again, perhaps Nasar doesn't trust Yau about this–and perhaps for that matter that fact-checker looked into this and found that he did in fact say such a thing at the press conference; there surely were witnesses that could have been consulted.

Lubos, you presumably remember very well the 50-25-30 distribution of credit, since you wrote a blog post featuring it. It seemed to make a very real impression on you and many other people around the world. If Yau didn't believe in this, the time to distance himself from this was immediately afterward–but he didn't see fit to do so at the time. (Yang a few days later apparently gave an interview–AFAIK only ever published i

AFAIK only ever published in Chinese–saying that he (Yang) wasn't qualified to give such a distribution of credit…but Yau is someone who is qualified to do so, and I'm not aware of him retracting anything prior to his interview with Allyn Jackson in the September Notices, if you even count that.) Instead, Yau went on to give the talk at Strings '06 which, again, trumpeted very heavily what Cao and Zhu did (and also everything that Yau did that could at all be connected to the conjecture–remember a certain blogger who explained that Yau had given "a talk about the Poincare conjecture and how he proved it!"?). Only later, when criticism of this distribution started mounting, did Yau suddenly decide that it would be prudent to move away from it. Throughout June, Yau was presenting the proof of the Poincare conjecture as a triumph of Chinese mathematics. Nasar and Gruber had every right to report on this, and to view Yau's modest reversal on this issue as insincere.

There follows a weird reference to Nasar and Griffiths' "relationship" and the confident declaration that the negative comments obtained from other mathematicians about Yau only resulted from Nasar poisoning their mind with nasty rumors about him. Well, I seriously doubt that every mathematician I've talked to who has a negative opinion of Yau has talked to Nasar and got it from her. These opinions circulate widely throughout the community, and it's much more likely that the community passed them on to Nasar than the other way around.
Much of page 6 discusses the Cao-Zhu paper and the amount of credit it gives to Perelman. The statements are framed very carefully in order to make Yau (and Cao-Zhu) look like they're giving as much credit to Perelman as possible and that Nasar was denying this, but it also doesn't bother to provide any actual statements in the article that contradict anything being said here (there is a reference to a sensationalistic subtitle and to the picture–probably neither of which was Nasar's work). These paragraphs also commit what I would say is a slight misdirection–what's at issue in the New Yorker article is not how much credit the Cao-Zhu article gives to Perelman (indeed neither Cao nor Zhu come off at all badly in the article, I thought) but rather whether Yau's public behavior was aimed at giving an unreasonably large amount of credit to Yau and his proteges at Perelman's expense. Note that the Cao-Zhu article was never even publically available until July (or maybe late June in paper form), and the number of mathematicians (and laymen) who had some exposure to Yau's actions in the press in June is much larger than the number who have looked at the text of the Cao-Zhu paper. And Yau's actions in June (which admittedly may have been misrepresented by the Chinese press–but that's something for him to take up with them, not the New Yorker) sure looked a lot like he was claiming credit for himself and his proteges

–the only debate anyone was having back then was whether said claim was valid; I don't recall any of Yau's defenders saying at the time that the claim wasn't being made.

Starting on page 7 there's a discussion of the Givental flap. The letter of course neglects to mention that the article says, "Liu maintains that his proof was significantly different from Givental's," but does complain about the fact that the article didn't refer to specific arguments that Liu made to support this statement. I don't know a lot about this specific dust-up, beyond the fact that at least a significant number of people believe that Yau's behavior was inappropriate here and that the Lian-Liu-Yau paper claimed more credit than was fair. When Givental came up for tenure at Berkeley, the department of course consulted experts in the field about this, and you can guess what the outcome was based on where Givental is now. This was certainly natural background for the authors to give, and while again I can understand if Yau thinks the description of the Givental conflict was unfair to him I can't imagine what could be considered libellous about it.

Then we get into the issue of the authors' statement that although Yau had been publishing prolifically it has been a decade since his last major result. Yau may not like this statement, but it's so subjective (what's a "major result"?) that once again I just don't see anything that deserves a libel suit here. I'm not an expert on Yau's work, but I'm sure not aware of anything that he's done in the last decade that has been anywhere near as influential in mathematics as a lot of the work he did in the period from, say, 1975-86. Or as influential as the proof of the Poincare conjecture. Of course Schoen and Smoller (in the former case talking about one of his pet sub-subjects (special Lagrangians) and in the latter case talking about his own joint work) are entitled to their own opinions here. Quoting Stroock (a famous probabilist) of all people about string theory doesn't exactly do wonders for the credibility of the argument being made here.

OK, if Mike Anderson's account is true then the magazine should probably run a correction removing those words from his mouth. The letter then mentions Stroock's (or rather "Strook's") complaint that he was taken out of context. That may be true, but I strongly suspect that every magazine and newspaper in the country would go bankrupt if they were sued every time they took someone's statements out of context. Like so many other things in the letter, this is just filler that is not remotely cause for a lawsuit. And it's also worth mentioning that Anderson's and Stroock's widely-circulated letters that are critical of the article's treatment of Yau appear were directed to Yau, seemingly at his insistence. Stroock did write a letter to the editor of the New Yorker, the published version of which had a quite different focus.

The first section of page 10 raises a subjective matter of interpretation–again, this is filler.

The implication of the start of the next section is that it's libellous and/or defamatory to point out (truthfully) that Yau has never spent more than a few months at a time in mainland China. Hmm…

"Yau's efforts to combat institutional corruption at the highest levels of academia in China," referred to many times in the letter, have nothing to do with the question of whether the article in question is libellous.

Presumably if this whole thing goes anywhere (it probably won't), we'll find out whether the mysterious Chern relative really exists, and whether the claims about Yau trying to move the ICM to Hong Kong (which the article acknowledged that Yau denied–of course the letter doesn't mention this) have any basis in fact. I'm getting tired of going through this page by page by now, but I think I've addressed most of the main points. It may be 12 pages, but there's really not much there beyond lawyerly intimidation that I suspect the magazine will easily see through.

Now that I think about it, Yau's main goal here may not be to extract anything in particular from the New Yorker, but rather to get his version of the story out in wide circulation. And I guess he's succeeded in that.

28. **Peter Woit**
September 20, 2006

Curious Bystander,

Anyone who frequents Lubos's blog should be aware that he has a policy of deleting comments he disagrees with, especially if they are substantive and present facts that he doesn't like.

29. **geometer**
September 20, 2006

werdna,

You wrote: "There are anonymous commentators who post responsibly, and then there are those who hide behind a cover to hurl personal attacks and baseless accusations at others… As has been pointed out, free speech does not mean free slandering".

I fully support polite intellegent discussions. However, it seems to me that you and MathLover confuse "slander" with the "difference in opinions". One is yet to PROVE in court that Nasar's article is slander, and I think, this might be difficult. I assure you there are many very respectable mathematicians that feel the article is basically correct. You may well disagree, just please do not call this slander. And there is nothing wrong in anonymous postings as long as they are polite and responsible.

You wrote: "Personally, I would not write to Nasar myself. Those who have been misquoted by her had made repeated requests to correct inaccuracies and distortions in the past, but their attempts were unsuccessful. If the messages of these victims were ignored, what good would my letter to her do? Do you think she would even respond?"

She would not, and this was exactly my point. It makes no sense for a Prof. Nobody to openly critisize to Prof. Yau, who would not even respond. However, Prof. Nobody can still express her opinions anonymously in a forum, as long as she is polite.

You wrote: "As for your other point, I believe MathLover has addressed it satisfactorily. Note that the June 4th Chinese news report was quickly rescinded on June 9th."

So I figure you can read Chinese. I truly envy you. Could you kindly translate for me the exact quote where the 1st news report was rescinded?

30. **werdna**
September 20, 2006

geometer,

The slandering I was talking about were the "personal attacks and baseless accusations" that have been deleted in this blog by Peter. Please read my entire paragraph again. I have always been supportive of polite, fair, and meaningful discussions here and elsewhere, and have never tried to silence anyone for a difference of opinions.

I did not say Nasar's article was "slander." Please read my earlier post above. I said it "apparently contains a lot of fiction." This is based obviously on the new information provided by the attorney's letter and the letters written by the academics who were (mis)quoted in the article.

You said that "I assure you there are many very respectable mathematicians that feel the article is basically correct." If that is the truth, then let the truth be told honestly. Why does a writer need to use deceptive interviewing methods and questionable editing styles to twist people's words? Wouldn't it be easier to just tell it like it is?

Finally, the June 4th and June 9th dates were taken from the attorney's letter. It is written in English, not Chinese.

31. **jeremy**
September 20, 2006

Curious Bystander writes,
"A general issue that I would mention first is that, as I indicated earlier, I think that Nasar probably got the impression by talking to a lot of people that Yau wasn't trustworthy."

You think? Nasar probably? So, you just went on writing everything based on your imagination. I thought that we are here to talk about irresponsible writers.

32. **Moeen**
September 20, 2006

MathPhys said: "The episode in Nasar's article regarding the publication of Cao and Zhu's paper is not mentioned in Yau's lawyers' letters because it has nothing, and I repeat nothing, to do with this entire sad story."

I thought what the authors were trying to get across was that Yau was trying to get more than his fair share of credit, and ramming the Cao-Zhu paper through the journal and bypassing the usual procedures was an example of him doing that. How then does it have "nothing" to do with this story?

33. **geometer**
September 20, 2006

werdna

"Finally, the June 4th and June 9th dates were taken from the attorney's letter. It is written in English, not Chinese."

Oh, so you simply believe what is stated in the attorney's letter. I have no more questions. If you ever wish to research the original sources try the direct links in Chinese listed at
http://boards.newyorker.com/thread.jspa?threadID=721&tstart=0
I wish someone could translate all this for me.

34. **Curious Bystander**
September 20, 2006

Jeremy writes: "You think? Nasar probably? So, you just went on writing everything based on your imagination. I thought that we are here to talk about irresponsible writers."

1. Though I agree with most comments made by "Anon" in my post I do not want to attribute the credit for his thoughtful remarks on the subject to myself.
2. We are not talking about imagination but of opinion. This opinion agrees we the opinion of a lot of machinations in this and other blogs. I, like "Anon" also believe that "These opinions circulate widely throughout the community, and it's much more likely that the community passed them on to Nasar than the other way around."
3. The previous posting was not about responsible or irresponsible writes (though I believe that Sylvia Nasar is a responsible one) but of the grounds for a legal dispute.
4. Talking of responsibility, why does nobody complain about completely irresponsible remark in Dr Yau's letter on "relationship between Ms. Nasar and Mr. Griffiths"?

35. **jeremy**
September 20, 2006

Moeen writes,

"I thought what the authors were trying to get across was that Yau was trying to get more than his fair share of credit, and ramming the Cao-Zhu paper through the journal and bypassing the usual procedures was an example of him doing that. How then does it have "nothing" to do with this story?"

How did Yau get his share of credit? It is Cao-Zhu's paper, right? If there is redit to get, it would be credit for Cao-Zhu. Do people really give credit to someone who talks about a problem being solved rather than give it to the ones who wrote about how to solve it?

How fast a journal wants to publish a paper is solely decided by the editor of the journal. In this case, it was Yau. If everything in the Cao-Zhu paper is correct, he can take credit for publishing a good paper. But if something turned out to be wrong in the paper, he will be humiliated publicly at least in the mathematics community. So, it is a fair game and there is nothing wrong with it.

36. **TheGraduate**
September 20, 2006

Mooeen,

I think you've got it slightly wrong, at least according to my reading of the article, it implies that Yau was motivated by trying to get as much credit for China as possible.

They are implying that he wanted credit but what they are implying that he wanted credit for was as a leader in promoting chinese mathematics not for his intellectual efforts.

37. **Peter Shor**

September 20, 2006

New Scientist has always been pretty flaky, but whatever happened to the other science magazines on a similar level? There seem to be a lot fewer of them now than there were ten years ago, and they all seem to be increasing their flakiness content. Maybe it's just that I'm increasing my standards, though. Other opinions?

38. **TheGraduate**
September 20, 2006

P. Shor,

I think people that are fans of science magazines like for science articles to be inspirational in a sort of pseudo-religious way. The commercial entities that sell these magazines are aware of it and twist the content to suit.

In other words, the job of New Scientist is to make money and I'm sure it does what it is made to do.

From the business perspective, that is what a business is supposed to do — make money. Anything else is superfluous and naive.

39. **Curious Bystander**
September 20, 2006

Oops, how stupid of me, I meant mathematicians, not machinations.

40. **geometer**
September 20, 2006

Jeremy,

You wrote: "How did Yau get his share of credit? It is Cao-Zhu's paper, right?"

In addition to what TheGraduate said, you should know that Cao is Yau's former student, and any success of a former student is (quite naturally) considered a success of his advisor. (Just imagine that you have had several students who are now tenured at top-5 universities?)

41. **CS Guy**
September 20, 2006

1. The first responsibility of any publication is to its readers. It has no responsibility to make anyone "look good" or to ensure that everyone written about is perfectly happy with how they are portrayed. Their responsibility is to inform their readers about interesting things that they would have otherwise been ignorant of. I think Nasar and Gruber did this admirably doing a lot of original reporting and conducting dozens of interviews. This is the very definition of a good magazine article.

2. Obviously S.-T. Yau has a right to present his own view. Indeed this is very much a good thing, so people can get both sides. But I do question the logic of a law suit. Imagine if GW Bush sued every news paper that portrayed him as an idiot or Bill Clinton sued every one who portrayed him as a liar? The fact that people say something bad about you does not mean it would be wise to sue them.

Here is a wikipedia article on libel. Based on the information presented there, I don't think S.-T. Yau has a chance unless he shows that the New Yorker *presented as fact something that they had no reasonable basis to believe was true*. Since the most damaging parts are public statements of Yau and quotes from fellow mathematicians, I don't see how he can win this.

3. Lastly, here is the response of The New Yorker:

> "Manifold Destiny," a 10,000-word article by Sylvia Nasar and David Gruber published in the August 28, 2006 issue of The New Yorker, is the product of more than four months of thorough, careful reporting and meticulous fact-checking. Ms. Nasar and Mr. Gruber spent over twenty hours interviewing Dr. Yau; they conducted approximately 100 other interviews with people in the field; corresponded by email with Dr. Yau and many others; and traveled to China where they conducted interviews and attended speeches and events discussed in the article. In addition, the magazine's fact-checkers spoke with Dr. Yau for approximately eight hours, they examined notes, tapes, and documents gathered by the authors, and the checkers conducted their own thorough research. Contrary to Dr. Yau's assertions, the article is nuanced and fair, and was prepared using ethical standards of journalism. Dr. Yau, his supporters and his point of view were given ample space in the article.

Basically, after reading this latest law suit, I am even more inclined to believe truth of The New Yorker article. We should be wary of covering up for famous people. That will only tell them that they can get away with anything and lead to more and more outrageous behavior.

42. **TheGraduate**
September 20, 2006

CS Guy:

Where is that quote of the New Yorker's response from?

43. **King Ray**
September 20, 2006

This whole Perelman-Yau thing kind of reminds me of the Einstein-Hilbert episode where Hilbert was going around discussing Einstein's ideas for GR and not attributing them to Einstein; this was right before his 1916 paper came out, if I remember correctly. Einstein had to write him a nasty letter to ask him to stop presenting Einstein's work as his own. Hilbert nearly beat Einstein to his Lagrangian for GR, or maybe he did find it a little before Einstein. There was also something where Einstein was publishing some work similar to what Cartan had done so Cartan wrote him and they ended up being great friends and collaborating on their teleparallel theory. Anyway, that is my recollection from reading about these things 20+ years ago, so I may be a little off.

44. **Molnar**
September 20, 2006

In answer to Peter Shor's question, I had the same impression about 20 years ago when I stopped reading Scientific American. I can't resist generalizing the observation to other periodicals, such as the New York Times, which I also no longer read. Given my advanced state of mental decay, I find it hard to believe my own standards are rising; I'm afraid the mainstream publishing business is going to hell in a handbasket. And speaking of the New Yorker, I still read it, but I think it, too, has declined in recent years (think of what A. J. Liebling would have written about Yau and Perelman).

45. **John Baez**
September 20, 2006

Peter Shor writes:

> *New Scientist* has always been pretty flaky, but whatever happened to the other science magazines on a similar level? There seem to be a lot fewer of them now than there were ten years ago, and they all seem to be increasing their flakiness content. Maybe it's just that I'm increasing my standards, though. Other opinions?

I don't think *New Scientist* was always so flaky. In the 70's it used to be pretty good, except perhaps with a left-wing bias (which some people like more than others).

Scientific American took a big slide downhill a while back. When I complained about it in This Week's Finds, one of the editors asked me to write some articles for them. I never got around to it. I didn't think it was a deliberate trick to prevent me from complaining further, as in "hey! how can you complain about us when *you're one of the writers?*" I even sort of wanted to do it, since Martin Gardner had been one of my heroes. But I just couldn't get up the enthusiasm to spend my expository energies in old-fashioned media where the readers have to pay and the writers don't get much of the money. I don't want a middleman.

And maybe I'm not the only one – maybe all the scientists busy blogging these days would once have been trying to write articles for pop science magazines! Maybe that's part of the reason for the downhill slide?

Or is the main problem the takeover of magazines by media conglomerates, who demand a certain percent of revenue growth per year? I always thought it was that.

Or, maybe, as you suggest, we're getting to be old crochety academics who whine about standards have dropped since the good old days when *we* were young. This reminds me of that *New Yorker* cartoon where two balding gentlemen are slouching in over-stuffed chairs in some faculty lounge, and one says:

"At least we never stooped to popularizing science!"

I don't really know. Whatever happened to *Omni*, and *Discover*, and the much better *Science News*?

Does anyone even care?

46. **CapitalistImperialistPig**
September 20, 2006

Peter,

I have posted a review of NEW on my blog.

47. **CapitalistImperialistPig**
September 20, 2006

John Baez,

While I can't disagree with anything you say, I have to say I'm sorry you never wrote those articles for *Scientific American*. There is something to be said for writing for the intelligent layman. It's certainly true that the magazine has gone downhill, but as a subscriber since approximately the time they started running the "25 years ago" column, I'm not going to give it up now.

48. **jeremy**

""""""""

Interesting. But do we all get jubilant about the achievements of our children, our students and our friends (well, forget about the friends part), no matter how small the achievements may be? Are we all proud of how they thrived in their life, in their work and in their research? Are these the most glorious feelings that any parents and teacher could ever have? Do we all have the urge to go out to tell everybody that we know about their success? And do we sometimes even exaggerate a little? Is that the natural behavior that made what we are as human? There is nothing wrong about it, isn't?

Ultimately, whatever we say about our children and about our students does not mean too much, because their achievement and success will be judged by the society and by their peers. Likewise, Cao-Zhu's contribution will also be judged by the mathematics community and by their peers, no matter what Yau says. And whatever Yau says, as a proud teacher, to praise his students is not wrong.

49. **Murray**
September 20, 2006

I am a Chinese but not a mathematician. I do read Chinese. I read of the 50%-25%-30% news on a Chinese News website a few months ago. The quot was attributed to S.T. Yau as I recalled. It's clearly aimed at bolstering Chinese self-confidence on Yau's part. I personally felt it's a rather silly act. Yau was doing a disservice to the very Chinese people he was trying to help in my opinion. However, I do not doubt Yan's motive. Yau is a Chinese patriot. Cantonese are among the most patriotic people in China.

About 80 years ago or so, the great Chinese writer Lu Xin wrote that the most damaging act to the Chinese people would be for teh Nobel committee to award a Nobel literature prize to a Chinese writer for the sake of being Chinese. I concurred 100%. If you read Chinese News from China today, you can feel the intense yearning from the public and academic circles alike for winning a Nobel prize for the Chinese people. Unbelievable!

50. **gunpowder&noodles**
September 21, 2006

By the way, this quote is interesting:

"Howard M. Georgi '68 wrote in an e-mail that Arkani-Hamed's work on split supersymmetry could be just as important as his research on large extra dimensions"

I have to admit that I suspect a touch of subtle Georgian humor here……..

51. **Chris Oakley**
September 21, 2006

I think that Georgi has got it right here. Arkani-Hamed's work on split supersymmetry *is* just as important as his research on large extra dimensions.

52. **Me**
September 21, 2006

« Hilbert nearly beat Einstein to his Lagrangian for GR, or maybe he did find it a little before Einstein.»

Yes, Hilbert got the action first.

53. **John**
September 21, 2006

I can't help being impressed by Einstein's note to Hilbert which is conciliatory without giving up the point at issue:

"There has been a certain resentment between us, the cause of which I do not want analyze any further. I have fought against the feeling of bitterness associated with it, and with complete success. I again think of you with undiminished kindness and I ask you to attempt the same with me. It is objectively a pity if two guys that have somewhat liberated themselves from this shabby world are not giving pleasure to each other." (from Corry, Renn & Stachel, Science, 1998)

54. **DMS**
September 21, 2006

As someone with no dog in this fight(Yau-Nasar), I must say that the mathematical community does not looking good.

Sure, there are always fights over credit in all areas, as in physics. At least in physics, they come out openly and say it(like Gell-Mann and Feynman), rather than say things behind someone's back(and maybe disown it later, if one accepts the New Yorker version).

And, as Mathlover says, if Perelman's papers were so clear and complete, why did others bother writing much longer papers to "explain" it—simply give Perelman the half million(other half to Hamilton).

55. **Peter Woit**
September 21, 2006

DMS,

Nobody is claiming Perelman's papers were "clear", as for "complete", the question is just whether they contained all the ideas necessary for an expert to work out the details of a proof, without having to do major original work and come up with new ideas themself.

The Clay foundation has specific rules about what one needs to do to claim the million dollars. A refereed paper, in a major journal, not necessarily by the person who came up with the idea of the proof, is part of the requirement. Perelman's preprints definitely didn't qualify. The two contenders for the required paper would be Cao-Zhu and Morgan-Tian. It's up to the Clay panel to decide if those who wrote up the proof did original work of a sort that deserves part of the $1 million. In this case I'd be surprised if they decide to give any of the money to either Cao-Zhu or Morgan-Tian.

56. **Anonymous**
September 21, 2006

Peter, members of the Clay panel have already indicated that they may waive the requirement of refereed papers in Perelman's case, or at least that's what I heard from second-hand but reputable sources at the ICM.

57. **Peter Woit**
September 21, 2006

Thanks Anonymous,

I was under the impression that Clay was refereeing and publishing the Morgan-Tian manuscript precisely so that there would be an unambiguous satisfaction of the refereed paper requirement, and that they were in no hurry to deal with the question of what to do about the million dollars, quite happy to have a couple years to let the dust settle. But, maybe they do want to get this over with…

58. **TheGraduate**
September 21, 2006

Concerning the part of the contraversy which involves corruption in China, I was thinking that it's not really a big deal if an academic allows himself to be listed as associated with more than one university as long as he is fulfilling whatever requirements are being asked of him.

I somewhat think of it like having more than one job. It seems to me that if I have more than one job, I'm not necessarily obligated to tell everybody I'm working for that I have more than one job as long as I'm fulfilling all my contractual obligations …

What is the academic concensus on this sort of behavior?

59. **Peter Woit**
September 21, 2006

TheGraduate,

It's not at all unusual for academics to have affiliations and be collecting checks from more than one institution. Sometimes this is part of a specifically negotiated deal a person has with the universities involved, sometimes it is part of the normal situation of someone visiting one place while being on temporary leave or not having to teach at another. Most universities have various specific regulations about what sorts of other paid work their faculty can take on without needing special permission.

I know nothing at all about the Tian situation that Yau is complaining about, but presumably both Princeton and the people in China know that he is involved with and being paid by another institution and are allowing this. I guess Yau is claiming that Tian's arrangement in China is unusual and "corrupt", but I have no idea what it is, and this just seems to be part of the unusually hostile and bitter relationship between the two of them.

60. **Thomas Love**
September 21, 2006

Now if we can just get Physical Review to stop publishing nonsense.

61. **MathLover**
September 21, 2006

What could be the Nasar-Griffiths relationship mentioned on page 5 of Yau's attorney's letter? Little facts can be found in internet, including following one:

In 1995-96 Nasar was a Direct's Visitor at IAS in Princeton, IAS director at time was Griffiths. There Nasar has done the research and interviews for her book "A Beautiful Mind".

Other connections between people around the New Yorker article can be verified in internet as well:

Shing-Tung Yau, PhD student of S.S. Chern at Berkeley (1971)

Phillip A. Griffiths, secretary of IMU 1999-2006, director of IAS 1991-2003, math faculty of IAS since 2004; a collaborator and good friend of S.S. Chern; holds an honorary degree from Peking University (Beijing, China)

James Carlson, the president of Clay Math Institute, was a PhD student of Griffiths at Princeton (1971)

Gang Tian, graduate student of Peking University, PhD student of Yau at Harvard (1988), faculty member of Princeton

Deane Yang, PhD student of Griffiths Harvard (1983), professor at Polytechnic University in Brooklyn, N.Y.

Prof. Yang was among three readers of New Yorker published letters on September 11 issue. Other two are Prof. Daniel W. Stroock from MIT (quoted in article) and Prof. Solomon Golomb from University of Southern California. Their letters see the link:

http://www.math.poly.edu/~yang/letters.html

Prof. Yang is also one of commentators using own real name at Peter's blog.

62. **TheGraduate**
September 21, 2006

Peter,

Yes, I would not have thought there was very much wrong with that sort of behavior. I guess there could be other complications that I am not qualified to assess: perhaps some rule in Chinese culture or specifically in Chinese academic culture. But to my mind, there is no way to secretly be on the faculty of two universities so it seems like the kind of thing each institution must be satisfied with.

Also, I am in the process of reading your book. It's been a very interesting read so far. Questions soon to follow.

63. **geometer**
September 21, 2006

Peter Woit wrote: "The two contenders for the required paper would be Cao-Zhu and Morgan-Tian".

You forgot Kleiner-Lott, whose writings were also supported by Clay Institute. Incidentally, there three papers are somewhat different. Kleiner-Lott's is a companion to Perelman's first and second paper, i.e. they have to be read together with papers of Perelman. Cao-Zhu covers the same ground and is self-contained; also Cao-Zhu could not understand some of the Perelman's arguments and it seems they have substituted their own arguments. These two papers cover the full geometrization including Poincare Conjecture. Morgan-Tian only give a proof of Poincare's Conjecture (but not the geometrization) in which they follow Perelman's three papers, so a unique feature here is that they cover the 3rd paper, which is a shortcut to the Poincare's conjecture and is not discussed by Kleiner-Lott and Cao-Zhu.

64. **Peter Woit**
September 21, 2006

geometer,

I didn't forget Kleiner-Lott. They certainly have a good argument that they were the first to work out the details of Perelman's arguments, but they did not submit their paper to a journal and it was not refereed, so it doesn't now satisfy the requirements of the Clay prize. They may yet submit it for publication and get it refereed.

65. **MathLover**
September 21, 2006

[Various accusations against Tian deleted]
I hope this post will add some background to the drama. If there is anything mistakenly stated, please correct it. Hope this stays as objective and Peter will not delete it.

66. **woit**
September 21, 2006

MathLover,

Do not even think of trying to carry on the vicious Yau-Tian fight in the comment section of this blog. I want no part of it, I think the whole thing is a complete disgrace and has done huge and continuing damage to mathematics. If you really think you must participate in that ugly mess, do it elsewhere.

67. **werdna**
September 21, 2006

I don't think any of the mathematicians who have contributed one way or another to the solution of the Poincare Conjecture cares about the prize money. Yau himself certainly doesn't seem to care about money, although he could use some of that now for a possible lawsuit…

What mathematicians in general care a lot about is the proper credit given for their original contribution to mathematical research.
For a famous problem like the PC, it is understandable that one might want to be acknowledged properly that he has contributed some part in solving it, even if it is, for example, "only" a lemma that is used in another lemma that is used to prove an important theorem. Just exactly how this credit is shared will be left to the math community, who will undoubtedly go through all the documents carefully and fairly, and this will take some time. Whoever made up the 2-year rule was wise indeed.

68. **TheGraduate**
September 21, 2006

I think pretty much everything that can be said about this Poincare buisness has been said. Information is limited. This is a bit surprising as we live in the information age and a lot of this stuff should theoretically be in the public domain. But I think all reliable information sources and conclusions have been exhausted. (And no random emails from unverified sources are not reliable information sources.)

My other thought is this stuff is blown way out of proportion. As werdna pointed out, this is probably going to get sorted out eventually and accurately. Even if we make the wrong call now, there will probably be some historian in 50 years who will read all the original documentation after everybody is dead and then he or she will sort it out.

69. **TheGraduate**
September 21, 2006

Peter,

In the intro. to your book, you said you moved to France as a kid. Do you speak french? I have often wondered that from your frequent links to french articles.

70. **Peter Woit**
September 21, 2006

The Graduate,

Yes, I speak French fairly fluently, although my standard joke is that, yes, I speak French, but like a 12-year old (which is how old I was when I moved back to the US).

The strange thing about this whole Poincare story is that it isn't really a case where there's any significant disagreement about who did what in solving the problem. Pretty much everybody agrees that:

1. Richard Hamilton (encouraged by Yau) had a program for finding a proof using Ricci flow, made a great deal of progress towards the solution, but got stuck.

2. Perelman came up with new ideas and techniques that overcame the difficulties Hamilton couldn't resolve, writing up a detailed outline of a proof.

3. Several mathematicians worked on filling in the details and checking the proof to make sure that it really worked. Kleiner-Lott did much of this, recently Cao-Zhu and Morgan-Tian produced two independent completely written up versions (both used the work of Kleiner-Lott).

Unlike many cases in science where there are real priority disputes over who did what first, in this case I don't think any of the above is controversial. What has generated controversy is people trying to simplify the above story and/or spin it for various purposes, and/or accuse others of trying to spin it.

71. **geometer**
September 21, 2006

I think what generated controversity is the statements made by Yau in June (or more precisely statements attributed to Yau by Chinese media). For example this one (in Chinese, which I have read via a web-translator)
http://gb.magazine.sina.com/chinanewsweek/20060710/2006-07-16/225714056.shtml
where he supposely said that "Chinese contribution is at least 30%". Yau now says that he made no such statements; well there seems to be no record that he publicly objected to any of the statements back in June/July.

Now it appears that after the ICM Yau has changed his mind (even though the only evidence of this is the statement of his attorney, which is not the same thing as Yau's own statement). So people say "there is no controversity, everything is fine".

I personally think that allegation of unethical behaviour of this magnitude should be investigated while it is still fresh in people's mind. This is because Yau is a public figure and eventually he may run for President of AMS etc, and it'd be helpful to know if the allegations are true.

72. **MathLover**
September 21, 2006

geometer says:

werdna,
……

You wrote: "As for your other point, I believe MathLover has addressed it satisfactorily. Note that the June 4th Chinese news report was quickly rescinded on June 9th."

So I figure you can read Chinese. I truly envy you. Could you kindly translate for me the exact quote where the 1st news report was rescinded?

To geometer:

I can give the link of English news items by Xinhua as follows:

http://news.xinhuanet.com/english/2006-06/03/content_4642313.htm
http://english.people.com.cn/200606/04/eng20060604_270860.html

http://news3.xinhuanet.com/english/2006-06/04/content_4644754.htm
http://english.people.com.cn/200606/05/eng20060605_271113.html

http://news3.xinhuanet.com/english/2006-06/21/content_4724497.htm
http://english.people.com.cn/200606/21/eng20060621_275840.html

The news on June 9th in Chinese:
http://www.gov.cn/jrzg/2006-06/09/content_305248.htm
has no English version from Xinhua. One reason is that I can't find the infamous 105% quote in English neither, hence no need to retreat from. I don't feel comfortable to translate it. Please use a translator program in internet (by yahoo or google). That will give you some idea. (Or believe what werdna said, I can confirm it is true.)

The journalist of the June 4th is called LI Bin. He was born in 1972 but has earned a good credit among his peers in Xinhua news agency. I can't explain what really happened. A post by "Columbia Chemist" may give you a clue. Nevertheless, it was unprofessional on Li's part first and very unfortunate to be spreaded by New Yorker's article, when we believe the letter by Yau's attorney and Nasar just ignored Yau's complain.

73. **Peter Woit**
September 21, 2006

geometer and MathLover,

The debate over the 30% is exactly what I had in mind here when I wrote that the problem is people trying to oversimplify and spin things. What Hamilton contributed to this proof is different than what Perelman contributed and these are both very different than the contributions of Kleiner-Lott-Cao-Zhu-Morgan-Tian. Trying to assign relative numerical values to these things is silly, you're comparing apples and oranges.

The contributions of Kleiner-Lott-Cao-Zhu-Morgan-Tian involve careful exposition and checking of details. This kind of work is considered an important service by the math community, but it is not considered the highest level of mathematics research, which is coming up with new mathematical ideas. What Hamilton and Perelman did was creative mathematics, in both cases they had to come up with something fundamentally new, something that wasn't there when they started. Hamilton came up with and did a lot of foundational work on what turned out to be a successful program, this is something research mathematicians value highly. Perelman also came up with unexpected new ideas and created new mathematics. In addition, he was the one to find the new ideas needed to finally solve the problem.

I think almost all mathematicians value much more highly what Hamilton and Perelman did than the work of Kleiner-Lott-Cao-Zhu-Morgan-Tian. Comparing the two of them though doesn't make sense. Hamilton had the correct vision and worked out a large amount of what was needed. Perelman was able to get around an obstacle that Hamilton couldn't surmount and get to the end. This kind of achievement is traditionally the one that ensures your name goes on a theorem. What to name theorems is also kind of silly, requiring huge oversimplification, but, no one is going to argue that Perelman's name doesn't belong on this theorem.

September 21, 2006

MathLover and geometer,

Again, I got the dates of June 4th and June 9th from the lawyer's letter. Whether the details there are correct, I do not know. It seems to come from a reputable source, and unless new information emerges to prove otherwise, I have no reason to doubt its accuracy for now.

75. **Gina**
September 21, 2006

Wouldnt it be a better use of both time and space to talk about these exciting three dimensional manifolds themselves and how they are now understood and what is perhaps left to understand (if anything) rather than about lawyers and credits and newspapers articles and prizes and slanders and power struggles etc??

76. **geometer**
September 21, 2006

MathLover said: "One reason is that I can't find the infamous 105% quote in English neither, hence no need to retreat from.

Well, "Columbia Chemist" gave a direct link for http://news3.xinhuanet.com/newscenter/2006-06/04/content_4644722.htm
for the 105% quote. It is in Chinese, and here is how google translates it:

"Reporters ask questions mathematician Yang Le. The IMC said that if divided by 100%, then the United States and in more than 50% of the contribution mathematician Hamilton, the Russian mathematician Perelman resolve the principal suspect in the 25% contribution. "Chinese scientists, including Qiu, Zhu Xiping and Cao Huaihu East, 30%. " Yang said that in a century, a major problem worldwide, 30% of the people of China can play a role, it will not be easy, which is a great contribution.

I also translated the link you provided, and here is what I got:

"Yang Le academicians believe that a quantitative description of scientists from various countries in proportion to the contributions made to break the Poincare Conjecture, or more than 300 pages of papers analogy of our scientists as" novel "and" not entirely accurate, I do not agree. However, Chinese scientists have indeed made 'outstanding contribution'. "

September 21, 2006

Gina said:
"Wouldnt it be a better use of both time and space to talk about these exciting three dimensional manifolds themselves.."

Well, the proof of Poincare's Conjecture means precisely that there is no exciting (simply-connected closed) 3-manifolds: all of them are copies of the 3-sphere. It'd be much more exciting if the Poincare Conjecture were false; unfortunately this is not the case.

78. **Gina**
September 21, 2006

Actually, I have a specific question that may be you guys can help me with. I vaguely remembered the wonderful story of this humble mathematician whose nick-name was "Papa" who worked on some things related to manifolds in dimension three and after years of effort managed to prove something really big. Thanks to Google and Wikipedea I found his full name – Christos Dimitriou Papakyriakopoulos and appearently he proved the "Dehn's lemma". I am curious if all this exciting new works also give a new proof to what "Papa" have done or is it still also "on his shoulders"?

79. **Gina**
September 21, 2006

Thanks, geometer,so are you telling me that this three dimensional saga is done and over with and we can go ahead to four dimensions?

80. **geometer**

September 21, 2006

Gina,

I am not a 3d-topologist but as far as I know Ricci flow arguments do not imply Dehn's lemma (as well as many other results of 3d-topology). To date Ricci flow only implies the geometrization (and all its corollaries), and unfortunately there are very few known application beyond that. On the other hand, I suspect that Dehn's lemma is used at the very last step of the Perelman's proof when he gets a collapsed 3-manifold and concludes (using collapsing theory and some topological results) that this must be a graph manifold.

As for whether "the three dimensional saga is done and over with and we can go ahead to four dimensions", well, there is still a lot of work for 3d-topologists, but the whole area has now become somewhat less exiting, and no so central anymore. Which is okay, in fact the area where Perelman was working all his life has never been a central area of math (until recently anyway).

81. **Gina**
September 21, 2006

Dear Geometer,

Many thanks for the interesting information. I do not know what a garph manifold is (never mind that) but I am very happy to hear that the proof of the Poincare conjecture still relies on the work of that dear man "Papa", Christos Dimitriou Papakyriakopoulos. From what I heard he was a very special person.

You said, "It'd be much more exciting if the Poincare Conjecture were false; unfortunately this is not the case. "

I beg to disagree with you on this point. The way I see it, it is exciting that the Poincare conjecture was proven true and it would have been exciting had it was proven false and perhaps, the most exciting thing is that we could not have known in advance. Not what will the answer be and not even if people will be able to crack this problem at all. Probably sometimes it looked going this way and sometimes it looked going the other way and sometimes it looked stucked.

By the way, before going to dimension four, is everything known about manifolds in dimension two?

82. **Peter Orland**
September 21, 2006

To Me:

Hilbert did get the action first, but not the right variational principle. He first found wrong field equations. In so doing, he duplicated an earlier wrong result for the field equations with matter, which Einstein had already published. The wrong result sets the Ricci tensor (not the Einstein tensor) proportional to the energy tensor. Since the Ricci tensor isn't covariantly conserved, these equations aren't consistent with local energy and momentum conservation.

The story I heard is that while Hilbert's paper was in press, he heard that Einstein had found different (and correct) field equations. These were obviously right because they WERE consistent with energy and momentum conservation. Hilbert then changed his paper's proofs before Einstein's article came out. In this way he was the first to publish the right result, though not the first to obtain it.

Of course the vacuum field equations (without matter) were published out by Einstein and his assistants a few
years earlier (1913).

83. **geometer**
September 21, 2006

Gina asked: "is everything known about manifolds in dimension two?"

Their classification is classical (pretzels with many holes and all that), but there are still some mysteries about surfaces, eg the studyng the mapping class group (ie the group of self-homotopy equivalences of a surface) is a very active area of research involving several brunches of mathematics, and there is an enormous literature on the subject.

84. **jeremy**
September 22, 2006

I really hope this Yau-Nasar fight will end soon and will end without being in court. It will be painful to see all the quoted mathematicians in the New Yorker article being dragged to the witness stand and to have them been quoted again, under oath this time. It will be unbearable to see their "beautiful mind" being fried by the lawyers in front of the whole world. It is better to leave this depressing saga behind without further damaging the mathematics community.

85. **Thomas Larsson**
September 22, 2006

The Einstein-Hilbert story (at least Todorov's version of it) can be found in physics/0504179.

86. **Juan R.**
September 22, 2006

Disputes of this class are often frequent on science. Usually one obtain a better perception of the history years after when historians do their work and check for all documentation they can find.

Take the case of Hilbert-Einstein. During decades people asked why Hilbert, if obtained the GR action first, did not claim priority. Well, the reply is that Einstein said not the true to Hilbert then as proven in this recently discovered mails:

(15 November 1915) Einstein to Hilbert:

Highly esteemed Colleague,
Your analysis interests me tremendously, especially since I often racked my brains to construct a bridge between gravitation and electromagnetics. The hints your give in your postcards awaken the greatest of expectations. Nevertheless, I must refrain from travelling to Göttingen for the moment and rather must wait patiently until I can study your system from the printed article; for I am tired out and plagued with stomach pains besides. If possible, please send me a correction proof of your study to mitigate my impatience.
With best regards and cordial thanks, also to Mrs. Hilbert, yours.

Popular physisicist's claim that Einstein was pionner in the search of an unified field theory is plain wrong. Hilbert was already working in unification!

Hilbert send a copy to Einstein of his paper on general relativity presented on November 16 at the Göttingen Mathematical Society. Hilbert's paper was submitted to print on Nov 20. Einstein replied:

[…] The system you furnish agrees – as far as I can see – exactly with what I found in the last few weeks and have presented to the Academy […]

BUT Einstein's reply was not accurate! Einstein did not obtain the correct equations of gravitation weeks ago like he claims in above correspondence, because Einstein presented a paper to Academia the day 4 (Nov 1915) containing the incorrect equations, and the day 11 submitted another paper containing again the incorrect field equations.

During years, Einstein agonized without obtaining a relativistic gravity. Only after of reading correct equations on Hilbert paper (presented the day 16, a copy sent to Einstein the day 18, and published the day 20), Einstein corrected his wrong equations and submitted the famous paper of day 25 containing the correct field equations. Moreover, as correctly noted by I. Todorov in above cited preprint, Einstein proposed *without any derivation or rationale* the correct equations of general relativity in his final paper of day 25. What is more, Einstein just 'forgot' cite or even acknowledge Hilbert crucial assistance.

Each one can obtain her/his own conclusions.

About the Science article cited above. It has been critized to be inaccurate and even sensationalist. It claims that the recently discovered gallery proof did not contain Hilbert action but the article failed to explain that proof was mutilated. That is, the paper did not contain the Hilbert equations because someone cut a third of the piece with the equations here!

Therefore together above petitions for NS and PR, i add Science journal also!

CapitalImperialistPig writes:

> John Baez,
>
> While I can't disagree with anything you say, I have to say I'm sorry you never wrote those articles for Scientific American. There is something to be said for writing for the intelligent layman.

There definitely is, and I want to do a bunch of that sometime. But, I probably want to do it in some way that's either free for the reader (like on my website), or will make me some serious money (like a sensationalistic, overhyped best-selling book).

Right now I'm having fun writing expository stuff for people who already know a bit of math and physics. There's a kind of market niche here that I seem to fill: math and physics have gotten so complicated that even most mathematicians and physicists can use a lot of help understanding it.

94. **TheGraduate**
September 22, 2006

MathLover,

Thanks. Quite interesting article. It reminds me of the worries about losing manufacturing jobs to China that is prevalent on the American side of the ocean. In this case, you have people in China worrying about academics that collect salaries while spending most of their time in America and then you have companies like Walmart that produce massive quantities of product in China but still want to be seen as American companies.

Globalization is good. Nationalism is so 19th century. I say we leave it to the universities to figure out whether they are wasting their money or not. My guess is they aren't.

95. **Peter Orland**
September 22, 2006

Juan R.

Your version of the Einstein-Hilbert question is very different from news reports that come out a while back. Be that as it may, General Relativity was invented by Einstein and collaborators, not Hilbert, in 1913, when they published the vacuum field equations. The issue of whether Einstein or Hilbert has priority concerns only the modification of these field equations with energy. The most revolutionary physical and mathematical ideas were in the 1913 work. One could argue that the field equations in the presence of energy was then going to be found by someone eventually.

96. **Juan R.**
September 23, 2006

Peter Orland, in short

Einstein recognized in several writtings that his 1913 work (so called Einstein–Grossmann theory) was wrong.

Einstein published many contradictory theories in subsequent years, in early 1914 returned to a scalar theory but in the last part of 1914 returned again to the metric theory of 1913 with modifications.

Hilbert presented objections to Einstein theory (1914 version) and since 1912 he was working in a unified field theory.

Einstein learned from Hilbert and contacted with him waiting his review of Einstein new works. Einstein published a series of subsequent papers with different theories (rejecting his previous ones and embracing Hilbert's criticism to previous versions) until the final work of 25 Nov 1915 containing the right version of GR. **But** Hilbert had did first!

General relativity is an outcome of the work of many people including crucial contributions from mathematicians as Poincare or Grossman. The GR action and the correct field equations and basic principles such as that of general covariance (initially rejected by Einstein) were pionerized by Hilbert.

I wait many distorsions of the history of relativity in physicists' textbooks can be eliminated in a future thanks to more accurate historical presentations. My posting here is my small tribute to Hilbert, Poincare, and others mathematicians.

Juan R.

Center for CANONICAL |SCIENCE)

97. **Peter Orland**
September 23, 2006

Juan,

I am not sure I should reply and keep this discussion going, but the idea of introducing a curved metric into gravity and the vacuum field equations is not due to Hilbert. Hermann Weyl, Hilbert's Goettingen colleague, in his book "Space-Time-Matter" did not give Hilbert credit for the idea of general relativity in 1913. If you have a copy, take a look. Weyl certainly does give credit to Hilbert for the action principle, which Hilbert deserves.

The only debate is who first got the details of the equations with matter in 1915. I think you are wrong on this too, but even if you were right, the 1915 result is much less significant than the 1913 vacuum field equations. Eventually someone would have got this right, whether Einstein, Hilbert or somebody else. Hilbert did not invent the principle of equivalence. Hilbert did not introduce the metric and curvature into gravity. Hilbert was not the first to realize the importance of the stress tensor. Hilbert did not find (exact or approximate) solutions of the vacuum field equations, or find their experimental consequences.

Like many ideas, general relativity is the work of many people, but
Einstein's work was primary, even if he made mistakes and changed his mind from time to time. After nine decades, some mathematicians still can't stand the fact that Einstein's contributions to relativity and gravity soar above their own. Why? I don't claim Einstein invented Riemannian geometry.

98. **Juan R.**
September 23, 2006

Peter,

From my part i do not desire to continue this discussion with you, since you continue putting in my fingers stuff i never wrote (this is the second time you are doing this).

I never said that Hilbert introduced the metric theory the first time and i already remarked the contributions of people as Grossman (precisely regarding some incorrect thoughts of Einstein regarding the nature of the metric tensor). Of course Einstein was not piooner here!

I never said that Hilbert were the only father of general relativity just remarked the field equations dispute therefore I fail to appreciate your criticism.

Hermann Weyl, was not a historian (was him?) and his 'personal' opinions about facts is a secundary source when compared with direct historical analysis of papers published by all people currently in the historians target.

It is not true that the only debate was "who first got the details of the equations with matter in 1915." The whole point is a little more complex than you try to present here.

"Hilbert did not find (exact or approximate) solutions of the vacuum field equations, or find their experimental consequences."

I would recommend you updating your sources since in last few years a number of very interestings works analize with care the history of relativity. You could begin with some of those:

Jürgen Renn and John Stachel, Hilbert's Foundation of Physics: From a Theory of Everything to a Constituent of General Relativity.

arXiv:physics/0504179v1

Friedwart Winterberg. Zeitschrift für Naturforschung (2004) 59a, 715-719.

Daniela Wuensch, "zwei wirkliche Kerle", Neues zur Entdeckung der Gravitationsgleichungen der Allgemeinen Relativitätstheorie durch Einstein und Hilbert. Termessos, 2005, ISBN 3-938016-04-3

http://arxiv.org/abs/physics/0405075

"After nine decades, some mathematicians still can't stand the fact that Einstein's contributions to relativity and gravity soar above their own. Why? I don't claim Einstein invented Riemannian geometry."

Now i can see you clearly…

Juan R.

Peter and Juan,
This Hilbert/Einstein argument is completely off-topic and not going anywhere. I'll delete any more attempts to continue this argument here.

100. **Mathematical Truth in Chinese**
September 23, 2006

On September 23, 2006

Here are some facts found in the Chinese world on the Yau case. Many puzzles in this case can be answered from these simple facts.

[Long comment including attacks on Morgan and Tian deleted]

101. **Curious Bystander**
September 23, 2006

1. Here is a quote from Cooper's (Yau's lawyer) letter:
"Professor Manin made clear that the mathematical community felt that work remained to be done to complete Givental's arguments"

2. And here is a post in the New Yorker forum:

"Although it may be uncertain what is the consensus, and remain unknown if Manin indeed suspected a flaw in Givental's arguments, it seems quite clear however why Yau's defenders refrain from quoting Manin's statement in full. It turns out that when the passage is read in its entirety, the conclusion that "some work remains to be done in order to complete his arguments" applies to the paper of Yau et al as well.
Here it is:
"Givental [Giv2] achieved a remarkable progress in proving the Mirror Conjecture for complete intersections in toric varieties where the precise construction of mirrors is due to Batyrev ([Ba1], [BaBo2]). He enriched Kontsevich's approach by passing to the equivarinat quantum cohomology. Some work remains to be done in order to complete his arguments."
As one can see, Manin is talking here about the Mirror Conjecture for complete intersections in toric varieties as formulated by Batyrev and his coauthors. As it is well-known to specialists this conjecture, strictly speaking, still remains open. The paper [Giv2] deals with complete intersection in projective spaces, i.e. simplest examples of toric varieties. In this case, the Mirror Conjecture cannot be attributed to Batyrev as it was known before his work (and this fact, no doubt, is known to Manin, as well as Yau). Thus, when taken literally, Manin's statement views [Giv2] as a "remarkable progress" toward a proof of the general Mirror Conjecture, but contrary to the claim of Cooper's letter, it does not indicate that [Giv2] per se is incomplete. "

I'm shutting off comments on this posting. Too many people are trying to use it as a Tian-Yau battlefield. I think this behavior is disgraceful and I want no part of it.

The Goldilocks Enigma

September 22, 2006
Categories: Book Reviews

Paul Davies is an author of many popular science books, often dealing with topics in cosmology and particle physics. He has been based in Australia for the last sixteen years, but is now moving to the US, taking up a new position at Arizona State University, where he will establish a new center he describes as a “cosmic think tank”.

He also has a new book coming out, entitled The Goldilocks Enigma: Why is the Universe Just Right For Life?, and a major concern of this one is the multiverse and anthropic reasoning. I was asked to write a review of the book for the British Magazine New Humanist, and the review has appeared in their September/October issue. One reason I agreed to do the review (besides the fee in the upper two figures) was that I thought I might write about the book here anyway. Here’s the text of the review. It’s somewhat different than my other postings here, since it’s written for a much wider audience and constrained by space limitations to be rather short. As a result, it unfortunately doesn’t go as deeply as I would have liked into discussing some of the issues raised in the book.

Review for New Humanist

Paul Davies’ new book The Goldilocks Enigma wrestles with some of the deepest philosophical issues around, but concentrates on one in particular: “why is the world the way it is?” He approaches this question through a discussion of a hot topic in theoretical physics that most scientists refer to as the “Anthropic Principle”, but which Davies chooses to label the “Goldilocks Enigma”. This refers to the fact that the physical laws that govern the universe are “just right” for the development of life. Relatively small changes in certain parameters would make it uninhabitable by the likes of us and we wouldn’t be here.

What should one make of this? Religion has a quick explanation, that God set things up so that we can exist. “Intelligent Design” is the currently popular name for explanations of physics or biology that invoke a higher intelligence that chose to make the world the way it is. This explanation suffers from the lack of any way to ever test it.

Davies spends much of the first half of the book providing an introduction to the modern scientific view of physical laws and cosmology, working up to the latest and trendiest of these. For more than twenty years now, theoretical physics has been dominated by a very speculative idea known as “string theory”. Very roughly, this involves replacing elementary particles with objects more like loops, and it crucially requires six extra dimensions beyond the three space and one time dimension we’re familiar with.

One must do something like wrap up the six dimensions to make them unobservably small, but then the properties of particles and thus our physical laws depend on how this is done. Initially there was much optimism that there would be only a small number of consistent choices for how to handle the six dimensions, and one of these choices would agree with what we observe. Recent results in string theory appear to show that this isn’t the case; instead an unimaginably large number of possibilities exist. Indications are that if one can get our observed universe this way, one can also get just about any variation of it, and legitimate scientific predictions are not possible.

Instead of abandoning string theory as a hopeless cause since it can’t predict anything, some string theorists have chosen to promote the idea that our universe is just part of a “multiverse” of all the nearly infinite possibilities allowed by string theory. One of the few thingsone can then predict is that we must be in a part of the multiverse that is “just right” to allow our existence. Debate rages amongst physicists over whether or not this idea is really testable and thus scientific.

Davies provides a careful description of this currently popular multiverse scenario and its explanation for why things are the way they are, including some mind-boggling implications involving infinite numbers of copies of ourselves, and the possiblity that the universe is a simulation. He contrasts it with the common belief among many physicists that there is a simple unique mathematical structure underlying the physical laws that describe the universe. The problem he sees with this belief is that there’s no reason to expect that such a mathematical structure should pick out exactly the parameters that are “just right” for life. But then again, does it really make sense to have any expectations about this? It’s not clear that a sufficient answer to the question “Why is the universe just right for life?” isn’t simply: because otherwise we wouldn’t be asking the question.

The last chapter of the book moves away from conventional points of view among physicists to some much more speculative answers to the “why is the world the way it is?” question that Davies finds appealing. These involve some version of the idea that life itself is in some way or other built into the laws of the universe, that they inherently lead to the evolution of life. He looks to information theory and quantum mechanics for hints of how this might come about. Like the multiverse, this kind of speculation tends to suffer from a lack of any known way to test it. The hallmark ofthe scientific method is the insistence that theories have the property that one can confront them with experiment in a way that allows one to decide whether they work or not. One’s answer to the “why is the world the way it is?” question should be a theory of this kind.

Davies concludes with the admission that, in the end, he finds all the different answers he has examined to be wanting. He notes that we’re the evolutionary products of the pressures of a specific environment, and only recently beginning to be liberated from these. Our minds may still be far too crude and our knowledge of the universe too fragmentary to allow us to perceive the correct answers to these existential questions. In the meantime, Davies has provided an engaging and very readable account of the range of answers we have come up with so far.

Comments

1. **alex**
   September 22, 2006

   When you write:

   ‘It’s not clear that a sufficient answer to the question “Why is the universe just right for life?” isn’t simply: because otherwise we wouldn’t be asking the question.’

   Is that you stating your opinion, as opposed to you quoting Davies? I read it that way, but it’s anthropic reasoning…

2. **Peter Woit**
   September 22, 2006

   Alex,

   That’s my opinion, and I guess it’s anthropic reasoning, but the question in my mind is whether anthropic reasoning here is anything but tautology. Is it sensible to ask “why X?” when “not X” implies that you can’t even formulate the question.?

   My problem with anthropic reasoning isn’t that it is never a legitimate form of logical argument, the problem is that it may not be science, since you can’t use it to make falsifiable predictions.

3. **urs**
   September 22, 2006

   > a simple unique mathematical structure underlying the physical laws that describe the universe.

We can have such a simple unique mathematical structure underlying the *laws* of the universe, and still have many possible solutions obeying these laws.

And this is how it has been for all our existing theories – always. Anything else would be rather shocking.

Alain Connes proposes a unique mathemtical structure behind the laws of the observable universe (the spectral action principle [#](#)). And yet, our world is described by just one out of infinitely many possible solutions (here: spectral triples) of this principle.

4. **Cristina**
September 22, 2006

Hello, I wandered here from John Baez's blog 🙂

I agree with your comment above, because the anthropic principle has always struck me as a vicious circle.

So the physical laws are good for the development of life as we know it — good. But it's a mistaking of cause and effect, because the Universe could be entirely different, composed of other basic building blocks, obeying entirely different physical laws, and still contain life, albeit absolutely different from what we call "life". (And those beings would probably have an anthropic principle of their own! :D)

The Universe is not here to allow us to exist — it is we who are here because the Universe in which we live is the kind of Universe which enables life similar to us to exist.

It all depends on how one defines life, really.
It's like wondering how come that it was exactly my parents who got to be together and, as a result, how come that it was exactly me who was born 🙂

Cheers,
Cristina.

5. **Vicky**
September 22, 2006

Nice review. It makes me want to read the book. (I hope that was consistent with your intention.)

I was unclear, however, about your concern regarding the notion of building the life into the fundamental laws of the universe. I can see why this might be directly untestable, but isn't it possible that such a dependence could eventually be logically derived from other, testable propositions? Surely valid science can permit untestable conjectures that are inevitable consequences of testable ones.

I ask because it sounds, from your brief description, like a line of thought that may be worth pursuing, and it beats some of the alternatives. I will have to read the book to see if his musings are pure conjecture or if they may have some merit.

6. **alex**
September 22, 2006

Thanks Peter,

If I may give my answer to the question in your reply…

In general whether or not "why X?" is a sensible or fruitful question is unrelated to any implications that "not X" may have for ones existence. For instance, I can learn something from asking why I survived the accident that might have killed me a few years ago. But I probably won't learn much if I am content with the answer that if I hadn't I wouldn't be asking the question. The question may or may not have a useful answer, but that's a different issue.

"Why is the universe just right for life?" and its big brother "Why is there anything at all?" may or may not have answers within human reach, but "Otherwise we wouldn't be asking" isn't an answer. It probably isn't even much of an indication as to whether they are likely to turn out to be fruitful questions.

7. **Tim**
September 22, 2006

May I make a brief comment on your claim "Religion has a quick explanation, that God set things up so that we can exist… This explanation suffers from the lack of any way to ever test it."

This suggests an unreasonably limited epistemology. A claim of Christianity, for example, is that God has intervened in history, supremely as a person (Christ), and communicated with people on topics including why we exist. Whether God has indeed intervened in world history can be subjected to tests in a similar way to a claim such as "Emperor Hadrian intervened in British history." For example, we can examine the quality of witness accounts and other documents, and we can look at the results of alleged interventions. Additionally, in the case of Christianity, one can ask whether the revelations amount to an unreasonably profound understanding of the human condition and whether prophesies have been fulfilled. If one concludes God has indeed intervened and spoken to us, one can seek an answer to whether He set things up so that we can exist, within what he has said.

Granted, this is not straight-forward! But I simply want to make the point that there are other reasonable routes to knowledge than the scientific method and those routes may be pertinent to the question you are addressing.

The anthropic principle is an emotive subject because it relates to the presence of a greater purpose. Perhaps one more example (due to John Lennox) might help in this context. Imagine Aunt Joan bakes a cake. Chemical analysis can determine the ingredients. You can write papers on the material properties of sponge and icing sugar. But whatever tests you perform on the cake, you will not discover why Aunt Joan baked it until she tells you it was to celebrate her grandson's birthday.

8. **Who**
September 22, 2006

http://www.amazon.co.uk/Goldilocks-Enigma-Universe-Just-Right/dp/0713998830

this says that the amazon.co sales rank of Goldilocks Enigma is currently 745 in the UK (among all books)

this is a pretty high standing. people in the UK are pre-ordering the book which is supposed to be available 28 September.

the amazon price is about 13 pounds

amazon.co.uk have paired it with Dawkins "the God Delusion" to make the usual two-for-less package deal.

9. **A Babe in the Universe**
September 22, 2006

Paul Davies CB (Order of the Bath) will be a huge addition to ASU and the USA too. He believes that the fundamental parameters are the result of a deeper principle. He has also written in Nature about the changing speed of light!

10. **John Baez**
September 22, 2006

I wonder if Davies raises the question: to what extent is the universe really "just right" for life?

If we saw life teeming throughout the universe, on every planet, asteroid and comet, then I'd say the universe was "just right" for life. In fact we've only seen it on one planet.

Maybe in fact the universe is not "just right" for life. Maybe life is not so tender and delicate as we think, either. Maybe life arises whenever conditions permit a sufficiently complex set of reactions. Maybe the Earth is the only place in the universe where this happened, maybe not.

It seems way, way premature to start wondering about *why* the universe is "just right" for life, before we know whether it *is*.

11. **TruthSeeker**
September 22, 2006

What a beautiful, well-written message, Tim. You have a way of explaining abstract concepts to the general public that even children can understand.

Sometimes we scientists do have a tendency to overanalyze everything. But perhaps – just perhaps – there is a simple explanation of why we are here, and of other related questions?

They say that it is incompatible to be a good scientist and believe in a Creator at the same time. But I don't see why it needs to be the case. The scientific method has been proven to be an appropriate tool to study the natural world. But perhaps it is the wrong tool to use to test anything in the supernatural world, where supreme beings reside? It would be like using a ruler to measure temperature, for example. Just because something cannot be tested by science does not mean it does not exist.

12. **John**
September 22, 2006

The scientific method can't hope to answer every question in fact one can't show, via the scientific method, that any question pertaining to the to the universe can be answered via the scientific method.

In simpler terms, one cannot use the scientific method to prove the validity of the scientific method, as a tool to answer questions about the universe. Hence, the answer to some questions about the universe may reside outside the scientific method.

13. **dave tweed**
September 22, 2006

@Tim: I think you're missing the point whe you say "The anthropic principle is an emotive subject because it relates to the presence of a greater purpose." The anthropic principle is emotive because it's not remotely clear whether it contains such a big vaguely defined concept (that we know what properties life has and what lower-level physics leads to/is incapable of leading to them) that any current _application_ of it seems to many to be untenable.

To give a completely impractical thought experiment: if we could somehow run simulations of a suitably huge sampling of all possible "rules for existance substrates" for suitably long "simulated times" AND we had artificial intelligences that were able to hunt through for any sign of "life" even if it didn't have the form we're used to AND they found no sign of anything like life, THEN I'd be more comfortable with the anthropic principle. (Note the point of the simulations isn't to test possible physics but to see if we can generate something that we'd class as life that doesn't have the characteristics of all the life we've seen so far.) If you'd firmly established this level of understanding that is presupposed by the anthropic principle, I wouldn't have any problems accepting as legitimate questions about whether this leads to "greater purpose" or "supreme beings".

The discomfort with the anthropic principle for many people is the jump from "I can't imagine any life which doesn't have this property" to "it is not possible for there to be life which doesn't have this property" in order to "get answers to question x" rather than accept "we can't get the true answer to the question x yet".

14. **Tim**
September 22, 2006

TruthSeeker – thank you for your comment.

dave tweed – I think the anthropic principle is found to be emotive by different people for different reasons.

15. **George**
September 22, 2006

RE: The Goldilocks Enigma.

I think the right question is really – Why is life just right for the universe?

16. **Gumbi**
September 22, 2006

Seems to me that the anthropic principle is not there so much to offer an explanation, as to suggest that no explanation is needed.

We don't wonder too much why earth is suitable for life, because we see that there are at least a few and probably very many other planets out there that are suitable to life to varying degrees.

But if there were only one planet in the universe, and it were earth, then the question of why this one planet was suitable for life would demand an explanation.

The anthropic principle, combined with multiverse concepts, suggests that some mysteries are not mysterious at all, and don't need explanations, just like the case of earth being so suitable for life.

17. **TheGraduate**
September 22, 2006

I think in general the anthropic principle is somewhat redundant and political. We all know that we may fail to find an answer to any question we seek to find an answer to. In that sense, the anthropic principle is redundant. Because it is so redundant, the only reason to bring it up is to convince people not to try and in that sense it seems political.

I consider the anthropic principle something like the 'god did it' principle. As long as this kind of idea is not part of making concrete progress, it seems a waste of time to focus on it.

18. **Chris W.**
September 23, 2006

TheGraduate,

Right. More specifically, it seems to me that the underlying premises of Christianity in treating these questions have been (1) apologetics – convincing unbelievers and doubters that God really exists, and (2) that rational investigation of nature without presupposing God's existence is tantamount to sin, and is the sort of thing that got us kicked out of Paradise. Therefore we have no business doing it. The existence of the world and ourselves as part of it ceases to be a mystery. Instead, it becomes a moral drama.

Returning to the subject of whether the existence of life tells us anything about the structure of physical law, the key point which always seems to be ignored is the role of physical law in accounting for any kind of *stability* in physical systems, and also the limits of that stability. Clearly, living things need some degree of stability or reproducibility in their environment and in their own constitution, combined with an allowance for change, the latter requiring some degree of *instability*. Some sort of balance needs to be struck, and the laws of physics are central to how it is struck and whether such a balance is possible. Of course there is something deeply reflexive about this, because the laws of physics are, by assumption, stable themselves. This begs the question, how do we account for the stability and universality of the laws?

There has never been an absolute answer to this question. When putative laws have been discovered to be limited in scope, ie, to fail under some circumstances, we have sought to understand this failure and *their prior success* in terms of a deeper and more all-encompassing law. The central question about a failed law is always "why and how did it ever work?" The relevance of relative velocities and the speed of light only became fully apparent with the advent of special relativity. Without it, the problems of reconciling Newtonian mechanics and Maxwell's electrodynamics and various observational anomalies could only be puzzled over.

I think we're at a point in the history of physics where the question of why nature has any law-like structure at all must be squarely confronted if we are to understand why it has the *particular* law-like structure that it does. In this connection, I should note that John Stachel has argued that Einstein's well-known objections to the indeterminacy of quantum mechanics were not due to its indeterminacy as such, but rather to the fact that the *degree* and form of the indeterminacy was unexplained. If we're going to admit some indeterminacy, then why not go all the way? Again, the subtle balance between indetermininism and determinism is the core issue, and calls for an explanation. Life seems to require it, almost by definition, but this fact throws little light on the fundamental basis of the balance.

19. **Arun**
September 23, 2006

The questions which currently interest us may not be answerable by application of the scientific method at this time. Progress in science as it is at a particular time depends on asking the right questions. If science is seen to be turning into philosophy, it is perhaps because we are not asking the right questions. Perhaps it is because the right questions at this time are relatively tame and boring compared to having theories of everything, and HEP theorists are no longer psychologically suited to tame and boring.

20. **TheGraduate**
September 23, 2006

Chris W. ,

Great comments. I think that to tackle the anthropic principle scientifically is at the moment a very lightweight approach and one really needs to read some of the analyses put forward by the philosophers to get to ideas with any kind of heft.

In defense of some christian philosophers, I think the motivations for their investigations are as you describe. However, I would not say that all their arguments fall into the categories you outlined.

One thing that Christians sometimes argue is that their way of looking at things is a complete theory of everything in that it attempts to describe all phenomena both physical and mental. In the sense that science has nothing to say on the question of 'what is a good life?' which is of incalculable importance to most human beings, Christians view the scientific enterprise as a quest toward a partial theory of everything where 'everything' for them includes intellectual, sensory, moral, emotional and physical phenomena in both the objective and subjective perspectives.

In a way, the scientific conclusion of the 'consistency' of physical systems is quite conditional in that one may take certain drugs; one may have dreams; one may have what is defined as a 'mental illness'; one may simply experience a state of mind that one tends to retroactively define as 'confused'; and during these times the rule of 'consistency' is thrown out the window.

To even approach the scientific method, one must lay down much conceptual frame work. For instance, one has to hypothesize that human beings have a certain frame of mind in which it is possible to do science and that the 'reality' of other frames of mind are invalid.

21. **John**
September 23, 2006

The question itself raises some problems; we are assuming that "natural processes", as we know them, held before or at the "creation" of the universe. In addition, physics can only describe the behavior of preexisting processes and material, but not "creation" where creation means something out of nothing. This goes deeper than the appearance of particles out of the quantum void, for you need laws to govern that void before anything can come from it, hence something exists.

Modern science always presupposes the existence of an underlying law governing the behavior of material objects. The problem is what happens when we ask about the origin of those very laws? We are in a quandary, we presuppose an underlying law, but wait the origin of the universe is the origin of all physical laws, so what kind of underlying law can govern the "creation" of the universe? We can't say its a physical law for ontologically speaking it must come before the physical laws, hence its a "meta-physical" law. Even if we did find an explanation via physical laws, we can always ask why those laws came about as they did and so on to infinity.

This is what I mean when I say the scientific method cannot validate itself; it always needs a preexisting underlying structure.

22. **Neznaika**

September 23, 2006

Peter,
Thank you for the interesting review. My question is about your earlier comment that one cannot use anthropic principle to make falsifiable predictions.
How about "Principle of Mediocrity"? I found a very interesting recent article on the subject by A. Vilenkin on Edge.com
(http://www.edge.org/3rd_culture/vilenkin06/vilenkin06_index.html). In that article and apparently in his new book, Many Worlds in One –
(http://www.amazon.com/gp/product/0809095238/qid=1151507616/sr=1-1/ref=sr_1_1/104-5849948-3641559?s=books&v=glance&n=283155),
Vilenkin argues that one can make testable STATISTICAL predictions using the Principle of Mediocrity. He also claims that his (and Weinberg's) prediction for the cosmological constant has already been confirmed.
What do you think about those arguments? Is that Science in your view?

23. **Neznaika**
September 23, 2006

Correction to my post:
Vilenkin's article has been published on Edge.org, not on Edge.com. Sorry about that.

24. **Who**
September 23, 2006

Amazon.co.uk has The Goldilocks Enigma in stock and is shipping.
http://www.amazon.co.uk/Goldilocks-Enigma-Universe-Just-Right/dp/0713998830

they guarantee delivery by 1 PM Tuesday 26 September, if ordered now, so I guess they mean business.

Goldilocks has UK salesrank #716 at the moment, which is very high for a physics book. For comparison, Not Even Wrong had UK amazon salesrank #1318 last time I looked.
And Hawking Brief History of Time (paperback) had rank around #4700.
so Davies book having UK salesrank 716 is really quite good

25. **Chris W.**
September 23, 2006

Neznaika,

The strength of Weinberg's argument has been questioned a number of times. See hep-th/0407174 for a recent example. It has also been questioned whether the argument is truly "anthropic", ie, whether the existence of life plays anything more than an incidental role in the argument.

TheGraduate: *To even approach the scientific method, one must lay down much conceptual frame work. For instance, one has to hypothesize that human beings have a certain frame of mind in which it is possible to do science and that the 'reality' of other frames of mind are invalid.*

This statement strikes me as quite unfounded. As my comment should have indicated, science can be seen as a natural outgrowth of grappling *consciously* with a problem that faces all living things. We must find and learn to rely upon some stability in the world for the sake of simple survival, if nothing else. The growth of science was galvinized by the gradual and surprising discovery that a certain kind of stability—stability of certain deep patterns of change—could be found in the world, and could be precisely and testably described, well beyond what seems practically necessary.

26. **TheGraduate**
September 24, 2006

Chris W.,

I am not quite sure what you mean. Could you elaborate? I understand that by stability you mean being able to replicate the results of experiments. But I think there is definitely a difference between the sort of investigative method that leads to science and the sort of reasoning people employ when they conclude things like: the sun will rise tomorrow, God is always on the side of the righteous and that poor people always steal. Nevertheless, on a subjective level, I think there is a sense for the people that believe these things that these are stable, replicable rules.

27. **John Bussoletti**
September 24, 2006

I've always wondered why those who espouse Intelligent Design seem to get so involved with questions of natural selection and the ideas of Darwin, when there really are some very basic aspects of nucleosynthesis that have even given me pause on occasion. Not that I'm espousing anthropic or Intelligent Design principles, but consider the following:

There is evidence that the chemical elements that make up our universe are created through nucleosynthesis processes in stars. "Hydrogen burning" creates helium. "Helium burning" critically depends on a "triple alpha" process, which is predicated on the existence of a 7.65 Mev excited state of Carbon to allow the production of Carbon. And from Carbon, production of all other elements follows

So there is in the nucleus of Carbon an excited state with zero net angular momentum at an energy level of 7.65 MeV, which is juist above the dissolution state of the nuclues into Berillium 8 (itself unstable to decay into two Helium nuclei) and an alpha particle. This excited state has an electromagnetic decay branch which emits a photon and decays to the 2+ excited state of the Carbon 12 nucleus, which is a bound state and itself decays by photo emission to the ground state.

Were the energy of this state of the nuclear system somewhat higher, the probability for a triple alpha interaction within solar interiors would drop precipitously, greatly reducing (eliminating?) the production of Carbon in our universe. Were it lower in energy, there might be no path for creation of Carbon. And without carbon, most other nuclei don't get produced.

The fundamental electromagnetic, strong and weak nuclear forces, and the values of the various undetermined constants in our various theories of particles and the universe as we know it, are just so, to allow the existence of this excited state, allowing synthesis of Carbon. Without the interplay of the various strong, weak and electromagnetic forces, there would be no carbon, let alone carbon-based life anywhere in this universe.

So, the Intelligent Design contingent, rather than worry about Darwinism, really ought to call greater attention to the very existence of Carbon.

Now, as much as the scientific method would like to argue against such an anthropic point of view, there is another fundamental problem, which was first explained to me by Jeremiah Ostriker in an Astrophysics course I took many years ago. In the early days of the course he explained the Copernican point of view by saying there are two fundamental assumptions that we make in Astrophysics: "First, we do not live an any special place in the universe. Secondly, we do not live at a special time."

With these two assumptions, we can make observations of that universe, build theories based on those observations, and have some confidence that those theories reflect some elements of truth.

The trouble with this is that these two assumptions are basically unprovable. That is, we're not able to subject them to the experimental test that the scientific method would dictate must be done. So as much as we might like to subject the universe to test, we're limited in time, space and even energy to explore only the very lowest excitations of the system. Our theories are nothing more than models that reflect those observations.

Robert Pirsig in "Zen and the Art Of Motorcycle Maintenance" quoted Bertrand Russell's description of science as "If bread is a stone and stones are nourishing, then I can eat bread and be nourished. So I do the experiment, I eat some bread and find that, indeed I am nourished, thus proving my theory that bread is a stone."

This is an extreme caricature of the scientific method, but unfortunately, it's also pretty accurate.

No matter what "fundamental" theory that one might propose, even should it explain "everything", the reality is that all we know how to do is construct models of the low level excitations of whatever it is that is in our universe at the particular time that we occupy it and in the particular place where we observe.

Landau had it right. All we can ever observe are effective interactions and so we're free to model them in whatever way is consistent with our observations.

But we can never prove correctness. We can only achieve utility.

That is, if our model is "good", it will allow us to build or control something. Basically, allow us to be engineers. But "Truth" and "Proof" elude us always.

So, the anthropic point of view directly opposes the Copernican assumptions. Both are unprovable points of view and both are largely irrelevant with respect to "utility". That's why Peter and others like him (I include myself among them) are so adamant that one must make predictions, testable ones, with whatever theory one creates. Without some ability of a model to make predictions, it has no "utility" and is, in the end empty. As much as science would like to establish proof, the reality is that the scientific method is largely a consistency argument, and in the end, is not provable.

But it can be very, very useful (sic).

28. **Adrian Heathcote**
September 26, 2006

"It seems way, way premature to start wondering about why the universe is "just right" for life, before we know whether it is."

Just a comment about John Baez's post.

I agree with this wholeheartedly. This is the point that no one seems to make in discussions of the Anthropic Principal. The most obvious thing about the Universe that we observe is that we seem to be alone in it. This may not be the case, of course. But that is the current evidence. People who talk about the fittingness of the universe to life must confront the difficult truth that it doesn't seem to be.

29. **Adrian Heathcote**
September 26, 2006

I think most people can see that the Anthropic Principle is a fallacy, the only real disagreement is what kind of fallacy it is. So let me add my 2 cents on this question. I think it is an example of what logicians call a "modal fallacy"—of which there are many examples in ordinary thinking. It is confusing a fact about the universe—that intelligent life exists—with a modal claim—that the universe *must* be such as to sustain life. But this is a case of inserting the necessity operator ("must") into the wrong position in the sentence. Fallacies that are generated by misplacing necessity and possibility operators are called modal fallacies.

The traditional statements of fatalism ("what will be must be") are likewise thought to be modal fallacies.

30. **Adrian Heathcote**
September 26, 2006

There is a second strand to the AP, evident in the post of John Bussoletti. The claim is that if the universe were different in some particular respect X then life would not be able to exist. Therefore since it does exist the universe *must* have this property X. This is the modal fallacy that I mentioned. The only thing that really follows is that the universe does have this property X.

31. **Neznaika**
September 26, 2006

To Chris W. and Peter,
Thank you very much for responding, Chris, since Peter is simply ignoring my question.
Actually, I don't care "whether the argument is TRULY "anthropic", (it's "anthropic" enough for me). Vilenkin's claims that 'The Principle of Mediocrity' is testable, since it can make VERIFIABLE statistical predictions and some of those predictions, for the cosmological constant specifically, have already been confirmed. I very much want to know if those claims are correct. I read the article on Edge.org and thought that Vilenkin makes a very convincing case but I am just a layman, I can't judge…
I am interested in Peter's opinion very much – he is extremely smart and seems to be the expert, so I asked him this very specific and simple question in response to his comments to Alex. I didn't receive any answer. Is he hiding, or he doesn't have an answer?

32. **Peter Woit**
September 26, 2006

Nezmaika,

I didn't answer your question because Chris already did, and I've written many, many times about these issues here. I'm just really tired of repeating the same points in response to the same overhyped claims. Once more:

The anthropic principle by itself is useless. It gives "predictions" that are tautologously true, so can't be falsified. The "principle of mediocrity", or more generally, the use of a multiverse model that gives an a priori statistical distribution of values of observables, combined with the anthropic principle as a selection effect, can in certain cases give predictions. If your multiverse model predicts a statistical distribution strongly peaked at a point, and that point is in the anthropically allowed range, then you should observe something near that value or the model is (probably) wrong.

The problem is that people are working with models (like the string theory landscape) that they have no control over and seem to have no useful structure, so people are just assuming the statistical distributions are flat. This is exactly the same assumption you make when you throw up your hands and say "I have no idea what is causing this", so, a priori, the distrbution of expected values is flat. You can't get something for nothing, and claim to be doing a serious non-trivial test of a model when the model's "predictions" are identical to those of just admitting you have no idea what is going on, so anything is equally likely. (I should note that Wilczek et. al have a calculation involving axions where they have some control over the a priori distribution, and it isn't flat, so maybe there is something more there).

The Weinberg "prediction" has been seriously overhyped, in many ways. First of all, it involves a flat a priori distribution of the CC values, so suffers from the problem mentioned above. It "predicts" a generic value of the CC in the anthropically allowed range, but that is also the "prediction" that comes from the model "the CC is determined by something purely mysterious such that I'll never know anything about its origin".

You can argue that this "prediction" is falsifiable: you may find that the CC has a non-generic value, e.g. very close to zero. If you observe this, then, you do have some information about the origin of the CC, it's not something random, but some unknown physics is giving it the non-generic value.

Despite the over-hyped claims you hear, this appears to be what is happening in the CC case. If you fix all cosmological parameters except the CC, you find that the observed value is somewhat smaller than expected, since it is one to two orders of magnitude below the top of the allowed anthropic range. If you allow other cosmological parameters to vary, the CC is much too small, many orders of magnitude below the top of the anthropic range. Vilenkin and Susskind's claims that the observed value of the CC is decisive evidence for the multiverse and landscape are absurdly overhyped.

If you take the string theory landscape seriously, there are lots of other similar "predictions" it makes which are just completely wrong. There appears to be no reason for the proton lifetime to be anything in particular on the landscape, but it is observed to be not generic, many orders of magnitude below the anthropic limits on proton decay. Same for CP violation, and lots of other things. If the people hyping these anthropic landscape "predictions" were honestly willing to give up their model when these "predictions" failed, that would be one thing. They're not, they don't take their own "predictions" that they are getting from these vacuous models seriously, so I don't see why anyone else should either.

33. **Neznaika**
September 28, 2006

Peter,
Thank you very much for taking time and answering this truly primitive question. I didn't realize that you've done it many, many times before, and I apologize for that. Your explanation is very detailed and clear; with your help I now understand the issue much better.
I agree that people make exaggerated, over-hyped claims about anthropic predictions but I find Vilenkin and Susskind's positions to be very different: they are interested in different kind of models. Susskind is interested in superstring theory and landscape, Vilenkin doesn't care about that. His only interest is cosmology: he uses 'The Principle of Mediocrity' for cosmological predictions.
I went to Vilenkin's colloquium recently (I am an alumni) about The Principle of Mediocrity. He made 3 points which I found interesting. Vilenkin is using a 2-step process to calculate the statistical distribution. He does assume AT FIRST that the statistical distribution of all possible CC values is flat. His argument that the range of all possible CC values in the multiverse is enormous and the allowed anthropic range is tiny by comparison. If you select a tiny range of ANY distribution curve, it appears flat as Earth surface looks flat to us. Next he goes on to CALCULATE the statistical distribution based on the number of galaxies, and that one is NOT FLAT. The PREDICTED (since it was done way BEFORE any experiments) and the observed CC values agree at 75% confidence level which looks pretty impressive to me.
Peter, I am very interested in Davis's book which is not available yet. Your review is great, so I have a question: I read your old Vilenkin's book review, you didn't like it at all. Davis's book review is much better but the subjects look similar. What are the differences and/or similarities in your view? Do they have a difference of opinions? Which one is better written and easier to read? Thank you very much.

34. **Peter Woit**
September 28, 2006

Neznaika,

Both books are written at a very low level, for a very unsophisticated audience. If one has a serious interest in these subjects, I'm not sure that either one is all that helpful. The Davies book is more about philosophical issues than the Vilenkin book. Its virtue is that it's even-handed: Davies explains the whole range of views on these topics, as well as what their problems are. Vilenkin's book is hyping one specific kind of theory, one that I find highly problematic since it is not really testable and thus not really science. On the whole, he also doesn't really bother to explain what the problems are with what he is pushing.

I can guess at what the "75% confidence level" claim is about, and I think it's heavily overhyped. For one thing, it completely ignores the problem I mentioned that if you allow other cosmological parameters to vary, the CC comes out much too small (probably so small that the standard experimentalists way of characterizing the situation is that Vilenkin's scenario is ruled out at greater than 99% confidence level).

35. **Neznaika**
September 29, 2006

Peter,
It's for ME! I AM that unsophisticated audience. I am trying to understand the science behind it but I don't want to fall asleep in the process, I want an interesting, well written book.
On a different subject: I read in your earlier post that Lubos Motl wrote a 'one-star' review of your book and "when his review is there, sales improve". I've noticed that Motl gave Vilenkin's book 5 stars (which is extremely rare for him). Do you think that Vilenkin's book sales are in real trouble?

Links and Gossip

September 22, 2006
Categories: Uncategorized

Well, no, I'm not going to start putting up here the really interesting gossip that people tell me. If I did so they'd stop telling me such things.

The Theoretical Particle Physics Jobs Rumor Mill has moved yet again. First it was hosted at the University of Washington, then the College of William and Mary, now it's at UC Davis. No idea why it moved this last time, but earlier this year some gossip told me the entertaining story of why it was booted out of Washington. To be honest, I've now completely forgotten all the details, so even if I wanted to violate their confidence, I couldn't.

The new Rumor Mill site confirms previous gossip I had heard that shows UC Santa Barbara having great success in hiring people in mathematical physics. Is Singer has been a regular visitor there in recent years, spending part of the year in Santa Barbara, part at MIT. This year they've hired two very good people: Dave Morrison and Sergei Gukov. Morrison has a mathematics background (algebraic geometry), and Gukov was educated as a physicist (a student of Witten's), but they both do interesting things at the interface of the two subjects.

Also at UCSB, Michael Freedman has moved his Microsoft Research group down from Redmond, and it is now temporarily in residence at the KITP, waiting to move into offices in the building next door when it is finished and will house the California Nanosystems Institute. Freedman is a topologist and Fields medalist, who was hired away from UC San Diego by my ex-grad school roommate Nathan Myhrvold when he was running Microsoft Research. From what I remember, at the time Nathan told me some mildly entertaining gossip about this, but, again, I've forgotten the details, so can't violate his confidence even if I wanted to.

Also on the move is John Horgan's blog. His Scientific Curmudgeon blog is being shut down, re-opened as a blog hosted by Discover magazine (which has its own blog). The new blog is called Horganism, and he has some advice which I don't endorse for would-be scientists;

Also, don't go into particle physics! Especially don't waste your time on string theory, or loop-space theory, or multi-universe theories, or any of the other pseudo-scientific crap in physics and cosmology that we science journalists love so much.

Seed magazine has some interesting new articles: one by mathematician Jordan Ellenberg about Fields Medalist and MacArthur winner Terry Tao, another by Joshua Roebke about Jim Simons and his Math for America project, the inspiration for which came over a poker game (OK, it was a poker game to raise money for charity).

The Cern Council Strategy Group has put out a briefing book that gives an excellent survey of the prospects for particle physics and particle physics experiments, especially in Europe, during the new few decades. Very much worth reading.

Comments

   Thanks for the link to Horganism, I wonder what a Horgasm would be like.

2. **John Ryskamp**
   September 23, 2006

   I also sent you an email about this. If you want a different perspective on string theory as it relates to the history of mathematics and physics, I strongly suggest you learn more about the important work which has been done over the past decade and a half in the history of set theory. Above all, read A. Garciadiego's BERTRAND RUSSELL AND THE ORIGINS OF THE SET-THEORETIC 'PARADOXES.' Some of the set theory paradoxes have already had holes poked in them, but Garciadiego does a remarkably thorough job in laying the groundwork for understanding the most important aspect of set theory: the response to it. You should ignore the huge number of typos in the book and pay close attention to the footnotes.

   But to the response: "natural" mathematics was developed, and traded under different names, with a program of "avoiding" the "paradoxes." This polemical point of view is well summarized in Penelope Maddy's polemic, NATURALISM IN MATHEMATICS.

   Poincare was one of the first of the "natural" mathematicians. The program informs his vastly influence SCIENCE AND HYPOTHESIS. Einstein rhapsodizes about this book. For many non-mathematical scientists, it was influential, and I believe Einstein took over its program into his physics.

   You should certainly ground yourself in the avant garde mathematics in which Einstein developed, if you propose to understand his work and what came after it. I believe you will develop a very different understanding, if you do.

   Here is my own take on the influence of "natural" mathematics during the twentieth century:

   Ryskamp, John Henry, "The Unity of Twentieth Century Ideas" (April 14, 2006). Available at SSRN: http://ssrn.com/abstract=897085

3. **Stefan**
   September 23, 2006

   Peter,

   As a (especially) theoretical physicist / mathematician of course you will not endorse John Horgan's advice to potential entrants; but what then are the [\italics]actual[italics] *realistic* responses to his qualm?
   I have been thinking about this for quite some time now, and each time it seems that going into HEP research would likely result in (or atleast set a path towards) financial and professional destitution and destruction (unless of course one possibly chooses to make fundamental compromises to one's intellectual principles, i.e. join one of the bandwagons of current theory [especially string theory]; this seems – sadly – more like playing Russian Rullet with one's professional career than anything else).

   My hypothetical responses to this quandary are the following:

   a) go into mathematical physics; [more on this below]

   b) go into condensed matter physics (atleast some job prospects can be expected after finishing studies);

   c) go into mathematics proper (-same reason as (b)-)

d) forgo this area (math and physics) and study something like ‘computational science’ (atleast there is some relation – albeit indirect to my knowledge – with theoretical physics; this area includes ‘chaos and complexity theory’ I assume;

e) forgo all of the above and become a computer scientist / programmer; this should be sufficient to guarantee a job no matter what the prevailing circumstances in academia (I hope!).

As for mathematical physics, what are the likely scenario(s) from your vantage point?

Stefan

4. **Stefan**
September 23, 2006

P.S.:

Peter, as you can guess I don’t know how to work the font system. Any suggestions?

5. **MathPhys**
September 23, 2006

Stefan,

In a certain sense, string theory really has nothing to do with high energy physics, although (like many other topics) it was motivated by questions arising in that subject.

String theory is very inspired (and inspiring) mathematical physics (or even mathematics).

Just forget about trying to make connections with what we see in (and expect from) high energy particle colliders and everything will be fine.

6. **woit**
September 23, 2006

Stefan,
Best advice about the fonts is probably to not even try to get that kind of formatting into comments here. Most blogging software handles html inside comments in an inconsistent way.

It’s very difficult to give people career advice about HEP research at this point. I certainly have no idea what the field is going to look like in a few years from now. A lot depends on what happens at the LHC, and how the physics community deals with the continuing dominance of string theory despite its conclusive failure to give any insight into unification. But, even in healthier times, going into speculative HEP research is not something someone should do who is looking for a straightforward career path and a well-paid, secure job. If those are important to you, do something else. There are just too many smart people and too few good permanent jobs in this field. On the other hand, if one has reasonably wide interests, and is very flexible in what one does to earn a living, one can most likely sooner or later find some reasonable sort of job after starting out trying to do HEP research.

If one is interested in the mathematical end of particle theory, one is probably better off getting a Ph.D. in math than in physics these days. Mathematics is a much healthier field, both intellectually and in terms of numbers of jobs. There are a lot of interesting questions at the boundary of math and physics to work on, and a reasonable number of good people and research activity going on in this area.

7. **anthropologist**
September 23, 2006

This is my first post here. While not exactly in the string theory, I am very fascinated by this whole psychology (people’s) angle. And, I have seen both Brian Greene’s and Ed Witten’s public talks, certainly, polished they were! So, these are my thoughts. On the side of the actual (tangible!) physics, what we have now is no new experiments that prove or disprove existing theories. Everything is wishy-washy, and there are no breakthrough experiments on the horizon, at least according to predictions by ANY theory. Yet it is still very desirable for people in the field of theoretical physics to eat (so to speak), and do something. So, these are the constraints.

One could argue that the string theory has evolved exactly to fit into this set of constraints. It captures public’s imagination, thus providing continuing public interest (and funding!). It cannot be readily falsified, so nobody can ever claim it is wrong, which also guarantees a good grace period for people to bail out if they start to have private doubts. Researchers are still able to do interesting (if irrelevant) mathematical things, with a twist, that instead of math they call it physics. And for a good reason, if they called it math, life would be a lot less comfortable, since math is more like art in terms of funding (most of practically useful math is probably no less than 50-100 years old).

Were the string theory doubted on a large scale, so that the public does lose the faith and interest, the funding for the entire field of theoretical physics might very well shrink. It is a mistake to think that the freed up funds would end up paying for less fashionable physics research areas, they might just go away altogether if the overall public interest is lower. For example, these money would go toward the “war on cancer”, where it is hard to believe that small increment of expenditures (percentage wise) will ever lead to any significant breakthroughs not achieved otherwise.

Now, coming back to the prevailing “strong peer pressure makes everybody conform” criticism that has been voiced in 2 recent books. In any event, if a “rogue” physicist has any good new ideas, then it would be possible to get tenure somewhere, and then just start promoting them heavily. That is because the personal gain in the case of true success is very high, perhaps, the Nobel prize (damn the string theory!). For a tenured faculty the risks would be relatively low, and the potential reward would be very high. Otherwise, why give up such a great brand such as “the string theory” for something that needs to be promoted, especially, if this new theory has no present day technical means to be proven/disproven even if offering falsifiable predictions? Of course, it might be that ALL theoretical physics people are too deep in the same hole, with the same set of tools. But visionaries like Enstein come once per hundred years, so, the whole vision thing is just very rare regardless of whether it is the string theory or something else.

So, it appears that while the criticism of the string theory might very well be valid, it is still the best thing for the physics field at the moment, since it keeps it going, and going strong. The only important thing is that the young people entering the theoretical physics fully understand the implicit rules of engagement, or otherwise irreversible damage to one’s career might result.

8. **Stefan**
September 23, 2006

Peter,

Thanks greatly for the advice; I do appreciate it. 🙂

You write:

“If one is interested in the mathematical end of particle theory, one is probably better off getting a Ph.D. in math than in physics these days.”

Coming from you [as a theoretical physicist] this is a little saddening and disappointing – one would have hoped there existed some optimism within the community. (This may be valid (indirect) confirmation that the “Golden Age” of particle physics has expired, and the field has changed in character from its glorious heydays…).

Anyhow, my question(s) then are:

1) What are the topics you recommend we study to gain expertise in this area [mathematics of particle theory]? (especially in relation to QFT-math; and if relevant – I suppose?! – to the Clay problem… one can hope, can’t one?!)

[If you have recommended texts, please include as you like.]

2) What (research) topics do you feel may pay dividends for future mathematical physicists (especially for the area above)?

3) [somewhat off-topic] What is the Representation Theory relation to all this? (You previously wrote that you were studying / reading the new text: ‘Dirac Operators in Representation Theory’.)

Regards,
Stefan

9. **Aaron Bergman**
September 23, 2006

And for a good reason, if they called it math, life would be a lot less comfortable, since math is more like art in terms of funding (most of practically useful math is probably no less than 50-100 years old).

A lot less comfortable? There are no monetary differences that I can discern. People call themselves physicists rather than mathematicians because the cultures are distinct. The training, the way problems are attacked, the standards of rigor and the incentives are all quite different.

10. **woit**
September 23, 2006

Stefan,

I have no idea what kind of ideas will ultimately solve the Clay Yang-Mills problem (or any other of the Clay problems..)

My 2002 arxiv paper is kind of a sketch of ideas that I find promising, more recently I’ve mostly been working on BRST (and its relation to the Dirac operator and representation theory). There’s a lot of mathematics related to BRST that has yet to be exploited.

Finally, geometric Langlands has all sorts of interesting math and possibly physics associated to it. If Witten keeps working in that are and turning up more things, it may get more people willing to join him and could get very interesting.

11. **Dan**
September 23, 2006

Speaking of links, the physics forum has a review of your book and a string theorists disagrees as a matter of fact with your book. While I suspect the reviewer is yours truly, the profile says France, not Harvard.

Here’s a link:

12. **Stefan**
September 23, 2006

Peter,

Thanks for the response; (was hoping for a more substantive one though). It’s alright however: I know you have other duties at hand too.

🙂

Take care,
Stefan

13. **woit**
September 23, 2006

Dan,

Please don’t repost long things here from the middle of discussions on other blogs. It’s fine to point out discussions elsewhere that people here might be interested in joining, but in general they should do so where the discussion is already taking place.

“R.X.” is not Lubos Motl, he’s a string theory partisan who posts on various blogs using various pseudonyms (from what I remember, I think he’s “MoveOn” when he posts here). For some reason he doesn’t want his real name and identity attached to what he has to say, perhaps because it is often incorrect and full of nasty personal attacks.

The comment of his you quoted doesn’t appear to be a review, since he doesn’t actually say anything about the book or claim to have read it. It’s just the usual ad hominem personal attack on me, together with standard issue string theory propaganda and incorrect claims (no, you can’t falsify string theory by not finding 10 d string excitations at the Planck scale, since some versions of string theory don't have these, ever heard of M-theory?).

14. **anthropologist**
September 23, 2006

Peter, actually, R.X. does not really attack anybody personally, where do you see that? R.X. does disagree with you, but surely healthy dissent is a good thing. Or you do not think so?

Also, R.X. points are well-reasoned, specifically, it is just not plausible that some smart individual would not abandon the string theory in heartbeat if something more promising came up. So I think that the particular claim of yours that "everybody is too locked up in the string theory to look around" does not stand under detailed scrutiny.

It is much easier to disagree with something than to be constructive. So again, R.X. argument is well-made, if you had some constructive material on the subject, you'd probably be publishing it in scientific, and not popular literature in order to properly collect your credit.

15. **Peter Woit**
September 23, 2006

anthropologist,

Actually, R.X., begins his comment with "I suspect if he [Woit] would be able to contribute something positive to science, he would have already done so in the form of real publications. Instead he chooses to gain his 15 minutes of fame by discrediting the work of others." and then goes on to not address any of the arguments in my book. I don't see why I should spend much time answering anonymous criticisms from people who personally attack me, show no willingness to even read what I have to say, and just endlessly repeat the same incorrect hype about string theory.

I'm not claiming there is an obvious much more promising thing than string theory that all string theorists should start working on. I am claiming that what they are working on has conclusively failed and they need to admit this. I don't think one can defend continuing to work on a failed idea. If they want to argue about this, they need to deal with my argument that string theory has failed. It's given in detail in the book. I'd be happy to argue these scientific issues with R.X. or anyone else.

Sure, it's very difficult to come up with constructive new ideas. I've written some of mine up, in hep-th/0206135.

16. **Peter Orland**
September 23, 2006

Stefan,

As a theoretical physicist, I don't agree with Peter (W)'s advice about going into math as a path to high-energy physics. Mathematicians have made valuable contributions here and there to physics, but going to graduate school in math won't make you a physicist. You will instead need experience doing
research in physics to understand the issues. I predict that whoever solves the Clay problem you mentioned above won't be a mathemtatician.

17. **anthropologist**
September 23, 2006

Peter,

Your approach is idealistic, and not realistic.

"I am claiming that what they are working on has conclusively failed and they need to admit this. I don't think one can defend continuing to work on a failed idea."

So, how do you exactly see such an admission? Like the following: All talks at the string conference would go "we failed, the string theory is dead". Then, since there is nothing obviously promising out there, upon return everybody turns in their resignation letters, and goes to work at McDonalds. Would that be the plan?

The only way the string theory would die out if it was displaced by something more promising (and not less!). That is the only possibility for an implicit admission. Without a replacement, the efforts on ST will continue.

Naturally, one way to gauge the real ST community sentiment would be to go to a string conference, feed some younger attendants some beer, and then collect opinions. Often big shots express their sentiments to the students, and those propargate, so with beer one could extract that. Many younger people not too close to the critical points of their career would be rather willing to discuss the perceived state of things, at least that is what I found in my field.

18. **Peter Woit**
September 23, 2006

anthropologist,

Have you read my book or Lee Smolin's? Both books very explicitly deal with the questions you are raising.

I've had many conversations with string theorists, young and old, over beers, wine and other beverages. Many of them are very disturbed about the current state of the theory and we agree on much more than we disagree.

The question is: how do you make it possible for the kind of young, bright, ambitious physicists who might be able to develop alternatives to get the kind of training needed and spend the years of work necessary to make some progress on alternatives, while still having a decent chance at a successful career? It seems to me a necessary ingredient is admitting failure. As long as the field is dominated by people who claim that string theory is the best thing for people to work on, refuse to admit that it has failed, and provide no support for young people trying to do something else, things will not change.

19. **anthropologist**
September 23, 2006

Peter,

I agree that to have a career one needs a lot of support from the establishment. And, with alternatives to ST, it still would be very risky to bet a career on an alternative, even with some supportive senior people (unless those have such great connections that a tenured job would be nearly guaranteed at a later point). That is because if you get relatively nothing interesting in a new area (no flashy or popular publications), you have nothing to apply for jobs with, and nobody would spend any time to understand what you did. Thus you would have been much better off incrementally improving the string theory where you would do something OK and be relatively widely understood, with good support by the establishement.

In my field, situation in some ways even worse, since there is certain "mafia" in the establishement which gets all the interviews for their people, so then not even the area is constraining, but the choice of people to work with! If you did not forsee that before, and ended up on the other side of such a divide, tough luck.

20. **nc**
September 23, 2006

"… tough luck." – anthropologist

I wish Peter or someone would plot out in a flow chart the standard responses to criticisms of string theory. All the responses are unoriginal, and follow the following sequence:

1. Critics should shut up complaining or else talk about an alternative to string. They all just want 15 minutes of fame.

2. OK, the critics have some ideas about alternatives, but they aren't hyped as much as string, so they must be wrong.

3. If you made the error of not being a sycophant of the stringy mainstream from your early years, tough luck.

This is really interesting because to ride out criticism, the stringy mainstream gets ever more arrogant. How long can such political tactics divert attention from their lack of physics?

21. **jeremy**
September 23, 2006

Stefan,

I am going to add something to what Peter (W) and Peter (O) already wrote, but I wouldn't call it advice.

In case you want to do your research in a mathematics department and working on the Clay problems, but still have worries about the future job opportunities, Navier-Stokes equations would be a good problem to work on. There has been a great deal of effort tackling this problem in applied mathematics in the last thirty years. So, in the worst case scenario, you don't get to win the million dollar prize given by Clay Institute and you cann't find an academic position in pure mathematics, but you always have applied mathematics to fall back on.

22. **Stefan**
September 24, 2006

Peter,

Thought this might be helpful to look through:

http://arxiv.org/abs/hep-ex/0108040

'Results of the Survey on the Future of HEP' by Young Particle Physicists (YPP) during the Snowmass '01 Conference.

Stefan

23. **Alejandro Rivero**
September 24, 2006

Re

"So, how do you exactly see such an admission? Like the following: All talks at the string conference would go "we failed, the string theory is dead".,"

A smotther way should be to produce a lot of talks to discuss "where did we go wrong?" and "why?" . There are some Field Medals relating to string theory, and one sould wonder how is that string theory has got to reach new mathematical structures.

My current answer is that these structures were so general than any bold attempt to go beyond QFT was dammed to find them in some disguise. It could follow that even if string theory is wrong, they were wronged by a mirage of some objects really related to physics, and it is still wothwhile to locate these objects. Of course better mathematics than strings is needed (here a toast to representation theory, for instance 😉

24. **Observer**
September 24, 2006

Peter,

I was thinking about this issue whether blogging and publishing polemic books constitutes scientific activity or not (it was raised several times on this blog).

And my conclusion is that it can be determined easily. If we assume that scientific activity is the thing that if someone does very well then he/she is entitled to a good academic job at a respectable university, then my question to you is this:

Do you think that anyone should be hired as a faculty member at a physics department based on his/her blogging and polemic book publishing activity?

If your (or anyone's) answer is 'yes' then you (or anyone) think(s) that blogging, etc, is a scientific activity, otherwise you (or anyone) think(s) that it is not.

Cheers,
Observer

25. **Peter Woit**
September 24, 2006

Observer,

Obviously it all depends on what is in the blog and in the book. If someone were to put up a correct proof of the Riemann hypothesis on their blog or include it as a chapter in their polemic book, obviously a respectable university should offer them a good academic job. It's also true that someone with no blog and no book, but a lot of worthless publications in journals on, say the Landscape, should not be offered a job by a respectable university.

One example of a blogger whose blog is devoted mostly to his ongoing research is Urs Schreiber. Respectable universities have certainly hired people based on worse scientific activity than that on his blog. My own blog entries dealing with current scientific research are often devoted to showing what is wrong with a new scientific argument. I happen to think this is scientific activity, and of non-negligible value, but also that more positve scientific activity (such as hep-th/0206135) is of much greater value. This kind of positive scientific work is on the whole likely to be too long and technical to fit comfortably as a blog posting.

This is completely off-topic, and I'm having trouble believing it's not personally aimed at me. Anyone who wants to discuss this further at a minimum will have to be willing to not hide their identity and credentials behind the cover of anonymity.

26. **anthropologist**
September 25, 2006

nc –

"2. OK, the critics have some ideas about alternatives, but they aren't hyped as much as string, so they must be wrong.

3. If you made the error of not being a sycophant of the stringy mainstream from your early years, tough luck."

Point 2 is more valid because people still have to do something to get noticed, and have a record to apply with. If the area is only weakly promising, and not much progress is made by a job applicant to be, then that is too tiny of a program to run on, so to speak. It is better to be a mediocrity in an known field, rather than in an unknown one.

Point 3 is valid because the present day establishement is all string theory, and rule 1 of academia that you do not go against the establishment when applying for jobs. In any field.

So these are not just purely pro-string theory arguments, but they are more generically relevant for any dominant worldview, however dillusional it might be.

27. **Thomas Larsson**
September 25, 2006

anthropologist:

So, how do you exactly see such an admission? Like the following: All talks at the string conference would go "we failed, the string theory is dead".

They could say something like string theory pioneer Dan Friedan did in hep-th/0204131:

"String theory has no credibility as a candidate theory of physics. […] Complete scientific failure must be recognized eventually."

The only way the string theory would die out if it was displaced by something more promising (and not less!).

As I pointed out in my 1999 manifesto, gr-qc/9909039, the multi-dimensional Virasoro algebra is the correct quantum form of the correct constraint algebra of general relativity (in covariant formulations). It is thus to GR what the ordinary Virasoro algebra is to perturbative string theory. That is why this mathematical discovery is a necessary prerequisite for quantum gravity, and that is why I decided to discover it.

28. **Stefan**
September 25, 2006

Peter,

Great reply! 😉

As a person not affiliated (directly, at least) with either side of this debate (or for that matter any committed research direction), I found it rather sorry-like (and even somewhat pathetic) that Ph.D. scholars [professional string theorists, albeit not all] were stooping to such un-professional levels to defend their position(s); this perhaps more than anything else suggests that inside each [defender / critic] lies a perpetual fear that his / her much-touted intellectual-academic enterprise may have lost its once-sparkling lustre, or even its stature within broader academia. The time has rightly come to conduct a *sobering* study of string 'theory', and (perhaps more importantly), how it has been effectively able to gobble up the lion's share of funding for hep-research… at the cost of other well-meaning avenues (i.e. LQG, twistor theory, non-commutative geometry, Algebraic/Constructive QFT, etc.).

P.S.: Incidentally, I am now studying Ch. 31 of Penrose's book [The Road to Reality, UK version] – 'Supersymmetry, supra-dimensionality, and strings' – and I would recommend any undergrad physics major contemplating doing future studies in hep to read his views on strings and supersymmetry. (I can assure you it reads nothing like Lubos' unintelligible and sometimes offensive/crude/impolite, (but all-in-all a great source of diversion and amusement), rants.)

Stefan

29. **Steve Myers**
September 25, 2006

On jobs & careers: industry needs good math & physics grads. People would be surprised at the level of math & physics involved with modelling. The pay is good & often the problems are interesting. But make sure you take a good statistics course. And no one in industry would be left to work on something that was as disconnected from reality as string theory.

But if you have a problem you must work on, one that won't let you go, get your phD & follow Einstein's advice and be a plumber. I haed a fellowship at NYU when I woke up in the middle of an exam and walked away froim the academic life.

30. **nc**
September 25, 2006

'If the area is only weakly promising, and not much progress is made by a job applicant to be, then that is too tiny of a program to run on, so to speak.' – anthropologist

The higher standards of alternatives make them more vulnerable to dismissal as 'only weakly promising' mainly because the people working on them don't hype them up so much.

Caution is wrongly taken as a sign of incompetence, or a sign that the researcher is at least not confident in the alternative idea.

Contrast this to the mainstream, who justify their extraordinary claims using extraordinary hype.

    Peter wrote:

    "If one is interested in the mathematical end of particle theory, one is probably better off getting a Ph.D. in math than in physics these days. Mathematics is a much healthier field, both intellectually and in terms of numbers of jobs. "

    The situation was the same when I was in graduate school. After a Bachelor's degree in physics(1968), I did one year of grad school in physics before my education was interrupted by the Vietnam war. After serving 5 years as a pilot, I returned to grad school, switching to math because I felt that my physics education had ceased and my indoctrination begun. In my experience, the physicists want us to sit in awe of their work and not question it. There is far more academic freedom in math than in physics. In the intervening years, the fads had changed but the math requirements for the newer fields were much greater. I wrote a physics dissertation (The Geometry of Elementary Particles, UCSC, 1987) for a PhD in Math. Some members of the physics department fought against its acceptance. I arrived at some conclusions the physicists didn't want to hear: Einstein was right about quantum mechanics;quarks are a mathematical fiction; the ultimate theory cannot be a lagrangian field theory. I've added more heresies since.

Unstrung

September 25, 2006
Categories: Not Even Wrong: The Book

This week's New Yorker has an article about the controversy over string theory, written by Jim Holt, with the title Unstrung. On the web-site there's also a link to Woody Allen's 2003 humorous New Yorker piece on string theory, Strung Out.

The New Yorker article pretty much gets the story right, although the description of the Bogdanov affair isn't completely accurate. The Bogdanov papers were about quantum gravity, but were not string theory papers (although they claimed to be motivated by string theory, and at least one referee described their results this way). Holt also describes members of the Harvard string theory group as unsure whether the papers were a fraud or sincere, which does correspond to an e-mail that circulated at the time. However he doesn't mention that at least one member of the Harvard string theory group to this day not only believes the Bogdanov papers were written sincerely, but considers them to be serious scientific research (an opinion shared by very few others).

Holt accurately describes Smolin's book as more accessible than mine, then chooses a very good example of an "indigestible" sentence from my book:

The Hilbert space of the Wess-Zumino-Witten model is a representation not only of the Kac-Moody group, but of the group of conformal transformations as well.

That is an example of some of the very advanced material I tried to include in a few places in the book. It's the precise expression of the mathematical relationship of representation theory and QFT that has been worked out in recent decades in two dimensions, exactly the thing that I would argue we should be trying to understand in the physical case of four dimensions. To the extent that the book contains a positive argument about alternatives to string theory, my decision was not to over-hype it, but to try and explain a point of view about the history of the relation of mathematics and quantum field theory that implicitly leads to this way of thinking.

Also out today is an article by JR Minkel on the Scientific American web-site entitled That's Debatable: Six Debates at the Frontier of Science. The first of the debates listed by Minkel is Is String Theory Unraveling?, and it's largely about the landscape. It includes a couple quotes from me, as often the case a bit abbreviated to make them sound even more provocative than I intended…

Update: The usual sensible commentary on the New Yorker review from Lubos. Holt is a "cretin from the garbage bin of the journalistic colleges", I'm the "black crackpot" (due to the color of the cover of my book, Smolin is the "blue crackpot"). Lubos reports on the reaction to the review from "one of the leading physicists of the current world" (presumably one of his colleagues):

*What's wrong with these people? Why don't they choose f***ing instead of writing about things that they don't like and they don't understand?*

Update: The story has made it to Slashdot.

Comments

   September 25, 2006

   This is a pretty disappointing article. Take

   "Nowadays," one established figure in the field has said, "if you're a hot-shot young string theorist you've got it made.

   for example. The quote is from a number of years ago. These days, if you're a hotshot young astrophysicist or phenomenologist, you've got it made. String theory jobs are getting harder to come by.

   And, regarding Friedel's e-mail about the Harvard string theory group, frankly I just don't believe it. Pretty much everyone I know who looked at the papers agreed they were nonsense. I find it almost impossible to believe that the Harvard faculty wouldn't agree. Even Lubos's ravings on the subject are to the extent that there might be some ideas in there, not that the mathematical content of the papers is at all coherent.

   I'm a bit tired of all this talk about how we should cultivate 'seers' or 'valley crossers' or perhaps 'people Smolin likes' without any concrete suggestions on how we change the current incentive system in physics. I don't think there is this great division of people between the mindless string theory computation-o-trons and the deep thinking everyone else. What there is is a lot of smart people working under a strong incentive to develop a long publication record. If you want people to spend more time on hard questions, you're going to have to find a way to have it not hurt their job prospects.

2. **Stefan**
   September 25, 2006

   Peter,

   You write frequently about representation theory and QFT, so might it not be a generally good idea to write something pedagogical for would-be physics grad students before they prematurely commit themselves to any specific research direction.

   In fact, I was thinking it may be even more helpful to write a 'Resource Letter' along with the topic-intro and post both on the arXiv. This may help to disseminate your idea(s) to a wider reader base, especially given the climate of doubt which seems to have settled within the string theory community.

   Adieu,
   Stefan

3. **Peter Woit**
   September 25, 2006

   Aaron,

   Do you really think that a young grad student or post-doc who came up with something new about string theory that got a significant amount of attention would have trouble finding a job now? That's not my impression, but maybe I'm wrong.

   Smolin and I do both make concrete suggestions about how to change the incentive structure. To get them taken seriously though will first require that leaders of the field acknowledge that there's a problem. Besides positive incentives, I also fear that negative incentives may be part of the solution. If people decide they won't be able to get a permanent job by producing a long list of unambitious papers on trendy subjects, maybe they'll do something else. I would love to see the NSF/DOE start to take this issue seriously and start a discussion about their role in the current incentive structure and how to change it.

I don't have a problem with Smolin's "valley crossers" analogy, but I will admit that I'm congenitally dubious about "seers".

The e-mail in question doesn't refer to "Harvard Faculty", it refers to the string theory group as a whole, and presumably the discussion being reported was largely among postdocs. Lubos was one of them at the time and, given his later behavior, I wouldn't be at all surprised if his comments were one of things the writer had heard and was referring to.

4. **Peter Woit**
September 25, 2006

Stefan,

Yes, I would very much like to write something expository about QFT and representation theory, starting with something basic about QM and representation theory. This spring it looks like I'll be again teaching the second half of our graduate course on representation theory. Last time I did this I wrote up some preliminary notes which are on my web-page. This semester I hope to have time to improve those, and add some more on the topic of the relation of QM to the subject.

5. **Stefan**
September 25, 2006

Let me know when you finish the work.

6. **Aaron Bergman**
September 25, 2006

Do you really think that a young grad student or post-doc who came up with something new about string theory that got a significant amount of attention would have trouble finding a job now? That's not my impression, but maybe I'm wrong.

Depends on how new it is. I can tell you that I know a fair number of long term post-docs who have done very good work, but are deeply worried about their job prospects.

Smolin and I do both make concrete suggestions about how to change the incentive structure.

Can you please tell me what they are, then? I think it'd be a lot more helpful than just continually saying how much string theory has failed to do. I'd love to hear some really specific ideas.

Lubos was one of them at the time and, given his later behavior, I wouldn't be at all surprised if his comments were one of things the writer had heard and was referring to.

And so again Lubos somehow becomes representative of the entire field? I swear, if Lubos didn't exist, you guys would be forced to invent him.

7. **Peter Woit**
September 25, 2006

Aaron,

Lee has various suggestions, I don't have his book at hand. I assume one of his main ones would be to basically implement what he has been doing at the Perimeter Institute on a larger scale, in more places.

Among the things I've suggested that people should consider are:

1. Giving people directly out of graduate school longer term postdocs (e.g. 5-6 years), so they have more than 1-2 years in which to come up with something for their next job.

2. Graduate student birth control, bringing the ratio of Ph.Ds to jobs to something reasonable, so that the job market is not so insanely competitive and people are more likely to feel that they can have a future in the field even if they don't work on the latest, hottest topic.

3. Senior theorists need to stop putting students to work on the latest, trendiest string theory topic, encourage their students to work on a wider variety of things. At the same time they need to change their standards for hiring postdocs and junior faculty, making it clear to applicants that they want to see original ideas, not the same thing everyone else is doing.

4. The NSF/DOE should explicitly admit that particle theory research is in trouble, give guidance to people reviewing proposals that copycat proposals on the latest string theory topic will not be funded, and emphasize that priority will be given to diversity, that proposing to do something different will be a lot more likely to get you funded. This applies to grants for workshops/conferences, as well as grants to individuals and theory groups.

As for Lubos, who said he's representative of the entire field? Unfortunately he does represent the Harvard string theory group, at least he often claims that he represents their opinions. If this is not the case and they're unhappy with him, I've heard nothing about this from any of them, directly or indirectly. They're the ones who, after dealing with the guy for a couple years as a junior fellow, decided he was the best young person available in the field and offered him a tenure-track position.

8. **TheGraduate**
September 25, 2006

Peter,

I had always kind of thought that the overproduction of graduate students was a means of keeping wages low and therefore reducing the number of full time professors one needed to work in a particular department.

I am not sure to what extent this reasoning is sensible but the overproduction of science PhD's probably lowers wages in all fields for which science PhD's are eligible.

As I understand it, the growth in wages of professors has not kept pace with the growth in wages of other middle class professionals such as doctors and lawyers.

I think rather than graduate birth control, there should be more simple truth from the beginning of the system to the end of the system. Isn't it fair to say universities overhype the potential job opportunities and leave it to the student to eventually stumble into the rather brutal truth?

Didn't you have to discover for yourself that there were no jobs for nonstring theorists? I find that kind of system fundamentally unfair. You could have probably started thinking about your transition to math years earlier and perhaps had a smoother transition.

9. **Bee**
September 25, 2006

Hi Peter,

Senior theorists need to stop putting students to work on the latest, trendiest string theory topic,

That does not only go for string theory. In general, senior theorists should not dominate over the next generation by applying selection criteria that primarily support their interest, instead of criteria that support the most talented researches – even if those might have been working on topics they don't find exciting at all. The problem is that this goes on long after graduation. Given the fact that the average postdoc is aged around 30, hiring institutions should trust in the candidates ability and responsibility to find promising research fields on their own.

Besides this, its kind of funny that the article picks out exactly the same sentence about the Kac Moody group that [I mentioned](). I also found the following remark *'actually, this is a serious over-simplification […]'* very amusing 🙂

Best,

B.

10. **Carl**
September 25, 2006

It is true that Smolin's book is designed for a more general audience. What is amazing is that Woit's book, despite being fairly technical, is selling enough copies to be number 2 in physics book sales on Amazon after Smolin.

And this concept that the next big advance in physics is going to come from a graduate student is a little iffy. The idea is based on observations of the past, but as time has gone on it has become more and more difficult to reach the frontiers of physics. This alone would suggest that older researchers are more likely to make the advance.

Smolin had an interview where he said that his "seers" and "craftsmen" wasn't as good as someone else's "peak climbers" and "valley crossers", where the peak climbers push the old ideas to their limits, and the valley crossers abandon old peaks for new ones.

11. **Peter Woit**
September 25, 2006

TheGraduate,

It's extremely difficult to get universities interested in the idea of reducing the number of Ph.D.s. The faculty like having large graduate programs so they can teach advanced courses, the universities like having huge numbers of people competing for jobs, they're basically flooding their own labor pool.

The situation in particle theory is rather unusual for a scientific subfield, with a much worse imbalance between numbers of Ph.Ds. and jobs than any other subfield that I know about. The situation is much much better in mathematics.

I certainly went into graduate study in particle theory knowing that the job situation was quite bad, and then, as now, I assume that most departments and advisors let prospective particle theory Ph.Ds know this (although if they can't figure it out for themselves, one wonders how bright they are…). String theory was a non-issue when I was a grad student (I finished my thesis and started a postdoc in mid-1984). I can't say that I was surprised to have trouble finding a job after my first post-doc. I'd say that string theory just turned what would have been a difficult situation into an impossible one, and it was just as well that it made it much more sensible to look for a job in math than to hang around trying to find not very good positions in physics.

12. **Peter Woit**
September 25, 2006

Bee,

Maybe because I'm older than you I'm less of the opinion that the problem is inherently in the judgment of senior people. As far as pushing people into working on bad ideas about string theory (or other trendy subjects), I just don't see that it's mainly the older people doing this.

Funny that you chose the same sentence as Holt (although quite possibly he reads your blog…). My book has gotten a lot of criticism from people for some of the more technical things I put in it, but I'm still quite glad I did this. The material is there to provide something new and challenging for almost every one, and Chapter 10 in particular is an effort to get down on paper the story of the successful interaction of math and physics over the last three decades. Not everyone is going to be able to follow this, but I still think it's a worthwhile effort.

I suppose I'd feel differently if hardly anyone was buying the book because of this. As it is, it seems to be selling all right, with Smolin's book doing better because it makes many of the same points pitched to a wider audience. This situation is fine with me.

13. **TheGraduate**
September 25, 2006

Peter,

I finished reading your book yesterday and I had a few questions. So is S-matrix theory the origin of the string idea in string theory? Do you view string theory then as the modern face of S-matrix theory? Also, it occured to me that the sorts of anthropic reasoning and interest in theological tendencies that afflicted S-matrix theory at the end of it's theoretical life seems to be the sort of thing affecting string theory now. Was this something you wanted to highlight?

Secondly, I felt like you were emphasizing group representation theory as perhaps having interesting and generally overlooked significance to HEP. Was part the goal of writing the book to encourage more curiousity in that relationship?

14. **andy**
September 25, 2006

I cannot agree with the idea of reducing the number of graduate students as some sort of solution to the problem of excessive competition among would-be professors. Some areas of research allow students to go on to productive careers outside of an university.

15. **TheGraduate**
September 25, 2006

andy,

I think most likely if the major universities coercively reduced graduate students then lower tier and fringe universities would start offering PhD's to any people that still wanted to persue graduate degrees. I think this is already happening. It would just happen more.

16. **Aaron Bergman**
September 25, 2006

The longer postdoc thing might be helpful. I'm not sure that just won't lead to people churning out lots of papers at the same place rather than multiple places, however. I'd be more inclined to enhancing a sense of job security, but that may be my own anxieties speaking.

The reason, I should say, why string theorists encourage students to work on popular topics is that they know that that's how jobs are obtained. Perhaps it's a viscious cycle, but in the current environment, it's good advice.

As for NSF proposals, I've never been involved in one, but in areas of theory are they really directed at specific research proposals? For one, I thought that it was often entire groups that were funded out of these grants. It doesn't make much sense to me to tie these grants to specific research directions given that things can change rapidly.

As for Lubos, who said he's representative of the entire field?

Well, somehow we go from Lubos thinks the Bogdanovs might not be completely and utterly full of crap to "even the Harvard string-theory group was said to be unsure" (in that wonderfully weaselly passive voice) to, apparently, the implication that string theory is barely distinguishable from nonsense.

Isn't it fair to say universities overhype the potential job opportunities and leave it to the student to eventually stumble into the rather brutal truth?

Every place I applied told me that job prospects were crap.

instead of criteria that support the most talented researches – even if those might have been working on topics they don't find exciting at all

How does one determine the 'most talented researche[r]s'? That's the rub, after all. Otherwise, we'd just give them all tenured jobs at 18 and let them do whatever they feel like.

17. **Peter Woit**
September 25, 2006

TheGraduate,

S-matrix theory was an approach to the strong interactions that led to the discovery of the Veneziano amplitude, and that led to string theory. The ideology behind S-matrix theory was that QFT could never give a theory of the strong interactions, so had to be abandoned. This turned out to be wrong. Another part of the S-matrix ideology was that symmetries were not fundamental, this also turned out to be wrong. My suspicion is that present day string ideology has the same problems: maybe there is a QFT that gives quantum gravity, and maybe to make more progress on fundamental QFT you need new and better ways of exploiting symmetries. Representation theory is precisely how one exploits symmetries, one point of the book is that this has been the right approach in the past, even when people called for it to be abandoned, and it may yet be the right approach for the future.

andy,

Particle theory is the only area where I am suggesting reducing the numbers of Ph.Ds. I've heard all the arguments about why the current system that produces 5-10 times more people trained to do particle theory research than there are jobs doing such research is a good one, but I don't agree with them. I think a system where it is much harder to get a particle theory Ph.D., but where the people who get ones have a better shot at getting a permanent research job if they do interesting research would be healthier than what we have now.

18. **Peter Woit**
September 25, 2006

Aaron,

NSF proposals don't just say "We're Prestigious U. and have done good stuff in the past, send cash", they include descriptions of the research directions people in the theory group intend to pursue. If word got out that the NSF was not looking kindly on certain research directions, that would have a big effect. In the past, I think the NSF has for good reasons been unwilling to ever do this, leaving things up to peer review.

As you know, the reference to the Harvard string theory group comes from an e-mail sent by someone visiting there at the time (I don't know who this was, do you?). Maybe he or she was making this up or exaggerating, but the fact that one of the Junior Fellows there at the time still can't see that the Bogdanovs are full of crap, and his colleagues thought he was a promising young genius and gave him a faculty job lends a certain amount of credence to the story.

19. **Aaron Bergman**
September 25, 2006

As you know, the reference to the Harvard string theory group comes from an e-mail sent by someone visiting there at the time (I don't know who this was, do you?).

In the e-mail the Bogdanovs sent to many people (so I think I can safely call it public knowledge, especially as I put it on my webpage at the time), it was quoted as follows:

> Date: Fri, 25 Oct 2002 10:10:29 -0400
> From: Laurent Freidel
> To: Laurent Freidel ,
> Marc Magro ,
> Philippe ROCHE ,
> Laurent GALLOT , Jean-Michel.Maillet@ens-lyon.fr,
> kgawedzk@ens-lyon.fr, francois.delduc@ens-lyon.fr,
> pierre.vanhove@cern.ch Subject: RE: Hoax: Alan Sokol phenomenon reversed
> (fwd)

> " What is going on??? guys?? the claim is now that the Bogdanoff brothers are not a fraud and that they not only won Phd's with these papers that no one can understand, that yesterday everyone was convinced were fraudulent, they won appointment as professors to a french university, Bourgogne!!!
>
> So no one in the string group at harvard can tell if these papers are real or fraudulent. This morning told that they were frauds everyone was laughing at how obvious it is. This afternoon, told they are real professors and that this is not a fraud, everyone here says, well, maybe it is real stuff".

Again, I wasn't there, so I can't speak of anything that happened there, but given that everyone I know who looked at the papers was ably to discern the problems, what I can do is express my disbelief of this particular e-mail.

20. **Peter Woit**
September 25, 2006

The e-mail was forwarded by Laurent Freidel to various people Undoubtedly he, like I, found it rather amusing. But I still don't know where he got it from.

21. **TheGraduate**
September 25, 2006

Peter,

Concerning the limiting of Phd's, I guess I was thinking if particle theory became any more elite, guys like Einstein and Witten probably wouldn't make it in. The former not being well rounded academicly at least in his youth and the latter being a history major. It seems to me that the natural way that people would make it more elite is to start expecting even higher grade point averages, more research at the undergrad level, even more stellar recommendation letters etc etc. In other words, the kind of measures that in large part probably describe many of the string theorists and seem to have contributed heavily to why string theory has come to dominate.

22. **Aaron Bergman**
September 25, 2006

Well, since this anonymous comment has now made it into at least one book and an article in the New Yorker, perhaps the writer of the e-mail could come forward and explain what they meant by it.

Until that happens, I don't have much reason to believe that it bears much resemblance to reality and a lot of reason to believe that it doesn't.

23. **Peter Woit**
September 25, 2006

TheGraduate,

I don't think Einstein or Witten would have had much trouble meeting a significantly higher standard than the minimum now needed to get a Ph.D. But, sure, the main problem is that the current system is incentivizing and rewarding behavior very different than coming up with good original ideas.

24. **Gina**
September 25, 2006

Here is a couple questions I had while reading NEW.

1. String theory in the first simplest version implies that the universe has 26 dimensions. Is it possible to explain in a few sentences or a couple of paragraphs why? (I heard many years ago a short 1-2 slides explanation in a half-popular talk but I completely forgot it.)

2. In the book there is a distinction (for very successful theories from physics) between "convergent series", "useful divergent series", and "useless divergent series". Is there any formal distinction between the last two types? Can it make sense in math?

3. The era before QCD and the standard model is described at least as confused and chaotic as the situation in string theory today. Maybe even more than today. (Peter push the analogy by telling also there about a physist who combined physics with eastern philosophy.) Yet people who promoted these unsuccessful but very dominant theories were not ask to admit failure; moreover, they did not fail: conceptual and technical ideas from these unsuccessful theories turned out useful later, and students of these scientists had crucial role in developing more successful and completely different theories. This looks like a good model to proceed, no?

25. **woit**
September 25, 2006

Gina,

1. Away from d=26 quantization introduces an "anomaly" in the symmetry of conformal transformations of the string worldsheet. Basically this means that the quantum string theory is more complicated and the metric on the world sheet becomes a dynamical variable you have to deal with. People study these "non-critical" string theories also. There are various different calculations that give you the 26, I don't know of any simple physical explanation for it.

2. Some divergent series are "asymptotic" approximations to some function, which means that, at a fixed order, the truncated series is a better and better approximation to the function as the expansion parameter gets small (even though, at fixed small parameter, as you go to higher order, the series sooner or later diverges). The perturbation series for QED is supposed to be such an asymptotic expansion. This kind of divergent series can be quite useful, giving very good approximations.

3. Actually, the bootstrap program did fail as a theory of the strong interactions, and was pretty much killed off by QCD. Many of the people who worked on it certainly admitted that it failed, other die-hards never did admit this, but stopped being taken seriously by most theorists. Certainly some things learned from this were ultimately useful, but the program failed to do what it was intended to, and sensible people admitted this.

26. **Tony Smith**
September 26, 2006

Maybe the superstring phenemenon in theoretical high-energy physics is NOT an aberration in the current world of science,
but

is an example of a more general phenomenon in which a given approach obtains by successful lobbying a dominant position with respect to funds and jobs, and then continues to expand, cancer-like, whether or not any real productive results are ever obtained.

For example, consider AI (artificial intelligence) and a 25 September 2006 article by Andrew Orlowski in the Register at http://www.theregister.co.uk/2006/09/25/bogus_ai/ which article says in part:

"… MIT's Professor Marvin Minsky's … linguistics-based approach to AI, symbolic AI, triumphed in the grants lotteries over an approach which preferred to investigate and mimic the neural functions of the brain. Minsky's non-stop publicity campaign helped ensure his AI lab at MIT was well-rewarded while neural networks starved. …

The Japanese … poured hundreds of millions of dollars into their own AI project, called Fifth Generation. They may as well have buried the money in the Pacific Ocean. Two decades later there are no intelligent robots, and "intelligent" computers are a pipe-dream. …

For the past week reports have again confidently predicted intelligent computers are just around the corner. Rollo Carpenter['s]… chatbot Joan won an annual AI prize for creating software that most resembles a human … Here's Joan, cited at the MIT's Technology Review … :
Judge: So what you're saying is that you are not just human but THE smartest human?
Joan: Yes, why, what did you think I was saying? …
Judge: How many degrees in a triangle?
Joan: 180 degrees.
Judge: Is it possible for more than 180 degrees to be in a triangle?
Joan: Probably not. You can change your opinion, but not your constitution.
Judge: It's not a question of opinion, it's a matter of physics and maths.
Joan: A five-ounce bird could not carry a one-pound coconut. …

Occasionally Joan will ask the interrogator if they are a robot, or chide them for being stupid. These are all pre-programmed rhetorical tricks. They may bore or bamboozle an interrogator, but this is no indication of intelligence. …".

It seems to me that the Minsky-worshipping AI community is similar to the Witten-worshipping SuperString community in at least the following ways:
1 – using PR-type publicity to get and maintain dominance in funding and jobs;
2 – starving competing approaches;
3 – no real results after two decades;
4 – calling critics "stupid" (AI using a computer program that is merely, as the Register article says,"a database of conversational snippets", while SuperStringers are using a Harvard physics professor).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – I am NOT saying that "artificial" intelligence is not possible (for example, maybe it could be achieved by closely studying the way the brain works and applying the results of those studies, or by using arrays of quantum computers, or by a combination of both such approaches, etc). I AM saying that it appears that the Minsky-type approach seems to have many of the same dysfunctional characteristics as SuperString Theory.

27. **Alejandro Rivero**
September 26, 2006

we'd just give them all tenured jobs at 18 and let them do whatever they feel like.

I agree with this. I think this was the goal, if any goal can be claimed, of the university uprising in Paris 1968 (also Madrid 1965 and others): never finish the university career, keep always being an student (and get food and shelter).

Also Peter, er, Kropotkine suggested to limit the job requeriments at a maximum of five hours per day, so the rest of the time can be dedicated to science or other leisures. This could be a solution of some appeal for the people forced out of academy but still interested: to try to arbitrate for non-research but part time jobs in the understanding that the rest of the day -say, the evening- one can keep research activity holding the same rights (travel, computer access, conferences, use of desk, coffee and blackboards) that a full time research professor.

28. **a**
September 26, 2006

Peter,

You say job prospects for math graduate students is very good, but how do number of applicants in math grad programs compare to that of applicants in physics programs. Perhaps there are lot less students applying for math programs? However, I think situation in physics (no. of jobs and no. of wanna-be physicists) is much better than humanities where apparently one needs to be already quite accomplished to get into graduate programs.

29. **Peter Woit**
September 26, 2006

a,

I didn't say job prospects for math Ph.Ds are very good, just that they're quite a bit better than for particle theorists. I don't know of any significant difference in how hard it is to get into physics and math graduate programs. I also know of no evidence that it is harder to get into graduate programs in the humanities. Again, what is at issue here is the very bad job situation in one particular subfield of physics, particle theory. The situation in math and in other subfields is mostly much better.

30. **TheGraduate**
September 26, 2006

a,

The job situation isn't that great for math PhD's as far as I understand it. The AMS has yearly reports so if you google a little bit you should find articles in the Notices about it.

There is a general oversupply of science PhD's and this keeps wages down not just for professors but for post docs and graduate students and research assistants both in the universities and in industry.

I think this state of affairs is not something the universities really have any incentive to address in any way whatsoever.

I know that people will eventually stop being interested in science as the bad career prospects become more generally known. The computer science departments have already had catastrophic losses in popularity.

31. **Stefan**
September 26, 2006

To All:

Does anyone here happen to know the current prospects for (any of the following):

a) computational science / mathematical programming;

b) software engineering / consultancy;

c) computer science;

d) computer hardware / electrical engineering and related;

e) biophysics;

f) physics-related Wall Street type jobs (is it called 'actuarial science' by any chance)?

Stefan

32. **Patrick**
September 26, 2006

Stefan,

I got lucky and am in my 2nd year in a tenure track position in biophysics. From my experience during my job search it seems to me that, if your goal is a tenure track position at a research university, the job market is pretty awful across the board. Part of this may be due to the fact that the biological sciences flood the market with Ph.D.'s to an even greater degree than physics. During 3 rounds of searching (3rd time's a charm), I interviewed at Chemistry, Physics, Biochemistry, Biophysics and Molecular Biology departments (all told I must have sent out >200 applications). On average there were ~300 applicants for every position and I'm told that this is normal.

Overproduction of Ph.D.'s is a problem in all of the sciences. Personally I think that part of the answer is to ecourage the creation of research options other than the holy grail of the tenure track position. Some of the most talented people I know simply want to do research and don't want the hassle of running and funding a whole group. As it is there are very few places for these people. The current system essentially forces you to find a tenure track job within a certain amount of time after your dissertation or else leave academic science entirely. I'd like to see the creation of more quasi-permanent research associate type positions. That way a person could pursue research and enjoy a reasonable degree of job security without landing one of the few available faculty positions. I suspect that science has lost a great deal of talent due to the "up or out" philosophy. And let's face it, the skills that make you good at building and funding a research group are not necessarily correlated with the skills that allow you to do important and original science.

September 26, 2006

Stefan,

Concerning the outlook for engineering, I found this webcast very interesting: http://mitworld.mit.edu/video/321/
(I hear one can hire 10 Indian engineers for the price of one American one.)

34. **Timothy Clemans**
September 26, 2006

Andrew Wiles (algebraicnumber theorist) and Edward Witten (mathematical physicist) should write an article together about their work and lives as academics who have had a profound impact on their subject. There's a really good book on becoming a mathematician called A Mathematician's Survival Guide: Graduate School and Early Career Development which I've read at the UW Mathematics Research Library. I really like Dr. Woit's biography of Edward Witten in his book exspecially the idea that he might be from outerspace, because he disappeared on Dr. Woit.

35. **Peter Woit**
September 26, 2006

Timothy,

I certainly think it would be great if Witten would write a memoir about his professional life, that would be fascinating. The part in the book about Witten possibly being from a superior race of non-humans was a joke (I think…)

36. **TheGraduate**
September 26, 2006

Patrick,

I think all the signals seem to suggest that the US is planning to buy its science from China and India one day. Everything seems to point to significant overfunding of 'stuff' (super computers, huge new buildings etc) and significant underfunding of people.

Tim:

The survival guide is excellent. Krantz is interesting … kind of ideosyncratic … naming some of his hypothetical people in the book after porn stars etc … last information that I saw on him, he was working on the mathematics of plastic surgery

37. **Timothy Clemans**
September 26, 2006

Dr. Woit,

I liked your reason for the thought because it sounded reasonable and it was a little fun part to read. A mention of a person thought to maybe teleporting when no one was thought to be watching in a non-fiction book about the wonderful connection between physics and mathematics and the problems with string theory was a great thing to put on paper especially since it was Witten.

What I don't understand about Witten is why he believes that he can conclude that strings and extra-dimensions do exist and that tring theory is testable. To me it he is taking Einstein's view that General Theory of Relativity was just too beautiful to be wrong and applied it string theory which can be made to say just about anything. Couldn't someone have overlooked the mathematics and missed something like what happened with Andrew Wiles when Nick Katz was reviewing his argument for the construction of an Euler system to give the precise upper bound for the size of the Selmer group, in 1992? – http://www.pbs.org/wgbh/nova/elegant/view-witten.html

38. **Timothy Clemans**
September 26, 2006

If Witten writes a memoir about his professional life, I hope he talks about how he was able to conclude that strings really exist.

39. **Peter Woit**
September 26, 2006

Timothy,

I've never heard Witten claim that string theory in its present state is testable, or that he is sure strings exist. As far as I know, his point of view is that string theory is an idea worth pursuing for various reasons, in its present state it may very well be wrong, but there is enough interesting structure to what has been learned about string theory to believe that it is somehow connected to reality.

There may very well be something crucially wrong in the standard arguments about string theory. Unfortunately the theory is not precisely defined the way Wiles's argument was, so you can't just go through it and look carefull for holes in the argument. The problem is that there are lots of possible holes…

40. **lostsoul Ph. D.**
September 26, 2006

Maybe the Simons model is the way to go: make some money by deploying the natural smarts characteristic of the profoundly numerate, then get down and do what you want. (Did Gibbs do this?) All told, though, this looks like a harsh option; to be at once both Gauss and Brunswick, or Hardy and Ramanujan? Maybe science will revert to the hobby status it had 200 years ago. That, at least, would weed out the supernumerary doctors among us.

41. **Carl**
September 26, 2006

The hilarious part of all this is that right after hearing a bunch of academics complaining about how hard academic jobs are to obtain because of excessive competition, they go into what crappy jobs they are in terms of pay and work hours. You'd think that a freshman class in economics would correct their thinking, but I figure that what they really need is a couple years hard work in the real world.

42. **Timothy Clemans**
September 26, 2006

"NOVA: It seems like the standard criticism of string theory is that it isn't testable. How do you respond to that criticism?

Witten: One very important aspect of string theory is definitely testable. That was the prediction of supersymmetry, which emerged from string theory in the early '70s. Experimentalists are still trying to test it. It hasn't been proved that supersymmetry is right. But there is a very precise relationship among the interaction rates of different kinds of particles which follows from supersymmetry and which has been tested successfully. Because of that and a variety of other clues, many physicists do suspect that our present decade is the decade when supersymmetry will be discovered. Supersymmetry is a very big prediction; it would be interesting to delve into history and try to see any theory that ever made as big a prediction as that."

"NOVA: Do you think it's possible that string theory will turn out to be wrong, or at least some branch of knowledge that just isn't connected to nature?

Witten: I guess it's possible that string theory could be wrong. But if it is in fact wrong, it's amazing that it's been so rich and has survived so many brushes with catastrophe and has linked up with the established physical theories in so many ways, providing so many new insights about them. I wouldn't have thought that a wrong theory should lead us to understand better the ordinary quantum field theories or to have new insights about the quantum states of black holes.

The question reminds me a little bit of the question about interpreting fossils. When fossils were first explored 100 or 200 years ago, some people thought they were traces of past life that had survived in the rocks and others thought that they had been placed there at the creation of the universe by the creator in order to test our faith. So I guess string theory might be wrong, but it would seem like a kind of cosmic conspiracy."
– http://www.pbs.org/wgbh/nova/elegant/view-witten.html

43. **Timothy Clemans**
September 26, 2006

Dr. Woit has Witten said anything about your book?

44. **Peter Woit**
September 26, 2006

Timothy,

I didn't realize that Witten had ever made that definite a claim string theory was testable by looking for supersymmetry. It would be interesting to know if he still would claim this, will also be interesting to see what he has to say after the LHC results are in, if they don't see supersymmetry. He could try and weasel out of his claim by saying that the supersymmetry breaking scale might just be higher than can be observed at the LHC, but that kind of non-straight-forward slipperiness doesn't normally seem to be his style.

Maybe he will finally admit that string theory doesn't work if the LHC doesn't see supersymmetry.

I sent him an early version of the manuscript, he wrote back with some comments, basically saying he disagreed with me, but that there were a lot of books out there he disagreed with. He also gave some of the standard arguments for supersymmetry and string theory, but he didn't claim that string theory was testable by looking for supersymmetry. This was now a couple years ago, I haven't discussed this with him recently.

45. **Timothy Clemans**

September 26, 2006

Okay now I'm just confused. Is Witten saying that if he assumes that strings exist then one of the conclusions is that there are extra-dimensions? If so then why does he implie that the existence of strings is very likely because otherwise it would seem like nature was playing tricks with us?

46. **Peter Woit**
September 26, 2006

Timothy,
If you want to know more about the standard story about string theory that Witten is one of the main people responsible for promoting, you should read one of the many books on the subject, like Brian Greene's, which answer questions like yours.

47. **woit**
September 26, 2006

Timothy,

You're kind of taking over this comment section, please stop.

48. **Gina**
September 26, 2006

Thanks, Peter, for the explanations. On the third point you wrote

"Actually, the bootstrap program did fail as a theory of the strong interactions, and was pretty much killed off by QCD. Many of the people who worked on it certainly admitted that it failed, other die-hards never did admit this, but stopped being taken seriously by most theorists. Certainly some things learned from this were ultimately useful, but the program failed to do what it was intended to, and sensible people admitted this. "

Let's take the analogy between string theory and the "bootstrap pogram" a little further. Judging from your attitude towards string theory, it looks that you would have expected proponents of the "bootstrap program" to admit failure even *before* an alternative successful theory (QCD) came along. This seems unreasonable.

It looks that the "bootstrap program" was a reasonable line of attack before QCD and had important contributions in any case. (You can thus say that Chew and the bootstrap people's were "false" but they were not "wrong" in the sense that these people did, as scientists, the right thing.)

Moreover, a theory "like" QCD as the solution
for strong interaction was something people considered.(In NEW you described how Gross almost succeeded to prove this task is impossible… just before he proved it being possible.) So for the case of strong interaction there was a reasonable alternative possibility of some quantum field theory being successful. Some people declared prematurely) this possibility as dead (from reasons that were and probably still are of some interest and value), but they were wrong.

On the other hand for the case of string theory there isn't really any "shelf" alternatives so this makes the situation even more favorable to string theory.

49. **TheGraduate**
September 26, 2006

Peter,

Could you take a moment to define the 'bootstrap program' ? If I'm not mistaken bootstrap is a bit of bayesian statistics which also seems to be the thinking behind the landscape. Can you discuss the relationship between the bootstrap program and the Landscape if there is one?

More press coverage of NEW and TTWP in today's New York Sun.
It pains me to see Professor Sir Martin Rees so unashamedly anthropic.

53. **Bee**
September 27, 2006

Hi Peter,

well if Holt doesn't read my blog, he should 😉

Maybe because I'm older than you I'm less of the opinion that the problem is inherently in the judgment of senior people. As far as pushing people into working on bad ideas about string theory (or other trendy subjects), I just don't see that it's mainly the older people doing this.

True, I didn't mean to blame age reasons. The problem is the judgement of established people who are in the power of selecting newly employed candidates. This however comes most often with an age gap. That doesn't mean though that this necessarily has to be the case, and I know several quite notable exceptions myself.

Then there is the issue of inertia. One person doing research might be willing and flexible enough to readjust his/hers projects over time. A group is less likely to do so. The larger the group the stronger the resistance to change. String theory is a prime example, but not the only one. It's not even a problem of science in the first place, but you'll find it in other fields as well. E.g. politics. How many of our current problems are caused by a generation of politicians who just keep doing what has been done, because that's what always has been done, and refuse to realize that things have changed dramatically in the last decades?

Best,

B.

54. **JPL**

Gina:

*Let's take the analogy between string theory and the "bootstrap pogram" a little further. Judging from your attitude towards string theory, it looks that you would have expected proponents of the "bootstrap program" to admit failure even *before* an alternative successful theory (QCD) came along. This seems unreasonable.*

Actually, unreasonable or not, that is more or less what took place. After the GWS model for Weak Interactions came along and Neutral Current experiments backed its perdictions, people began to believe that Strong Interactions were most likely also understood by a Yang-Mills theory (Sakurai had tried this in the early sixties before the Higgs mechanism came along); Deep Inelastic scattering experiments had essentially shown that quarks were massless point-sources at high energy which contradicted the whole "microphysical democracy" spirit of the bootstrap. By the late sixties early seventies the analytical S-matrix school had essentially lost steam even before assymptotic freedom was understood and QCD fully recognized.

Today we may be going through a similar stage where String theorising is losing steam on its own even if no obvious alternatives have been "shelved", as you put it! One thing does not imply the other, I am afraid.

55. **jeremy**
September 27, 2006

Peter,

This is a review on NEW, sort of.

http://www.nysun.com/article/40425

56. **Thomas Love**
September 27, 2006

Max Planck wrote:

An important scientific innovation rarely makes its way by gradually winning over and converting its opponents: it rarely happens that Saul becomes Paul. What does happen is that its opponents gradually die out, and that the growing generation is familiarised with the ideas from the beginning.
(New York 1949).

Unfortunately, his statement is true about untrue "innovations". Many of the major opponents of string theory are dying and leaving string theorists in charge.

The people who need to read NEW are the people who control the purse strings. Cut the financing and we will be able to hear the rest of the orchestra (good music requires more than strings).

57. **Gina**
September 27, 2006

WHY THE EMPHASIS ON TWO DIMENSIONAL MODELS?

Peter wrote

" It is the precise expression of the mathematical relationship of representation theory and QFT that has been worked out in recent decades in two dimensions, exactly the thing that I would argue we should be trying to understand in the physical case of four dimensions."

Indeed one very nice point raised in Peter's book is the fact that many of the successes of physics and mathematics related to string theory and earlier physics are coming from two dimensional model. I asked around among my friends:

" Why can't you do anything as impressive for D>2, after all nobody, not even strings theorists claim that our universe has two dimensions? "

It seems that for D>2 scientists are simply stuck and things look very gloomy. "Arn't there any ideas around," I asked. Well, there are a few. One guy told me with a spark in his eyes about an idea to move directly from D=2 to D=4 and to base models on "homological" notions which will extend important "duality" properties for planar model. He talked about things like "Poincare duality" and "signature" and was quite excited but then admitted that these are all just ideas. (I guess this is the same old Poincare.) Another guy had much hope from representation theoretic extensions of notions from conformal analysis which are prominent for two dimensional models. But this is also in a very premature state. A third guy praised the "Heisenberg Lie group" as a place to "be in high dimensions and to feel in two dimensions".

There are ideas but overall there is some feeling that studying higher dimensional models is a waste of time. Some of these guys actually spent a lot of time and got nowhere.

I tried to be tough on them and I asked if sticking to the cozy D=2 and looking for the coin under the lamp is all about the summer salary.

"No, Gina" they said "this is not the reason". They said they simply do not know what do. They need a tip of a string to hold to in order to start (Often it turns out they just hold their own shoe laces). In this case they have nothing, they said. The are quite savvy in failures they said. But doing D>2 leads to "not even a failure". They did sound convincing but you never know with these wise guys.

USEFUL DIVERGENT SERIES

Peter wrote to my question: "Some divergent series are "asymptotic" approximations to some function, which means that, at a fixed order, the truncated series is a better and better approximation to the function as the expansion parameter gets small (even though, at fixed small parameter, as you go to higher order, the series sooner or later diverges). The perturbation series for QED is supposed to be such an asymptotic expansion. This kind of divergent series can be quite use ful, giving very good approximations."

Hmmm, this sounds very good indeed. A sort of "Calculus I" way I can think about such a thing of a function which is described at any point by a useful divergent series is that the terms of the series are themselves only approximation to a correct description of the function by a convergent series. (and these approximations are worse and worse for higher terms in the series.) Is this naive way to look at it reasonable? Is there a better intuition for what these useful divergent series are?

UNIFORM OPINIONS

Peter asks in the book if mathematician will regard superstring theory as mathematics and writes: “They [mathematicians] would uniformly say: ‘certainly not!”

I do not know about mathematicians attitude about string theory but judging from my experience with mathematicians, I think that no set of mathematicians will have a uniform opinion about ANYTHING.

Just to make the mathematicians reading this absolutely happy let me state this deep insight more carefully

Every set of mathematicians will not have a uniform opinion about any issue except possibly for the following cases

1) It is the empty set of mathematicians

2) It is a set of a single mathematician over an infinitesimally small amount of time

58. **Thomas Love**
September 28, 2006

Gina Says:

WHY THE EMPHASIS ON TWO DIMENSIONAL MODELS?

As a PhD mathematician, I know the answer: because the math is easier there.

Gina, you and quite a few others seem confused about the meaning of higher dimensions. Think of a dimension as an entry in an inventory form; how many numbers are required to describe the situation? (the standard reporter questions) Clearly, we need to know where and when (x,y,z,y), but we also need to know the field strengths, electric, magnetic, gravity. etc. Each of those require another entry in the form, i.e. a dimension. We also need to know the field strength due to the presence of electrons, protons, neutrinos, pions, etc (some of thse numbers may be redundant). The list becomes interesting only when we can weave it into one coherent whole, one geometry. Then Einstein’s vision of particles emerging from geometry would be realized. After Ed Witten spoke at the 1987 AMS meeting in Salt Lake City, I asked him if strings emerged from the geometry or had to be imposed. He said they were imposed. I knew then that string theory would lead no where.

59. **Gina**
September 28, 2006

” Gina, you and quite a few others seem confused about the meaning of higher dimensions.”

You bet! I am very confused!!!

Anyway, I just wanted to say that people do try to study lattice models and other models for D>2 but somehow do not find there the miracles found for D=2 and they say it is very difficult.

60. **Roger Schlafly**
September 29, 2006

Peter, don’t let Motl bait you into name-calling. His name-calling makes him sound like someone who is upset because he has been exposed for what he is.

61. **Peter Woit**
September 29, 2006

Roger,

Thanks, the advice is good, but all I did was refer to him as “sensible”….

62. **Charles**
September 30, 2006

Dear Dr. Woit,

However much you might disagree with string theory, how can you justify endorsing an article written by a man who thinks that finding a final theory of everything will by an irrelevance hardly noticed by science.

You and Smolin give the outward appearance of caring very deeply about this subject, the solution to which could rightly be called the greatest scientific discovery of all time.

I understand you might have given the interviews in good faith, but I do not understand why you don’t wish to distance yourself from this man’s views. Instead, you proudly link to his text.

Is it the money from promoting the book? Or is your vendetta against the string community worth bringing down the whole of physics with it?

When physics is reduced to a branch of sociology in the public’s eyes, things like this happen. You and Smolin bear some of the responsibility.

63. **Charles**
September 30, 2006

My “this” link does not appear to work. It is supposed to link to an announcement made last week from Reading University, UK that they are closing down their physics department due to lack of students interested in physics.

64. **Peter Woit**
September 30, 2006

Charles,

I actually had nothing at all to do with the New Yorker article, never talked to Jim Holt and didn’t “endorse” what he writes, other than to note that he mostly gets his facts right. The last line of his text that you object to so strongly is just making the obvious point that most of science is decoupled from the details of any unified TOE. Go talk to any biologist and ask them what the impact of a TOE would be on their research work.

Your claim that the publication of my book and Lee Smolin’s this month are partially responsible for the closing of the Reading University physics department is just hysterical and absurd. Both Smolin and I care deeply about the field of fundamental physics and its health. We wrote our books not to make money (I'll remind you that mine was originally intended to be published by a university press, and was not aimed at the general public, but string theory referees stopped that), but because we are concerned about what we see as a crisis in the field and how it is being pursued. We're not the ones who created the crisis. You seem to think the answer to it is shooting the messengers.

65. **nigel cook**
September 30, 2006

By the way, my nearest university physics undergraduate-teaching department closed: see http://www2.essex.ac.uk/physics/ for the remains of the department and what it now does.

For the CAUSE of the decline see http://www.tes.co.uk/2268414

'… A-level physics entries fell 49.5 per cent between 1982 and 2005, from 55,728 to 28,119. Meanwhile, the proportion of 16-year-olds studying A-level physics fell from 6 per cent in 1990 to 3.8 per cent in 2004.'

See also http://www.google.co.uk/search?hl=en&q=A-level+physics+decline&meta= for much more info.

This correlates with string theory's rise to fame, not Peter Woit's activities (Not Even Wrong was only set up new in March 2004).

Stephen Hawking and other string supporters do raise public awareness of string theory to great heights in the UK, and physics books sell, but people don't study physics. Maybe there is a fear of extra dimensions and wormholes … or maybe they just don't believe it without some evidence.

66. **Who**
October 2, 2006

I've been looking for a way to gauge sales of NEW in the UK and found this:

http://www.amazon.co.uk/gp/bestsellers/books/278434/ref=pd_ts_b_nav/026-8303087-5718006

this is the UK amazon bestseller list in the "particle and high-energy physics" subcategory of "physics" in "nature and science"

as of Monday 2 October 1:00 PM eastern, when I looked, Not Even Wrong was #1 on that UK bestseller list

the UK edition of Smolin's book is scheduled to come out February 2007—as of now UK amazon is not selling the Smolin book, it simply refers potential customers to overseas dealers, presumably because this saves market for the UK edition next year.

interestingly at least at the moment with NEW #1 on the UK list, it is leading a number of other books with mass appeal such as Warped Passages (#5 on the list) and two of Brian Greene (Elegant, which is #13, and Fabric, which is #16)

I have no idea how this translates into numbers of copies sold, but it represents a strong comparative showing—-the other titles being aimed at a broader less technically sophisticated audience.

67. **Who**
October 3, 2006

to correct something I said yesterday,
as of today UK amazon is selling Smolin's book directly instead of referring the customer to overseas distributors
http://www.amazon.co.uk/Trouble-Physics-String-Theory-Science/dp/0618551050/ref=pd_bxgy_b_img_b/026-8303087-5718006?ie=UTF8

the price is 13-some pounds and the book is paired with Peter's book in a package deal for 26 pounds.

this is not how it was yesterday—then it looked like UK amazon was going to wait for the UK edition to come out in February. perhaps there was a cataloging error in the computer.

so far there are not many reviews of Smolin's book at its UK amazon page, only two that I saw

68. **Who**
October 6, 2006

after 3 days of selling the book, during which it shot up to #6 on the UK amazon physics bestseller list, and to the #2 place on the the narrower "general physics" list, UK amazon stopped taking orders.

It is now no longer selling the book but instead gives a link to some distributors in the USA where it can be ordered—this is back to how it was before 2 October.

it could be a "publisher turf" thing, or some hitch in logistics. for those three days UK amazon was trying to serve as a relay—"order it from us, we will get it from overseas and ship it to you" in an estimated 1 to 2 weeks. They did not have the book in stock. Probably got more orders than they could reasonably handle in that fashion.

Release of the UK edition of Smolin's book is planned for February 2007. I forget who the UK publisher is. The cover is not that nice electric blue color, so I reckon the US edition is way preferable and would recommend Brits order from overseas. 🙂

69. **Who**
October 10, 2006

I occasionally check the UK amazon physics bestseller list and have been seeing Peter's book at the top of it frequently during the past week or so, for instance today at 7 AM pacific, which I suppose is 2 PM greenwich

1. Not Even Wrong: The Failure of String Theory and the Continuing Challenge to Unify the Laws of Physics
by Peter Woit 1414

2. Wiring Systems and Fault Finding: For Installation Electricians
by Brian Scaddan 1824

3. The Illustrated Brief History of Time

by S.W. Hawking 1927

4. Physics (Revise AS & A2 (Combined) S.) 1935

5. God and the New Physics
by P.C.W. Davies 2197

6. The Mind of God: Science and the Search for Ultimate Meaning (Penguin Press Science S.)
by P.C.W. Davies 2205

7. University Physics with Modern Physics with Mastering Physics (International Edition)
by Francis W. Sears 2212

8. The Fabric of the Cosmos: Space, Time and the Texture of Reality (Penguin Press Science S.)
by Brian Greene 2550

9. The Art of Electronics
by Paul Horowitz 2705

the fourdigit numbers are store-wide sales rank, among all book sales.
the physics list, initial segment shown here, is obviously quite broad and includes exam review, pop phys, god-and-wonder, electronics, audio, straight physics textbooks. Yesterday it had a Terry Pratchett. And of course it has Brian Greene and Stephen Hawking. One can ask how a serious scholarly work like Peter's gets to the top of such a list.

2006 Nobel Prize for Physics

September 26, 2006
Categories: Uncategorized

No, I don't have any idea who will win this year, but the announcement will be a week from today, on Tuesday October 3. After my initial success in Nobel Prize prognostication, I've now retired from that game, but encourage others to play.

Comments

1. **Tommaso Dorigo**
   September 26, 2006

   I would vote for Giorgio Bellettini (with a few possible others) for the top quark discovery. Wishful thinking of course, but who knows ?

   And I know I am biased, but I think the man would deserve it for his lifelong effort, which indeed culminated in the CDF 94 evidence and then CDF-D0 95 observation.

   Cheers,
   T.

2. **Shantanu**
   September 26, 2006

   I would say someone from the COBE team for discovsering anisotropies in the
   CMB. This year they got the Gruber prize.

3. **Peter Orland**
   September 26, 2006

   The evidence for the acceleration of the expansion of the universe is now quite good. Why not someone involved in the supernova red shifts?

4. **BobD**
   September 26, 2006

   I think the COBE team did a beautiful job, but in my view they simply confirmed existing expectations.

   I consider the evidence for an accelerated expansion as still iffy, though that result remains an electrifying possibility. However I wouldn't bet against some recognition of dark matter this year. Though Zwicky is gone, Vera Rubin is still quite active…

5. **Jimbo**
   September 26, 2006

   Has everyone forgot ? Alan Guth (& probably Andre Linde) were smiling the entire week the WMAP 3rd yr. observational reports were announced. Alan is a shoe-in, & perhaps Andre as well.

6. **Analyzer**
   September 27, 2006

   Alan Guth (& probably Andre Linde) were smiling the entire week the WMAP 3rd yr. observational reports were announced. Alan is a shoe-in, & perhaps Andre as well.

   Pffft, no way. WMAP's results have kept inflation healthily afloat, but it's hardly as if the matter is closed and inflation is proven. The evidence for dark energy is more convincing, and even that is not up to Nobel snuff; the prize committee goes for sure things, often many years or decades after the actual research was done and after everyone agrees on the results.

   I don't know enough about the entire range of subfields of physics to make a guess, but the last few years looked like this:

   2005: Quantum optics
   2004: QCD
   2003: Superconductivity/superfluidity
   2002: High-energy astrophysics
   2001: Bose-Einstein condensation
   2000: Semiconductors
   1999: Electroweak interactions

   Draw what conclusions you will, but remember, when you cast your prediction, that there is more to physics than particle physics and speculative cosmology.

7. **Relativist**
   September 27, 2006

   Well firstly it won't be a string theorist (at least not for their work on string theory).
   The two outstanding ones not yet given:
   – Higgs, Yang and Mills for the Higgs particle and Yang Mills theory (Yang has it for parity but not for Yang-Mills – I assume it is the same Yang?) But maybe also Goldstone? Higgs and Goldstone one year, Yang and Mills another?
   – Aharonov and Bohm for the Aharonv Bohmn effect. Well Bohm is dead but Aharonov is still alive I think.

8. **Thomas Larsson**
   September 27, 2006

   If the Higgs is discovered, there will probably be two rapid prizes: a theoretical one to Higgs, Brout and Englert (Polyakov and Migdal probably not), and an experimental one for the actual discovery. But we are not there yet.

My personal favorites are Belavin-Polyakov-Zamolodchikov for the application of CFT to statistical physics, but I'm sure that they won't win this year neither.

9. **David Cobden**
September 27, 2006

With Aharonov they'd have to include Michael Berry of Berry's phase, which is a more general concept and surely deserves a prize in its own right.

10. **ObsessiveMathsFreak**
September 27, 2006

The guys who created the Bose-Einstien condensate deserve some kudos. That was a top class piece of experimental physics.

11. **A**
September 27, 2006

To Tommaso: not discovering the top would have deserved a Nobel prize. Discovering that top (or its right-handed component) is composite would deserve a Nobel prize. But, so far, discovering the top with the expected charge, expected strong interactions, expected weak interactions, expected spin, expected mass (from precision data) and expected name is not interesting enough.

12. **Navneeth**
September 27, 2006

ObsessiveMathsFreak,
http://nobelprize.org/nobel_prizes/physics/laureates/2001/index.html

13. **JK**
September 27, 2006

Eli Yablonovitch and Sajeev John for the theory of photonic crystals. Although 3D crystals are found in nature and 2D crystals are already technologically important, perhaps the prize will wait for an experimental synthesis of 3D crystals.

Victor Veselago and John Pendry for theory of negative refractive index. David Smith for experimental realisation.

14. **sean m.**
September 27, 2006

i have to second michael berry (and perhaps aharonov). this has been wildly influential work in condensed matter.

15. **ksh95**
September 27, 2006

JK says:

> perhaps the prize will wait for an experimental synthesis of 3D crystals.

They have been making 3D crystals since the very begining. Jesus man; experimentalists are infinitely more capable than that. 3D photonic Crystal fabrication is an undergraduate project at a low level non-research institution.

Anyway I dont think Photonic Crystals are Nobel worthy. It's basically only classical field theory in periodic space.

Try supersolid

16. **ksh95**
September 27, 2006

Analyzer says

> but remember, when you cast your prediction, that there is more to physics than particle physics and speculative cosmology.

Yes people, remember that the blogosphere does not represent the average physics department…In fact, I'm reasonable confident that the majority of physicists specialize in condensed matter.

17. **Belizean**
September 27, 2006

David Deutsch, founder of quantum information theory. Primitive quantum computations have been performed in labs. So you have an important theory confirmed by experiment.

18. **Zelah**
September 27, 2006

Hi!

The only outstanding candidates spoken about here are
M Berry and V Rubin!

My vote is for V Rubin, but the Crafoord prize 2005 was awarded James Gunn, James Peebles, and Martin Rees for Dark Matter (in my opinion scandalous!). So I do not have much hope.

Onto M Berry. The problem is that who would he share the prize with?

Does anyone care about Statistical Mechanics? And anyway, there is the small problem of R Baxter, McCoy, Wu et al……

Expect the unexpected!

Zelah

19. **Christine**
September 27, 2006

The evidence for the acceleration of the expansion of the universe is now quite good.

There are some evidences, but they are not unquestionable. For instance, we first must learn much more about Type Ia supernovae.

Christine

20. **DMS**
September 27, 2006

Yoichiro Nambu.

21. **Bee**
September 27, 2006

I'd also put my bet on WMAP/CMB, exact measurement of parameters in LambdaCDM, esp confirmation of cc nonzero. I don't know though who'd be the person to name.

22. **A.J.**
September 27, 2006

Nambu may deserve a Nobel, but I'd be surprised if he gets it this time around. He'll probably have to wait till after the LHC turns on.

23. **A Babe in the Universe**
September 27, 2006

I echo Kea and Christine in that evidence for inflation and cosmic acceleration is still shaky. The low-l data rules out inflation's prediction. Evidence for acceleration is based entirely upon redshifts.

24. **Dick Thompson**
September 27, 2006

Fadeev and Popov, who showed how to quantize gauge theory and discovered the "ghosts".

25. **King Ray**
September 27, 2006

Peter Woit and Lee Smolin for their efforts on behalf of the welfare of theoretical physics.

26. **Jeff**
September 27, 2006

How about Paul Ginsparg for his contribution to the development of physics?

27. **Renormalized**
September 27, 2006

Belizean Says:
"David Deutsch, founder of quantum information theory. Primitive quantum computations have been performed in labs. So you have an important theory confirmed by experiment."

Do you have a link to this experimental evidence? I don't believe quantum computations have been verified.

28. **CYD**
September 27, 2006

David Pines for plasmons and the random phase approximation, and Conyers Herring for spin waves and the orthogonalized-plane-waves method in solids.

29. **Tommaso Dorigo**
September 27, 2006

A said:

"not discovering the top would have deserved a Nobel prize. Discovering that top (or its right-handed component) is composite would deserve a Nobel prize. But, so far, discovering the top with the expected charge, expected strong interactions, expected weak interactions, expected spin, expected mass (from precision data) and expected name is not interesting enough"

Dear A,
I do not think some thing has to be intrinsically unexpected to deserve a nobel prize. The top quark discovery was largely expected, but it involved two decades of searches, at least one published wrong observation (UA2 1987), and theoretical predictions for the mass which scaled with the experimental lower limits for quite a while. The CDF experiment was conceived in 1980 or so, built by 1985, started taking data in 1987, saw the first top event in 1988, and had to be upgraded with a silicon detector to find the elusive top, whose mass kept it unreachable otherwise. I think the overall achievement of observing a picobarn-sized signal in collisions occurring with cross sections of 60 millibarns is quite a feat, and the people responsible for the discovery deserve recognition.
Cheers,
T.

30. **Belizean**
September 27, 2006

Renormalized,

Here's one that took 10 seconds to with Google:

http://domino.watson.ibm.com/comm/pr.nsf/pages/news.20011219_quantum.html

31. **Scott Aaronson**
September 27, 2006

Do you have a link to this experimental evidence? I don't believe quantum computations have been verified.

Small quantum computations have been performed — see here for experimental confirmation that 15=3*5 (with small probability of error). The challenge is scaling up to a nontrivial number of qubits.

Of course, the *interesting* experimental discovery would be a fundamental reason why quantum computing *isn't* scalable!

32. **Florifulgurator**
September 27, 2006

Here´s my tip:

Give it to Mathematical Physics,
not String Theory,
but Knot Theory,
(Knit String Theory would be O.K. for me….)
E.g. Witten or Drinfeld,
or you suggest a 3rd one.
Since Maths works slow,
it would be good to surpass the rule that only living ones be Nobel pontificated,
& sharing the Prize money could be Dadificated (randomized in a certain sense)
e.g. by awarding it to an element of a time-space-brainlard chain of a tree (or Feynman Diagram) of brainlard evolution:
E.g. give it to Witten for the Witten-Jones Generalization (skipping Kaufmann)
or e.g. give it to Drinfeld for his Quasitriangular Quantum Groups (generalizing the Yang-Baxter relations).
…

33. **Florifulgurator**
September 27, 2006

…(cont)
Since both had the Fields medal,
suggested Nobel Prize could probably form a noice antiparticle to Perelman

34. **Douglas Natelson**
September 27, 2006

I'd really enjoy M. Berry and Y. Aharonov. Great stuff. There's also a long-overdue prize to recognize the great materials growers (MBE?). Regarding Conyers Herring, they'd better hurry…. He was not exactly a spring chicken when I was a grad student at Stanford ten years ago. Supersolid is too new and too controversial. For those interested in chemistry, at some point I'd be willing to bet a fair bit of money on Whitesides for self-assembly.

35. **David Heffernan**
September 28, 2006

I'd like to see it go to Kobayashi and Maskawa for their theory of CP Violation. As of this summer the unitary triangle is looking very consistent, and their names have come up before, so I don't think it would be too unexpected.

36. **hongbao zhang**
September 28, 2006

If the prize were given to theory, I think there would be two possilbilities.
1 to C.N.Yang Dyson and Fadeev etc
2 to Hawking and Bekenstein etc

:)^_^

37. **David Cobden**
September 28, 2006

I don't think the prize has ever gone to a theory that was not already experimentally verified to a very high degree, such that it was essentially completely uncontroversial within the physics community. (Is asymptotic freedom an exception?)
Nor I think has it gone to a technical prediction (such as photonic bands) that hasn't already had significant practical consequences. That makes several of the above suggestions seem very unlikely.

38. **Physiker**
September 28, 2006

My bet:

Sir Samuel Edwards.

Among other things:

Together with Phil Anderson (Nobel laureate), he pioneered the replica theory of disordered systems which has found far reaching applications even beyond physics.

Together with P. G. de Gennes (Nobel laureate), he pioneered the field theoretic approach to polymer physics and placed soft matter physics in a solid theoretical foundation.

39. **Patrick**
September 28, 2006

Physiker,

If they gave it to Edwards would they have to include G. Parisi as well?

40. **anon.**
September 28, 2006

A.J. wrote:

Nambu may deserve a Nobel, but I'd be surprised if he gets it this time around. He'll probably have to wait till after the LHC turns on.

What idea of Nambu do you have in mind? I thought some of the people involved in the early development of QCD (Nambu, Bjorken…) deserved a prize, but I don't expect that one to ever be given now that the later development of asymptotic freedom got the prize.

Then there's Nambu – Goldstone, but it's hard to imagine why that would get a prize now since it hasn't in the past. (It is a fundamental idea that's experimentally verified and applicable to all sorts of physics, so it seems as Nobel-worthy as any theoretical development I can think of.)

41. **Kent G. Budge**
September 28, 2006

Since I can't find an email address on your page (probably for good reasons) please indulge me in asking an unrelated question here. I have a Ph.D. in astronomy, and I have some familiarity with the mathematics of the Standard Model, but I'm by no means a particle physicist. Can you recommend a book or books on post-Standard Model theories that would be at my level?

Everything I've found so far seems to be aimed either at nonmathematicians (and is therefore useless for trying to understand the mathematics behind the models) or at people who are almost as knowledgeable as the author (and is therefore an inpenetrable display of how smart the author thinks he is.)

I'm looking for something on the level of Cottingham and Greenwood's "An Inroduction to the Standard Model of Particle Physics,", which I enjoyed immensely.

If you think your own book is in this category, then I'll accept that datum; but my sense is that you have largely avoided formulas. I want formulas, but I want them patiently explained.

42. **A.J.**
September 28, 2006

anon.,

Yes, I was thinking of spontaneous symmetry breaking. Nambu was the first to introduce the idea into particle physics, so he's certainly a candidate for the prize if they find a Higgs boson at LHC. I don't think he's a sure thing though. There were a lot of people involved in the idea. I think Higgs is the only one I'd put money on.

43. **anon.**
September 28, 2006

It seems strange that a Nobel prize for general properties of spontaneous symmetry breaking should be contingent on the discovery of a Higgs boson. The understanding of SSB due to Nambu, Goldstone, and others is amply supported by superconductivity, by chiral symmetry breaking in QCD, and other applications. I would think a Nobel prize for the Higgs should go specifically to people who studied SSB applied to gauge theories; as far as I know, Nambu didn't specifically propose that, while plenty of others did.

I think Nambu and Goldstone probably do deserve a Nobel, but it would seem odd if it were only given now, decades after it could have been. On the other hand, Ginzburg just got the prize recently, so maybe it wouldn't be so unreasonable.

44. **Count Iblis**
September 28, 2006

What about the theory of granular media? This is a relatively new but very important field in condensed matter…

45. **Peter Woit**
September 28, 2006

Kent G. Budge,

My book does contain short descriptions of many ideas about beyond the standard model physics, together with suggestions for further reading about these subjects. I don't know of a single good book of the kind you are asking about. One thing a little bit like what you are asking for is a book by Pierre Ramond called "Journeys Beyond the Standard Model".

46. **Jimbo**
September 28, 2006

Dear Kent,

THE book you're seeking is entitled:"The Ideas of Particle Physics, an introduction for scientists", by Coughlan & Dodd, 2nd ed., Cambridge press, ~ 200 pgs. A good companion book for it(at the same math level, but in more depth) is `Elementary Particles', by Hughes, 3rd ed.,also on Cambridge, ~ 400 pgs. Both are in paperback.

47. **Scott Aaronson**
September 28, 2006

Kent: If you want something more discursive than a textbook, try Penrose's *The Road to Reality*. It doesn't cover the post-Standard-Model theories with any pretense of rigor, but it does have formulas and it doesn't aim low.

48. **Kent G. Budge**
September 28, 2006

Thanks to all for the suggestions. It happens I live and work in Los Alamos, so if the local library doesn't have these works, it shouldn't take much of a nudge from me to get the library to acquire them And there's always the LANL technical library.

I am particularly curious about doubly special relativity. Is it covered by any of these books?

Thanks again. Sorry about the thread hijack.

49. **Jimbo**
September 28, 2006

Kent,
DSR is largely covered by the work of Smolin & Magueijo; just do an arxiv search & I'm sure you can pull up a review article. I don't think its covered in any recent texts.

50. **Kea**
September 28, 2006

I feel there is a Nobel Prize in the WMAP evidence. Of course, the theory must match it accurately. Like Bee, I wonder who the best candidate is?

51. **A.J.**
September 28, 2006

Anon,

I agree that it's weird that Nambu & Goldstone should be made to wait till after the discovery of a Higgs boson. But I can't think of anything else the Nobel committee could be waiting for. Perhaps they prefer to give the prize out for less abstract achievements..?

52. **JoAnne**
September 29, 2006

Kobayashi and Maskawa, for their prediction of the 3rd generation (before it was observed) as a means of explaining the observation of CP violation.

53. **Shantanu**
September 29, 2006

One more possibility which no one has pointed out.
Irwin Shapiro, Pound and Rebka (for proposing & measuring
"shapiro delay" and gravitational redshift of photon which
confirmed GR.)

54. **A**
September 29, 2006

answering to Dorigo: we agree that microvertex is an important technology. But my point was different. An analogy with leptons might clarify it: somebody first detected that nu_tau exist, and somebody discovered their oscillations: who got the Nobel prize?

55. **Physiker**
September 29, 2006

Patrick,

Parisi is one of the fathers of the replica symmetry breaking idea which is still contentious. Edwards-Anderson proposed the replica trick for the treatment of disordered systems which is something more fundamental and more widely accepted (not without critique, though). Edwards' contribution to physics is broader. Together with de Gennes, he transformed into physics what used to be a kind of "stamp collecting" (the study of polymers, membranes, interfaces, etc.).

Someone mentioned granular matter. We still don't have any breakthough of Nobel caliber there, but Edwards' mark in the major developments in the area is clear.

56. **anon.**
September 29, 2006

David Cobden wrote:

"I don't think the prize has ever gone to a theory that was not already experimentally verified to a very high degree, such that it was essentially completely uncontroversial within the physics community. (Is asymptotic freedom an exception?)"

Asymptotic freedom is definitely not an exception. In fact there were good experimental reasons for wanting it to be true before it was theoretically discovered, and the experimental evidence has continually improved in the past 30 years. In fact, Bjorken had proposed a related property called "scaling," which Feynman interpreted in terms of "partons" (small pointlike constituents of hardons). This idea was confirmed experimentally by deep inelastic scattering experiments at SLAC, a few years before asymptotic freedom. These ideas pointed to flaws in the "dual resonance" (i.e. string theory) model of strong interactions. So when asymptotic freedom was found, it was accepted fairly quickly because there was already good experimental evidence.

57. **dir**
September 29, 2006

why not adler et al. for their work on the anomaly?

58. **Count Iblis**
September 29, 2006

A. Belavin, A. Polyakov and A. Zamolodchikov

59. **Peter Orland**
September 29, 2006

Adler and Jackiw won’t get the Nobel because anomalies are mainly used as a guideling for model building. By themselves, anomalies predict nothing. It does help solve the U(1) problem in QCD, but only says why the eta and eta-prime are heavy. There is no way to use the anomaly to compute their masses.

Belavin et. al. won’t get it. Most conformal field theories are testable by computer, not by nature, except a few which are fixed points of models which are solvable anyway.

Baxter and co. won’t get the prize because their work is too specialized to specific theoretical models. Special cases of the 8-vertex model (besides the Ising model) can be realized (I think helium adsorbed onto graphite is well described by the hard hexagon model). This work is not general enough yet.

Anyway, any speculation that the above could win is wishful thinking on the part of theorists.

People can’t get the prize for great mathematical ideas alone, even
if somewhat relevant experimentally. A prizeworthy idea has to solve a crisis in the field or make a stunning experimental prediction.

Perhaps Nambu and Goldstone probably won’t get it for chiral symmetry breaking because Feza Guersey, who is the third person responsible for the idea (he invented the sigma model) is no longer living.

Someone said that the dark energy discover is not yet well established because the type 1a supernova candles can’t be calculated precisely theoretically. This was true some years ago,
but I thought they were now better understood (a stellar astrophysicist would know better). There is also other data, found by completely different means which confirms dark energy, as I understand it. Perhaps it won’t get the Nobel this year, but this work seems prizeworthy.

60. **Haelfix**
September 30, 2006

Another shout for the COBE experimentalist teams, they’re shoe ins for a noble prize at some point (though it might have to wait till Planck).

Vera also will get it eventually, but still too early IMO.

It would be a scandal if Guth and Linde got a prize for inflation, as its an idea and not a specific model (and the original model was falsified). One day in the year 2300 they very well might still have their names on it, but I very much doubt they’ll ever have a Nobel in their lifetime. I can think of several people more deserving for ‘accepted theories but not a specific model’ off the top of my head, including Adler/Jackiw and Hawking/Penrose.

Kobayashi and Maskawa should have received a Nobel a long time ago, but as usual there is some confusion there, so they’re perenial contenders.

I suspect the Nobel will be outside Astrophysics and Particle physics this year again so that ends my 2cents.

61. **A**
September 30, 2006

actually, only very recent B-physics experiments could test if the single Kobayashi Maskawa phase accounts for more than one CP-violating process.
As the result was yes (some anomalies present in past years data largely disappeared), as these experiments are almost completed, as more experimental tests would need many more years, I dare telling omedetoo gozaimasu for the Nobel prize that Kobayashi-Maskawa will get within 3 years.

62. **Ben oit**
October 2, 2006

Anatole Abragam and Richard Geller for their pioneering works on Nuclear Magnetic Resonance and Electron Cyclotron Resonance and their application to Medecine.

Too much criticisms were made against Physics. It has become crucial that people also see that fundamental works also save lives every day !

63. **Paul**
October 2, 2006

I heard some rumor that the prize will be awarded for research in biophysicists; in particular the names of Carlos Bustamante from Berkley (he is apparently a pioneer in single-molecule visualization) and Hermann Gaub from Ludwig Maximilians University of Munich have been mentioned.

64. **biophysicist**
October 2, 2006

Well if Paul is right I (as my name uhh no doubt indicates) would be pretty ecstatic. It’s probably still a little early for biophysics to be awarded physics Nobels, but that day will come (and lest we forget that biophysicists have won biology Nobels and even the Dirac medal already). Also Dr. Bustamante would be totally deserving – his work is inspirational.

65. **Thomas Larsson**
October 3, 2006

My wife thinks that the medicine prize is cool. One of her former students is a postdoc in Fire’s group.

66. **Mark Callaghan**
October 3, 2006

Hi folks – this just in- The Nobel prize for physics goes to Snoot and Mather for their work on the cosmic microwave background

67. **MathPhys**
October 3, 2006

Years ago, I tried to read Smoot’s book “Wrinkles in Time” but found it too boring. Maybe I should try again.

68. **Christine**
October 3, 2006

[Nobel prize laureates 2006]

John C. Mather

and

George Smoot

Congratulations!

Christine

69. **TTT**
October 3, 2006

I cannot believe it. Even schoolkids know that the Russians disovered anisotropy several months earlier using their “Relict” satellite.

So here goes another BS Nobel. What a waste!!:-)

70. **Checkmate**
October 3, 2006

TTT,

Please provide references for your assertions!

71. **Who**
October 3, 2006

COBE is the single most widereaching bunch of results since a long ways back—it is superNobel class.

that oval map of the CMB mottled blue and red for temperature was more ikonic of discovery than the first images of earth from space

it has become the face of the universe

when Smoot and the other COBE team presented the perfect fit of the all-sky spectrum to a perfect Planck blackbody for the first time to an international body of astronomers—-when they showed that slide—there was a standing ovation.

when you have a slide of the blackbody curve with your data superimposed, and it gets the whole IAU to give a standing ovation, it is something.

I only mention this because some misguided person said “BS nobel”.
On the contrary giving Nobel for mapping CMB validates Nobel and is overdue.
==============

simply detecting anisotropy was done using U2 airplane years before COBE, we are not talking about “discovering anisotropy”

please correct me if I have misremembered some facts here, am rushed and dont have time to check

72. **LDM**
October 3, 2006

Who,

Good post.

73. **TTT**
October 3, 2006

I’m retracting my criticism.
Was confused by:

http://hea.iki.rssi.ru/pazh/

Astronomy Letters,
Volume 18, 1992, Issue 5
Anisotropy of the microwave background radiation
I.A.Strukov, A.A.Bryukhanov, D.P.Skulachev, and M.V.Sazhin (pp.387-395)

74. **Relativist**
October 3, 2006

The interesting thing is that they excluded the theorists who first predicted the broad nature of the anisotropy patterns – R K Sachs and A M Wolfe, Ap J (1967).

75. **Relativist**
October 3, 2006

p.s. – Sachs and Wolfe did not predict the accoustic peaks in the power spectrum, but then COBE did not observe those peaks (its resolutin was too low). The peaks were confirmed by later observations (BOOMERANG, WMAP in particular), which will surely now be in the line for a Nobel prize. And again the theorists who predicted those peaks before they were observed will probably get left out. But that was a triumph of cosmological theoretical prediction, confirmed by extraordinary delicate observations.

This Week's Hype

September 28, 2006
Categories: Uncategorized

Fewer and fewer science writers these days are credulous enough to keep promoting string theory, but there still are some around willing to keep writing overhyped stories about how theorists have finally found a way to get some sort of prediction of something observable out of string theory. One of these is Tom Siegfried, who has a new article in Science magazine entitled A Cosmic-Scale Test for String Theory? which reports that "some string theorists now believe they've found a way to make superstrings observable."

Siegfried reports for Science from PASCOS 2006, where he finds two results worth writing articles about. One of these is the recent preliminary neutrino oscillation results from MINOS, which certainly are worth reporting, but the second is the cosmic superstring hype that has been around for nearly three years now, and which I've commented on in various places, including here and here. The hype surrounding this topic first got seriously going with a press release from UCSB more than two years ago, in which Polchinski claimed that cosmic superstrings were "potentially visible over the next year or two" at LIGO. Now that this time period is up, the hype has to be modified, and Siegfried informs us that:

LIGO may not be sensitive enough to detect them, but a planned set of three space-based gravitational wave detectors known as LISA would be a good bet.

As is always the case with string theory, there aren't any real predictions here. The hype is based on the fact that, among the nearly infinitely complicated string theory models people have studied, it is in principle possible to come up with ones in which superstrings created in the early universe would expand to a very large "cosmic" scale and thus be observable. They would show up in various astronomical observations, but no one has yet seen the slightest evidence of such a thing. One can claim that it is logically possible that such things exist, with exactly the right properties to have escaped observation so far, but to be visible to the LISA experiment if it really does manage to get funded and operate sometime in the next decade. While this is logically possible, saying that "it would be a good bet" is pretty absurd; I doubt that any physicist would be willing to put money on this unless given very high odds.

The hype surrounding cosmic superstrings tends to completely confuse the kind of cosmic strings that occur as defects in the Higgs field in some GUT models (which have been studied for about 30 years now) with the kind that are supposed to come from elementary strings. Siegfried's article includes a graphic purporting to show a "network of enormous 'superstrings'". As far as I can tell, this is nonsense, since the same graphic occurs here, in an article from 2000, long before the "cosmic superstrings", where it is described as showing "cosmic strings form from a random initial distribution of phases of a hypothetical field called a Higgs field."

Oh, and the fact that I think this is a pretty sad example of bad science reporting by someone completely taken in by the string theory hype machine has nothing to do with the fact that its author recently wrote an extremely hostile, unfair and inaccurate review of my book…

Update: For an example of the kind of misinformation spread by stories like this, see this blog entry by another science journalist, over at Seed's ScienceBlogs.

Comments

   Every review for NEW on amazon.com is gone, gone and amazon.com also says thar it has not been released yet.

3. **woit**
   September 28, 2006

   Timothy,

   Looks like some sort of mix-up at Amazon, they never did get the publication date of the book right. I've asked the people at Basic Books to look into it.

4. **anthropologist**
   September 29, 2006

   I went to see Smolin at his book presentation in Princeton just this week. I think since the guy is taking on the string theory, his salesman skills ought to be better. His presentation definitely lacked the passion that would ignite the masses. Sometimes he was getting carried away and talked too much about specifics, I do not think most of the audience was up for that. Even worse, he started to make excuses on the subject why he discussed the sociological factors in the book at all in an unconvincing sort of way.

   I think that you guys (critics) must concentrate your efforts on making your message well defined, coherent, and easy to understand. Then just keep hammering it. OK, you are not gonna win the admiration of the string crowd, that is clear, but what about just giving great presentations? Sell your criticism, you've chosen to do this, so stick to it. That is why some reporters may not understand it, because you are not impressing them enough. Give them drama, they will chose to promote it for their own selfish reasons.

5. **Seth**
   September 29, 2006

   To anthropologist,

   I think it's a real shame if it turns out that scientific truth has to be debated in sound bytes rather than reasoned arguments.

6. **Stefan**
   September 29, 2006

   Peter,

While I fully support (and applaud) all your committed effort(s) to keep theoretical physics from spiraling into the void of (unverifiable) speculation and flights of imagination, I think inevitably the only realistically *result-driven* way to attract individuals to your cause is to provide a reasonable alternative (or alternatives) to the current paradigm [i.e. string theory]. If you are harping – irrespective of what you criticise against – about how all of string theory has been unable to predict any new physics without providing a meaningful alternative to the prevailing circumstance(s) your voice will not resonate as much as it would otherwise; yes, it's true there are valid and substantive reasons for not believing in string theory "hype", but show us an alternative: until then, you are only trying to tell people to do 'nothing' instead of 'something' – and perhaps that may not go down well with generally motivated young people in hep…

[To further remark, it is to my knowledge (YPP Survey) that most people who join HEP research do so for intellectual satisfaction; therefore, to tell them to remain idle – instead of working on what is perceived as one of the best approaches currently available for unification – is probably not going to go down well… The only solution is to provide a viable alternative and demostrate verifiable results… 'string theory' may not do that as yet (or perhaps it may never be able to do so) but as Urs Schreiber writes in his review of NEW, it has many fascinating properties that *may* be of significant value in the future… none of us can really tell as yet…]

Stefan

7. **Tom Siegfried fan**
September 29, 2006

Peter, how can you know for certain that strings haven't already been discovered, and merely have been misunderstood?

Atoms were long around before people knew for certain they existed.

For example, maybe widely-observed 'UFOs' are actually the ends of cosmic strings, flying about in the Earth's upper atmosphere?

Extra-dimensions have evidence long broadcast on TV (see the Twilight Zone and other programmes). Maybe ghosts and psychic phenomena, widely reported, are the really solid evidence for string theory. Nobel Laureate Professor Josephson has long said so, and has a paper on arXiv: http://arxiv.org/abs/physics/0312012

8. **Geon**
September 29, 2006

Stefan, I agree 100% with you.

9. **Stefan**
September 29, 2006

To add, I am greatly encouraged by your research-topic. I have perused Amazon[.com] for relevant titles. I am quite interested in RT-QFT connections.

Where should I start? Give us [non-experts] clear guidance…

Post-Script:

As per your suggestions I have included the various titles you recommended to my 'To Purchase Now' Wish List. If you want to include other titles please feel free to e-mail me.

Regards,
Stefan

10. **TTT**
September 29, 2006

Guys, this blog did an excellent job demoting string theory, so that whenever I hear the word 'string" I wanna scream, it makes me wanna p**k. The problem with all this is that having reached this critical disgust mass I begin to p**k every time you push your bashing further. I think it is important to stop from time to time and direct your energy (blog's pages, that is) to something really really different and interesting. We have already heard everything we need to know about how ****ed up the string theory is, so, please, for a change, just to keep your fans sane, do something different.

It is just the nature of human psychology at work here. Now, I'm a little bit nurvous everytime I open your page: I'm simply afraid to find another dragging about the string theory, about someone reporting something from some string conference, etc etc, and it doesn't matter anymore whether it turns out negative or positive.

How about a month without the word "string"?? would that be too hard?

sorry but you begin to seem like a cult of its own, and that's not good. This is just a friendly remark:-)

Something different! Pleeeease?:-)

11. **Peter Woit**
September 29, 2006

anthropologist and TTT,

Let's see, one of you wants me to simplify the message and keep hammering on it, the other one thinks I've gone too far and that I should stop mentioning string theory…. I'm tempted to conclude that maybe I've got it about right. The posts of the last couple weeks actually have had relatively little string bashing, although there has been a lot of string related stuff because I'm mentioning the reviews of the book (that topic should die down soon). It seems to me that the amount of string hype appearing in serious publications has definitely decreased, but as long as it's still appearing in places like Science, I intend to keep commenting on it.

Stefan and Geon,

Yes, of course it would be much better if I had an alternative TOE that made testable predictions that I could explain to everyone here, thus giving them something obvious to work on. Unfortunately I don't have that. If I did I probably wouldn't be spending time writing this blog, but instead would be enjoying the high life of fame, fortune and groupies that attends Nobel-prize winning theoretical physicists. I really think people who want to work seriously on particle theory at this point should just get over trying to find someone to tell them what to do, string theorist or anti-string theorist, and just try and come up with their own ideas. If you don't want to do this, but want to join a promising, healthy research program where you can make useful contributions to science by following someone else, you probably shouldn't be trying to work in this particular field at this particular time.

12. **Stefan**
September 29, 2006

Peter,

Thank you for your feedback, but you did not give me any titles for RT-QFT connections. Are there any (yet)?

13. **David Tong**
September 29, 2006

Peter,

I think your criticism is severely misplaced.

Firstly, you're right that it's important to draw a distinction between cosmic strings and cosmic superstrings. It's a shame the author didn't make more of an effort in this regard. It's kind of a shame that you didn't either because at times I can't quite work out what you're complaining about. In particular, the line

>

seems to apply to cosmic strings of all types. It also seems to miss the main point that cosmic strings have a strong and distinctive gravitational wave spectrum. LISA, should it fly, will give us a new window on the universe. At the very least, it will bring down the bounds on the possible existence of cosmic strings by many orders of magnitude. Spergel and other prominent cosmologists find this exciting. Maybe you disagree, but I think it's right that this work is hyped in the popular press, especially given the current situation at NASA and the fact that LISA is one of the most important science projects in the pipeline.

As for string theory, the excitement of cosmic superstrings comes partly because they are a generic prediction of large classes of string models. Not seeing cosmic strings will therefore rule out large classes of string models. (You should be happy about this although no doubt you will compain that it will not rule out all string models). But mostly the excitement comes because the properties of cosmic superstrings differ from the properties of gauge theory strings.

Now one can certainly have a discussion about whether these differences are potentially observable (by LIGO, by LISA, depending on string tensions, etc). One can also discuss whether it's possible to cook up gauge theories to mimic the behavior of cosmic superstrings. If you wanted to make any kind of constructive criticism of this work, there are plenty of opportunities to do so in the usual scientific fashion — by long calculations and hard work. Instead you prefer to simply bash out another skewed polemic from the sidelines, glossing over the key issues just as glibly as the science journalist you're complaining about.

14. **TheGraduate**
September 29, 2006

I think probably nobody is more qualified to figure out what is good for the site than Peter. I say this because he has access to the number of visitors per day and we don't. Don't forget the lesson of the string theory debacle. We must be data driven!

It can be hard to stand in front of a bunch of people and criticize others! And I have more respect for people that don't come to this kind of thing easily.

15. **David Tong**
September 29, 2006

I'm not sure what happened with your comments section, but the line I quoted didn't appear: it was

"One can claim that it is logically possible that such things exist, with exactly the right properties to have escaped observation so far, but to be visible to the LISA experiment"

16. **Peter Woit**
September 29, 2006

David,

Sorry if I wasn't clear enough, but I thought that it should have been clear that what I was criticizing were the claims being made about fundamental superstrings, not the traditional kinds of cosmic strings that occur in gauge theories coupled to Higgs fields.

I have no trouble with Spergel or anyone else promoting LISA or other experiments for their ability to set better lower bounds on cosmic strings, although I disagree with you about the desirability of scientists who want to keep their credibility hyping things to the public to get them to be willing to finance experiments. What I seriously have a problem with is what this writer was doing, based on the hype he was being fed by string theorists, which is to promote the idea that LISA is going to "test string theory". You're engaging in exactly the same kind of overhype here, with your claim that "not seeing cosmic strings will rule out large classes of string models". By this argument, since one can find a string theory that predicts just about anything, any particle physics experiment that measures something new is doing this. The Tevatron has "ruled out large classes of string models" and the LHC will rule out more. This isn't why these machines are important or should be financed.

I think the superstring models being used here are convoluted, ugly, and there's not the slightest evidence they have anything to do with reality. Obviously I thus don't think I or anyone else should be wasting their time on them. People who think otherwise are welcome to do so, they should just stop dishonestly hyping this work to overly credulous reporters, as well as complaining when someone points out the dishonesty.

17. **Tony Smith**
September 29, 2006

Peter, you said that if you "… had an alternative TOE that made testable predictions that [you] could explain to everyone here … [you] probably wouldn't be spending time writing this blog, but instead would be enjoying the high life of fame, fortune and groupies that attends Nobel-prize winning theoretical physicists. …".

Or,
you might find that:
1 – you are labelled a "crackpot" by Harvard, represented by a distinguished Harvard professor;
2 – you are blacklisted from posting your "alternative TOE" on the arXiv; and
3 – your offers to "explain" your "alternative TOE" at seminars etc are ignored by the physics establishment.

Oh, wait … 1 has already happened to you even without an "alternative TOE".

Maybe your reference to "fame, fortune and groupies" is more telling than you consciously intended, as it is consistent with the real objective of the present-day theoretical high-energy physics community being, NOT a "TOE …[with]…testable predictions",
but in fact
winning the game of pursuit of grants, funding, jobs, and bureaucratic empire.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

18. **Peter Woit**
September 29, 2006

TheGraduate,

Actually I don't think that the amount of traffic here is a good measure of whether what I'm trying to do is successful. I'm not trying to reach the widest possible audience. One goal is to expose string theory hype, thus reducing the amount of it.. Over the last couple years the amount of this has definitely gone down, for whatever reason, and I'm glad to see that. I also look forward to a near future in which there is so little of such hype in the serious scientific press that it's not a problem that needs to be paid attention to.

19. **Peter Woit**
September 29, 2006

Stefan,

The connection between representation theory and QFT has only really been developed in the 1+1 d case. Most relevant here are WZW models. An example of where this is explained is

Fuchs, Affine Lie algebras and quantum groups

There's also a lot of relevant material in the books by Mickelsson, and Pressley and Segal that I've recommended. Another place with a lot of material about this kind of thing is the Goddard-Olive reprint volume on Kac-Moody and Virasoro algebras.

20. **hack**
September 29, 2006

Uh oh, you've been Slashdotted.

21. **TheGraduate**
September 29, 2006

hack,

Is this the link you mean?

http://science.slashdot.org/science/06/09/29/1735237.shtml

22. **SD**
September 29, 2006

Dr. Shellard was my advisor a long time ago, and I'm pretty sure that picture is just "regular" cosmic strings. 😉

"The hype is based on the fact that, among the nearly infinitely complicated string theory models people have studied, it is in principle possible to come up with ones in which superstrings created in the early universe would expand to a very large "cosmic" scale and thus be observable. They would show up in various astronomical observations, but no one has yet seen the slightest evidence of such a thing."

Try not to get too upset by hype. I think workers in the field, but outside the string theory cathedral, know that it's interesting to see a prediction made, but not to take it too seriously. Indeed, if the bet were too good the observation would be boring!

It's a bit unfair to yell at people for hype, and then engage in hyping the other side as well. That "no one has yet seen evidence" (the slightest evdience, even!) is really not a way to make a substantive remark.

23. **Thomas Love**
September 29, 2006

I was disappointed that neither Peter nor Lee referenced:

Constructing Quarks: A Sociological History of Particle Physics by Andrew Pickering

The same sort of thing is going on now.

"He who does not know the past is condemned to repeat it"
—George Santayana

And physicists are notorious for their ignorance of history, prefering to pass on historical myths to their students.

24. **woit**
September 29, 2006

SD,

That no one has seen the slightest evidence for cosmic superstrings is not "hype", but an accurate, substantive statement. If there were some very slight evidence for such things, one might think it was a good bet that more sensitive observations would produce conclusive evidence. But there isn't.

25. **Yatima**
September 30, 2006

> "Constructing Quarks: A Sociological History of Particle Physics by Andrew Pickering"

Reference:

1984…a venerable age. Good book? I remember once reading a review of a book with
a similar title in which it was claimed that the book under review was
'post-modernist'/'relativist' in the sense that it denied the objective existence of
quarks at all.

The Economist's latest edition cautiously moves the spotlight to LQG:

http://www.economist.com/science/displayStory.cfm?story_id=7963608

26. **Arun**
September 30, 2006

NPR, Weekend Edition Saturday had a about two minute mention of string theory, Not Even Wrong (and Smolin's book) – it was at about 8:30 on WNYC.

27. **TheGraduate**
September 30, 2006

Peter,

I think that the public is an important part of ending the hype becasue the opinion of the public matters to:

1. those who ultimately fund physics

2. those who run universities

3. those who print magazines and newspapers and air tv shows

I think a lot of activities surrounding the hype are prestige seeking activities and therefore, a lower opinion of string theory in the public sphere will probably diminish the returns of such prestige seeking.

The String Vacuum Project

September 30, 2006
Categories: Uncategorized

Last week at the KITP, Keith Dienes gave a talk on A Statistical Study of the Heterotic Landscape. He gave a good idea of the state of the art of the investigation of the Landscape, focusing on one special type of models, heterotic models. The results he presented gave statistical distributions for just two very crude aspects of these compactifications, their gauge groups and cosmological constants. These models remain highly unrealistic, since the cosmological constants are of order the Planck scale and the compactifications are not stable.

The models studied have gauge groups of rank 22, and while many of them contain the standard model SU(3)xSU(2)xU(1), they also contain many more gauge group factors, with typically not one, but about seven SU(2) factors. These models, with their instabilities, far too large gauge groups and cosmological constants, are extremely far from anything like the standard model. It's not at all clear what the point is in enumerating them and studying their statistics, but Dienes describes in detail various problems that arise with the whole concept of generating "random" models of this kind and trying to get sensible statistical distributions. He also looks for correlations between gauge groups and cosmological constants, finding that at small cosmological constant one is somewhat more likely to get many factors in the gauge group (although in his case, both the gauge group and the cosmological constant are very different than in the real world).

Despite the very crude state of these calculations, Dienes reports that a group of 17 prominent string theorists have banded together to form the "String Vacuum Project", with the goal over the next few years of accumulating a database of 10s of billions of string models, with the hope of finding within this mountain of data about 100 models that have crude features of the standard model. I don't at all see what the point of this is, but it certainly is a computationally intensive project that could keep many people occupied for a long time. It also appears to be just the beginning, with the longer term goal being to devote the next decades to expanding from 10s of billions farther into the 10^500 or whatever exorbitantly large number is thought to be the number of all string models.

The String Vacuum Project submitted a proposal to the NSF last year, which seems to have been turned down, and they appear to be planning to resubmit the proposal. They have a Wiki, with all sorts of details about the project. Most recent additions to the Wiki are from Bert Schellekens in August, who discusses a proposed "String Vacuum Markup Language" (SVML) format, with links to a web-page that produces data in this format for certain sorts of models. There's also a European String Vacuum Project web-site.

7. **Tony Smith**
   September 30, 2006

   The SVP wiki page at http://strings0.rutgers.edu:8000/ProjectOverview says in part:
   "… Our primary goal is to construct string compactifications which lead to the Standard Model …
   A related goal is a broader study of standard-like models, by statistical and other approaches, …
   and
   … to be able to estimate the number of SM's which should exist among all known types of constructions …".

   So, if the SVP succeeds, it will not only be the authoritative catalog of superstring models, but will also be THE authoritative catalog of ALL physics models.

   Further, the SVP wiki page at http://strings0.rutgers.edu:8000/ProjectOverview/DiscussModelFormat says in part:
   "… Suppose one of us, or some independent group of string theorists, establishes the existence of a string compactification leading to a concrete low energy model, and wants to submit it to the SVP database.
   What should he/she do?
   … the first thing to do is to write a standard research paper and submit it to the arXiv …

… Having done this,
the key thing to do is to provide, or be able to provide, the information about the model in a standard format, which we might refer to as "String Vacuum Markup Language" or SVML . …".

Suppose somebody, say, Peter working on representation theory, comes up with a model that is consistent with the Standard Model plus Gravity,
and
suppose Peter meets the first requirement of posting his model on the arXiv.
Then,
if the SVP has obtained dominance roughly equivalent to the physics-community dominance of the arXiv,
Peter MUST fit his model into the SVP strait-jacket of "String Vacuum Markup Language" if he wants his model to be considered at all by the physics establishment.

If Peter's model were to be so unconventional (from a superstring point of view) that it woudl not fit happily into the "String Vacuum Markup Language" strait-jacket, then no matter how realistic and useful it might be, it would never be accepted or used.

Since the SVP proposal at http://www.physics.rutgers.edu/~mrd/SVP-v2.ps says in part
"… A group of theorists in Europe … have come to similar conclusions, and are writing a similar proposal to European agencies. We would join with them to strengthen the entire activity further. …",
it is clear that the objective of SVP is not merely dominance of the USA theoretical high-energy physics community,
but is to achieve global domination (as is now in fact the case with the arXiv).

Therefore,
I think that the SVP proposal is quite dangerous to the future of physics,
because
it seems to me that gate-keeping by the SVP powers-that-be, using such things as requiring "String Vacuum Markup Language", will be so restrictive as to make the blacklisting-by-moderators practice of the arXiv seem pale by comparison.

Tony Smith
http://www.valdostamusuem.org/hamsmith/

PS – My opinion in this comment is substantially objective, since the SVP proposal will probably not have much impact on acceptance/rejection of my work because blacklisting by the arXiv has already done the damage to me and my work that might be done by SVP.

8. **Gina**
September 30, 2006

This is a very nice project for the following reasons:

1) It can help to demonstrate that string theory can provide "a theory of everything" even if not "the theory of everything". This will be a great intellectual achievement. (As far as I understand from reading Peter's book, there is no guarantee that even a single one out of the 10^500 different string theories (or more, infinitely many??) will have the desired properties.)

2) It can go both ways. It can also lead to (mild but important) negative conclusions about string theory. E.g. if certain unrealistic or problematic features cannot be avoided in all the proposed models.

3) It does not have the sex-appeal/snob-appeal of hyper/super 23-century mathematics but is rather a down-to-earth programming-intensive project.

4) Projects of this kind are very demanding and often lead to difficult and thankless work. They are also rather risky.

So based on what Peter wrote I would recommend the NSF to support this project very very strongly.

9. **Jean-Paul**
September 30, 2006

Thanks to referees and panelists who were able to protect NSF from wasting money on ridiculous String Vacuum Project and String Vacuum Markup Language. You don't have to be a physicist to recognize that it is complete nonsense. Actually, I don't believe that theorists who are proposing this activity are acting in good faith — they must know that the only goal would be to keep the ball rolling… The logic is: let's get postdocs, whatever it takes… but then, would they really hire a programming expert? No, they would try to hire somebody working on more serious stuff listed on "daily specials"="menu du jour". They must be completely burned out and desperate or plain delusional like the person who proposed SVML.

10. **Carl**
September 30, 2006

That was an amazing wiki. Absolutely no comprehension of the magnitude of the problem. Just trying to figure out what sorts of biases are present in the data would be insane.

11. **Farrold**
October 1, 2006

If I may be excused for asking a question about the broader issue of vast size of the Landscape:

What is the standard response to the argument that any theory that does *not* predict a vast number of possible vacuua, but instead picks out a unique set of physical laws, would leave us with the problem of explaining the apparent fine-tuning of the observed set of laws to be consistent with life? From this perspective, the Landscape would seem to be an asset, rather than a liability.

12. **a**
October 1, 2006

to Farrold: about 10^10 vacua would be enough to interpret the apparent fine-tuning you mention: with intensive computer work one could find the true one. However, if the cosmological constant is small only due to a fine-tuning (that makes it practically uncomputable), about 10^100 vacua are needed, and this already seems a hopeless situation. If you have 10^20 buckets you can empty the ocean, but with 10^500 vacua what can you do? If you find 10^400 realistic vacua, where do you put them?

Despite this, computer tools that manipulate generic Lagrangians are being developed to study LHC data: if after LHC there will be nothing better to do, why not using them to explore a bunch of vacua?

13. **Peter Orland**
October 1, 2006

Gina Wrote:

1) It can help to demonstrate that string theory can provide "a theory of everything" even if not "the theory of everything". This will be a great intellectual achievement. (As far as I understand from reading Peter's book, there is no guarantee that even a single one out of the 10^500 different string theories (or more, infinitely many??) will have the desired properties.)

Gina:

It isn't clear to me that finding some string vacuum among many which describes nature would be a great intellectual acheivement. There is no prediction in such an endevour unless EXACTLY ONE vacuum of string theory describes nature at experimentally accessible energies. If two are found, no prediction can be made. Even if exactly one realistic vacuum is found, there may be no testable prediction. I suspect that people think that they can find a distribution of vacua whose predictions have a peak around observable values. This probably won't happen and isn't a proper
application of probablilty anyway.

Such a program MAY be of value. But I would go along with the
NSF on this one. There is a big risk for them that nothing substantive will result. Furthermore, since string theory hasn't been properly formulated yet, all these vacua could disappear in the future, which would really embarass whoever funds the project. If people really believe in the project, they may have to commit their
own time to it, without external funding. The NSF doesn't have much money these days, and they have to be careful how they spend it.

I suspect that in the end, this project will be funded by sheer lobbying, and some good competing proposals will lose out.

14. **A Babe in the Universe**
October 1, 2006

Einstein would say that the definition of insanity is doing the same thing 10^500 times expecting a different result.

15. **Who**
October 1, 2006

From Farrold: **What is the standard response to the argument that any theory that does not predict a vast number of possible vacuua, but instead picks out a unique set of physical laws, would leave us with the problem of explaining the apparent fine-tuning of the observed set of laws to be consistent with life?**

I think you mean the observed set of CONSTANTS which occur in the laws, and not the overall format of physical law. It is the set of dimensionless constants that people sometimes think presents us with a problem of fine tuning.

the distinction between the numerical parameters and the laws in which the occur is fuzzy but nevertheless useful. explaining the format of physical law would be a deeper puzzle than just trying to say why the CC is such a small positive number or why alpha is around 1/137.

However I think you are mistaken. A theory which picks out a particular set of fundamental constants would NOT present us with a fine-tuning problem. It would explain why the constants are what they are—perhaps all derivable from the value of some deeper numerical relationship. They would not be "tuned"—they would simply have to be what they have to be.

Life, an accident, would be constrained to be whatever can work within the context of those necessary predetermined constants. It's abundance or rarity would not explain anything about the constants because they would be explained by the theory which you have imagined.

A theory already exists which makes testable predictions and which explains observed values of fundamental dimensionless constants without making reference to life.

See for example pages 167-168 of Smolin's new book **The Trouble with Physics**
http://www.amazon.com/gp/bestsellers/books/14560/ref=pd_ts_b_nav/102-4540543-7840144

16. **Jean-Paul**
October 1, 2006

Babe in the Universe — calling 17 prominent string theorists insane is not justified (except for the SVML author). It would be a compliment — after all, Galileo, Copernicus et al were also considered insane. The problem with SVP is that it is proposed by a group of hypocrits and opportunists who want to suck up money that would normally go to serious hep-th research and spend it on 1) self-promotion of their old (wrong, 100% excluded) models by packaging them in a useless catalogue 2) taking control of the postdoc market.

17. **outside_observer**

22. **Farrold**
October 1, 2006

    Who remarked:

    > A theory which picks out a particular set of fundamental constants would NOT present us with a fine-tuning problem. It would explain why the constants are what they are—perhaps all derivable from the value of some deeper numerical relationship. They would not be "tuned"—they would simply have to be what they have to be.

    I take your point. There would, however, still be a degree of mystery similar in kind (but not in magnitude!) to the mystery in Sagan's novel, *Contact*, that is, the encoding a large, pixel-based image of a circle deep (yet far too early) in the digits of pi.

    > A theory already exists which makes testable predictions and which explains observed values of fundamental dimensionless constants without making reference to life. [Smolin 2006, *The Trouble with Physics*]

    I assume that you mean it explains how one *could* derive observable values, rather than that it explains (by deriving) *the* observed values.

    In his 1997 book, *The Life of the Cosmos*, Smolin suggested that universes spawn new universes with different physical constants, and he proposed this as an answer to the fine-tuning problem. Does he now argue that the form of the laws, if understood deeply, would imply the constants?

    For example, one current idea (as I understand it) describes particles as braids in structures in loop quantum gravity, which in turn emerges from structures in a spin-foam model. If the spin foam model were as parameter-free as theorists would like, then the theory would derive all the physical constants from its form. I'd be happier with a theory that had several arbitrary (i.e., tunable) parameters that enabled (in principle) precise calculation of the many arbitrary parameters in the Standard Model.

23. **TheGraduate**
October 1, 2006

    The fine-tuned universe: http://www.xkcd.com/c10.html

24. **Farrold**
October 2, 2006

    (continuing)
    One would of course want a theory of this sort to explain how these N parameters appear through a spontaneous symmetry-breaking process which results in a multi-dimensional continuum (or fine-grained distribution) of possible sets of parameter values.

    In the multi-dimensional continuum case, the theory would be consistent with an actual infinity of possible vacua. Nonetheless, taking measurement of the Standard Model parameters as the experiment, the theory would be falsifiable: It would predict that the parameter values are constrained to an N-dimensional surface ($N << 29$) embedded in the 29-dimensional space of unconstrained parameter values. This surface either would or wouldn't intersect the error-box of our measurements.

    I agree with many of Peter's criticisms (and I usually root for the loop/foam team), but I think that a similar case can be made for a *possible* outcome of Landscape studies. One scenario would be **(a)** that the Landscape includes a set of vacua with 3+1 macro-scale dimensions and with physics that can be approximated by parameterizations of the Standard Model, and **(b)** that in every member of this set, the 29 parameter values fall on an N-dimensional surface ($N << 29$) embedded in the 29-dimensional space…and so on, as above.

25. **gina**
October 3, 2006

    Dear Peter O.

    Many thanks for your comment.
    I think that demonstrating that string theory can "in principle"
    give a theory (or 2 or 1,000,000) which is consistent with the standard model and can be regarded as a "theory of everything" will be a big step forward inspite of having no prediction power.

    (If a unique such a theory can offer some predictions it is quite possible that some predictions can be offered even if more than one found.)

    A nice feature of this proposal is that unlike most proposal in the area, the outcomes can go both ways as far as string theory is concerned. In some (weak) sense this project is an empirical tests for the ideas of string theory.

    "This probably won't happen and isn't a proper application of probablilty anyway."

    This is a very nice sentence. (We do get a lot of milage using probability in ways which are not entirely proper,…probably.)

    "But I would go along with the NSF on this one. There is a big risk for them that nothing substantive will result. Furthermore, since string theory hasn't been properly formulated yet, all these vacua could disappear in the future, which would really embarass whoever funds the project."

    I diasagree with you on this point. I think NSF (and also individual scientists) should take risks.

26. **copa**
October 3, 2006

    Are you sure it isn't called the
    VACUOUS STRING PROJECT?

27. **Lubos Motl**
October 3, 2006

Dear crackpot Peter, you are a damn asshole. I will sue you for the lies those crackpot commenters telling on me on your crackpot blog.
I hope you will die soon. The sooner the better.

So: be prepared to hear from my lawyer.

Best Lubos

28. **Shocked and Saddened**
October 3, 2006

This comment above by Lubos is beyond the pale. Here he wishes physical harm for Peter for hosting a mostly-open forum where sometimes some nasty comments are posted about Lubos (invariably in response to Lubos' own writings), while on the other hand his own writing has a take-no-prisoners style — his own blog posts are riddled with name calling and put-downs, and he makes no attempt to moderate nasty comments about Peter by others. From my perspective Lubos has lost a a certain connection with objective reality, and it appears to me that it is getting worse with time. He seems to be unaware of the great disconnect between his complaints and his own actions, for example complaining (in the past) about censorship on Peter's blog while practicing censorship to a much greater degree himsef (witness the on-going thread Peter started for those comments); he frequently rails against political correctness, yet people who do not behave in a politically correct way on *his* blog (i.e., according to *his* politics) typically meet with either censorship or intimidation tactics. There are other examples that I see as hypocritical behavior on his part, but no need to enumerate them.

I am no lawyer, but it seems obvious that Lubos has absolutely no chance of winning any kind of legal action against Peter. A quick read of his blog speaks volumes about how his verbally abusive tactics invite unsavory comments about him. Importantly, he has willingly made himself a public person, and his blogging style promotes the kinds of comments he deplores here. His reaction above to those kinds of comments look to me like yet another example of loss of objectivity. Presumably his lawyer will inform him that different standards for slander, etc. apply to public figures than others.

I hope Harvard University becomes aware of his comment. They need to know how a person who prominently puts their banner at the top of his blog is reflecting on them.

29. **Shocked and Saddened**
October 3, 2006

I should clarify one statement I made above, especially given Lubos' current litigous mood:
… he frequently rails against political correctness, yet people who do not behave in a politically correct way on his blog (i.e., according to his politics) typically meet with either censorship or intimidation tactics.
By "intimidation tactics" I am referring to ridicule, name calling, and other forms of put-downs that often await the hapless person who openly disagrees with him. I consider these to be intimidation tactics because their end result is often that the target of the verbal abuse feels intimidated and afraid to disagree in the future. In its worst form, the person may be afraid to take a public stand on a related issue in the future, even far away from Lubos' verbal reach, just because they are afraid of a repeat of the bad experience. This kind of intimidation-based suppression of free speech (in the sense above) is not healthy for science, nor for a democratic socieity in general.

30. **M-theory**
October 4, 2006

In his blog Lubos proposed to scan all 10^500 string models to show that string theory is predictive. In the comment section of his blog I answered: let's ask 10^500 monkeys to type 10^500 random field theories; both approaches will likely lead to something like 10^300 models (string models or monkey models) compatible with all data we have.

My comment was deleted.

I think Lubos understood the scientific value of the Monkey-theory Vacuum Project: in case DOE or Harvard are going to develop a cluster of monkeys my lawyer will start a legal action for plagiarism.

31. **Another TheGraduate**
October 4, 2006

I don't know if it's valid physics but it seems like a pretty interesting life-science project.

32. **Juan R.**
October 4, 2006

String theorists promised answers to current problems and misteria in fundamental physics. After many decades, they offered not a single consistent and good solution. Then now the hype is that whereas string theory is not physics it has been good for mathematics.

If this project start (i do not wait), that would we heard in next 40 years, that string vacuum project failed but was useful for developing new markup and computational capabilities?

Juan R.

Center for CANONICAL |SCIENCE)

33. **Chris W.**
October 4, 2006

The post mentioned above is here. It is an interesting and forthright exposition of how at least some string theorists view the question of falsifiability as applied to string theory and its offshoots. Consider the following quote:

> As Barton Zwiebach wrote, the prescription to decide about the validity of string theory is straightforward: simply list all possible vacua of string theory, calculate their properties with a sufficient precision, and compare them with reality. Either one of them will match the reality or not.
>
> The answer just can't be ambiguous just like the answer whether "2^32,582,657-1" is a prime integer cannot be ambiguous. And you bet it is a prime. The greatest known prime as of today. A naive critic of mathematics could say that the question whether the number is prime is not even wrong because one would have to test the potential divisors up to the square root of the number i.e. up to "2^16,000,000" or so. One would need "2^16,000,000" units of time. It is even more than the number of the flux vacua and it's not possible to check it. That's why, the critic would argue, it's not science, it's not even wrong, there are troubles with mathematics, blah blah blah. The reality is that one computer in GIMPS needed one month or so to verify that the number is indeed prime (and a faster computer rechecked it in a few days). There exist more sophisticated and faster methods to decide about the validity of a statement than the primitive critic of mathematics could imagine. The case of physics is analogous.

Ah, yes. Now, if we could just discover those more sophisticated and faster methods…

34. **Andy**
October 4, 2006

I keep getting "Cannot find server" error when I try to link to the SVP Wiki-page. Has it been removed or firewalled?

35. **dark-matter**
October 8, 2006

If you believe in the anthropic Landscape, then the next logical step is to statistically analyze 10^500 vacua. Indeed, analyzing 10^1000 would be better and would produce more scientifically convincing results. I am convinced it will spit out the nature of dark matter, calculating from the first principle of ST. However, it is somewhat risky to apply to NSF for funding for this vital project – it may cause the US Government debt to hit $15T. I suggest instead apply directly to CERN to divert all of its massive computing facilities to the String Vacuum project. After all, ST is far more important then LHC. The LHC can wait. I nominate Prof Motl as project lead to get the necessary funding from CERN, and scientific approval from NSF and his superior at Harvard. As the certified Clown of String, he is uniquely qualified. This is his chance for a Nobel! You know, after 25 years I still find ST so exciting ….

36. **Bee**
October 10, 2006

Hi Arun!

Thanks so much for the link to the short story! I read that story an eternity ago, forgot author and name, and have been trying to find it ever since.

Every once in a while, these comments are actually worth reading 😉

Best,

B.

37. **Bee**
October 10, 2006

About the svp: even though I think that the appearance of the st landscape is a serious indication that either a) we've misunderstood something about st or b) it's not the TOE, the project itself I find worth an investigation. I mean, even if it's not clear why THIS point in the landscape, wouldn't it be good to know it, so we can work with it? We also don't know why spacetime has Lorentzian signature, but still we can work with it. (Or if you know, tell me.)

What scares me however are the dimensions of the planned project, the potentially low level of possible knowledge gain, and what it means when I recall that we are living with finite resources, money, people. Questions to ask: Are there other, better, proposals that would suffer from a support of the above? Is the project likely to draw people away from other fields? Is it? I mean, look, those who support the svp have a research interest, so they write a proposal, whats wrong about that? Did they make any scientifically wrong claims about what knowledge gain it would yield? And, no, I wouldn't finance the project — of course I would support my own proposals…

B.

PS: regarding the above nasty comment allegedly written by Lubos, I seriously doubt he wrote it. I have seen very similar sounding comments appearing in his comment section, but signed with Peter Woit. I found myself thinking, no way Peter would write that. However, these comments disappeared within some minutes, so I guess Lubos just deletes them.

38. **M-theory**
October 10, 2006

Bee, maybe you should ask Lubos. I suggested him to state that he did not wrote that, but my comment was deleted with no answer.

39. **Bee**
October 10, 2006

Hi M, to be frank, I don't really care. I don't want to spend my time trying to psychoanalyze Peter's and Lubos' virtual realities. I found myself thinking recently it would be really interesting to lock the both of them together in a room for 48 hours, with a live webcam. –B.

And now that things are changing for the worse,
See, its a crazy world we're living in
And I just can't see that half of us immersed in sin
Is all we have to give these –

Futures made of virtual insanity now
Always seem to, be govern'd by this love we have
For useless, twisting, our new technology
Oh, now there is no sound – for we all live underground
~ Jamiroquai

40. **Who**
October 10, 2006

hi Bee, according to my understanding both the two persons you mention are nice and polite in reality, but little motivated to converse with each other—-so the locked room experiment would not be what you call "very interesting", but would, on the contrary, turn out to be quiet, and uneventful.

It is true that Lubos has a "Wildman" personality on the web. But I suppose that this is merely his web persona. Maybe you know him in real world, and can contradict me

41. **Arun**
October 10, 2006

Bee, a new version of Schrodinger's Cat?

42. **Bee**

October 10, 2006

Who, that’s what I had in mind 🙂 You think I would want to put them in a room together on the danger that only one of them comes out again? Hey, I am a nice girl! No, I think, there’s too much energy loss in friction here that could be better used. Since neither Peter nor Lubos are stupid they probably have noticed that as well.

Falsifying String Theory: Not

October 1, 2006
Categories: Uncategorized

Back in April a paper appeared on the arXiv from string theorist Jacques Distler and collaborators that made a rather outrageously overhyped claim to have found a way to "falsify string theory". The paper was entitled Falsifying String Theory Through WW Scattering, and was discussed extensively here. After the Wall Street Journal published an article in June about the problems of string theory, Distler wrote them to complain that the article was incorrect, because he and his collaborators had shown that string theory was falsifiable.

I had heard that this paper was going to be refereed, and was wondering whether a referee would really let the authors get away with the outrageous claim of their title. Well, it appears that the answer is no. A new version of the paper is now on the arXiv, with a new title: Falsifying Models of New Physics via WW Scattering. The abstract, which originally claimed that violations of the bounds they described "would falsify string theory" has now been modified to no longer make this claim; the new language is "would falsify generic models of string theory".

The paper has acquired a new co-author and been extensively rewritten. I'm assuming many of the changes were made to satisfy a referee. Besides changing the misleading, overhyped title, criticisms of earlier work embedded in one reference have been removed, and nine new references to earlier work have been added.

Comments

1. **optimist**
   October 2, 2006

   It sounds to me that any model from string theory should obey Lorentz Invariance, Unitarity and analyticity in S-matrix.

   So if one believes that these properies are essential for any realistic theory then this paper is tautology, giving potential overhyped claim to layman.

   But if one believes that nature could show strange behavior from the view point of conventional physics then string theory is indeed a falsifiable theory because string theory can not admit those kinds of strange behavior.

   The point is that how many people expect nature would not obey those properites. If the number is too small then it could be overhyped claim. If the number is not too small then it is a reasonable claim, I think.

2. **Who**
   October 2, 2006

   you mention the new co-author Rafael Porto.
   I see that Distler et al reference [22] is
   http://arxiv.org/abs/gr-qc/0402118
   A relational solution to the problem of time in quantum mechanics and quantum gravity induces a fundamental mechanism for quantum decoherence
   Rodolfo Gambini, Rafael Porto, Jorge Pullin
   13 pages
   Journal-ref: New J.Phys. 6 (2004) 45

   "The use of a relational time in quantum mechanics is a framework in which one promotes to quantum operators all variables in a system, and later chooses one of the variables to operate like a "clock". Conditional probabilities are computed for variables of the system to take certain values when the "clock" specifies a certain time. This framework is attractive in contexts where the assumption of usual quantum mechanics of the existence of an external, perfectly classical clock, appears unnatural, as in quantum cosmology. Until recently, there were problems with such constructions in ordinary quantum mechanics with additional difficulties in the context of constrained theories like general relativity. A scheme we recently introduced to consistently discretize general relativity removed such obstacles. Since the clock is now an object subject to quantum fluctuations, the resulting evolution in the time is not exactly unitary and pure states decohere into mixed states. Here we work out in detail the type of decoherence generated, and we find it to be of Lindblad type. This is attractive since it implies that one can have loss of coherence without violating the conservation of energy. We apply the framework to a simple cosmological model to illustrate how a quantitative estimate of the effect could be computed. For most quantum systems it appears to be too small to be observed, although certain macroscopic quantum systems could in the future provide a testing ground for experimental observation."

   (P.W. the original post had a typo where it said WWW scattering instead of WW scattering, you may already have corrected it by the time I submit this comment.)

   Gambini and Pullin do a variant of non-string QG related to LQG. they and Porto have more recent papers than the one cited which discuss the minimal rate of decoherence that necessarily attends using real clocks.

3. **MathPhys**
   October 2, 2006

   I don't say why the words 'string theory' show up there at all. They seem to be making very general statements that have nothing to do with strings.

4. **Chris Oakley**
   October 2, 2006

   > the original post had a typo where it said WWW scattering instead of WW scattering

   I hope it is not too late … there may already be an entry on the Reference Frame on the lines of "Anti-Science Crackpot Unable To Tell The Difference Between The World-Wide Web And The W Boson".

5. **SFB**
   October 2, 2006

   Who, I don't know what the relational post has to do with the rest of the thread, but the paper is interesting. However if you look at what I had thought was at least implicit in quant-ph/0506228 the calculations in the paper you mentioned seem confused. I tried to tell people about this in the mid 90's. Instead everybody ran with Rovelli's better publicized version, which is fine, but the understanding is superficial and they make all these fun but philosophically unmotivated calculations.

   I have started writing yet another paper explaining the old ideas, one that I hope will clarify this situation once and for all. Physicists like to calculate, whether in a philosophical vacuum or not, and string theory is just an extreme form of this calculate-itus.

6. **Chris W.**
October 2, 2006

SFB,

At some point you may have encountered an anecdote about Einstein's exasperation with a certain theorist, which Einstein expressed by the remark "the man can calculate, but he can't think." I believe I came across it in a book published during the centennial year of Einstein's birth (1979).

7. **Crimson**
October 2, 2006

I think there must be a confusion. Well, my confusion anyways. I just checked hep-ph/0604255 out of
curiosity, and I can only find version 3. I cannot find the v4 you link to and discuss in your comment. None of the changes you mention are there in v3.

8. **Crimson**
October 2, 2006

Ok, now v4 is actually there….

9. **Who**
October 2, 2006

Crimson, try
http://arxiv.org/abs/hep-ph/0604255v4

You say

it sounds like you just used the first link Peter gave and not the second

10. **Benni**
October 2, 2006

Lubos Motl has a new blog entry on this:
http://motls.blogspot.com/2006/10/falsifiability-in-physics.html
He calls Peter a nutcase….

11. **Jimbo**
October 2, 2006

I would strongly suggest that anybody who has seen Lubos' most recent rant, would agree that he is totally out-of-control, foul-mouthed, and should be severely disciplined by Harvard for utterly unprofessional behavior. He is beyond doubt, academia's best approximation to a human pit-bull, and should be de-clawed & neutered.

12. **Tony Smith**
October 2, 2006

Benni refers to a new blog entry by Lubos Motl.
In it, Lubos Motl says in part:
"… Lorentz symmetry breaking, breaking of unitarity, locality, rotational invariance … can't be embedded in string theory …",
and concludes that string theory is falsifiable because any one of those things, if shown experimentally, would therefore falsify string theory.

Lubos Motl goes on to say, in part:
"… String theory … has fixed Lagrangians and quantitatively accurate and rigorous formulae … it predicts various masses and cross sections. Moreover, it has no continuous non-dynamical adjustable parameters.
On the other hand, it has a large discrete set of classical solutions – possible universes. The number of them that have a chance to be compatible with the basic features of reality is probably finite.
Each of them accurately predicts the values of the usual quantities used in quantum field theory – masses and couplings. …".

Note that Lubos Motl does NOT show EVEN ONE example of a string theory solution that makes such predictions that are consistent with the experimental observations of the Standard Model.

Further, Lubos Motl goes on to say:
"… given the obvious progress and unique results with the supersymmetric vacua, we are confident that an answer to these questions exists in the non-supersymmetric case and it will be unique just like it was in the supersymmetric cases. …".

THIS IS AN IMPORTANT CHANGE IN HIS POSITION.
Back in 2004, acting as a sci.physics.strings moderator, Lubos Motl said:

"… "String theory" is a shorthand for "superstring theory" …"

His statement was made in the context of his opposition to my (non-supersymmetric) string version of my physics model that I put on the web as CERN-CDS-EXT-2004-031 as an example of a physically realistic (although non-supersymmetric) string theory.

Perhaps Lubos Motl has realized that the smart money is betting that the LHC will rule out the type of supersymmetry upon which "superstring theory" relies,
and
is now hyping non-supersymmetric string theory as a way to preserve the Bureaucratic Empire of SuperString Theory.

Even though my CERN-CDS-EXT-2004-031 could be seen as at least one concrete example of a realistic string theory,
something that Lubos Motl and his ilk have been unable to come up with themselves,
it is my guess that his hatred of me (he describes me as a "moronic crackpot") will outweigh his desire to exhibit it as such an example.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

13. **Vogelsang**
October 2, 2006

Wasn't it the observational discovery of the acceleration of the Universe's expansion that has led String Theory to its current sorry state of confusion? If so, it would be fair to say that it was Astronomers who showed that String Theory is not phenomenologically viable. That, in turn, would explain why Lubos hates Astronomy to such an irrational extreme.

14. **TheGraduate**
October 3, 2006

John C. Mather and George F. Smoot are our newest Nobel prize winners in physics!

15. **Stefan**
October 3, 2006

Lubos has written something on this topic [string theory falsifiability, or lack thereof] on his blog. As may be expected, it's the usual rant with semi-relevant and -valid technical points and arguments to give his post the requisite scholarly-authoratative lustre. All in all, I think he did a fairly decent job.

Moving on to other topics:

Peter,

Please help me!! [… or atleast help me to help myself!] make some sense of the Amazonian labyrinth that is hep textbook titles at Amazon.com [no pun intended : –)]. I feel like Bush ; –) in the White House when I surf through Amazon[.com] trying to figure out EXACTLY *which* titles are the best buys.

P.S.:
If anyone else wants to assist me, by all means send a 'yes' reply and I will provide access to my 'To Purchse Now' Wish List to you.

Stefan

16. **Who**
October 3, 2006

we could be entering a new stage of the game.
maybe stringery CAN be falsified as a fundamental picture of nature
and yet not falsified as an EFFECTIVE theory, permitting calculations.

one can have an effective theory which one knows is wrong, but which provides good approximate calculations.

so far one cannot calculate anything from stringery so one cannot check if it is a useful effective theory.

but at least one can imagine being able to show that it is fundamentally incorrect as a picture of nature. I think this is the direction that Distler et al paper is going:

Distler et al begins to persuade us that stringery might actually be falsifiable in a certain PHILOSOPHICAL way by general reasoning like, for example, this:

Gambini Porto Pullin showed on general grounds that realistically speaking time-evolution cannot be unitary. It is only approximately unitiary. There is a certain minimum necessary rate of decoherence.

Perhaps the most accessible paper is not the one which Distler et al cite but these more recent ones:
http://arxiv.org/abs/quant-ph/0608243
Relational physics with real rods and clocks and the measurement problem of quantum mechanics
Rodolfo Gambini, Jorge Pullin
19 pages

"The use of real clocks and measuring rods in quantum mechanics implies a natural loss of unitarity in the description of the theory. We briefly review this point and then discuss the implications it has for the measurement problem in quantum mechanics. The intrinsic loss of coherence allows to circumvent some of the usual objections to the measurement process as due to environmental decoherence."

http://arxiv.org/abs/gr-qc/0603090
Fundamental decoherence from quantum gravity: a pedagogical review
Rodolfo Gambini, Rafael Porto, Jorge Pullin
9 pages

We present a discussion of the fundamental loss of unitarity that appears in quantum mechanics due to the use of a physical apparatus to measure time. This induces a decoherence effect that is independent of any interaction with the environment and appears in addition to any usual environmental decoherence. The discussion is framed self consistently and aimed to general physicists. We derive the modified Schroedinger equation that arises in quantum mechanics with real clocks and discuss the theoretical and potential experimental implications of this process of decoherence."

Relational physics, using realistic clocks instead of presumed absolute time, is primarily an invention of Carlo Rovelli (that is, from the standpoint of Jacques Distler, the devil) and it has been most actively developed by Gambini, Pullin and by Distler's new co-author Rafael Porto.

Based on general arguments of Gambine et al, it is a NO BRAINER that string is falsifiable. Indeed it is already falsified as a fundamental picture of how nature is. So Distler wins the argument that it is falsifiable, right? String cannot be right because it assumes time evolution is unitary.

Conceivably also beginning next year one might be able to show that string cannot be a correct picture because it lacks the very slight energy-dependence of the speed of light appearing in other post-string QG theories—something that may be observed by the GLAST.

But these are very tiny effects which would in any case only falsify string as a fundamental theory. If it could be made to produce numbers, then it could still be tested as an effective theory. In this context I think Distler et al paper can be seen as a kind of shifting, which could be called progress.

It is why I made comment about the paper's reference [22] earlier, with the abstract of the 2004 Gambini Porto Pullin paper. I think Rafael Porto could be a big help to

Distler, if he is disposed to listen to reason 🙂

please excuse the rank speculativeness of this comment 🙂

17. **Garbage**
October 3, 2006

I think the paper didnt change its goals at all, indeed it made them broader!
I think the new version has effectively new results for WW scattering, which was unclear in the old version, and was discussed here as far as I recall. A violation of the new given bounds, in the absense of a light Higgs, will still falsify string theory in all of the forms currently known, or uknown if they obey the S matrix constraints discussed in the paper. One could argue that M theory (whatever that is) could get around this bounds but I pretty much doubt it if the latter desires any reality check. Even though experimentally speaking it is extremly unlikely the bounds will be violated, or the existence of a heavy Higgs for that matter, the idea remains appealing and deserves further study…

18. **Clark**
October 4, 2006

You may be interested by Burton Richter's Reference Frame in the October Physics Today: Theory in particle physics: Theological speculation versus practical knowledge
"…String theory was born roughly 25 years ago, and the landscape concept is the latest twist in its evolution. Although string theory needed 10 dimensions in order to work, the prospect of a unique solution to its equations, one that allowed the unification of gravity and quantum mechanics, was enormously attractive. Regrettably, it was not to be. Solutions expanded as it was realized that string theory had more than one variant and expanded still further when it was also realized that as 3-dimensional space can support membranes as well as lines, 10-dimensional space can support multidimensional objects (branes) as well as strings. Today, there seems to be nearly an infinity of solutions, each with different values of fundamental parameters, and no relations among them. The ensemble of all these universes is known as the landscape…
What we have is a large number of very good people trying to make something more than philosophy out of string theory. Some, perhaps most, of the attempts do not contribute even if they are formally correct…."
Richter ^

19. **Clark**
October 4, 2006

Corrected Link to Richter

20. **Tony Smith**
October 4, 2006

Clark mentions Burton Richter's Reference Frame article in October 2006 Physics Today.
In that article, Richter also discusses supersymmetry, saying:
"… If, for example, the Higgs mass is quadratically divergent, invent supersymmetry to make it only logarithmically divergent and to keep it small. The price of this invention is 124 new constants, which I always thought was too high a price to pay … a conceptual nicety was accompanied by an explosion in arbitrary parameters. However, the conceptual nicety, matching every fermion with a boson to cancel troublesome divergences in the theory, was attractive to many …
The Large Hadron Collider at CERN will start taking data in 2008 and we will know in a couple of years if there is anything supersymmetric there. If nothing is found, the "natural" theory of supersymmetry will be gone. …".

Richter's present-day view of supersymmetry is consistent with what he said 6 years ago in hep-ex/0001012 :
"… supersymmetry … was introduced to stabilize the Higgs mass which is quadratically divergent in the standard model and only logarithmically divergent in the supersymmetric variants of the standard model. Supersymmetry does reduce to the standard model at "low" energies, but it also introduces 80 real and 44 complex constants. The theorists who are fans of supersymmetry are groping for variants that reduce these 124 new constants to a handful. If the supersymmetric successor to the standard model cannot reduce the total number of constants, it would seem to me to be a step backwards rather than an advance.
To the experimenters I would say that supersymmetry is a pure "social construct" with no supporting evidence despite many years of effort. It is okay to continue looking for supersymmetry as long as it doesn't seriously interfere with real work (top, Higgs, neutrinos, etc.). …".

As I mentioned in comment 12. above, it seems that now even Lubos Motl seems to ahve lost his blind faith in the validity of supersymmetry,
possibly because he realizes that it is likely that the LHC will not find supersymmetry,
and that, as Richter said, "… the "natural" theory of supersymmetry will be gone. …".

With respect to the LHC, it may be worthwhile to quote some excerpts from Richter's hep-ex/0001012 :

"… LHC … experiments are huge and the sociology will be complex.
Beware of too many boards and committees … a bureaucratic overlay to the science with committees that decide on the trigger, data analysis procedures, error analysis, speakers, paper publications, etc.
The participating scientists are imprisoned by golden bars of consensus….".

October 4, 2006

Hello to All:

I am currently nearing the end of Ch. 31 of Penrose's mega-tome-mini-encyclopedia – 'The Road to Reality'. Chapter 31 is especially fun and informative as it relates to his views on 'strings', 'supersymmetry', and 'extra dimensions'.

I am hoping to start a lively discussion forum of interested individuals at my newly-started blog: 'Space-Time-Matter' [http://faustscorner.blogspot.com]. Interested readers are welcome to share their thoughts on the text.

Stefan

p.s. I haven't started posting on the topic yet; that will be tomorrow. (I have other things to do today.)

22. **Anonymous Coward Michael**
October 4, 2006

Hey Peter,

how's your own research coming? We are still waiting for you to explain to us all the subtleties of the BRST formalism. Surely you must be about to finish up your long awaited paper, right!?

23. **kramnik**
October 4, 2006

I'd just like to mention this paper hep-th/0610043 (and no I'm not one of the authors). It seems to be suggesting that N=8 super gravity might not be as plagued by infinities as first thought, which leaves the door open to a quantum field theory of gravity.

Any opinions?

24. **Peter Woit**
October 4, 2006

Garbage appears to be a sock-puppet…

I urge everyone who feels the need to discuss Lubos Motl's rants here to keep in mind John Baez's excellent advice that while it is difficult to ignore Lubos, it always repays the effort. I suspect John would have the same advice about Lubos's fan Michael.

25. **Who**
October 4, 2006

October 6, 2006

Dear Friends,

I have posted my first entry at my very own site: 'Space-Time-Matter'.

Please make my site a success, by:

a) visiting it (thought this was obvious, but you never can tell these days);
b) leaving a helpful commentary.

Thank you.

Controversy, Controversy….

October 4, 2006
Categories: Uncategorized

There's almost too much to keep track of the last couple days on the string theory controversy front:

Burton Richter of SLAC has a Reference Frame piece in the latest Physics Today entitled Theory in particle physics: Theological speculation versus practical knowledge. Richter shares my point of view that the Landscape studies currently popular in string theory are not science:

To me, some of what passes for the most advanced theory in particle physics these days is not really science. When I found myself on a panel recently with three distinguished theorists, I could not resist the opportunity to discuss what I see as major problems in the philosophy behind theory, which seems to have gone off into a kind of metaphysical wonderland. Simply put, much of what currently passes as the most advanced theory looks to be more theological speculation, the development of models with no testable consequences, than it is the development of practical knowledge, the development of models with testable and falsifiable consequences (Karl Popper's definition of science)…

The anthropic principle is an observation, not an explanation… I have a very hard time accepting the fact that some of our distinguished theorists do not understand the difference between observation and explanation, but it seems to be so…

What we have is a large number of very good people trying to make something more than philosophy out of string theory. Some, perhaps most, of the attempts do not contribute even if they are formally correct.

The issue of Nature that just came out today has an article about the controversy by Geoff Brumfiel with the title Theorists snap over string pieces: Books spark war of words in physics. He describes Lubos Motl's reviews of the Smolin book and mine on the Amazon web-site, and quotes Polchinski and Susskind. The reaction of string theorists to the books is said to be:

Few in the community are, at least publicly, as vitriolic as Motl. But many are angry and struggling to deal with the criticism. "Most of my friends are quietly upset," says Leonard Susskind, a string theorist at Stanford University in California.

and

The books leave string theorists such as Susskind wondering how to approach such strong public criticism. "I don't know if the right thing is to worry about the public image or keep quiet," he says. He fears the argument may "fuel the discrediting of scientific expertise".

Susskind will be giving a public lecture October 17 at UC Davis on String Theory, Physics and the "Megaverse".

Polchinski avoids the problems associated with the failure of string theory as a unified theory, and promotes in a somewhat overhyped way the idea that string theory explains the RHIC data.

Finally, Smolin makes an offer to string theorists that I feel I should try and match, hoping they will read his book to better understand exactly what he has to say:

If they don't want to buy it, tell them to get in touch with me and I'll send them a copy.

One thing Brumfiel gets a bit wrong is that my problem with string theory is not quite what he says "a fear that the field is becoming too abstract and is focusing on aesthetics rather than reality." The problems I see are rather different, with mathematical abstraction one of the few tools still available to theorists trying to make progress.

The same issue of nature contains an editorial Power and Particles lustily repeating much of the standard hype about string theory, noting that there are problems, but ending with:

Critical-mindedness is integral to all scientific endeavour, but the pursuit of string power deserves undaunted encouragement.

The editorialist definitely does not seem to be of the opinion that alternatives also deserve to be encouraged.

Finally, lots of reviews of Lee Smolin's book:

Unburdened by proof by George Ellis, also in Nature. Ellis takes the opposite point of view from the Nature editorialist, calling for more research on alternatives to string theory.

A loopy view by Michael Duff, in Nature Physics. Duff is extremely hostile to Smolin's book, sneering at Smolin and claiming that his book will "leave the reader rooting for strings" (funny, but this doesn't seem to have been its effect on most reviewers…). Duff agrees that there are problems with string theory, but claims that the problems Smolin correctly identifies are exactly the ones that he himself first identified back in 1987. String theorists like Duff seem torn between claiming that criticisms of string theory are crackpot nonsense, and that they themselves made them first. He goes on to furiously attack various straw men, accusing Smolin of "denying that any progress has been made!" (something I don't think Smolin does at all), and answering the criticism that string theory makes no predictions despite more than twenty years of effort by discussing how theories that did make predictions have sometimes taken a long time to be confirmed (or remain unconfirmed).

The string theorists were scammed! by Peter Shor on Amazon.

The Trouble With Physics by Sean Carroll at Cosmic Variance. If I can find the time, I may write about some of my problems with this review as a comment over there.

Comments

1. **fooltomery**
   October 4, 2006

   Peter,

   If the quarter you're looking for didn't fall near the streetlamp, looking for it near the streetlamp won't help. Perhaps the truth about nature lies far outside the circle of light cast by current theory's streetlamp. Perhaps that truth is stringy, perhaps not, but, as Peirce was wont to say, do not block the way of inquiry. Perhaps the exhaustive investigation of string theories will at least have the merit of revealing where the truth about nature is not.

2. **Peter Woit**
   October 4, 2006

fooltomery,

I think the exhaustive investigation of string theories has already had the merit or revealing where the truth about nature is not. Now the question is what is to be done to make progress on figuring out where it is.

3. **Michael Nielsen**
October 4, 2006

John Walker, founder of AutoDesk (makers of AutoCAD), has a review of Lee Smolin's book at: http://www.fourmilab.ch/fourmilog/archives/2006-09/000758.html

4. **Thomas Love**
October 4, 2006

Burton's article was great. Thanks for the link.

When I read the following in "Cranks, Quarks and the Cosmos" by Jeremy Berstein, I thought immediately of how the comment applies to string theory. Bernstein was discussing the errors Schroedinger made in his book "What is Life":

"What is Life" is proof that a brilliant but wrong idea in science can often have more of an impact than a dull but correct one. (page 63)

As I reread that, I realized that it only partially applies to string theory: String theory is wrong, but is not brilliant. Neither is it science.

5. **Kea**
October 4, 2006

Will any of my pro-M theory comments remain undeleted?

To say that String theory is not brilliant is a tall order, mathematically speaking. Personally, I am very, very tired of all this pointless bickering masquerading as intelligent conversation. It should be perfectly obvious that *both* the broad String formalism and some elements from alternative approaches will prove to be relevant to the eventual picture. Also perfectly obvious is that none of the approaches typically mentioned is correct.

6. **Michael Nielsen**
October 4, 2006

Peculiarly, I had forgotten that Walker also reviewed Peter's book:

http://www.fourmilab.ch/documents/reading_list/indices/book_502.html

7. **Who**
October 4, 2006

a propos controversy
in the long run I think Vilenkin's CNS paper, posted today on arxiv, will be important because of opening up the controversy over CNS—-which I think will prove significant as a falsifiable conjecture bearing on the determination of fundamental constants.

http://arxiv.org/abs/hep-th/0610051
On cosmic natural selection
Alexander Vilenkin
4 pages

"The rate of black hole formation can be increased by increasing the value of the cosmological constant. This falsifies Smolin's conjecture that the values of all constants of nature are adjusted to maximize black hole production."

Vilenkin goes to considerable lengths to refute the CNS conjecture: his argument involves black holes coming into existence by a "quantum fluctuation" and indeed at one point he invokes SOLAR MASS black holes coming into existence by quantum fluctuation

some heat could develop around Vilenkin's paper

8. **Garrett**
October 4, 2006

"If they don't want to buy it, tell them to get in touch with me and I'll send them a copy."

Oh great — I read this just after buying both books.

9. **Thomas Love**
October 4, 2006

Kea Says:

To say that String theory is not brilliant is a tall order, mathematically speaking.

–exactly the point! Some great mathematics has been done along the way, but there is no physics coming out!–

It should be perfectly obvious that both the broad String formalism and some elements from alternative approaches will prove to be relevant to the eventual picture.

—It is obvious to me that most of string theory will fall by the wayside. But I guess we won't know for sure until the eventual picture is revealed—-

10. **Dan**
October 4, 2006

hi Peter,

I did read your book, and have some thoughts:

1- I might have expanded as a full-length chapter on the history of extra-dimensions in physics, starting with Kalula-Klein, and how they failed, and what that might mean for string theory

2- I might have expanded as a full-length chapter on the history of GUT theories in physics, such as SU(5) and SO(10), and how they were falsified, and, what's more, how *conservative* they are, in comparison to string theory, and how given several candidate GUT's have been falsified, what this means for string inspired unification scenarios.

3- I might have expanded as a full length chapter history of physical theories that were "falsified" or found to be inconsistent, and what this might mean for string theory.

4- Maybe with a co-author (i.e Rovelli, Ashketar, Penrose, etc.,) I would have written a full-length chapter on quantum gravity, and how supergravity failed, and then the status of string theory as a theory of quantum gravity, and how well it succeeds in this claim.

5- Given more treatment on failed predictions of string theory. Go into detail string's version of particles and the standard model.

6- delete the chapter on string theory and mathematics and bogandov affair. Replace it with the SM and GR as to why they are a physics theory, and string theory, why it is not a physics theory.

7- explain that historically speaking, staying with 4D and observation and experiments have resulted in science, as opposed to speculation.

Dan

11. **Peter Woit**
October 4, 2006

Garrett,

It's an offer for string theorists….

Dan,

Thanks, some of the things you suggest are things I would have done if I had the energy and desire to write a longer book. Other things you mention I'm just not that interested in, and in that case think people are better off learning about these things elsewhere (and there are plenty of other places).

I really wanted to write about my own take on the subject, which concentrates not on quantum gravity, but on particle physics, and on the relationships to mathematics.

Luckily for people, there's Smolin's book too, which covers a lot of what I didn't.

12. **nontrad**
October 4, 2006

For what it's worth, a reply to Carroll's review would, at the very least, be appreciated by at least this one reader.

In the mean time, with Richter's juxtaposition of Thomas Aquinas and the Anthropic Principle, I can't help but wonder how Weinberg fits with all this…

13. **Peter Woit**
October 4, 2006

nontrad,

I hope that Smolin will find time to respond himself to that review, since it's a more serious criticism than many others. I took the time to write about one part of it, don't have time for more than that now.

14. **Aaron Bergman**
October 5, 2006

For whatever it's worth, I've only skimmed Smolin's book in a B&N, but from what I read, I pretty much agree with Sean's review.

I'd probably end up being a bit more snide, though.

15. **a**
October 5, 2006

it seems to me that Richter promotes the opposite unreasonable extremism.

First, he omits other successes of naturalness (corrections to the electron mass, to the mass difference between charged and neutral pions, etc). Anyhow, this sort of discussion would have been useful 10 years ago, but is now useless: LHC should soon conclusively tell if the weak scale is natural, or if we lost 30 years on a wrong track.

Second, no experiment tells that the cosmological constant is unnaturally small, because we never probed gravitons at energies above 10^-3 eV. Of course, we all expect that the theory of general relativity can be extrapolated at such "high" energies, giving a naturalness problem.

Third, like it or not, some (but not all) constants of nature really seem fine-tuned for "life". Since long ago this suggested that a theory that predicts everything does not exist, but it does not suggest that theory should predict nothing; the situation is not necessarily as bad as string theory suggests. For example, LHC data might allow us to reduce the number of free constants by confirming SUSY-GUT.

About RHIC: strings as an approximate model for RHIC is a minor result. One can easily predict that, in the present situation, any attempt of over-over-over-over-hyping it will fail.

16. **Bee**
October 5, 2006

reg. the Nature articles see also [The inverse problem]

17. **Thomas Love**
October 5, 2006

When I told my wife that Richter had compared String Theory to Theology, she replied: “What an insult to Theology”.

18. **bill lama**
October 5, 2006

Peter,
I’m a retired physicist (PhD in quantum optics, 1971) who would love to read the string and quantum gravity literature. While the popular books (including yours) are wonderful reading, they do not help one who wants to follow the calculations.

The research papers are incomprehendable, unnecessarily so in my opinion. Great physicists have found it possible to write advanced research papers that could be followed by a graduate physicist who was not a specialist in the sub-field. That quality is missing in the string and LQG literature.

I believe that could be corrected and wrote an “Open Letter to the Theoretical Physics Community” with a few suggestions on my blog http://palosverdesblog.blogspot.com.

Am I asking for an impossibility?

Keep up the great blogging.

Thanks,
Bill

19. **Gina**
October 5, 2006

DAN’S SUGGESTED CHAPTERS

I’d love to read the chapters Dan suggested to add. In particular, I will be happy to have any more detailed but accessible information (or links) on why the high dimensions (26 or 10). Actually, if Dan himself can say more on items 1-3 and 5 on his list and Peter wouldn’t object this will be great!

Some remarks on the controversy:

DO WE REALLY HAVE A CONTROVERSY (YET)?

A striking fact about the debate concerning string theory is that there is almost a complete agreement on factual matters between what string theorists say and what people who attack string theory say. (Can you list some real disagreements?) The interpretation of the facts is sharply different but many of the issues concerning the interpretation are not specific to string theory and are of very general nature.

CAN PHILOSOPHY OF SCIENCE HELP DOING SCIENCE?

This is a fascinating aspect of the discussion here and in Peter and Lee’s books. Philosophers will probably be the most skeptical about such “practical” applications of philosophy, for example, of Popper’s point of view. It is hard to consider various theories in philosophy of science as normative and it is hard to consider them as descriptive. (They also are in conflict, of course.)
These theories can be regarded as a way toward understanding and discussing in a scientific way what science is.

IS STRING THEORY FALSIFIABLE?

Well, I am not sure it is clear what string theory IS. But from the rough description of what it is, it seems very clear that string theory is falsifiable. For example, as Peter explained in the book the 26-dimensional model without supper-symmetry was rejected because it have consequences to physics that are regarded unreasonable. This, in principle, can happen to the super symmetric string theories.

THE BUSINESS OF FALSIFIABILITY

Falsifiability is not just a box you have to check and then forget about but rather it is a major part of the whole endeavor. It is not enough that the theory can be falsified in principle but researchers in the theory should devote considerable amount of efforts in this direction.

DESTROY STRING THEORY AND SAVE PARTICLE PHYSICS?

Peter’s noble reason for his attack on string theory is the desire to save particle physics. Well, one has to be very skeptic about claims of the form “Destroy X to save Y”. In this particular case one can be quite skeptical as well. But, in science, (appropriate) efforts to falsify a theory are as noble as efforts to prove it.

20. **nontrad**
October 5, 2006

Peter,

Fair enough; re the reply. I’ll look for Smolin’s comments in respective arenas. Thanks for the link none the less.

Aaron B,

With all due respect, I freely admit that I’m one of the worst sorts of skimmers myself, but surely, to review someone’s work requires perhaps more then simply skimming?

All the best,

nontrad

21. **Aaron Bergman**
October 5, 2006

Which is why I didn’t write a review.

HTH!

I’ve been listening to Lee on WGN radio for a while now, and he hasn’t said anything that makes me like him any more, though.

22. **anthropologist**
October 6, 2006

Well, one ought to give both of you guys (Peter and Lee) some serious credit. You forced the issue about the string theory into the open, and since "Nature" noticed it, many other people will take a notice too. That is a remarkable achievement, and not easy by any means! Sociology is not an easier science than physics, influencing masses takes some serious skill. No less than juggling some string equations around 🙂

Is this another episode in the series "Revenge of the Nerds" ? I do not know, but it surely does look so. Oh, the sweet revenge, on the establishement that is always right.

Guys, wow in it, you deserved it 🙂 There is so much political BS in the sciences, at least periodical upset of the status-quo somewhere should remind the establishment that it is not always right.

Signed, "closet revolutionary" 🙂

23. **Aaron Bergman**
October 6, 2006

Controversy is easy. The anti-establishment storyline is an especially easy sell.

And who's claiming that string theory is right?

24. **Tommaso Dorigo**
October 6, 2006

Hi Peter,

"Susskind will be giving a public lecture October 17 at UC Davis on String Theory, Physics and the "Megaverse"."

For some reason, while reading this sentence I could not help smiling, as this reminded me of those kinds of threats faced by people who become the target of fundamentalist muslims, like "we know your address"… As if you were disclosing where Susskind will be talking in order to unleash your adepts against him.

Because this is becoming more and more like a war. A good war – Free Science against String Theory fundamentalists. Should good wars be fought ? Is the risk that one "fuels the discredit of scientific expertise" worth running ?

I think so, but this is a rather odd situation in science, so we have little guidance from the past… The risk exists.

Cheers,
T.

25. **Alejandro Rivero**
October 6, 2006

Well, you do not need to look for fundamentalism muslims. Here in Spain, the pubs of RightWind and LeftWind fundamentalists had, pasted in their bulletin boards, this kind of lists of names of addresses of the opposite band.

Hmm, we have Spires anyway.

26. **Peter Woit**
October 6, 2006

Tommaso,

I should make clear that encouraging people who disagree with Susskind to attend his talk and in any way bother him was not my intention at all. I mentioned his talk just as an example to show that the pro-Landscape publicity machine is still in action.

These days, the anti-string theory point of view has been getting so much attention that I'm sure much of the audience for his talk will have heard that there are reasons to be skeptical of what he has to say. I don't think there's any reason at all for people who disagree with him to go out of their way to attend his talk.

27. **Ari Heikkinen**
October 6, 2006

Hi,

I'm en engineer for training and I understand your critisism about string theory. However, to mention one, I've read Greene's book about string theory and I think he's as honest as anyone could ever be about it. He clearly states that string theory might be wrong, and judging from his interviews I think he's the most reasonable physicist I've ever heard. Same goes for Kaku. Now, I don't really know if they're right or wrong. They might very well be wrong. Same goes for Newton and Einstein. Their stuff could very well be only an approximation. What do we really know about the universe? Nothing. We have space telescopes and we can look into the past and make educated guesses about things around us. Now, string theorists have their mathematical models that make sense to them and they make educational guesses based on them. Isn't that really what science is all about?

28. **Tommaso Dorigo**
October 6, 2006

Sure, Peter, mine was just a remark to share the funny feeling I had reading your post. But you did well in pointing out you are in no way encouraging people to disagree with Susskind… There indeed is already enough garage fights going on over string theory these days that it is better to state very clearly one is not interested in participating.

Cheers,
T.

29. **Who**
October 6, 2006

BTW the UK edition of Peter's book was #1 on UK amazon's physics bestseller list today.
Their physics category is quite broad: their next larger category up
"nature and science".
I'd say a #1 physics bestseller is worth celebrating.
http://www.amazon.co.uk/gp/bestsellers/books/278409/ref=pd_ts_b_ldr/026-8303087-5718006
At one point today I noticed it's overall sales rank among all the books they sell was #662 which looks pretty good for a book of this sort.

Here's to booksales Peter. Cheers!

30. **a**
October 7, 2006

dear Ari,
Greene forgot to tell that, unlike Einsetin and Newton, string theory seems intrinsically unable of telling anything about physics: whatever you ask, you get 10^500 alternative possible answers.

For example: does string theory predict that we will see supersymmetry?
Answer 1: yes. Answer 2: no. Answer 3: no. Answer 4: yes. etc etc etc 10^500 times.
In practice this can be summarized as: maybe, I don't know.

There are attempts of getting something out of this bad situation, but so far everything failed. Giving up and starting something else is the common-practice when doing research; but in the case of string theory this process is more difficult, because strings were publicly over-hyped.

31. **Spear Mark the Second**
October 8, 2006

Burt's article was interesting reading… he has been repeating that basic content for some time. Among particle experimenters, he has long been one of the most sympathetic to string theory.

There is a whole generation (maybe even two generations) of particle experimenters who came of age contemporaneously with string theory. Experimenters of all types tend to be skeptics and non-believers, and they are hard to characterize. Generally there is a lot of tolerance for our theoretical friends from grad school, who we often know, and know the talents of, pretty well.

I was turned into skeptic about even SUSY when no new particles were found at PETRA, PEP-I, and the SPPS. That the symmetry breaking scale was near 100 GeV and not a single member of the new particle families was less than that mass seemed (and still seems) suspicious. Of course, we're not done yet… a neutralino as light as 10 GeV is still a possibility, technically.

Which is a very important point: conclusively ruling out a conjecture as basic as the MSSM is a very strenuous, detailed, and exhausting experimental endeavor. Our theoretical colleagues long ago stopped providing us solidarity in that venture, and the decimation of budgets in HEP is related to our theorists losing interest in the actual physical world. Look at all the cancellations in the accelerator world…. KAMI, CKM, KOPIO, RSVP, BTeV, Braidwood (technically a reactor experiment), not to mention a witchhunt over the problems in Run II at the Tevatron. Add the sunset of PEP-II and CESR. On the one hand, many of these experiments don't seem to be at the energy frontier, and the energy frontier is always the most fruitful. On the other hand, crucial information has come from off the energy frontier… that SUSY generally provides large, flavor-changing neutral currents is a huge problem, and the experiments that failed to see those neutral currents are now over 40 years old, and were not even then performed at the energy frontier.

Let me go back to Burt for a second… there are significant details about him. They concern this oft-repeated statement that experimental particle physics has been in stasis for 30 years… with Burt, remember, that puts his discovery as the last truly significant one on the experimental side (well, maybe, the tau lepton discovery makes the cut too… done by his colleague Martin Perl, although Burt took his name off Perl's initial paper).

As someone who worked hard in experimental accelerator-based particle physics over those past 30-years, I'd say Burt minimizes the impact of other work (that he did not do) during that 30-year period. Of course he would minimize the impact of others' work… acknowledging others' work in those 30 years does not shine his star at all.

Many, many times during those 30 years the Standard Model seemed in jeopardy. Experiments that pursued the apparent shortcomings of the Standard Model during that period were crucial, and IMHO, way, way more important than all of the string theory developed contemporaneously. First, because experiment does provide a measure of empirical certainty, that string theory has not provided (so far). We don't have to argue any more about whether the Standard Model is mostly right anymore… had the experiments *not* been done, we'd have to constantly add conditions or admit the possibility that the Standard Model might be wrong about heavy quark mixing, low energy parity violation, etc.

Second, many of the experiments done in the last 30 years were the best chance at the time to actually find violations of the Standard Model. Effort was focused where sensitivity seemed apparent to new phenomenon, and actually, the sensitivities so achieved provide very strong constraints on anything new.

Turns out Burt was not very successful at doing most of those experiments. The SLC (his main project) was a fabulous and visionary effort, but was also marred by his organizational shortcomings and tendency to be arrogant.

The SLC got blown away by LEP (and I'm a SLAC alumnus). But now Burt says with some relish that it didn't matter, since LEP found nothing fundamentally new.

What else happened in those 30 years? I had to think hard to remember all the stuff, because, after all, the bottom line is right that the Standard Model was resoundingly verified. It is easy to just remember that, and forget the tortuous journey we all took. That journey (as I remember it) has a bunch of twists and turns, from excellent and ingenious experiments… I'll list a few, but I'm sure I overlook many…. the neutral charmed meson lifetime looked very long, but was finally nailed down by a terrific Fermilab experiment… the b-quark lifetime looked an order of magnitude longer than predicted, and turned out to be right… then neutral B mixing turned out to be way larger than predicted, also turned out to be right… these measurements led hard core phenomenologists (not string theorists) to successfully predict a very large top quark mass… the very large top quark mass is probably the central feature of the fermions in the Standard Model, and not a single string theorist predicted it, and indeed, they have reduced the phenomenon to a simple arbitrary parameter… well, then the Tevatron doggedly pursued the top and succeeded due to incredibly dedicated and ingenious work… the top quark discovery dwarfs all of string theory's contributions (so far) IMHO, and I was not involved in it. Then in CP violation, direct CP violation was an incredible source of controversy throughout the 1980's and 1990's, and was finally resolved again through terrific and ingenious experimentation. CP violation in the B meson system turned out to be observable, because of the surprisingly long lifetime and the large mixing, and again fantastic experiments were done on that topic.

Of course, there is the amazing story of neutrino oscillations and mass, that starts in the 1960's and still has not resolved itself. The major clues were *not* from accelerator based experiments, however, the final decisive experiments *will* be done at accelerator (or reactor) supported facilities.

BTW, is neutrino mass is *not* part of the Standard Model, and
is the first clue of physics beyond it. And many of the key experiments took place during the `30 year hiatus' that seems to have crept into the string theory apologias.

Of course Burt wants to reduce all that to a wish-sandwich, he was not involved. But the entire experimental community is still there, and knows. They know, they know, and they don't stand still, and they don't give up.

October 8, 2006

A couple of quotes from Sean Carroll's piece:

"It seems worth emphasizing that the dominance of string theory is absolutely not self-perpetuating. When string theorists apply for grants, they are ultimately judged by program officers at the National Science Foundation or the Department of Energy, the large majority of whom are not string theorists. (I don't know of any who are, off the top of my head.) And when string theorists apply for faculty jobs, it might very well be other string theorists who decide which are the best candidates, but the job itself must be approved by the rest of the department and by the university administration. String theorists have somehow managed to convince all of these people that their field is worthy of support; I personally take the uncynical view that they have done so through obtaining interesting results."

and

"To be clear, the scientists working on LQG and other non-stringy approaches to quantum gravity are not crackpots, but honest researchers tackling a very difficult problem. Nevertheless, for the most part they have not managed to convince the rest of the community that their research programs are worthy of substantial support. String theorists are made, not born; they are simply physicists who have decided that this is the best thing to work on right now, and if something better comes along they would likely switch to that. The current situation could easily change. Many string theorists have done interesting work in phenomenology, cosmology, mathematical physics, condensed matter, and even loop quantum gravity. If a latter-day Green and Schwarz were to produce a surprising result that convinced people that some alternative to string theory were more promising, it wouldn't take long for the newcomer to become dominant. Alternatively, if another decade passes without substantial new progress within string theory, it's not hard to imagine that people will lose interest and switch to other problems. I would personally bet against this possibility; string theory has proved to be a remarkably fruitful source of surprising new ideas, and there's no reason to expect that track record to come to a halt."

I think those are excellent points.

October 8, 2006

Spear Mark II,

Thanks for the excellent, informative and thought-provoking long comment!

Ari,

Please don't take up space here putting in long quotes from material I've already linked to and encouraged people to look at. You're not adding anything at all to the discussion.

I responded over at Cosmic Variance to part of Carroll's piece, for the piece that Ari quoted, there's an interesting response here:

http://angryphysics.blogspot.com/2006/10/hiring-string-theorists.html

If there's an interesting discussion going on at other blogs, it would be best if people not try and move it over here, but carry it on at its original location, perhaps providing pointers from here.

Strung along

[Los Angeles Times, Book Review section, Sunday, 8 Oct 2006]
http://www.latimes.com/news/science/la-bk-cole8oct08,1,4278240.story?ctrack=1&cset=true

Not Even Wrong The Failure of String Theory and the Search for Unity in Physical Law Peter Woit Basic Books: 292 pp., $26.95

By K.C. Cole,
K.C. Cole, who teaches science journalism at USC's Annenberg School, is the author of "The Universe and the Teacup: The Mathematics of Truth and Beauty."
October 8, 2006

The Trouble With Physics: The Rise of String Theory, the Fall of a Science,and What Comes Next
Lee Smolin
Houghton Mifflin: 392 pp., $26

IN physics, truth and beauty often walk hand in hand. Physicists describe theories as "ugly" or "beautiful," talk about ideas that "smell" or "feel" right. Often, aesthetic judgments lead to discoveries: as in Einstein's theory of gravity and Paul A.M. Dirac's discovery of antimatter. Aesthetics, French physicist Henri Poincaré said, is a "delicate sieve" that sorts the true from the misleading. Or as Dirac famously put it: "It is more important to have beauty in one's equations than to have them fit experiment."

To mathematician Peter Woit and physicist Lee Smolin, however, the search for beauty is ruining physics. Their ire is directed at "string theory," a magnet for physicists because it is so, well, beautiful, and has such great promise for solving what may be the central mystery of the universe — the incompatibility between the two grand laws that describe everything we know.

Quantum theory — which explains the subatomic world with exquisite precision — reveals that at close range, matter, energy and motion are a choppy mosaic of jittery bits. Think pointillist painter Georges Seurat on a triple espresso. Einstein's theory of gravity, which describes the large-scale cosmos with exquisite precision, tells us that space and time are woven into a smooth, seamless surface that warps under the influence of massive objects — a universe painted by Salvador Dali. Where the two realms meet, the quantum jitters shatter the glassy surface of space-time like a child cannonballing into a pool.

String theory is the first approach that seems to bring the two together naturally, and such unification of opposites, like electricity and magnetism, has driven physics for more than a century. Simply put, string theory does this by replacing point-like particles with tiny strings of some fundamental stuff vibrating in 10-dimensional space — their harmonies creating everything from quarks to galaxies. The loops of string don't let anything get small enough to let quantum fidgeting rip space and time apart.

String theory has its troubles, which the authors analyze in great and sometimes lucid detail: It appears to be untestable because the strings are too small to be seen, and recent research suggests that the theory may have an infinite number of solutions, so it can't make predictions. And string theory is so ill-defined that even ardent supporters admit they don't know what, exactly, it is. This is why Woit calls the theory, and his new book, "not even wrong," a play on a put-down by the late physicist Wolfgang Pauli.

These issues are well worth addressing, which makes it all the more disappointing that Woit, and Smolin in "The Trouble With Physics," write mostly about how string theory has ruined their careers — and physics as well. It has "choked off" investigation of "equally promising approaches," Smolin says. It is a "cult" in which "believers don't care about evidence." Physicists who don't work in string theory are rejected and shunned. "The ability to do mathematically clever work … [is] valued over the possession of original ideas," he complains. As for beauty, he writes that "elegance" is irrelevant, and "more sober minds" should insist on "a connection to reality."

Although Smolin's book is fairer and far more readable, both suffer from an overflow of jargon. And their language is telling: String theory is described as a "fad," "fashion" or "trend," its culture as "brash, aggressive, and competitive." String theorists "swagger." References to Smolin's kind of physics, on the contrary, are accompanied by words such as "deep" and "thoughtful."

Smolin is a respected physicist, having earned a PhD at Harvard University and written several delightful popular books, including "The Life of the Cosmos" and "Three Roads to Quantum Gravity." He helped found the Perimeter Institute in Waterloo, Canada, as well as a perhaps promising theory called "quantum loop gravity." He's also a former string theorist, so his book is well-informed.

Woit is a different story. As a postdoctoral fellow at State University of New York at Stony Brook, he couldn't find another position because, he says, he wasn't working on string theory. Woit then moved to Harvard, where the physics department "let me use a desk as an unpaid visitor." He's now a math lecturer at Columbia University.

The authors are right to say that physicists can get cliquish; that some of them swagger; that they frequently fool themselves and that science has become too risk-averse. On the other hand, dozens of astrophysicists, cosmologists, relativists and people who study fundamental particles and interactions in ways not related to string theory do quite nicely; some even dip into theory now and then. In fact, many highly esteemed physicists who formerly disdained string theory (Nobel laureates Steven Weinberg and Murray Gell-Mann among them) have become fans.

So it's hard to believe, as both authors charge, that physicists have been led like sheep to pursue a "failed theory," mostly by Edward Witten, now at the Institute for Advanced Study in Princeton and generally acknowledged genius — and also a nice guy. (In addition to his multiple prizes in physics, Witten also won the Fields Medal — the "Nobel Prize" of mathematics.)

True, Witten is highly influential. But it's hard to imagine him ruining an entire generation of physicists. They are not, in general, followers; getting them to agree on anything is like herding cats. They love nothing better than to prove each other wrong.

The claim that string theory can't be tested is serious; experiment is the ultimate arbiter of truth. But it's impossible to know what is ultimately testable. When the ghostly neutrino popped up in one of Pauli's equations, the physicist admitted he'd done "a terrible thing. I have postulated a particle that cannot be detected." Then in 1956, traces of neutrinos were seen in the wash of radiation spewing from newly commissioned nuclear reactors.

As for Woit's claim that string theory has "absolutely zero connection with experiment," experiments already planned for a new European particle accelerator will look for the existence of extra dimensions and extra families of particles — both predicted by string theory. In fact, many statements about string theory in these books are plain wrong. To say, as Smolin does, that string theorists are not trying to figure out how space and time came into being will surprise the dozens who do just that. To say, as Woit does, that fundamental mysteries about neutrinos are being ignored will come as news to the dozens of physicists who've been working on these problems for years.

So what good, ultimately, is beauty? As the late physicist Victor Weisskopf said, "What's beautiful in science is that same thing that's beautiful in Beethoven. There's a fog of events, and suddenly you see a connection."

Neither Woit nor Smolin sees the beauty in string theory. But perhaps they haven't spent enough time in the fog. Theories often seem impenetrable at the time they are being discovered — and clear and simple (and beautiful) only in retrospect. One of the strangest charges against Witten is that he's often openly muddled. Asked his opinion about a recent turn in string theory, he answered: "I just don't have anything incisive to say. I hope we will learn more." Smolin interprets this as Witten being "stumped." Perhaps it's a sign that he's thinking.

In the end, Smolin admits that he hasn't managed to do much better than string theorists, and his book is "a form of procrastination." One hopes he will soon dive back into the fog and start making connections.

=== end quotation from L.A. Times ===

38. **Tony Smith**
October 11, 2006

Spear Mark the Second said:
"… the very large top quark mass is probably the central feature of the fermions in the Standard Model, and not a single string theorist predicted it …".

Ari Heikkinen said:
"… Sean Carroll …[said]… "… If a latter-day Green and Schwarz were to produce a surprising result that convinced people that some alternative to string theory were

more promising, it wouldn't take long for the newcomer to become dominant. …".

In the present climate of controversy over superstring theory, I think that one who produced a "more promising … alternative" would NOT "become dominant", but would be attacked and ostracised.

In support of my view, I offer my personal experience:

For over 20 years

(published as early as two papers in the International Journal of Theoretical Physics (vol. 24 (1985) 155-174) and vol. 25 (1986) 355-403) , the papers having been received by IJTP on 27 February 1984 and 16 October 1984, respectively, around the time that CERN was claiming to have found the T-quark at around 40 GeV, prompting John Maddox to write a Nature article (Nature 310 (12 July 84) 97) headlined "CERN comes out again on top")

I have espoused a physics model that in fact did and still does explain "the very large top quark mass"
(in terms of combinatorics and physics-related geometry motivated by, but not identical to, the ideas of Armand Wyler)
but,
far from me being a "newcomer" who has "become dominant",
I have been blacklisted by the Cornell arXiv and characterized on the web as a "moronic crackpot" by Harvard's superstring theory web-spokesman, Professor Lubos Motl.

One result is that, when I recently made an attempt at explaining the basic ideas of my constituent mass calculations, it was not posted on the arXiv, and can only be found on the web from my web site at
http://www.valdostamuseum.org/hamsmith/July2006Update.html#factorsphysics
and
another result is that, as Peter mentioned in another entry in this blog,
Michael Green is able to say (without fear of contradiction from the establishment) "There is no alternative to string theory. It is the only show in town – and the universe.".

Still another result is that, if even only some part of my model turns out to be correct and useful, it will remain unknown to the established physics community because its members will not risk damage to their careers by investigating the work of a blacklisted "moronic crackpot".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

39. **Ari Heikkinen**
October 11, 2006

Come on, Lubos' hardly a spokesperson for physicists or even string theorists. As far as I know most physicists aren't string theorists anyway.

If someone says a writer of a paper is a crackpot claiming he's wrong even thought it's right then he'd ruin his reputation. It's amusing to say that one person could ruin someone's career. I think everyone's well qualified to do that themselves.

I think the general public is more or less amused of physicists and theoretical physicists calling eachothers crackpots. It's just a shame that good science projects get cancelled because scientists can't get along.

And lets not forget that mostly taxpayers pay science. It's just sad to know tax money goes for salaries of people who, instead of doing good work, waste their time calling eachothers crackpots.

40. **Robert Ehrlich**
October 13, 2006

As a retired academician / statistician and having just read Smolen's book, a major premiss is not the physical unreasonableness of ST but that ST is a means of replacing the parametric problems in QM with another set in ST. The result is that essentially no progress is made. Smolens' physical arguments are cogent, but to one who has been burned before, the charge of legerdemain of the parameters is striking, if true.

Navier-Stokes Equation Progress?

October 5, 2006
Categories: Uncategorized

Penny Smith, a mathematician at Lehigh University, has posted a paper on the arXiv that purports to solve one of the Clay Foundation Millenium problems, the one about the Navier-Stokes Equation. The paper is here, and Christina Sormani has set up a web-page giving some background and exposition of Smith's work. I should emphasize that I know just about nothing about this kind of mathematics, but I'm reporting on this here for two reasons:

1. It looks plausible that this really is important.

2. Penny Smith tells me that she is a regular reader of this weblog.

Update: There's an informative news article about this on the Nature web-site.

Comments

   October 5, 2006

   With Cao and now Smith, is Lehigh becoming a new powerhouse in math?

3. **Jud**
   October 5, 2006

   "With Cao and now Smith, is Lehigh becoming a new powerhouse in math?"

   Becoming? 🙂

   (I grew up in Bethlehem, PA, where Lehigh is located, and live nearby.)

4. **fh**
   October 5, 2006

   I heard Prof Ehlers talk about her work on GR late last year, it sounds as if her methods are capable of solving some long standing problems in mathematical physics. Very impressive.

5. **Demonic Gerbil**
   October 5, 2006

   This certainly looks promising. I wish I was better versed in the relevant details so I could attempt to judge it for myself.

6. **nc**
   October 5, 2006

   Thanks for reporting on this 9 page paper, 'Immortal Smooth Solution of the Three Space Dimensional Navier-Stokes System'.

   Wikipedia's page http://en.wikipedia.org/wiki/Navier-Stokes_equations says:

   'A $1,000,000 prize was offered in May 2000 by the Clay Mathematics Institute to whoever makes substantial progress toward a mathematical theory which will help in the understanding of this phenomenon.'

   Wiki on another page http://en.wikipedia.org/wiki/Navier-Stokes_existence_and_smoothness lists the exact problems. So it is solved unless there is an error in http://arxiv.org/PS_cache/math/pdf/0609/0609740.pdf

   'We prove the existence of a smooth solution for all time – under physicially reasonable hypothesis on the initial data – for the Navier-Stokes System in three dimensions.'

   How long will that take to be properly peer-reviewed before publication? (I trust it will be checked far more carefully than the Bogdanov's physics papers on string theory…)

7. **fh**
   October 5, 2006

   nc, this is building on a long string of well established, peer reviewed papers Smith has written over the last few years.

   This should be "relatively" straightforward to check.

   BTW, just for fun, her Mathematical genealogy traces back through Weierstraß to Gauß, and in a different branch via Hilbert and Klein to Poisson and Fourier and on to Lagrange, Euler, Bernoulli and Leibniz.

   http://genealogy.math.ndsu.nodak.edu/html/id.phtml?id=47125

8. **John Baez**
   October 6, 2006

   It would be really great if Penny Smith – or anyone! – made some serious progress on the Navier-Stokes equation.

Does anyone know whether this is the same “Penny” who used to post to sci.math and sci.physics?

9. **jamzik**
October 6, 2006

Yes,
PSmith9626 seems to fit the bill, Lehigh University, an interest in the Navier-Stokes equation – but it appears she stopped posting in early 2005. She must have found something that occupied her time.

10. **MathPhys**
October 6, 2006

John,

Yes, it’s the same Penny.

11. **erno**
October 6, 2006

Katherine Hayles summarizes Luce Irigaray:

“The privileging of solid over fluid mechanics, and indeed the inability of science to deal with turbulent flow at all, she attributes to the association of fluidity with femininity. Whereas men have sex organs that protrude and become rigid, women have openings that leak menstrual blood and vaginal fluids… From this perspective it is no wonder that science has not been able to arrive at a successful model for turbulence. The problem of turbulent flow cannot be solved because the conceptions of fluids (and of women) have been formulated so as necessarily to leave unarticulated remainders.”

And indeed, it takes a woman to solve it! (Maybe) Physics? HA! Postmodern 5th Wave Feminism has the answers.

12. **Yatima**
October 6, 2006

May I suggest some intense sessions with a good Freudian analyst (not that I think that psychanalysis is anything other than ‘not even wrong’)

13. **csrster**
October 6, 2006

Oh gawd, that was something that also lurched unwanted from my suppressed subsconscious when I first read this item. (At the time I first heard it I was a PhD student in Cambridge Applied Maths, a powerhouse of mostly-male fluid dynamicists.)

14. **Dick Thompson**
October 6, 2006

I have always cited the state of fluid mechanics, where the equations have been known forever, but no real analytical progress ever seems to occur, as my comeback to dreams of a final theory.

Do I have to change my tune now?

15. **Gina**
October 6, 2006

GO PENNY GO!

(Of course, we have to remember that the NS problem is infamous for
“fighting back” as the Hungarian mathematician Paul Erdos used to say about famous problems.) I wonder if the approximation of NS by certain hyperbolic equations used by Smith have physics relevance/intuition on their own, or are just technical tools in the mathematical proof.

16. **TheGraduate**
October 6, 2006

I wish somebody knew enough to place odds. This is intriguing.

17. **Michael**
October 6, 2006

Hey Peter,

this Navier-Stokes paper is quite interesting. I don’t dare to judge its contents, though. I hope some math colleagues will enlighten me with their expert opinions soon.

Mind if I ask how your own research is coming? You ignored my question last time I asked.

You announced in the spring that a paper of yours on some BRST-subtleties would be fourthcoming this year. Can we hope to read it soon?

18. **Walt**
October 6, 2006

Erno: I forgot all about that Irigaray quote. If Smith has really solved it, that would be an incredibly funny development.

19. **Peter Woit**
October 6, 2006

Michael,

I ignored your question because, from past experience, I don’t think you’re interested in the answer. The answer though is that my work on BRST is not moving as fast as I would like since the response to the book has been kind of overwhelming and it’s taking all of my free time to deal with it. I hope this will die down soon and I’ll get back to making progress on that project.

20. **John Baez**
October 6, 2006

Various unnamed sources say the proof doesn't seem plausible. Probably best to cool it and wait until the paper is refereed.

21. **penn smith**
October 6, 2006

John, it's penny. Can you email me and tell what these "unnamed sources" think is wrong?

Here is one (not important) error found in "Perron's Method for Hyperbolic Systems Part I": In Theorem 21 One needs POSiTIVE
initial data and positive g. IT then takes a little more work to prove the
comparison principle for sub and supersol with the SAME initial data.
Similarly, in Theorem 22. Otherwise counterexamples occur.

However, in both the Einstein and NS papers, I provide a different comparison principle (used in three space dimensions only) with a different proof.

22. **penn smith**
October 6, 2006

The point is that in the proof of theorem 21 of that paper, to apply the
Protter maximum principle to the parabolic approximating equation, one needs postive (not non-nonegative) initial data. In my handwritten version, I had that, and the inequality got miscopied in typeing.
Again, in the two later papers, a comparison principle with the SAME initial data, is proved and used only in three space dimensions by
a different method.

23. **penn smith**
October 6, 2006

And what is this " Unnamed sources tell me that something is implausible" nonsense.
If they have a real mathematical issue, they should (out of courtesy and out of mathematical professionalism) email it to me, so I can look it over.

That is what someone did with the issue that I just posted. I thanked them too!!

THAT"S HOW MATH WORKS. We are grateful for error correction.
We are not a cult.

And I personally care only about truth. I don't care about ego nonsense.

24. **mathjunkie**
October 6, 2006

Does Penny's solution mean that it is the solution describing turbulent flow?

25. **Brooks Moses**
October 6, 2006

Well, the various sources that I've seen claiming that this "doesn't look plausible" are one that are responding to claims that this is a constructive proof (with implications that it will be directly useful in simulations of fluid flow). That claim is, in my opinion, quite implausible — but I don't have the math background to back it up. However, I'm pretty sure that's not the claim Penny is making; at the least, she's certainly not claiming that implication, and that's the really implausible part.

Meanwhile, to answer mathjunkie's question: Given that it's possible to define a non-turbulent initial condition that will lead to turbulent flow in an infinite domain (namely, a sufficiently strong shear flow, at least in a localized region), the solution that Penny's paper describes does, indeed, have the potential to contain turbulence. Since it's not a constructive proof, though, it's not too clear to me what relevance that will end up having to the study of turbulence — though the actual smoothness-of-solution result may well be useful.

Now, my curiousity is how difficult it will be to apply this to flows with boundaries — and whether the method of doing that will involve the analytical equivalent of the computational "immersed boundary method", in which a flow with a boundary is simulated by taking a flow in an infinite domain and applying forcing functions to it that cause the velocity to match a prescribed velocity along a certain manifold. Though that may be a bit tricky, given that the forces are usually Dirac delta functions, and thus the velocity isn't smooth on the manifold. (I think there are ways around that, but I'm a computationalist, not a mathematician.)

26. **penny smith**
October 6, 2006

More detail, for those reading that paper:
In theorem 22 we require $w_{1}(x) =w_{2}(x)$ and
$L(u_{1}}>0.
This arises because to get nonstrict inequalities Protter (for the parabolic max principle) adds an exponential NOT IN MY HYPOTHESIZED FUNCTION SPACES.

IN THEOREM 21 we require $w_{1}= w_{2}$.

That kills the counterexamples.

To get Theorem 21 from Theorem 22, on page 365 line 7, we apply the
proof (not the statement) of Theorem 22 with a sequence of positive inhomogenous terms and initial data decreasing to zero.

AGAIN, NONE OF THIS USED OR NEEDED in either the Einstein Cauchy or the NS papers!

27. **penny smith**
October 6, 2006

Thanks Brooks,
It is NOT a constructive proof. It is an existence theorem.

The Perron method gives a solution as a lower envelope of a transfinite set of supersolutions and are then doing a triply countable sequence of those approximations to get the NS solution.

It is NOT applied computational math.

28. **Brooks Moses**
October 6, 2006

Gina: the approximation by these particular hyperbolic equations does indeed have physical relevance on its own. The incompressible Navier-Stokes equations have some variables (specifically, pressure) that have effectively zero relaxation time. In an incompressible fluid, a pressure wave travels at infinite velocity. One can add a bit of "compressibility" to the equations by giving the pressure a finite relaxation time, and thereby make the problem hyperbolic — and that's what Penny's formlation of the hyperbolic equations does. This was a relatively common computational solution method some decades ago, and is referred to as an "artificial compressibility" method. There are also more modern methods that are based off of that, but do a convergence to a truly incompressible solution.

Since Penny's forumulation also breaks things up into a first-order set, there's a similar issue (without as much physical significance to the problem) in the stress tensor, and so she adds a relaxation constant there; this, I haven't seen before in exactly that form, probably because it doesn't map to a computational problem the way the zero relaxation time on the pressure does.

29. **Richard**
October 6, 2006

"Various unnamed sources say the proof doesn't seem plausible."

I can't believe that John actually posted this comment. "Various unnamed sources" has the ring of a Bush administration leak, and "doesn't seem plausible" is dismissive while having no other content or value of its own.

This is more typical of a Motl drive-by shooting. I'm demoralized.

30. **John Baez**
October 6, 2006

I should not have mentioned vague second-hand doubts about Penny's proof on this blog. My only sensible point was that people should calm down and wait until some experts have had a chance to go through this proof.

31. **John Baez**
October 6, 2006

I should add that I would like nothing better for Penny's proof to be right!

32. **nontrad**
October 7, 2006

To John's last comment: Hear, hear!

Beyond the fact that NS is a intricately interesting system of equations (I encourage all to muck around with these equations if they never have; since everything from GR to QCD to EM and, infact, huge swaths of PDE can pop up in suprising ways depending on one's background) — it would be really truly *great* if Dr Smith's work really did knock over this historical giant…

Looking forward to learning more, and hoping for the best on this concern!

33. **penny smith**
October 7, 2006

Brooke is very smart. He understands.
By the way, I have posted the stuff I wrote here about the corrections to the earlier paper at arxiv. It will appear late on Monday EST. You people got first dibs.
Thanks for the interest in my paper.

34. **Johan Richter**
October 7, 2006

What would the physical relevance, if any, be if this paper held up?

Also how long do you think it will take before the paper is checked? It is short so we should not have to wait as long as we did with Poincare should we?

35. **MathPhys**
October 7, 2006

Perelman's papers are not that long. That was the trouble 🙂

36. **surlygrad**
October 7, 2006

pardon my ignorance, but is the analogous result known for the IBVP, on some reasonable domain?

37. **jeremy**
October 7, 2006

Penny,

Can you write an "expository paper" for your work on NS equation, meaning to have all the details in one paper? It makes a difficult read having to check all the references; some of them are yet to appear. Hopefully this would not require too much of work.

38. **Michael**

October 7, 2006

Peter,

no need to doubt that I wanted to know what I was asking. Yes, I dislike your populist anti-science crusade. But that makes me all the more interested in what you have might have to say on a more technical level.

Let me freely admit that I don't believe you are doing any research at all. I believe you are pretending to make yourself look more serious and competent than you are. I would happily stand corrected, however, if you could demonstrate the ability to write a decent research paper — no matter if it's math or physics. I'll be patient and check back with you every few months to see if you are making any progress. Please keep us posted. Thanks.

39. **penny smith**
October 7, 2006

This doesn't affect either my proof of NS or Einstein Cauchy.

I posted some fixups here of theorems 21 and 22 of "Perron's Method for
Quasilinear Hyperbolic Systems PartI" and have now found another fixup needed
so I have decided to ditch those theorems and replace them by Theorem 4
of my Einstein Cauchy Arxiv paper math.DG/ 0605352.

This gives the results of the Part I Perron paper above in all space dimensions that are odd and bigger than or equal to three. Lately, I seem to care only about three space dimensions (smile).

The correction will appear at arxiv late on Monday evening.

40. **Peter Woit**
October 7, 2006

Michael,

Thanks for your interest, although I think you have me confused with someone else (Lenny Susskind?), since I've never been on a "populist anti-science crusade".

41. **penny smith**
October 7, 2006

Dear Jeremy,
The Corrigendum to the old paper is at both JMAA (electronically through science direct), and at Christina's Somani's webpage for me.

When the dust settles and I get more than two hours a night sleep, I may indeed write something expository, but odds are that someone else will do it.
best
Penny

42. **jeremy**
October 7, 2006

Penny,

Thanks for the information. I hope you will get some more sleep and get refreshed.

All the best.

43. **Michael**
October 7, 2006

Peter,

believe me: I wouldn't confuse you with Susskind in a million years. You see, he is a maverick with incredible skill and talent. I don't agree with many of his views, but I sure admire his many important and beautiful papers.

44. **Marty Tysanner**
October 7, 2006

re: "Michael"

There is an interesting discussion of a potentially very important mathematical result going on here, and what does this "Michael" contribute? Pure noise and jarring distraction that has absolutely nothing to do with the topic at hand; his demonstrating thatcomments here are unsubstantive by any measure. As usual, "Michael" is acting like someone who is clueless about what is going on around him, someone who has an adolescent fixation on heckling Peter because he disagrees with Peter's broader viewpoints about the direction of research in string theory and particle theory in general.

But this is what we have come to expect from "Michael" — nothing of substance, just air-headed commentary that is almost invariably on the same topic: *So, Peter, how's your research coming? I think you are a charlatan. Blah, blah, blah…* I don't know what he *thinks* he is accomplishing by this immature mode of discourse, but to rudely interrupt a meaningful discussion with mindless, irrelevant blather like his above comments is bound to convince others that he is nothing more than an insensitive, anti-intellectual boor.

I wish Peter would be more merciless about deleting such worthless comments.

45. **Peter Woit**
October 7, 2006

Marty,

For better or worse, I've had a policy of allowing string theorists to post whatever comments they want here, without deleting them. Some people are convinced that I'm deleting all the intelligent comments with substantive responses to my criticisms of string theory, and just leaving the juvenile, worthless ones. Not so at all.

46. **surlygrad**
October 7, 2006

why isn't anyone asking the important question: how are we at columbia going to sucker penny smith into coming to present her work?

while the N-S solution will be fantastic if true, these results on a comparison principle for hyperbolic equations are interesting in their own right and i'd love to see them.

47. **David Purvance**
October 7, 2006

Sounds incredibly coincidental, but a "Fer Product" solution to the 3-space periodic Navier-Stokes was posted on arXiv on 2Oct2006. Has anyone looked at or commented on this paper?

48. **Nets Katz**
October 7, 2006

Perhaps this is not the right place to have a philosophical discussion on the theory of PDE. I confess that I have not attempted to verify the proof line by line, but having looked at the paper, I will nevertheless go out on a limb and say that I have doubts.

In order to solve a hard problem, generally you have to overcome the difficulty. The difficulty in Navier Stokes has little to do with the linear terms – the parabolicity of the equation – but has more to do with the nonlinear terms – supercriticality. For fixed energy, if we scale down a pulse, the nonlinear term dominates the linear ones.

What I find very curious about this claimed solution is that supercriticality is never addressed. We replace the equation by a 1st order system which can always be done by introducing derivatives of the original unknowns as unknowns. We add a tiny bit of differentiation in t to make the equation hyperbolic. We claim that hyperbolicity is all that matters, and we even get to take a limit making the terms that caused hyperbolicity to disappear.

But there are genuinely hyperbolic problems where supercriticality is the issue. Why not try to do the same thing for, say, the 3d quasilinear wave equation with 7th power defocusing nonlinear term.
\Square u – |u|^6 u= 0.
It is an open problem whether this has "eternal solutions" even in the radial case.
For that matter, why not study the focusing version of this equation
\Square u + |u|^6 u=0
(I may have switched the signs.)
Is there any reason the same method can't take care of both? That would be odd because the focusing one is known to have short time blow up.

Can anyone explain why my doubts are unfounded?

Nets

49. **mathjunkie**
October 7, 2006

I have some doubt about the result that an immortal smooth solution can exist. But, first, I have to admit that I am no expert in turbulence. Navier Stokes equation describes turbulence which is usually chaotic, then it is unlikely that an immortal smooth solution exists.

50. **Navier**
October 7, 2006

I think the paper needs a lot of work to be more readable. And one can check the details. Independently of the validity of the previuos results of the author.
For instance, based on the definition of the prolongation of the Heywood force, the pressure is given as part of the force F. But then in Theorem 2 an assumption of the regularity of F (continuous and bounded) makes the pressure continuous (by assumption). However it is well known that if the pressure is continuous then the solution (the Leray solution which known to be "immortal") is regular.
May be it is a typo and the pressure is not in F, but if it is we are faced with a circular argument.

51. **Euler**
October 7, 2006

It seems that the same proof works for the Euler equations and the Burgers equations!!!!!! If it doesn't, it would be nice to get an insight on the role of the dissipation in this proof.

52. **NS Fan**
October 7, 2006

1. Does the proof of existence of the solution also mean that the analytical solution is also availble or available soon? If Penny's solution turns out to be a valid one, she should be awarded $10Million.
2. Can we construct solutions to some special cases using her method to compare with the known solutions in order to gain more confidence, excitement?

Penny, no matter what, great job!

53. **Brooks Moses**
October 8, 2006

Nets: This particular paper is essentially one of the "we reduce the problem to a previously-solved problem" sorts of papers — where the previous problem is the question of smooth solutions for hyperbolic equations with this sort of term. You'll have to read Penny's other papers (given in the references) to find the things you're looking for. Specifically, this is handled in the "proof" section of Theorem 2, I believe, which references her previous papers Sm2 and Sm4.

MathJunkie: Turbulence, so far has been observed, does not contain any cusps or other non-smoothness (and certainly there's no reason why it would need to!); thus, it's not at all incompatible with an "immortal smooth solution".

Navier: A valid point! However, upon inspecting the equations, it appears that the inclusion of p in F is indeed erroneous; there should not be an undifferentiated p term anywhere in the Navier-Stokes equations, and certainly not in the equation that puts it in.

Euler: It can't work in the Euler or Burger's equations, because both of these have well-known counterexamples involving shock waves. I suspect you'll find the role of viscosity to show up in the referenced things that I pointed Nets at.

NS Fan: 1. No, it regrettably does not mean that. 2. The only parts of Penny's method that construct a solution are the limit-of-hyperbolic-approximations part of the proof. That portion of the method is closely related to existing computational methods which are already quite well-tested. Unfortunately, the rest of the proof doesn't appear to offer any opportunities for such testing.

54. **Mr. T**
October 8, 2006

>Navier Says:
>
>October 7th, 2006 at 8:51 pm
>I think the paper needs a lot of work to be more readable.
>…

I agree with Navier. It is not a good idea to use boldface to emphasize what is important and to emphasize. This is mathematics, not literature.

It seems that she is not familiar with TeX. She should just calm down and do a bit of work to make her paper look fairly neat.

In addition, I would not advise her to argue mathematically technically on the internet. I do not want to tell why.

With regards,

Mr. T

55. **Euler**
October 8, 2006

Brooks Moses: I am sorry to report that the Burgers equation does satisfy the conditions of the hyperbolic systems considered by Prof. Smith. In fact the presence of the dissipation complicates things for NSE and she had to augment them to make NSE fit with her previous theory. My guess is after a day or two, this result will be proven to be incomplete, since Burgers equation to known to be blow up in finite time.

56. **Benni**
October 8, 2006

Penny has withdrawn her paper. It seems that euler is correct.

the dreams are gone…

(sometimes it is good, to talk to more people and hear opinions before submitting anything to arxiv or journals. It can damage reputation to be "another one, who tries to get a clay prize"…..)

Hopefully Penny can correct her paper and make it complete…..

Good luck, Penny!

57. **anon**
October 8, 2006

The paper has been withdrawn, it seems.

58. **Lianhong Gu**
October 8, 2006

Don't give up, keep working, Penny!

59. **D R Lunsford**
October 8, 2006

A friend with long experience in turbulence comments as follows:

"I recently had an interesting discussion with someone who described his own interesting but unsuccessful work on this problem. (He tried to bound the "enstrophy" production – basically dissipation / viscosity).

"He told me that the solutions absolutely must exist, because if there really were some singularities, they would signal the breakdown of the NSE into something Boltzmann-like, anyway some kinetic level description.
But the fact is, there are no known breakdowns in any fluid phenomenon known to be governed by the NSE. In other words: non-existence of solns some sort of singularity breakdown of NSE, which we would
know about.

"Of course, it's good to look for real proofs, but this "argument" more or less settled the issue for me.

"Anyway, it's curious that according to your first link, the paper was withdrawn by the author due to fatal flaws. Also, it was interesting that she also looked at GR. I heard a talk about the GR equations as a hyperbolic system, with a view to existence of solutions, by Arthur Fischer from UC something or other, years and years ago. This seems more interesting to me — existence of
solutions to some system the validity of which we really have no independent knowledge of. An existence proof for NSE would very likely have zero impact on turbulence. But who knows, maybe not. Maybe it would reveal some new property."

-drl

60. **Euler**
October 8, 2006

Every serious mathematician who worked on the Navier-Stokes equation spent at least one night thinking they have the proof of the regularity problem, but they usually sober up after a day or two. Smith's idea to look at NSE as a singular perturbation of a slightly compressible fluid is a well known technique numerically and analytically. However, the slightly compressible NSE is as difficult as the NSE, and may be more. Another problem is the convergence of the solutions to the slightly compressible to the incompressible is not trivial. I hope Smith will take the responsability of a good researcher and clears the status of her preprint with Nature and all the news media who jumped on this.

61. **woit**
October 8, 2006

Polite comments explaining what the problem or problems with Penny Smith's work are are welcome here, rude ones containing no substance aren't.

62. **Chris W.**
October 8, 2006

From an interested bystander:

Leaving aside its apparent failure (pending possible revisions) does this attempt explore significant new territory? Does it suggest ways to approach the problem that haven't been considered before?

63. **penny smith**
October 8, 2006

Dear Euler,
I certainly did.
I loathe the way they wrote articles so quickly.
Arxiv is supposed to be a preprint file—not a journal or a newspaper.
This has hurt me a lot.
I might quit math.
Penny

64. **penny smith**
October 8, 2006

Well, no. I wont quit math.
But, I do feel rather depressed.
Anyway, life is about ups and downs.

65. **Michael**
October 8, 2006

Hey Penny,

please keep your head up. See Lubos Motls comment, who is in the business of being blunt and honest, rather than polite:

"Nevertheless, I think that Prof. Smith has nothing to be ashamed of: serious thinking sometimes requires a trash can."

I think Lubos speaks for many colleagues, certainly including myself.

Surely you were very brave to make this public before a thorough peer review. Oh well — live and learn…

66. **mathjunkie**
October 8, 2006

(sometimes it is good, to talk to more people and hear opinions before submitting anything to arxiv or journals. It can damage reputation to be "another one, who tries to get a clay prize"…..)

Submitting an article to arxiv is fine. The experts in the field can soon point out the problems with the article. The author soon knows what goes wrong with the article or otherwise it is actually a complete proof.

67. **Benni**
October 8, 2006

mathjunkie wrote: Submitting an article to arxiv is fine.

But not such thinks. If you are doing this twice or more times, nobody will take you seriously anymore. Such work is best send to a journal with long referee reports before publishing it at arxiv.org.

68. **Marty Tysanner**
October 8, 2006

I agree with the comments of "Michael" above. I think it was brave of you to put your results out to a wider audience to get feeback, even though it exposed you to potential public embarassment. Fortunately you discovered your error before things got even more public. In any case, you could do a lot worse than to make errors on such a difficult problem!

(To "Michael": It was very refreshing to see a reasonable comment from you. I don't mean that in a condescending way — I am sincere. If you would take such a reasonable tone when you want to debate Peter, leaving behind the taunting and mocking behavior and ad hominem attacks and sticking with well formed arguments, I and probably others would be more interested in what you have to say.)

69. **Michael**
October 8, 2006

Marty,

Penny clearly distinguished herself from the likes of Peter Woit by making an honest attempt at solving a very hard problem. Peter only mocks other people's work and caters to the prejudices of the half-educated. I just do not believe that he deserves the same kind of courtesy — next best thing is to try and expose him for what he really is.

Is it really so difficult to understand this basic difference? What good are well-formed arguments if the addressee is disingenuous? They are about as effective as stickers at the cockpit door "Please do not hijack this aircraft" against Islamic terrorists. Incidentally, for well-formed arguments you might try the arxiv instead of this blog.

Take as an example my recent inquiry about Peter's alleged research activities. Want to make a bet that no research paper of his is forthcoming within a year from now?

70. **Christine Dantas**
October 8, 2006

To Penny Smith:

> We are made to persist. That's how we find out who we are.

— Tobias Wolff

Best wishes,
Christine

71. **Navier**
October 8, 2006

To Penny Smith:

I understand very well you frustration.
The mathematicians who thought they proved the regularity of NSE were depressed. In any case there published papers using previous papers which are known to be wrong. This is science, and you need to continue your work.

I would really like to know what is the error that led you to retract your previous papers?

72. **MathPhys**
October 8, 2006

Isn't true that Boltzmann killed himself because he couldn't solve the Boltzmann equation? Well, that was silly.

I think posting a paper on the archive is just as good, or as bad, as talking to a colleague next door about your work. It's no big deal.

73. **Arun**
October 8, 2006

Penny Smith,
Nothing ventured, nothing gained. Don't give up, please!

74. **surlygrad**
October 8, 2006

so is the earlier work on the comparison principles for hyperbolic equations also void or is it just the NS proof?

75. **Richard**
October 8, 2006

Has anyone else wondered if medals and large monetary prizes in mathematics may have a dark side? I suppose that that they do place mathematics more prominently in the public eye, which is probably a good thing, but recently lawyers were dragged into the picture in another infamous case involving egos and lack of egos, and now Penny has been a victim of premature media hype and heated internet propagation, which probably would not have happened without this "famous" problem having been given such a high monetary profile.

And Penny — the heartbreak of mistakes is part of the territory. Get right back up on that horse!

76. **Daniel Grumiller**
October 8, 2006

Penny, I don't know if this will cheer you up, but it is a well-known story about Werner Heisenberg, who graduated on turbulence and later became one of the co-founders of quantum theory and a famous physicist:

He said he wanted to ask God two questions:
1. Why Relativity?
2. Why turbulence?
He was optimistic to get an answer on 1.

Don't give up. And maybe find a simpler and less depressing problem in the meantime.

77. **CapitalistImperialistPig**
October 8, 2006

I have read (in P. A. Davidsons *Turbulence*) a version of the questions Daniel Grumiller attributed to Heisenberg attributed to Horace Lamb. In that version there were two things he wanted God to explain:

1. Quantum Electrodynamics
2. Turbulence

Since this was dated 1932, you have to say he had a nice insight into at least the order in which God would provide explanations!

78. **Timothy Clemans**
October 8, 2006

One thing to note about the Nature article about Smith's work is that is clearly addressed the issue of how review would be done. Look problems have come up in many manuscripts that looked like they had promise. The important thing is that the serious flaw was found now and not two years from now. The news media is very important in these kinds of issues. They are real developments that need to be covered.

"Has anyone else wondered if medals and large monetary prizes in mathematics may have a dark side?" The Wolfskehl prize for Fermat's Last Theorem generated a lot of manuscripts which overwelmed universities.

79. **D R Lunsford**
October 8, 2006

Dear Penny,

Thank you for taking on this problem. Hang in there.

-r

80. **D R Lunsford**
October 8, 2006

PS let us know what you find out

81. **Marty Tysanner**
October 9, 2006

Michael,

Out of respect for everyone else, I don't want to belabor this point, but I think it is important. You said about Peter,

I just do not believe that he deserves the same kind of courtesy — next best thing is to try and expose him for what he really is.

I see two different issues here. The first is whether or not you should show courtesy to Peter. The second is that you want to try to expose him for what you think he is. Key questions are, who are you trying convince in your exposure, and what is the best way to go about it?

The main problem I see with your past tactics is that you come across as someone who wants to make a lot of noise by heckling Peter rather than someone who has something useful to say. If you were at a talk listening to a well known speaker and somebody in the audience stood up and started shouting and making a lot of noise would that make you sympathetic to that heckler? I would be very surprised if you welcomed it and changed your opinion of the speaker's point of view because of the outburst. Why should it be any different here? If you want to show anyone how wrong Peter is, you need to use reasoned arguments and counterexamples rather than just trying to "put him in his place." For one thing, whether or not Peter is right about the role string theory should play in particle physics is quite orthogonal in most people's minds to whether or not he has an alternative program of his own. (In fact, if he did have his own program, others would probably accuse him of trashing string theory to make his own ideas look better — the "hidden agenda.") For another, evaluating the merit of a scientific program or idea is meaningful in its own right — grant administrators need to do it, and so does anyone who referees a paper. That's the way I see it, anyway, and that's a key part of why I don't think your tactics of heckling, ad hominem attacks, and ridicule of his scientific activities will resonate much with most impartial observers.

The other question is, who you are trying to sway with your tactics? If you are trying to use rude comments and interruptions as a way of gaining the praise of other people who already agree with you, then perhaps your tactics are appropriate. But catering to people who already agree with you seems like a really pointless thing to do. Displaying bad manners and disrespect while identifying yourself with string theorists could easily look to everyone else like a reflection of the attitude of some string theorists. In the eyes of the less educated public and other decision makers who ultimately control funding, "some string theorists" could easily become "all string theorists," and their general perception of string theorists could spill over into attitudes about the viability of string theory in general. Again, that's the way I see it. Of course, the fraction of the public and decision makers who frequent this blog is probably not substantial, but you are already aware that this blog is a magnet for some journalists who can interpret what is going on here, and thereby disseminate their preceptions to a much wider audience. What kind of perception of string theorists do you personally want to help create in the minds of others?

So it seems to me that the real audience you should be thinking about is the people who aren't likely to ever be string theorists: scientists other than physicists, physicists who aren't string theorists, opinion makers, and the general public who frequent this and other blogs out of interest in science or just a chance to watch a little controversy. There are a lot more of those people than there are theorists in fundamental physics, and they ultimately are a lot more important to the future of string theory funding. And those people aren't going to be the least bit impressed by tactics like the ones you have favored in the past.

82. **TheGraduate**
October 9, 2006

Navier:

The information concerning the nature of the error can be found on her website. Perhaps it would be best to look there …

83. **mathjunkie**
October 9, 2006

A side issue.

Penny said she submitted the article to Journal of Mathematical Analysis and Applications (JMAA).

Is JMAA's rejection rate high? Is it a prestigious journal in pde? I just wanted to submit an article on pde.

84. **Sacha**
October 9, 2006

I think possibly every maths person has had moments where they think they've solved some hard problem, and then later found an error in some assumption or something with the effect that their proof instantly collapsed. Painful, yes, but helpful, as it means that that path was not the right one to take! And in trying, you learn a huge amount.

Keep up the research Penny.

85. **a**
October 9, 2006

By the way, why arXiv does not have a trackback to this post, that contains very informative comments?

86. **penny smith**
October 9, 2006

As to earlier work on hyperbolic comparson principles:
With a necessary (based on counter examples) additional condition,
I can still prove these results for short time depending on the initial data.
I am going to submit a paper on that: fixing my JMAA paper to a journal where it will get a decent referee job. In math that can take a while.
I have written it in manuscript form already.

This means the Einstein Result will also be true for short time
depending on the initial conditions.

87. **penny smith**
October 9, 2006

The necessary condition is on the sub and supersolutions and only such sub and supersolutions will have a comparison principle.
That's true for systems.

For the semilinear wave equation, no extra condition is needed, but there my comparison principle was proved for short time only.

88. **penny smith**
October 9, 2006

This means that my Perron method for hyperbolic systems also works for short time depending on the initial data. And, that is the paper that I am rewriting for submission to a journal.
Step one: Write and send that paper, with the corrected comparison
principle included.

89. **penny smith**
October 9, 2006

As to JMAA. It is a great and prestigous journal. It has a high rejection rate.
Nevertheless, they (and I) screwed up on that paper. So did the reviewer for Math Reviews.
This sort of thing happens. It is my bad luck. If the error had been
noticed by a referee, I would have fixed it in a few days and resubmitted and that would have been that.
Now, I look terrible and feel worse.

90. **penny smith**
October 9, 2006

The support here is helping me heal though!

91. **woit**
October 9, 2006

a,

The arXiv policy, set by its moderator Jacques Distler, is to censor any and all trackbacks to this blog, whether they're about math or physics. I tried for a while to do something about this, finally gave up since it wasn't worth the time or energy.

92. **D R Lunsford**
October 9, 2006

Penny,

How did you become interested in the NSE in particular? If you want to discuss offline I am at antimatter33 at yahoo dot com.

-drl

93. **Michael**
October 9, 2006

Marty,

thanks for your effort of explaining. I disagree with your fundamental assumptions, and therefore reach very different conclusions.

>> would that make you sympathetic to that heckler?

Are you able to understand the difference between academic discourse and deception for personal gain?

>> If you want to show anyone how wrong Peter is

I don't! Some very accomplished people think that string theory is a waste of time and effort. Plurality of opinion is generally good. What I despise is the way Peter makes no scientific contribution of his own while exploiting his populist criticism for attention and personal gain.

>> What kind of perception of string theorists do you personally want to help create in the minds of others?

Do I have to care? Is string theory a public relations affair? The moment this determines more than the level of background noise I have to endure is the moment I quit.

>> The other question is, who you are trying to sway with your tactics

Nobody, of course. You are free to believe in a democratic approach to science, I don't. I have seen that some people dislike my comments here and stick up for Peter as a result. (You are probably in that group.) Maybe it makes you a good buddy, but there would be less positive things to say about it.

94. **Andreas**
October 9, 2006

Oh boy, this blog documents is a real tragedy.

95. **jeremy**
October 9, 2006

Michael,

If you want to sneer at Peter, he has given you plenty of opportunities. But you as everybody else here know that this is not the place. Can you please show some respect for the decencies?

96. **John Baez**
October 9, 2006

Don't worry, Penny, no reasonable being will think ill of you for making this mistake. On the contrary, they should be impressed at your ability to accept it and move on.

97. **Chris Oakley**
October 9, 2006

Good luck, Penny.

A whole lot of annoying aphorisms spring to mind, like the fact that a theoretician's best instrument is his/her waste paper basket, and that nothing of value comes easily.

Don't give up!

Someone expressed reservation earlier about the whole concept of a Millenium Prize, and I agree with these reservations. A lot of problems remain unsolved because they are – with existing techniques, anyway – insoluble. Encouraging people, using large cash prizes, to continue to bang their heads against brick walls when they might otherwise be going off in orthogonal, and perhaps more productive directions may not be such a good idea.

98. **John Baez**
October 9, 2006

On a wholly other note, I wish Michael would spend a few days pondering Marty Tsysanner's wise and well-meaning advice. I'm sort of amazed at the careful thought Marty put into writing that.

99. **a**
October 9, 2006

I agree with Baez (2 posts above): in my view scientists that admit their mistakes are more trustable than ones that don't. Unfortunately withdrawing wrong papers is not the common-practice among us physicist.

100. **Editor**
October 9, 2006

Why is P. Smith publishing all of her results in JMAA.
I just noticed that P. Smith is on the editorial board of JMAA.
Does that help get a paper accepted without a thorough review?
I do have serious issues with this.

101. **penny smith**
October 9, 2006

Maybe, they trusted me too much because of that.
Not my doing.
I have plenty of papers not published at JMAA
Penny

102. **dave tweed**
October 9, 2006

@Editor:
I don't know any of the facts in this case. However, in general people are on the boards of journals in subject areas they understand well (even though they may not be detailled reviewers themselves any more). The areas they understand are likely to be the areas they are working in, so it's quite likely that they'll be submitting to those journals.

As to submitting to journals with less thorough reviews, I don't know of anyone who believes the work they do isn't actually correct, so thoroughness isn't a reason for choosing where to submit. (There are more "debatable" reasons guiding submission choices, such as not submitting to journals that are so popular that they can afford to reject papers that are merely "good" and not "exceptional". But that's different from hoping incorrect work will be accepted.)

I think the saddest thing about this is as an instance of the "I was there" phenomenon: we want to have been there when something amazing happened, so we force the interpretation that something groundbreaking _has definitely_ happened rather than leaving it to experts to figure out "at a natural pace". Given the history of things like Kempe's flawed proof of the four colour theorem, I'm not surprised that it takes a while for erroneous steps to be spotted; however Kempe chains are (so I'm told) an important element used in the correct proof of the four colour theorem.
So lets let things "cook" for a few months and then make a considered judgement of things.

103. **penny smith**
October 9, 2006

Dear John,
Well, first thing is to fix any wrong results, and get that published.
Also, I have other papers to write.
Thanks for the supportive comment.
All that really matters is getting the correct results in print, because that is SCIENCE.

104. **penny smith**
October 9, 2006

It's going to take more than a few months, because most math papers are reviewed VERY slowly.
I wish JMAA had been much slower.

105. **Marty Tysanner**
October 9, 2006

(Once more, I apologize to others for my part in keeping this subthread alive. I expect this will be the last time.)

Michael,

You said that

What I despise is the way Peter makes no scientific contribution of his own while exploiting his populist criticism for attention and personal gain.

Clearly you are putting yourself in the position of being a judge of Peter and his character. Who made you a judge of others? What makes you so certain of your infallible judgement of others and their motivations that you can make such pronouncements without any doubt? Clearly there are many others here who don't share your conclusion about Peter's motivations by the fact that they are participating in various discussions under his auspices. Even Penny, whose efforts you praised, is apparently a regular visitor, and also someone who felt that the quality of the audience here was sufficient to discuss her results. Do you think she and others would have done this if they thought Peter was doing all of this just for his own personal gain? Yet you seem to place yourself above others here in your belief that Peter is really just a fraud, and furthermore that your True Judgement empowers you to use disruptive tactics and otherwise reflect badly on string theorists in general. Your behavior may negatively affect a lot of people, but Peter is only one of them.

You said,
Nobody, of course.
in response to my question about who you were trying to sway with your tactics. If this is true, then your entire participation here is completely pointless and a waste of your time. But I don't believe that you don't care about swaying anyone, because in your first response to me you said,

I just do not believe that he deserves the same kind of courtesy — next best thing is to try and expose him for what he really is.

If you want to expose him, then you clearly want to expose him to others, to convice them that Peter is the fraud that you think he is. At least that's the way I read what you wrote. So I think you still need to think about who you are trying to convince, and what is the best way to go about it. I have already explained why I think your past tactics are a completely counterproductive approach, so I guess I really don't have anything else to say on the subject that is any more likely to reach you.

106. **Navier**
October 9, 2006

Dr Smith,

Please tell us what is error in your previous publication!!

107. **Michael**
October 9, 2006

>> Clearly you are putting yourself in the position of being a judge of Peter and his character. Who made you a judge of others?

I did. What do you want? You criticize me — what's your entitlement?

>> What makes you so certain of your infallible judgement of others and their motivations that you can make such pronouncements without any doubt?

You are getting weirder by the minute. I'm not infallible. Just voicing an opinion and acting on my personal convictions.

>> your entire participation here is completely pointless and a waste of your time

No. It makes Peter's unethical behavior less rewarding. I find it quite worthwhile…

>> But I don't believe that you don't care about swaying anyone, because […]

Swaying people's opinions in a scientific matter is just completely different from exposing a crackpot. I find it hard to take you seriously if I have to explain this to you.

>> I have already explained why I think your past tactics are a completely counterproductive

Yes, in essence it's because you believe in persuasion and democratic voting on scientific matters. And I don't.

108. **jeremy**
October 9, 2006

Michael,

OK, but why do you have to be a jerk?

109. **a**
October 9, 2006

Peter, this off-topic discussion is annoying. If you do not want to censor Michael, what about creating a separate posting where people can insult you without disturbing other readers?

110. **Peter Woit**
October 9, 2006

a,

Sorry about this, presumably “Michael” will get tired of this soon, and in the meantime he’s an excellent example of the reaction of the string theory community to the appearance of my book. The unwillingness to deal with what I have to say there, coupled with personal viciousness and cowardice, are quite telling. It seems that “Michael” divides his time between UMass in Amherst and the HEP group at Brandeis. Someone familiar with one of these places might want to tell us who he is. I strongly suspect that if he had to sign his name to what he writes, he’d stop doing it.

111. **TruthSeeker**
October 9, 2006

I don’t understand what is the rational reason for putting other people down because they’re not making good progress in research or hit a snag when solving a very difficult millennium problem. Such actions do not enlarge a person, further their own career, or enlighten them in any shape or form. So why do it? To get a cheap kick out of insulting others that lasts maybe 5 seconds? And then you’d have to pile on more insults to get the same “high” the next time; this is addictive. Nip it in the bud, Michael.

112. **Ray L**
October 9, 2006

Wow! Not hard to find every one of the seven deadly sins on this blog. Who says math is boring?

113. **mathjunkie**
October 9, 2006

From my experience, making mistakes is almost inavoidable in research. Don’t give up, Penny!

114. **Michael**
October 9, 2006

Dear TruthSeeker,

why don’t you try reading this:

http://www.math.columbia.edu/~woit/wordpress/?p=470#comment-17132

You might just advance to OccasionalTruthFinder.

115. **TruthSeeker**
October 9, 2006

Michael,

You must be talking about the first sentence of my previous post. Well, the first part of it refers to people such as yourself, and the second part of it refers to people who posted rude things that subsequently prompted the Oct 8th comment above by Peter. (That rude person has apparently stopped posting here.) I hope that clears up your misunderstanding.

116. **King Ray**
October 9, 2006

Penny, never ever quit. If you never quit, you’ll be astounded at what you can accomplish.

117. **Richard**
October 9, 2006

Geez, this thread was begun to discuss the NSEs and Penny’s heroic attempt at it, and then this boring and boorish “michael” intrudes once again with his own agenda. Sorry Peter, but I think that “michael” behaves like a pathological crank caller, and he will never grow tired of this.

118. **Daniel**
October 10, 2006

Dear Penny,

Thank you for telling us the truth. I have a question
and a suggestion:
1. Where did you get wrong? How did you find it out?
2. You possibly need someone to help you to keep the mistakes (I mean the serious ones) from you.

Best Wishes

119. **Timothy Clemans**
October 10, 2006

According to http://comet.lehman.cuny.edu/sormani/others/SmithNavierStokes.html and http://comet.lehman.cuny.edu/sormani/others/smith.html an anonymous mathematician found an error and reported it to her in one of her published papers which her preprints “Immortal Smooth Solution of the Three Space Dimensional Navier-Stokes System” and “Eternal Continuous Viscosity Solutions of the Einstein Cauchy Problem” relie on. Based on the following Smith said in this thread, “It’s going to take more than a few months, because most math papers are reviewed VERY slowly. I wish JMAA had been much slower.”, I believe that the paper with the flaw is one that was published in the Journal of Mathematical Analysis and Applications.

Your seggestion does not make sense to me, because I do not think that mathematician such as Smith would benfit from not having the details on any flaws in their papers.

120. **desA**
October 10, 2006

Prof. Penny,

I salute you & your brave efforts. You will come back to fight another battle. I wish you well.

I am currently researching the N-S from a physics perspective & have observed a slow-fast phenomenon which allows a suitable decomposition of the system into esentially 3 equation groups (eg. Reynolds decomposition).

How would your proposed solution affect such decomposition concepts? This is one of the typical approaches used in turbulent model development – bulk + fluctuating + closure.

Thank you & best of success…

desA

121. **anonymous expert**
October 10, 2006

"Heroic attempt."

Isn't this a bit of an overstatement?

I don't blame Penny for trying unsuccessfully to obtain global solutions to NSE and other nonlinear equations. I don't even blame her for deluding herself into thinking she had done it.

But the sycophancy of this thread is starting to grate. The reason anonymous experts said early on that the proof did not look plausible without knowing the exact line in which the error was is that the proof did not seem to be based on any propert of NSE or overcoming any of the known difficulties.

Everyday, there are experts with a deep knowledge of NSE looking for ways of making incremental progress against those difficulties. The reason they aren't making bold announcements isn't that they are further away from a solution than Penny Smith. It is that they better understand the field. Let us not forget their brave attempts while commending the attempt by Smith.

AE

122. **desA**
October 10, 2006

"anonymous expert", you are very cruel & unkind.

desA

123. **MathPhys**
October 10, 2006

No, I don't think AE is "very cruel and unkind". I think he's honest and fair. After all, this is science.

124. **Chris Oakley**
October 10, 2006

> The support here is helping me heal through!

Good … but think how much people would have hated you if you had been right.

125. **Testy**
October 10, 2006

I was wondering if Navier Stokes had any relationship to Quantum Gravity?

126. **Andreas**
October 10, 2006

Testy:

Navier Stokes (NS) describes momentum conservation in the classical limit of a quantum field theory (the diffusion coefficient in NS is a remainder of this quantum heritage); and quantum field theory is likely to be a low energy limit of quantum gravity. voila!

127. **Andreas**
October 10, 2006

…and because of this connection it wouldn't suprise me if turbulence itself is a phenomenon grounded in the quantum realm.

128. **Deane**
October 10, 2006

To do good research, you must have the utmost respect for those who have also tried to atack the same questions. And you must also have the utmost respect for those who will study at your work.

While you're doing your research, you don't have to know what others have done or what ideas they have tried. Usually, it's better to know, but sometimes it's good not to.

But the respect for others is critical after you think you have done something. At that point, you have to ask yourself, "why have I succeeded when others have failed", and it is absolutely critical to educate yourself and answer this question carefully and honestly before you announce anything to the world.

Testing your work against the simplest examples (as described so well by Feynman and suggested in the comments above) is the first thing every serious mathematician does, and it demolishes 99% of our efforts.

And if that test passes, it is only the beginning. There is an illusion that the responsibility for checking a proof lies in the referee of your paper. But that's just not true; very seldom do referees have the time to check a proof in detail. The ultimate responsibility lies in the author of the paper. So before you submit a paper to a journal or even arxiv.org, you have to sweat blood to find every error in your paper and correct it.

And after you've done all you can, you have to enlist as much help as you can manage to do another round of checking, because it is very difficult to find all the errors by yourself. But the help has to come from experts in the field, so posting your work on arxiv or putting up a web site is *not* the right way to do this.

And you do this for papers that don't come within light-years of proving a Millennium Problem.

Doing anything less than this wastes the extremely valuable time of those who will study your paper.

I consider both Penny and Christine friends, but I have to say that I think they both got a little too excited by the signficance of the problem and strayed from the fundamental rules of doing research just when they needed them the most. Normally, the consequences of this error are small, but, coming right after Perelman's proof, everything got blown out of proportion. I wish Penny the best and hope that everyone involved will proceed with a little more caution and level-headedness in the future.

129. **Aaron F.**
October 10, 2006

Prof. Smith — Just wanted to put in my hopes that this will get cleared up. I've never been very interested in fluid dynamics or differential equations, but the news about your paper was, and still is, very exciting for me. I'm sure something good will come of this whether or not Navier-Stokes is solved, but in the meantime, I'm hoping for the best. I know we can all think of at least one famous result that had to be retracted and repaired before it was accepted. 😉 Good luck!

130. **ksh95**
October 10, 2006

Dear Michael,

A good way to determine if some one is speaking nonsense is to take n -> infinity. If, after we take an argument to the extreme, we find nonsense. We have to conclude that, in the absense of some critical point, the whole argument is nonsense.

****
A pogo-stick theorist decides that the best way for a human to visit mars is to hold ones breath, get on a pogo-stick, and jump as high as one can.

The naysayer says, "*that's crap, human lung capacity is to small and it's impossible to generate enough energy to bounce all the way to mars on a pogo-stick. Everybody look at me and give me attention. I want to be famous.*

The pogo-stick theorist replys, "*screw you, you don't have a better idea and you are clearly seeking fame. Therefore, you can't criticize my idea*"………

I leave as an exercise for the reader to find the nonsense.

131. **ksh95**
October 10, 2006

BTW, Peter's opinion is clearly an opinion. I could be correct or incorrect, but it is not illogical.

132. **Anonymous**
October 10, 2006

one year ago Peter posted about a big theoretical claim in cosmology: No Cosmological Constant?. In a comment Sean told that the claim seemed suspicious. Indeed, it turned out to be wrong for that reason. The wrong paper still is on arXiv.

Deane: I see something to be blamed here, not in the paper that Penny has promptly widthdrawn.

133. **One Comment**
October 10, 2006

At least one Fields medalist first announced a false solution to the conjecture he later became famous for solving, then a serious flaw was found, and a year or so later he solved the problem in spectacular and career-making fashion. The jury is still out on Prof. Smith's work and failing to solve a big problem is no big deal.

See also Alain Connes remarks in one of his papers on Riemann Hypothesis. As a young student, he got advice that by publically attempting a famous problem one risks embarrassment. Connes then writes, that as he got older, he realized that the opposite approach, avoiding the embarrassment by not trying the hard problems, was equally self-defeating.

134. **SteveM**
October 10, 2006

The Navier-Stokes equations won't give up their secrets without a fight, but people putting a lot of hard work into honestly trying to solve these very diffciult problems deserve a round of applause even if the work is found to be flawed. However, important new ideas often emerge in an incomplete or flawed form and, like anything worthwhile with big payoffs, it takes a lot of effort and pain to get there. The millenium problems also attract a lot of attention and a lot of media attention though and this can be detrimental. But I hope Penny gets back to work on the problem with renewed determination.

My own encounter with Navier-Stokes was in the 90s when I began a Phd on "Turbulence in Blood", which was to be a detailed piece of applied math/mathematical biology. Unlike the "simple" problem of turbulence in water, the density and viscosity are variable and determined by the fractional violume of red cells in suspension– which are essentially deformable bi-concave discoids– and by the blood proteins and clotting factors/thrombin and their chemistry, or what state they are in. Blood tends to be remarkably laminar until it encounters an inhomogeneity like a clot and so on. I gave up after about 3-4 weeks and was allowed to switch to something infinitely more tractable!! (Maybe it could be simulated on a supercomputer, or has been). My knowledge of hydrodynamics is mostly in statistical hydrodynamics so I have interpreted turbulence as a stochastic process or stochastic flow with dissipation. (Does anyone know how this or the well-known Kolmogorov 5/3 law fits into this millenium problem?). Anyway Navier-Stokes=damn hard. I would like to learn more though about what people like Penny are doing in this field. More knowledge of the N-S equations would be useful in applied science, engineering and biology.

Someone said: "does anyone know how Navier-Stokes are related to quantum gravity". Both the Navier Stokes and Einstein equations could be interpreted as nonlinear, large-scale continuum approximations to deeper underlying miscrocopic descriptions. The N-S equations are continuum approximations describing the dynamics of a fluid which is really a statistical mechanical ensemble at shorter distances. The Knudsen number for example is K=L_{m}/L, where L_{m}=molecular mean free path and L=distance scale of interest. When L_{m} > L_{p}. This is very much like the Knudsen number of a fluid. The idea is that quantum gravity (maybe string theory) will take over before things get too "turbulent" as we approach the Planck scale or strong coupling regime. (I believe Briane Green had some computer graphics demonstrated something like this in his nova series). There is a lot of talk of "emergent spacetime" and "emergent gravity" bandied about but the comparison with the N-S equations could be useful here since they are clearly "emergent" too. In this sense I have never thought it made any sense to take the nonlinear Einstein equations as a starting point (as in LQG) and "quantize" them–the Einstein equations/GR should arise naturally in quantum gravity as a large-scale or continuum limit of the theory with no apriori assumptions of what the classical gravitational theory is like. At any rate, both the N-S and Einstein equations are among the most fascinating and difficult in mathematical physics, with the fun coming from the nonlinearity and the possibilities of blowups and singularities.

135. **Deane**
October 10, 2006

I am certainly not advising people not to try to attack the big unsolved problems. I think everyone should! It's a lot more fun than nibbling around the edges of a subject. What I am advising is that before you announce a solution, make sure you know where the critical issues are and understand why your approach deals with them properly (what is it that you know that no one else did?).

Penny's effort (a proof of the Navier-Stokes problem with a one month effort without ever having attacked the problem seriously before) cannot be seriously compared to Andrew Wiles' (a seven year effort, which probably included at least 3 man-years of checking his own work and which followed many more years of work torwards his proof).

To believe so easily that the Navier-Stokes equation can be solved with such little effort is, frankly, a huge insult to many top mathematicians who have sweated blood to prove much less, including but not limited to Fields Medalists such as Jean Bourgain and Terence Tao.

Unfortunately, there is a prevalent misconception that doing mathematics involves thinking up lots of ideas until the right one pops into one's head. The top mathematicians are certainly usually brilliant, but they also devote day and night to uncountably many failed calculations and proofs before they stumble onto anything worthwhile. I would even go as far to say that many if not all top mathematicians are at the top not because they are smarter than everyone else but they are fearless and relentless in their work. In other words, they succeed not because they know a good idea when they see it but because they have simply tried to work out the details of a hundred times more different calculations and proofs than anyone else.

Neither Penny nor Christine should have dismissed Penny's proof out of hand; it was certainl possible that the right idea had somehow popped into Penny's head. But the relative ease with which she obtained the "proof" should have been a clear signal for proceeding with extreme caution and skepticism. It should also have been a clear signal to everyone reading about their announcements for extreme caution and skepticism (it certainly was for me).

Caution and skepticism are not the same thing as dismissal. You can be extremely cautious and skeptical and yet hopeful at the same time. But those of us who have made serious attempts to attack difficult questions in mathematics know all too well how often our brilliant and ingenious solutions turn out to be mud. But sometimes it turns out to be gold, and the feeling you get when it does is like nothing else in the world.

136. **geometer**
October 10, 2006

I second what Deane has said. In fact a few days ago I showed Penny's proof to our local NS-expert and within 5 minutes he found the same difficulty with the proof that was later pointed out in this blog by Euler. Here is the rule I follow: before making any significant work public, I show the stuff a trusted expert, and if things go wrong, it just passes as a silly question…

137. **SteveM**
October 10, 2006

Part of my post (3rd paragraph) seems to have gotton mangled/lost when I pressed submit.

138. **SteveM**
October 10, 2006

Here it is again in case anyone is remotely interested:)

Someone said: "does anyone know how Navier-Stokes are related to quantum gravity". Both the Navier Stokes and Einstein equations could be interpreted as nonlinear, large-scale continuum approximations to deeper underlying microscopic descriptions. The N-S equations are continuum approximations describing the dynamics of a fluid, which is really a statistical mechanical ensemble at shorter distances. The Knudsen number for example is K=Lm/L, where Lm=molecular mean free path and L=distance scale of interest. When Lm is much less than L then the continuum approximation provided by the N-S equations holds, and so these equations (and similarly the equations of continuum mechanics) can be studied without worrying about the underlying molecular physics. When L is of the order of Lm, or L is less than Lm then you are in the realm of statistical mechanics.

Similary, the nonlinear hyperbolic Einstein vacuum equations ought to be a continuum or infrarad limit or consequence of a deeper microscopic description of spacetime structure. Of course, the Einstein-Hilbert action, coupled to additional fields, emerges as the long wavelength or low-energy effective field theory limit of string theory. (Regardless of what people here might think of string theory this remains a very interesting result). Also, the old idea of spacetime foam, which is a kind of "turbulence" occurs when Lp/ L is of the order of unity, where Lp is the Planck scale, and classical general relativity is recovered when L is much greater Lp. This is somewhat like the Knudsen number of a fluid. The idea is that a quantum gravity (maybe string theory) should take over before things get too "turbulent" as we approach the Planck scale or strong coupling regime. (I believe Briane Green had some computer graphics demonstrated something like this in his nova series).

There is a lot of talk of "emergent spacetime" and "emergent gravity" bandied about but the comparison with the N-S equations could be useful here since they are clearly "emergent" too. In this sense I have never thought it made any sense to take the nonlinear Einstein equations as a starting point (as in LQG) and "quantize" them–the Einstein equations/GR should arise naturally in quantum gravity as a large-scale or continuum limit of the theory with no apriori assumptions of what the classical gravitational theory is like. At any rate, both the N-S and Einstein equations are among the most fascinating and difficult in mathematical physics, with the fun coming from the nonlinearity and the possibilities of blowups and singularities.

139. **Christine**
October 10, 2006

If I understand this correctly, it seems that my name is being cited here because of my words of support to Penny Smith. I would like to mention that these words of support do not mean at all that I agree with her submition procedure to the arXiv. In fact, one can clearly notice from the records that I only post to the arXiv after my paper is accepted by a refereed journal. And it is clear that the responsability of the results published is of the authors. That is my procedure, and one can also verify that I am the first (or only) author in all my papers so far, so I am quite aware of the responsability envolved.

I do not wish to judge Penny Smith or anyone else's scientific posture here. But as a scientist colleague, I understand her genuine efforts, and having recognised a mistake in a moment when all attention was over her was a very difficult situation. That is why I have given her my words of support and they stand.

Best wishes,
Christine

140. **Christine**
October 10, 2006

Deane Says:
I consider both Penny and Christine friends, but I have to say that I think they both got a little too excited by the signficance of the problem and strayed from the fundamental rules of doing research just when they needed them the most.

As I read this again, it continues to be very strange. I have nothing to do with the research by Penny Smith. How can someone judge that I have "strayed from the fundamental rules of doing research"? Based on my words of support to Penny Smith?? What does it mean to consider "friends"??

Christine

141. **Deane**
October 10, 2006

Christine,

I don't claim to have judged the situation correctly, but it does appear to me that you went to considerable effort to promote Penny's work without the caution and skepticism that I think should have been warranted under the circumstances. I think your efforts to help Penny were well-intentioned but misguided.

Regards,
Deane

142. **Christine**
October 10, 2006

OK, after reading again Woit's initial post, I can only conclude that Deane confused Christina Sormani with me, Christine Dantas. Well, at least I hope so.

Christine

143. **Deane**
October 10, 2006

Christine ,

Oops! I do mean Christina Sormani and not you! I should check names as carefully as I check my proofs! I am very sorry!

Deane

144. **Christine**
October 10, 2006

Dear Deane,

That is all right.

Christine

145. **ttt**
October 11, 2006

I was wondering if Penny was interested in writing a textbook?
You seemed to have garnered alot of genuine interest in your work!

I would be interest in buying that book!

146. **csrster**
October 11, 2006

SteveM re: Kolomogorov: I would think the answer is "not at all" in the sense that the challenge is to prove that solutions to NSE remain finite precisely on the smallest, dissipative, scales where Kolmogorov breaks down.

Of course we computational fluid dynamicists all know the result, but we'd still like to see a proof 🙂

147. **oub**
October 11, 2006

Hello,

The paper is withdrawn, but can somebody point out to me the
regularity of the solutions, as stated in her original work?
Are they supposed to be classical solutions?

Thanks

148. **MathPhys**
October 11, 2006

I just looked up Sormani's web site, and there is a statement there that reads

"Regretably the journal referee did not catch the error or Smith would have corrected it before publication, either restating the result or rewriting the theorem.

If the restatement wasn't strong enough to obtain the immortal smooth solution to the Navier Stokes, she never would have made a claim to have found one.

It is possible it was a very subtle error that could only be picked up due to the combined efforts of all the mathematicians who looked at Smith's work".

So it's the fault of the referee and/or all the mathematicians who read the paper. I didn't know that!!!

149. **MathPhys**
October 11, 2006

Seriously, Smith had an idea, and it turned out to be wrong. No big deal, we all make mistake. Just don't blame the poor referee.

150. **penny smith**
October 11, 2006

It was indeed a VERY subtle error. And, I can mostly fix the paper
(except for Navier StoKES) if people would stop beating me up for makeing a subtle error. It is not as if I have been dishonest.

Moreover to answer some people nasty comments. I have been working on nonlinear PDE my whole 30 year working career–and have scored big sucesses. My first paper solved a major problem in compressible gas dynamics including three dimensions. My second Paper gave a smooth family of transonic flows in a plane exterior problem disproving
a famous and incorrect theorem.
I didn't get to Institute for Advanced Study by being a moron,
even if today I do feel like a moron.

Second, not everyone has experts on tap to check their work on NS.
I submitted to a preprint file, and was glad that an error was found.

I am not dishonest. I am not arrogant. I do not seek publicity.
I just try to do math the best I can, and have endured considerable sacrifices to do that.

I have some big successes. I now have some failures. Please don't beat the shit out of me. Ok?

Moreover, working on hard problems makes errors more likely.
Newton, Gauss, Poincare, Einstein, Hilbert all have published false
theorems. Were they morons?
It's hard enough as it is.

151. **MathPhys**
October 11, 2006

Penny,

No one says you were dishonest or arrogant. But when Christina Sormani implies that it's basically the referee's fault, I find that that's unfair on her part.

152. **jeremy**
October 11, 2006

I don't know how many of us have gone through all Penny's relevant papers, but suddenly some of us decided to give advices to Penny on how to conduct her research. I don't know if that is necessary. Every researcher has his/her own style of doing research, hardly anyone can claim one is better than the other. Remember Perelman, if he has waited for the expert's opinion, he would never have waited who knows how many more years to post his papers on arXiv.

Penny made a mistake in her research. We all make mistakes in our researches, mistakes that sometimes were also pointed out by others. If she decides to admit the mistake, which she did, and move on, I believe that all everybody else needs to do is to show respect.

153. **Deane**
October 11, 2006

I agree that Penny made an honest mistake and should be given a break here.

But I'd also appreciate a little more appreciation of how difficult it is to prove these big theorems. And, again, difficult in the sense of grueling labor over a long period of time and not in the sense of being brilliant.

For instance, someone has now cited Perelman as someone who doesn't do what I described. Well, besides the fact that Perelman is a pretty unique singularity that no one should try to emulate, Perelman did in fact do at least some of what I advised. He worked on the Poincare conjecture for approximately seven years. Again, I do not know but am confident that nearly half that time was devoted to checking his work. (why do I think that? Because whenever I've proved a new theorem, by the time I'm finished, 90% of my time was spent on checking my work. I'm assuming Perelman is much better at it than I am). Finally, he *did* send emails to other experts consulting them and asking them questions. I concede that he didn't actually show them his proof, but he did try to verify critical points in his proof with experts. Hamilton did not respond to Perelman, but others did.

No one should have the illusion that Perelman wrote those short sketchy papers without spending years (yes, years!) verifying the details that underly those papers. I am willing to bet that thousands of pages of calculations and proofs were written down by Perelman before he wrote those papers. And that's not counting all the calculations and proofs that didn't work out.

I think we mathematicians have been all too successful in hiding the fact that doing mathematics is 99.9% grueling labor and approximately 0.1% brilliant ideas (I hope I got the math right).

154. **penny smith**
October 11, 2006

Guess what people.
Now that my head has cleared.
The JMAA paper on PERRON is CORRECT!
The counterexamples were for nondiagonal systems, and that paper was for diagonal systems.

I was worried about I theorem of Ladyzenskya that I used, but it wasn't even necessary.

Several experts wrote saying they couldn't find an error in that paper.

I OWE THE REFEREE AND THE JOURNAL A DEEP AND ABJECT APOLOGY!!!!!!!!

IF HE/SHE IS READING THIS, ALL THAT I CAN IS THAT I WAS TERRIBLY DEPRESSED AND HURT AND I OWE THEM AN APOLOGY
AND ANY FAVOR THAT THEY WANT.

The error was in the use of unpublished theorem 4 of the Einstein Paper. That theorem had a very subtle error in the infinite time
comparison. I have extended it to show that the time of comparison depends (for the experts) on the C^{1} norms of L(
sub super solution).

155. **Christina Sormani**
October 11, 2006

I wrote:

"Regretably the journal referee did not catch the error or Smith would have corrected it before publication, either restating the result or rewriting the theorem. If the restatement wasn't strong enough to obtain the immortal smooth solution to the Navier Stokes, she never would have made a claim to have found one. It is possible it was a very subtle error that could only be picked up due to the combined efforts of all the mathematicians who looked at Smith's work."

I do not see this as blaming the referee.

On another note: the writer of the poem above doesn't even know undergraduate ordinary differential equations if he doesn't understand how one takes a second order equation and turns it into a first order system.

156. **penny smith**
October 11, 2006

Deane, I also spend thousands of hours doing calculations, just like you and just like everyone who does math research. That "month" alluded to by Nature was based on a misquote by me. I said:"
I have spent years (in fact about ten years) on these hyperbolic
papers and about a month on NS" –(most of which was checking NS, by the way!).
I posted on A PREPRINT FILE to get possible priority. I didn't claim a
theorem that was unpublished.

What exactly is your beef with me?

157. **penny smith**
October 11, 2006

And since when, DEANE, did I claim to be brillant?
What is your need to beat me up?
Penny

158. **woit**
October 11, 2006

Please, everyone. Stick to discussing math here, not who to blame about what. I can't even figure out how to moderate this if people start doing things like writing verse that may or may not contain personal criticisms. Enough already.

159. **Deane**
October 11, 2006

My only point is that it is highly unlikely that anyone can come up with a solution for the Navier-Stokes problem, write it up, and check it properly in less than a year, never mind a month. My guess is that I couldn't do it if the proof were dictated to me.

I'm willing to forgive you for your haste, since, as you say, you wanted priority and probably got a little overexcited. But I am dismayed by how many people without seeing your paper appeared to be so willing to believe that this was a reasonable scenario. One of your friends or colleagues should have grabbed you and said, "Penny, wait! Let's go slow and careful on this."

I was not trying to beat you up. I was trying to beat everybody else up. I'm sorry that my aim was so poor.

160. **Daniel Grumiller**
October 11, 2006

Penny: Honestly, I don't think Deane is beating you up. We all love you for your attempt (there you go – consider how many people would have hated you if you had succeeded…), but the issues Deane mentioned ring true.

161. **TruthSeeker**
October 11, 2006

Penny,

As an impartial observer reading his comments here, I, too, did not get the impression that Deane was beating you up. His (constructive) criticism was apparently based on the fact that he mistakenly thought you had worked on the problem for only one month. If there's anyone to blame, it would have to be the journalist (again?) who misunderstood or misquoted you for whatever reason. I hope you will focus your energy on math again and not give up on your passions. The journey of discovery could be just as exciting as the discovery itself. It all depends on your perspective.

162. **penny smith**
October 11, 2006

Dear Truethseeker,
I love doing math. I just hope people are still willing to read, referee and publish my papers.Thanks.
As the example of Yau shows beware of journalists.
Even well intentioned ones like mine. She just missed a point in what I said. All humans make errors–Journalists included–and the MOST important thing in life is not intellect but kindness to others.

163. **Brad Stone**
October 11, 2006

Penny,

Rock on with your math self! I have been fascinated to witness this exchange, and depressed to watch the nature of the media attention around you. I hope that you have the oppurtunity to get away from all of this nonsense and get back to peacefully attacking your PDE research.

As for Deanne, I simply have to say that his argument about the amount of time you spent on NS research is without force. It saddens me to have to remind her/him of the productivity of one summer in 1905. 3-months and 3-earth shattering papers. Even though you were misquoted by the reporter, Penny, I find some observers' close-mindedness troubling.

Good luck with the corrections!

164. **Benni**
October 11, 2006

Dear Penny
I think the problem is not the nature article, or that it was published so fast. The problem was, that you told the reporter the following words:

"I'm pretty confident that my result is right, or I would never have submitted it anywhere," says Smith. She hopes to serve as a role model for women in mathematics. "On the other hand, I certainly want the prize,"

Dear Penny, why don't you just have told nature:
"Sorry. This is only a preprint, which might be wrong. I posted it on Arxiv because it maybe something but I don't have an Navier stokes expert in my department who I can ask. So it has to be emphasized that my paper might well be wrong"

Perelman is a good example. He never wrote in his papers something like: "Here I solve a millenium problem"….
Instead, in the perelman papers, everywhere is caution!

No mathematician has the right to say, "he is certainly right" when he is attempting a millenium problem, otherwise he is likely to make a fool of himself because in 99% the "proof" will be wrong!

165. **TruthSeeker**
October 11, 2006

Penny,

There is no reason why people would not want to read or referee your papers, since you've already established a good reputation before all this. Mathematicians are generally fair-minded individuals who like to see proof and evidence in everything, rather than going by rumors or gossip. And frankly, there hasn't even been much of the latter going around anyway. You mentioned that you were depressed upon discovering the mistake in your NS paper. I hope you feel better now.

166. **geometer**
October 11, 2006

According to mathscinet, during 1982–2006 Penelope Smith has published 18 papers which were cited 11 times by 8 authors. Of course mathscinet does not pick up all citations, but surely it picks up more than half. This is a decent record, but I wish Prof. Smith were a bit more modest while talking about her accomplishments.

BTW, Perelman so far published 17 papers cited 198 times by 111 authors (and this of course does not include his yet unpublished work on Ricci flow).

167. **Genghis Cohen**
October 11, 2006

Mathscinet picks up only reviews since 1998 or so. So geometer's statistics are pretty irrelevant.

I don't know why you're all being harsh on her. So many mathematicians announce big results that are wrong. Think Poincare Conjecture or Jacobian Conjecture or so many others.. It's true they spend more time and exercise more caution than she did.. but many of the people behind the false proofs don't admit making mistakes easily and cause much more of a nuisance for mathematicians than this did. This whole episode lasted what, 3 weeks, and the paper (including its predecessors) was short. So it's not like the whole field was ground to a halt by this.

168. **Richard**
October 11, 2006

"Penny: Honestly, I don't think Deane is beating you up."

I disagree. There's a lot of snide condescension in the tone of many of these posts by some who for whatever reason do not have the confidence and backbone to identify themselves, their own backgrounds, and their own accomplishments and failures. Frankly, this discussion has become awfully disgusting, despite the attempt of some to discuss math, and I'm sorry that Penny, who I do not know at all, has been dragged through this.

169. **woit**
October 11, 2006

This endless discussion has become both unpleasant and tedious. No one seems to have anything else to say about mathematics, rather they just want to personally criticize someone or another for something or other. As a result I’m shutting off comments here. If you’ve got something new and substantive to say about this, e-mail me and I’ll consider turning them back on.

Richard,

Many people here are posting anonymously and you are right to point this out. Deane is not such a person, he has often identified himself here, he’s Deane Yang, a rather distinguished geometer, one who has worked with Penny in the past.

Schroer’s “Samizdat”

October 6, 2006
Categories: Uncategorized

Bert Schroer has a new version of his paper that was discussed here earlier this year, now with the amended title String theory and the crisis in particle physics (a Samizdat on particle physics). He claims that the version reflects a change in viewpoint due to his participation in this and other weblogs, and I believe he would like the opportunity to discuss this further here. There’s also a posting about this at the weblog of Risto Raitio.

Update: Schroer, agreeing with his critics that his paper had too many typos, has sent me a corrected version, which is available here, for use until the arXiv version gets updated. He also agrees that an “s” should be a “z” in Samizdat…

Update: Schroer has a new paper out, which contains a review of AQFT and a discussion of light-front holography, with further comments on the relation to the Maldacena conjecture.

Comments

1. **Thomas Love**
   October 6, 2006

   Peter, Thanks for the link, that is why I visit daily. As I scannned Schroer’s article, seeing the section “The only game in Town”, this story flashed into my mind: After the Titanic hit the iceberg, a woman was looking for her husband and found him in the poker parlor. “What are you doing here”, she asked. He responded “It’s the only game in town.”

   Physics has hit an iceberg: string theory. Hopefully some will be smart enough to get off before they go down with the boat.

2. **TheGraduate**
   October 6, 2006

   sam iz dat

   1. a clandestine publishing system within the Soviet Union, by which forbidden or unpublishable literature was reproduced and circulated privately.

   2. a work or periodical circulated by this system.

   (Thought others might also wonder what a samizdat was.).

3. **LDM**
   October 6, 2006

   It was a good read until the suggestion that only Witten is able to follow all mathematical developments in string theory.

   Von Neumann once expressed the opinion that the body of mathematics had become so vast that he only understood maybe 50% of it. If string theory uses “almost all areas of mathematics”, then Schroer should make a stronger statement than he makes — and include Witten in the group who is unable to follow all developments in string theory.

   It is difficult to understand the deference to Witten.

4. **MathPhys**
   October 6, 2006

   LDM,

   Have you met him?

5. **Tim**
   October 6, 2006

   The distinguished Bert Schroer must have a very strong opinion well worth publishing if he changed his viewpoint after some random rants and raves on a weblog.

   Best,
   Tim

6. **Tim**
   October 6, 2006

   Sorry guys, this is just too obvious, I can’t let it pass:

   page 16. “The message from this illustration is that one theory can only be asymptotically contained in a more fundamental one if the structures harmonize.”

   According to Bert Schroer the phrase “the structures harmonize” is not a metaphore but terminus technicus and on top of that he made rigorous and not metaphorous conclusions about the ST -> QFT limit based on the QFT -> QM limit, in other words he has proven rigorously that these two limits are analogous even though according to him ST does not even make sense.

   page 17. “The fact that thousends (sic!) of publications were written about this problem and that even the still ongoing research has not been able to come any closer at proving/disproving this conjecture is a unique mind-bending phenomenon in the history of particle theory.”

   Unique? May I suggest Bert Schroer to substitute “the existence of QCD as a non-perturbatively defined QFT with a mass gap” in place of “this conjecture”? Please don’t respond with the experimental relevance of QCD as opposed to AdS/CFT since clearly the AQFT crowd can not possibly be further from experiments than it actually is.

   I guess I’ll read on just for the fun of it but quit reporting the most hillarious parts here, there will probably be just way to much.

Best,
Tim

7. **Tim**
October 6, 2006

I promise this is the last comment, the only reason I add it is because of a genuine desire to aid Bert Schroer in his future publications: please, please, get a spell checker installed on your computer.

Best,
Tim

8. **Thomas Love**
October 6, 2006

Tim Said:

"The distinguished Bert Schroer must have a very strong opinion well worth publishing if he changed his viewpoint after some random rants and raves on a weblog."

The ability to change one's mind when confronted with new evidence is called the scientific mindset. People who will not change their minds when confronted with new evidence are called fundamentalists.

The comments here are, for the most part well reasoned arguments. Except for the quotes from "he who must not be named".

9. **Bert Schroer**
October 6, 2006

I suggest to read the text in a more careful manner.
The analogy with QFT—QM is taken as a warning because in d=1+2 in the presence of braid group statistics there is no QM in the nonrelativistic limit; the maintenance of the spin&statistics theorem prevents the emergence of QM!! This is an illustration of a structural disharmony. I am only rejecting scale sliding arguments if they are unaccompanied by a prior structural conceptional reasoning .
The comparision with the state of QCD is misleading because QCD is not in an epsilon environment of a rigorous theorem but the M-conjecture is!!
Fortunately these misunderstandings have nothing to do with misspellings.
My greatest change of mind is the way I now view the Harvard professor Lubos Motl

10. **MathPhys**
October 6, 2006

Can someone please summarize to me what Schroer new point of view is? I find it difficult to see the point in 49 pages of polemic.

11. **H. K.**
October 6, 2006

I found the "(possibly infinite) Russian matryoshka" metaphor interesting.

12. **Stefan**
October 7, 2006

Peter,

All this time you were searching for an alternative [to string theory] to work on: why not AQFT?

Stefan

13. **Tim**
October 7, 2006

After carefully reading the manuscript I concluded that Bert Schroer simultaneously thinks the following about the AdS/CFT correspondence:

1. it does not make any sense
2. it is a conjecture to be proven or disproven
3. it is trivial, its rigorous form was known for a long time
4. it was recently proven rigorously
5. no more papers should be written about it
6. not enough papers are written about its rigorous proof

Did I miss something?

Best,
Tim

14. **Egbert**
October 7, 2006

It is a thought-provoking article, but it can really be separated into an examination of string theory and its situation and an advocacy of the axiomatic approach instead.

I think the identification of the prevalence of metaphors is the most important and relevant point at the moment, though. Metaphors can play their role in communicating proofs, but they are not in themselves valid proofs of anything. If one has the correct metaphors, however, one can know the procedures that one should perform, without understanding why you are doing those procedures.

So if you are a "shut-up and calculate" type, who say that you understand once you knows what to do, then metaphors will be good enough for you, provided they get the message across. On the other hand if you demand that you can say "X literally has the relation Y to Z" before you agree that you understand, then metaphors will never be enough for you.

And if somebody who only knows the metaphors and knows how to do what is expected of him has to teach an enquiring young student, then the young student will be told what is expected of him and given some metaphors to help explain what is expected of him. The student will then have three choices.

He can accept that he is now in a society where “understanding” means being able to execute the procedures and recount the metaphors, and that he will never have any deeper understanding than this.

He can pester his teacher to explain in a satisfactory way why he is supposed to do these computations, without using metaphors. This will irritate the teacher because the teacher himself has abandoned any attempt to understand in a non-metaphorical way, and the teacher will be ashamed of this and will react aggressively to the student to cover his shame, putting the blame for the confusion on the student’s lack of intelligence.

Or he can say that the arguments the string theorists give are unpersuasive.The string theorists will point out that he is not qualified to judge, since he doesn’t know string theory, and he can only know string theory if he’s been accepted by the community, and he won’t be accepted by the community unless he is able to “understand” string theory, that is, unless he finds the arguments persuasive.

15. **Bert Schroer**
October 7, 2006

Yes you did, I said the structural theorem which was proven is in serious contradiction with any possible interpretation which one can attribute to the (not precisely formulated) Maldacena conjecture. Your statement that the rigorous proof in the two cited papers support Maldacena’s conjecture and that I claimed that there are any proofs of it is your fancy, it has nothing to do with my essay.
You also take the word “trivial” out of context. It refers to the fact that the rigorously proven correspondence is a change in the spacetime encoding of the same algebraic substrate (pretty much like a change enzyms cause in the substrate of stem-cells by enforcing different spatial differentiation).
I think that you already belong to the misdirected post-string generation which I allude to, and as I told you already before you do not seem to be able to read a scientific article whose content does not fit your prejudices.

16. **Bert Schroer**
October 7, 2006

Egbert, you really got it. And is you correctly suggest the ideas in the last section (which partly come from AQFT) are meant to counteract the no other game claim and are not to be considered a commercial for any other fad.

17. **Egbert**
October 7, 2006

The distinction that I draw is related to Lee’s distinction between the seers and the craftsmen, or, perhaps, is the same distinction.

The seers, in my interpretation, are engaged in the task of arranging what they know into literal statements, so that they can be regarded as being actually true. This is important for theorizing because we can only perform logical inferences with literal statements. Metaphors and logic don’t mix.

The craftsmen, on the other hand, can make do with the metaphors once they know how to carry out their tasks. And they can (and do) dismiss any attempt to seek a “deeper understanding”, beyond being able to do what’s expected of you, as philosophical nonsense.

Seers and craftsmen are still metaphors, of course.

18. **Egbert**
October 7, 2006

Bert,

I see the connection now.

19. **MathPhys**
October 7, 2006

I must say I find Maldacena’s conjecture not only stunning, but also very deep and beautiful. Of course nothing so deep in physics can be ‘proven’ in the mathematical sense of a proof, but people can keep on working out examples, and verifying it incrementally, which is what they have been doing.

I find invoking ‘the anthropic principle’ disheartening, and I find the behaviour of a certain junior string theorist to be unacceptable. But to rope in the AdS/CFT conjecture into that too goes a bit too far.

If we ask string theorists to be open minded about alternatives, we should equally expect non string theorists to appreciate certain aspects of string theory.

20. **Bert Schroer**
October 7, 2006

MathPhys
If the incremental verification would lead to a clarification how this conjecture has to be formulated in order to agree with the rigorous structural theorem (the same rigor as TCP, spin&statistics, but may be of lesser physical relevance) I would agree with you!
But I am willing to make a bet that this is not what will happen. Its too late, the caravan (~4000 papers) has passed already and the conjecture has turned into one of these metaphoric legendary flying dutchmen who will circle above our heads without ever finding a landing place.

21. **MathPhys**
October 7, 2006

Bert,
I’m not qualified to respond to what you say in a way that would settle this discussion, but on this very point I think most of what you say is polemic nonsense.

22. **Arun**
October 7, 2006

Quote:

“A profound mathematical theorem reveals that there is even a unique correspondence between Local Quantum Physics {QFT both Lagrangian and non-Lagrangian} models in n+1 AdS spacetime with a n-dimensional conformal invariant Local Quantum Physics model…{Being a structural theorem, it does not identify the models} it only relates their LQP algebraic structures…..I have tried all possibilities of what Maldacena could have meant and none of them seem to be consistent with the above structural theorem."

End quote.

I, for one, could use some help here, with a further elaboration.

23. **Stefan**
October 7, 2006

Bert,

Is there a freely available introduction to LQP? or do I *have* to buy Haag's book if I want to study it properly?

Stefan

24. **Renormalized**
October 7, 2006

Tim and Lubos both sign there work with "Best". That is an unusual practice.

25. **Bert Schroer**
October 7, 2006

MathPhys
A better way than to make such unqualified statements would be to familiarize yourself with the content of the references where the correspondence theorem is proven and then to compare it with what you think is the content of Maldacena's theorem. This would force you to enter a new non-metaphoric and non incremental verification state of mind in which conceptual clarity and mathematical rigor reigns. It is not easy, and I could help you if you made a serious attempt, but I have no cure against prejudice and community-caused infections. Why do you use the pseudonym MathPhys?

26. **Peter Woit**
October 7, 2006

Renormalized,

It's not that unusual, and I am sure that Lubos and Tim are not the same person. I urge everyone here to avoid bringing Lubos into the discussion, or behaving in any way like him.

27. **Bert Schroer**
October 7, 2006

Arun, if you study the cited papers (not mine!) and come up with some questions I am willing to answer them. But it is futile to argue about the result of years of subtle thinking (left on the wayside by the great caravan) on a weblog. If I read (some) papers coming from the string community people like you (this also includes MathPhys) should also look at references outside their main research.
Stephan: the area of LQP is a rapidly developing research subject and Haag's book (which is very nice to make a first brush) only covers the area up the the end of the 80s. There is presently no up to-date book perhaps because the whole area is in a process of rapid change. A recent not so difficult reference on the powerful new localization concept (by which QFT sets itself apart from ST and LQG) is http://br.arxiv.org/abs/math-ph/0511042

28. **Rae Ann**
October 7, 2006

Renormalized, signing off with "best" is very common, especially on academic blogs.

Bert S., what exactly is your goal in your attack of Lubos Motl? To embarrass and shame him into shutting up because you disagree with his manners? Above, you say, "I have no cure against prejudice and community-caused infections." It looks to me like you have become a source of "prejudice and community-caused infections." Your apparent change in view of Lubos is caused by what exactly? His political and social views? The way he speaks? The people he associates with? His 'faith' in his work? If he is acting as a filter of papers for others it is because his assessments are considered valuable to them. This is how an efficient community works, by delegating duties, so to speak.

29. **Bert Schroer**
October 7, 2006

Stefan don't do this. These things are much better understood now. If you just follow the chronological order of the articles in http://unith.desy.de/research/aqft/ including thesis and Diploma publications you get an excellent view about the state of the art. There is also a book by Logunov, Todorov,..in which Bogoliubov is a co-author which is better than the original Bogoliubov-Shirkov books.
But it is very tough going, especially if you do it on your own and have nobody to consult.
Best

30. **Bert Schroer**
October 7, 2006

Rae Ann
No my main problem is with the string community and with the chairman of the Harvard Physics Department who tolerate the posting of death threats against the owner of this weblog.

31. **woit**
October 7, 2006

I will delete any further efforts to discuss Lubos Motl here. Please do this elsewhere if you must. It should be made clear that Bert is wrong about this, the chairman of the Harvard Physics department is not someone who has been willing to tolerate Lubos's recent behavior.

32. **Arun**
October 7, 2006

I left professional physics more than a dozen years ago; but I will try to read the cited papers and understand. The idea that the Maldacena conjecture cannot be made consistent with a general structural theorem, and yet has many, many people pursuing it is one that commands attention.

33. **Bert Schroer**
October 7, 2006

I would be extremely interested to have some comments about my essay from the Great Inquisitor.
Bert

34. **Tim**
October 7, 2006

Bert,

I trust you I will make an appearance in the acknowledgments of the new preprint version for drawing your attention to the untolerable number of typos. Please use the following formulation if possible: "[…] and also would like to thank Talicska Tim for a careful reading of the manuscript."

Best,
Tim

35. **Egbert**
October 7, 2006

Bert,

I understand the importance of the role that metaphors have played in the patterns of thought that have led people to invest so much of their self-respect in their "understanding" of string theory, but I think that there's another important factor at play.

The notion of "fundamental physics", or of what is going on "at the fundamental level" has played a very large part in string theory – more than any other theory so far. On inspection, it appears to be a mythological-religious notion pervading modern theoretical physics. I am informed, by theoretical physicists in general, that the mathematical description of what is "happening at the fundamental level" is actually what God sees when he looks at "the Universe". It is supposed to describe what truly exists, and is the cause of everything else.

This is rather far from the usual understanding of science. I think the notion of "how the world looks to God" has had a lot of influence in the minds of a group consisting mostly of athiests and people who profess to despise religion. It seems to me that the reason for this is a confusion over what constitutes a cause and what constitutes an explanation. What they want is a complete understanding, that is, an explanation of everything, but this has become confused with the idea of a most fundamental cause.

It may well be that a metaphor can be "understood", but not "literally understood", if it contains within itself a confusion between a cause and an explanation. But I think that this confusion must always be present in any discussion of "fundamental physics".

36. **Daniel Grumiller**
October 7, 2006

I have read Bert's paper as part of my editorial duties and I enjoyed it a lot. Naturally, any work of such a nature – a mostly historical paper on subjects whose history has not ended yet – is biased by the author.

It would be interesting to press the "save" button right now, fast forward a century or two, and compare with future historians their assessment of 20th/21st century string theory. I really don't know what I should expect to read, but I imagine one of the four scenarios:

1. An experimentum crucis has been performed which convincingly provides evidence for string theory. Bert's paper will be a historical example of misjudgement (because string theory was right after all).

2. An experimentum crucis has been performed which convincingly falsifies string theory. This blog will be a historical example of misjudgement (because string theory could be falsified after all).

3. No experiments, but an alternative has been discovered which is more convincing than string theory. Either it will be celebrated as the successor of string theory, from which it emerged, or as its opponent.

4. No experiments, no alternatives, string theory has become a quasi-religious dogma.

I think we all agree that 4. ought to be avoided by all means, and this, in my opinion, is the main point of Bert's paper.

37. **AdamBalm**
October 7, 2006

I completely agree, Dan.

Best,
AdamBalm

38. **Bert Schroer**
October 7, 2006

Egbert,
we both seem to agree that the phenomenon we are trying to understand cannot be solely explaine in terms of the action of some very intelligent and charismatic individuals who succeeded to inspire or mislead (according to standpoint) a whole community. If I understand your point correctly you attribute the present confusion to a clash between cause and explanation and consider it as an inevitable consequence of the quest for knowing what is going on "at the fundamental level". In other words the path of unraveling the fundamental truth will end in mysticism. In a way this sounds to me like an adaptation to science of the more sociological oriented "critical theory" of Adorno and Horkheimer ("ënlightenment must convert into mythology") which I refer to in section 3 of my essay (with an interesting footnote quoting from a passage of one of Horkheimer's essays).
I personally think that it is more a millennium phenomenon. After the cold war when globalized capitalism strengthened its grip on hegemony there was the new ideology of an "end of history" and the coming of an era of peace and happiness. The physics ideology of a theory of everything unfolded parallel to these sociological

developments in complete chronological analogy. In may essay I argue that this is not accidental, it is rather a manifestation of the millennium Zeitgeist. This will give the hope that after the passing of time the pendulum may sway into another direction.

39. **Egbert**
October 7, 2006

I think there is more to Bert's paper than Daniel has stated.

There is a value to attempting to seriously examine the relationship between string theory and QFT while simultaneously considering how communities communicate and affect one another's perceptions and motivations. After all, string theory is undeniably a community of people bound together by a commitment to a specific guess, and each of them has taken a gamble, and they communicate with each other quite a lot, and it is an interesting and valid and very relevant and topical question to ask:

When you have a community like this, where every member of the community has taken a gamble, and there is no way to know, for the foreseeable future, how that gamble will turn out, and the members of the community constantly talk to each other about the gamble that they have taken, how do they affect each other's perceptions of the likelihood of their position turning out to be right?

It would also be nice for each string theorist to state, for the record, that he has never allowed the confidence of other string theorists to influence his estimate of the probability of string theory being the One True Theory of the Universe. If there is even a small effect whereby seeing the confidence of others in the Truth of string theory leads to having confidence oneself in the Truth of string theory, then this effect will be amplified through a positive-feedback loop as the members of the community talk to each other.

So the question for the sociologists is: Do communities of people who have all taken the same gamble always eventually convince one another that the gamble will pay off, and that the people who share this assessment are more intelligent than the people who don't?

If the answer is yes, then the argument can be presented to the string theorists:
Given what we know about sociology, and given that spending one's doctorate on string theory is a gamble which people freely take, and given that the truth will not be known for a long time, it is 100% certain that the string theory community will end up declaring themselves to be sure of the truth of string theory and declaring people who disagree with this assessment to be less intelligent than themselves.

I think the response of the string theorists will be to say that the described sociological effect does not occur or string theorists are immune to it (due to their exceptional professionalism and intelligence). Are there any string theorists who would accept that this sociological effect is real and affects them?

40. **Egbert**
October 7, 2006

Bert,

The millennium Zeitgeist seems to be a recurring feature of society. It would then appear to be no coincidence that string theory is dominant more in the United States than any other country, and that it developed here. The millennium Zeitgeist is particularly strong here.

But the argument from the string theorists would be that the mainstream of science (which they consider string theory part of) is not so strongly influenced by the fads and fashions of society, and that theories of physics in particular, do not get swept away by changes of mood accompanying world wars.

So the question is what is it that distinguishes string theory from other areas of science by making it more vulnerable to Zeitgeists?

With regard to viewing things as superstition and mythology, my grandparents would talk about people (in my family and my neighborhood) as being posessed by spirits, and I have talked to them about it and understand what they mean. A "spirit" is something like an attitude, so that a person is said to have the "spirit of charity" if they are charitable and is said to be in "high spirits" when they are happy. A man is said to be "possessed by a spirit" when he has gotten some idea into his head and he has adopted some attitude and behavior. The idea of a spirit may even be a folk recognition of the concept of a meme, recently introduced to the world of scientists by Richard Dawkins and widely celebrated as a great insight.

But the traditional scientific rejection of mythology has tagged the idea of possession by spirits as completely insane gibberish. I think that string theorists may view Zeitgeists in much the same way. As my grandparents would say, they're posessed by spirits.

41. **ZZZ**
October 8, 2006

Tim said:

… drawing your attention to the untolerable number of typos …

Tim, it's no biggie to make a few mistakes when using big words. The correct English word here is "intolerable". Try to build a tolerance for typos.

Best,

ZZZ

42. **Egbert**
October 8, 2006

Thinking more about Zeitgeists, I think you may be right. It's not a question of being vulnerable to them, but the attitude of the population at large was unusually suitable for the emergence of string theory. It certainly seemed as though there was a role which the entertainment industry needed filled and string theory auditioned and got the part.

So if I understand you then, the Zeitgeist causes confusion for the individual string theorist because it provides confidence that humans in general have basically figured everything out, and the string theorist translates this into confidence that the leaders of the string theory community know what they are doing, even though he is not able to find satisfactory proofs that this is the case, but must rely largely on trust, or metaphors.

43. **amanda**
October 8, 2006

If BS wants people to turn from string theory to AQFT, he will have to find a way of presenting the latter that does not make it look very, very, *very* boring.

44. **Bert Schroer**

October 8, 2006

amanda,
In an ealier comment to Egbert I stated that this is not my intention. Anything which tries to compete with ST will sooner or later inherit all those aspects which I criticize in my essay. The strength of AQFT is its secrete charm, it is only accessible to people who are willing to make a series effort. It is our most precious post millennium investment and it is still in the process of growth and should not be thrown onto the market. That you find it boring confirms that I did not sex it up.

45. **Tim**
October 8, 2006

ZZZ,

Thank God I didn't write that down in a paper only in a weblog! The reason for that is simply that I run papers through a spell checker which is the thing I suggested to Bert Schroer as well. Everybody makes typos after all but nobody can stop you from installing a spell checker 🙂

And since according to Peter Woit Bert Schroer corrected his typos as a result of my suggestion I truly believe I have a reserved seat in his acknowledgments. Otherwise I must be lead to think that he similarly neglects other sources from where he is drawing inspiration while writing a paper.

Best,
Tim

46. **Thomas Larsson**
October 8, 2006

we should equally expect non string theorists to appreciate certain aspects of string theory.

Some of the work done by *string theorists* is certainly being appreciated – Peter obviously admires Witten's work in mathematics, and the success of CFT in 2D statphys has largely formed my own worldview; my research circle around generalizations of algebraic structures from CFT to higher dimensions.

However, being on the receiving end of 20 years of unchallenged pro-string propaganda is a formative experience. It is possible that AdS/CFT is an physically important development, but since every claim in the past about string theory's relevance to the real world has been a vast exaggeration at best, I would instinctively assume the same about AdS/CFT.

Especially since both sides in the duality seem unphysical. AdS/CFT relates a string theory in AdS space, with negative cc, to an N=4 supersymmetric gauge theory. Last time I checked, neither a negative cc nor N=4 susy were particularly good descriptions of reality. I do find quite disturbing is when string theory partisans like Sean Carroll claim that there is overwhelming evidence for gauge/gravity duality, but don't mention that both the gauge and the gravity side are unphysical.

47. **Bert Schroer**
October 8, 2006

Tim, here you have your way:
I am particularly thankful to Talicska Tim (or whoever hides behind this name) for suggesting the use of a spellcheck to improve my essay on string theory and the crisis in particle physics.
You can print it out and stick it onto your office-wall. If you surface mail me a printout to my Rio address, I will hand-sign it and send it back.
But now you owe me an acknowledgement. If your misrepresentation of the content of my essay on one of your previous blogs (especially the issue of M-conjecture) was not intentional then you thank me for correcting your misunderstanding.

48. **TheGraduate**
October 8, 2006

Thomas Larsson:

You said "It is possible that AdS/CFT is an physically important development".

I don't know very much about the mathematics of this but AdS/CFT is a conjecture not a theorem right?

49. **Egbert**
October 8, 2006

Media mention of string theory alert

50. **Bert Schroer**
October 8, 2006

Dear Thomas Larsson,
although I agree with the content of your statements, I want to stress that my criticism of the Maldacena affair is not based on some physical gut-feelings but on the use of rigorous mathematics guided by a physical conceptual frame (i.e. not that amok-running mathematics which combines well with the physics metaphors). The issue of physical relevance of this superoverhyped issue was not the main issue. Actually if you read my essay careful you will realize that it is not that superoverhyped aspects in itself which deeply worries me but rather the fact that there exists a structural theorem on AdS—CFT which the caravan did not bother to address.

51. **elan**
October 8, 2006

I don't believe that an enemy of my enemy is necessarily my friend. Not even if his essay is free of typos. Bert Schroer is notorious for bizarre behavior at research seminars, conferences and other public occasions, not unlike this forum's favorite Harvard faculty member. His science (algebraic field theory) suffers from the same ailments as string theory and, in addition, nobody cares about it. His fascination with Pascual Jordan, a discredited Nazi physicist, who (after his "rehabilitation") pushed for remilitarization of Germany and questioned postwar borders in Europe is truly puzzling: it is like emphasizing that Hitler was really a decent painter…

52. **Bert Schroer**
October 8, 2006

Yes, I find it fascinating that the protagonist of QFT (the unsung hero of QFT according to Schweber's historical book on QED) who was point-right on quantum physics could be so dead-wrong in his political ideology (by the way, diffent from Heisenberg who was the leader of the uranium club, Jordan was an absolutely useless figure for

the Nazis, that is why they banned him to Rostock).
Sorry for keeping a distance to the "good guys (we) against the bad guys (them) or "who is not with us is against us" . I think that human nature is more complex than that. I have not attended any conferences for ages and I am not responsible if I appear in the blogges fantasies.

53. **TheGraduate**
October 8, 2006

Bert,

Can I ask you whether AdS/CFT is a conjecture or a theorem?

54. **Bert Schroer**
October 8, 2006

The AdS-CFT is a rigorously established structural theorem of QFT.
The Maldecena idea that particular (beta=0 and hopefully conformally invariant) SUYM models link up with certain strings in 5 AdS dimensions in a certain limit N –> infinity is a conjecture which is in apparent conflict with what the structural theorem says.
What renders the situation difficult is that even if there is a conformal invariant SUYM CFT, the N—> infinity is an object which does not enjoy the status of a QFT. The big question is whether people who do some approximate calculations have the correct interpretation as the AdS correspondent of their (alleged) conformal QFT.

55. **Lolka**
October 8, 2006

Dear Bert,

If the N -> infinity limit produces something that is not a QFT than how is the rigorous methods of AQFT are in any position to judge the Maldacena conjecture? Why don't honest AQFT people say that "Okay, this Maldacena guy is talking about something which is not a QFT, so we can't say anything about it, since we are only able to make statements about QFTs and similarly our rigorous structural theorems don't apply in this case, since our structural theorems only apply to QFTs. Hence we are not in a position to judge the Maldacena conjecture because our tools are not appropriate to this kind of problem." ?

56. **David B.**
October 8, 2006

Dear Graduate:

The AdS/CFT is a conjecture with a lot of supporting evidence going for it. Wether you cal lthe evidence overwhelming or not depends on personal opinions. So far no one has found a "contradiction", and the number of tests that have beeen performed is huge.

The "structural theorem" that Bert refers to makes no mention of quantum gravity, so it explains nothing in the AdS/CFT.

The structural theorem, as far as I understand it says: the conformal group is SO(d,2). Therefore
the physical spectrum of the CFT is classified by unitary irreducible representations of SO(d,2). A field theory in AdS willl have the same symmetry group, therefore the two are equivalent. It also gives no information of the dictionary between both sides.

I'm sure Bert can give you a more technical essay on what the theorem means and he will very likely disagree with my assesment of those results.

If the correspondence were just that, it woud have been discovered very quickly and people wouldn't be working hard trying to understand it.

I think regarding the AdS/CFT, Bert is just wrong.

Sorry to spoil the anti-sting party.

Best,

David B.

57. **Bert Schroer**
October 8, 2006

No, the theorem is not just a relation of spacetime symmetry groups (this and the ensuing equality of the spectrum was already known way back by Fronsdal) but it is a correspondence between the full QFTs in all their details. It is a bit difficult to express this in terms of standard Lagrangian QFT setting because one of the two sides is non-Lagrangian if the other is. But there is a more general concept of QFT (which is already in constructive use because most of the 2-dim. factorizing models are non-Lagrangian http://br.arxiv.org/abs/math-ph/0601022, http://br.arxiv.org/abs/hep-th/0609130)
Although one side is non-Lagrangian it is still a QFT and not a ST.
So the only saving grace is that the incremental evidence for Maldacena is not given the correct interpretation; perhaps another case demonstrating the conceptual confusion which originates from premature terminology.

58. **Bert Schroer**
October 8, 2006

Lolka o.k., but isn't the Maldacena conjecture one which is claimed to involve CFT on one side?

59. **Moshe**
October 8, 2006

I don't have the time or inclination to get into a long discussion. However, I did find that wrong statements on the internet have a tendency to percolate to unexpected places, most importantly to the minds of young students. Let me then refer anybody that is interested in true statements about ads/cft (as opposed to various polemics) to the classic review hep-th/9905111, that is a good starting point.

60. **Bert Schroer**
October 8, 2006

Actually to disconnect this discussion from any attributions of values, if you say that the incremental evidence indicates something deep and contains an important messages, I have no counterargument. Whatever it is, it is defintely not an illustration for a AdS-CFT correspondence about which there exists a rigorous proof (a structural theorem on par with TCP, Spin&Statistics…). If you distingush a conjecture called the Maldacena conjecture (even if I do not understand its true meaning in terms of QFT concepts) from a structurally established AdS–CFT correspondence then all my problems (and may be even yours) are solved as far as the discussion on this weblog goes.

61. **optimist**
October 8, 2006

Thomas Larsson Says:

Especially since both sides in the duality seem unphysical. AdS/CFT relates a string theory in AdS space, with negative cc, to an N=4 supersymmetric gauge theory. Last time I checked, neither a negative cc nor N=4 susy were particularly good descriptions of reality.

=====================================

Physical reality of both sides is not the point. If at least one side is realistic then it is OK because it can be just a tool. Now you complain that for AdS/CFT neither side is realistic. String theorists and nuclear theorists know it and try to make "some gravity/QCD" version. I think these approaches have given qualitatively satisfactory results so far. It's not exaggeration at all.

62. **Bert Schroer**
October 8, 2006

I repeat, there is the maldacena conjecture about a relation between a duality relation between a N–> infinity gauge theory and some form of 5-dim. gravity and there is a mathematical theorem about a AdS–CFT holography (or better correspondenc) and both have, according to our best knowledge nothing to do with each other. From a conceptual point of view the correspondence is rather trivial because the same substrate of matter is only changing its spacetime encoding (for more details see may essay) and olthough the physical interpretation changes it does not change miraculously (e.g. a spin 2 particle must have been there already on the CFT side). If the more than 400 people who worked on this problem would in addition to their computations have leaned back a while and looked at the published theorem may be we would have known by now what the Maldacena conjecture really mean conceptually. But I would predict that nobody at this late time will do this, the right time has passed. Certainly I would not loose time on such a physically fruitless project, but on the other hand as mathematical physicist I find this change of spacetime encoding in holographic projections very interesting; most interesting if the smaller spacetime is not a brane but rather a null-surface (see my last section and the cited literature).

63. **Yatima**
October 8, 2006

I don't understand much of your learned discussion but I liked the reference to Leibniz. And please — no smearing by convoluted association. Why should the fact that Pascual Jordan was card-carrying NS party member be at all relevant (except if he threw out important research avenues because they looked 'jewish' or something)?

An old Usenet rule went that the first mention of H*tler or He*nlein would immediately end the discussion thread. Beware!

64. **Bert Schroer**
October 8, 2006

He did not. In fact the reason why despite all his ouvertures he remained a suspicious character to the Nazis was precisely because his publications up to 1934 were overwhelmingly with jewish collaborators. But he was a Nazi and a militarist.

65. **MathPhys**
October 8, 2006

Vafa and collaborators considered Maldacena-type dualities between simpler gauge theories and string theories.

This led to Chern-Simons/topological string dualities, which can be tested in great detail. It all works just fine. The results are so far purely mathematical, but the inner consistency of the underlying ideas is undeniable.

66. **Matti Pitkanen**
October 8, 2006

Some comments to Bert Schroer about quantum holography, Chern-Simons action, and null surfaces, or lightlike surfaces, as I have used to call them.

3-D lightlike surfaces in 4-D space-time, which itself is a surface in 8-D space-time H=M^4xCP_2, can be seen as fundamental quantum dynamical objects in Topological Geometrdynamics. They are identified as parton orbits. The effective metric 2-dimensionality with ensuing super-conformal symmetries makes D=4 as a space-time dimension unique.

The infinitesimal transformations respecting null surface property form a Kac-Moody type algebra of conformal transformations of H localized with respect to X^3 decomposing to representations of 1-D Kac Moody algebra.

The cones H_+/-= delta M^4_+/-xCP_2 are also crucial for the formulation of theory and the 3-D lightlikeness of delta M^4_+/- makes possible super-conformal symmetries of new kind based on canonical algebra of H_+/- and its super-counterpart. General Coordinate Invariance predicts quantum holography at level of H_+/-apart from effects implied by the failure of the complete classical determinism of the classical theory.

The resulting theory at fundamental parton is *almost* (absolutely important physically!) topological CFT defined by Chern-Simons action for Kaehler gauge potential of CP_2 projected to X^3. The second quantized fermionic counterpart of C-S action is fixed by the requirement of super-conformal symmetry. The theory allows N=4 super-conformal symmetries of various kinds broken for lightlike 3-surfaces which are not extremals of C-S action (have CP_2 projection with dimension D>3). No space-time (Poincare) super-symmetries and thus no sparticles are predicted.

Super-symmetrization of super-canonical algebra is possible for a sub-algebra of superconformal symmetries for which Noether charges defined as 2-D integrals over partonic 2-surface reduces to 1-D integrals as duals of closed 2-forms. The elements of this algebra has vanishing spin and color quantum numbers and thus leaves invariant the choice of various quantization axis. The vertices of the theory are described by almost topological having stringy character.

Correlations between partons (propagators) involve interior dynamics determined by a vacuum functional defined as a determinant of the Dirac operator and assumed to reduce to an exponent of Kaehler action for absolute extrema playing the role of Bohr orbits for particles identified as 3-surfaces: this is quantum holography at the level of space-time surface. Interior dynamics of space-time surface codes for non-quantum fluctuating classical observables allowing to realize quantum measurement theory at fundamental level.

The mathematical methods of string theory can be applied to TGD and one can see the target space of string theories as a fictive concept associated with the vertex operator construction assigning to the Cartan algebra of Kac-Moody algebra a target space. In TGD framework spontaneous compactification can be seen only as an ad hoc attempt to give physical content to the theory.

For more details see my blog and homepage, in particular What's New sections to get view about the recent rapidly evolving situation in TGD.

With Best Regards,
Matti Pitkanen

67. **Bert Schroer**
October 8, 2006

MathPhys
the theorem about the AdS–CFT correspondence does not apply to topological field theories because they lack the notion of localization which is the Faraday-Maxwell origin of the meaning of "field". Top. field theories strictly speaking are not field theories, they are only called this way because Witten and other people (who view QFT through the functional integral glasses) started to use this metaphoric name. Intrinsically they are combinatorial theories based on tracial algebras and this is also the name mathematicians as Vaughn Jones, Anthony Wassermann,… as well as people in local quantum physics call them. They are so to say the bones of a QFT after you remove the localization flesh to use a metaphoric language. The process how this works is very rigorous but not suited for a weblog.
David B.
I have given more details in may essay and there are 3 important references (not to my own papers). Believe me I would not say something like this and wreck my reputation in public if I would not be completely sure. The theorem has been carefully checked by experts and it has (as I mentioned) the firm status of TCP or Spin&Statistics. I am not disputing that there has been perturbative evidence for something called the Maldacena conjecture, but the interpretation of these calculations in terms of a model illustrating the AdS–CFT theorem (which is a structural theorem valid for all CQT) is metaphoric, it is something else which only a more series conceptual investigation can tell. But this is the problem of the people who do such computation, certainly I will not loose any time on computational details one something which I consider as unphysical as supersymmetry (a social construct in the words of Burt Richter and I agree with him).

68. **Thomas Larsson**
October 9, 2006

Optimist, I did not object AdS/CFT per se, only that people who promote it neglect to mention that in the well-established case, both sides are unphysical. The attitude seems to be that non-stringers should be kept blissfully ignorant about such petty details.

69. **MathPhys**
October 9, 2006

Bert,

Your entire career and that of your best friends, such Swieca, was devoted to the study of simple 2-dimensional models.

These models are at least as far removed from 'real' 4-dimesional quantum field theories, as topological field theories are removed from the usual ones.

However, no one stopped you. You did what you could do, and what you wanted to do, and you learnt something from that.

Your critique of Vafa et al is not only irrelevant, but also unfair.

70. **Bert Schroer**
October 9, 2006

elan
Thinking about when I ever have gotten into an public argument with somebody at a conference, I could only recall one incident at a conference at Lake Tahoe at the begiining of the 90s when there was some brawl with Peter Goddard, the present director of the Princeton IAS. Although he may still hate me for that, I cannot image that he would compare mediocre paintings with Jordan's creation of QFT and hide behind a pseudonym which is reserved for graduate students and non-tenured colleagues who may fear retaliation as a result of speaking their mind. This would be so absurdly off the standard set by the great Robert Oppenheimer (with whom I had the priviledge of personal contacts during my one year visit of the IAI at the beginning of the 70s) that I have dismissed this idea. And by the way my interest is not fixed on Jordan, I am interested in general in the complexity of humans which show up if a genius scientist outside his area of competence is dead wrong e.g. by supporting the Iraq war (which destroyed an entire country and destabilized the whole world order) http://xxx.lanl.gov/abs/physics/0603095
It is fascinating because it tells us something about the complexity of our own nature (not "them").
MathPhys and David B.
Your attitude with respect to the Maldacena conjecture and its controversial relation to the AdS—CFT correspondence theorem confirms the main thesis in my essay: when big caravan's of hundreds of people writing thousands of papers have manufactured a fact then its all over. Nobody will return to a deep problem where he runs the risk of not enjoying the impact increasing community support. An individual researcher in the old-fashioned sense would never ignore such a theorem because it would show his lack of professionality (maybe even lack of intellectual honesty). The problem is not ST in itself as Peter and Lee often state it but rather the stringy metaphoric way of doing particle physics. As anti-Semitism can exist even without Jews, this new accepted metaphoric way of a scientific discourse (and probably will) will be self-feeding without ST. I ask you honestly, would you besides a weblog contribution really sacrifice time and make an effort to study the theorem, its proof and its physical implications? of course not. Why should you, after thousands of publication it has converted into a fact. This is only one illustration of the many conceptual craters which have been left in the landscape of particle physics. As long as things were progressing smoothly, there was no reason to worry about this and now it is not only difficult to cover them in order to be on less swampy conceptual ground, but the present system of scientific production does not support such an activity. Attempts to point out some of the holes are considered to be not sexy (on the scale that ST is).

71. **Bert Schroer**
October 9, 2006

MathPhys
Sorry, the papers with Swieca (and in part with Voelkel) do not contain minimal models (this was done 10 years later by BPZ) but they do contain the decomposition theory into conformal blocks (called nonlocal components of the local field) in n-dimensions with particular emphasis on the chiral decomposition in two dimensions. This came out from the resolution of a rather deep paradox, the causality paradox of (global) CFT (discussed in previous work) The only model known at that time was the massless exponential Bose field and everything was checked in that example. If you call that unphysical that is your privilege. Whereas ignorance can be combatted, There is simply no remedy against (probably wanton) misrepresentation.

72. **Bert Schroer**
October 9, 2006

But where did I ever criticize Vafa? I said (in connection with L.B.s death threat against the owner of this weblog) that the ST people should keep their house in order, is this what you mean? It seems that they meanwhile tried, because the real foul ranting has not appeared for some time. Lets see whether they had a sustainable success. Fortunately physics is one of the most democratic human endeavours.

MatPhys, I have wield no power, I am a retired but still curious physicist, so why do you need the protection of a pseudonym? Be a man and have your outing!

73. **David B.**
October 9, 2006

Dear Bert:

I have no qualms about the results you were quoting. It's just not a proof of the AdS/CFT correspondence.

You want to call it algebraic holgraphy, that 's fine by me to.

I meant you were wrong with regards of a proof of the AdS/CFT being available. It's not. A proof has to contain gravity, or show that it is impossible to do that. Neither of the papers that you quoted explains this to any level.

It is clear that you misunderstood my post and now you are attacking my professionalism and trying to put me down with a rethorical statement. I will not have that, nor will I respond in kind.

It is exactly this attitude in weblogs that makes it very hard to have a real discussion. I might not be the most articulate person, and sometimes what I write can be misinterpreted. That is a risk l take when I post in this kind of forum.

The reason I posted in the first place is to make it clear that the AdS/CFT has not been proved yet, and that you were wrong saying that it has been proved. That is a misleading statement. Something elese was proved. I did not say you were being dishonest, nor lacking in professionalism.

Even professionals can be wrong, and that happens quite often in my experience.

David Berenstein.

74. **Moshe**
October 9, 2006

Hey David, hope you and yours are doing well, looking forward to seeing you soon. Just a word about your comment- as I indicated above and previously, it is important to correct wrong statements since they spread. I am glad you did that for that "proof of ads/cft". On the other hand, it is probably not necessary to get into extended discussions with people not really interested in exchange of ideas. Hopefully sometime soon there will be more forums adequate for precisely such exchange, hope to chat with you there.

75. **Bert Schroer**
October 9, 2006

Dear David, you seem to think that "algebraic" distinguishes it from "field theoretic" but here you are (probably in a large company) misunderstanding what this framework stands for. It has been known that pointlike fields are just algebraic coordinatizations, so it is not a change of content of QFT but just a conceptually very powerful way of avoiding to make a commitment to any particular (composite) field (see Weinberg who way back also became aware of this problem). In your work you have accepted this important step to "intrinsicness" in differential geometry, but you obviously have no familiarity with a more autonomous formulation of QFT which is nothing else but doing the analogous step in QFT. This is not surprising since the new setting (without changing a jota in the physical interpretation of QFT) has taken 2-3 generations to come into the present shape and if one is involved in serious computational work on incremental perfection of the Maldacena conjecture (please no cynism) one does not have the time to immerse oneself into subtle conceptual matters, so this is not an accusation! If you try to find the AdS correspondent of the free massless Bose field (to which the theorem of course also applies) you will understand exactly why one does it that way. I think in the other paper and the lecture Rehren is more reader-friendly and indicates how this can be translated into the setting you are more familiar with. And let me encourage you (since you have strong computational power) to find out what the Maldacena conjecture (as a computational support for a relation of a new object to a particular object called the N–>infinity limit of a CFT, not itself a CFT) could conceptually mean; it is definitly not an illustration of a AdS—CFT correspondence of QFTs (not even in the widest sense of the use of "QFT")!
And by the way I do not mind if you are a little rough with me (I like young enthusiastic scientists) as long as you do not behave as L.M.

76. **David B.**
October 9, 2006

Dear Bert:

I will read those papers carefully.

Regarding notation: I was calling it algebraic holography to distinguish it from gravitational holography. I was not trying to make anything else implied. I was trying to separate the objects of the discussion to avoid confusions.

Now I'll be signing off this discussion thread.

Best,

David B.

October 9, 2006

Bert,
The reason I use a pseudonym has nothing at all to do with this discussion which will not get anywhere. Signing off too.
I wish you all the best.

78. **Arun**
October 9, 2006

David B., hope to hear of your conclusions whenever you have the time.

79. **Bert Schroer**
October 9, 2006

David, I understand, this time I misred you. Let me point out that the null-surface holography is much much more interesting than that on (possibly infinitely distant) branes. This type of holography is explained in my CQG article

http://br.arxiv.org/abs/hep-th/0507038
I also reworked the second part which I will send as an replacement probably during this week. This is the case of double cone holography which is closer to the problem of black hole entropy (with some remarks about black hole entropy which could interest you). If you want I can send a copy to your private address, only the reference list has still to be ordered (hope to find time soon). You probably realized that I am a little bit of a loner in the sense that that I do not represent a community and only occasionally collaborate with people who have a similar conceptual-mathematical background. My critical attitude towards string theory is less its content and more the metaphorical way of thinking which it (and other allegedly fundamental proposals) supports. In my essay the fact that it did not lead to predictions is hardly mentioned.

I now understand that you had t'Hoofts vision of holography in the context of gravity in mind; but my use of the word applies to bulk matter in Minkowski spacetime hologaphically projected onto its causal horizon. I think it is not so difficult to understand why this cannot be done in any Lagrangian setting (quantities as entropy have nothing to do with a particular "field-coordinatization). The most important result is that you get a notion of entropy ("localization entropy") which is consistent with the new quantum local covariance principle (related to background independence) which the string theoretic calculation (and also Weinberg's vacuum polarization estimates of the cosmological constant) is not.

In 2002, the two big problems were
http://www.esi-topics.com/brane/interviews/MichaelDuff.html

"What is the theory? How do we make realistic predictions?"

81. **Bert Schroer**
October 11, 2006

I am somewhat surprised that there was no comment on my emphasis on new contributions (not my own!) in papers which throw considerable doubts on the standard (ST and LQG) mantra that gravity is irreconcilable with QT. In view of
http://br.arxiv.org/abs/gr-qc/0603079
and the development over the last 5 years quoted therein, discussions like that between Sean and Lee look obsolete (and appear a confirmation of my suspicion in may essay that communities are a hindrance to progress).
The main point here is that ,although the emphasis on background independence is very important (the original sin of ST), its implementation through diffeomorphism-invariant states (as in LQG) is misleading. Rather the local covariance principle (diffeomorphism-independence) reflects itself in an algebraic property which (since states are dual to algebras) in terms of states is the invariance of a whole folium of states, but not that of its individual members (these things are explained in previous contributions of the authors). It is precisely the operator Einstein-Hilbert equation which brings about the background independence (it allows to make "symmetry-transformations" around the original background see B-F) and this is independent of whether the perturbative implementation has a finite number of parameters or not ((no)nrenormalizable). The recent perception that massless finite helicity representations have natural string-localized fields with excellent short distance behavior
http://br.arxiv.org/abs/math-ph/0511042
generates new hope that the last word on finite versus infinite parameters has not yet been spoken.
A similar tendency (a return of reconciliation of gravity with QFT) is evident in
http://br.arxiv.org/abs/gr-qc/0610018
the problem in that approach is how one can reconcile the asymptotic safety requirement with the continued validity of background independence for short distances (or whether one should give up b. i. for s.d.)
Finally I would like to express my wholehearted sympathy with Nakanishi's recent critical view on these problems
http://br.arxiv.org/abs/hep-th/0610090
His postulate: In the ultimate theory, any concept of classical physics must not"appear logically prior to its quantum-theoretical construction" is nothing else than Pascual Jordan's plea to walk (in QFT) without classical crutches which is also the Leitmotiv of AQFT.
In fact the characterization of QFT in terms of relative modular positioning of a finite number of copies of a "monade" in the last section of my essay (not a metaphoric picture but a rigorous theorem!!) is a nice illustration that even the last vestiges of classical thinking can be removed from QFT.
I do not understand his distinction between on- and off- shell supersymmetry but I am in complete agreement with his emphasis on un-naturalness of this concept (for me it is even too rigid for finding any beauty in it). I don't think that SUSY can be broken in any meaningful sense of this word (it is much too rigid for that). Already in the most soft way of symmetry breaking (by bringing the system into contact with a heat bath) it collapses instead of suffering a spontaneous breaking

October 11, 2006

Dear Peter Woit,

For your second-edition NEW (perhaps published after LHC results?)
have you considered

1- adding lots of pictures and diagrams, pictures of GUT, standard model particles, SUSY-breaking scenarios, Feynman diagrams, Kaluza Klein etc.? Pictures fo SM and then MSSM, picture of GUT SU(5), etc., A picture of how large a number 10^120 (for cc) and 10^500 (for vacua) is helpful in comparison to pictures and photos of deviations from observation QFT anomlous moment of electron, and GR on binary neutron stars, is. pictures of Higgs, pictures of Higgs triplets. picture of how string theory is supposed to make up the SM, and pictures on why this scenario is probably wrong.
pictures of W Z Y bosons and how Higgs is supposed to break them. Picture of Higgs self-energy and fine tuning.

2- have a chapter written by someone else (i.e Rovelli) on why strings fails as a theory of quantum gravity? (with pictures of course).

3- Whether KKLT is plausible or unphysical (with pictures on what these flux wrapping look like) along with pictures of epicycles.

4- A chapter first on the ethical responsibilities of scientists, the need for scientists to be skeptical, and printing colorful email and weblog responses from string theorists (i.e lubos, jaques, and possibly others) — For the reader's entertainment and insight on what some string theorists fall from the idea of what a scientist should be. pictures of the major string theorists might be helpful. pictures of obnoxious string theorists who write obnoxious emails also helpful.

5- FAQ chapter of standard string theorist objections and your counter-arguments with pictures, if applicable. Jaques Distler for example, compares string theory vaccua to infinite QFT'S.

6- Summary of predictions of string theory (or lack thereof) perhaps in table format.

Such a book could reach a wider, popular audience.

October 12, 2006

Dear David,
you said:
"I will read those papers carefully.
Regarding notation: I was calling it algebraic holography to distinguish it from gravitational holography. I was not trying to make anything else implied. I was trying to separate the objects of the discussion to avoid confusions."
Take your time because the conceptual and mathematical complexity is not lesser than in ST (and if I would take notice of the existence of ST for the first time, it would take me much more than a week only to get a rough impression of what it is about).
My problem with 't Hoofts "gravitational holography" is that I simply don't understand it (too vague). The post 't Hoofts paper which comes my mathematically and conceptually very precise form of (Minkowski and CST) holography close is one of Susskind's paper where he connects it with the so-called "lightcone quantization" without anything gravitational. The problem is that this was not even done correctly in the case of free fields (there he is in the company of all the lightcone quantizers). But whereas in that special case there really exist a linear relation between the free field in the bulk and its appropriately defined lightfront restriction, this ceases to be the case and I do not know any other way than to convert the bulk field into the operator algebra it generates (also generated by all its composites) and to carry out the holographic projection with this algebra. At the end you may express the net of algebras indexed by the natural compact regions on the lightfront (which are nonlocal relative to those in the bulk) again in terms of one of its generating fields (these are the fields which obey the transverse extended chiral field relations similar to W algebras). The conceptual and mathematical structure is explained (as well as I am presently able to) in
http://br.arxiv.org/abs/hep-th/0511291
whereas the technology has been done in the first part of this 2-part paper. If you look into it you will see the subtlety of statements like the degree of freedoms "live" on the horizon or in the bulk.
Compared to the null-surface situation the AdS–CFT case is easier (from a conceptual point of view) because that relative nonlocal behavior is absent. In that case the AdS—>CFT direction can be done directly in terms of local fields. For those CFT which come from a "standard" (this can be made very precise) AdS the inversion in terms of pointlike fields is tricky but still can be done (and the result is a nonstandard CFT), whereas the inverse CFT—>AdS for a standard CFT is best done in terms of algebras. It is very instructive to start with a conformal free field. Then you get one of those "hollow" nonstandard AdS theories (see the the paper of Duetsch-Rehren and the lecture notes of Rehren).
Bert

October 12, 2006

I always considered the Kaluza-Klein idea to be incompatible with the structure of internal/external symmetries (external is short hand for spacetime) of QFT. The reason why younger physicists do not see any problem with K-K I ascribe to the fact that the kind of deeper knowledge about particle physics has already been eroded by decades of string-caused metaphoric thinking. I feel very comfortable in the company of Noboru Nakanishi who says in his recent article "Spacetime in the Ultimate Theory":
"It is the cheapest idea to extend the spacetime to the one having a dimensionality higher than 4. Nevertheless, recently, it has become quite fashionable to investigate the theory of extra dimensions. The grounds for considering it seem to be the excuse that any possibility is worth investigating as far as it is not completely denied by experimental evidences and the expectation that it might be possible to resolve the hierarchy problem stated in [A] by introducing new parameters in the extra-dimension space. It is quite disgusting to revive the old Kaluza-Klein theory without any essentially new idea for resolving the fundamental problem of how to expel the extra dimensions from the physical world. Furthermore, the higher-dimensional theory makes ultraviolet-divergence difficulty out of control; the extradimension people merely hope, without showing its ground, that the divergence problem might be resolved by a non-perturbative treatment.
The dimensionality of the spacetime where we live is undoubtedly 4. There is no other observation more manifest than this fact. The extra dimensions, whose number is denoted by □, are qualitatively different from the physical spacetime dimensions from the outset. Recently, the superstring people have proposed the hypothesis that all fields other than the gravity are confined to a soliton-like (according to their claim) object called the "□-brane", but it would be quite difficult to formulate such an idea within the framework of the (4+□)-dimensional quantum field theory. A theory is worth being called a (4+□)-dimensional one if and only if its fundamental action is (4+□)-dimensionally symmetric. But such a theory remains (4 + □)-dimensionally symmetric unless one breaks it artificially. In order to make the □-dimensional extra space invisible, the extra-dimension people are forced to make it round into a tiny one by hand. This procedure implies that they are actually considering the 4-dimensional spacetime accompanied with an □-dimensional internal space. If so, they should honestly claim that the extra dimensions are internal. Then there is no logical basis for adopting a (4 +□)-dimensionally symmetric action. It is quite non-scientific to pretend as if such an action were a privileged one according to the symmetry principle.
There may be the objection that the extra dimensions are made round not by hand but "spontaneously". Certainly, there is no "proof" of the no-go theorem stating that the desired spontaneous compactification can never take place. But if they assert the possibility of such compactification, the responsibility of verifying it must be attributed to those who assert it. That is, the extra-dimension people should construct at least one model in which the spontaneous compactification of the extra dimensions takes place in a natural way. I cannot believe that such a model can be constructed without greatly changing the framework of the conventional quantum field theory, because the situation encountered here is qualitatively different from the ordinary spontaneous breakdown of symmetry.

In fact this is corroborated by the most profound results about internal symmetries from AQFT. In that conceptual framework of QFT the relation of inner symmetries (including statistics) with the spacetime localization structure arises from the representation theory of local observables (bosonic by definition). In 4-dimensional theories this leads to the field algebra with a compact group symmetry (the structural DR theorem admits in principle any compact group). Supersymmetry is the extremely artificial (and unstable under total collapse, not symmetry-breaking) situation in which the observable algebra is fine-tuned and amalgamated together with one of its fermionic representations.
This representation theoretical origin of internal symmetries is incompatible with "little curled up spacetime dimensions". Such a picture is only possible in a classical setting i.e. one has to do it there and then quantize. This is in complete agreement with what Noboru Nakanishi (and I think every particle physicist who made his career before the great string theory sell-out) says.

85. **Rickkkk**
October 13, 2006

I have not yet read the paper or any of the comments in this post, but I must say I'm excited to hear this news. Bert's other paper earlier in the year was very enlightening for me as an outsider and deals with things that to the uniniated such as myself seem to not be given due scrutiny. Can't wait to read it.

86. **egbert**
October 16, 2006

Bert says:

> Finally I would like to express my wholehearted sympathy with Nakanishi's recent critical view on these problems
> http://br.arxiv.org/abs/hep-th/0610090
> His postulate: In the ultimate theory, any concept of classical physics must not"appear logically prior to its quantum-theoretical construction" is nothing else than Pascual Jordan's plea to walk (in QFT) without classical crutches which is also the Leitmotiv of AQFT.

I disagree with this postulate. The following is the reasoning: What is quantum mechanics? Is it something which tells us what the Universe is? Or is it a prescription for saying what the probability of getting experimental results is?

The idea that we need to get rid of "classical crutches" supposes the former. The overwhelming consensus of the physicists who took the time to think carefully about the issues involved (the Copenhagen school) is that the latter is the case. Everybody can have his own opinion of course, and the people who do not carefully go through the arguments which lead to the Copenhagen interpretation will probably not arrive at the same conclusion. The people who like to go with their "gut feeling" will choose the other conclusion, because it is nicer to think that the mathematics we use describes the Universe itself rather than encapsulating our knowledge of the statistics of experimental results. But the only reason I have ever heard for dismissing the idea that the mathematics describes statistics of measurement results is "gut feeling", and perhaps an expression of contempt for careful thought.

In fact, in answer to the question of where the confusion in modern physics comes from, it seems clear to me (and I think Lee Smolin, among others, agrees with me) that it starts with quantum mechanics, and after quantum mechanics nobody knows what's real and what isn't. That's when metaphors replace literal statements. And we have aggressive insistence from various people that there's nothing to be confused about and everything is clear, but different people are selling different interpretations and they disagree with each other violently and dismiss each other's views as not worth considering.

Question: Does the string theory project implicitly assume that the Copenhagen interpretation is wrong? Remember that Copenhagen is still the official interpretation of mainstream physics.

So, we have a clear and unambiguous interpretation of quantum mechanics as a formula for predicting results of measurements. But this needs the classical concept (or "crutch") of a measurement and its result. People propose to get rid of the measurements and their results and what do they have left? Just a Hilbert space and an element of it (the hypothetical "wave function of the Universe"), and no way to relate it to observed phenomena (stories about unobservable parallel worlds are supposed to make up for it), the same problem that string theory suffers from.

87. **Bert Schroer**
October 16, 2006

Egbert
there is a fundamental misunderstanding here; what Jordan had in mind and what I mean has nothing to do with Bohr's (and the Kopenhagen school) emphasis that our language for interpretating QM must be the classical one which relates to our perception of the material world. What was at issue is the classical parallelism called (Lagrangian) quantization. QT is more fundamental than classical theory and quantization is a very limited and entirely metaphoric way to access QT. The deep conceptual insight is to understand how the classical world re-emerges from the quantum setting, but this is the opposite of quantization.

88. **Bert Schroer**
October 16, 2006

Egbert
there is a nice old bom mot from the mathematician and mathematical physicists Ed Nelson:
(first) quantization is a mystery but second quantization (without interactions) is a functor.
mystery=metaphor

89. **John Gonsowski**
October 16, 2006

Bert, is what Jordan had in mind by any chance found in Jordan Algebra? John Baez in a coversation with Tony Smith once said that what you want is something that is both a Lie Algebra and a Jordan Algebra. Very loosely I think this could mean Lie Algebra is the classical-like thing and Jordan Algebra is the quantum-like thing. The relationship between Lie Algebra and Jordan Algebra might then be what you called a deep conceptual insight. Lee Smolin wrote a nice paper on the relationship between Jordan Algebra and String Theory.

http://xxx.lanl.gov/PS_cache/hep-th/pdf/0104/0104050.pdf

One of the references in this paper is a bosonic M-theory paper by Horowitz and Susskind. If only Susskind would work more on this than the Landscape!

90. **Bert Schroer**
October 16, 2006

John Gonsowski
certainly not. The plea for a new access to QFT without "classical crutches" is from 1929 and as far as I remeber the propsal about Jordan algebras is from 1934/35 (the best is the joint work with von Neumann and Wigner). Jordan algebras play an important role in generalizing QM (in particular to get a good understanding of the relation algebra—states, see the book by Bratteli and Robinson). But I think there is a theorem that (under very general condition) each infinite dimensional Jordan Algebra is a von Neumann algebra (see also a paper by Jochum). The 1929 Jordan plea goes into a quite different direction namely to liberate QFT freom those nasty (intrinsically singular) "field-coordinatizations" in analogy to the liberation of geometry from coordinates in modern Diff. geometry. This has been achieved in AQFT, in fact AQFT came into beiing precisely as a result of removing the undesirable features of the (Borchers) singular composite field classes (i.e. to have instead of infinitely many field coordinates just one object: the net of local algebras (which any one of them generates)

91. **Bert Schroer**
October 23, 2006

If my apprehensions that years of co-existence with stringy metaphors breeds ideological prejudices still needed confirmation, the reader can find it now in the writings of Distler and Motl. (see also remarks in my lecture notes which aooeared on Mondays hep-th posting)
Distler: "The troubling aspect is the totemic power of the word "Theorem," and its ability (in the minds of some) to trump sound physical arguments and abundant calculational evidence." Have string theorists (after their sociologically successful magic trick three decades ago to liberate themselves from the bonds of observational control) now also abandoned any commitment to mathematical checks because they feel threatened by Rehren's theorem?
"…were it not for the peculiar amplifying nature of the internet that has, apparently, given these ideas a certain currency among impressionable young students."

Perhaps we have to go back to Socrates and his contemporaries; what about threatening Rehren with the cup of hemlock (after all one of the opponents of rigorous theorems is also a specialist in death threats)?
"when we met in person, he seemed like a very nice guy",
does Distler expect that opponents of string ideas look like teeth-grinding monsters?
Putting the re-hashing of a non-continuous quantization of the Weyl algebra (which in the beginnings of QM was invented to show that not every representation of it allows a return to the Heisenberg commutation relation) on par with a recent deep AdS—QFT holography theorem can only be done by somebody who does not understand the theorem or willfully wants to exorcise it because goes it may cross the path of his holy grail; in the present case the motivation seems to be a mixture of the two.
The problem why Rehren has these difficulties with the string community is that they apparently are not aware that holography is not a manifestation of gravity (it can be derived with or without gravity). They do not seem to know that there is now a generalization of QFT which incorporates the local covariance (diffeomorphism covariance) principle and which also shows that a perturbative treatment of quantum gravity is consistent with background independence (if the QFT obeys the quantum Einstein-Hilbert equations). It would be interesting to say something more about these recent results on this on this blog (in case of interest) since this new insight destroys the mantra of ST and LQG that QFT and gravity are not compatible.

92. **Anon**
October 24, 2006

What's the difference between "diffeomorphism covariance" and "diffeomorphism invariance," and which is one the correct notion to apply in quantum gravity?

93. **Thomas Larsson**
October 24, 2006

Bert, sorry, but this case I fail to see what's wrong with what Distler/Motl say. In physics, a theorem can fail not only because it is technically wrong, but also because the axioms are wrong. E.g., a century ago people rigorously proved that Bohr's model of the atom was wrong – according to classical mechanics, the electrons will lose energy an eventually fall into the nucleus. The problem was that the theorem was wrong because the axioms of classical mechanics do not apply to the hydrogen atom.

Similarly, it is possible that there are some exotic systems that obey the axioms of QM in a generalized sense, but that does not mean that such systems are realized in nature. It seems to me that LQG's failure to reproduce the harmonic oscillator as we know it is a show-stopper, plain and simple. There is hardly any system better studied that the oscillator, neither theoretically nor experimentally. Convincing physicists that there is a new kind of quantization which gives different result for the oscillator is not going to happen.

About Rehren duality, I really have no opinion, because I don't understand it. However, if what Motl write is correct, that a bulk field psi(x,y,z) is dual to a boundary field psi_z(x,y), then it seems pretty trivial to me. Besides, I think that the value of dualities are highly overrated. A duality is only interesting if one side is physical and the other is tractable, something which seems to be the case neither for Maldacena nor Rehren duality.

Rather than giving up established knowledge, progress is obtained by finding the loopholes. The loophole relevant to quantum gravity can be found here. Note how Robert reluctanty agrees with me, and how Motl and Distler refrain from explaining that I am an incompentent moron who does not understand the difference between a gauge and a global symmetry, which they undoubtedly would have done if I had given them a chance.

94. **Thomas Larsson**
October 24, 2006

In the unlikely case that somebody cares, I did point out to Lee Smolin that the LOST theorem might be wrong because its axioms are wrong here, before Distler and Motl did so.

95. **Bert Schroer**
October 24, 2006

Anon
Diffeomorphism covariance (or simply local covariance) is a concept that Einstein introduced. In special relativity, even though Newton's absolute space-time has been abandoned, it was still meaningful to talk about events as spacetime points in a given background.
In general relativity spacetime points however loose this apriori meaning because the principle of general covariance forces one to consider a point as belonging simultaneously to many different spacetimes (an unusually abstract idea which most students of GR became aware only very late). The reason for this abstraction is as follows. Imagine that you have a classical system of electromagnetic field strength and metric tensor satisfying together the Maxwell-Einstein equations. Suppose these fields are known prior to some spacelike surface Σ then, indeed, without conditions for the coordinatization of future points one has no Cauchy problem. As is well known, the Einstein equations give four constraints for the metric field and its normal derivative on the surface Σ and only 6 "dynamical" equations for the 10 quantities $g_{\mu\nu}$. If the observer establishes the
labelling of future points of M (coordinatization) by means of conventions using only $F_{\mu\nu}$ and $g_{\mu\nu}$, then the mentioned diffeomorphism will have no effect on his observations. The "change of the physical situation" is exactly compensated by his
change of the labelling of the points. The field equations together with such coordinate conditions provide a deterministic scheme.
The active interpretation of general covariance demands therefore that we imagine the possibility of decoupling the labelling of (future) points of the manifold from the prevailing configurations of
fields which obey a closed system of intrinsic field equations. The upshot of this is that a point which was contained in a spacetime region is as well belonging to any other spacetime region which is isometric to it. In other words if you live in a world in which only a (causally complete) part is physically accessible then you cannot distinguish this situation from any other world which has a patch which is isometric to the original region. This is a consequence of the active interpretation of transformations (i.e. diffeomorphisms and not coordinate transformations) and therefore comparisons with gauge theories (where one was forced to introduce to introduce redundant descriptions) may be misleading (those do not have an active interpretation).
The phantastic progress in QFT in CST was the recognition that with a more abstract notion of what constitutes a QFT (a new functorial concept which contains the old one as a special case) you can implement local covariance in QFT in CST
http://br.arxiv.org/abs/gr-qc/0603079
(look also at the literature cited therein)
This is after Einstein and black holes the third great step in gravity!
If in addition you quantize gravity (say perturbatively) the already established local covariance will automatically pass to background independence i.e. the change of one background to another one becomes a symmetry transformation in the full quantum theory (the argument on page 120). The problem whether there are other ways of quantizing which make QG a theory with a finite number of parameters (the standard way leads to an ever increasing number with increasing perturbative order) is not entering here because any perturbative approach will lead to a perturbative fulfillment of the Einstein-Hilbert like operator equation and hence the B-F argument applies. Hence the claim that QT and gravity are not compatible has finally been shown incorrect. This also is relevant to Lee Smolin who seems to have internalized this mantra during his years as a ST.
I have bothered Peter to have a special blog on this important matter which changes the rules of the game in town, but he is immersed in combating the ST backlash via embedded journalists. What criticism can be stronger than this invalidation of the ST mantra?

96. **Bert Schroer**

October 24, 2006

Thomas Larsson
I will return to your question later on. Meanwhile you may read what I wrote for Anon, because the Maldacena issue is not independent of these new developments in QFT.

97. **Bert Schroer**
October 24, 2006

Thomas Larsson
the short answer to your remark is the following question:
Is the starting point of Maldacena (not what he actually argues but how he wants his conjecture to be understood) a conformal field theory (even one having a Lagrangian description: SUYM) a 4-dim CFT, yes or no?
If the answer is yes then Rehren's theorem applies, he does not have any other assumptions. But then how can M be correct? If the answer is no than Maldecena may be correct but the boundary value he imagines cannot be a CFT. I do not know whether the N->infinity limit is conformal, in fact I have never seen a proof that one obtains conformality for finite N. I think the only safe statement seem to be the vanishing of the beta function in lowest order. Lets for the sake of the argument assume that not only beta=0 but also conformality (stronger than beta=0). Then one would think that this property is maintained for N=infinity. Here one has to be a bit careful because that double limit (large 't Hooft and large color) is not a naive limit which maintains field theoretic properties. But to imagine that bluff!!, suddenly conformality is lost in the limit is a bit far-fetched.
As Rehren has pointed out in his discussion with Distler (he stopped that discussion after it became obvious that there was no point in a continuation) that "restriction" and what they call"duality" in that discussion is the same (this to me very surprising and highly nontrivial statement was shown by Duetsch and Rehren).
I think that the origin of this misunderstanding of Rehren's work by ST is the way in which 't Hooft conceived "holography" as a mysterious property of gravity. This picture (the metaphoric part of Distler's discussion) is incorrect, holography is defined with or without gravity. In addition this picture would contradict the unity achieved via that fantastic extension of QFT which I sketched in my comment to anon.
The whole situation is very tragic because it shows that with the market force and embedded journalists the survival of individual researchers against corporate groups is endangered, at this point Lee is 100% right. This weekend I have watched the KITP glee club with the embedded cantor. While I was listening I laughed the lung out of my body. But as every indulgence breeds remorse I thought afterwards in bed, my God how could this happen to a once proud and purposeful science.
All the tangible progress (including the work mentioned before) has been done by individual researchers and nothing has come from those globalized communities. Let them fight it out, while we move on.

98. **Anon**
October 24, 2006

"comparisons with gauge theories (where one was forced to introduce to introduce redundant descriptions) may be misleading"

So you're saying the 10 components (d(d+1)/2 components in d dimensions) of the metric tensor are not a "redundant description" along the lines of the 4 components (d components) of the vector potential of electromagnetism?

99. **Bert Schroer**
October 24, 2006

Anon
No I am not saying that; if you work with pointlike metric tensor quantum fields you presumably have to use some BRST ghosts in order to reduce to the physical cohomology even literally speaking the theory is not a gauge theory. I understand that such a formalism is presently being worked out by Brunetti and Fredenhagen. I am looking at this problem (together with Jens Mund and Jakob Yngvason) without using ghosts by setting up a perturbation theory with our string-localized metric potentials.
What I had in mind in that phrase was that in the classical theory as well as in QFT in CST the local covariance principle forces one to interpret diffeomorphisms in the active sense (this is what they mean to mathematicians) and not as a change of coordinates whereas the gauge transformations in electrodynamics are purely passive.

100. **Anon**
October 24, 2006

Active or passive, the bottom line seems to be that you allow to compute observables that are not diffeomorphism invariant, where everyone else says only diffeomorphism invariant observables are physical.

101. **Bert Schroer**
October 24, 2006

I tried to be very careful about diffeomorphism covariance and diffeomorphism invariance. The first property is the local covariance of Einstein and its very non-trivial recent adaptation to QFT (necessitating a very novel and surprising generalization of being forced to think about all globally hyperbolic manifolds at the same time even if for defining just one QFT in the new sense). Once this problem was solved the second problem of invariance (background independence) follows almost without additional sweat by converting the metric tensor into a quantum field (you only have to accept that by cohomological descend you get the operator Einstein-Hilbert like equations similar to the way you argue about the Maxwell operator equations).
It would be helpful if questions could be limited to things which are not carefully explained in the papers.

102. **Anon**
October 24, 2006

All I'm asking is for a clear explanation of why, if you allow to compute non-diffeomorphism-invariant observables, all but 2 (d(d-3)/2 in d dimensions) of the components of the metric tensor still decouple.

I don't see why the situation is any different from a gauge theory where you allow to compute non-gauge-invariant observables.

103. **Bert Schroer**

Anon
the remark about 4 constraints versus 6 propagating components was made in connection with a well-defined Cauchy problem for the classical Maxwell-Einstein equation. The purpose of that discussion was not to make analogies with gauge theories but rather to argue for the active interpretation of diffeomorphisms (in contrast to the passive interpretations in genuine gauge theories). This is basically the upshot of the Einstein hole argument
Norton, J.D.: The hole argument. Stanford Encyclopedia of Philosophy, http: //plato. stanford.edu/
entries/spacetime–holearg
The result is quite revolutionary recognition that The principle of general covariance forces one to regard spacetime points simultaneously as members of several, locally

diffeomorphic spacetimes. It is rather the relations between distinguished events that have a physical interpretation.
The adaptation of this principle to QFT (a very nontrivial step) led Brunetti, Fredenhagen and Verch to their paradigmatic change in the definition of what constitutes a QFT.
Concerning the analogy to gauge theory the following remarks are in order. The zero mass finite helicity class of Wigner representations permits to introduce pointlike field strength. For h=2 the field strength is a linear version of the Lorentzian Riemann tensor. But as for h=1 one cannot write the Wigner inner product in terms of an integral over a local density in these Field strength and last not least it is not possible to formulate ultraviolet-tame (or better "finite parametric classes" of) interactions with field strength, rather one needs "potentials" (for h=2 the analog of the metric tensor). Classically this is not a problem at all. Although I have not done the calculations (perhaps one finds this in the literature) I believe that the connection between the potentials and the field strength for the genral helicity case can be encoded into a gauge principle. For the QT the conceptual situation is very different since there is the unitarity (positivity) requirement. There are two ways to handle this problem: either you convince yourself that although pointlike-localized potentials are not possible, there are string-localized potentials (this is the way Mund, Yngverson and I propose in our joint work). In that case you face the new conceptual problem to adapt the Epstein-Glaser iteration to string-like fields. The standard way is to insist in pointlike potentials and forget about QT (the Hilbert space) in intermediate steps hoping that by some ghost extension with cohomological properties you can use all the advantages of the standard pointlike formalism and still return to physics at the end. This has worked for h=1. Whether it does so for interactions involving h-2 is the subject of present investigation. In such an approach the analogy to gauge theory in Minkowski spacetime is perfect.
This analogy is however obfuscated since GR requires an active interpretation of diffeomorphisms in the above sense of the new BFV notion of QFT demanding that the algebraic substrate of QFT is "living" on all isometrically equivalent spacetimes simultaneously! (this includes submanifolds of two given global ones which are isometric i.e. local diffeomorphism).
I ask you Anon, what is for you an observable in gravity? Is it a gauge invariant in the above setting of an h=2 particle theory? In that case the potential (metric tensor) would be gauge-dependent but the field strength (Lorenztian Riemann tensor) is gauge invariant hence observable in the sense of gauge interpretation. But according to the (always active) diff-interpretation the latter is presumably not observable.
I can of course answer your question in one sentence, but that answer would cause more conceptional damage than enlightenment.

104. **Bert Schroer**
October 25, 2006

Peter,
my response to Anon got again stuck in the spam filter

105. **Arun**
October 25, 2006

It seems to me that AQFT practitioners find the Lagrangian path integral method of QFT to be unreasonably successful. Well, if AQFT is indeed the way to do QFT, then the success (and limitations) of the Lagrangian path integral should be explainable within AQFT. Presumably the successful Lagrangian formulations are taking care automatically somehow the setting up of the unique hyperfinite type III_1 factor algebra, the modular positioning of a finite number of abstract monades, etc., etc.

Since "For higher than 3 spacetime dimensions the presently known descriptions still look somewhat concocted", but we have highly successful 4 spacetime dimensions Lagrangian path-integral QFTs, presumably making the connection suggested above will enable us to see what a not-concocted example looks like.

IMO, this kind of demonstration is the only way to convince a large number of physicists that AQFT is actually useful.

106. **Anon**
October 25, 2006

I'm sorry to say that I find Schroer's long and rambling responses impossible to follow. Peter Woit clearly thinks that Schroer's work is of such importance that he posts something on his blog, every time Schroer posts or revises one of his papers on the arXivs. Since Peter is such a clear writer, maybe he could boost the physics content of his blog by posting a summary/explanation of this work by Schroer and collaborators.

It would be a great public service.

107. **Bert Schroer**
October 25, 2006

arun,
this is all deja-vue, we (maybe without you) discussed this in this blog in April/May.
From the phrasing of your question I sense that it is declamatorical, but nevertheless I will ignore this and answer it to the best of my knowledge
1) Funct5ional integrals are extremely limited; you cannot treat QFT in CST in this setting (that is why in mathematical physics presentations like those of Wald you wan't find it) and as far as I remember i have explained why this is not possible. Question: do you think the QFT in CFT is not interesting?
2) you cannot solve any 2-dim. massive system, even in case it admits a Lagrangian presentation. Most of the systems do not even have a Lagrangian; they are characterized by a crossing symmetric unitary S-matrix (just like string theory, except that it is not metaphoric). And for chiral CFT even you would not use Lagrangians but rather the methods of AQFT (represent6ation theory of observable algebras, that is what AQFT is if you do not artificially limit it to 2 dimensions).
3) Most free fields cannot be characterized as being of Euler-Lagrange type (above spin 2 I do not know any) but their use is perfectly legitimate in causal perturbation theory (where you only use interaction polynomials in free fields) although the most important ones can
4) The Lagrangian approach where it works in your sense is an artistic device: you write something on paper in good faith, develop it in perturbation theory, see that it does not make sense (the integrals diverge) and use your hindsight and good physical sense to repair it (renormalization) and at the end you realize that you have a perfectly reasonable result which however (if you try to check whether it its into your original functional representation) fails to satisfies your original functional representation. There is nothing wrong with artistic arguments as long as one keeps some awareness about their nature. Imagine that Heisenberg would not have come up with QM in 1925. Then we would have presumable have learned clever artistic tricks (using our physical hindsight) to go somewhat beyond the H-atom and it would have been quite disastrous if we would have been satisfied with artistic explanation.
The artistic device of functional integrals (in QM it is mathematical) works because the whole idea of locality is so strongly incorporated that you cannot fail to extract the right result (if you have a good covariant formalism which was not available before 1949).

108. **Bert Schroer**
October 25, 2006

Anon
neither Peter nor I are willing to serve as your Nanny. Do you really expect that these subtle recent developments in QFT can be explained in a weblog. The only thing one can do is cite the literature and make some guiding remarks and that is what I did. The rest you have to do; there is nothing in my commentaries which is not in detail explained in the existing literature. But if metaphoric tales are more to your taste than autonomous mathematical physics, then you really should stay with string theory or something alike and join one of those globalized communities where you find people who are very experienced in telling you nice-sounding metaphors which have a higher entertainment value than what you can get from me.

109. **Anon**

October 25, 2006

OK, so give me a reference (e-print and page-number) where it is explained why all but d(d-3)/2 components of the metric decouple, despite the fact that you allow to compute non-diffeomorphism-invariant observables.

This isn't a complicated question and, if it is answered in the literature, you could avoid writing paragraphs and paragraphs of gibberish by giving a detailed reference to the answer.

110. **Bert Schroer**
October 25, 2006

Anon,
That the propagation of the metric tensor according to the E-H equation leads to 4 non-propagating constraints (Cauchy problem) is in most texts on classical gravity (e.g. Wald's book). Its use in connection with establishing the active interpretation of diffeomorphisms (in contradistinction to the passive interpretation of gauge transformation) you find in the introduction of
Fredenhagen, K., Haag, R.: Generally covariant quantum field theory and scaling limits. Commun. Math. Phys. 108, 91 (1987)
and the nontrivial adaptation to quantum matter in
http://br.arxiv.org/abs/math-ph/0112041
and a formal argument that background independence (diffeomorphism invariance) follows from diffeomorphism covariance automatically upon quantizing the metric potential (and fulfilling the operator form of the E-H equations) in
http://br.arxiv.org/abs/gr-qc/0603079
It would not be advisable to eliminate some g components (in gauge theory you would not work with the Coulomb gauge either), you rather prefer to find a BRST ghost extension and encode the elimination job into the BRST cohomological descend (or if you, like I, do not like ghosts in intermediate steps one works with string-localized metric potentials). Ergo in QFT in CST you may eliminate, in a full QFT including gravity you never do that.
The length of my previous contribution resulted only from trying to point out some subtle differences between gauge theories and background independent quantum gravitation since I had the impression you looked for a more intimate contact than a vague analogy.

111. **Anon**
October 25, 2006

10-4=6, not 2. I am asking how you propose to get from 10 down to 2.

Brunetti and Fredenhagen (gr-qc/0603079) do not address this issue. In fact, except for the very last page of their paper, they do not address the quantization of the gravitational field at all.

Nota, when they do turn to some tentative remarks on the quantization of the gravitational field, they say

"A possible obstruction could be that locally the cohomology of the BRST operator is trivial, corresponding to the absense of local observables in quantum gravity. Another problem is the fact that the theory is not renormalizable by power counting. Thus the theory will have the status of an effective theory."

And they do not try to depart from the usual condition that only diffeomorphism-invariant (BRST-invariant) observables are to be computed.

You, on the other hand, say you can compute local, non-diffeomorphism-invariant, observables.

So, I'll ask again, how is that compatible with the decoupling of all but d(d-3)/2 components of the metric? A reference to one of your papers, where this is explained (a page number, please), will suffice.

112. **Bert Schroer**
October 25, 2006

Anon
in any theory based on BRST you compute of course also non-diffeomorphism invariant objects, it is only after the cohomological descend that you find the physical objects (diffeomorphism covariance passes to diffeomorphism invariance). The elimination procedure you seem to like so much is a special treatment of constraints by solving them explicitly. This in QED would amount to the (non-covariant) Coulomb gauge approach and I have never seen any honest computation in that setting. The Arnowitt-Deser-Misner Hamiltonian framework faces this problems of constraints (but I know to little about it in order to say that what they do is an explicit elimination of components).
Could I ask you what is your interest in such horrible elimination procedures (I never advocated them, it is only in the famous classical "hole argument" that one implicitly uses them but you seem to have a monomanic interest in them).
The two helicity degrees of freedom are only manifest if you use our string-localized matrix g-potentials (in the BRST treatment they are masked through the presence of the BRST ghosts). String-localization is explained in
http://br.arxiv.org/abs/math-ph/0511042
We meanwhile know their two-point functions but we are still struggling with the conceptual problems of formulating a perturbation theory for string-localized fields.
The remark of B-F about the effective theory means that it is diff-invariant but cannot be used up to the Planck length (since the number of parameters increase with perturbative order).

113. **Anon**
October 25, 2006

Brunetti and Fredenhagen:

"A possible obstruction could be that locally the cohomology of the BRST operator is trivial, corresponding to the absense of local observables in quantum gravity."

Are you saying that they (and not just they) are wrong, and that there are BRST-invariant local observables?

Or are you saying that you can extract sensible physics (e.g. achieve the desired decoupling) while working with BRST-non-invariant local observables?

In either case, could you give me a reference for the precise statement?

114. **Bert Schroer**
October 25, 2006

Anon,
I have no opinion whether the diff-invariant theory possesses still localizable flesh (localizable monades) or whether it only contains topological (or combinatorial according to once point of view) "bones" (type II_1 algebras, the ones Vaughn Jones uses in subfactor theory leading to the Jones polynomial. And I do not advocate a

physical interpretation of BRST non-invariant objects.
The reason I am so much interested in the string-localized formulation of metric potentials is precisely to clarify this issue. In that case the g's do act in the physical Hilbert space and the only thing which could go wrong is that they generate semiinfinitely extended spacelike strings which have horrible domain properties (e.g. create infinite energy states from finite energy ones). If this is not the case then the theory has in addition to E-H diff-invariant state other states in its Hilbert space. I am pretty confident that this picture is an alternative formulation to ordinary gauge theory but I would not make any bet in the gravitational case. String localized fields are not local observables in the strict sense, but neither are the highly useful fermion or anyon fields.
In any case if that "bone"scenario of B-F turns out to be true then the Maldecena conjecture in the sense of an AdS–CFT correspondence could not be true apriori, even if you go along with that weird idea that in addition to the known holography there is another gravitational one.
I told you that I believe that B-F are working on a BRST formulation, so we have to wait and see.

115. **Anon**
October 25, 2006

Doesn't the AQFT approach rely on the existence of BRST-invariant local observables?

What can you hope to achieve in that approach, if there aren't any (which is the conventional wisdom)?

"In any case if that 'bone' scenario of B-F turns out to be true then the Maldecena conjecture in the sense of an AdS–CFT correspondence could not be true apriori …"

To the contrary: the Maldacena conjecture relies on the fact that there are no local BRST-invariant observables in quantum gravity. If there were, then the Maldacena conjecture would most certainly be false. But I don't see the point of discussing the Maldacena conjecture with you. There are plenty of experts on it, who could do that.

"I told you that I believe that B-F are working on a BRST formulation, so we have to wait and see."

Above, you made some very grand claims for the AQFT approach to quantum gravity. In the absence of a proof that the conventional wisdom, about the absence of BRST-invariant local observables, is wrong, I think those claims are overblown.

116. **Bert Schroer**
October 26, 2006

The idea to use a BRST approach is not an idea emanating from AQFT, rather certain formal analogies to gauge theory (but not a naive identification of formalism). Since it has not been done it seems reasonable to do it before entering the blue yonder of amok running speculations. There are also other conservative ideas to formulate perturbative QG which are expected to lead to an operator version of E-H-like field equations on suitably determined states.
The nice aspect of the B-F argument (only on the level of string theoretic rigor one would call it a theorem) is that any implementation which achieves that is background independent i.e. background independence is a free ride and the hard work was done before while establishing diffeomorphism-covariance.
I appreciate your admission that you do not know much about the AdS–CFT correspondence and the Maldacena conjecture (your statement about a relation between BRST and the M-conjecture is rubbish) and that you prefer to leave that matter to experts.

117. **Anon**
October 26, 2006

Perturbative quantum gravity was studied exhaustively, starting with de Wit and Feynman, and followed by many others. The BRST approach to it was introduced by de Wit. Stating results found many decades ago is not "blue yonder of amok running speculations."

As to Brunetti and Fredenhagen, as I said, the only "quantum gravity" in their paper is a page of speculations at the end. Most of the paper is about quantum field theory in curved spacetimes, a subject that was well developed when Birrell and Davies wrote their book. In their AQFT approach, B&F miss (gloss over?) almost all of the subtleties that make the subject an interesting one.

"your statement about a relation between BRST and the M-conjecture is rubbish"

No, my statement is correct.

All I'm saying is that, if you want to discuss AdS/CFT, you should do it with someone like Distler (who seems to have written quite an acute summary of Rehren's proposal), not with me.

118. **Bert Schroer**
October 26, 2006

Egbert,
the concept of internal symmetries was since its inception (the SU(2)isospin of nuclear physics introduced by Heisenberg) one of the most mysterious proposals. Whereas it is natural to accept spacetime symmetries (since they accompanied us in the classical setting since the time of Newton) the understanding of internal symmetries is a mysterious concept in QT (in classical physics you can only get them by reading back QT concepts into classical physics i.e. they are classically unnatural). This problem was finally solved in the work of Doplicher, Haag and Roberts during 1970-1990
There idea was to abstract internal symmetries by taking a dichotomic view about QFT: local observable algebra

119. **Bert Schroer**
October 26, 2006

continuation
The representation structure of interests coming from the DHR theory in low dimensions is richer, in this case the observable structure leads to representation sectors which carry a representation of the braid group (a generalization of the symmetric group) and instead of the field algebra you find something which does not permit a clear-cut separation into inner and outer (spacetime) symmetries.
Suppose now that you have gone through this analysis in a higher dimensional QFT and you compactify certain spatial dimensions and make them small. Do the correlation functions of such a QFT in the limit approach those of a QFT with smaller spacetime dimensions and a larger symmetry? Of course not. The observable algebra on such a brane becomes awkward (it develops those disagreeable physical properties which Rehren mentioned in his discussion with Distler) and its representation theory of physical interest will not develop new sectors which come from the small spatial coordinates.
What people mean by KK is a Fourier decomposition in the small coordinates in the classical theory and retaining only the lowest component; it is only there (i.e. before quantization) that KK works but it does so in a completely childish way.
What Lunsford attributed to Pauli is something slightly different (this was the reason for my interest). If I understood it correctly it says that you cannot apply KK to a higher dimensional Einstein-Hilbert theory (diff-covariant) into a lower dimensional E-H (lower dim. diff-covariance) and remaining gauge part. This sound very plausible, but it seems to be a classical statement.

120. **Bert Schroer**

October 27, 2006

My complete contribution to KK is now available at
http://kaluza-klein.blogspot.com/
I am mentioning this here because there was a mistake in my previous blog here which now has been corrected.

Corrections…

October 8, 2006
Categories: Not Even Wrong: The Book

I'm well aware that there's far too much these days on this blog about the controversy over string theory, but two things have appeared today in the press about this that aren't accurate, and I can't resist using this platform to issue corrections. Readers who have had enough of this are warned to move on to some other blog with fresher material.

The Observer (the Sunday version of the British newspaper the Guardian) has an article today by Robin McKie, entitled String theory: Is it science's ultimate dead end? On the whole, the article is a well-written piece about the controversy over string theory. I talked to McKie on the phone, and he quotes me as saying something that is probably an abbreviated version of what I actually said.

'Too many people have been overselling very speculative ideas,' said Woit – author of Not Even Wrong – last week. 'String theory has produced nothing.'

The first part of this quote is fine, but "String theory has produced nothing" is not what I think, and presumably was part of some longer statement. String theory has certainly produced some very interesting mathematics, as well as some promising ideas about strongly coupled gauge theories. It has produced nothing useful about unification and how to get beyond the standard model.

The McKie piece also has some strong quotes in defense of string theory from David Gross, Samjaye Ramgoolam and Michael Green:

'String theory is on the right path,' said David Gross, of the University of California, Santa Barbara, and another Nobel prize winner. 'But this path is quite long. Further breakthroughs are required.'

I'm kind of wondering why he claims that definitely string theory is on the right path. Perhaps he also had some caveats that got dropped.

'said Sanjaye Ramgoolam, of Queen Mary, University of London. 'There are a number of ways that we could prove – or disprove – string theory. For example, Europe's new Large Hadron Collider may well be powerful enough to provide evidence that suggests we are on the right road.'

This kind of invocation of the LHC as being able to prove or disprove string theory always strikes me as less than honest.

According to Green:

"There is no alternative to string theory. It is the only show in town – and the universe.'

Again, perhaps some caveats have been dropped here.

The second piece with inaccuracies that appeared today is a review of my book and Lee Smolin's in the LA Times by K.C. Cole. It's entitled Strung Along and is basically a hit-job on me and Smolin. Some of the things in it are so dishonest and incompetent as to be pretty hilarious:

In fact, many statements about string theory in these books are plain wrong… To say, as Woit does, that fundamental mysteries about neutrinos are being ignored will come as news to the dozens of physicists who've been working on these problems for years.

At first I couldn't figure out why she was attributing to me the insane statement that "fundamental mysteries about neutrinos are being ignored", but after taking a look at all the references to neutrinos in the book, I finally figured it out. On page 93 of the US edition I write, after giving a description of the things the standard model leaves unexplained, including a parameter count that ignores neutrino masses:

One complication that has been ignored so far involves neutrinos.

and then go on to explain about the experimental evidence for neutrino masses. The "ignored so far" obviously means "ignored so far in this chapter", not "fundamental mysteries about neutrinos are being ignored" by physicists. This recalls some of the hilarities in Lubos's review of my book. It's absolutely amazing that a supposedly serious journalist would do this kind of thing.

There are plenty more claims in the review that are pretty much the opposite of reality:

To mathematician Peter Woit and physicist Lee Smolin, however, the search for beauty is ruining physics.

Actually my view is quite the opposite: what's ruining physics is pursuing very unbeautiful theories (Susskind is fond of calling them "Rube Goldberg machines") for which there is no experimental evidence.

I've never met Cole and she knows nothing about me personally, but she seems intent on painting me and Lee as embittered failures:

Woit, and Smolin… write mostly about how string theory has ruined their careers.

I don't think there's anything in Smolin's book about how string theory has ruined his career (and he's had quite a successful one). As for me, there's no such sentiment expressed in the book and my feelings about this are quite the opposite. If it weren't for string theory, most likely my academic career would have led at best to a job at a not very good institution in a place I really wouldn't be very happy living. Because of string theory I moved into mathematics early on, and have ended up with an academic position I'm extremely happy with, living in my favorite place in the world. String theory didn't "ruin my career", it made a very happy one possible.

As I said, I don't know Cole, so I don't know why she decided to write this kind of dishonest hit-job. Perhaps it has something to do with her professional association with string theorist Clifford Johnson at USC. I've long suspected that Clifford was the author of the referee report for Cambridge which compared doubting string theory to doubting the theory of evolution, and constructed evidence that I didn't know what I was talking about by taking a sentence in my manuscript out of context and changing a word. One is often wrong about such guesses, probably I'll never know…

Update: Amazing how quickly one finds out things one thinks one will never know. Over at Clifford Johnson's blog, Capitalist Imperialist Pig asked him if he was the referee who tried to stop Cambridge University Press from publishing my book. His answer: "that's all just silly and irrelevant". OK, now I know…

The funny thing about this is that Clifford has been bitterly complaining about the fact that the book is being marketed and publicized to a wide audience, but it appears that he was the one who stopped it from being published a couple years ago in a form where it would have reached many fewer people. Priceless.

Update: Thanks to "Another Grad Student", who in the comment section over at Clifford Johnson's blog did a better job than I could of explaining to him why I was no longer bothering to respond to his endlessly condescending, sneering and dishonest comments. Anyone who thinks there is anything to the accusations Johnson and Distler are making about me over there is encouraged to read for themselves some of the many comment threads where I have tried to have serious discussions with them.

More substantively, it's clearly a waste of one's time to try and debate these issues with someone who is on record as claiming that criticizing string theory is like criticizing the theory of evolution.

Update: Clifford Johnson has denied being the CUP referee in question, or having anything to do with the Cole "review", saying here that he has not even read the book. My apologies to him for incorrect suggestions made in this posting, and my misunderstanding of his later comments.

Comments

1. **CapitalistImperialistPig**
   October 8, 2006

   Having read Cole's "reviews" I'm left wondering what books she actually read. Many of the knocks against both you and Lee Smolin seem too weird to have been generated from the contents of the books.

   I am left wondering what the nature of her "professional association" with Clifford is though. I thought she was a journalist and he was a string theorist. Can you clarify?

   Finally, have you asked Clifford if he reviewed your manuscript?

2. **J.F. Moore**
   October 8, 2006

   Naturally, I can only speak for myself, but I don't think that you are writing too much about the bubbling controversy. I think it's fascinating to see how people behave when forced to justify their beliefs.

3. **Peter Woit**
   October 8, 2006

   CIP,

   K.C. Cole also teaches at USC, and she runs an evening program about science called "Categorically Not!" which is often discussed in Clifford's blog. If you look at the web-site for the program

   http://physics.usc.edu/catnot/

   you'll see that the text is written by her and her picture is on the front, but that:

   "This page made by Clifford V. Johnson and is brought to you by the Department of Physics and Astronomy at USC."

   As I wrote, I know very little about Cole, actually the main place I had heard about her was on Clifford's blog.

   No, I've never asked him if he was the Cambridge referee.

4. **LDM**
   October 9, 2006

   It is surprising that somebody that TEACHES science journalism writes such scientific nonsense. I was of the impression that journalists subscribe to something call "journalistic ethics and standards".

   As for Woit's claim that string theory has "absolutely zero connection with experiment," experiments already planned for a new European particle accelerator will look for the existence of extra dimensions and extra families of particles — both predicted by string theory. In fact, many statements about string theory in these books are plain wrong.

   In fact, the opposite is true…and both these books are well reasoned and generally correct to the extent allowed in a general presentation aimed at a layperson audience.

   If in fact the European particle accelerator does manage to muster a meaningful test for an extra large dimension…so what? There will be a negative result (or do you really believe the world is 10 dimensional?), and so one can predict string theorists will just maintain the extra dimension is not large, and so we will be back to the case of having an untestable theory.

5. **Spear Mark the Second**
   October 9, 2006

   I know KC a little… generally, I've liked her, and I've found her to be fair and smart. But her review in this case is off base, don't know why.

   A small point about the LHC… most scattering experiments since Rutherford have looked for an unusually large cross section at high momentum transfer. Rutherford discovered that nuclei were in essence point particles, Hofstadter probed the nuclear form factors, and Friedman, Kendall, and Taylor found quarks.

   Does anyone seriously think that the only reason experimenters will look for unexpectedly large cross section at LHC is extra dimensions from string theory? Large cross sections are always sought after… don't need a weatherman (or a string theorist) to know which way the wind blows.

   Since Sam Ting in the 1970's, everyone also looks for leptons in the final state, and since the W was discovered, missing energy too. Those are by no means signatures of string theory alone, and we did not need string theorists to know to look for those signals.

6. **Spear Mark the Second**
   October 9, 2006

   Just read KC Cole's review… she messed up on the neutrino discovery as well… the real key experiment was that of Ellis and Wooster, predating Pauli. Ellis and Wooster (part of the Cavendish group) proved there was missing energy, and that the energy was not electromagnetic in nature. Given that experiment, there were only two serious choices… that energy/momentum/spin conservation was wrong, or that a new particle was carrying off the energy/momentum/spin. All the experimentalists knew that at the time, but Pauli grandstanded and made a big deal about postulating the more detailed properties of the neutrino.

7. **MathPhys**

> It is surprising that somebody that
> TEACHES science journalism writes such
> scientific nonsense.

Why?

8. **Bourgeois Nerd**
   October 9, 2006

   Very disappointing to read that review, since I quite enjoy K.C. Cole's science writing. I have a feeling that you're right, Peter, that her relatonships (not just with Clifford, but with a lot of other string theorists) clouded her view you and Smolin's book. Also, string theory really is rather up her alley; she's all about "elegence" and "aesthetics," and, since a lot of people think that's what strings bring to the table (I, being a total outsider to such high-level math and science outside of popular articles, books, and blogs such as this, have no way to judge whether it is or, as you've argued, is not), I can see her being very, very attached to it.

9. **CapitalistImperialistPig**
   October 9, 2006

   Peter – Well, I did ask my question (re: the manuscript review) of Clifford and his response was:

   As for the other thing about Peter's guesswork… that's all just silly and irrelevant.

   In the political blogosphere, I think we call that a non-denial non-denial.

10. **Arun**
    October 9, 2006

    CIP, many thanks for asking the question!

    All of this has been extremely illuminating. Thank you, Peter, for persisting and publishing your book.

11. **wolfgang**
    October 9, 2006

    Peter,

    in the comments on the Asymptotia thread you wrote about Lubos
    "Remarkably, his colleagues at Harvard promoted him and so far have been willing to tolerate his behavior (although his recent public calls for my imminent death may change that situation)."

    When and where did Lubos call for your imminent death?
    Can you provide a link or something similar?

12. **King Ray**
    October 9, 2006

    I never liked string theory precisely because it is not beautiful or elegant. Just look at all the fields that they have living on the string worldsheet. I once computed all the maximal subalgebras of a single E8, using Dynkin diagram techniques, and it was amazing what all was in there. At that time E8xE8 was in vogue. The ultimate theory should be simpler than current theories, not orders of magnitude more complicated. To use Einstein's phrase, string theorists can calculate but they can't think. I also think there is a lot of hole drilling where the wood is thinnest.

13. **andy**
    October 9, 2006

    The webpage at USC's Anenberg School for Communication obfuscates the background of its faculty. On a science department's webpage the faculty listing will tell you what degrees the professor has and where he or she earned them. I can't seem to find that for that department.

14. **Peter Woit**
    October 9, 2006

    Wolfgang,

    The latest occurence of this was

    http://www.math.columbia.edu/~woit/wordpress/?p=467#comment-16818

    and a few days earlier he discussed his opinion that death would be too good for "the black crackpot" (that's me, color of cover of my book, Lee is "the blue crackpot") given my sins against physics. After I complained to people at Harvard, Lubos did edit this first occurrence to remove the reference to my death. A few days later he posted the above comment.

    I brought this to the attention of people at Harvard, and can report that some people there (not members of the theory group) agreed that this behavior was not tolerable.

15. **d.liman**
    October 9, 2006

    I'm assuming, since Peter brought it to the attention of folks at Harvard, that he was reasonably confident that it was likely an authentic post.

    There is a remote chance that it could just be someone who signed it with Lubos' name. On his blog he claims that this happens often.

16. **Peter Woit**
    October 9, 2006

    d.liman,

    I'm confident this came from Lubos. After it appeared I wrote in to his blog to ask him if it really came from him. He did not deny it.

17. **Anon**
October 9, 2006

Peter religiously checks the IP addresses of his commenters. I'm sure he checked this one, before reporting the incident to the Harvard authorities.

Right?

18. **Tim**
October 9, 2006

Peter,

I find it amusing that in the very same post you complain about journalists taking words and phrases out of context and interpreting them according to their own tastes without being very careful about the original intention and yet you do exactly the same by reminding us of a short phrase by Clifford Johnson without giving us the opportunity to review the original circumstances and intentions of those words.

Most funny!

Best,
Tim

19. **Peter Woit**
October 9, 2006

Tim,

Good point. Problem is I've been advised it's not really kosher to make public documents written by people who assumed what they wrote would not be made public. I'd suggest you ask Clifford to post a copy, it would be all right for him to do so.

20. **d.liman**
October 9, 2006

Thnx for the response, Peter. Keep up this great blog. Its disappointing that people like Lubos can't argue calmly, and not lose their cool. Hopefully someone in the Theory Group at Harvard will advise him how to behave properly.

21. **Gina**
October 9, 2006

Peter and Tim,
If you are talking about the referee report that Peter is attributing (with little evidence) to Johnson, I think, in this case, ethics is going the other way around. Trying to reveal the identity of an anonymous referee, certainly in public, is not so ethical. But I see no problem in posting (without distortion) the content of a referee report. (But I am not sure on this point, I'd be interested to hear if I am missing something.)

Of course, these are conventions and we can imagine a system where both the identity of referees and the reports are in the public domain.

22. **anon**
October 9, 2006

Gina, this sentence is quite fuzzy.
"Trying to reveal the identity of an anonymous referee, certainly in public, is not so ethical."
Who is trying to reveal?
Peter didn't ask Clifford. It was CIP who asked him. Are you accusing CIP of being unethical, for asking Clifford, IN PUBLIC? Clifford didn't have to answer, but he did answer. Peter FIRST quoted Clifford exactly, and then reached his own conclusions about the meaning of the quote. I don't think that is unethical.
I think for a reporter to write an article, with so many errors, and so one-sided in favor of her firend Clifford, now that is unethical.

23. **Gina**
October 9, 2006

Dear Anon

Hmmm, interesting comment. I certainly do not "accuse" anybody of anything. For a scientist to try to speculate in public about the identity of a referee is somewhat unethical, or perhaps a better word is unconventional.

Actually, Clifford did not confirm that he was the referee at all and he reacted in the appropriate way when he was asked – whether he was the referee or not – not confirming and not denying. So for Peter to reach a conclusion that Clifford was the referee, and to continue the discussion based on this assumption is not a very good logic and not very conventional/ethical. Again, I am referring to conventions for a scientist. The conventions for journalists are different.

My point was that I do not see any reason why posting a referee report is unethical. (I agree that it is not particularly common.)

This is a just little point. I suppose there is also the issue of ethics and conventions for weblog behavior. This looks like a truly a fascinating subject but I do not have anything to contribute. What can be the ethical rules for a CapitalistImperialistPig? I suppose whatever he do he cannot really be kosher.

24. **Anon**
October 9, 2006

I agree with Gina. It is definitely unethical to publicly accuse (or state that one "supects") someone of being the anonymous referee.

That puts the accusee in the untenable position of being unable to either confirm or deny the accusation.

It is not unethical to print an (unfavorable) referee report about one's own work.

The former is highly corrosive of the anonymous refereeing process (on which we all depend). The latter, not at all.

25. **Peter Woit**

October 9, 2006

I’m not the one who put Clifford on the spot about this, blame that on CIP.

I’ve suspected that referee was Clifford for quite a while now (since one day after seeing his behavior in response to challenges to string theory, and looking up over my desk and seeing a copy of his book on my bookshelf. I realized it was published by Cambridge, and a light dawned…). I finally decided to mention this publicly because I really had enough with the way he was going on about what a money-grubbing publicity hound I am, promoting my book to the general public who can not understand the subtler points of what I am saying. If it weren’t for him, the book would have been published two years ago by Cambridge, in a form aimed at and marketed to a small audience. He decided to stop that, and leave me no choice but to find a trade publisher. He has no business at all complaining about how this book was published, and it was unethical of him to do so knowing full well that he was responsible for this.

I’m pretty sure I know who the second string theorist referee was, but won’t say anything publicly about that. Unless he gets a blog and starts complaining about how the book was published….

26. **Anon**
October 9, 2006

“I’m not the one who put Clifford on the spot about this, blame that on CIP.”

Why?

You are the one who publicly stated the accusation (excuse me, the “suspicion”). CIP merely brought it to Clifford’s attention, which someone else would have done sooner or later, anyway.

And then you were the one who took Clifford’s non-committal response (the only ethical one he could make) as a confirmation.

27. **CapitalistImperialistPig**
October 10, 2006

I don’t really think it’s unethical to speculate on who anonymous reviewers are – I’ve certainly heard a lot of reputable scientists do so. Is it unethical to ask? It’s a bit hard for me to believe that it is, but if it is I apologise, abjectly but not profusely, to the gods of ethical physics, if such there be. Generally speaking, the baloney I serve on my blog *is* strictly Kosher.

In any case, Clifford had several options – to ignore my question, criticize my question for violating the sacred bond between a publisher and the authors it already publishes, or to say something noncommital. He chose the last option, but in a rather strange fashion – one that I thought looked like a politician’s non-denial non-denial.

In any case, I’m not much impressed with anonymous review anyway. I’ve had the experience of running technical review for a publication system with all reviewers public, and I don’t think the loss of anonymity was a major problem.

28. **Gina**
October 10, 2006

The whole hype issue is very much over-hyped. Let’s say that string theory had the blessing (which can quickly turn into a curse) of unproportional media attention, so what? It will not make the next major scientific step any easier (or any harder). I do not understand this issue.

29. **Marty Tysanner**
October 10, 2006

Peter,

Having occasionally “defended” you in the past, I would feel a little hypocritical in keeping silent on this. From what I have seen, I agree with Gina and Anon that you should not have publicly aired your hunches this way about Clifford’s possible role as The Referee. It tends to create a suspicion of him without objective evidence. I also agree that you should not have publicly concluded that Clifford’s non-answer to CIP showed that he really was that person. The whole thing just looks too much like dirty politics, with one candidate creating suspicion of ethical failure by an opponent, and then taking the opponent’s refusal to confirm or deny the accusation as “proof” of guilt. I didn’t think you were running a political campaign.

While I can understand how some of your experiences with Clifford could make you resentful, and it doesn’t seem unreasonable to *privately* suspect him of the role you imply, the whole idea of publicly throwing suspicion on him this way is distasteful to me. It doesn’t seem like one of your finer moments.

30. **Arun**
October 10, 2006

That LA Times review would make anyone wonder.

31. **Clark**
October 10, 2006

Jim Weatherall at [The CSW Blog] provides some numbers that, for me at least, added interesting perspective to the discussion. This will not be news to Peter, who has been the chief interlocutor there, but may be of interest to some readers.
If this falls under the prohibition of not mixing blogs, please feel free to delete this post.
One of the most illuminating of recent developments has been hearing from the experimentalists, such as Richter, Spear Mark II,
and Weatherall, who may not have been as concerned as theorists in publicizing their viewpoint and observations.
For instance, SM II’s appraisal of Pauli’s role in the neutrino hypothesis suggested a consensus among the experimentalists
of which I must concede having been unaware.

32. **Thomas Love**
October 10, 2006

Searching for K C Cole led me to:

http://www.ncswa.org/archive/workshops/2004/3cole.html

Opening talk by K.C. Cole, Los Angeles Times

By Elise Kleeman

"Really good science writers need to lie, cheat, and steal, said K. C. Cole in the first plenary of the workshop. She outlined 15 rules for writing in her talk, but focused most on the value of lying."

That says a lot about her review, does it not?

33. **woit**
October 10, 2006

Marty,

Perhaps you're right. It's certainly true that I was highly annoyed about Clifford's recent behavior on his blog and because of that my judgement at the time may have not been the best. But still, I think mentioning my suspicions can be justified, even beyond the grounds I gave earlier that Clifford should not be criticizing how this book was published unless he is willing to have his own role in that story examined.

Part of the story of string theory is the story of how it has acquired and kept its dominant position. Some string theorists claim that this is purely through its "triumph in the marketplace of ideas", but, especially recently as a critical point of view on string theory has gained traction, less than ethical tactics have been used to try and discredit me and Smolin. I suppose I should be extremely careful of my own ethics. The question about Clifford is bit of a tricky one, since it has to do with what tactics are acceptable in order to expose less than ethical behavior and attempts to censor legitimate scientific views.

34. **woit**
October 10, 2006

Thomas,

That's pretty funny. One hopes that her "rules" (which seem to include "eschew objectivity and quote out of context") are tongue-in-cheek, but I'm not so sure…

35. **TheGraduate**
October 10, 2006

"Quotes are always out of context"

I guess that explains the way she used the neutrino quote which for me was bizarre.

36. **LDM**
October 10, 2006

The problem is Cole is writing on topics she probably does not deeply understand, and hence cannot really explain well…and instead of lying and cheating, better to write nothing at all…but if she were to need an example of honest science writing, she should read Feynman.

The Feynman Lectures are maybe the best examples of how to explain ,without lying and cheating, advanced concepts — accurately — to an not particularly advanced audience.

…When explaining things, Feynman did omit the details of lengthy calculations (that would normally be found in advanced texts or papers on the topic he was discussing) so he could concentrate on the PHYSICS…
(For a concrete example, see the discussion of the Molecular Hydrogen Ion in Feynman vol 3– all results are complete and correct, but many details of the standard calculations, normally laborious (Born- Oppenhemeir, etc) are simply not given)

37. **Michael Bacon**
October 10, 2006

"And then you were the one who took Clifford's non-committal response (the only ethical one he could make) as a confirmation."

I know I'm missing something here, but why was it the only ethical statement Clifford could make? Even if there are certain prohibitions on publically acknowledging that one was a referee, I believe that there must be limitations on this type of prohibition in the context of subsequent controversies that may arise; perhpas like this one. In such cases, a simple acknowledgment or deniel would settle the issue, and no real violence to ethics would be done.

38. **Peter Woit**
October 10, 2006

Michael Bacon,

In general I don't think there are prohibitions against a referee revealing his or her identity, either publicly or privately. Anonymity is there to allow the referee to give an honest and unbiased opinion without having to worry about having to suffer repercussions because of this. That's why Marty is right it is not a good idea in general to try and pierce this anonymity.

On the other hand, anonymity of referees has a dark side, with anonymity allowing a referee to behave unethically, knowing that he or she won't have to answer for less than completely professional behavior. So, it's not always so simple….

39. **Gina**
October 10, 2006

I agree that the issue of refereeing is not simple and sometimes loaded. In fact, almost every negative referee report is a little controversy. A completely open system may be an option, a "double blind" system is another option. But I do not see a simple solution except the universal advice: "take it easy".

I read Cole's review and it does not look to me as that negative. It is critical both to string theory and to the books by Lee and Peter, and this looks reasonable.
There were 20-30 reviews on the book, most are positive, a few (like mine) are mixed or negarive. I do not think it is right or wise, Peter, to regard negative reviews as "hit jobs" (it is also completely meaningless) and to "go after" the people who write them. If you want that people will listen to your criticism you should be ready to accept criticism, and if your success rate with string theorists or other sientists will be as high as with science journalists you will be in a good shape :).

40. **John Ramsden**
October 10, 2006

Apologies if it's already been mentioned, above or in another article in this blog, but last week Bert Schroer issued a new version of his anti-string-theory polemic (or "samisdat" as he calls it – I must look up that word) at http://www.arxiv.org/abs/physics/0603112.

Before rereading the paper, I was rash enough to mention its revised release in a footnote to one of my replies on Lubos Motl's blog (http://motls.blogspot.com/) but this reply mysteriously disappeared within minutes. However, the mystery was solved when I did get round to reading it the next day, and reached page 21 😉

Cheers

41. **Arun**
October 10, 2006

"Woit, and Smolin in "The Trouble With Physics," write mostly about how string theory has ruined their careers" – balance is not being equally negative or positive about both sides – i.e. "It is critical both to string theory and to the books by Lee and Peter, and this looks reasonable."
It wouldn't matter if Cole was uniformly critical of Lee and Peter and uniformly supportive of string theory, as long as she didn't misrepresent what the books were about.

Whether or not a book is worth reading is opinion, and one can have any opinion. But what is in the book or not in the book should not be lied about.

42. **Gina**
October 10, 2006

Arun,

indeed this quote striked me as very unfair but I double checked and it is not the full quote. Here it is:

"These issues are well worth addressing, which makes it all the more disappointing that Woit, and Smolin in "The Trouble With Physics," write mostly about how string theory has ruined their careers — and physics as well."

I think it is correct to characterize Peter's position as claiming that string theory ruined particle physics and this is what Peter mostly writes about, in the polemic part of the book. (As I already said the, 80% of the book is an excellent and inspiring description of particle physics and related mathematics.) Now, the part about string theory ruining Peter's career is an interpretation of Cole of what Peter tells in the book about himself. This is what Cole reads between the lines. It is a legitimate interpretation (for a journalist). I do not agree with this simplistic interpretation and would not have written it myself – but I am not a journalist.

Overall, the sentence is somewhat unfair but not nearly as much as seen from cutting the last words "– and physics as well".

Anyway, overall Cole's review is not that negative, and overall she is doing a good job describing the controversy, and overall, even if there are a few cheap shots here and there it is wrong and unwise (and a waste of time) to "go after" people who write negative reviews.

43. **anon**
October 10, 2006

Gina, I've never, ever heard Peter say that string theory ruined his career. In fact, Peter sounds to me as happy with his career as a pig in mud. Cole's sentence is groundless, a calumny, a character assassination; what she means is that Peter criticizes string theory because he is bitter; that his criticism has almost nothing to do with any shortcomings of string theory .

44. **Gina**
October 10, 2006

OK, I agree that Cole should not have written as a fact that the books are about string theory ruining Peter and Lee's careers even if she believes or just conjecture that this is what is 'going on'. (I criticize Peter himself for mixing too much the factual matters, his own interpretations, and unrealeted "gossip items", and I certainly do not like when journalists do it. But they do it all the time.)

45. **jeremy**
October 10, 2006

If someone wrote a review for my book, I would first thank him or her for at least taking time to read the book. I agree with Gina that it is not wise to "go after" the reviewer. It is reasonable to correct reviewer's misquotes and, sometimes calculated, distortions, but consider a review with different opinion as "a hit-job" is, for me, not prudent. It is really unnecessary for Peter being overly sensitive to criticism. Any review, positive or negative, will only make more people become aware of "the failure of string theory", and increase the possibility of bringing in fresh air to the research. It is a good thing that someone is willing to read your book and writing a review about it. I would suggest Peter, borrowing a line from Gina. "take it easy" on the reviewers.

46. **CapitalistImperialistPig**
October 10, 2006

Gina,

Your defense of KC Cole's review does not conform to a reasonable interpretation of the facts. Neither does her review. It wasn't merely biased, it was deeply dishonest.

Writers (and actors, painters, and others) are totally justified in criticizing their critics, especially those who don't evaluate them honestly.

Since you have strongly insinuated yourself in this debate, including questioning my ethics, let me ask the following: what is your expertise? Are you a string theorist? A physicist?

47. **LDM**
October 11, 2006

I went to the library, examined one of Coles books, "The Hole in the Universe" for myself just so I could accurately gauge her level of science writing first hand — and the content is watered down to the extent of either being meaningless or, unfortunately, just physically misleading if not wrong…

Also telling is that on the cover was a blurb by string theorist Briane Greene…So obviously an endorsement by Greene is not worth too much.

Essentially, she is a reviewer who does not understand the subject , has no problem distorting (lying) the subject, and seems to be strongly associated with string theorists. Interesting.

48. **John A**

October 11, 2006

> More substantively, it's clearly a waste of one's time to try and debate these issues with someone who is on record as claiming that criticizing string theory is like criticizing the theory of evolution.

Actually that's been done before in climate science. To criticize Greenhouse Warming as a hypothesis that makes no useful testable predictions gets the critic compared to creationists (and deniers of evolution therefore) and deniers of the Holocaust. It doesn't get more tasteless than that.

Now again, I do not make the case that Peter Woit agrees with my views on climate science, only that for reasons that appear to me obvious, the same dynamic of attacking the person rather than engaging in the actual questions of substantial scientific import are occurring in disparate fields.

BTW Peter, I bought Lee Smolin's book rather than yours because I'm frankly not up to the math and I felt happier dealing with Smolin's more general approach. I'm also reading QED by Richard Feynman, and find myself chuckling over Feynman's direct attack on theories that don't predict anything no matter how beautiful they are.

49. **Arun**
October 11, 2006

Gina,

If you are correct then it should have read:

"These issues are well worth addressing, which makes it all the more disappointing that Woit, and Smolin in "The Trouble With Physics," write mostly about how string theory has ruined physics, though they disclaim any impact on their careers.

50. **Gina**
October 11, 2006

Well guys, appart from the controversial sentence and misunderstanding about neutrinos, Coles review is good:

Take this one sentence explanation of string theory:

"Simply put, string theory does this by replacing point-like particles with tiny strings of some fundamental stuff vibrating in 10-dimensional space — their harmonies creating everything from quarks to galaxies. The loops of string don't let anything get small enough to let quantum fidgeting rip space and time apart."

and the critique on string theory

"String theory has its troubles, which the authors analyze in great and sometimes lucid detail: It appears to be untestable because the strings are too small to be seen, and recent research suggests that the theory may have an infinite number of solutions, so it can't make predictions. And string theory is so ill-defined that even ardent supporters admit they don't know what, exactly, it is."

and

"The authors are right to say that physicists can get cliquish; that some of them swagger; that they frequently fool themselves and that science has become too risk-averse."

Arun,
maybe she should have change the ordering and write

"These issues are well worth addressing, which makes it all the more disappointing that Woit, and Smolin in "The Trouble With Physics," write mostly about how string theory has ruined physics — and their careers as well."

It is legitimate for Cole to think that the books express personal frustration
even if not explicitely expressed. She does not have to prove it, and it is common not to distinguish facts from interpretations, this is journalism and not science. (But I agree that even in this form it is unfair to Peter and Lee and not referring to the careers would be a much better choice.)

51. **Bert Schroer**
October 11, 2006

"Simply put, string theory does this by replacing point-like particles with tiny strings of some fundamental stuff vibrating in 10-dimensional space — their harmonies creating everything from quarks to galaxies. The loops of string don't let anything get small enough to let quantum fidgeting rip space and time apart."

Well, this mantra with which string theorists used to start their talk is totally metaphoric, the fact is that the intrinsic quantum localization of the Nambu-Goto string is pointlike and not stringlike (see respective remarks in my samisdat contributio).

52. **Renormalized**
October 11, 2006

"Simply put, string theory does this by replacing point-like particles with tiny strings of some fundamental stuff vibrating in 10-dimensional space — their harmonies creating everything from quarks to galaxies. The loops of string don't let anything get small enough to let quantum fidgeting rip space and time apart."

This would be wonderful if it were true. The truth is we have never seen a string, never had a experiment which inferred there were strings, never have seen a dimension beyond the 3 space and one time. We have never seen this so called "fundamental stuff". We have never heard the so called "harmonies". We have never found a loop of string. This is what you have never gotten in your head Gina. It is all a fantasy! This is what happens when you get one good idea about how the universe "might" work and then have many brilliant people working on it for many years, teaching brilliant students to work on the idea and then forgetting it was just a idea that "might" work.

53. **DMS**
October 11, 2006

Peter,

No point wasting time "debating" these public string theorists(I liked InvestorBanker's comments as well). You are winning the argument, both on the substance, and on style.

On the one hand we have Jacques, who thinks his use of straw man arguments, italicizing comments, and use of "Huh?", makes him sound so brilliant.

And then we have Clifford, who makes the initial pretence(a nice front) of trying to be “serious” and “respectful” and then go down the same path.

No point in bringing on the others.

Frankly, this dishonest conflation of string theory for RHIC and string theory for the Theory of Everything is pathetic.

Simply ask these public string theorists one question: What exactly does string theory say we will see at the LHC???

Finally, these string theorists think they are the among the most brilliant people on the planet. With the singular exception of Ed Witten, again this is hype.

DMS

54. **Bert Schroer**
October 11, 2006

As a mathematical theorem this is true for the quantized N-G string.
The proof is actually quite simple, you only have to understand a deep theorem which relates the positive energy representation of the Poincare group inexorably with localization of states (totally intrinsic)
http://br.arxiv.org/abs/math-ph/0203021
http://br.arxiv.org/abs/math-ph/0511042
and convince yourself that in the decomposition of the highly reducible representation of the Poincare group of the N-G model (take the supersymmetric version in order to avoid tachyons) there is no massless “infinite spin” component (which would introduce string-like localization). Since the the physical field (after BRST descend) is a c-number, the quantized N-G “field” is actually a generalized free field with the well-known mass-tower particle spectrum. The confusion of classical localization with intrinsic quantum localization is an unfortunate heritage of the Atiyah-Witten geometric way of looking at QFT.
For mor on this I refer to my eassay.
And by the way, the only polemic I permitted myself was to the Lord of Misuse. My illustration of how ST manufactures facts is no polemic at all, it is based on 3 original refences to ST sources.

55. **Bert Schroer**
October 11, 2006

Sorry for the two misprints

56. **Ari Heikkinen**
October 11, 2006

Just to point out that not every negative review of your book is a conspiracy of string theorists and their friends, Peter.

57. **Bert Schroer**
October 11, 2006

The corrected phrase for
“Simply put, string theory does this by replacing point-like particles with tiny strings of some fundamental stuff vibrating in 10-dimensional space — their harmonies creating everything from quarks to galaxies. The loops of string don’t let anything get small enough to let quantum fidgeting rip space and time apart.”

should read:
simply put, string theory does this by replacing point-like particles by quantum objects which are obtained from the quantization of classical supersymmetric Nambu-Goto-like strings (which still remain pointlike-localized in the autonomous quantum sense) whose spectrum in ten spacetime dimensions is described by an infinite tower of pointlike particles…….

58. **The Graduate**
October 11, 2006

Peter,

How come you haven’t mentioned your interview with Horgan?

59. **Peter Woit**
October 11, 2006

The Graduate,

Partly because there’s been a lot to keep track of, so some things like this haven’t gotten mentioned, partly because I find the idea of myself on video kind of appalling. Bad enough that there’s audio out there of me, I just got used to that. Anyway, rumor is there’s an interview by Horgan of me on this web-site

http://www.stevens.edu/csw/cgi-bin/index.php

I’m not going to watch it, I suppose others could if they must…

60. **TheGraduate**
October 11, 2006

Peter,

It was a good interview (better than I would have done). I don’t like watching myself on video either!

61. **Boaz**
October 11, 2006

Peter,
I enjoyed reading your book.
One section I was particularly interested in were your comments on John Hagelin/TM/String Theory etc. You mentioned that particle theorists used to put up the MIU/MUM posters connecting fundamental physics to Maharishi’s Hindu concepts on their doors. Was this mostly done because they actually thought it was cool/interesting/insightful, or was it more a joke- as in “look at all the craziness out there!”?

Thanks,
Boaz

62. **woit**
October 11, 2006

Boaz,

It was definitely a joke. I think…

63. **Boaz**
October 11, 2006

Thanks…
I figured so, but that was the 80's, so you never know.

64. **Chris Oakley**
October 12, 2006

The Maharishi, who used to place full-page ads in national newspapers, was an important bellwether in deciding what was was "cool" in particle physics. It started with SU(5) GUTs, moving on to Supergravity, and finally to Superstrings. If you were a HEP theorist, but not working on the topics he mentioned, then your academic career was probably going nowhere.

65. **Boaz**
October 12, 2006

That's interesting Chris.
I wonder if it was solely due to John Hagelin, or whether the Maharishi actually knew anything technical about this stuff. I know that he studied physics at least to the undergraduate level.

Rube Goldberg's Instruction Manual

October 11, 2006
Categories: Uncategorized

Since string theory first became popular in 1984-5, attempts to connect it to particle physics have suffered from various problems. One of the most severe of these goes under the name of "moduli stabilization". Six dimensional Calabi-Yau manifolds come in families, parametrized by "moduli". The dimensions of these moduli spaces can be of order 100 or so.

Naively it might appear that string theories are characterized by a choice of a topological class of Calabi-Yaus (no one knows if the number of these is finite or infinite), and then a choice of each of the 100 or so parameters that fix the size and shape of the Calabi-Yau. According to the standard string theory ideology, this is not the right way to think, instead there is really only one string theory, with different moduli values corresponding to different states. The moduli parameters are supposed to be dynamical elements of the theory, not something parametrizing different theories.

The problem with this is that if you promote the moduli to dynamical fields, they naively correspond to massless fields, and thus give new long-range forces. So you have to explain away why we don't see 100 or so different kinds of long-range forces, and the experimental bounds on such forces are very good. Some kind of dynamics must be found that will "stabilize moduli", giving them a non-trivial potential. The moduli fields will then be fluctuations about the minima of this potential. If the quadratic piece of the potential is large enough, their mass will be high enough to have escaped observation.

One needs a potential with non-trivial minima, and has to ensure that the dynamics is not such that the moduli will run off to infinity. In recent years, ways of achieving this have been found that typically involve "flux compactifications", i.e. choosing non-trivial fluxes through the topologically non-trivial holes in the Calabi-Yau. On the one hand, this seems to provide a long-standing solution to the problem of how to stabilize the Calabi-Yau, on the other hand, it appears that there is an exponentially large number of possible minima. This is the origin of the "Landscape" and the associated claims of 10^{500} or more possible vacuum states for string theory.

The constructions involved are famously exceedingly complex and ugly, with Susskind referring to them as "Rube Goldberg machines", and one of their creators, Shamit Kachru, the "Rube Goldberg architect". Very recently a new Reviews of Modern Physics article by Kachru and Douglas called [Flux Compactification] has appeared. It can be thought of as a manual describing how to construct and count these Rube Goldberg machines.

Many string theorists had long hoped that whatever method was found to stabilize moduli would have only a small number of solutions. Then, in principle one would get only a small number of possible models of particle physics for each topological class of Calabi-Yaus. If the number of these was finite and not too large (the known number of constructions is something like 10^5-10^6), then to see if string theory could make contact with particle physics, one would just have to do a moderately large number of calculations, check them against the real world, and hope that one matched. If it did, it would then be highly predictive.

The existence of the flux compactifications with stabilized moduli described in the Douglas-Kachru article has convinced many string theorists that this old dream is dead. Some have tried to claim that this is a good thing, that the exponentially large number of states allows the existence of ones with anomalously small cosmological constants, and thus an anthropic explanation of its value. The problem then becomes one of how to ever extract any prediction of anything from string theory. Small CCs are achieved by very delicate cancellations, and it appears to be a thoroughly calculationally intractable problem to even identify a single state with small enough CC.

Many string theorists are now claiming that this is not really a big deal. So what if there are lots and lots of string theory vacua, it's just like the fact that there are lots and lots of 4d QFTs! For arguments of this kind, see recent comment threads here and here. There's something fishy about this argument, since discussion of flux compactifications has from the beginning focused on whether it is possible to use them to make predictions, whereas no one ever was worrying about whether (renormalizable) QFTs were predictive or not.

The source of the problem lies in the combination of the large numbers of string theory vacua with their Rube Goldberg nature. Consistent 4d QFTs are characterized by a limited set of data (gauge groups, fermion and scalar representations, coupling constants), and it has turned out that among the simplest possible choices of such data lies the Standard Model. String theorists commonly describe the Standard Model as "ugly", but it is among the simplest possible 4d QFTs, and is extremely simple and beautiful compared to something like the flux compactification constructions. One could hope that while flux compactifications are inherently rather complicated, one of the simpler ones might correspond to the real world. As far as I know there's no evidence at all for this, such a hope appears to have nothing behind it besides pure wishful thinking. Some string theorists like Douglas and Kachru don't seem to think this is possible, focussing instead on statistical counts of more and more complicated flux compactifications, hoping to find not a simple one that will work, but a statistical enhancement of certain complicated ones that would pick them out.

4d QFT is a predictive framework not because the number of possible such QFTs is small, but because our universe is described extremely accurately by one of a small number of the simplest of such QFTs. A few experiments are sufficient to pick out the right QFT, and then an infinity of predictions follow.

Is the QFT framework falsifiable? One could imagine that things had worked out differently, that instead of the Standard Model predictions being confirmed, each time a new experimental result came in, one could only get agreement with experiment by adding new fields and interactions to the model. It might very well be that the QFT framework could not be falsified, since one could always evade falsification by adding complexity. This happens very often with wrong ideas: they start with a simple model, experimental results disagree with this, but can be matched by making the model more complicated. As new experiments are done, if the original idea is wrong, it doesn't get simply falsified, but the increasing complexity of the models needed to match experiment sooner or later causes people to give up on the whole idea.

This is very much what has happened with string theory. The simple models that got people excited about the idea of string theory unification don't agree with experiment, with the moduli stabilization problem just one example. It appears one can solve the problem, but it's a Pyrrhic victory: one is forced into working with a class of models so vast and so complicated that one can get almost anything, and never can extract any real predictions.

Douglas and Kachru do address the question of whether one can ever hope to get predictions out of this class of models, but their answer is that they can't think of any plausible way of doing so. They mention various things that people have tried, but none of these ideas seem to work. The best hope was that counting vacua with different supersymmetry breaking scales would lead to a statistical prediction of this scale, but this has not worked out for reasons that they describe. In the end they conclude:

For the near term, the main goal here is not really prediction, but rather to broaden the range of theories under discussion, as we will need to keep an open mind in confronting the data.

This acknowledges that no predictions from this framework seem to be possible, and that continuing work in this area just keeps producing yet wider and wider classes of these Rube Goldberg machines. They are suggesting basically giving up not on string theory, which would be the usual scientific conclusion in this circumstance, but instead to for now give up on the theorist's traditional goal of making testable predictions. They advocate not giving up on string theory no matter how bad things look, instead just continuing as before, hoping against hope that an experimental miracle will occur. Maybe astronomers will find evidence for cosmic superstrings, maybe the LHC will see strings or something that matches up with characteristics of one of the Rube Goldberg models. There's not the slightest reason to believe this will happen other than wishful thinking, which has now been promoted to a new program for how to do fundamental science.

Update: Via Lubos, for those who don't know what a Rube Goldberg machine is, two examples are here and here.

Comments

October 11, 2006

>> This is very much what has happened with string theory.

You are factually incorrect. The flux vacua were always there, it just took researchers some time to realize it. No one has ever added a single complication to string theory, because it is not possible. If you want to discover something in string theory it had better be there in the first place.

2. **anon**
October 12, 2006

Michael said (sort of):

You are factually incorrect. The flux vacua were always there, it just took our brothers some time to realize it. No one has ever added a single complication to the Bible, because it is not possible. If you want to discover something in the Bible it had better be there in the first place.

Hallelujah, brother Michael

3. **M-theory**
October 12, 2006

Michael is right: this problem could have been realized or advertized many years ago, and he would have spent all these years working on something better. This situation can be extremely disappointing, but it is not Peter's fault. So, please stop fighting on each word.

4. **Joseph Conlon**
October 12, 2006

Dear Peter,

I strongly disagree with your claim that

>one is forced into working with a class of models so vast and so complicated >that one can get almost anything, and never can extract any real predictions.

In the IIB flux framework there is by now a substantial literature on studying supersymmetry breaking, computing soft terms, running them down to the TeV scale and analysing the phenomenology of the resulting sparticle spectrum.

There are also `generic' results: if moduli are stabilised by non-perturbative effects, as occurs in all these models, the moduli mass is lifted above the gravitino by a factor ln(M_P/m_{3/2}) while the corresponding gaugino mass is lowered by a similar factor.

Generally different methods of moduli stabilisation are quite specific, and have typical outcomes and mass scales, and I do not see any evidence at a technical level for the claim that one can get almost anything.

Best wishes
Joe Conlon

5. **Bert Schroer**
October 12, 2006

Peter,
"It might very well be that the QFT framework could not be falsified, since one could always evade falsification by adding complexity."
The framework of QFT is of cause falsifiable. One of the proud achievements of particle theory of the 50s and 60s was the derivation of structural consequences of micro-causality: the adaptation (rigorous derivation from the principles, not just perturbative checks) of the Kramers-Kronig dispersion relation. The experimental check in high-energy scattering experiments was carried out and QFT passed with flying flags. Micro-causality is the epitome of QFT and the experimental test of dispersion relations is one of the finest falsifiability tests of QFT (would have been worthwhile to be mentioned in your book, but by the time you entered physics this nice conquest was already taken for granted).
With specific models of QFT this is of course harder since in the present state of developments there are no hard (nonperturbative) facts one can abstract from Lagrangian names (or similar model characterizations) if one still does not know whether there is a living child behind that name (this is of course infinitely worse in ST).
A good illustration of this difficulty is the previous discussion (with David Berenstein) about the AdS–CFT structural theorem (crystal-clear) and the Maldacena conjecture (which is a statement about one of those baptized models in the limit N–>infinity where it slips out of the framework of QFT).

6. **Arun**
October 12, 2006

There are myriads of QFTS, need experiment to make the choice. There are myriads of flux compactifications, need experiment to make the choice. It sounds fishy but the fishiness is elusive. If we forget that low energy physics was supposed to be a prediction of string theory, and simply say, here are two methods of constructing models – QFTs, string compactifications – and there are many choices in each – where is the fishiness in that?

Somehow there is a difference between pre-Revolution and post-Revolution thinking, but I can't put my finger on it.

7. **Arun**
October 12, 2006

Let us imagine that string theory is true and we live in a multiverse. Let us imagine, in a science-fiction way, we are able to communicate with intelligent agents in another universe. Suppose our task is to find out what is the low energy content of that other universe. We are provided the results of collider experiments from that other universe and to request specific experiments be performed. We would build the model via QFT, not via flux compactification – even though flux compactification is the "true" !

8. **D R Lunsford**
October 12, 2006

The clear lesson of this entire episode is that one cannot do physics by exhaustion of a mathematical idea. The world has to guide the choice of ideas, the ideas cannot be forced onto the world. A corollary is that a successful idea must be backed up by a clear metaphysics – both quantum theory and relativity needed Democritus first.

My personal hero in the history of science is Kepler. He did not allow his personal love for his shell model, based on the regular Platonic solids, to stand in the way of dealing with the facts. Even more than Bacon, this set the tone for how to do science. Invent, but pay attention.

-drl

9. **woit**
October 12, 2006

Joe,

Are you claiming that you always will get the relation between moduli, gravitino and gaugino masses that you mention? So, if we measure these masses and don't see this relation, string theory is just incorrect?

Or, are there some vacua where this relation isn't true?

10. **Joseph Conlon**
October 12, 2006

Dear Peter,

My comment applied for the IIB flux vacua, where complex structure moduli are stabilised by fluxes and the K\"ahler moduli are stabilised by non-perturbative effects. It is these vacua which are the principal basis for the claims about the landscape. If this small logarithmic hierarchy does not exist, then I do not see how these vacua can describe nature.

The point is that although there may be 10^500 ways of turning on fluxes, that doesn't mean that every feature of the low energy theory can take 10^500 values: there can be, and are, aspects that are insensitive to the fluxes.

There are string vacua where this relation isn't true – for example exactly supersymmetric compactifications or if you stabilise moduli perturbatively.

Best wishes
Joe

11. **T.**
October 12, 2006

As a person who used to work on this subject and switched to more formal problems in ST, let me make the following comments.
1) Flux compactifications exist in the literature since the 1996 paper of Polchinski and Strominger and were ignored for a long time for a very good reason: they have no CFT description, therefore they are not "calculable" by using standard ST techniques.
2) Around 2001 several respected string theorists, including Kachru, largely ignored this problem (or argued that in some special cases one can circumvent it) and started using the effective field theory description (EFT) for moduli stabilization etc. Then Douglas started counting such EFT vacua, and the landscape bandwagon took off (taking with it a whole generation of students).
3) It should be made clear that 99.9% of work on flux compactification, including those of the authors of the review, KKLT, Joe's etc, is made within (quite an eclectic) EFT.
4) There is no reason to believe that EFT is a good (or any type of) approximation because alpha' and loop corrections are out of control — we simply do NOT know how to compute them, so there is no reason to believe that the landscape of 10^??? vacua really exists. I can guarantee the existence of only one "non-standard-model" ST vacuum: maximally supersymmetric toroidal compactification.
4) In conclusion, the landscape has no solid theoretical foundations and can be safely ignored. If you are seriously interested in these topics, you should work on developing a full-fledged ST description of flux compactifications (RR backgrounds etc…)

12. **Joseph Conlon**
October 12, 2006

Dear T.,

I find this statement a bit odd,

>4) There is no reason to believe that EFT is a good (or any type of) >approximation because alpha' and loop corrections are out of control — we >simply do NOT know how to compute them, so there is no reason to believe >that the landscape of 10^??? vacua really exists.

Effective field theory has been used in discussions of string compactifications ever since the subject started, so I don't see any principled objection to its use in flux compactifications that doesn't also apply to its use in (say) old-style unfluxed heterotic models.

With regard to alpha' and loop corrections, I don't see what is wrong with the conventional statement that in a regime of large volume and weak coupling, the alpha' and g_s expansions are ordinary weak-coupling perturbation expansions, and so can be controlled.

Best wishes
Joe

13. **T.**
October 12, 2006

Joe,
Even if alpha' corrections are "small" in what you call "large volume" limit, you cannot prove that they do not destabilize the vacuum. Landscape counts all vacua, with {\em massless} moduli — and these can be destabilized by "infinitesimal" corrections. On the other hand, if you construct a model with all moduli (including large volume) stabilized (i.e. massive) then your EFT calculations make sense, similarly to old heterotic constructions involving gaugino condensation (assuming that the dilaton is stabilized in the weak coupling regime, which is very difficult to achieve). But then it's not landscape — it's model-building.

14. **r hofmann**
October 12, 2006

Dear Joe,

being (for a good reason) quite ignorant about how fluxes and nonperturbative effects stabilize the moduli of a type IIB model my naive question is: Where do the fluxes come from, what governs THEIR dynamics (I guess only their existence is guaranteed by topological arguments) and what precisely hides behind the mysterious-sounding term `nonperturbative effects´?

By the way, the reason why I don't even believe in supersymmetric field theory and the SM's Higgs mechanism
is the emergence of spin-1/2 excitations in the completely
confining phase of pure SU(2) or SU(3) YM. The mass of the stable and charged excitation essentially is given by the Yang-Mills scale . I have not yet an answer to the question why Yang-Mills scales are set into a hierarchical pattern but I'm pretty much convinced of the nonexistence of gauginos, gravitinos, sfermions, and fundamental scalars and SCALARINOS.

With my best regards, rh

15. **Ahmad**
October 12, 2006

Hi Peter;
Im an electrical engineer, but Im really fascinated by physics. I have read your book and that of Smolin. I really find it hard to imagine that even with (Sociology) and its dynamics, the physics community can be so naive. How can Witten et al, be allured and not know it, if the facts are so clear to you and others. What do they have to say to what you call a naive assumption about the moduli? if even a Fields medalist agrees to use it, how come ?

16. **Peter Woit**
October 12, 2006

Ahmad,

I don't know what Witten thinks of these flux compactifications. He hasn't worked on them, my unsubstantiated guess would be that he would like them to not exist or find a reason to show that they aren't real vacua of string theory, but he doesn't know how.

I think the whole idea of trying to get physics out of these things is clearly unworkable, and I suspect more than a few string theorists feel the same way. Quite a few of them definitely don't work on this area, and generally don't want anything to do with it. The problem for them is how to answer the argument that these things are something that string theory seems to inevitably lead to. Commenter "T" here gives one attitude towards this.

17. **anonymous**
October 12, 2006

Actually, Witten wrote one of the foundational papers on flux
compactifications (arXiv:hep-th/9906070) with Gukov and Vafa.

And almost all string theorists have worked on the subject, as the
gravity duals of field theories arising in AdS/CFT are flux vacua, the
simplest being AdS five times a 5 sphere.

18. **Peter Woit**
October 12, 2006

anonymous,

I was referring not to general flux compactifications, which would include AdS/CFT, but to the ones discussed in the Douglas-Kachru paper as providing a way to stabilize moduli.

Thanks for the reference to the Gukov-Vafa-Witten paper. Again, I was thinking of the more recent constructions with stabilized moduli, but you're right to point out that that is part of the story.

19. **anonymous**
October 12, 2006

The GVW paper is actually about precisely the kinds of fluxes used in the moduli potentials. Witten wrote more papers about this (eg about G2 models with flux). So did Vafa.

And, the fluxes that are crucial in confining examples of AdS-CFT, are precisely used in the moduli fixing constructions. See Klebanov-Strassler.So, the subject cannot be divided up between AdS CFT fluxes, and the ones used in the constructions you dislike.

20. **Jean-Paul**
October 12, 2006

You are wrong. The GVW abstract reads:
"We consider F/M/Type IIA theory compactified to four, three, or two dimensions on a Calabi-Yau four-fold." Lanscape studies are based on IIB orientifold compactifications to four dimensions, focussed on totally different aspects of compactifications.

21. **anonymous**
October 12, 2006

Look up the meaning of f theory. The f theory compactifications to 4d are another name for IIB orientifolds in 4d at generic points in their moduli space. The GVW superpotential is the one used in ALL these models, with equal justification.

22. **Joseph Conlon**
October 13, 2006

Dear T.,

>On the other hand, if you construct a model with all moduli
>(including large volume) stabilized (i.e. massive) then your EFT
>calculations make sense,

But this is what almost all/most/a lot of the work on the `landscape' is about. As soon as you have the Gukov-Vafa-Witten superpotential, you are stabilising the dilaton and complex structure moduli, and then nonperturbartive terms come in to stabilise the K\"ahler moduli. You have to check the EFT for consistency.

I do agree with you that this is basically model-building, and I think that is a good thing,

Best wishes
Joe

23. **r hofmann**
October 14, 2006

… not even wrong, Joe…

24. **Jean-Paul**
October 14, 2006

To F-theory/orientifold expert: your attitude of deciding what research direction is good based on associations with W et al is exactly what ruined ST. Just try to think, maybe it's not late for you to start thinking independently. Otherwise hide in Langlands. Good luck.

25. **Vogelsang**
October 14, 2006

Peter, nice post, and thanks for the link to the review by Douglas and Kachru. It's very nicely written. The authors definitely do not hide behind technichalities, so even non-experts like myself can learn much about the ideas and the status of the field from them.

26. **T.**
October 14, 2006

Joe,
Of course, model-building is very interesting and useful. However, most of the remaining 10^??? vacua will never be investigated in such detail, and the debate is whether they really exist in full-fledged ST. The 10^??? counting includes all possible vacua with massless moduli: my hope is that they will turn out to be inconsistent, in a similar way as non-supersymmetric closed ST is inconsistent beyond one loop (due to the dilaton tadpole).

27. **anonymous**
October 15, 2006

T:

A cursory reading makes it clear that the vacua being counted have no massless moduli, and even looking just at those with weak (stabilized) coupling, there are a huge number. They aren't counting moduli spaces with unfixed moduli.

28. **anonymous**
October 15, 2006

Jean Paul:
Actually I am just going through the review, I don't know or care what W thinks. The logic seems clear, and also seems to extend beyond f theory to other regimes of string theory.

29. **T.**
October 16, 2006

My cursory reading of the review is very different from yours, so let's try to clarify it. Let's look at page 47, subsection VB of section V "Statistics of vacua". It considers IIB on CY with no complex structure moduli, ignoring Kahler moduli. I am no expert in CY, so can you tell me how many CY have no complex moduli, and zero Kahler moduli? I see that you are a big fan of GVW, but their superpotential can stabilize only the dilaton and some complex structure moduli. In order to stabilize Kahler moduli, you need D-terms, so you need magnetized D-branes, Joe's non-perturbative effects etc. It's not so simple. As far as I can tell ALL vacua treated so far statistically contain massless moduli, so please correct me if I am wrong. All what I am trying to say is that one needs a better understanding of flux compactifications before jumping to a conclusion that ST in inherently unpredictive and needs a special treatment by antropic reasoning etc.

30. **anonymous**
October 16, 2006

T:
The KKLT construction fixes the Kahler moduli; explicit e.g.s are
given now by several groups cited in the review. The statistics Douglas et al give for complex moduli can be used in any of the models with fixed Kahler moduli, and as long as the flux potential isn't too large, doesn't destabilize the Kahler moduli. That is indeed the entire point of the KKLT construction of the landscape. As I read it, in the IIA theory, even just the fluxes suffice to stabilize all of the moduli; the analogue of the GVW superpotential depends on all moduli at tree level.

31. **anonymous**
October 16, 2006

To be clear: this isn't just my reading of the review , see their citations to
Douglas Denef Florea; Douglas Denef Florea Grassi Kachru;
Lust Reffert Scheidegger Schulgin Stieberger; Balasubramanian, Berglund, Conlon, Quevedo;
and for IIA
DeWolfe Giryavets Kachru Taylor; Acharya Benini Valandro;
Derendinger Kounnas Petroupoulos Zwirner; Camara Font Ibanez.

These papers have lots of equations and seem to do what the review says they do. Which is stabilize all the scalars.

32. **Gina**
October 17, 2006

This is an excellent post, Peter, and so is the discussion.

If I understand correctly the non-technical parts it appears that people
agree that the landscape is a problem for (or a challenge to) ST. There is a
comment though that the evidence for the huge number of vacuua is

not yet theoretically solid. There is a suggestion (Joe) that some predictions will be possible common to all these theories. (And even some specific suggestions for such predictions were raised.) There is also a suggestion/hope (T) that most of the 10^** possible theories will be disqualified based on contradictory physics consequences. In any case, the fact that the damaging evidence was discovered by string theorists themselves speaks for the integrity of the ST endeavor.

33. **Peter Woit**
October 17, 2006

Gina,

You're adding nothing to the discussion here, just repeating in garbled form what others who do understand the issues have written. In particular, Joe does not claim to have predictions common to all theories, he was discussing something that is a feature of one class of compactifications but not others. Please stop adding to the noise level here.

34. **anonymous**
October 17, 2006

I am just an intermediate grad student, but I agree with Gina.
As far as I can tell, the situation is: there are "old" string theorists
who are stuck in 1985 and hope the whole thing will go away;
more modern string theorists who realize this is a real issue with
the whole theory (but the theory may well still be correct and one
has to deal with the issue); and finally a bunch of people like
Peter and Smolin who really dislike string theory, for reasons you
can judge yourself (they don't seem very sound to me). Anyway
I need to read my next review now (about supersymmetry), so
I'll sign off.

35. **Jean-Paul**
October 17, 2006

Hi anonymous,
Before you run away, I am just curious why do you want enter a research field which is in the state of crisis, at least according to some "old" people. For 20 years, these old people led the pack, and only a handful of younger people (like Kachru) made a real impact (Douglas is still an older generation). What do you expect to learn? If you take landscape seriously, ST is no longer a TOE, so it doesn't seem to contain this "romantic" flavor of fundamental theory that brought in the previous generations of students. I am also curious what is your advisor's point of view.

36. **TheGraduate**
October 17, 2006

I think taken in the best light, where we assume some of the strongest claims for what has been so far achieved, one would have to argue that string theory was a theory of properties of a final theory but I think it seems a bit unreasonable to claim there is anything that will force uniqueness … am I right?

I think the stuff about all possible universes having to exist just because the equations say so seems… dumb … that's like saying because we can define all possible humans using DNA sequences then all possible humans exist …

The other issue is, that one can never be sure that one has discovered all the possible restrictions …

It's an assumption (and a silly one at that) that there must be a direct correspondence between the universes being studied and actual universes …

37. **anonymous**
October 17, 2006

Jean-Paul:
I talked to many people, and it seems the people who entered
the field in the 80s and 90s (before say 1996) all felt strongly discouraged from doing so (apparently the senior theorists at Harvard openly ridiculed the theory in the late 1980s). I feel now, maybe, like they did then: there is criticism of this theory, but it is based on irrational factors. The theory unifies gravity and quantum mechanics. Given that inflation occurs, any theory with many vacua will have the landscape issue to deal with. And it is hard to imagine a theory with a unique vacuum giving our bizarre word (even grand unified theories have many vacua). Maybe I'm wrong. We'll see.

38. **ak**
October 18, 2006

possibly adding to the 'noise level' here, I pose the question if 'flux compactification' has actually a rigorous mathematical background and if so if this would fit into a yet-to-be-established picture of mirror symmetry, for instance: is there an algebraic counterpart of 'flux compactification' in Kontsevichs picture or what could it be? Furthermore, I wonder if 'monodromy'-questions are involved in questions of 'fluxes', families of Calabi-Yau manifolds being topologically trivial but symplectically nontrivial etc. or related questions of stability of special lagrangians in families. If someone knows a reference relating mathematical and physical research in these respects I would be thankful.

This evening a very interesting paper appeared on the arXiv, entitled [Instantons Beyond Topological Theory I] by E. Frenkel, Losev and Nekrasov. The authors are studying theories with a topological sector (supersymmetric quantum mechanics and 2d sigma models on a Kahler manifold, N=2 supersymmetric YM in 4d), but are interested in sectors of the theories that are not purely topological. I'm looking forward to reading the paper over the next few days, but it is a bit daunting. This paper is nearly 100 pages long, and it is only part I of three parts, and actually just the simplest part, that involving quantum mechanics.

HEPAP is meeting today and tomorrow, here's the agenda. From the slides of the talk about NASA, the budget situation there for fundamental science missions doesn't look good, and there is discussion of the upcoming NRC committee charged with figuring out which of the "Beyond Einstein" missions to allow to go forward. At Dynamics of Cats, Stein Sigurosson has been writing about this in terms of the missions being sent to Thunderdome, only one to emerge alive.

Slides from the talks last month at the conference in honor of Nigel Hitchin's 60th birthday are available.

Joe Lykken has a nice review article about the standard model, in which he notes:

There is only one diagonal Yukawa coupling that is of order one, and that is the top quark Yukawa. But even this case is mysterious. The top Yukawa is not really of order *one: it is equal to one! For example, using the 2005 combined Tevatron value for the pole mass of the top quark, the corresponding Yukawa coupling is 0.99 +/- 0.01. The entire particle physics community has chosen (so far) to regard this fact as a 1 per cent coincidence. I should point out that similar percent level equalities, e.g. supersymmetric gauge coupling unification or the ratio of the total mass-energy density of the universe to the critical density, have spawned huge theoretical frameworks bolstered by thousands of papers.*

Difference is that, as far as I know, nobody has an idea why this Yukawa coupling should be one. Maybe this is a big clue…

Over at Backreaction, there's an excellent posting about Does String Theory Explain Heavy Ion Physics?, one of the very few places to find a non-overhyped discussion of this topic.

Davide Castelvecchi has a well-done review of my book at his sciencewriter.org web-site.

At this week's physics colloquium at Penn, Andre Brown reports that Robert Cahn emphasized that "half the particles needed for supersymmetry have already been discovered." He also recalled a quote from another colloquium about supersymmetry: "Supersymmetry has stood the test of time. There is no evidence for supersymmetry."

Update: A couple people have pointed out the following rather accurate cartoon.

   October 12, 2006

   Concerning the reduced budget etc … does anybody have some insight into why the US gov is determined to spend less and less on basic science? It all seems quite weird.

   Compared to other types of investment, it seems like scientists are a rather cheap resource and the rewards of a larger scientific community are so great.

   Even in the face of fears of greater competition from China and India and almost daily fretting about outsourcing of jobs, absolutely nothing seems to be done and day by day, less and less is spent … year after year of decreasing budgets …

   Is there something I am missing?

3. **Peter Woit**
   October 12, 2006

   TheGraduate,

   The US government actually is increasing the budget for fundamental physics research. NASA seems to be a different story, with all the manned space flight issues.

4. **King Ray**
   October 12, 2006

   At the KITP (then the ITP), someone from the NSF once gave a talk on science budget issues, and they showed a graph that demonstrated how entitlements were squeezing everything else out of the budget. You didn't have to project the trends very far forward to get to a point where there was no money for science.

5. **TheGraduate**
   October 12, 2006

   King Ray:

You said “they showed a graph that demonstrated how entitlements were squeezing everything else out of the budget”

What kind of entitlements did he mean, like health benefits, sabaticals and tenure?

6. **TheGraduate**
October 12, 2006

Peter,

When you say it is increasing, do you mean it’s increasing this year or it has always been increasing and does this increase still hold up if we correct for inflation?

I hope it actually is increasing. That would be great.

7. **Tony Smith**
October 13, 2006

Peter said “… Joe Lykken has a nice review article about the standard model [at hep-ph/0609274], in which he notes: … The top Yukawa … is equal to one! …”.

Peter goes on to say: “… as far as I know, nobody has an idea why this Yukawa coupling should be one. …”.

One natural reason for the T-quark Yukawa coupling to be “equal to one” would be for the Higgs to be a T-quark condensate, as in a modified Nambu-Jona-Lasinio (NJL) model such as that described in hep-ph/0311165 Michio Hashimoto, Masaharu Tanabashi, and Koichi Yamawaki.
In that paper, they say “… the scalar bound state of tbar-t plays the role of the Higgs boson in the SM …”.
To avoid some of the problems of a simple NJL model, they consider Kaluza-Klein type “TeV-scale extra dimension[s]” and “… found that the bulk QCD coupling can … become suffciently large to trigger the top condensation for … D = 8 …[and]… predict the top quark mass
mt = 172 – 175 GeV for D = 8 …”.

Since their result is close to an observed value of a T-quark mass peak in Fermilab data, and
since their work is consistent with 8-dimensional structures in my physics model, and
since related structures seem to me to be related to some Fermilab experimental data in the ranges of mt around 130 GeV and around 225 GeV that seem to me to be important,
I described in a talk I gave at the April 2005 Tampa APS DPF meeting the above results of hep-ph/0311165 by Michio Hashimoto, Masaharu Tanabashi, and Koichi Yamawaki.

Joe Lykken chaired the session at which I spoke, and he seemed interested while I was giving the 10-minute talk. At the end of the talk he told me that he would take the ideas in my presentation back to Fermilab, and see if the people there had any interest in working on such approaches.
In the year that has followed, no interest has been expressed by Fermilab, and I see that the work of Hashimoto, Tanabashi, and Yamawaki (who are from Pusan, Tohuku, and Nagoya) is not mentioned in Joe Lykken’s paper at hep-ph/0609274, which is a subject of this blog entry by Peter.

I am disappointed and puzzled at the lack of interest in such an approach with obviously realistic contact with experimental results. Sometimes I think that maybe my status as a blacklisted “moronic crackpot” may discourage interest, and sometimes I think that maybe there really is a bias in the USA against the Nagoya group (after all, Kobayashi and Maskawa have yet to get a Nobel, even though it has long been obvious that they deserve it)).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Since the DPF meeting this year (around Halloween) is a joint meeting in Hawaii of the APS DPF and the JPS, and is designated “Joint Meeting of Pacific Region Particle Physics Communities”, I looked at the list of participants at http://www.dpf2006.org/DPF06%20Participants.pdf
to see whether MIchio Hashimoto, Masaharu Tanabashi, and Koichi Yamawaki might be participating.
To my regret, I did not see any of them listed (the list was dated 10-12-2006) as participants.

8. **TheGraduate**
October 13, 2006

I think with the issue of string theory, it is best to look at things the way a banker would. When one goes to a banker looking for money, he looks at your financial history, if in the past you have not made money, it will be difficult to get more money in the present. It is evidence based decision making.

I think while we all tend to sympathize more with the person in search of funds, we want someone like the banker in charge of our children’s college fund. Last thing you want to hear is that the banker put everything on something with no track record!

I think its pretty easy to get wrapped up in present details about how it will ALL BE DIFFERENT FROM NOW ON. (That’s how people talk when they are all caught up in any activity! It doesn’t really mean anything that people feel that way.)

What matters is waiting for a potential project to build up a record before funding in large amounts. Of course small amounts are okay. Now, the other thing to think about is if concrete measures show that two approachs are on equal footing then they should both be funded with equal probabilty (and with small amounts!).

I liked Smolin’s discussion of venture capitalism. I think he gets it.

9. **Capitalist Wanker**
October 13, 2006

The top Yukawa coupling is convention dependent and runs with energy. Who cares if it is exactly one in some conventions at some energy scale? The other quantities that Lykken mentions people working are not of this type.

10. **woit**
October 13, 2006

TheGraduate,

In HEP US funding has been flat or decreasing for quite a few years, but is supposed to increase significantly for the coming year and for the next few years. For some reason, Bush made physics research a central part of his “American Competitiveness Initiative”.

11. **Alejandro Rivero**
October 13, 2006

Capitalist Wr, the idea about the coupling being a convention emanates from the ideology of GUT, that says that every prediction must be imposed at the GUT scale and then run down to the electroweak scale (or even downto the IR limit?).

What we have here is that there is low energy relationship between Fermi constant (which sets the electroweak vacuum) and the top quark mass (which relates to the electroweak vacuum via its coupling constant).

12. **D R Lunsford**
October 13, 2006

For all its success, it's good to be reminded of just how balled up and complex the SM really is, and how critically tuned to the Higgs mass it is. That has always seemed to me to be odd.

-drl

13. **Thomas Love**
October 13, 2006

Peter said "Joe Lykken has a nice review article about the standard model".

I greatly enjoyed Lykken's article "Standard Model: Alchemy and Astrology," especially his statement:

"A decade from now, we will look back on our current understanding of the Standard Model and be amused at its lack of sophistication."

Peter, I thought you liked the standard model and I was surprised that you would provide a link to an article which compares the Standard Model to Alchemy and Astrology!

14. **D R Lunsford**
October 13, 2006

Thomas,

The SM occupies a strange place in physics history. The basic idea is gauge theory – which in itself, requires long-distance interactions. To make the SM work, you have to remove the very thing that characterizes the main idea. No other real theory is like that. In other theories the main idea assumes a prominent role. When this issue is resolved, the Higgs mechanism will indeed look outmoded.

One should not slight either alchemy or astrology. The former lead to psychology, and the latter, to astronomy.

-drl

15. **Bert Schroer**
October 14, 2006

Instantons Beyond Topological Theory I
This paper is just another exhibit of a misconceived relation between mathematics and physics which presents impressive mathematical results using metaphoric particle physics terminology. The potential harm of just papers is exclusively on the side of physics (with newcomers of QFT who are still struggling with its conceptual basis). The physics side of this much heralded new age between math. and phys. which ever since Atiyah-Witten (for lack of a better name for this math. phys. trend) has been metaphoric on the side of QFT (its relation to QM was more balanced than that to local quantum physics) left particle physics empty-handed. Where at the beginning it had the positive effect for serving as a kind of innovative catalyzer for new mathematics, it now flows back emanating from mathematicians who obviously think they are doing mathematically rigorous QFT whereas they are using physical metaphors to present excellent mathematical results. QFT is unitarity (positivity), causal locality and stability properties (energy positivity, KMS thermal states) and its hallmark which separates it from QM is interaction-caused vacuum polarization. Free field like constructions whose only physical nontrivial aspect is due to using non Lorentzian living space for fields may be mathematically interesting but they do not help for a mathematically controllable construction of interacting quantum fields.
The Standard Model: Alchemy and Astrology
The main source for the presence of Alchemy and Astrology in the SM is the unfortunate (but apparently ineradicable) metaphoric presentation of the Schwinger-Higgs mechanism of charge-screening (the abominable "fattening of the photon"). A slightly less metaphoric way consists in starting with pointlike massive free vectormesons: http://br.arxiv.org/abs/hep-th/9906089
In order to remove the last metaphoric vestiges one has to substitute the BRST gauge formalism by a different description of massive vectormesons in terms of a string-localized field with a very nice short distance behavior (without change of physical content). I have described this in the last section of my essay (see the Samizdat weblog) but did not find the time to elaborate it.

16. **Bert Schroer**
October 14, 2006

I forgot to explain why the Schwinger-Higgs mechanism has nothing to do with symmetry-breaking (already known through Elitzur's old paper) but rather describes screening. This becomes obvious if one takes the decoupling limit for the Higgs particle (can be done perturbatively) which leads to charge liberation (the opposite side of the medal).

17. **Alejandro Rivero**
October 14, 2006

The point is, one starts from Fermi Constant, as measured eg in muon beta decay, G_F=1.16637(1) 10-5 Gev-2, and from this one extracts an "EW vacuum", sqrt(G_F sqrt(2)) = 246.221. You can see this quantitiy in the [standard report](). The Yukawa coupling is calculated from a quantity differing by sqrt(2) and that we also call the "EW vacuum". It is thus 246.221 sqrt(2) = 174.104(1) GeV. Both quantities are used in the standard model because the later is more simple when attaching to fermions, but the former gets a nicer expresion against the mass of W. Nicer only in the sense that people is used to it.

So ok, we have 174.104(1) Now go again to the pdg and take the values of the top mass, either directly measured, 174.2+-3.3, or from the SM global fit, 172.3+10.2-7.6. Ok, from this global (conservative) fit you get only a quotient .9896+0.059-0.044. But from the *measurement* you get 1.0005 +- 0.019

Dorigo has also tryed to champion on this regularity. What is worse is when theoretist say "it is of order one". I mean, if you think it is just a casual thing, you should not mention it ever; it you think it is not casual, it is not of order one, but it is is exactly one plus, if you wish, corrections of about order alpha (or your favorite coupling constant here). What happens is that a log of GUT, SusyGUT and higher models (including some from the string with "free fermions") get to relate the scale of EW breaking with the mass of the Top (hey, even Connes's models do it), and the people presenting results find more convenient to think on "order one" from the theory than to face the experimental result. You can argue that the experiment still allows a 3% deviation easily, but even so, we have already not a o(1) but a o(0.1) gained, and with a huge probability of being o(0.01)

18. **Alejandro Rivero**
October 14, 2006

Hmm sorry, it is 1/sqrt(G_F sqrt(2)) (as obvious from the units).

19. **Capitalist Wanker**
October 14, 2006

So, Sqrt(2) is supposed to play a fundamental role? What if you needed Pi Sqrt(3) to get the ratio to be 1? Would that be as exciting? As I said before, it is convention dependent. Putting in the Sqrt(2) just cleans up some formulae. It has nothing to do with GUTS. And of course it runs, so at higher energies this relation would not be true.

20. **Tim**
October 14, 2006

Peter,

It's really entertaining to read your blog when I have a minute or two to kill. I have no idea what the purpose of the comment section is but it definitely contributes to certain individuals calling you 'crackpot', 'crank', etc. Please see Bert Schroer's comment. If I as an outside observer see such a comment on a whatever blog I — no matter how impartial, unbiased, etc I am — would certainly conclude that this blog is a gathering spot of leisure crackpots.

Sorry to bring bad news but you would do yourself a favour if you would simply delete crackpot comments instead of contributing to publishing them and afterwords complain that people accuse you of the exact thing you actually do: contribute to publishing crackpotism.

Best,
Tim

21. **Peter Woit**
October 14, 2006

Tim,

This is a real problem, but since one person's "crackpotism" is another person's serious scientific idea, I'd prefer to describe it as a problem of too much noise. All physics blogs that I know of that attract a significant number of comments have to struggle with this. It's frankly a huge pain in the ass: how would you like to spend a significant amount of your time examining nearly 50 comments a day, trying to figure out what to do with them, and fielding outraged e-mail from people who feel that something they took a lot of trouble to write has been deleted?

Partly to keep this from completely taking over my life, I've tended to adopt a policy of erring on the side of not deleting comments. Undoubtedly this would be a better blog if I put more effort into moderating things and keeping the noise level down. But one thing I should point out to you, is that, from what I recall, you submit a significant number of comments that are non-substantive and off topic, definitely adding to the noise level here. If I do find time to be more aggressive about deleting comments, you might find many if not most of yours not appearing.

And please, this is off-topic. I'll delete any more comments here about this. Stick to discussing what is in the postings. If you have a brilliant idea about what I can do to reduce the noise level without having to spend a lot more time on it, send it to me via e-mail.

22. **Alejandro Rivero**
October 14, 2006

CW, I do not know that to do of your last comment. Initially it seemed to me the typical damage from the [misinterpretation of, if you wish] doctrine of effective theories: As the Langrangian of Fermi beta decay is not the real thing, why to bother to learn it? And for the same token, as the formalism of the standard model is not the real thing, why to bother to learn it? On second reading, it seems that you are perfectly aware that these square roots come from the usual notation for that lagrangians and for the vector of electroweak breaking (the "higgs vacuum", if you prefer), and that one puts them in advance to aliviate notation after normalisation of some vectors. But then you should know they come forcefully from these normalisations, and you should not to play with "pi sqrt(3)" as a pausible ratio (incidentally, pi is specially misleading, as you can not get a trascendent number as solution of an algebraic equation).

So, are you being serious in your question, or just rethoric?

Some old authors, by the way, never were happy with these squarerootings, and they used to say that the value of the electroweak vacuum is about 175 GeV

23. **newcomer to QFT**
October 14, 2006

"This paper is just another exhibit of a misconceived relation between mathematics and physics which presents impressive mathematical results using metaphoric particle physics terminology."

I don't understand this criticism since the paper in question is about QM, which is mathematically well defined. QFT is mentioned, but is to be treated in the forthcoming sequels.

I'm sure I'll learn much about QM by studying this paper. However I've never seen thermal KMS states teach anything about quantum statistical mechanics that wasn't already known by traditional (although less mathematically rigorous techniques). Even the treatment of the thermal harmonic oscillator by Narnhofer and Thirring (Letters in Mathematical Physics, Vol 23 No 2 pg 133-142) seems to be similar to the coherent state treatment, but dressed up in fancy mathematical clothing. Do thermal KMS states teach us anything (physically interesting) about BEC or the Ising model that isn't already widely known?

24. **Bert Schroer**
October 14, 2006

My comment is about the use of these methods in QFT. Let us see whether there will be anything including interactions (and the inexorable vacuum polarization going with interactions) coming from such methods. If there is, I of course will correct myself in public. I do not care about the spacetime dimension as long as it is at least 2. Oscillators do not impress me.

25. **Bert Schroer**

October 14, 2006

It is precisely that balance between mathematics and physical concepts which one finds in Thirring's writing (and more generally in most of math. phys. coming out of Europe with the exception of Amsterdam and from string theory groups) which has been lost in that part of the particle physics community which takes its math from Atiyah and Witten.
By the way, there are meanwhile also quite nontrivial 2-dim. QFT which have been shown to be well-defined (most recently a very original AQFT method to show exitence for massive factorizing models has been discovered).

26. **Arun**
October 14, 2006

Another side to metaphorical thinking (perhaps?) is in the Jaffe/Quinn paper referenced in the n-Category Cafe:
http://golem.ph.utexas.edu/category/2006/10/wittgenstein_and_thurston_on_u.html>here

This is from 1993:

"When reliability of a literature is uncertain, the issue must be addressed. Often "rules of thumb" are used. For example, mathematicians presume that papers in physics journals are theoretical. This extends to a suspicion of mathematical-physics journals, where the papers are generally reliable (though with dangerous exceptions). Another widely applied criterion is that anything using functional integrals must be speculative. One of us has remarked on the difficulties this causes mathematicians trying to use solid instances of the technique [J]. These kinds of rules are unsatisfactory, as is the caveat emptor approach of letting each paper be judged for itself. Proponents of this latter view cite Witten's papers as successful
examples. But a few instances can be handled; it is large numbers that are a disaster. Also, it is a common rule of thumb now to regard any paper by Witten as theoretical. This short-changes Witten's work but illustrates the "better-safe-than-sorry" approach mainstream mathematics tends to take when questions arise."

27. **Jonathan Vos Post**
October 15, 2006

Not having a Science subscription, I can only get this teaser online, and wonder whether it relates to one of your recent references, and what it's about:

Science 13 October 2006:

PARTICLE PHYSICS:
Tidy Triangle Dashes Hopes for Exotic Undiscovered Particles
Adrian Cho

Physicists have proved that their explanation of matter-antimatter asymmetry is essentially the whole story–even though many hoped the theory wouldn't add up.

28. **Bert Schroer**
October 15, 2006

In my use of the attribute "metaphoric" I should have differentiated between a benign connotation and a malignant one. Clearly the use of the Higgs mechanism (the mass-dressing of the photon through the Higgs "condensate) and the gauge theoretic use of ghosts (which are not there in the beginning nor can they be tolerated in the final physical objects) are benign metaphors. Whether you compute using these metaphors or follow an autonomous path does not matter, you end up with the same renormalized expressions for the physical (gauge invariant in the metaphoric treatment, pointlike local in the autonomous derivation) quantities.
An example for a malignant metaphor is the statement that the Maldecena conjecture is an illustration of a mathematical theorem about the AdS—CFT correspondence. A pharaonic constructed erected by hundreds of people in thousands of publications cannot be undone by any rational argument. The only hope is that as a result of the unphysical nature of SUYM and AdS it will cease to circle over our heads and eventually become exclusively a topic for historians and sociologists of science.
For those among you who have not lost their sense of humor I attach a parody which Noboru Nakanishi (with his consent) wrote in 1986 i.e. at a time when skeptics as myself (and perhaps also Peter Woit) were still in a "lets give it a try" state of mind.

This is a faithful reproduction by LaTeX of a joke paper written in May, 1986 (unpublished).

COMMENTS ON THE SUPERSTRING SYNDROME

Noboru Nakanishi
Research Institute for Mathematical Sciences
Kyoto University, Kyoto 606, Japan

A recent epidemic among the Elementary Particle Theorists is the Superstring Syndrome, which causes the Kaluza-Klein symptoms. The pathogen is said to be much much smaller than any virus known and in shape of a string or a ring. Nothing certain is known about this virus, however, since nobody has ever seen it. There is a rumor that this virus has been cultivated under strict supervision of Drs. Green and Schwarz
By the way, it is said that these doctors are characters in the German-English translation of a famous novel by the distinguished writer Stendhal. It is also said that the translator is red-green blind.

and was released to outside by a researcher at the P-University (the author has chosen not to name him). This disease, unlike AIDS, does not have a tendency to prevail among homosexuals. In general, however, young and cheerful people are observed to be more susceptible to this disease. The infection occurs usually through mouth, as is true for the influenza. But since the infection occurs occasionally through eye, special precaution is necessary.
The String Syndrome had also been epidemic about ten and some years ago. At that time, the damage was a rather minor one, since it was not associated by the Kaluza-Klein symptoms. Eventually, the Yang-Mills was found to be an excellent remedy, and thus most of the patients were said to be completely cured. However, the current Superstring Syndrome is a much severe disease, for which the Yang-Mills may cause undesirable side-effects rather than remedy it. Adding further to the worries is the fact that brain might be affected. Under this disease, it is said that the patients fall in to a belief that something called "anomaly" is at the root of everything. In contrast to healthy people, who regard normal states as they are and then observe anomalous states as something deviating from them, the patients credit anomalous states and then observe normal states as deviations from them. Researchers of abnormal-psychology are therefore quite interested in this symptom.
The patients of the Superstring Syndrome believe in a Miracle. This is not a small miracle like the one in which Moses divided the Red-Sea into halves, but is the Great Miracle of the whole universe that the 10-dimensional space-time is divided into the 4-dimensional space-time and the 6-dimensional space. Although this separation has to be done completely, homogeneously and permanently throughout the whole universe, they cannot understand at all why it can be so. The patients just simply believe in it. It is said that a magic spell "Calabi-Yau" enables them to see clearly the extremely varied structures of the six-dimensional space. In fact, they must have experienced the wonderland stranger than that of Alice. In the very, very, very, very tiny world that is 20-orders as small as the scale of a nucleus, the classical geometry is claimed to hold to extreme accuracy. In that world, the mini-dragon Pyrgon must be striding in the vicinity of the Planck Length District wearing the top-mode of Anomaly-Free. The patients can easily see this hallucination without LSD. They use new drugs called SST I and II. Although it is not yet known what exactly they are, it can be guessed

from their pronunciations that they are similar to LSD. Since their safety is not confirmed by any clinical studies, it is advised that people should avoid their habitual use. The trouble about the Superstring Syndrome is that, like drunks never acknowledging their drunkenness, the patients do not acknowledge their own abnormality. They regard the Kaluza-Klein symptoms as normal and lose the sight of the fact that this real world we live in is the genuine four-dimensional space-time. The present author is deeply concerned about the possibility of a disastrous situation in case an effective remedy is not invented in near future.
[Translated by Hideaki Aoyama. The original article is published in Soryushiron Kenkyu (Researches of Elementary-Particle Theory), Kyoto, 72 vol.6 (1986) 345, in Japanese.]

29. **D R Lunsford**

Bert, pretty tame compared to Warren Siegel's magnum opus "The Everything of Theory", about TOENAIL (theory of everything not appearing in laboratories 🙂

-drl

30. **anon**
October 15, 2006

Joe Lykken writes that in 10 years we'll look back and be amused at how unsophisticated the Standard Model of today is.

Is anybody amused by the lack of sophistication of the Standard Model circa 1996? What measurable quantities can we calculate now that we couldn't calculate then?

31. **arivero**
October 15, 2006

Jonahtan, it is an article about the status of the unitary triangle after the recent measurements of B-meson mixings. Surely you can find more in the public reviews of the Particle Data Group.

32. **MathPhys**
October 15, 2006

Bert,

No one ever said that the Maldacena *conjecture* amounts to a *mathematical theorem* — If it were, how come everyone uses the word *conjecture*????

What more can people do than to keep on saying *conjecture* ????

It's statements like these that are malignant and obfuscating and hurts the cause of any meaningful criticism of the current status of string theory as a physical theory which is far from being in good shape.

Please don't confuse things. If anything, it surely hurts your cause.

Further, I find it unreasonable on your part to claim priority in discovering aspects of conformal field theory which you say is very physical (namely conformal blocks) before BPZ when it suits you, then criticize string theory for being a theory of free fields.

As I'm sure you know, string theory is based totally and completely on conformal quantum fields in 2 dimensions. Interactions come in via vertex operators, multi-genus Riemann surfaces, etc, etc. That's the whole point.

Further, I don't think that you have discovered conformal blocks (in the accepted definition of this concept) at all, since you didn't know anything about Virasoro algebras, central extensions, and you definitely didn't know about the minimal models.

There is another physicist who also likes to make such claims, but similarly, they are strictly unfair.

You all missed working at c smaller than 1.

33. **Walt**
October 16, 2006

MathPhys: It is far from the case that the Malcedena conjecture is always referred to as a conjecture. I was confused on this very issue until recently, simply because people are not that careful.

34. **MathPhys**
October 16, 2006

Walt,

Show me one serious string theorist who refers to it a mathematical theorem, and I'll be very happy to admit being wrong.

35. **Thomas Larsson**
October 16, 2006

Further, I don't think that you have discovered conformal blocks (in the accepted definition of this concept) at all, since you didn't know anything about Virasoro algebras, central extensions, and you definitely didn't know about the minimal models.

Claiming that one can understand conformal symmetry in 2D without knowing about the Virasoro algebra is about as absurd as claiming that one can understand diffeomorphism symmetry without knowing about the analogous Virasoro-like extension of the spacetime diffeomorphism algebra. But then again, absurdity has never prevented people from making such claims.

36. **MathPhys**
October 16, 2006

I think they were dealing with 2D massive models, which they can now say are off critical deformations of conformal field theories.

But then again the proper treatment of the latter requires knowledge of the underlying deformed infinite dimensional algebra, something that was studied only after BPZ, and I'm not so sure is well understood to this day.

Aside from that, I'm afraid I will not believe a word of what you say about a central extension of spacetime diffeomorphism algebras until you write a paper on that, and it gets refereed and accepted for publication in a regular math journal.

37. **Thomas Larsson**
October 16, 2006

The extension proportional to c_2 was published in
T.A. Larsson,"Central and non-central extensions of multi-graded Lie algebras"
J. Phys. A. 25 (1992) 1177–1184.

The extension proportional to c_1 was published in
S.E. Rao and R.V. Moody, "Vertex representations for N-toroidal Lie algebras and a generalization of the Virasoro algebra"
Comm. Math. Phys. 159 (1994) 239–264.
The paper is available online.

The representations were understood geometrically in
T.A. Larsson, "Extended diffeomorphism algebras and trajectories in jet space"
Comm. Math. Phys. 214 (2000) 469–491.
It is available online as math-ph/9810003.

It might be worth pointing out that Bob Moody is somewhat famous, e.g. for the codiscovery of something called Kac-Moody algebras back in 1968. But then again, maybe you don't believe in Kac-Moody algebras neither.

38. **MathPhys**
October 16, 2006

Thomas,

Thanks for the references.

It's nothing personal, but I'm wary of claims that are not published.

PS I know who R Moody is.

39. **Thomas Larsson**
October 16, 2006

Mathphys, sorry for blurting out. After the search for, and discovery of, the multi-dimensional Virasoro algebra met with nothing but silence and ridicule for almost 20 years (from physicists, mathematicians have acted very differently), I have become quite hostile per default.

And why should physicists care about genuinely new math, when there are so many exciting new ideas around. Like the anthropic principle and LQG.

40. **Matti Pitkanen**
October 16, 2006

Thomas Larsson Said:

"Mathphys, sorry for blurting out. After the search for, and discovery of, the multi-dimensional Virasoro algebra met with nothing but silence and ridicule for almost 20 years (from physicists, mathematicians have acted very differently), I have become quite hostile per default."

Dear Thomas,

I share you belief on higher dimensional Virasoro and Kac-Moodies although I have a different realization in mind. I share also your frustration. Average colleague does not seem to have the necessary minute or two (or perhaps it is ability after all) to concentrate to a new idea unless it is proposed by authrority.

Lightlike 3-D surfaces X^3 possess X^3-local conformal transformations of imbedding space act as symmetries respecting lightlikeness. Ordinary 1-D Kac Moody algebra emerges naturally as a Kac-Moody algebra associated with the lightlike coordinate and the algebra decomposes into subspaces remaining invariant under the action of this algebra. Infinite number of representations ordinary Kac-Moody are fused to a larger structure. One might think that this could stimulate some interest but landscapeology seems to be more fascinating.

Best Regards,
Matti Pitkanen

41. **Bert Schroer**
October 16, 2006

MathPhys
I found the commutation relations of the chiral energy-momentum tensor pursuing John Lowenstein's (the idea came from Wally Greenberg) of "Lie Fields". in 1973 and presented the results at the January 1974 conference in Rio de Janeiro. In his thesis John did not find any higher dimensional illustration (we now know that there is a no-go theorem) and my finding was the first natural illustration of this concept.
B. Schroer , A trip to Scalingland, Brazilian Symposium on Theoretical
physics, Rio de Janeiro, January 1974, Vol. I, ed. Erasmo Ferreira, Livros T´ecnicos e Cientificos, Editora S. A.
if you give your mailing address I send you a copy.
The Wit-Virasoro algebra, contrary to popular opinion (nobody seems to look at the original Virasoro paper), does not appear in Virasoro's paper, together with Wit Virasoro does not have the central term and different from Wit he only has the positive frequency (perhaps the reason for missing the central term).
My paper is a structural theorem always including the interacting case. Doing two-dimensional QFT in those days was extremely unpopular (the reason for not sending such things to international journals).
I tell you a funny story which underlines this. At one of the international conferences Swieca was teased by a well-known theoretician (whose name I will not reveal): Andre why do you work on that 2-dimensional stuff? Swieca's reply: I get lost in higher dimension. Without his sudden death in 1980 the story could have had the following cintinuation: Hy Andre what are you doing these days? S: I am looking at charge screening problems (the Schwinger-Higgs mechanism) in 4-dim. gauge theories. The unnamed physicists: but dont you know Andre that everything happens in two dimensions, in order to understand higher dimensions one only must understand 2-dim. conformal field theory!
MathPhys if you are honestly interested in the rich pre- Wess Zumino-Witten history about 2-dim. models I refer you to a review (published in AOP)
http://xxx.lanl.gov/abs/hep-th/0504206

it is very unfortunate that the connection to the representation theory of current algebras (later loop groups) was cutoff by introducing a Lagrangian terminology which is totally metaphoric and added nothing in substance (in fact the WZW people only pay lip-service to that Lagrangian and continue to compute with the prior current algebras representation theory).
but I genuinely doubt that you are; you seem to be one of those folks who only use weblogs primarily to denigrade others.

42. **woit**
October 16, 2006

Let me remind everyone to please avoid personal attacks here. There is all too much of this going on, it is just annoying and very unenlightening.

Also, Matti and Thomas. Please stop continually trying to use my blog as a forum to promote yourselves and your ideas.

43. **Garrett**
October 16, 2006

http://xkcd.com/c171.html

44. **Walt**
October 16, 2006

MathPhys: You're moving the goalposts. They don't call it a theorem, but they don't always call it a conjecture. And seriously? I'm supposed to show you an example of a serious string theorist? What, are you paying me? I am not an anti-string partisan: I do not have a definitive judgement of the subject. I was sharing with you my personal experience, that I was confused on its status as a conjecture until recently. If that means nothing to you, then what does that say?

45. **Bert Schroer**
October 16, 2006

There is an established theorem which completely covers the AdS-CFT correspondence, but it has nothing to to with Maldacena (the theorem has been established by Rehren). In fact in my Samizdat essay I have provided additional arguments why the growing suspicion that Maldacena's conjecture (which links a N–>infinite SUYM with a classical limit of a) 5-dimensional AdS string theory) can be sharpened to an outright contradiction to the theorem.
The confusion comes from interpreting the M-conjecture as an illustration of AdS–CFT correspondence in the sense of the theorem. The M-conjecture maybe correct, the problem is with its interpretation.
What makes the arguments on this weblog so painful is that the sociology of 4000 or so papers wins against a rigorous and clearly presented mathematical theorem. There is no reason to continue this discussion, you can read the paper about the theorem and my arguments in may essay but it is futile to invoke democracy against a theorem.

46. **Peter Woit**
October 16, 2006

I encourage people who want to discuss the relation between the Maldacena conjecture and Rehren's theorem to do so where it is on-topic, at Jacques Distler's new posting on the subject:

http://golem.ph.utexas.edu/~distler/blog/archives/000987.html

Based on my experience with him, what Distler writes on this kind of subject is often highly misleading (for a recent remarkable example, see what his comments on a recent thread at Clifford Johnson's blog). I know nothing about Rehren's argument, so I have no idea what is going on in this case, but encourage people who do know about this to discuss it over there.

47. **Bert Schroer**
October 16, 2006

Dear Peter,
Thanks, and let me add that this subject is really not appropriate to be discussed in any weblog. Way back in the Sci.PhysicsResearch Archive Rehren tried once, only to be cut down by the ST pittbull. It was that incident which made me aware of the exitence of new barbarians and their attampted sell-out of QFT.

48. **A.J.**
October 16, 2006

Jacques' summary looks quite accurate to me.

49. **A Babe in the Universe**
October 16, 2006

Dr Scroer, your input is appreciated. Please don't let some cowardly pitbull discourage your contributions. That person has attacked many of us and GM=tc^3 is still here.

50. **Peter Woit**
October 16, 2006

Please, when I referred people to Distler's weblog, I was encouraging them to read what he has written, and if they want to discuss it, do so over there. I was definitely not trying to start a discussion of this here.

51. **Tommaso Dorigo**
October 16, 2006

I think the coincidence of the top quark mass with the Yukawa coupling is not numerology, but a quite interesting observation – very few other "coincidences" of this kind exist, and Alejandro Rivero has noted a couple in recent papers.

Should we shrug our shoulders at these coincidences ? I think we should take all clues we have from experimental data very seriously. However, there seems to be a sort of immobility in theoretical trends, and these clues do not get picked up with enough momentum… I Guess I know the reason.

T.

52. **barbarian**
October 16, 2006

>Is anybody amused by the lack of sophistication of the
>Standard Model circa 1996? What measurable quantities can
>we calculate now that we couldn?t calculate then?

I, for one, am. Let's take 1994 instead of 1996, for the sake of argument.

In 1994 we didn't know whether the top quark actually existed, if it was standard, and what its mass was. We didn't know that neutrinos have mass, that they oscillate, and whatever happened to the missing solar neutrinos. We believed that the cosmological constant was either small and negative or zero.

In 1994 we thought that ST unambiguously predicted SUSY, and that the SSC was probably going to observe the MSSM.

In 1994 most (if not all) of the 7 parton QCD amplitudes were not yet known. Unquenched lattice calculations were virtually unheard of. Two-loop computations in the SM were nowhere near as widespread as they are now.

I'm just quoting from the top of my head. If I'd taken the trouble to actually checking the literature I'm certain I'd be able to write a much longer and precise list.

A lot of progress happened in the last ten years. And a whole lot of stuff is going on right now. Lykken is definitely right.

53. **barbarian**
October 16, 2006

By the way, in 1996 nobody knew how to renormalize fully relativistic baryon chiral perturbation theory at the one-loop level…….

54. **Anon**
October 16, 2006

Bert wrote:

"Thanks, and let me add that this subject is really not appropriate to be discussed in any weblog."

How many posts have you made on this weblog, about Rehren's duality versus the Maldacena conjecture?

Maybe you mean it is not appropriate to be discussed on any other weblog but this one.

55. **QWERTY**
October 16, 2006

HELLO PETTER HAVE YOU MISSED ME? I HAVE MISSED YOUR WEBLOG AND ALSO YOU. I HAVE BEEN ON A HOLIDAY!!

ANYWAY I WAS JUST WRITING TO SAY THAT YOU SHOULD ALSO MAKE LINKS TO TERENCE TAO AND HIS BRAND NEW AND VERY CLEAR EXPLANATION OF TEH POINCARE CONJECTURE.

http://www.math.ucla.edu/~tao/preprints/Expository/perelman.dvi

TERENCE TAO IS A GENIUS AND IT IS ALWAYS GOOD WHEN ONE GENIUS EXPLAINED THE WORK OF ONE MORE GENIUS. ALSO HIS COSMIC DISTANCE LADDER ARTICLE IS VERY ILLIMUNATING EVEN FOR PHYSICISTS.

http://www.math.ucla.edu/~tao/preprints/Slides/distance_ladder.pdf

WHAT DO YOU THINK?

56. **woit**
October 16, 2006

QWERTY,

I can't honestly say that I've missed you and your defective keyboard, and in general I try and discourage off-topic comments. But I hadn't heard about the Tao piece on the Poincare proof, which appears to be extremely good. The three available detailed proofs are hard to read, this looks like a much more accessible summary, an excellent contribution to the subject.

57. **nontrad**
October 16, 2006

re: our long lost cravings for QWERTY's long lost defective keyboard…

Too funny!!!

Keep up the good work Peter: Such a healthy sense of humor is well worth it's weight in gold.

p.s. Don't get me wrong, Tao is a large pile of papers in the corner of my office that I have yet to even begin to skim through. So good job QWERTY (even though it's got nothing to do with nothing in this comment section).

58. **MathPhys**
October 16, 2006

Bert,

Indeed, the central extension is not in Virasoro's original paper. It was discovered by Joe Weiss right after Virasoro's work became public.

How come we don't say "Virasoro-Weiss algebra"? Weiss died (he got himself killed on a weekend trek in the Juras while visiting CERN, or so I've been told).

Anyway, these are historical comments of no scientific content.

Re the discussion of Rehren's work on Distler's bolg: most illuminating (damn it Henning, you let the formalism confuse the issues, yet again).

59. **Bert Schroer**
October 17, 2006

MathPhys
correct, as far as I remember Weiss died in an alpinist accident (similar to Renner who was Gell-Mann's student).
Besides the ST line there is also a field theoretic line via the c.r. of the energy-momentum tensor. In that case it is impossible to miss the correct structure, even for the case of free Fermions it is there. Follow the advice and do not confuse names of ideas with the protagonists of ideas. Strictly speaking the Born probability interpretation for the Schroedinger wave function appears the first time in Pauli's work. But Max Born's proposal to interpret the scattering amplitude in probabilistic terms of a cross section is morally the same as Pauli's later contribution.

60. **MathPhys**
October 17, 2006

Bert,

Thank you for the advice.

Actually, Virasoro's derivation (and presumably Weiss' and everyone else's after that) is precisely what you call "the field theoretic line". It's all 2-dimensional field theory. Virasoro was just careless.

Historical quiz: When and where was Weiss' central extension mentioned for the first time? In what context?

61. **Thomas Larsson**
October 17, 2006

Gelfand-Fuks 1968?

62. **MathPhys**
October 17, 2006

Is that so? Not Feigin-Fuks?

63. **Thomas Larsson**
October 18, 2006

There are many hits for Gelfand-Fuks cocycle, e.g. this. Among other things, I think Feigin and Fuks were the first to publish a proof that the Kac determinant is singular where it is, but that is a different story.

John Baez has mentioned somebody who found the cocycle in characteristic p. Perhaps that was even earlier.

64. **Bert Schroer**
October 18, 2006

MathPhys
maybe some brief remarks concerning your doubt about the conformal decomposition theory (into conformal blocks) in my 1974/75 paper with Swieca and Voelkel could help you.
I think you were expecting something similar to BPHZ (where the conformal block decomposition arose as an important tool for analyzing the minimal models) and you were disappointed. Since we did not have those models (only exponential Bose fields and the closely related massless Thirring model were at our disposal) we had to argue on purely structural grounds. Our decomposition theory was based on a prior observation called "the global causality paradox of CFT" which in turn originated from the observation that for certain zero mass fields with anomalous scale dimensions (e.g. the massless Thirring field) the Huygens principle was violated (the anticommutator was nonvanishing in the timelike region called the "reverberation" phenomenon). In such cases the global causality notion had to be adjusted to the covering of the compactified Minkowski spacetime (something which was already done before by Irvin Segal). The decomposition theory simply resulted from the realization that anomalous-dimensional conformal fields (in any even spacetime dimension), although behaving irreducibly under "small"conformal transformation, are highly reducible under the action of the center of the covering group; the resulting decomposition is the block decomposition theory. We also payed special attention to the 2-dim. situation for which one obtains a block decomposition for each chiral component. We were somewhat surprised about our findings because the component fields were not Wightman fields since they came with a source and a range projector. We did not continue our research (the minimal models could have been found by just pressing ahead, one does not really need to know anything about Kac-Moody algebras) because we thought that our rich decomposition theory had no genuinly nontrivial realizations.
Let me tell you that I was impressed as anybody with BPHZ and it took me and Rehren almost 2 years to make the bridge from the old structural theorems to the new wealth of very nontrivial models (we published several joint papers on this subject).
I have no problem with the way history developed. It is not only those who are too late who are punished by history (Gorbatchov); this is a fact of life.
But it hurts me a bit if somebody claims that the old papers contain nothing. Deep ideas almost always have predecessors and the older results were usually obtained through very different arguments.

65. **MathPhys**
October 18, 2006

Bert,

When you say BPHZ, I'm sure you mean BPZ as in conformal field theories, and not BPHZ as in momentum cut-off renormalization theory.

Yes, I know of your earlier work (before BPZ) and I'm aware of the fact that you didn't press ahead long enough.

You know of course that others, most notably Gervais and Neveu were in a very similar situation. They also didn't persist.

I definitely have a lot of respect for your earlier works, and I didn't mean at all to belittle it. I just wish to be very precise about what has been done before and after BPZ.

I'm also familiar with your 2 papers with Rehren, and with Rehren's paper on his own that followed your joint work.

All the best.

66. **MathPhys**
October 18, 2006

PS So do you know where the first reference to Weiss' central extension of Virasoro appeared in the physics (not mathematics)literature?

67. **Bert Schroer**
October 18, 2006

MathPhys
sorry, I meant BPZ. I do not know the work of Gervais and Neveu, is it published?
The paper with Rehren on the exchange algebra of the conformal Ising model was the turning point when I really understood how the old stuff fitted together with BPZ. And it also increased my appreciation of Leo Kadanoff's work (which in my opinion has been underestimated relativ to Wilson's contributions).

68. **MathPhys**
October 18, 2006

Bert,
Yes, Gervais, together with Neveu and/or others have an almost infinite series of papers, in which some aspects of BPZ were "anticipated".

Tell me if you, and no one around you, knows when and where was the first mention of the Virasoro central extension in a physics paper. Don't be too proud 🙂

69. **Bert Schroer**
October 18, 2006

MathPhys
I think it was around 1972 for free Fermions via an explicit calculation by somebody around Dave Olive (Peter Goddard?). I am sure that I was not the first, but I may have been the first who derived it for the general case by an entirely structural argument. In any case my motivation was to find a class of "Lie fields" in the sense of Greenberg and Lowenstein; at that time my knowledge about string theory (the dual model) was closed to zero.
Concerning Joe Weiss. I met him at CERN but I think his deadly accident did not occur in the Alps but after his return to the US in the Rocky Mountains. When you suggested that he may have seen the Virasoro algebra I agreed instinctively because he was extremely bright and certainly up to the task. But I do not know a reference. Alpine accidents were quite common within the particle physics community; besides bruno Renner I think that also heinz Pagels died under similar circumstances.

70. **MathPhys**
October 18, 2006

Bert,

The first reference to Weiss' result was in a footnote in a paper on strings by Fubini and collaborators (the Italian mafia at CERN). That's when strings were a theory of hadrons in 4 dimensions.

After using the Virasoro algebra without a central extension, the footnote reads

"We have been informed by J Weiss that there is an extra term in the above equation. However, this does not change any of our conclusions".

The String Wars

October 18, 2006
Categories: Favorite Old Posts, Uncategorized

I noticed recently that George Johnson will be journalist in residence and giving a talk on Friday at the KITP in Santa Barbara about "The String Wars". Somehow I don't really think that it's a good thing that this is now being perceived as a "war". Johnson is the author of an excellent biography of Murray Gell-Mann and writes for the New York Times.

For controversy on the East coast, tonight the Center for Science Writings at Stevens Institute for Technology in Hoboken will be hosting a panel discussion and debate on The End of Science?, featuring John Horgan and Michio Kaku.

This week's New Yorker has a couple letters to the editor responding to their recent article about the string theory controversy. One points out that particle theory and quantum gravity is not all there is to theoretical physics. The second is by Lisa Randall, and mainly concerned with claiming that there is now a healthy interaction going between string theory and phenomenology, with most particle physicists eagerly awaiting the LHC.

Update: Today's New York Times has an Op-Ed piece entitled The Universe on a String by my Columbia colleague Brian Greene, in which he responds to recent criticism of string theory. As you might guess, Brian's piece doesn't really convince me to change my mind (as my book and Lee Smolin's don't seem to have convinced him).

Brian mentions the possibility of seeing supersymmetry or extra dimensions at the LHC, and possible effects of quantum gravity in the CMB, but acknowledges that these are not definitive predictions of string theory that can be used to falsify it. He also mentions the recent attempts to apply AdS/CFT to heavy ion physics, but these don't address the use of string theory as an idea about unification.

He deals with the landscape only by making an argument I've heard him make before: that just having a unified theory of gravity and particle physics would be a big accomplishment, even it this theory didn't explain any of the things about the standard model that one would like it to explain. Besides the fact that string theory still doesn't provide a fully consistent unified theory (since it has no non-perturbative formulation), I've always found this point of view problematic. If string theory can't make any definitive predictions about particle physics, it's very unclear that one can ever test it, which is a huge problem.

Brian does, unlike some string theorists, acknowledge that it's possible that string theory is wrong and will have to be abandoned, in particular if "future studies reveal an insuperable barrier to making contact with experimental data". My argument is that if string theorists accept the existence of the Landscape, such an insuperable barrier appears. He describes string theory critics as calling for research on string theory to be dropped, which really isn't accurate. Neither Smolin nor I have ever called for this, rather our argument is that research into alternatives to string theory needs to be encouraged.

Update: The George Johnson talk is now available here. It seems that many of the string theorists at the KITP are not very happy about my book and Smolin's, although it's unclear if any of them have read either of the books. Amanda Peet claimed that both books have many errors (invoking the NYT review by Tom Siegfried), while Johnson repeatedly told her that it would be a good idea for her to actually read one of the books. She also kept claiming that there is "a backstory" that explains why Smolin wrote his book, but she was dissuaded from elaborating on this when someone pointed out that the talk was on video and would be on the web.

The experience of watching the talk was pretty odd, since Johnson began by connecting to my blog and discussing the fact that I was discussing his upcoming talk. I watched a lot of the talk during commercials of an episode of Numb3rs, and during this episode "Larry" the physicist was working on calculations involving branes, and playing hooky from a string theory conference.

Update: Davide Castelvecchi has put up an interview with George Johnson on his web-site.

Update: Clifford Johnson and Lubos Motl have their own takes on the KITP video.

Update: It appears that there will be a second talk by George Johnson about this, String Wars 2. After the first one, I'm having trouble figuring out why anyone at KITP thought a second one would be a good idea.

Comments

1. **Jonathan Vos Post**
   October 18, 2006

   The End of Science? When exactly did that happen?

   Stephen Wolfram thinks it began when Newton invented the Calculus (soory, Fluxions) to do Physics, if the cosmos is actually a cellular automaton.

   The late 19th Century thought it had come, with only more decimal points to be added to measurements.

   Deterministic materialists think it came in with Quantum Mechnics.

   Aether theorists think it came with Michelson-Morley, or maybe Einstein and Poincare.

   Then there's that pesky String Theory, which certainly blocked the rest of Physics from getting equal access to funding and tenure-track employment.

   As J. D. Bernal wrote in "The World, the Flesh, and the Devil"): "we are still too close to the birth of the universe to be certain about its death."

2. **Timothy Clemans**
   October 18, 2006

   "Will science ever solve the riddle of the universe once and for all?"

   "This should be able to prove or disprove string theory. Personally, I feel no need to prove the theory experimentally, since I believe it can be proven using pure mathematics." – http://www.longbets.org/12
   Kaku

   Well according to Kaku he thinks that question will be answered by deducing string theory from some physical axioms so to him it may not be science that answers the question but mathematics.

3. **TheGraduate**
   October 18, 2006

"For controversy on the East coast, tonight the Center for Science Writings at Stevens Institute for Technology in Hoboken will be hosting a panel discussion and debate on The End of Science?"

What, no live webcasts?!

4. **King Ray**
October 18, 2006

I think fitting the universe with string theory is like fitting a sine wave with square waves, only it's much worse.

5. **Aaron Bergman**
October 18, 2006

Then there's that pesky String Theory, which certainly blocked the rest of Physics from getting equal access to funding and tenure-track employment.

The "rest of Physics"? Snort.

For controversy on the East coast, tonight the Center for Science Writings at Stevens Institute for Technology in Hoboken will be hosting a panel discussion and debate on The End of Science?, featuring John Horgan and Michio Kaku.

Ugh.

6. **Peter Woit**
October 18, 2006

OK, folks, I realize this "string controversy" coverage is getting old, and I promise to put up something on a different topic soon, but can we aim for a somewhat higher level of discourse than the above?

7. **Thomas Love**
October 18, 2006

Peter, The string controversy is not getting old. You fired the opening salvo in the string wars. You can't cut (the strings) and run! I'm hoping to hear about the final demise of string theory and I expect to read it here!

8. **Gina**
October 18, 2006

Goodbye!

This is a little off-topic, but I hope Peter will allow it, just this time. Over the last eight-ten weeks I made occasionally comments on several issues discussed here and in Peter Woit's book. I did put a lot of thought into my comments, although in the blog speed I could not be always on par. My comments were mainly on issues regarding philosophy of science and the practices and ethics of debating science. Without the technical background but with some comon sense and at times help from more informed friends (e.g. my comment on 2- and 4 dimensional lattice models,) I tried sometimes to relate in a non-technical way to specific scientific matters. Following my attempt to summarize the recent landscape discussion and Peter's rather negative comment 10 minutes later, Peter informed me that as this weblog "is largely intended for people who work professionally on the issues in math and physics that I'm interested in" and since my contributions drew a lot of criticism by other participants, a criticism that he shares, I will not be able to post here without prior monitoring. This practically means that I will not be able to comment here anymore.

It was an interesting experiece, even if unsuccessful. best wishes everybody.

9. **woit**
October 18, 2006

About Gina's comment:

As the volume of comments has increased here, it has become more and more difficult to keep the noise level down. There are far too many people who think it is a good idea to repeatedly post comments that are off-topic, unsubstantive, uninformed, and too often a waste of everyone's time. Dealing with this is taking up more time than I can afford, especially difficult is the phenomenon of people who sometimes post something sensible and interesting, but all too often something that isn't. I then have to spend my time trying to decide what to do with each of their comments, and dealing with complaints from them about the ones that I deleted. I don't have the time for this.

Please help me by only posting comments that are on-topic, substantive and well-informed. "String theory sux" or "string theory rules" comments are not welcome. If it's a technical issue that is the topic, I strongly encourage people with expertise to contribute and enlighten us, and equally strongly discourage people who are not informed about the issue from adding to the noise level by telling us all what they think.

Thomas,

I'd like to make clear that, as far as string theory goes, I have a simple goal here, and it's not to vanquish string theorists in battle. It's to provide accurate information about string theory, both about those parts of the subject that are not working, and about those that are more promising. My belief is that if the physics community were operating with a much more realistic and accurate view of what parts of the string theory program are getting somewhere, and which have failed, particle theory would be a much healthier subject. One aspect of this would be greater willingness to encourage research on non-string theory formal quantum field theory research.

10. **surlygrad**
October 18, 2006

Re: "The Rest of Physics"

God forbid some of us should be interested in topics (many particle systems, heterogeneous materials, etc.) that you physicists have deemed unworthy of your time and tossed to the engineers.

11. **Walt**
October 18, 2006

String theory sux.

12. **Walt**

October 18, 2006

Just kidding.

13. **TheGraduate**
October 18, 2006

I think a lot of what is missing in the comment section of this blog in general is an honest structured discourse. For one thing people tend not to respond to what other people have said. But even so this is a minor trait common to most blogs.

A more major problem, in my opinion, is the tendency of the discourse to careen off into minutae. It often has the form of a general discussion beginning on whether fast food is good for you and ending in a furious debate about the third decimal place in the solubility constant of FD&C Red No.40.

Isn't it fair to say there is a lot of ambiguity about the status of different propositions in any string theory discussion? Either a proposition is logically proven, a conjecture or substantiated by experiment. Either a proposition is marginal or it's critical to the argument. If one can already be satisfied on whether a particular proposition of string theory is marginal or critical and it's proof status then to me this is progress compared to how discussions usually progress on the blog.

Maybe there is a lack of good argument standard. I think in a physics argument there can only be two objective standards, substantiated experiment and mathematial proofs. Everything else is just what you feel inside (which you are allowed to feel but it's hard to say why what you feel is more important than what anybody else feels. And I think just because your feeling has an equation attached to it that doesn't make it suddenly more valid.)

(I often read the blog. I don't always comment on everything I see but I think I might have something sensible to say on this issue.)

14. **anon**
October 19, 2006

Peter, I think the problem is that you have outgrown your blog tools. In my opinion, any blog that gets more than 5 comments per article is already too burdensome. What you need is a blog in which (1)each article you post can grow threads (2) commenters grade each other. Free Software for this "uberblog" already exists; viz., Slashdot.

15. **Garbarge**
October 19, 2006

This blog could be an interesting place, and not just Lubos' trash can as once became, if one would be able to read the first and last comment and make any sense out of them. I dont read here that often, but I am amazed by the rapidity with which it degenerates into totally off topic discussions. In the other hand, and on the edge of toss my words into the garbage disposal too, I think the String Theory war has become a big parody/comedy with little or no contain. As long as the theater prevails over the science, I see no glean of fruitful thinking emerging from here. It is a pitty, this media has become such a powerful mean….

16. **A.J.**
October 19, 2006

One solution to the noise problem: Post on more technical topics! It's relatively easy to form and offer an opinion on controversies and pop sci reporting. But it takes a bit more effort to come up with something to say about e.g. stacks or elliptic cohomology.

Well…I guess there's always "stacks sux" or "Hopkins is teh rul3z0r".

17. **Thomas Love**
October 19, 2006

In "The Rise of the Standard Model'', Mark Bodnarczuk has an interesting article, "Sociological Consequences of the Standard Model", with this footnote:

Using numerous case studies, David Hull claims that not only are infighting, mutual exploitation, and even personal vendettas typical behavior for many scientists, but that this sort of behavior actually facilitates scientific development. David Hull "Science as a process"

So the rise of string theory is really not that different.

18. **ksh95**
October 19, 2006

Peter,

Find people you trust and give them admin access. This is similar to running a business, when you grow you have to add managers.

Gina,

I have a Ph.D in physics, yet I would never be arrogant enough to go to n-category cafe, start posting uninformed nonsense, jump in the middle of discussions I can't fully understand, and then sulk when my posts get deleted. **Instead**, I would read every day, try to learn as much as I could, and feel lucky that I was privy to such a high level discussion.
Any post I would make would be to thank the blog owners for making such interesting discourse public. OR, to ask for simple laymen explainations.

19. **Peter Woit**
October 19, 2006

Thanks for the suggestions. For a while I was interested in the idea of having a Slashdot-like self-moderated comment section. Then I read the comments associated with some of the items there about string theory. As far as I could tell, moderation was not working at all, with huge amounts of idiocy prominently displayed and substantive comments buried way down. I'm also skeptical of threaded comments, partly because they make it much harder to see what is new since one last looked, partly because they encourage people to get on off-topic threads, instead of encouraging a discussion of a single topic.

20. **John A**
October 19, 2006

Peter,

Can I say with the benefit of experience, that you cannot choose what level your commentators write at. As Aaron Bergman has amply demonstrated, sometimes people just simply don't want to express themselves in a rational way, but simply want to disrupt, flame or just be an asshole, hoping to drag down the discussion and turn away interested posters and shut down proper debate.

That said, my suggestions to you would be to shorten your posts to one or two key points, and invite your visitors to make discoveries/comments/reviews for themselves.

In my view you should take the initiative, talking about short topics in your book, or within other books and looking at alternatives to string theory in the same critical light.

You are not using categories on WordPress which is a mistake. This means that when a topic or topics covers a particular subject, and those topics disappear from the front page, then it disappears from your active discussions as well. Try to make good references both to your previous posts and to interesting comments in your newest postings.

In my view, its not the noise that's increasing, its the signal getting a little weaker.

21. **Hal**
October 19, 2006

To add something missing from ksh95's comment I would like to wish Gina well since she did, after all, give her best wishes to everyone.

22. **Aaron Bergman**
October 19, 2006

As Aaron Bergman has amply demonstrated, sometimes people just simply don't want to express themselves in a rational way, but simply want to disrupt, flame or just be an asshole, hoping to drag down the discussion and turn away interested posters and shut down proper debate.

So that's why I'm here.

I've been trying to figure it out myself….

23. **A.J.**
October 19, 2006

John A,

What are you talking about? Aaron's consistently been one of the most reasonable and well-informed commenters here.

24. **Peter Woit**
October 19, 2006

John,

Please stop with the attempt to start a flame-war. I can understand why Aaron had the reaction he did to the things he quoted, just wish he'd ignore some things, make more substantive comments on others. There's a lot of less than completely intelligent stuff posted here in the comment section, even after a fair number of deletions. People are encouraged to ignore such stuff and not feel that it is necessary to respond.

25. **Kent G. Budge**
October 20, 2006

"is largely intended for people who work professionally on the issues in math and physics that I'm interested in"

When I was a new astronomy graduate student at Caltech, I sometimes wondered if I ought to switch over to theoretical physics, since I believed I had much more aptitude for mathematical analysis than for observational and experimental technique.

However, during my first year, I had the poor judgement to ask a dumb question at a physics department seminar. I wasn't trying to start a flame war and I wasn't being *deliberately* ignorant; I was a young graduate student struggling to understand some of the basics of quantum field theory. However, the speaker thought it appropriate to take five minutes to respond to my question by berating my stupidity and wondering out loud how I ever got to Caltech.

At the time, I was humiliated and deeply hurt. However, in retrospect, I think the speaker may have done me a favor, by disabusing me of the notion that the physics department at Caltech saw itself as a teaching institution, and by steering me away from what would probably have been a poor career choice, given my dislike for feeling stupid and for getting in arguments.

Perhaps you are doing me a similar favor here. S'long.

26. **woit**
October 20, 2006

Kent,

I'm not berating anyone for stupidity or questioning their credentials. If someone who doesn't know what is going on asks an uninformed question in a seminar, it's perfectly appropriate for the speaker to say that he or she doesn't want to take everyone's time by answering it, especially if the answer is not something that can be given in a sentence or two. It's not appropriate to do this in an insulting way.

Similarly, here I also need to deal with uninformed comments, sometimes by telling the commenter that this is not an appropriate place for the kind of comments they are making. I hope that I do so in a polite way.

27. **ak**
October 20, 2006

anyway, I point out that a seminar circles by definition around a well-formulated subject or theme, it is by definition designed to fit persons with similar 'background', knowledge base and interest. At least as I understood the internet blogosphere is of a fundamental different character and this does not exclude excpetions as 'the n-category cafe' as it was mentioned. Undenied the fact that any blog owner might design his or her blog in a given way or directed to a chosen public and might do so by explicit forms of moderating, at least from my point of view this was not the initial aim of the phenomenon 'blog'. That certain characteristics of this initially 'liberal' form of electronic discussion also carry over to scientific forms cannot be regarded as a pure 'noise phenomenon'. The more informal and liberal form makes it possible to share information flow between possibly poorly overlapping subjects and standpoints and people with very different knowledge backgrounds. As far as physics and mathematics as classically highly impenetrable subjects for non-experts share responsibility to communicate with the 'outer world', the scientific blogosphere possibly

could realize this with relatively low levels of formal and financial effort. To be more concrete: as it ssemed to me Gina, fo instance, did have a scientific background, which while it aparently did not quite overlap with particle physics (chemistry?) does not quite exclude her form any form of rational reasoning.
The scientific blogosphere could well be aware of even much more radically differing forms of scientific reasoning having potential and justified interest in informal discussions with the mathematical or physical world, I mention philosophers, sociologists as already discussed, not to mention cultural scientitists or even artists, baring viewpoints which could 'possibly' be of interest or benefit for physicists or mathematicians themselves and who up to now share mostly very deformed and wrong views of scientific knowledge in the mathematical or physical sphere, I think the most 'distant' views shared in this blog came from engineers, so I do in fact think the situation could be much 'worse' (or better, what you prefer).

28. **Peter Woit**
October 20, 2006

ak,

A "blog" is just a software tool, and people are using it with many different purposes. Many scientists have blogs designed to try and explain and promote science to the widest possible public. Many people would like this blog to be a forum for the discussion of their and other unconventional ideas about physics. Those are fine things to do, I'm just not interested in doing them. One reason is purely a lack of time: maintaining this blog is already taking up too much of my time and I'm trying to figure out how to change that.

Sorry to be a bit obnoxious about this, but one of the whole points of the blog technology is to allow people to try and create an information source and discussion forum of whatever kind they want. I'm trying to make one for people who share some of the same interests as me, with the highest possible level of substantive material. Doing this requires deleting comments from people who want to use this to discuss something I'm not interested in, as well as comments that are uninformed. One obvious thing to point out to people who don't like this is that the technology is free, you're welcome to create your own blog, and there you can do exactly what you want.

29. **Jud**
October 20, 2006

I thought the suggestion about allowing some trusted folks to perform moderation was not an awful idea, though of course I don't know what your supply of such folks may be.

30. **Tony Smith**
October 20, 2006

Brian Greene's 20 October 2006 New York Times Op-Ed says:
"… at high energies, the electromagnetic and weak nuclear forces seamlessly combine … at even higher energies the strong nuclear force would also meld …
For decades, however, the force of gravity stubbornly resisted joining the fold. …
Time and again, attempts to merge the two theories resulted in ill-defined mathematics
…
Such was the case until the mid-1980's, when a new approach, string theory, burst onto the stage. Difficult and complex calculations … gave compelling evidence that this new approach … unified gravity and quantum mechanics …".

There is a very significant omission in Brian Greene's recital of historical "context":
In fact,
the first approach that successfully "unified gravity and quantum mechanics" was supergravity, in which gravity and other forces were unified by the use of Lie superalgebras and description of gravity by mechanisms of the MacDowell-Mansouri type, using either the anti-deSitter group Spin(2,3) = Sp(2) or the conformal group Spin(2,4) = SU(2,2).

Interest in supergravity waned in the mid-1980s when it seemed difficult to get it to contain the Standard Model groups and it also seemed that it might not have the cancellations needed for finiteness (although the difficult calculations have yet to be done).

Then, as Brian Greene said, in the mid-1980s conventional superstring theory became dominant in the high-energy theoretical physics game, and it maintains its dominance even now.

As Brian Greene said, the basic idea of conventional supertstring theory is to change the view of "matter's fundamental constituents" from "point-like dots of virtually no size" to "minuscule, vibrating, string-like filaments".

The competing basic idea of supergravity, ignored in Brian Greene's discussion of history, is to change the view of forces from being based on the generators of Lie algebras to being based on the generators of Lie superalgebras.

While the conventional superstring theory approach focuses on a new view of matter as filaments rather than points,
the supergravity approach focuses on a new view of the setting for force generators.

Even if changing the setting from Lie algebras to Lie superalgebras might not have been totally successful,
there are some other natural settings for the force generators (one of which is to look at them as root vectors, which is what I like to do)
and
I feel that such generalized/modified-supergravity approaches should be investigated as alternatives to conventional superstring theory,
especially
since supergravity (despite Brian Greene's omission of it from his recital of historical "context") was actually the first theory that successfully "unified gravity and quantum mechanics".

31. **Gumbi**
October 20, 2006

In some ways the dispute reminds me of the old debate about the Many-Worlds Interpretation of QM. The MWI is just like textbook QM except there is no wave function collapse. Instead, proponents argue that in a universe with no collapse, macroscopic observers would see the illusion of collapse, which is consistent with what we observe.

This may be good philosophy but the problem from the scientific perspective is that the MWI is too perfect. It reproduces the predictions of regular QM so well that no experiment can distinguish them.

We are left with philosophical arguments – MWI proponents advocating its somewhat more parsimonious axiomatic basis, while opponents object to its version of the "landscape". All those parallel worlds, all those alternate histories and variations on ourselves, all as real as we are. It's a lot to accept.

Although the analogy is not exact, we might end in a similar situation with regard to string theory. If the string theory landscape is not falsifiable, then we can't prove the string theory landscape is real; but we also can't prove that the idea is wrong. In the end it may be a matter of philosophical taste as to which theoretical approach produces the most attractive and elegant model of the universe.

32. **Peter Shor**
October 20, 2006

I'm going to stick my neck out and say you're being too harsh on Brian Greene in at least one respect. I think that having a unified theory of gravity and quantum mechanics would be a big step forward (not that string theory is actually one yet).

Why do I say so? Because I suspect that all consistent unified theories of gravity and quantum mechanics are going to share a lot of properties, and if we could figure out what some of these properties are, then it might help us to figure out the right theory of quantum gravity. I believe that it is quite possible that any consistent theory of quantum gravity is going to lack one of the things we think are absolutely essential, for example Lorentz invariance, unitarity, or locality. (All three of these seem to be crucial in formulating the black hole information loss paradox.) One possible reason we haven't come up with any reasonable theories of quantum gravity might be that we're looking in the wrong place. So if we could formulate a non-perturbative theory of string theory (even in 10 or 11 non-compactified dimensions), it might teach us something something about all theories of quantum gravity.

I'm sure that one of the string theorists reading this will object and say that string theory has all these properties, and is also a consistent theory of quantum gravity. But my understanding is that we only "know" that perturbative string theory is unitary, and that this theory lives in the limit where the curvature of space-time doesn't change. The black hole information loss paradox is perfectly consistent with unitarity in this limit.

In fact, this is where I first lost some of my trust in string theorists. Shortly after quantum fault tolerance was discovered, I was talking to a famous string theorist, and trying to explain to him Kitaev's result about error correction with anyons, which I was very excited about at the time. This result led Preskill (I believe) to speculate that the laws of nature might be non-unitary at bottom, but that this non-unitarity is masked by an inherent error-correction process, which makes everything look unitary at any scale significantly larger than the Planck length. He was very dismissive, and said that it had been proved that any non-unitarity at small scales would also show up at large scales. Since this result was exactly contrary to the one I was trying to explain to him, I asked where this proof was, and how it worked. He couldn't tell me exactly who had proved it, or whether it was written down, and he muttered something with the words "at least in the generic case …" in it. At this point, I gave up.

I still think that Kitaev's result shows that it's possible that the true theory of quantum gravity is not unitary. Unfortunately, I have come to realize that it gives very little guidance as to where to look for a non-unitary but self-correcting theory of quantum gravity, so it seems unlikely that anybody will come across the correct theory of quantum gravity starting from this direction.

33. **Garbage**
October 20, 2006

To Peter Shor,

http://arxiv.org/abs/gr-qc/0603090

http://arxiv.org/abs/hep-ph/0604255

and why not.

http://arxiv.org/abs/quant-ph/0507262

I agree, unitarity is not such a sacred concept. Also, axiomatic constraint may be very well tested.

34. **Peter Woit**
October 20, 2006

Peter Shor,

My comment just reflects my often expressed worry about quantum gravity: what if there are lots and lots of them, and there is no way to ever get any experimental evidence about which one corresponds to reality? If you believe the most optimistic claims of string theorists these days, they have not one consistent theory of quantum gravity, but 10^500, and nothing at all about these theories is experimentally testable. This seems to me to be highly problematic.

It's certainly true that you may learn something generic about quantum gravity by thinking about all these models. But, I'm really a particle physicist, and you're not going to learn anything about particle theory by thinking about them. Where string theory has failed is not as a theory of quantum gravity, but as a theory of particle physics. If string theorists would just admit that, and formal particle theory was no longer so heavily dominated by string theory, we'd be a lot better off.

35. **anonymous**
October 20, 2006

I have never heard a string theorist say string theory gives rise to 10^500 theories of quantum gravity. Many of them think there is one theory with 10^500 solutions. It is a very big difference.

36. **Garbarge**
October 20, 2006

"Many of them think there is one theory with 10^500 solutions."

Well, it might be 5 or so after all

Peter, I think the main purpose of ST is to provide a theory of quantum gravity, which happens to include all of particle physics [Something inevitable, if you believe "Georgi"]
String theory has some achievements in that area. Like the entropy calculations/predictions for extreme BH, although it fails in more reasonable circunstances. Also one could say the ADS/CFT correspondence opens the bridge to understand gravity as a field theory as well. I agree ST does sort of what Peter Shor says, although still falls short to get the M-picture. I personally think the "background independence" issue is a big *problem* not yet fully addressed/understood. I asked once Ed Witten about this, his answer was:

"…another point is that though string theory was discovered historically in the context of a fixed spacetime background, it turns out that the string describes fluctuations in the geometry, though we don't understand very fully how this happens."

37. **woit**
October 20, 2006

anonymous,

I'm well aware of what the string theory ideology is, with its "one unique string theory", which no one actually knows the definition of. The fact of the matter is that current known definitions of string theory depend on a choice of "background", and many string theorists believe there are 10^500 or more different such choices.

38. **Chris W.**
October 20, 2006

> I have never heard a string theorist say string theory gives rise to 10^500 theories of quantum gravity. Many of them think there is one theory with 10^500 solutions. It is a very big difference.

Given that any one of those solutions is potentially an effective theory for describing the entire *observed* universe, and a failure of any one of them in fulfilling that goal merely sends us off on a wild goose chase through the other 10^500 looking for a solution that does work, one can say that we have 10^500 theories, for all intents and purposes.

We would be in somewhat the same predicament in atomic physics (non-relativistic quantum theory, shall we say) if it allowed for millions of solutions (stable or meta-stable configurations), we only had only example of such a system to test the theory against, and we couldn't independently observe the configuration to prevent the theorist from saying "no, wait, it's not a helium atom in state X," or "it's actually a boron atom in state Y [or an iron atom in state Z, etc, etc]". Now think of the options afforded us by a vast array of vacua, not to mention braneworld scenarios, and on and on.

Arguably, the central lesson of investigations into quantum gravity is that the issues are *inherently* cosmological in character. This enormously raises the stakes and and increases the risks of running off the rails epistemologically and methodologically. I can see why a sober particle physicist would just as soon avoid the entire territory while attempting to understand the existing problems of the Standard Model. The question is, is this really possible? What could a satisfying solution of these problems look like without involving gravity, or the dynamical structure of spacetime, in an essential way?

39. **Aaron Bergman**
October 20, 2006

The fact of the matter is that current known definitions of string theory depend on a choice of "background", and many string theorists believe there are 10^500 or more different such choices.

If you want to be a stickler about it, none of the examples with all moduli stabilized have a description as a perturbative string theory at all because of the presence of Ramond-Ramond fluxes. However, if you believe that string theory has supergravity as a low energy limit, you can tunnel between vacua and see that they cannot be considered separately.

On the other hand, Tom Banks might argue that none of these things will change the asymptotics of the solution and that different choices of asymptotics should be considered different theories.

Frankly, I'm not sure why anyone should care whether string theory should be thought of as a framework (like QFT) or as one theory with zillions of (not-so-rigorously constructed) vacua. What matters are the results of the calculations that you do.

If you believe Steve Carlip, there are plenty of inequivalent quantizations of 2+1D quantum gravity, so perhaps the same holds 3+1 also. I still think that string theory is interested because, at least with AdS/CFT, I believe that it really is a theory of quantum gravity. As such, even if it's not the right theory of quantum gravity, we can learn things about how the usual problems associated to quantum gravity might be solved. String theory has succeeded towards that end in some respects (black hole entropy, for example) but not entirely in others. (The black hole entropy calculation does not 'fail' in far-from-extremal situations as in give the wrong answer, in case there was some misunderstanding; it is just not doable yet.)

For Peter Shor, we know that AdS/CFT is unitary, and there the metric is fully dynamical. This argument is essentially what convinced Stephen Hawking as I remember it.

40. **Moshe**
October 20, 2006

Peter Shor, in my mind there are some indications in string theory that black hole physics does not require modifying QM, but there is nothing I know of that amounts to a watertight proof.
\
I am curious though about something related, in particle physics circles it is common belief that QM is "rigid" in the sense that there are no consistent "small" modifications of QM (e.g adding small non-linear terms to Schrodinger equation), example that is cited often is Weinberg's attempt to modify QM.
\
On the other hand it is my impression that in other communities the sitaution is different. So, out of curiosity, are you aware of any model that modifies QM and reduces to it for observable physics? Do you feel like something like that ought to exist?

thanks,

Moshe

41. **nontrad**
October 20, 2006

Aaron B,

Thanks for bringing attention to 2+1 QG. In the above posts discussing the posibility of several QG's I immediately thought of 2+1, which is an odd place / 'laboratory' in more ways then one.

Again, thanks for bringing attention to this point.

Regards,

nontrad

42. **anon.**
October 20, 2006

For Peter Shor: one of the arguments that is sometimes referred to in the context of claims that modifications of unitary QM are dangerous is a paper by Banks, Peskin, and Susskind, motivated by the black hole information problem:

http://www.slac.stanford.edu/spires/find/hep/www?key=1135198

They argue that modifying QM to try to get around the black hole information problem leads either to acausal signal propagation or to violations of energy-momentum conservation. They further argue that these effects are not suppressed by powers of the Planck scale. Their argument applies to a class of modified QM theories with a "superscattering matrix."

I'm not expert in these things and I don't know what the space of all reasonable modifications of QM looks like, so I don't know whether there is any danger for the sort of thing you have in mind. I am fairly confident, though, that this is the paper that has devolved into the sort of "folk theorem" you mention that "any non-unitarity at small scales would also show up at large scales."

43. **Tony Smith**
October 21, 2006

Peter Shor said "… Kitaev's result about error correction with anyons … led Preskill (I believe) to speculate that the laws of nature might be non-unitary at bottom, but that this non-unitarity is masked by an inherent error-correction process, which makes everything look unitary at any scale significantly larger than the Planck length. …".

John Preskill said in his paper Fault-Tolerant Quantum Computation, quant-ph/9712048:
"… In Kitaev's spin models, we might imagine that localized processes that destroy quantum information are quite common. Yet were we to follow the evolution of the system with coarser resolution, tracking only the information encoded in the charges of distantly separated quasiparticles, we would observe unitary evolution to remarkable accuracy; we would detect no glimmer of the turmoil beneath the surface. …".

Stephen Adler said, in his book Quaternionic Quantum Mechanics and Quantum Fields ((Oxford 1995):
"… If the multiplication is associative, as in the complex and quaternionic cases, we can remove parentheses in … Schroedinger equation dynamics … this … fails in the octonionic case, and hence one cannot follow the standard procedure to get a unitary dynamics. …
[so there is a]… failure of unitarity in octonionic quantum mechanics…".

Would the Preskill idea of non-unitarity at Planck energies be consistent with an octonionic-non-unitary model at Planck energies that becomes quaternionic-unitary by "freezing out" a preferred quaternionic subspace at sub-Planck energies ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

44. **Garbarge**
October 21, 2006

hey anon,

you might like to read this,

http://arxiv.org/abs/gr-qc/0305098

along with the other references I pointed out before.
There is no real *danger*, unitarity isnt such a sacred principle. One can conserve probabilities and charges (including H) without it. This has been known for a while in the theory of open systems (Lindblad formalism) . The nice thing about these papers is that the modified Schroedinger dynamics is derived from quantum gravity ideas, and applies independently of any other environmental decoherence effect. Also that the black hole paradox is rendered *practically* unobservable

http://arxiv.org/abs/gr-qc/0501027

http://arxiv.org/abs/hep-th/0406260

and provides a conceptually satisfatory solution to the problem of time,

http://arxiv.org/abs/gr-qc/0402118

There are indeed attempts to experimentally detect this type of effects,

http://arxiv.org/abs/quant-ph/0406007

nice reading… 🙂

bed time…

45. **Peter Shor**
October 21, 2006

Anon,

Many thanks for the reference. I've looked at it now, and I'm convinced you're right: this is probably the paper that turned into the folk theorem. As for AdS/CFT, I'm not going to be completely convinced by this until somebody can explain exactly why the black hole information paradox goes away in AdS/CFT. I've discussed this with a couple of string theorists, and they admitted they didn't understand it completely themselves.

Peter Shor

46. **Lee Smolin**
October 21, 2006

Dear Peter Shor,

If it really is the case that fault tolerant quantum computing can provide a counterexample to the Banks-Peskin-Susskind argument that is very worth working through carefully and writing up.

As to small testible modifications from quantum theory, it has been known for a long time that one can add terms to the schroedinger equation that are non-linear in the wavefunction Psi, which violate unitarity but not conservation of probability and then use precision experiments like the Lamb shift or neutron diffraction to bound their coefficients. (I wrote such a paper in the mid 80s but it was already an old idea then.)

As to consistent quantum theories of gravity which show that general principles like Lorentz invariance must be modified, let me recommend the recent Freidel-Livine work on 2+1 gravity with matter, which shows that Poincare invariance is necessarily quantum deformed as a result of including quantum gravity. (btw, not for the first time, I have no idea what the ambiguity is in 2+1 quantum gravity some people keep refering to. Carlip wrote about different appraoches to 2+1 gravity but my understanding is that with the same matter content they all give the same theory.)

Thanks,

Lee

47. **Aaron Bergman**
October 21, 2006

Let me quote from Carlip:

> Perhaps the most important lesson of (2+1)-dimensional quantum gravity is that general relativity can, in fact, be quantized. While additional ingredients—strings, for instance—may have their own attractions, they are evidently not necessary for the existence of quantum gravity. More than an "existence theorem," though, the (2+1)- dimensional models also provide a "nonuniqueness theorem": many approaches to the quantum theory are possible, and they are not all equivalent. This is perhaps a bit of a disappointment, since many in this field had hoped that once we found a self-consistent quantum theory of gravity, the consistency conditions might be strin- gent enough to make that theory unique. In retrospect, though, we should not be so surprised: quantum gravity is presumably more fundamental than classical general relativity, and it is not so strange to learn that more than one quantum theory can have the same classical limit.

48. **Lee Smolin**
October 21, 2006

Carlip concludes however (p 46).

"A more general problem is to understand which of the approaches described here are equivalent. In particular, it is not obvious how much of the difference among various methods of quantization can be attributed to operator ordering ambiguities, and how much reflects a deeper inequivalence."

Here is why I suspect that it is the former. Let us consider the case of no matter, to which his comments mostly refer. Given a compact two topology and a value of Lambda, there is a fixed finite dimensional physical phase space for 2+1 GR. Given that the physical phase space is finite dimensional, there are only two ways that one can get inequivalent quantizations. First, from different choices of subalgebras of the physical phase space algebra to be quantized. Second, from different representations of those algebras. Both of these kinds of ambiguities are well understood in conventional quantum mechanics. One cannot expect the situation here to be better than in ordinary QM, but if it is no worse than it is misleading to say that different approaches lead to different theories.

49. **Hmm**
October 21, 2006

Peter Shor–

Talk to better string theorists; the understanding of the information paradox is now relatively standard. The process of black hole formation and evaporation in AdS space can be desribed in the unitary boundary CFT. Furthermore, for the case of eternal black holes in AdS, there is a sharp form of the information paradox and its resolution as discussed by Maldacena in 2001, hep-th/0106112; this was the paper that convinced Hawking to capitulate. The sharp form of the paradox in this case is this: correlation functions for (say) a scalar field in the BH background naively fall exponentially to zero–whereas a unitary description would say that it can't get smaller than exp(-S). Of course the dual CFT tells you precisely this. There is a separate question of how to understand the breakdown of Hawkings original argument. Maldacena (and subsequently Hawking) suggested that this arises from a sum over all bulk geometries, including ones where the BH doesn't form, but this is still controversial. This does not change the fact that AdS/CFT provides the correct answer-no information loss.

With all due respect to you and your great accomplishments in quantum computing, your questions and comments on quantum gravity are somewhat naive. This also goes for a number of your "the world in a quantum computer!" colleagues too. This makes your insinuations that the string theorists don't know what they are talking about a mite annoying. Perhaps in the future you should consult some of the standard literature. Of course actually being an expert in some subject and actually knowing what one is talking about is completely at odds with the ethos of the blogosphere, especially here…

50. **woit**
October 21, 2006

Garbage,

My apologies. Your last comment ended up in multiple copies in the spam queue (presumably because it had multiple links, something this mysterious software is very suspicious of). I was trying to delete most copies, keep one, managed to irretrieveably delete them all. Please repost if you still have a copy.

Peter

51. **Aaron Bergman**
October 22, 2006

One cannot expect the situation here to be better than in ordinary QM, but if it is no worse than it is misleading to say that different approaches lead to different theories.

I can't quite understand this sentence — perhaps it's missing a word? Anyways, I think the point is that there are physically different theories of quantum gravity in 2+1D, ie, they have the same classical limit but different quantum predictions. For whatever reason this may be true, it would be very interesting to know how true it is in 3+1D (or more).

52. **Jean-Paul**
October 22, 2006

Johnson's talk was completely disgusting. I did not know that he was the journalist who wrote the (in)famous article on "probing string theory". Actually, he mentioned it,

and seemed quite proud of it. The seminar was from "we journalists know…" to "you string theorists you know" how to fool the public. What was most striking that there was no mention or even speculation on what is the impact of sensational journalism on public who reads it. Both Johnson and the audience did not care at all about readers' perception. No mention of the basic journalists' obligation to be objective. Instead, contempt for "ignorant" public. Very cynic remarks on "to be sure" paragraphs with a very fine print "it's just a hype". The moral was: we journalist look for a story, and the more hype and confusion you physicists create, the more stories we can write.
We are used to the sensational coverage of the entertainment world, but science writers are no better…

53. **Arun**
October 22, 2006

Started watching Johnson's talk and was quickly reminded of Gartner's Hype cycle, which should be familiar to people in the technology sector.

http://www.floor.nl/ebiz/gartnershypecycle.htm

I wonder if String Theory maps onto this cycle. Perhaps it is past the Peak of Inflated Expectations, but where it is beyond that point is beyond me.

54. **Arun**
October 22, 2006

I'm halfway into the Johnson talk, and I'm not very impressed by the audience either.

55. **Who**
October 22, 2006

I disagree with your take on it, Arun. The talk by Johnson was informative and increased my respect for his professionalism as a science journalist. One got a sense of what journalists do to successfully communicate their interest in science to the public—and the constraints within which they work.

Also the Q and A, the running dialog he had with KITP, really helped me to better understand the points of view of the string theorists in the room. And I think that Johnson spoke very well (and basically reassuringly) to their concerns.

I found that I could not watch the video very well in STREAMING mode because it kept stopping—-maybe due to heavy traffic. So based on my experience I woul recommend that anyone interested in watching should DOWNLOAD the whole movie (in my case "quicktime") file so that they can watch continuously and at their convenience.

this conversation is extremely informative and interesting—-and, as I say, gives me the highest impression of Johnson's cool, senses of humor, likeablility, and professionalism. One also gets to know KITP people much better, and their viewpoint and concerns. Instead of reacting scornfully, or churlishly, to this excellect video we should thank and congratulate KITP on contributing to improved understanding of all these issues. (sorry to disagree so strongly, Arun—I usually appreciate your posts very much.)

56. **Kris Krogh**
October 22, 2006

I agree with Who that Johnson's talk was excellent. His standards for scientific objectivity are much higher than Amanda Peet's.

In the comments afterward, David Gross complains about Lee Smolin's book. He says Smolin privately acceded to his argument that a background-independent version of string theory exists, but wrote the opposite. I'm hoping Lee will give his side of that.

57. **LDM**
October 22, 2006

I also enjoyed the Johnson talk…some comments (on the need for higher dimensions…) were very funny.

It is unbelievable that one theorist had not read the books, but still had strong opinions about their accuracy.

At one point, it almost seemed like there was an attack on Smolin and loop quantum gravity, which was a little strange, because the arguments against string theory do not rely on loop quantum gravity in anyway.

58. **Arun**
October 22, 2006

Who,
No need to be sorry for disagreeing strongly with my opinion. At most, I am put to the trouble of explaining what I heard.

Of the persons who spoke and could be heard, Johnson was the best. I did appreciate his telling someone to read the book first. The crowd was dismaying, with its "Swollen" and its challenge to Johnson to poll the room on whether Smolin is a crackpot. Also, the (perhaps my misinterpretation?) that Smolin and Woit belong to the same category of marginal people as John Horgan. I too want to hear Smolin's side of his alleged two-facedness.

The whole thing was vaguely reminiscent of the discussions I have seen on the Pakistani GeoTV channel about Pakistan's problems stemming from its bad image, the right PR formula is yet to be found. (I'm not Pakistani, fyi). Bringing string theory to the public cannot be called popularization of science, at least by the standards of my youth, where the popular science books (that were available to me) were always about well-established science. Kaku, Greene, etc., did the first disservice by hyping these in public, and if the string theory community did not feel discomfort then (did it?) it is a bit much if they protest now that there is a dehype. If Woit and Smolin were the first to bring string theory to the public, I'd agree that the ST folks irritation would be justifiable. However, from the POV of "what will the public think?", Woit and Smolin are a correction to the backdrop set by Greene, et. al.

——

If it is science we want to discuss and not PR, then the root problem is not yet addressed. Let's agree that primarily nature and secondarily limited funding have reduced the ability of particle physicists to have the close interplay with experiment that they used to have. Then we need new criteria on how to objectively say that we are not wrong so far in any particular line of research. Perhaps it is there implicitly within the community, it now has to become more explicit. Then one will also know what to tell the public.

59. **Peter Shor**
October 22, 2006

Dear Hmm,

Let me say that if string theorists routinely insult people who are trying to understand aspects of string theory, they are not going to get very many converts to their side.

I am aware of the "universe is a quantum computer" contingent, and I am not ashamed to say that I am not very impressed with their reasoning (unlike some string theorists, who will never criticize each other in public).

Best regards,

Peter Shor

60. **Jean-Paul**
October 22, 2006

Arun, Kris and Who,
With all due respect, I am afraid that you are missing the point. Johnson is a journalist. He can listen to tirades on background independence, attacks on the competence of Smolin/Woit but he cannot make his own judgment, and he admits it. Similarly, I would not discuss with him the issue of scientific objectivity. What I would like to hear is not a bundle of cynical jokes how journalists work, but a serious discussion of JOURNALISTIC objectivity and responsibility. When you write an article about "probing string theory" you would better ask 5 or so experts who would give you a wide range of opinions. Similarly when you write about a "crisis in ST".
Do you think that Johnson does a better job than somebody writing for the Enquirer? Certainly, science should be popularized, but at what expense? Is it OK to mislead the public? I wish Johnson could address these questions.

61. **Lee Smolin**
October 22, 2006

Hi, to respond to David Gross's claim mentioned by Kris Krogh above, I have been both clear and careful in the book. For example on p 240:

"Thus many quantum-gravity theorists believe there is a deeper level of reality, where space does not exist (this is taking background independence to its logical extreme). Since string theory requires the existence of a background-independent theory to make sense, many string theorists have indicated that they agree. In a certain limited sense, if the strong form of the Maldacena conjecture (see chapter 9) turns out to be true, a nine-dimensional geometry will emerge out of a fixed three-dimensional geometry. It is thus not surprising to hear Edward Witten say, as he did in a recent talk at the Kavli Institute for Theoretical Physics at UC Santa Barbara, that "most string theorists suspect that spacetime is an 'emergent phenomenon,' in the language of condensed matter physics."2
Some string theorists have finally begun to appreciate this point, and one can only hope they will follow up by studying the concrete results that have already been obtained. But in fact, most people in quantum gravity have in mind something more radical than the
Maldacena conjecture.

The starting point is nothing like geometry. What many of us in quantum gravity mean when we say that space is emergent is that the continuum of space is an illusion…."

In more technical language, what has usually been meant by background independence is that no classical metric, field or global symmetry appears in the definition of a theory. Thus, by definition, formulations of a theory with asymptotic boundary conditions are excluded. This definition, and the motivation for it is discussed many places in the literature, for example in my recent hep-th/0507235. For a discussion of why the Maldacena conjecture does not satisfy what is usually considered background independence, see pages 23 and 24. There I am responding to various discussions with string theorists including David Gross, who insisted that string theory does not need a background independent formulation, because the AdS/CFT correspondence gives string theory a non-perturbative definition.

However, in my most recent conversation with Gross, he argued instead that the AdS/CFT correspondence should be considered to satisfy a form of background independence. Recently others made the same argument to me. Their claim is that if the strong form of the AdS/CFT conjecture is true, a dynamical ten dimensional asymptotically AdS spacetime will have arisin out of a theory defined on 4d Minkowski spacetime with global Poincare symmetry. This does not satisfy the definition just given. But it is true that 6 of the ten dimensions transmuted from the space of scalar fields in the N=4 SYM theory to dimensions of space in the dual theory. In this limited sense a weak form of background independence will have been achieved. This is what I agreed to in conversation with David and others.

But, as I thought I made it clear in these discussions, there is a big difference between this and what has usually been meant. Classical GR achieves this usual meaning, as do LQG, spin foam models, causal sets, causal dynamical triangulations, and not, at least so far, string theory.

In a recent discussion, Brian Greene proposed a new terminology to straighten out the confusion. Brian proposes to use manifest background independence for what quantum gravity people and philosophers have up till now meant by background independence and background independence for the weak form satisfied by the (strong form of the) AdS/CFT conjecture.

If it helps to distinguish between a strong or manifest form of background independence and a weak form, then I can agree to use this language. But I don't see that changing the meaning of technical terms advances the issue. Brian and others (perhaps not David) agree that string theory should have a manifest or strong background independent formulation, and that it does not yet.

By the way, each time I note that string theory does not have the property of strong or manifest background independence, this is more than anything a criticism of myself as, to my knowledge, few others took the problem of making such a formulation of string theory seriously enough to spend years working on it, as I did.

Thanks,

Lee

Ps Just in case anyone thinks it is plausible that I and other people in LQG be considered crackpots, they can consult my cv which is at
http://www.thetroublewithphysics.com. I didn't listen to the tape, but if someone actually said that they should be ashamed of themselves.

Indeed, what is remarkable to me is that no one in this or, to my knowledge, any other discussion of my book says something like, "On page x of Chapter 12, Smolin says A and that is false for this reason. This is not just because some string theorists have not read the book, because if no one at KITP has, I know of others who have read it in detail, and if they had found errors of fact they would have said so. I wouldn't be surprised if this had happened, because in the chapters leading up to the evaluation of string theory I give in Chapter 12 a large body of technical results is summarized in non-technical language. It is very hard to do this and not get something wrong, even in one's own field, and I worked very hard, and checked and double checked with experts to be sure of having the facts right. Of course, if anybody finds such an error I would be grateful.

62. **Arun**
October 22, 2006

Perhaps it would be best to download and listen to the podcast (15 MB, quicktime player would suffice to view/listen).

63. **Kris Krogh**

October 22, 2006

Thanks Lee!
—
Jean-Paul,

For me, there's no distinction between scientific and journalistic objectivity. Isn't there only one truth? By urging a string theory audience to read Smolin and Woit's books, I think Johnson showed more concern for objectivity and the "scientific method" than many of the scientists he spoke to.

Especially in theoretical physics, there seems to be an unhealthy tendency to decide issues on authority, instead of blindly weighing evidence. (Like the woman with the scale.) Just vote on the smartest person (or who's a crackpot) and call their ideas reality.

64. **Lee Smolin**
October 22, 2006

Just to be sure, regarding David Gross's comments, I also wrote on page 189 of my book: "…if the strong form of the Maldacena conjecture turns out to be true — which is also consistent with the present evidence — then string theory provides good quantum theories of gravity, in the special case of backgrounds with a negative cosmological constant. Moreover, those theories would be partly background-independent, in that a nine-dimensional space is generated from physics in a three-dimensional
space.

There is other evidence that string theory can provide a unification
of gravity with quantum theory…."

The text was finalized before David and I had the conversation he is refering to in July and, as you can see, the text is consistent with his memory of what I said. Shall I conclude that he also commented on my book without checking to read it first?

Thanks,

Lee

65. **Tony Smith**
October 22, 2006

Arun says: "… The crowd was dismaying, with … its challenge to Johnson to poll the room on whether Smolin is a crackpot. …".

Lee Smolin says: "… Just in case anyone thinks it is plausible that I and other people in LQG be considered crackpots, they can consult my cv which is at http://www.thetroublewithphysics.com. …"
and goes on to say:
"… no one in this or, to my knowledge, any other discussion of my book says something like, "On page x of Chapter 12, Smolin says A and that is false for this reason. …".

Kris Krogh says: "… Especially in theoretical physics, there seems to be an unhealthy tendency to decide issues on authority, instead of blindly weighing evidence. … Just vote on … who's a crackpot …".

Since Kris Krogh is in the psychology department at UC Santa Barbara, which is the host institution for KITP where the talk in question took place,
maybe he could shed some light on the psychology of why the KITP superstring community is relying on authority and on "vote[s] … on …. who's a crackpot", instead of
on substantive discussion such as "… Smolin says A and that is false for this reason …".

If Kris Krogh were to prefer to defer from shedding such light himself (possibly saying something like he is a "Senior Electronics Technician" rather than a practicing psychologist),
perhaps he could prevail upon some of the practicing psychologists in the UCSB psychology department to shed such light.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

66. **Garbage**
October 22, 2006

Thanks Peter, it's alright, I was trying to point out, in particular to Smolin and Shor who brought the subject in, that unitarity can be violated without outrageous consequences. I mentioned in my answer to anon a few papers they might like reading. I think these provide a very satisfatory solution to the problem of time and black hole paradox, and perhaps even more, of the measurement problem itself. The following is a nice review:

http://arxiv.org/abs/gr-qc/0603090

thanks again.

67. **Aaron Bergman**
October 22, 2006

Lee —

[emergent geometry]

Some string theorists have finally begun to appreciate this point, and one can only hope they will follow up by studying the concrete results that have already been obtained.

I don't think the idea that spacetime would be emergent was remotely controversial. Even before AdS/CFT, there were various matrix models. I'd be surprised if there weren't papers speculating along these lines well back into the 80s. Holography is certainly a sort of emergent geometry, and I think you'll find that a fair fraction of string theorists believe that there is something fundamentally holographic about string theory.

But it is true that 6 of the ten dimensions transmuted from the space of scalar fields in the N=4 SYM theory to dimensions of space in the dual theory.

This is probably not a good way to think of AdS/CFT. It is true on the D-brane that the vevs of the scalars correspond to moving the brane around, in the AdS/CFT conjecture, ie, after you take the near-horizong limit, you have a five sphere and a five dimensional AdS. The fifth dimension of AdS corresponds to a RG scale in the field theory. The field theory can usefully be thought of as living on the boundary. Thus, the lack of background dependence in the YM field theory exactly corresponds to the fixing of the boundary of AdS. It's probably best to think of this (minor in my opinion) background dependence as necessitated by the need to do something there to make sense of anything in AdS.

I notice you mention CDT as a background independent approach, but last I checked, they fix a spatial topology (somewhat akin to fixing a boundary condition as in AdS/CFT). Has this restriction been removed and they sum over topologies now?

By the way, each time I note that string theory does not have the property of strong or manifest background independence, this is more than anything a criticism of myself as, to my knowledge, few others took the problem of making such a formulation of string theory seriously enough to spend years working on it, as I did.

How do you know? People have certainly considered it in the context of nonperturbative approaches. There's not terribly much to say in the perturbative approach after all. What most string theorists are interested in is finding a general nonperturbative approach. It is only in that context that the question can be usefully addressed.

I should mention that I just spent some time reading chapters 16-20 of your book in the bookstore (actually, I skimmed 17). I can't help but wonder, especially with all the blind quotes in chapter 16, who are these people? They certainly don't seem like the vast majority of the string theorists I know. Just to pick one example, the issue of whether or not string theory is correct or not is hardly verboten. Most of your list of seven facets of string theorists (which I confess to not remembering very well — perhaps someone with the book could summarize them again) didn't seem particularly representative of the people I know either.

When your book wasn't angering me (for reasons we've talked about in the past and which I won't get into here), it was immensely frustrating because you circle around some real problems but completely miss, in my opinion, the real issues. You base your solutions, it seems to me, on the idea that there exist these two types of people, the seers and the craftspeople. That seems to me to be fundamentally misguided. What we have are smart people doing their best to get by in the incentive structure that exists in theoretical physics. This structure rewards production. It rewards brilliant results also, of course, but there is a strong incentive to write lots of papers so as to get a job. Obtaining more seers is not a matter of identifying the iconoclasts (who in physics isn't a bit iconoclastic, after all?), but a matter of figuring out how to make it less dangerous for a young person to devote a significant amount of time thinking about extremely difficult problems that may not get solved.

People are doing their damnedest to get by in a market where there are scarce resources, and, contrasted with your proclaimed dissident seers, the lack of respect you evince (to my mind) towards the people who are willing to work and survive in this framework is dismaying.

68. **Lee Smolin**
October 23, 2006

Dear Aaron,

Just to address your last point. There is absolutely no disrespect involved. I just recognize that there are different types of scientific characters, who approach research differently and I emphasize that science needs several different types. I have a great deal of sympathy for the situation you describe, as I am much more like you in my skills than the people I am discussing here. I did fit into the incentive structure and did, as you put it, work and survive. This is because most of my work has been straightforward applications of QFT to gravity. LQG is after all, not radical, its just gauge field theory studied using techniques that are compatible with diffeomorphism invariance. It was also easier 30 years ago,.

Nonetheless, I recognize that there are people who either decline to or are incapable of fitting into the incentive structure you describe. They are , as you put it, unable to "work and survive in this framework."

Some of the people I am referring to do not believe the kind of work that the incentive structure rewards will be able to solve all the problems we face, because they believe the current conceptual framework requires revision. For example they may see the necessity of first altering the foundations of quantum mechanics or obtaining a conceptually and mathematically consistent understanding of what an observable is in GR. You and I are not such people, but they do exist and when they do succeed they make crucial contributions to science. I gave some examples in the book, such as Barbour, Deutsch and Valentini.

There is no incentive structure for such people to fit into, no matter how good they are and how important their work turns out to be, because they are working on problems either that were not clearly problems before they solved them or were not thought important. So in some cases they end up working outside the academy, in others they survive in small colleges or in math or philosophy departments.

A philosopher I know recently said to me that sometimes you have to recognize that an important problem cannot be solved by you, because it requires a person with a different kind of mind. Related to this is the advice that you are most likely to succeed at anything if you choose to work on problems that are compatible with how you think best.

All I am doing here is making the case that the progress of science would proceed faster if we made room for a small number of these individuals, who presently fall outside the incentive structure. This requires broadening the incentive structure a bit to recognize the fact that the progress of science requires a diversity of kinds of minds and skills. There is no disrespect meant or implied towards anyone.

Thanks,

Lee

69. **a**
October 23, 2006

unfortunately the word "war" that Peter does not like seems appropriate. So, why the first public scientific debate degenerated into a war?

First, Peter's criticism was perceived as a preventive war. Peter uses the word "failure" when some (little?) hopes remain open: maybe LHC will discover large extra dimensions, maybe some landscape statistics is peaked, maybe LHC will discover supersymmetry broken in some stringy way…

Second, the string hype. A naive extrapolation suggests that without the preventive criticism, some string theorists would have mispresented as a triumph of strings whatever LHC will see.

Third, somebody tried to close the traditional scientific channels to Peter's criticism. Ten years ago this could have been the end of the story, but nowadays this attempt transferred a private debate into a public internet war.

Fourth, Lubos Motl.

70. **Aaron Bergman**
October 23, 2006

Lee — I strongly disagree with that point of view. Just because someone is unwilling to work within the strictures that currently exist doesn't make them any better than those who are willing to do so. It just makes them more stubborn. Or flaky.

And I stand by my statement about the lack of respect you show. It comes across to me (and others, I would guess) in almost all your writing on the subject.

71. **ksh95**
October 23, 2006

This *"war"* is exceedingly healthy. Never before have such specialized and technical issues been debated in such a public manner. Force the naysayers to answer their critics, make the orthodoxy defend their ideas. And at the end of the day we will find truth, or we will witness theoretical high energy physics turn into philosophy…..You gotta love it!
/
Anyway, it strikes me as odd that the awe-inspiring, fabled and feared string theory propaganda machine is this ineffective. Woit and Smolin make substantive points and the machine calls Woit and Smolin poo-poo heads, babbles about conspiricy theory "back-stories", and accuses the people of seeking fame…..weird!
/
Even more queer is the fact that there exists an exceedingly convincing paper, in my opinion, explaining why string theory is the best(only) game in town. (the paper is recent and was mentioned on this and other blogs…I don't have the time or desire to find it).

72. **LDM**
October 23, 2006

Aaron,

You complain about a perceived lack of respect.

There are many physicists who simply do NOT respect what string theorists are doing in any way…who think it is wrong, and do not believe what you are doing is physics. Yet, string theorists still teach physics (and thereby influence a new generation of students), still have access to university physics resources, still consume tax dollars that would otherwise be spent on physics.

Weisskopf said it is a privilege to be a physicist, and I would contend that the way *publicly supported* string theorists have over-hyped and misrepresented any successes of string theory is just an abuse of that privilege.

73. **Aaron Bergman**
October 23, 2006

You miss the point. This isn't about respecting what people are doing; it's about respecting the people. I don't get angry when people attack string theory in an honest manner.

74. **Peter Woit**
October 23, 2006

Aaron,

I think this whole argument about who is dissing who is kind of ridiculous, more appropriate to teenage street gangs than serious scientists. In any case, given the attitudes and behavior of all too many string theorists, claiming that the problem with string theory's critics is their lack of respect for others is really a case of the pot calling the kettle black.

I think Lee has a point, but I'm not a huge fan of his "seers" vs. "craftspeople" distinction, since my own prejudice about the current problems of particle theory is that they are extremely hard, and making progress on them will require people who are some of both: iconoclastic enough to work on something different, with the technical skills and persistence necessary to get something beyond a vague, speculative idea. Particle theory needs new ideas and people ambitious and visionary enough to come up with them and pursue them (Lee's "seers" if you will), but the most likely way for someone to come up with these ideas is by immersion in the difficult technical issues surrounding quantum field theory and the standard model.

The great breakthroughs I've seen in math have come from people like Wiles and Perelman, who combined deep new insights, great technical skill, and seven or more years of dedicated single-minded work, during which they had nothing to show publicly for their efforts. How does one change the culture of particle theory to encourage this kind of effort?

75. **Aaron**
October 23, 2006

claiming that the problem with string theory's critics their lack of respect for others

I'm not claiming that. I never mentioned it in my review of your book, for example. This is a problem I have with Lee's writing on the subject.

As for the rest, I don't disagree with your last paragraph.

76. **DMS**
October 23, 2006

Aaron Bergman Says:
October 23rd, 2006 at 12:03 pm
You miss the point. This isn't about respecting what people are doing; it's about respecting the people.

While I appreciate the times you have clarified aspects of string theory on this blog(and I hope you get a faculty position soon…), I think you are way off the mark here. I have not read Lee's book, but nowhere on the blogs have I seen him be "disrespectful" to string theorists. On the other hand, there have been **numerous instances** on blogs where some(and no, not just LM) do not show the same courtesy to either Lee and **especially** Peter Woit.

And what I find bizarre is that neither of them are asking for string theory to be unfunded; they just ask for some other avenues of research to be funded. What is so wrong with this idea that gets some string theorists in apoplectic rage(when that could be directed to the "Rube Goldberg architects", for instance)???

Now I have copies of GSW, Polchinski, and Zweibach next to NEW on my bookshelf (I might even get the new Becker-Becker-Schwarz book IF it offers a new insight; getting bored with the same old discussion of the Polyakov action…). There is no contradiction. String theory has some astonishing successes and has offered some deep insights to mathematics(some of which I learn from this blog), even if it has failed miserably in its original goal.

On the other hand, one is always free to dismiss outsiders as “crackpots”…

77. **Aaron Bergman**
October 23, 2006

Courtesy and respect aren’t the same thing, and I should probably leave it at that.

78. **Lee Smolin**
October 23, 2006

Dear Aaron,

I don’t say that the people who are not working within the incentives you describe are better. I say only that the contributions of such people have from time to time been essential for the progress of science, and that this is one of those times. I do not see how an argument for greater diversity in academia is an argument against anyone. And I agree with Peter, there are a few people doing great work in ordinary QFT who are both visionary and unapreciated, and these are in the same category I called “seers.”

I do take your complaint seriously as I do think that respect among people who disagree is essential for science to work. I apologise if you feel disrespected as this was the opposite of my intention. It was rather to bring attention and appreciation to a kind of scientist who is often disregarded and disrespected. I am sorry if this had the unintended effect of making you feel disrespected.

While we are talking about disrespect, I hope you agree that to call serious scientists “crackpots” and to spread wrong information about their books without reading them, is outside of the bounds of acceptable professional behavior? No one is obligated to read a book or paper or comment on one, but if you do comment on a publication you have an obligation to have read it first. Do you agree?

Thanks,

Lee

79. **Aaron Bergman**
October 23, 2006

I do not see how an argument for greater diversity in academia is an argument against anyone.

As best I can tell, you think that there are different sorts of people and that we need to find these out of the mainstream people and anoint them with positions to do their out of the mainstream things. In contrast, I think there are lots of smart people, and we need to broaden the mainstream that they work in. In particular, it would be nice to find a way to make it safer to work on longer term projects with less a probability of success. I just don’t think it’s an easy thing to do.

As for the issue of respect, it has little to do with your attempts to “bring attention and appreciation” to other sorts of scientists. Without your book in hand, I can’t get into too much detail, but you could read this for a little example of what I’m thinking about.

And, finally, I think you’ll agree that a tit for tat on who is disrespecting who else the most is hardly productive. As for myself, I did sit down and read a fair chunk of your book.

80. **Chris Oakley**
October 23, 2006

Re: Lee’s article linked by Aaron above.

I was enjoying it until I read about the need for background independence. In particular, this:

> Meanwhile, many of those who continue to reject Einstein’s legacy and work with background-dependent theories are particle physicists who are carrying on the pragmatic, “shut-up-and calculate” legacy in which they were trained. If they hesitate to embrace the lesson of general relativity that space and time are dynamical, it may be because this is a shift that requires some amount of critical reflection in a more philosophical mode.

… which seems to ignore the fact that there are several orders of magnitude between the levels of experimental verification for SR and GR.

I have to say that criticism of String Theory will be seen as more legitimate if it is not combined with an advertising campaign for a particular alternative.

81. **egbert**
October 23, 2006

Aaron said, about Lee:

> As best I can tell, you think that there are different sorts of people and that we need to find these out of the mainstream people and anoint them with positions to do their out of the mainstream things. In contrast, I think there are lots of smart people, and we need to broaden the mainstream that they work in.

I think a part of the problem is that there is disagreement about what counts as mainstream. It was once the case that, for something to be mainstream science, it had to satisfy the usual conditions of making predictions and so on. Now string theorists have not yet made a prediction from string theory but hope to, and they insist, forcefully, that what they are doing is mainstream (without saying what the new criteria for mainstream science are), and are quite explicit about the fact that they do not regard any other approaches to quantum gravity as mainstream.

82. **Kris Krogh**
October 23, 2006

Lee wrote:

“Some of the people I am referring to … believe the current conceptual framework requires revision. For example they may see the necessity of first altering the foundations of quantum mechanics or obtaining a conceptually and mathematically consistent understanding of what an observable is in GR.”

It’s also possible the foundations of GR may need modification to agree with quantum mechanics. I agree with Chris Oakley that GR is not so well tested, and it hasn’t been shown the world is background independent. I predict the results from Gravity Probe B will shed some light next April.

83. **Aaron Bergman**
October 23, 2006

I clarified what I meant by ‘mainstream’ there in the sentence right after the ones you quoted.

Nobody working in quantum gravity has made any prediction, so perhaps it’s all out of the mainstream by your thinking.

84. **Kris Krogh**
October 23, 2006

    Aaron,

    There are two predictions here: http://arxiv.org/abs/astro-ph/9910325

85. **egbert**
October 23, 2006

    Aaron,

    Thanks for making references to my thinking. The sentence you say provides a clarification of what you mean by mainstream is:

    > In particular, it would be nice to find a way to make it safer to work on longer term projects with less a probability of success.

    Less than what? Longer term project than what?

86. **jeremy**
October 23, 2006

    On the way back from a recent trip to Cambridge, MA, sitting next to me on the plane was a middle age lady reading NEW. Curious, I made an effort to start a conversation. A friendly chat revealed that she was going home after visiting her child who is studying physics in one of the universities in Cambridge. Her child is planning to go to graduate school for theoretical physics and now is very worried what to do after reading the “black book” and the “blue book” (her own words, it took me a few seconds to realize what she meant, but not before she pulled out the “blue book” from a bag). As a mother, she wants to find out the details that made her child worry, although she knows little about physics. Is there a “war”? I don’t know. For a brief moment, I could almost smell gunpowder. As for the rest of my trip, it was very pleasant indeed.

87. **Kea**
October 23, 2006

    Jeremy

    You should have told the lady that it couldn’t possibly be a *better* time to go into Theoretical Physics, with so many great ideas in development.

88. **Chris Oakley**
October 24, 2006

    I have “The Elegant Universe” and “Not Even Wrong” next to each other on my bookshelf. I have surrounded the bookcase with detectors in the hope of seeing some interesting new quark states when they annihilate. Unfortunately, though, nothing yet has happened. I wonder if this is because I did not actually pay for Brian Greene’s epic, having got it as a present?

89. **Thomas Larsson**
October 24, 2006

    Is there a “war”? I don’t know.

    It is the third string revolution.

90. **Ari Heikkinen**
October 24, 2006

    Well, if anyone read that piece by Brian Greene, he’s pointing out the same things he’s wrote in his books and other pieces (and I apologize for the quotes in advance, but I feel I can’t make my point without posting them here, so I’ll make them short) like:

    “Nevertheless, mathematical rigor and elegance are not sufficient to demonstrate a theory’s relevance. To be judged a correct description of the universe, a theory must make predictions that are confirmed by experiment.”

    and

    “Nonetheless, should an inconsistency be found, or should future studies reveal an insuperable barrier to making contact with experimental data, or should new discoveries reveal a superior approach, I’d change my research focus, and I have little doubt that most string theorists would too.”

    Now, I’ve read again and again from some critics accusing that the advocates plain “lie” about the theory and some even claim they “falsify its results” to keep it going, but atleast of what I’ve read of the more prominent figures over the years they’ve basicly gone along Brian’s lines here.

    And I also tend to agree with this:

    “But to suggest dropping research on the most promising approach to unification because the work has failed to meet an arbitrary timetable for complete success is, well, silly.”

    I think both the advocates and the critics (atleast the sensible ones) are right on atleast the points that other research shouldn’t be abandoned in the name of string theory and also that it would be silly to abandon all that tens of years of promising research on string theory simply because the work hasn’t met some arbitrary timetable.

    I guess some progress is made when the fiercest critics and the foremost advocates can atleast respectfully disagree without calling eachothers crackpots. Now, if they could just go on with their research and start writing interesting papers again to prove their points would be even better.

91. **Tony Smith**
October 24, 2006

    After downloading and listening to George Johnson’s KITP talk about the books of Peter Woit (“Not Even Wrong”) and Lee Smolin (“The Trouble With Physics”) at http://online.itp.ucsb.edu/online/resident/johnson2/ the following excerpts (transcribed from my hearing, with George Johnson denoted by "Johnson" and various audience members denoted by "KITP" because I am not sure of the various audience voices) seemed to me to be interesting:

"…
Johnson – I don't think anyone would call Lee Smolin a crackpot.

KITP – … Would you like to take a vote on that? …

Johnson – Did you read the books?

KITP – Me? No. No.
…
KITP – I think that what bothers me is that people in the media are reading these books and thinking that what's in them is true. …

Johnson – I think that you should read at least one of the books.
…
KITP – You know, if you know Lee [Smolin], it's because he wants our money. It's because he doesn't have it that he wants to cut us down. …

KITP – It is clear that a lot of people are upset with ths book and feel damaged by it. …

KITP – these criticisms … the ones that are correct are the ones that are "of issue" that are being discussed within our community.
That [blog] is really not the right forum or the right set of antagonists to discuss … the problems we face in the current stage of string theory
so
I still think that the right attitude is not to engage in this kind of blog war … or public debate with marginal figures. …".

It is striking to me that:

1 – The KITP superstringers regard debate about superstring theory, NOT as a debate about physics, but as a fight over money;

2 – The KITP superstringers regard the funding they receive as "our money",
when in fact all their USA government support is taxpayer money, and therefore is as much my money as it is theirs;

3 – The KITP superstringers concede that some of the criticisms are "correct"
but
they say that even "correct … criticisms" should be discussed ONLY "within our community"
and
should NOT be discussed in blogs or public debate with "marginal figures";

4 – The KITP superstringers describe even well-credentialled people such as Peter Woit and Lee Smolin as "marginal figures"
(perhaps in the eyes of KITP superstringers everybody outside "our community" is "marginal").

I will leave it to readers (perhaps even some with Congress/NSF/DOE influence) to draw their own conclusions from the above statements coming directly from the mouths of the KITP superstringers.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

92. **TheGraduate**
October 24, 2006

Tony,

This is a horrible transcription and very, very inaccurate. I strongly suggest to anyone that reads this to be aware that these are isolated quotes from different speakers.

I do want to stress that the spirit of the conversation is accurate in my opinion but the combined effect of representing several speakers as one speaker and omitting large amounts of the conversation both within quotes and between quotes is to render the whole transcription a gross distortion of what actually occured.

Your inclusion of "…" just does not do justice to the huge swathes of conversation between some of the quotes.

93. **Tony Smith**
October 25, 2006

TheGraduate says that, in my comment 91, I was "… representing several speakers as one speaker …".

That is NOT true.
I explicitly said that my transcription was with
"… various audience members denoted by "KITP" because I am not sure of the various audience voices …".
Further,
each line beginning "KITP" contained excerpts from a single speaker.

It is true that I did not quote the entire hour-long talk, but I DID include a link from which the entire hour-long talk can be downloaded by anyone interested in hearing the exact context of each excerpt.

i am happy that it is the opinion of TheGraduate that, from my comment 91, "the spirit of the conversation is accurate".

As to whether or not the excerpts I quoted "render the whole transcription a gross distortion of what actually occured", I leave it to the readers to download the entire talk and decide for themselves,
bearing in mind that my stated purpose was NOT to transcribe the entire talk, but only to list some "excerpts" that "seemed to me to be interesting" and to comment on them.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – If TheGraduate, or anyone else, can identify each of the various KITP audience members that I denoted by KITP, please feel free to do so. I would be interested in knowing who they are.

94. **TheGraduate**
October 25, 2006

    My point is really just that bad quotes leave people with wiggle room later.

95. **Tony Smith**
October 29, 2006

    Lubos Motl, in his “take… on the KITP video” posted yesterday (28 Oct 2006), said:

    “… David Gross and other famous physicists …[hold an]… opinion [that] is a qualified extrapolation of the old good times in which the foes of science were irrelevant, an era in which the enemies of well-established physical theories … could be humiliated or ignored by the scientists, according to the scientists’ choice.
    But if you listen to David Gross more carefully, you can tell that he is not so certain that his assumption continues to hold.
    We arguably live in the first decade of the human history in which … online technologies including the blogosphere have made …[the failure of his assumption]… possible. …”.

    It is interesting to me that:

    1 – Lubos considers that it would be “good” if “enemies of well-established physical theories … could be humiliated or ignored by the scientists”; and

    2 – Lubos laments that “online technologies” make it difficult for “the scientists” to “humiliate… or ignore…”
    those who offer alternatives to “well-established physical theories”
    (and are therefore perceived by “the scientists” as “enemies”).

    Maybe that explains Lubos’s ad hominem attacks on physicists who don’t blindly follow the “well-established physical theor[y]” of superstrings (for example, calling the books by Peter Woit and Lee Smolin “the two slanderous books” and talking about “the intellectual dishonesty of the authors of the books collectively referred to as Swolin”, and calling me a “moronic crackpot”).

    Tony Smith
    http://www.valdostamuseum.org/hamsmith/

96. **woit**
October 29, 2006

    Tony,

    The funny thing here is that Lubos considers string theory to be a “well-established physical theory”. Thinking that one’s pet theory for which there is no scientific evidence is well-established physics sounds like crackpotism to me…

King of Infinite Space

Categories: Book Reviews

Back when I was a graduate student trying to figure out how to define and calculate topological charge in lattice gauge theory, at one point I went over to the math department to ask some people I knew if they had any idea about how to calculate the volumes of spherical tetrahedra. I was taken to the math department lounge to consult with the master of 3 dimensions, Bill Thurston. Thurston explained to me that this could be done by breaking the tetrahedra into "double-rectangular tetrahedra", whose volumes were then expressed in terms of the angles defining them using something called Schläfli functions, defined back in 1860. This experience helped cure me of my prejudice that modern mathematicians were probably ignorant of the older more concrete mathematics of the 19th century.

Thurston also pointed me to a more modern reference for this, a paper by H.S.M. Coxeter from 1935 entitled The Functions of Schläfli and Lobatschefsky. I ultimately found a much simpler way of computing topological charges, but I always wondered about this early 20th century mathematician, whose parents had given him a set of initials reminiscent of a British naval vessel. Later on in life, I learned a bit about some important algebraic constructions called Coxeter groups, and also heard that there was an active mathematician in Toronto named Donald Coxeter. I assumed that there were at least two and maybe three mathematicians named Coxeter out there, perhaps relatives.

It turns out that these are all the same Coxeter (the M. is for MacDonald), and there's a very nice new biography of him that has recently appeared, writtten by Siobhan Roberts and entitled King of Infinite Space. Coxeter only died quite recently, in 2003 at the age of 96, and Roberts was able to get to know him while writing the book. It contains a wealth of information about pieces of mathematical history I was not aware of, often buried in the very extensive footnotes.

Coxeter's main interest was in "classical" geometry, the geometry of figures in two and three dimensional space and he wrote a very popular and influential college-level textbook on the subject, Introduction to Geometry. Much of this subject can be thought of as group theory, thinking of these figures in terms of their discrete symmetry groups. This subject has always kind of left me cold, perhaps mainly because these groups play little role in the kind of physics I've been interested in, where what is important are continuous Lie groups, both finite and infinite-dimensional, not the kind of 0-dimensional discrete groups that Coxeter mostly investigated.

One theme of the book is to set Coxeter, as an exemplar of the intuitive, visual and geometric part of mathematics, up against Bourbaki, exemplifying the formal, abstract and algebraic. Bourbaki is blamed for the New Math, and I certainly remember being subjected by the French school system in the late sixties to an experimental math curriculum devoted to things like set theory and injective and surjective mappings. On the other hand, I also remember a couple years later in the U.S. having to sit through a year-long course devoted to extraordinarily boring facts about triangles, giving me a definite sympathy for the Bourbaki rallying cry of "A bas Euclide! Mort aux triangles!". To this day, both of these seem to me like thoroughly worthless things to be teaching young students.

Actually Bourbaki and Coxeter ended up having a lot in common. They both pretty much ignored modern differential geometry, that part of mathematics that has turned out to be the fundamental underpinning of modern particle physics and general relativity. Coxeter's most important work probably was the notion of a Coxeter group, which turns out to be a crucial algebraic construction, and ended up being a main topic in some of the later Bourbaki textbooks. A Coxeter group is a certain kind of group generated by reflections, and Weyl groups are important examples. Coxeter first defined and studied them back in the 1930s, part of which he spent in Princeton. Weyl was there at the same time giving lectures on Lie groups, and used Coxeter's work in his analysis of root systems and Weyl groups.

Coxeter groups and associated Coxeter graphs pop up unexpectedly in all sorts of mathematical problems, and Roberts quotes many mathematicians (including Ravi Vakil, Michael Atiyah and Edward Witten) on the topic of their significance. There are quite a few places where one can learn more about this. These include various expository pieces by John Baez (see for example here, based to some extent on this), as well as a web-site set up by Bill Casselman. The AMS Notices had an interesting series of articles about Coxeter and his work, written shortly after his death. The proceedings of a recent conference at the Fields Institute in Toronto entitled The Coxeter Legacy – Reflections and Projections have recently been published. In a couple weeks there will be a special program in Princeton about Coxeter, aimed at the general public.

One reason I'd started reading the book about Coxeter was to get away from thinking about string theory, but this was definitely not a success, since the book contains a rather extensive discussion of string theory. Coxeter was aware of string theory, it seems it reminded him of Jabberwocky, and he's quoted as follows:

It's like reading about a part of mathematics that you know is beautiful, but that you don't quite understand. Like string theory. That's as much a mystery to me as it is to anyone else who can't make head nor tails of the eleventh or sixteenth dimension.

Roberts quotes Witten (who she says is known as the "pope of strings") about the possible relevance of Coxeter groups and E(10) to string theory. She describes string theory in somewhat skeptical terms:

But rumblings are that if a bigger breakthrough doesn't occur soon, and in the form of streams of empirical evidence, string theory will at best be a branch of mathematics or philosophy, but not part of physics.

She quotes Amanda Peet as proposing that string theory become "a faith-based initiative", and Susskind as "There's nothing to do except hope the Bush administration will keep paying us."

Update: Siobhan Roberts has set up a web-site for the book, and she tells me that she'll soon be starting up a blog there.

Update: There's a very good expository paper by Igor Dolgachev that discusses Coxeter groups, and generally the way reflection groups appear in algebraic geometry.

Comments

1. **Thomas Love**
   October 19, 2006

   It is hard to get away from the topic of string theory, it pops up in the most unexpected places, like the comic page of the Times. But then, perhaps the comic page is where string theory belongs.

   Thanks for the review, I'll have to look up the book.

2. **Xerxes**
   October 19, 2006

   Your comment about spherical tetrahedra reminded me of a project I worked on where I needed to find the volumes of convex 3d polyhedra and 4d polytopes. I know how to work out simplex volumes and arbitrary convex 2d polygons, but I searched the literature for a long time on the higher-dimensional problem and never came up with anything. Eventually I resigned myself to estimating them using Monte Carlo techniques. Maybe somebody knows a better solution?

3. **D R Lunsford**

October 19, 2006

I remember reading "Regular Polytopes" as a kid and discovering empirically a fact about the Platonic solids. I was eating a lot of Dannon Yogurt at the time – the container was environment-friendly wax paper which however was rather weak. To strengthen the top, a circular cardboard disk was inserted. I pried out a bunch of these identical disks and used them to make the five solids by inscribing regular polygons in them etc. In the end, each face of each solid thus could be inscribed in the same circle. When I set them on my desk, I noticed that they paired up in altitudes, the cube and octahedron having the same altitude, likewise the icosahedron and the dodecahedron, while the tetrahedron was paired with itself, being self-dual! I went on to prove this little factoid by brute force. I often wondered if a simple proof could be had. I always thought Coxeter would have been delighted by that.

-drl

4. **Ben Recht**
October 19, 2006

Xerxes,

Surprisingly, Monte Carlo techniques are your best bet for high dimensions. Computing the volume of polytopes is #P-Hard.

http://en.wikipedia.org/wiki/Sharp-P

On the other hand, there are Monte-Carlo techniques that yield approximations to the volume in time polynomial in the dimension. See

Simonovits, M. "How to compute the volume in high dimension?" Math. Program., Ser. B 97: 337–374 (2003)

for a survey and lots of references.

Cheers,
Ben

5. **D. Eppstein**
October 19, 2006

One point I found odd in the book's discussion of the Coxeter-visual-geometry vs Bourbaki-formalist-algebra dichotomy was that it seemed to be placing Hilbert on the formalist side. The author of Geometry and the Imagination, an enemy of visual thinking in geometry?

6. **D R Lunsford**
October 19, 2006

Eppstein – yes, absolutely. Courant in fact to some degree rebelled against his teacher Hilbert. Hilbert once said "physics is too hard for physicists" – this was the beginning of a bad trend in math/physics, that Courant lamented in later life. Hilbert believed in axiomatics – Courant, like Weyl, had a more metaphysical approach and did not like drawing fine lines between the subjects.

-drl

7. **Alexandre Borovik**
October 19, 2006

Yes, I agree that Bourbaki and Coxeter ended up having a lot in common. The treatment of Coxeter groups by Bourbaki (N. Bourbaki, Groupes et Algebras de Lie, Chap. 4, 5, et 6. Hermann, Paris, 1968.) is perhaps the best written chapter in his treatise (it even contains an illustration!). It was written by Pierre Cartier; a very revealing account of his work on the text is given in his interview:

M. Senechal, The continuing silence of Bourbaki—An interview with Pierre Cartier, June 18, 1997. The Mathematical Intelligencer 1 (1998) 22–28.

8. **Steven H. Cullinane**
October 19, 2006

Another Weyl-Coxeter connection is furnished by the *quincunx lattice*. See "For Sir Thomas Browne" and "Geometry's Tombstones."

9. **Steve**
October 20, 2006

What's E(10)? I thought there was only E(6), E(7) and E(8).

10. **Tony Smith**
October 20, 2006

A web page at http://planetmath.org/encyclopedia/NicolasBourbaki.html says in part:

"… Once Bourbaki had finally finished its first six books, the obvious question was "what next?". … Pierre Cartier was working with Bourbaki … Its second series … consisted of two very successful books :
Book VII Commutative algebra
Book VIII Lie Groups
… Bourbaki was now becoming involved in a battle with its publishing company over royalties and translation rights. The matter was settled in 1980 after a "long and unpleasant" legal process, where, as one Bourbaki member put it "both parties lost and the lawyer got rich" …
In 1983 Bourbaki published its last volume : IX Spectral Theory. …".

I am sad that Bourbaki did not continue. As Alexadre Borovik said, Book VIII Lie Groups contained some of the best material by Bourbaki, and it would have been nice to have seen further development of such material described by Bourbaki.
Maybe such further description might have shown clearly how, as Peter said, "… Bourbaki and Coxeter …[had]… a lot in common …".

It is interesting to me that the law of "intellectual property" had a role in the end of Bourbaki.
It reminds me of a legal conference (in the 90s) in which an audience member said to a panel something like "the internet is a medium for free exchange of ideas", whereupon a panel member (corporate lawyer) said "Corporate interests are taking over the net and anarchists like you will be put down".

Tony Smith

11. **Aaron Bergman**
October 20, 2006

What's E(10)? I thought there was only E(6), E(7) and E(8).

Add two dots to your Dynkin diagram and hope for the best. You get an infinite dimensional Kac-Moody algebra which seems to be related to the compactification of M-theory down to one dimension on a T^10. This looks like an introduction.

12. **Thomas Larsson**
October 20, 2006

E(10) is not just infinite-dimensional, but **very** infinite-dimensional (of exponential growth). This makes it quite untractable mathematically, unlike the affine Kac-Moody algebras which only are of polynomial growth. To quote Victor Kac:

"It is a well kept secret that the theory of Kac-Moody algebras has been a disaster."

13. **Curious minds want to know**
October 20, 2006

That Amanda Peet?? http://www.adoring.net/amandapeet/

14. **Steve Myers**
October 20, 2006

A note on volumes in many dimensions: Hamming has an amusing proof (in "Numerical Analysis for Scientists & Engineers") that as dimensions increase, volume goes to the surface.

15. **h**
October 20, 2006

Xerxes:

You can subdivide any convex polytope to simplicies. There are trivial and not-so-trivial algorithms to do that, which are easy to find in the literature. 3 or 4 dimensions is low enough, so this should be fast, and also gives exact results (for rational polytopes).

16. **Fabien Besnard**
October 20, 2006

About the new maths and triangles : I've also been exposed to both, since i was about 10 at the end of the new math era, and had a teacher in high school that was in love with triangles (I suspect he had an affair with the Euler line). I did not find this boring at all, and both were very useful in learning rigour and the joy of discovery. As a child I remember a day when our teacher showed us how to count in the octal and binary systems. It was really exciting. In high school there was nothing more thrilling to me than working on a geometric problem for the all week end. Later, the French education changed and they got rid of both the new maths and almost all of elementary geometry. I had to teach in a high school for four years : now everything is more practical and "useful", less abstract… and so damn boring !

17. **D R Lunsford**
October 20, 2006

Curious, no this one.

-drl

18. **Andy**
October 20, 2006

(OT: There's an Op-Ed on ST by Brian Greene in today's NYT.)

19. **Tony Smith**
October 20, 2006

Peter says "… Siobhan Roberts … quotes Amanda Peet as proposing that string theory become "a faith-based initiative" …".

However, on her web page cited by D R Lunsford, Amanda Peet herself says:
"… I study … the fundamental dynamics of quantum gravity … using string theory …
Thus far, significant progress has been made … [i]n the search for string theoretic mechanisms for resolution of spacetime singularities. …
I will also be very interested to see how new ideas about the Landscape may inform the old question of vacuum selection in string theory …".

Peet's web page says that it was "Last updated: 2006/09/22", so it seems to me that it is probably a current statement of her views, and not an out-dated web page containing stuff about which she has changed her mind.

Since I think that Peet herself is more likely to give an accurate description of her own opinions than a third party, it seems to me likely that
Roberts has substantially distorted Peet's view of string theory,
and
that makes me very skeptical about the accuracy of other statements made by Roberts.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Maybe my opinions above are affected by my opinion of some journalists (the Amazon page says "Siobhan Roberts is a journalist"), which is exemplified by an interview of Joe Namath shortly after he became a New York Jet. A reporter asked him if, at the University of Alabama, he had majored in basket-weaving. Joe replied: "No, basket-weaving was too hard, so I majored in journalism."

20. **Peter Woit**
October 20, 2006

Tony,

The quote from Amanda Peet was clearly a joke by her.

Andy,

Maybe I'll add a couple comments about Brian's op-ed to the previous posting.

21. **LDM**
October 20, 2006

(OT: There's an Op-Ed on ST by Brian Greene in today's NYT.)

The interesting thing about this letter, is, that in another 20+ years, Briane will be able resubmit it to the NYT almost verbatim.

22. **Siobhan Roberts**
October 20, 2006

Tony,

Yes indeed, Amanda Peet has a good sense of humour. She made the comment at the Strings '05 conference in Toronto at a public session on "The Next Strings Revolution," which was dubbed as an "airing of our dirty laundry" session— downloadable proceedings are available at the Fields Institute website, http://www.fields.utoronto.ca/programs/scientific/04-05/string-theory/strings2005/, though if memory serves I don't believe Peet's comment, which was made during the Q&A afterward, was included on that recording. Her comment, and the jocularity of the event in general, was nicely covered by Dennis Overbye in the NYT Science Times, "Lacking Hard Data, Theorists Turn to Democracy," August 2, 2005 — http://select.nytimes.com/search/restricted/article?res=FA0E10FA355B0C718CDDA10894DD404482

As far being a journalist goes, accurate observation, documentation, and portrayal of events — as with science — is of utmost importance!

Best,
Siobhan

23. **DT**
October 20, 2006

How, in a group this nerdy (in a good way) could you mention Lobatschefsky in the post and have nobody comment on the eponymous Tom Lehrer song? Here's a link for the lyrics: http://members.aol.com/quentncree/lehrer/lobachev.htm

If you don't know the song, you should. NB: same guy, different spelling.

24. **Siobhan Roberts**
October 20, 2006

There is also a Lehrer song about the Bourbaki-inspired New Math!

http://members.aol.com/quentncree/lehrer/newmath.htm

25. **Tony Smith**
October 20, 2006

Siobhan and Peter,
my apologies for being too dense to realize that Peet's "faith-based initiative" remark was merely a joke intended to reflect her true views.
In light of that, I will consider Siobhan to be one of the (all-too-few) good-guy journalists,
and
not in the class of "some journalists" such as the Joe Namath interviewer (and all-too-many of the partisan talking-heads on TV "news").

As a concrete manifestation of my changed opinion, I have ordered a copy of "King of Infinite Space", and Amazon says I should get it on Monday.

A question:
Could a student today get a PhD and a job (and grants) by following in Coxeter's footsteps ?

If so, would the student's success be more likely:
1 – by working in string theory physics ?
or
2 – by working in a pure math department ?
or
3 – by some other path (if so what)?

If not,
does that mean that it is now unlikely that we will see any more ideas that are as out-of-mainstream as Coxeter's have sometimes been considered ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

26. **Tony Smith**
October 20, 2006

typo correction:
In my previous post
"… merely a joke intended to reflect her true views …"
should have been

"… merely a joke NOT intended to reflect her true views …".

My apologies again.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

27. **Siobhan Roberts**
October 20, 2006

Tony,

That's an interesting question. A number of people remarked when I was researching the book (and I may or may not have included it, can't recall) that Coxeter's students, all very talented mathematicians (Willy Moser, Asia Ivic Weiss, Barry Monson, Chris Fisher, to name a few), have not approached anything near Coxeter's stature. And Coxeter's position at the UofT was not filled with a "pure geometer" when he retired — and you'd think if anywhere, then there. Coxeter was one of a kind in many ways. But I'd be inclined to say 1) or 3), and I'm not sure what form the the latter category would take — perhaps a computer animation scientist at Pixar, or a mathematician in residence at Microsoft or At&T (and in that, their Coxeterian interests might take the shape of a nicely subsidized sideline for the most part, occasionally breaking through with an application). I talk about this in part two of the book, discussing where Coxeter's style of classical geometry pops up in "modern" and applied contexts. Hope you enjoy it!

Siobhan

28. **Siobhan Roberts**
October 20, 2006

Addendum:

Re 2) can Coxeterian geometers finding positions in pure math depts: John Conway at Princeton is in many ways considered Coxeter's spiritual successor as a geometer, in terms of the breadth and depth of his interests and work, and then there's the aforementioned Bill Thurston at Cornell. Many "Coxeterian" geometers find positions in math depts, but the nature of Coxeter's classical geometery, so to speak, has transcended its origins in terms of current research paths.

Siobhan

29. **yasir**
November 3, 2006

Its not the mutha-string – its the cosmic humor you seem to be striking upon repeatedly that is at the bottom of everything, and keeps everything going !

bravo.

The Hype Goes On

October 23, 2006
Categories: Uncategorized

The Ottawa Citizen today has an Op-Ed by string cosmologist Jim Cline, headlined The Big Idea That Won't Die, with a subtitle "The fact that string theory is suddenly under attack only underscores its success as a path to a unified description of nature." There's a lot that it outrageous about this piece, beginning with the subtitle. Normally scientists don't start going on about the success of their theories until they have some experimental evidence for them.

Most outrageous are Cline's claims that Smolin's book and mine are written in a "defamatory style", and are "slandering" string theory. Since he gives no evidence for either of these claims, there's not much to say about them except that they're defamatory and slanderous.

Cline makes the standard claim that string theory should be accepted since it has legitimately triumphed in the marketplace of ideas, while clearly being rather upset about the success that critics of string theory have recently been having in this same marketplace. Somehow, overhyping string theory is a legitimate marketplace activity, pointing out its problems is not.

He makes many of the by now standard bogus claims about supposed predictions and tests of string theory. At some point I suppose I should write a FAQ about these, since the string theory hype machine keeps promoting these things in a less than honest way to a public that is not well-equipped to see through the hype. Here's a pretty complete list of the bogus "predictions"

String theory predicts supersymmetry and extra dimensions. The LHC will test these predictions.

The problem is that there is no prediction of either the scale of supersymmetry breaking or the size of the extra dimensions; in string theory these could be anything. All we know is that the energy scales involved are at least a TeV or so, since otherwise we'd have seen these phenomena already. There's no reason at all to expect the extra dimension scale to be observable at the LHC, even most string theorists think this is highly unlikely. There is a standard argument that the hierarchy problem could be explained by a low supersymmetry breaking scale, but this is already starting to be in conflict with the lack of any observations of effects of supersymmetry in precision electroweak measurements, and now string theorists seem very willing to say that supersymmetry may be broken at an unobservably high scale.

String theory predicts observable effects in the CMB or gravitational waves.

If you look into this, this is based on very specific cosmological scenarios such as brane inflation, and again string theory doesn't tell you even what the energy scale of the supposed predictions is. Undoubtedly you can get "predictions" from specific models, once one chooses various parameters, but not observing these "predicted" effects would not show that string theory is wrong but just that a specific scenario is wrong, with many other possible ones still viable. There's a new review article by Henry Tye where he claims that "string theory is confronting data and making predictions", which isn't true. It is only certain specific scenarios that he has in mind, he admits that other, equally plausible, scenarios (such as using not branes but moduli fields as the inflaton) make no predictions at all. For more about this, one can watch recent talks by Tye and Polchinski at the KITP.

The anthropic landscape predicts the value of the cosmological constant and will make other predictions.

The latest contribution to the anthropic landscape hype is from Raphael Bousso and is entitled Precision Cosmology and the Landscape. I've written many times about the problems with the cosmological constant "prediction". Bousso claims that "there is every reason to hope that a set of 10^500 vacua will yield to statistical reasoning, allowing us to extract predictions". He doesn't give any justification at all for this, neglecting to mention arguments about the inherent computational intractability of this question, and the failure of the program to try and predict the answer to the one question that seemed most likely to be approachable: is the supersymmetry breaking scale low or high?

String theory makes predictions testable at RHIC.

There are lots of problems with this, but the main one is that the "string theory" involved is a different one than the one that is supposed to unify particle physics and quantum gravity.

Update: For more promotional material about string theory, you can buy a set of lectures by Jim Gates entitled Superstring Theory: The DNA of Reality. I haven't seen the videos, but Gates is probably not indulging in the kind of claims about "predictions" of string theory being made by many others.

Update: A couple people have pointed out that a new paper has appeared pointing out that the one "prediction" of the landscape claimed by Susskind, that of the sign of the spatial curvature, isn't sustainable. This issue was discussed here with Steve Hsu, who was blogging from a conference where Susskind made that claim, and wrote about it in more detail here. Hsu is one of the co-authors of the new paper.

Update: There's a rather critical review of Lee Smolin's book in this week's Science magazine by Aaron Pierce entitled Teach the Controversy! Somehow I suspect Pierce did not write the headline, since he doesn't seem to think much of opposition to string theory or that it is a good idea to encourage any dissent about it. In his review, he pretty much completely ignores the fact that string theory is supposed to be a unified theory, explaining the standard model as well as quantum gravity, discussing just the question of string theory as a theory of quantum gravity. This is rather odd since quantum gravity isn't even Pierce's specialty. I'm somewhat curious what he might think of my book, which is pretty much all about string theory's failure as an idea about particle theory.

Comments

1. **anonymous**
   October 23, 2006

   Cline correctly writes that (tenured) theorists can choose to work on the ideas that look more appealing. Maybe he could also explain why some theorists work on brane collisions: the idea of putting two perfectly parallel branes looks to me so childish (sorry, I cannot find a more polite word) that I never got interested in addressing its problems in getting inflation and problems in getting scale-invariant perturbations.

2. **Arun**
   October 23, 2006

   A FAQ is an excellent idea.

3. **hack**
   October 23, 2006

   Uh oh. Looks like another string theory "prediction" bites the dust.

http://arxiv.org/abs/hep-th/0610231

4. **M**
October 24, 2006

hack: interesting work, but you are too drastic; it just means that strings can now make statistical predictions for the sign of the curvature. (Just to be sure: this is a joke).

There is another interesting paper today: hep-th/0610231.

5. **AdamBalm**
October 24, 2006

Yeah, I'd second the call for an FAQ. It's a bit frustrating trying to bring this issue up with some people unfamiliar with the subject, and when they ask for more information or clarification, the best I can do is point them to this blog or tell them to read the book. So yeah, having it all in one place would certainly make it easier to introduce people to the current points of contention than expecting them to wade through hundreds of articles over the past year. (Not to mention it might force some other people to try and think up some fresh arguments for a change.)

6. **Chris Oakley**
October 24, 2006

> I suppose I should write a FAQ about these, since the string theory hype machine keeps promoting these things in a less than honest way to a public that is not well-equipped to see through the hype.

Great idea.

7. **r hofmann**
October 24, 2006

M,

that is, indeed, witty.

Peter,

FAQ is a very good idea. Maybe it is helpful to invoke simple parables to get the points across.

8. **LDM**
October 24, 2006

I agree with the FAQ idea.

I only wonder why Peter should have to waste his time doing this, when the string theorists themselves should be exercising the required level of scientific scrutiny and mentioning both the pro and con in their ideas.

If the FAQ could get permission to reprint Feynman's "Cargo Cult Science" essay– the antithesis to hype in my opinion — the layperson could have a first-rate understanding of what it means to be honest, as a scientist, in ones scientific claims.

9. **dark-matter**
October 24, 2006

Jim Cline writeup is a reasonable defense of ST. The good part is he didn't propose to redefine science in order to accommodate ST. He suggested a number of predictions to be tested by experiments. But he should know suggestions is very different from writing them up in a scientific paper in collaboration with the experimentists to specify meaningful prediction parameters. No such papers have appeared with regard to any experiments confirming or falsifying any claim of ST. The way ST have developed, no such papers will likely ever appear. Is Jim prepared to do another writeup proclaiming ST to have entered the realm of metaphysical religion?

10. **relativist**
October 24, 2006

Lubos Motl is back in the amazon.com reviews, thinly disguised as Non-String Physics Grad Student, complete with a series of fake endorsements of his review of Lee's book. He certainly has time on his hands. Interesting he classifies himself as a graduate student.

11. **woit**
October 24, 2006

relativist,

It doesn't sound to me like Lubos, who is not the only person with a very hostile attitude toward Smolin's book (and mine). The review reads to me exactly like what it purports to me, the work of a student who knows little or nothing about string theory.

12. **LDM**
October 24, 2006

I may be mistaken, but I don't recall Lubos showing knowledge of decoherence in QM…but perhaps it was off topic so just never came up.
It is quite true, as the grad student alludes to, that there is a body of research and experiment indicating that QM is now understood (contrary to the famous Bohr dictum to the contrary), using decoherence, and Smolin did not mention this in TTWP.

I concur that the grad student review seems legitimate.

13. **steve**
October 24, 2006

One point in this proposed FAQ that could be helpful would be to clarify the relationship between theories and models. I sometimes have trouble tracking the claims here– is the theory non-testable or incoherent and hence not even wrong, or is it falsified? It seems that some of the confusion here comes from mixing together claims about theories versus specific models within those theories.

Is it common in theoretical physics to insist on the testability of a theory, or is it OK, if less desirable, to be able to test specific models (or classes of models) within that theory? I bring this up because a theoretical framework or approach may be a fecund source or inspiration ("the context of discovery," as the philosophers say) for specific testable models, without itself being testable in toto. So is the claim: a) Individual models made of stringy components may be testable (and may have been falsified), but because there are zillions of such models you can't experimentally rule all of them out, b) No individual stringy model has ever been produced which is testable, or c) No testable individual stringy model CAN ever be produced? Each of these claims is distinct and has distinct implications.

In particular, if a) is the claim, then it might be reasonable for a theorist to say "String-type theory is the best idea I have for how to construct testable models that might explain quantum gravity (or whatever). I can't prove that some other starting point might not be a better place to start looking, but this is where I want to spend my time." If enough theorists agree with this point of view, it will look like string hegemony, but in this hypothetical case it would just be convergent individual judgments about research prospects.

On the other hand, if c) were the claim, sticking with strings would suggest serious problems with the field. And of course an unwillingness to consder alternatives seriously would also hinder progress.

I think of science as working like the stock market–in the short run it is a voting machine, but in the long run it is a weighing machine. My sense is that the critics of string theory believe that the voting period is extending well beyond the point where weighing should have determined the outcome. The string theorists don't agree, and the discussion is really about when to give up and why. I would find this discussion clearer if the theory/model distinction were more apparent.

14. **Lee Smolin**
October 25, 2006

To LDM: Decoherence is of course a real phenomena, and is mentioned briefly on p 252 of TTWP. While there are claims in the literature that it by itself solves the measurement problem this has, in the view of many experts, been shown wrong, indeed quite a long time ago, for example in papers of Abner Shimony. Decoherence does play a role in some formulations of quantum theory that address the measurement problem, for example the consistent histories approach. But I believe that I correctly characterized the situation in Chapter 1, which is that there is no consensus among experts as to whether any of the proposed interpretations or reformulations of quantum mechanics so far proposed are completely satisfactory. You can find arguments in the literature pro and con many different viewpoints and approaches. Had I represented one of them as a consensus view I would not have been accurately representing the field.

Thanks,

Lee

15. **Aaron Bergman**
October 25, 2006

For whatever it's worth, I agree with Lee on this point. Decoherence makes it a pain in the neck to figure out what on earth is going on with the quantum to classical transition, but it doesn't actually solve anything.

16. **a)**
October 25, 2006

Steve,

a) is true, and it is the big problem: it means that whatever we observe, among the 10^500 string models, 10^300 or so should be able of "explaining" it.

Presumably string theorists will try for a few years to study if the situation is so bad. Unless some good surprise will be found, anybody who wants to spend his time on this approach should put his 10^300 models in a big bag and move to a philosophy department.

17. **LDM**
October 25, 2006

Lee,

Yes, decoherence is even in the index in TTWP — I should have checked instead of trusting my memory. Sorry.
Also, thank you for the Abner Shimony reference. The book I am reading — "Decoherence and the Appearance of a Classical World in Quantum Theory" has 51 pages of references at the back , but I am unable to find Shimony mentioned at all. However, if you have a reference to the particular paper of Shimony that you are referring to, would you mind posting it? Thanks.

18. **steve**
October 25, 2006

a): If in fact a) is correct, then it's hard to argue that string theory is some sort of plague. It's just an urn into which some people are reaching hoping to draw out a black ball (testable and correct model) instead of a red ball (untestable or falsified model). Other people get to draw from other urns. My concern would be if the community somehow had different standards for what is black or red depending on which urn the ball came out of.

19. **Milan**
October 25, 2006

The absurd argument that the fact that idea X is criticized underscores its success is a bizarre form of scientific stalinism. In its original form, J. V. Stalin emphasized that the resistance of the capitalist class will increase as the march toward communist utopia goes on closer and closer to its perceived goal – and it was the major pretext for all purges in 1930s and 40s, with the tragic loss of millions of lives. Now, we here the same moronic nonsense invoked in defense of string theory!? I suppose the author of that nonsensical piece of propaganda also "predicted" that the criticism of stringy nonsense will also mount and increase in ferocity as the time goes on, offering even more "confirmation" to its successes, and so on, ad infinituum and ad nauseam.

20. **Derek Teaney**
October 25, 2006

Dear Peter,

I have been reading your blog for a bit and like it a lot. Regarding RHIC (which is my field) it is certainly true that the connection between the AdS/CFT correspondence and the actual experiment is very vague and wildly exagerated. However, the qualitative features of the kinetics of strongly coupled plasmas predicted by the correspondence are so wildly different from their perturbative counterparts, that if the QCD plasma were to behave anything like the AdS-Super Plasma there surely must be observable consequences at RHIC or the LHC. Hopefully someday we'll find a nice crisp observable which can probe these qualitative differences.

21. **Kea**
October 26, 2006

Interesting point, Derek. Do you have any handy references for AdS/CFT plasmas? I am actually working on this myself now.

22. **Peter Shor**
October 26, 2006

I would agree that the graduate student review is legitimate. I've had discussions with Lubos Motl on quantum mechanics which make me think that his views on decoherence and his objections to the book would be quite different than this reviewer. In fact, I'm quite sympathetic to the graduate student on this. While I don't think the quantum-to-classical transition is a solved problem yet, I expect that it will be solved through a more complete analysis of decoherence, unlike Smolin's other four problems, which are likely to need new physics for their solution.

On the other hand, since Penrose and 't Hooft side with Smolin on this one, I am nowhere near presumptuous enough to claim that any of them show a deep misunderstanding of physics.

23. **Bert Schroer**
October 26, 2006

Peter Shor
I don't think that decoherence can explain the process of factualization of potentiality, I think this remains outside present QM. What it can do is find an excuse which is sufficient for all practical purposes.

24. **Mike**
October 27, 2006

Hi Peter, just wondering if you'd seen this from a week ago.

http://online.itp.ucsb.edu/online/resident/johnson2/

25. **Peter Woit**
October 27, 2006

Mike,

There's a long discussion of it two posts back, the one on "The String Wars"

26. **Bert Schroer**
October 28, 2006

Of all the criticism of ST I find that of Phil Anderson the most penetrating.
Of course I 'have tremendous admiration for Peter's courage and I did not trust my eyes when several years ago I saw his critique on the lanl server. Lee's criticism had this important sociological component from the very beginning, this risk in his case was more to become an enemy of his former colleagues without desiring this role (as the director of an institute he did not suffer a direct career threat).
Not that there were no other critical minds; among my QFT colleagues I do not know any one who did not think of ST as freakish. But they have interesting projects and do not want to be sucked into controversies (especially since most of them have ST colleagues which, as Glashow at Harvard, they could not prevent the course of metaphoric physics). I myself belong to that class of cowards who only after retirement open their mouth.
But in the present situation in which we find our-self the criticism of Phil Anderson is the most fitting one. The hubris and prepotence state of mind as a result of the undeserved luck which led to discovery of the standard model is certainly the powerful combustion force which has brought us into the present mess. It would be very difficult for anybody to say this because it involves some of his Nobel colleagues and a field medal winner, but he can do it. It is a deep shame (and certainly be an issue for historians of science) that the particle physics community was unable to keep its house in order.
Of course neither Phil Anderson nor all those other critical minds have any illusions, there is nothing which can stop that collective madness, it just has to play out. This is not different from similar phenomena in the political realm, in fact some proponents of ST are at the same time apologist (or at least were) of the destruction of Iraq in the name of regime change and a new order of the near east (despite the many voices which predicted the present mess). Given the human nature, in both cases it has to play out to the bitter end. But it testifies to the power of human self-reflection to have articles as that by Phil Anderson.

27. **LDM**
October 28, 2006

The 'Non-String Physics Grad Student' review is gone from Amazon. It would be interesting to know if he has re-thought his views and so deleted the review himself, or whether Amazon removed it.

28. **egbert**
October 29, 2006

Re: factualization of potentiality. Of the people who believe that quantum amplitudes and wavefunctions represent information about the physical world (rather than representing physical states of affairs directly), nobody thinks there is a measurement problem, or anything unusual about collapse. As Heisenberg said, the world doesn't change discontinuously, but our information about it does.

On the other hand, of those who believe the opposite, namely that the quantum amplitudes and wavefunctions represent the actual state of affairs, everybody agrees that there is a problem which needs to be solved. Decoherence was presented as a candidate solution but most agree that it doesn't really help.

Over the course of the twentieth century, the number of physicists in the former camp has dwindled and the number in the latter camp has grown to include almost everyone. I asked Penrose, after a talk, about why he thought this had happened, and if he knew of any proof or argument implying that the view of the former camp was wrong (since he's firmly in the second camp along with almost everyone else). He said that he didn't know of any such proof but that the wavefunction "seems objective".

29. **Bert Schroer**
October 29, 2006

(This is probably not the right place, but perhaps Peter permits me to come to a closure with my previous somewhat sketchy remark)
The decoherence solves the problem for all practical purposes, but being within QM it cannot explain the closure of this process namely the irreversible factualization which happens at the moment of registration (which may be done by a machine).

30. **Christine Dantas**

October 29, 2006

Bert Schroer wrote:

(…) the irreversible factualization which happens at the moment of registration (which may be done by a machine).

Could you please elaborate? If Peter Woit thinks this is not the right place to continue the discussion, allow me to announce that I will be accepting guest posts to commemorate the [1 Year Anniversary of Christine's Background Independence] (refer to my last post over at my blog for instructions).

Best wishes,
Christine

31. **Bert Schroer**
October 29, 2006

Christine,
I think Peter will not mind a very short answer, since it comes with a citation of a lovely personal account of a giant of QFT, the creator of AQFT Rudolf Haag (which, I am sure, also Peter will read with great interest)
http://br.arxiv.org/abs/hep-th/0001006
there is also a whole section on factualization i.e. the conversion of potentialities (e.g. the process of decoherence) into events. Since irreversibility is outside QT, there is as yet no theory about it.

32. **Christine Dantas**
October 29, 2006

Dear Bert Schroer,

Thanks! Muito obrigada!

Christine

33. **Bert Schroer**
October 29, 2006

After that short excursion on factualization and the problem of reality from the perspective of QT, let me return to the main topic of this section: hype.
All my colleagues from QFT who know that framework of particle physics (say beyond e.g. the Peskin-Schroeder level) agree with me that holography from d+1 to d dimension is nothing else than changing the spatial encoding of a specified algebraic substrate which was given in the natural spacetime labeling of a d+1 spacetime to the labeling which associates naturally with its horizon (in the highly symmetric case of AdS one takes a brane at infinity). Of course physics depends not only on the substrate but also on its spacetime organization. It is a bit like stem cells which by encymes can be forced to organize in different ways (organs). Localization in QFT, independent of whether it can be physically realized (as in case of black holes) or just thought about (Localization in Minkowski spacetime a la Unruh), leads to thermal manifestations which are caused by vacuum polarization near the causal (or event) horizon. The Hawking effect is fully accounted for by quantum matter in a Schwartzschild spacetime. Any state which extends from the outside into the black hole will lead to Hawking radiation at the Hawking temperature (in particular the state which is invariant under the Killing motion). Nowhere in the existing derivation are gravitons or QG entering. Since the state is thermal, it has also an associated entropy. To compute that localization entropy, I have developed a formalism of holography on null-surfaces (which led to extended chiral QFT) which explains why the entropy follows an area law. This area behavior is totally generic and has nothing to do with Bekenstein. In fact one obtains a one-parametric family of entropies depending on the chosen thickness epsilon of the vacuum polarization "atmosphere". This family corresponds to the family of boxed Gibbs systems which one introduces to define the thermodynamic limit. Of course one can use Bekenstein's classical formula and equate it with this microscopically computed entropy to determine epsilon (I have not done this, but there can be no doubt that at this point the Planck length enters). The calculations are in two papers (the first one is published in CQG and the second has been submitted there)
http://br.arxiv.org/abs/hep-th/0507038
http://br.arxiv.org/abs/hep-th/0511291
The reason I did not do the calculation in curved space time directly for the Schwarzschild model is very simple: by doing it for double cones in Minkowski spacetime I have a chance to slip through the prejudice of a possible string referee who would immediately reject a calculation of black hole entropy because there is no use of QG but who does not mind to do some (in his mind irrelevant) calculation on the thermal manifestation of double cone localization in Minkowski spacetime.
The important application of holography to the AdS—CFT and its connection with ST hype will be explained tomorrow in a separate blog.

34. **Bert Schroer**
October 29, 2006

Addition
I forgot to highlight the most important lesson: the localization entropy which I compute is not a counting entropy. Counting entropies (QM-like level counting in a global QFT) contradict the principle of local covariance (mentioned in earlier blogs) and the same holds for the energy caused by localization through vacuum polarization. This is also the reason why no expert of QFT in CST (as e.g. Hollands and Wald) accepts the Weinberg kind of counting estimates for CC (those which led to those absurd values).
The mysterious connection of holography with QG process came through 't Hooft and it is interesting to note that Susskind in one of his first papers had the right intuition that holography has something to do with the lightfront. Since he was very impatient he never got beyond the old lightcone quantization which is contradictory and has to be replaced by the much more subtle lightfront holography. If he would have been more patient and careful he would not presently find himself stuck in that metaphoric lanscape trao from which he will never get away any more.

35. **Bert Schroer**
October 30, 2006

Here is the continuation:
As the null-surface holography is a change in the spacetime encoding of an algebraic substrate which is given in bulk form (explained in my previous blog), so is the AdS—CFT correspondence. In that case the change of the spacetime ordering-device is more gentle and has a unique inverse (without necessitating additional assumptions). This has been elaborated with great clarity by Rehren in a series of papers, including the demonstration that it agrees with Witten's version of a prescribed conformal source in a functional integral representation (to the extend that the artistic functional integral approach dan be used for proofs). I do not know any competent quantum field theorist who does not accept Rehren's work as the correct formulation of AdS—CFT holography (Hollands, Wald, Brunetti, Fredenhagen, Verch, Buchholz,….)
On the other hand the Maldacena conjecture alleges to address the AdS—CFT correspondence, but it burdens the AdS side with that vague 't Hooft idea of holography as

a consequence of QG (in Maldacena's case the QG attributed to ST) which it is not capable to carry.
As argued abobe this is not what holography can deliver, but since the computation is so vague (involving not only perturbation theory but also additional limiting assumptions), and there is no clear structural expectation on the AdS side, the ST people think that their computational massaging has supported whatever their conjecture is. One should say in addition that even their assumption that their SUYM is conformal has never been shown (apart from conformality it is not even clear that the beta-function vanishes in all orders, and in addition the N–>infinity limit is not really a QFT). We are seeing in front of us precisely that situation which Phil Anderson describes: the unmerited success of the SM has created an era of hubris and self-delusion fueled by two Nobel laureates and one Field medal winner (but if I may add even Nobel laureates would not be able to do this without the foot soldiers being ready for a new age physics). I would bet a case of good wine with any reader of this blog that the Maldacena conjecture will never be proved, it will just fade away as all conjectures coming from ST.
In a weird attempt to maintain the Maldacena construct Distler and Motl have ignited a conceptual stink bomb (using the truism that in applying theorems one has to check prerequisites) accusing Rehren of something which they and not Rehren committed. This is to burden holography with the requirement of producing a quantum gravity Fatah Morgana on the AdS side.
The metaphoric approach to particle physics will certainly continue (on Friday there was a paper where the conjecture is used as the bases for meta-metaphoric excursions into the blue yonder). There is nothing which can stop it, similar to things in the political era hubris has to play out all the way.

October 30, 2006

Smolin's post is full of misleading statements. For starters, he claims to mention decoherence in his book.

"Decoherence is of course a real phenomena, and is mentioned briefly on p 252 of TTWP."

This is completely misleading. He mentions decoherence in a context completely unrelated to quantum mechanics and measurements, and without any explanation whatsoever. The term decoherence appears as an offhand remark about particles propagating through spin networks. Sorry, but merely mentioning a word in a book just so that you can point to it in your index doesn't count.

Then, just to make clear to everyone why he doesn't understand quantum mechanics, Smolin says:

"While there are claims in the literature that it by itself solves the measurement problem this has, in the view of many experts, been shown wrong, indeed quite a long time ago, for example in papers of Abner Shimony. Decoherence does play a role in some formulations of quantum theory that address the measurement problem, for example the consistent histories approach. But I believe that I correctly characterized the situation in Chapter 1, which is that there is no consensus among experts as to whether any of the proposed interpretations or reformulations of quantum mechanics so far proposed are completely satisfactory. You can find arguments in the literature pro and con many different viewpoints and approaches. Had I represented one of them as a consensus view I would not have been accurately representing the field."

First of all, the papers he is referring to by Abner Shimony (from 1974) are deeply flawed and completely miss the point of decoherence. They prove a theorem that there will generally be cross terms in the final density operator for an experimental apparatus after a measurement takes place, and thus the experimental apparatus isn't a mixture of definite eigenstates corresponding to definite results.

Well, DUH! That completely misses the point of decoherence. In decoherence, there will certainly be cross terms. The point is that all cross terms have coefficients that go like ~e^(-t/tau) for some small rate constant tau, and thus go to zero exponentially fast. The cross terms aren't literally zero, but in an extremely rapid time interval (for an object like a table sitting in a room filled with air molecules, at time scale of order

37. **anonymous**
October 30, 2006

10^-43, which is essentially instantaneous since time scales that small don't really make sense anyway) the cross terms become completely undetectable by any other observer, directly or indirectly, and thus are really gone. If no other observer could ever even in principle distinguish between a density operator with such infinitesimal cross terms and a density operator without them, then you are pretty crazy to demand that they exist in any physical sense any more than invisible pink elephants.

Look, there are certainly issues when quantum mechanics is applied to the universe as a whole, to the big bang, etc. Quantum mechanics may need to be revised, extended, or replaced by a deeper, more general framework. But there are simply no remaining issues with quantum mechanics as applied to "every-day systems". And it's time physicists stop telling the public otherwise.

And no, I'm not Lubos.

38. **Bert Schroer**
October 30, 2006

anonymous
I cannot speak for Smolin, but I agree with you (see my contribution here before Christine); decoherence leads to a loss of phases for all practical purposes and hence solves the measurement problem fapp. However the event of observation (blackening of a photoplate, click in a counter) is irreversible (factualization) and QM (decoherence is part of QM) is reversible.

39. **Peter Woit**
October 30, 2006

I really wish people would take discussion of the foundations of QM elsewhere, it's off-topic, and definitely not something I want to moderate a discussion of here.

Anonymous,

I don't think you're Lubos, but you share some really obnoxious behavior with him (and you are at Harvard, what the hell has gotten into the drinking water there?). Your claim that Smolin "makes clear to everyone why he doesn't understand quantum mechanics" is just rude and idiotic. From my reading in this subject, the opinion that decoherence does not completely solve the interpretational problems of QM is a pretty conventional one among experts on this.

I don't happen to share Smolin's opinion that thinking about these foundational issues of QM is probably necessary to make progress on quantum gravity, but there are quite a few very prominent physicists who agree with him, and until the question of quantum gravity is settled it's definitely a valid position.

If you want to argue with Smolin about QM, find somewhere else to do it. You might also consider whether anonymously insulting people is really an acceptable thing to be doing, no matter what the circumstances.

40. **Eric Dennis**
October 30, 2006

Assuming this doesn't overtax Peter's patience with the digression, it ought to be mentioned that one of the very prominent physicists who would presumably agree with Smolin's opinion that foundational issues may be important for further progress in fundamental physics is the guy who first came up with the very idea of decoherence way back in 1952 (Phys Rev). That guy would be David Bohm. And he certainly did not think the mechanism of decoherence *by itself* could resolve the foundational problems in QM.

Prospects For a String Theory Phenomenology

October 24, 2006
Categories: Uncategorized

Yesterday at the KITP Michael Dine gave a very good survey talk on [Prospects for a String Theory Phenomenology](). It's pretty much hype free, has a much more realistic point of view than most talks on string phenomenology that I've seen, and gives a good idea of the current state of the subject.

Dine claims that almost all string theorists now accept the existence of flux vacua, although only some have adopted the anthropic landscape philosophy of Susskind et. al. He describes some string phenomenologists as closing their eyes to the problems represented by the large number of these vacua, and just working on some of the more tractable examples in the hope that something will turn up that will allow them to make some connection to the real world. He himself is convinced by the Denef-Douglas argument that even identifying a single vacuum state with sufficiently small cosmological constant is impossible, so that one has to make statistical arguments. He tries to have some optimism that perhaps this statistical study will allow one to make some kind of prediction, perhaps about whether the scale of supersymmetry breaking is low or high, although so far this has turned out to be impossible.

The discussion at the end of the talk is very interesting, with Dine acknowledging that there are lots of reasons he may be barking up the wrong tree and saying that he would be happier if this turned out to be the case. He quotes Witten as telling him that what he is doing can't work, that there isn't much point in trying to do the calculations he is trying to do because:

A.: "You are probably not going to succeed", and

B: "If that is all you can do it would be a great disappointment. We have this beautiful theory and we are going to get everything out of it" .

Comments

1. **Peter Orland**
   October 25, 2006

   Hi Peter,

   As you and I have privately discussed, I don't object to string theory as a laboratory to study gravity or unification per se. On the other hand I find myself very frustrated with the many scenarios devised to do phenomenology. The problem is not that these scenarios are complicated. It is that the complications cannot be forseen.

   Imagine if early 19th century chemists, cooked up an atomic theory and tried to explain the bulk properties of matter (hardness, thermal conductivity, phase diagrams). They would certainly fail because they would lack statistical mechanics and the basic ideas of spontaneous symmetry breaking (crystallization). The only property they would have understood is the density of compounds and alloys (as Dalton did). The mathematical concepts needed to understand the rest would never been discovered without experiments. I am not a historian, and for all I know, some brilliant chemists in 1810 actually tried this. I admit am guilty of pseudo-historical speculation to justify my point, but I think it is obvious regardless of this speculation.

   Often when experimentalists probed some higher orders of magnitude in energy scale, collective phenomena were discovered which were not forseen. This doesn't only apply to particle physics, but from the first investigations of matter to the study of crystals and kinetic theory, to
   atoms, etc.

   If string theory (or something like it) is right, it seems far too ambitious to think that we can pick out the right scenario to describe nature. Nature is smarter than any of us.

2. **gunpowder&noodles**
   October 25, 2006

   Would I be right in saying that this is the first time Witten has been quoted as saying definitely that he thinks the landscape approach is probably wrong/not worth working on?

3. **Benni**
   October 25, 2006

   Suesskind also said in Munich to me in person that Witten hates the landscape because "we cannot get any predictions from it". "Witten hates it" Suesskind said.

4. **AdamBalm**
   October 25, 2006

   I'd definitely second Peter (Orland, not Woit). But it irks me whenever someone says that ST is far too advanced to be probed with current technologies.

   This seems to me to be an example of petitio principii, or 'begging the question' in an argument. It's a false analogy because it is proved by its own premise. If I chose to construct any theory that I said was the most advanced of all, but that could not be experimentally verified, I could easily state that it cannot be falsified or verified precisely because it is so advanced. There's no way to argue against it because this is circular logic. This form of argument is used by Intelligent Design advocates fairly often. For example, I've actually heard someone say: "Looking at the complexity of the natural world and saying that there is no designer is like looking at Mount Rushmore and trying to find out what geological processes created such human-like rock formation". You see how deceptive such logic games are, while essentially proving or saying nothing at all. I could make the same argument that you gave, for any form of quantum gravity that doesn't make testable predictions. If one chose to play by those rules, one could say that the Flying Spaghetti Monster is so advanced so as to escape detection. The theory that music originated before language was brought up by Dennett as an example of theories that might sound great, but since there's no way to verify that in the present, they are essentially of no use to us.

   So essentially, we could choose to 'take it on faith' that ST is so advanced that all we can do is sit and wait for a few hundred years and that it will eventually proved correct, once the rest of science catches up to the level of brilliance that ST theorists are already working at. But this is something that has never been asked in the history of science. Theories, like definitions, sometimes aren't so much right or wrong as useful and useless. ST can provide a useful context and has helped people in understanding gauge theories and so forth (or so we are told), but overall has it been very useful to theoretical physics as a whole? I think this is a more important question than if it is right or not, is asking the old 'What has it done for us lately?'

5. **anonymous**
   October 25, 2006

   I find it very amusing that while you accuse string theorists of being a cult of Witten followers, they rationally look at the equations of the theory, while you guys fixate on what he “likes” or “hates”. This is physics: who cares what someone likes? Truth matters!

6. **milkshake**
October 25, 2006

P. Orland: Your analogy about chemists is misleading. Using atomic theory, they could make all kinds of qualitative and quantitative predicticon: exact composition of yet-undiscoverd salts. Behaviour of gases. Connectivity rules/molecular shape of carbon-based chemicals. Periodic table.

First you guess. Then you figure consequences of the quess and compare them with experiment. If it’s wrong…

7. **woit**
October 25, 2006

gunpowder,

As far as I know, Witten’s only public comment about the landscape so far has been something like “I wish it weren’t true, but I have no good arguments against it”.

anonymous,

I’ve repeatedly, in great detail here, made the scientific case that the kind of computations Dine is talking about can’t possibly lead to a legitimate scientific prediction. In response I’ve been denounced as a crackpot and repeatedly informed by string theorists that I don’t know what I’m talking about. I’m not going to apologize for reporting that Dine says Witten agrees with me on this point. As you might have noticed, I have an extremely high opinion of Witten, while at the same time being quite capable of disagreeing with him when I think the truth of the matter is not on his side.

8. **anonymous**
October 25, 2006

Peter:

A legitimate scientific prediction, in model building, consists of writing down your model, giving a convincing argument that it isnt yet ruled out, and making at least *one* prediction that can be verified by future experiment. Tye’s
inflationary models and Tye/Polchinski’s cosmic superstring ideas certainly fall within this rubric. So do many ideas for particle physics models motivated by the string constructions. None of them are a “prediction of string theory,” they are models which came out of string theory and which are predictive at the normal level of particle physics or cosmological model building. I find it very disingenuous to try and claim string theorists need to derive the whole world from top down to be doing legitimate model building. No one else ever does that, in science. Dine was, unfortunately, apparently focused on that unlikely goal

9. **woit**
October 25, 2006

anonymous,

If Tye/Polchinski would stop talking about “predictions of string theory”, and be careful to explain that they are talking about specific models, not string theory itself, there would not be a problem. That’s not what they’re doing.

People are welcome to work on specific models, they just shouldn’t sell the implications of these specific models as “predictions of string theory” or “tests of string theory”.

10. **anonymous**
October 25, 2006

Hi Peter:

If one of their models were verified, and the resulting string network had
the low P or multiple species of (p,q) strings characteristic of the
warped throat models, I would consider this evidence for string theory.
That is the sense in which such people call searches for such things tests of string theory; verification would provide evidence for a natural string based model, while falsification means that kind of string model is wrong. I completely agree (as would they I am sure!) that none of these models are inevitable consequences of string theory. Most string theorists I have heard go out of their way to stress this when presenting any model building type results. But verification of some prediction of this kind of model would be a big clue for string theorists, maybe telling them which limit of the theory is relevant to nature (if any). This is how all of science works; this process also led to the correct quantum field theory description of particle physics (it was not some instantaneous top down epiphany, but rather winnowing of a large structure to limits that seemed consistent with data). Anyway this view seems to be in partial agreement with yours. But I do think that because of this kind of model building, combined with future experiments, string theorists may well eventually learn which kind of vacuum is relevant, and make some predictions.

11. **a**
October 25, 2006

anonymous: can you give concrete examples about which possible developments could lead to which predictions?

12. **George Giles**
October 25, 2006

When Einstein was working on the General Theory of Relativity he had some experimental facts, and a load of intuition. He had the physics but not the math. Marcel Grossman and he then went looking for it and found it in Riemannian Geometry. It seems that String Theory is taking the opposite approach, a whole load of math (formally undecidable theories at that) and are searching for the physics.

Now even a blind pig finds an acorn every now and then, but it seems that the current approach is from a historical prospective, unlikely to be successful. My gut feel is Newton followed an approach like Einstein, not one like Witten et al.

I have to wonder if String Theory has gone from diminishing returns to vanishing returns to paraphrase Milton Friedman.

13. **anonymous**
October 25, 2006

a:

Well, I already mentioned, discovery of cosmic strings with certain network properties would give evidence for a class of models of inflation discussed in many papers over the past few years, and some of these properties were first suggested by string constructions (not field theory ones). There are other kinds of inflationary experiments (measuring nonstandard features of the density/temperature fluctuation spectrum) that will be launched in the next five years and could test another class of string inflation models.

In particle physics, obviously large extra and warped extra dimensions drew much attention because they have spectacular signatures at LHC (though I think they are quite unlikely). Verification of either would again be a big hint about which kinds of string models matter; both warped and large extra dimension models have recently been found in detailed studies of string compactification with flux.

5th force experiments may eventually find moduli with small mass. In supersymmetric string models, one class of gauge mediated models would predict moduli in the sub eV range. If both the moduli and the spectrum of gauge mediation were seen, this would be a hint.

Other people have found mediation scenarios where distinct spectra of sparticle masses result from specific extra dimensional structures (anomaly mediation, gaugino mediation, mirage mediation,…) which you can read about in review articles.

Altogether, the discoveries of LHC, future CMB experiments, and 5th force type experiments (together with gravity wave detectors) have all kinds of ways of giving us hints about high energy physics. A confluence of several hints could select the right kind of string model. Of course luck would also be required (how lucky would we be if there are extra dimensions at LHC??). But thats always been the way experiment helps theory; a lot of hard work developing the theory, and eventually, a decisive stroke of good luck in what is discovered. Arguing that one cannot be sure that experiment will give big hints about the right string model in the next decade is silly; that is obviously true, and has been equally obviously true for all really interesting theoretical developments in the past century. We will need to get lucky, but there are many ways to do so, some of which we haven't thought of yet. Thats why I am excited about this field.

14. **steve**
October 25, 2006

The following statement from our host clarifies what I asked about models vs. theories on the previous thread:

"If Tye/Polchinski would stop talking about "predictions of string theory", and be careful to explain that they are talking about specific models, not string theory itself, there would not be a problem. That's not what they're doing.
People are welcome to work on specific models, they just shouldn't sell the implications of these specific models as "predictions of string theory" or "tests of string theory"."

If string "theory" is just a framework for generating specific models, and it is specific models rather than the framework as a whole that are to be tested empirically, then the dispute collapses to a much smaller and more manageable level. The only residual problem would be if, regardless of their merits, models developed out of the string framework received more favorable evaluations than models constructed some other way. Absent evidence of that, I'd be inclined to think that the hype about strings is silly but not too damaging.

15. **anonymous**
October 25, 2006

All of the models of TeV scale physics I mentioned (large extra dim, warped
extra dim, gaugino mediation, anomaly mediation,…) were actually developed by people who received PhDs that are NOT in string theory. They all classified themselves as particle phenomenologists or model builders. Those works are all famous and well cited, and their authors received faculty positions (those who did not already have them). String theorists were very happy to build on their ideas, or try to find them in string theory. So there has been interplay, but I think it would be grossly unfair to say that only models that are constructed by string theorists, or first derived from string considerations, have been "hyped". It would be hard to imagine more hype than that surrounding the extra dimensional models that were NOT conceived of (first) by string theorists. More generally, however, the interaction between strings, cosmology, and particle phenomenology has been very healthy in the past decade. It is now hard to even classify some people who work in two or three of the fields. This is a good thing.

16. **Dick Thompson**
October 25, 2006

Just on the topic of a nineteenth century calculational atomic theory, Daniel Bernoulli in the eighteenth century used basic "corpuscles" acting elastically under conservation of momentum to derive PV = const. He or someone else might have taken the next step, identified "heat" with the summed *vis viva* of the corpuscles and the temprature with their mean *vis viva* and derived the virial theorem. I don't think a limited "kinetical chemistry" theory was impossible at that time, and historical analogies are always questionable because of the great influence of individual personalities on both past and present.

17. **Peter Orland**
October 25, 2006

Milkshake,

I think you missed the point of my analogy.

As you say, you make a guess. Calculate. Check against experiment. Make another guess. And so on. The point is that none of us is smart enough to start from a very high (low) energy scale and guess how nature should be at a very low (high) energy scale without a LOT of guesses and calculations and experiments
in between. Well, I think it can't be done.

The reason it can't be done is that every time you go to smaller scales, there is the possibility of new statistical/collective/nonperturbative phenomena happening. In
my foolishly naive analogy, I was trying to say that this is like
starting from the notions of atoms and calculate properties
of matter. It's impossible without investigating the molecular
level (kinetic theory), van der Waals forces (electricity
and magnetism), electrons and nuclei (quantum mechanics), and
the mean field theory of crystals (spontaneous symmetry breaking).

Continuing this analogy (since I don't have a better one), string theory would be like the quantum theory of electrons and nuclei. Imagine trying to extract bulk properties of matter from a many-body theory of electrons an nuclei! It can only be done in hindsight. Too many sophisticated phenomena happen between an Aangstroem unit and a centimeter.

I'm not saying that it isn't worthwhile to study the theory we guess is fundamental. I just have no confidence that one can stretch that theory from the Planck mass to 10 TeV and make sensible predictions. That doesn't mean the theory is wrong, but that we aren't smart enough to guess what happens at intermediate energy scales.

18. **a**

October 25, 2006

anonymous, you answered mentioning many possible natural solutions to the Higgs mass hierarchy problem. Do you still hope that dark energy will turn out to be something natural, rather than an unnaturally small cosmological constant?

If not, it seems better to see nothing new at LHC and get a second stroke on naturalness: a defeat naturalists vs anthropists = 0 : 2 would carry a strong message, while an impact 1 : 1 would not clarify this big issue.

19. **anonymous**
October 25, 2006

Hi a:

There are as yet (as far as I know), no good "natural" solutions to the
cc problem. But logically speaking, all the evidence for the string landscape just means that there are many vacua, some of which plausibly have small enough lambda. It could be that they are "populated" by cosmology in such a way that some dynamics enters in explaining the observed value. Needless to say, despite very many attempts in this direction (with various modifications of the Hartle/Hawking wavefunction, or more…questionable…approaches by Turok and Steinhardt), nothing less tuned or more convincing than just a small cosmological term explained by Weinbergs argument has emerged. But again, the evidence for the landscape just means small lambda can be accomodated in string theory, it does not necessarily mean anthropics has to be the explanation.

Arkani-Hamed and Dimopoulos and various others have tried to think of ways that LHC could give evidence for un-naturalness. The attempts are kind of forced, since there are good explanations for the higgs mass that come pretty easily out of string theory (at least as easily as their more contrived, though very testable, proposed "anthropic" models). But I agree if one of those models, or "higgs only," came out at LHC, it would be another big pointer to a new notion of naturalness, very possibly indicating the landscape again.

20. **relativist**
October 26, 2006

Hi anonymous

"the evidence for the landscape just means small lambda can be accomodated in string theory" – the word `evidence' here has taken on a rather unusual meaning. You presumably mean something like `theoretical support' rather than evidence in the usual sense of the word. Indeed Vilenkin tries to run it the other way and say that the small value of Lambda (which is evidence in the usual sense – it is an observed piece of data!) is evidence for the landscape – and for the multiverse, which is not observable in any ordinary sense of that word. This seems to be stretching ideas of scientific proof to a great degree – compare with what is taken as adequate proof in say solid state physics or quantum optics.

21. **Thomas Larsson**
October 26, 2006

OT: I suppose everyone has noticed that physics/0610168 references our host.

22. **anonymous**
October 26, 2006

Relativist:

Yes, I just meant evidence for many vacua in string theory, using standard physical techniques to abnalyze the vacuum structure. I did not mean there is experimental evidence. But it is true that the many vacua may well turn out to offer the best hope of accomodating (explaining??) The small cc in a quantum gravity theory. Of course we would need other more traditional tests of string theory to make this at all convincing, as all reasonable string theorists would acknowledge.

23. **Who**
October 26, 2006

OT: I suppose everyone has noticed that physics/0610168 references our host.

I noticed that. It is Hedrich's paper reporting on a study he did for the German equivalent of NSF, about the state of theoretical physics. I think our host had a blog sometime back that was partly about Hedrich and some coverage in the German press.

24. **LDM**
October 26, 2006

Referring to footnote 12 of the physics/0610168 about string theory and GR…

If you actually check what Feynman said in the "Feynman Lectures on Gravitation", page 30…you will see that the (so far undetected) graviton, does not, a priori, have to be spin 2, and in fact, spin 2 may not work, as Feynman points out.

This elevation of a mere possibility to a truth, and then the use of this truth to convince oneself one has the correct theory, is a rather large extrapolation.

25. **Anonymous 17**
October 26, 2006

Has anybody noticed hep-th/0610241, which seems to be the start of non-commutative geometry phenomonology. Connes and co-authors predict the mass of the Higgs boson. String theory appears to be starting to fall behind.

26. **Bert Schroer**
October 26, 2006

I find this point which Hedrich revives quite interesting. The massless finite helicity Wigner representation (say integer spin for simplicity) have all one property in common, their inner products cannot be written in terms of integrals over local densities. In order to do this (and also to implement interactions) you have to introduce "potentials"(the vectorpotential for h=1, the metric potential for h=2 where the field strength would be the linearized Lorentzian Riemann tensor etc.). This creates a dilemma in the quantum theoretical setting (none if one stays classical) since there is a No-Go theorem: there are simply no covariant pointlike fields in the Wigner-Fock Hilbert space. There are two ways out. Either you give up the Hilbert space in intermediate calculation and admit ghosts (which of cause can only be used as "catalyzers" because you have to get rid of them at the end of the calculation); this is the BRST cohomological setting. The alternative is to use covariant potentials which however describe string-localized fields (which fluctuate simultaneously in Minkowski- and the string-directional de Sitter space). In both cases you end with potential fields whose

short distance behaviour is not worse than that of a scalar free field (in contradistiction to the field strength whose scale dimension increases with the helicity). The renormalizable interactions are precisely of the "gauge" kind (although that language is not very appropriate in the second setting since you never leave the physical Hilbert space) but for the sake of this discussion it would be justified to call them all "gauge theories" (not only the case h=1).
In some sense the Einstein-Hilbert gravity interaction should be in this family of interacting h=2 theories. But there is a profound conceptual problem: the diffeomorphism invariance (according to Einstein an active transformation which also changes the points) is not the same as gauge invariance (phase transformation) which only effects the fibers over points.
I think it would be very interesting to re-investigate the issue of ref. 12 of Hedrich using the gain in conceptual understanding.
By mere coincidence some of this points were discussed yesterday in the samizdat blog.

27. **D R Lunsford**
October 26, 2006

Bert said

In some sense the Einstein-Hilbert gravity interaction should be in this family of interacting h=2 theories. But there is a profound conceptual problem: the diffeomorphism invariance (according to Einstein an active transformation which also changes the points) is not the same as gauge invariance (phase transformation) which only effects the fibers over points.

Yes, this is exactly the key point and why all attempts to make the gauge potentials part of the metric via KK ansatz are doomed. Pauli already knew that.

-drl

28. **D R Lunsford**
October 26, 2006

The paper by Hedrich is outstanding and long overdue.

-drl

29. **Bert Schroer**
October 26, 2006

The word "phase transformation" may be misleading (I was already thinking about coupling these higher helicity potentials as external fields to quantum matter). I would expect these transformation to be linear (generalization of h=1 gauge transformations). I would be surprized if this issue has not been already adressed in the literature. What is however important here is to start from the Wigner representation theory in order to avoid playing formal games with ad hoc higher tensor fields.

30. **Bert Schroer**
October 26, 2006

D R Lunsford
I did not know about Pauli's criticism, very interesting! Where did you see this?
There is an independent much more profound argument against KK coming from algebraic QFT. This is based on the observation that inner symmetries result (the DHR analysis) from the representation theory of local observables. It is the representation theory (modulo isomorphisms) of these local nets which leads to the statistics of particles as well as to the existence of charge-carrying fields which intertwine the charge sectors and encode the statistics into inner symmetry properties of these charge carrying fields such that the original observables are reproduced as the fixed point algebra of the field algebra. In 4 spacetime dimensions the emerging symmetry concept is that of compact groups. If you would not have locality the possibilities of representations would be too big and not be classifiable. The conceptual situation of observables—charge carrying field algebra (i.e. its construction from the observables) is precisely following Marc Kac's dictum: "how to hear the shape of a drum". It is totally absurd to think that such a situation can emerge from little rolled up spatial dimensions (KK is however possible in the classical setting, but is does not solve any physical problem). But there is nothing which one can do against collective madness; one just has to let it play out.

DRL said:

> Bert said
>
> *In some sense the Einstein-Hilbert gravity interaction should be in this family of interacting h=2 theories. But there is a profound conceptual problem: the diffeomorphism invariance (according to Einstein an active transformation which also changes the points) is not the same as gauge invariance (phase transformation) which only effects the fibers over points.*
>
> Yes, this is exactly the key point and why all attempts to make the gauge potentials part of the metric via KK ansatz are doomed. Pauli already knew that.

Is there a simple and obvious way to get from the first observation (diff inv is not gauge inv) to the second (KK is doomed)? I'm probably missing something that's obvious to both of you, but it sounds like Witten is missing that same thing as well, among others, so perhaps I can be forgiven for not seeing it right away.

32. **D R Lunsford**
October 26, 2006

egbert – Witten is a mathematical genius but Pauli was connected at the belly button to the Universe, and his arguments win in my book. Having great skill at math does not confer physical insight.

October 26, 2006

Please, this is not sci.physics. Stop trying to turn it into a discusssion forum for your favorite ideas about GR. This is completely off-topic.

34. **Bert Schroer**
October 26, 2006

I agree with Peter that this does not fit the headline of this blog, sometimes an interesting issue throws a weblog of topic.
It is however a subject which I addressed in my Samizdat article. So may be Egbert I could answer your question over there. Another possibility is that you use my email

address. But then an interesting subject will be lost to the typical reader of Peter's weblog which is not fitting the purpose of a scientific weblog. Since Peter is very interested in the use of representation theory for particle physics he may actually also be interested to know arguments which show that in the quantum setting there is a deep clash with the KK idea (independent of Witten's opinion).

35. **egbert**
October 27, 2006

Let's continue at my new blog.

In fact, I propose that, whenever a conversation wanders into realms that aren't appropriate for the host blog, a new blog post should be instantiated somewhere and a link posted to the original blog, so that those who wish to follow the conversation can do so.

36. **Bert Schroer**
October 27, 2006

Egbert
when I tried to follow your suggestion to move my 2 last contributions under Samizdat over to your new blog (as a kind of branched-off sub-blog to Peter's) and to start a more extensive discussion from there I realized that there must have been a malfunction with Peter's weblog because the list of names on the right margin does not correspond to the content after opening. What worries me even more is that only the continuation of my yesterday's contribution appears fully, the blog I wrote immediately before is incomplete (it lost 2/3 of its content) and unforyunately I did not make a copy. So before moving over, let us wait and see if Peter can check what happened.

37. **Peter Woit**
October 27, 2006

Bert,

I have no idea what the problem might be. What you see in the comment section of the blog is all that there is.

38. **Bert Schroer**
October 27, 2006

O.K., maybe there was a malfunction in the uploading. Of course I can reconstruct what I wrote and place it as a comment into Egbert's comment section, but I need some time (I will be able to do this today). So I invite all reader's who are interested in that particular issue to move later in the day to Egbert's weblog
http://kaluza-klein.blogspot.com/
(which I do not want to see as a competition to Peter's but rather as a means to continue with interesting points which are slightly off-topic).

39. **C**
October 27, 2006

Hi anonymous

"both warped and large extra dimension models have recently been found in detailed studies of string compactification with flux."

Could you provide a link to this work, or a hint such as the names of the authors, to help me find the papers?

Thanks very much.

C

40. **anonymous**
October 27, 2006

Hello C:

There are by now lots of papers on these things, but I think it is reasonable to point to:

For scenarios involving exponential warping like Randall/Sundrum, a standard reference is now arXiv:hep-th/0105097 by Giddings et al. The references in that paper and the citations to it provide a much larger guide to the relevant literature. Those models are important in hep-th/0301240, the original "KKLT" paper on flux compactification.

String derived models of large extra dimensions are described in
hep-th/0505076 by Conlon et al which focuses on phenomenology, and the citations/references of that paper.

42. **Thomas Love**
October 27, 2006

Peter, Thanks for the link to Michael Dine's talk. I listened to it and it was just like being there. I fell asleep 15 minutes into his presentation and was awakened by the applause at the end of his talk. I did go back the next day and listen to the whole thing. His comments at the end seem to reflect the reality of the problems with string theory, he was discussing the many states of string theory:

At 1:08:12 into the recording(slightly edited):

"You line up your graduate students. You give them each a barcode for one of these states. They start calculating. They come back 6 months later and they've calculated the second order correction. It looks pretty good. They come back two years later they've calculated the third order. It looks pretty good. Twenty years later they come back with the eighteenth order—it didn't work. Ok, throw this out."

I only listened because Dine is at UC Santa Cruz, where I received my PhD. I'm glad I got out in time. I wouldn't want to spend twenty years getting a PhD! His comments reminded me of why I left physics after one year of grad school and switched to math: the whole paradigm of perturbation theory makes no sense whatsoever!

Finite Generation of the Canonical Ring

October 26, 2006
Categories: Uncategorized

The last few weeks have seen the appearance of two papers giving very different proofs of a quite important result in algebraic geometry, resolving a question that had been open for a very long time, and in the process helping to make progress in the classification of higher dimensional projective algebraic varieties. Readers should be warned that this doesn't have anything to do with physics, and my knowledge of this kind of mathematics is highly shaky, so I'm relying largely on second-hand information from people much better informed than myself.

The theorem in question concerns the "canonical ring" of a smooth projective algebraic variety X, which is the graded ring R(X) defined by

$$R(X)=\oplus_{n=0}^\infty H^0(X, nK)$$

Here K is the canonical line bundle (top exterior power of the cotangent bundle) of X, nK is its n'th tensor power, and $H^0(X, nK)$ is the space of holomorphic sections of the bundle nK. This is also called the [pluricanonical ring.]

The new theorem says that this graded ring is finitely generated, and this implies quite a few facts about projective algebraic varieties of any dimension. In particular it implies the main goal of the "minimal model program" (also known as the [Mori] program) for classifying higher dimensional algebraic varieties.

A proof of this theorem was [claimed] back in 1999 by Hajime Tsuji, but it appears that there are problems with this proof. The arXiv preprint went through many revisions, but was never refereed and published. A couple weeks ago, a group of four algebraic geometers (Caucher Birkar, Paolo Cascini, Christopher Hacon and James McKernan) posted a [preprint] on the arXiv claiming a proof. Yesterday, Yum-Tong Siu, a well-known complex geometer from Harvard, posted another [preprint], giving a very different, more analytical, proof of this theorem. Siu notes that he has been lecturing on this proof for over a year, first at last year's Seattle [conference on Algebraic Geometry].

The mathematicians involved in creating these two proofs are well-known experts, and it seems likely that both proofs are correct. Given that there are two of a quite different nature, it now seems extremely likely that this theorem has been proved.

For more detailed explanations of this result and its implications, I'm afraid that you're likely to require someone who knows a lot more about algebraic geometry than I do. Perhaps some of my more expert readers here can help out.

Comments

1. **Aaron Bergman**
   October 26, 2006

   I know next to nothing about this, but I believe that Proj of the canonical ring provides a nice model for the space.

2. **Walt**
   November 3, 2006

   I'm planning on spending some time looking into this later, since it's not my area, but it looks like this gives a minimal model for varieties of general type (i.e. most varieties given by high-degree polynomials). This is a big step forward for the minimal model program, which (in my understanding) splits birational classification into two steps: find minimal models for varieties, and then determine when varieties have multiple minimal models. I think that it's hoped that varieties of general type only have one. But as I said, it's not my area.

3. **xyz**
   November 3, 2006

   That is not quite true. There can be more than one minimal model, but only one canonical model (=Proj(R(X,K_X)).

4. **Walt**
   November 5, 2006

   Even for varieties of general type?

5. **xyz**
   November 5, 2006

   Yes. Why not? they are connected by flops and they are easy to construct. If a variety is of general type, then it follows that the # of minimal models is finite.

Earlier this month there was a workshop on twisted K-theory held at Oberwolfach. Here is a report, also slides from a talk there by Greg Landweber about the Freed-Hopkins-Teleman theorem. Freed is giving a course on the subject this fall, and Hopkins is giving a series of lectures about TQFT in Gottingen this week. Urs Schreiber has reports on the lectures here and here. Also at the n-category cafe is an advertisement by John Baez for the work of my new Columbia colleague Aaron Lauda on TQFT, which I'll second here. For yet more on TQFT, see notes by Kevin Walker here, and the book by Bakalov and Kirillov, an early version of which is on-line.

Last week in Paris there was a conference dedicated to Joel Scherk, celebrating 30 years of supergravity.

There's an interesting interview with Alain Connes on the French TV network ARTE here. For his recent work on non-commutative geometry and the standard model, see this preprint, and talks here from the on-going workshop at the Newton Institute in Cambridge.

Comments

1. **Adam Balm**
   October 26, 2006

   Great. The first chance I had to see Alain Connes and it's in Real Audio.

   Anybody ever heard of youtube?

2. **nit**
   October 27, 2006

   Nice Alain Connes interview.
   Somehow, Connes' way of talking, maybe it's the gestures, reminds me of Feynman. Relaxed, confident, playful, enjoying the questions…
   My god, I must say the interviewer is very charming!

3. **Alejandro Rivero**
   October 27, 2006

   There is audio (in English) for talk II and III in the Newton Institute website. I strongly recommend to download them into your MP3 machine so you can heard them while in the tube. Every talk recapitulates the previous one, so if you ony can allow for one, start with III. In England, the series will continue November the 9th, plus some another "one-short" talks around. I do not know if there is some similar, or even more gossip-rich, presentations in France. Hints anyone?

   There is detailed coverage in the October posts of the n-category cafe, and some more sparse coverage in Motl's.

4. **Bert Schroer**
   October 27, 2006

   "Nice Alain Connes interview"
   this is indeed a very enjoyable style, remarkably different from that of those car-salesmen which we often are exposed to.
   As a physicist one notes that all mathematicians (perhaps with the exception of Vaughn Jones and some others who entered QFT from subfactor theory) continue to have that lighthearted attitude with respect to the Euclidean—Lorentzian relation (and the related issue of localization) which for the mature quantum field theorists are among the conceptually most subtle and delicate (and even not generally valid) issues of particle physics.

5. **Justin**
   October 27, 2006

   Sorry for the somewhat off topic post, but here is a concrete sign that the opinion of string theory is changing in the public's collective unconscious. I was reading an article on realclearpolitics about a controversial interpretation of the polling data:

   > A few people did not like that argument. They accused me of "rationalizing the results," which, to an extent, is understandable. It is not appropriate to start applying theories before you have offered some initial testing of them – unless of course you are a Marxist or a string theorist, neither of which I happen to be.

   http://time-blog.com/real_clear_politics/2006/10/a_republican_meltdown_part_ii.html

   Ouch!

6. **Clay Aiken**
   October 27, 2006

   Thanks for the links Peter! I've been meaning to catch up on TQFT for some time, finally my schedule will allow me to do this.

7. **Matti Pitkanen**
   October 27, 2006

   I read the articlle of Connes and like Bert Schroer I was astonished that he mentioned only in brackets that the spacetime metric has Euclidian signature and made no further comments about the significance of this. As a physicist having at least second foot in this world I find it very difficult to understand how a physicist proposing a unification of all known interactions can have such a light-hearted attitude.

8. **Tony Smith**
   October 27, 2006

   Connes explicitly states in the pdf version of his talk "Spectral action and gravity coupled with matter III" that is on the web at
   http://www.newton.cam.ac.uk/webseminars/pg+ws/2006/ncg/1011/connes/all.pdf

   "… The spectral action principle asserts that the fundamental action functional S

that makes it possible to compare different geometric spaces at the classical level
and is used in the functional integration (after Wick rotation to euclidean signature) to go to the quantum level,
is itself of the form … Trace (f(D / /\ )) …
where D is the Dirac operator and f is a positive even function of the real variable while the parameter /\ fixes the mass scale. …".

Maybe some people don't like such use of Wick rotation, but Connes is model-building,
and if he can construct a physically realistic model using such Wick rotation
then
in my opinion it will be so useful that it will be (and should be) as widely accepted as are
some not-yet-rigorously proven aspects of the Standard Model
and
any objections as to rigor should be motivation for further work on the model
rather than justification for trashing the model.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

9. **Bert Schroer**
October 27, 2006

well Tony, that is what I meant by lighthearted. Something like Osterwalder Schrader is not lighthearted.
But I agree with you that it is not illegetimate to do that and (as long as results are interesting and one does not forget that there is a conceptual problem) defer such questions to a later date (although this has been going on for more than a decade). However it is only a theory after these quations have been settled.

10. **Tony Smith**
October 27, 2006

As to objections about localization,
Connes said in the pdf file that is on the web at http://www.newton.cam.ac.uk/webseminars/pg+ws/2006/ncg/1011/connes/all.pdf

"… Assuming first that we deal with a classical manifold, one can form a number of such invariants (under suitable convergence conditions) as the integrals of the form
[Integral over M] F(K) sqrt(g) d^4x (9)
where F(K) is a scalar invariant function … of the Riemann curvature K.
Such invariants, of the form (9) appear as the single integral observables i.e. those which add up when evaluated on the direct sum of geometric spaces.

Now while in theory a quantity like (9) is observable it is almost impossible to evaluate since it involves the knowledge of the entire spacetime and is in that way highly non localized.

On the other hand, spectral data …
(the data of spectral lines are intimately related to the Dirac Hamiltonian, hence to the geometry of "space") …
are available in localized form anywhere,
and
are (asymptotically) of the form (9) when they are of the additive form
Trace (f(D / /\ )),(10)
where D is the Dirac operator and f is a positive even function of the real variable while the parameter /\ fixes the mass scale. …".

Again,
Connes is NOT ignoring the issues of localization and Wick rotation,
but is explicitly stating how he is building his model,
and
if his model is realistic, I think that it is useful.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

11. **Alejandro Rivero**
October 27, 2006

The goal in that paper was to get coincidence with Veltman's Diagrammar. Let me note that one of the first impulses, fifteen years ago, was Daniel Kastler, who did a lot of the calculations of the Higgs potential in the old models.

12. **Matti Pitkanen**
October 27, 2006

The idea about spectral data of Dirac operator as a manner to code nonlocal data locally is beautiful. I cannot avoid temptation to briefly mention (Peter can delete this posting if it is too much about pet ideas) an approach in which Dirac operator associated with lightlike 3-surfaces which by Diff^4 invariance can be chosen to be fundamental dynamical objects. Vacuum functional is coded as a Dirac determinant (appropriately defined) having interpretation as action exponential characterizing interior dynamics of space-time. In this case lightlikeness is the source of all superconformal symmetries, it defines parton level dynamics as almost topological CFT, and it gives rise to quantum gravitational holography. Everything would be lost by Euclidization trick.

13. **C**
October 28, 2006

On the topic of the conference in memory of Joel Scherk. Obviously Joel Scherk did very great work, and it's very tragic that he died. The proceedings of the 1979 Stony Brook supergravity conference, which were dedicated to his memory, said he had diabetes, and got stuck somewhere without his insulin, and went into a coma. But the Wikipedia article, which is just a stub, doesn't mention diabetes, and contains a link to a review of a book by Leonard Mlodinow, which contains a paragraph that provides different information. Could anyone provide more historical information?

Fit To Be Tied

October 27, 2006
Categories: Uncategorized

This week's Science News has a quite good article about the string theory controversy by Peter Weiss, unfortunately available on-line only to subscribers. The title is "Fit to be Tied: Impatience with string theory boils over". There's nothing much in the article that will surprise anyone who has been following this story here. It includes some accurate quotes from me and some from Lee Smolin, with the string theorists represented by Zwiebach, Polchinski and Strominger.

Polchinski claims that experiments will soon probe some elements of string theory, promoting the possibility that the LHC will observe extra dimensions. Zwiebach points to work on black holes: "In string theory, the black hole can be seen as built from strings and branes. It's a spectacular insight." Strominger on the one hand is quoted as finding it inappropriate that Smolin and I are criticizing how string theory research is conducted, while also saying he thinks that the way string theory has been promoted has given the public the wrong impression: "I've felt for a long time that the general public's impression of what string theory had accomplished and how much of it was correct was too positive."

Comments

1. **ObsessiveMathsFreak**
   October 27, 2006

   > "I've felt for a long time that the general public's impression of what string theory had accomplished and how much of it was correct was too positive."

   I think the general public deserve a little more credit. I've spoken to many "lay" people who regarded the string theory programs or newspaper reports they read with a good degree of skepticism.

   Now, the general public does regard things like Relativity and Quantum Mechanics with skeptisicm when they first hear about them(who doesn't), but at least in these cases they can be shown experiments and effects which give credance to the theory. Show anyone the double slit or Michealson-Morely experiments and they can at least appreciate that the universe is not always as logical as we think it is.

   But with string theory, there are no experiments. It really is all just symbols on paper, with only its supposed mathematical "beauty" holding it aloft. Faced with this, all that can be presented to the public is 3D animations of vibrating strings, and appeals to various scientific authorities(minus Feynman). Increasingly, more dishonest methods like violin concerts and cooking shows used as well.

   But I think general man on the street is not as guillable or as confused as certain people take him to be.

2. **r hofmann**
   October 28, 2006

   I entirely agree with the statement that the general public in a more or less working, technologically, morally, and culturally highly ambitious society should not be regarded as an unknowing, unsuspecting, and uncritical something that scientists can impose their fashion-of-the-day ideas on while standing on a disconnected, elevated platform. After all, scientists, being themselves a part of society, enjoy the privilege to unadulturatedly conduct their research just because the broad public is materially supporting them. The only way to leave a lasting impression on our collective conscience is the unearthening of scientific truth that, by definition, is backed up by strong empirical evidence, that is, by numerous and independent experimental confirmations of theoretical predictions (Smolin's ring of truth) and that, by historical experience, turns out to feed back into future everyday life in one way or another.

3. **anon**
   October 28, 2006

   ObsessiveMathsFreak, I disagree.

   I've had many friends approach me on this subject (I rarely initiate these discussions on my own devices) and my general impression is quite the opposite. The people I have discussed this with are usually people with a broad set of interest and usually with some basic knowledge of math and physics and good knowledge in say economics or history.

   My perception is the opposite, I am usually received with a lot of distrust and sometimes down right disdain when I say that string theory:

   *hasn't had any kind of experimental verification (both direct and indirect) attributed solely to it
   *doesn't replicate all previous physical theories, not even a reasonable subset of those (uniquely at least)
   *is not a coherent theory with a well set of fundamental principles, but so far only a set of rules glued together in an ad-hoc way

   The reaction is usually one of the following:

   *If it's so bad, why is it so popular? Seems to me you are just ignorant about it and just dismiss what you don't know of (I am far from knowledgeable about string theory but I think what I wrote so far is essentially true)
   *If all these uber-smart people and prize-winners do it, things can't be as you say
   *But I read an article in a top notch newspaper/magazine where it said string theory explains almost everything

   I've even had one you didn't know of the standard model (not serious sonce this was not his field) but thought that what explained all those particles was string theory and not the standard model (now this is serious).

   The truth is, humans are generally stupid about things they have barely any expertise on (myself included, and sometimes even about things they have expertise on) and usually rely on authority to make judgements about the validity of those subjects (this I try not to follow).

   Sad but it's the reality of things..

4. **TheGraduate**
   October 28, 2006

   One of the more interesting aspects of this debate has been the frequent appearance of anti-democratic tendencies. Basically, one designates a population whom one thinks is too ignorant to comment and then any comment from that group is unwelcome. I suppose my point is that, there is nothing god given about who gets to decide who is too stupid to possibly have anything useful to say. The defacto result is that whoever has the power decides.

The only recourse for those excluded from the conversation, if they so choose, is to make overt attempts at control such as using the media to amplify their agenda.

In other words, without conversation one is left with an environment where ‘might makes right’.

The other points I would like to make are:

1. Too many people perform a bait and switch in this argument where they claim it is about the good of science whatever that means. *This debate is about money and resource allocation.*

2. Essentially string theorists argue that they deserve their allocation due to their brilliance. Those opposing argue that 20 years without testable results negates this argument.

3. Those opposing argue that equally failed (experimentally unsupported and unverifiable) theories should be funded equally.

Overall the structure of the argument is very simple even if the details are admittedly complicated. Even somebody with no background in physics should be able to understand the flow of this argument.

5. **Arun**
   October 28, 2006

   Sorry for the digression, but there is no open thread here. Delete if appropriate. I’m posting this because Richard Dawkins is invoking the anthropic principle as an explanation (and as an explanation much superior to God. IMO, the anthropic principle is no more scientific than God).

   “We explain our existence by a combination of the anthropic principle and Darwin’s principle of natural selection. That combination provides a complete and deeply satisfying explanation for everything that we see and know.”

   http://www.huffingtonpost.com/richard-dawkins/why-there-almost-certainl_b_32164.html

   Because the arguments are all mixed up with religion, Peter may not want to talk about it here. But it hardly constitutes the “complete and deeply satisfying explanation for everything we see and know”.

6. **Bert Schroer**
   October 28, 2006

   My comment: atheism is no protection against amok running metaphysics. To the contrary, mixed with ST it even seems to facilitate the rise of metaphors at the expense of scientific autonomy.

7. **Ajax Minor**
   October 28, 2006

   This recent paper by Anthony Zee and collaborators might be appropriate to point out in this thread (or maybe in the one about ST phenomenology),

   hep-th/0610231
   Does string theory predict an open universe?
   Authors: R. Buniy, S. Hsu, A. Zee
   It has been claimed that the string landscape predicts an open universe, with negative curvature. The prediction is a consequence of a large number of metastable string vacua, and the properties of the Coleman–De Luccia instanton which describes vacuum tunneling. We examine the robustness of this claim, which is of particular importance since it seems to be string theory’s sole claim to falsifiability. We find that, due to subleading tunneling processes, the prediction is sensitive to unknown properties of the landscape. Under plausible assumptions, universes like ours are as likely to be closed as open.

8. **Juan R.**
   October 29, 2006

   Anon,

   Your collection of reactions is very interesting and highlights one of the true problem of string theory; i mean social issues and misinformation of people and noticeable consequences such as lack of funding of promising (but not so popular) approaches and others.

   I think that we can offer a reasonable reply to each one of reactions you listed. Peter woit, maybe this could be interesting for the FAQ.

   ***If it’s so bad, why is it so popular?**

   Popularity is not synonim for scientific trust. Electromechanical classical models of atom were very popular, but all popular models failed and just a single revolutionary model fitted exp. data.

   ***If all these uber-smart people and prize-winners do it, things can’t be as you say**

   Smartness and prizes are not proofs for scientific statements. The history of science is full of Nobel winners and other smart guys were wrong regarding some scientific statement. There is also well documented cases of entire comunities of brilliant scientists promoting a wrong vision of the world. The next paradigm is then labelled like scientific revolution.

   ***But I read an article in a top notch newspaper/magazine where it said string theory explains almost everything**

   The same that above. People also read in top magazines about Pons’ cold fusion but it was a sound scientific fiasco.

The Proof is in the Blogging

October 29, 2006
Categories: Uncategorized

Seed has a new article out by Stephen Ornes, called The Proof is in the Blogging, about the way the story of Penny Smith's solution to the Navier-Stokes problem played out here. I'm quite fond of the photo included in the Seed article.

I'm not sure there's anything more to be said about the Navier-Stokes story. One of my colleagues pointed out that mathematics is one of very few subjects in which bringing together a bunch of people with opposite views on what is true generally leads to one or more of them agreeing that they were wrong.

There's also a short article about this on Slashdot. Taking advantage of the arXiv trackback mechanism, the author found the discussion of this on Lubos's blog. I was going to take the opportunity to complain about the arXiv censoring links to this blog, but it turns out in this case there is one there. The ways of the arXiv are endlessly mysterious, I have no idea what their trackback policy is these days.

Maybe it's also relevant to mention that for some reason the hot news retailed here about the proof of finite generation of the canonical ring is not attracting the kind of attention indicated in the Seed picture.

Comments

1. **Anon**
   October 30, 2006

   Perhaps it's only hep-th which doesn't give you trackbacks?

2. **Chris Oakley**
   October 30, 2006

   It is interesting that the recent Navier-Stokes controversy was played out here rather than sci.physics.research or sci.math.research, where it more naturally belonged. I think that this is partly because the moderation takes too long on these newsgroups (some of my posts on SPR have taken days). If they adopted Peter's policy of allowing posts to appear before deleting them rather than just preventing what they see as irrelevant/obnoxious/uninformed posts at the outset, the whole thing might work better. Also, the collective quality control exercised by the moderators seems to be less effective than Peter's personal control. A bit like Communism vs. Capitalism.

3. **TheGraduate**
   October 30, 2006

   I didn't have much to say during the Navier-Stokes case as I couldn't think of anything helpful to say. I'm sorry about the way it played out though. My thinking is it wasn't as bad as it seemed to the people most emotionally involved in it, but I guess it must have felt that way.

   Discussion boards take a lot of getting used to. People probably take them more seriously than they should. (Some grow out of this and some do not.)

4. **ObsessiveMathsFreak**
   October 30, 2006

   I honestly don't see what all the fuss is about. The system worked *exactly* as it was intended. A preprint was posted on the arXiv, people viewed it, discussed it, found problems, and gave the author quick and concise feedback. The preprint was withdrawn, and the author can begin working on any problems found.

   The system works.

   Compare the quick turnaround to the tradiational publishing ringmarole. It could have taken Smith over 18 months to find out her paper contained a flaw. The flaw may never have been found at all. And if the paper, or the next version, had no flaws, the journal may have had problems publishing it anyway.

   The only problem in this paticular case is that Nature rushed the story to print. If some less than professional scientific publications choose to base their stories on *preprints*, that could deter people from posting preprints online so as to avoid any publicity and potential embarrassment, and that would be a big setback for the very good thing arXiv has got going.(Aside from unrelated censorship issues)

5. **Deane**
   October 30, 2006

   The system, in the sense of arxiv.org, works. I don't think any of the fuss is about that.

   What stunned me was seeing how too many bloggers, commenters on blogs, and "official" media such as Nature jumped on the bandwagon and touted Penny's work well before anybody with serious credentials had a chance to do a serious assessment of her claim. People who appear to have no expertise in the subject and have no way of understanding what was in Penny's paper posted their own personal (always positive) evaluations about Penny's work.

   You might ask what's the big deal, but some of the people who did this promote themselves as people who know math and how to judge what good math is. So their misleading statements create a higher level of FUD than what we sheltered pure mathematicians are used to.

   All in all, I think as math gets more publicity and attention, mathematicians like me are going to have to get used to the extra noise. Overall, I'd rather have the attention. But I think a lot of my colleagues feel differently.

6. **MathPhys**
   October 30, 2006

   Yesterday, there was a retraction of a paper on math.ph from 2004 on smooth solutions of 3D Navier Stokes.

7. **MathPhys**
   October 30, 2006

   PS That photo is great. You should have it framed 🙂

8. **anonymous**
October 30, 2006

This was an extraordinary case. What I find annoying are the many small mistakes present on arXiv. They get corrected in final published versions, but i) the most read version is the first one; ii) too many authors think that fixing errors in revised version without indicating them in the "comments" line is a good idea.

Please, instead of just writing "Comments: 26 pages, 7 figures, LaTeX" add "sorry, when we posted version 1 we were drunk, now version 2 is ok" and I will trust more your future works.

9. **anthropologist**
November 4, 2006

Now that I have read through all the comments on NS it does appear that Penny overhyped things quite a bit. And while the system of peer review did work as intended, the negativity she got is purely of her own making.

Again, Is N=8 Supergravity Finite?

October 29, 2006
Categories: Uncategorized

The main argument generally given for working on string theory is that it's the only way to get a finite theory of quantum gravity. One often hears claims that gravity can't be quantized using QFT, that string theory is needed to "smooth out the violent space-time fluctuations at the Planck scale", or some such explanation for the inherent non-renormalizability of quantum field theories of gravity. From the earliest days of their study, it was hoped that supergravity theories would have better renormalizability properties, with the maximally extended supergravity, N=8 supergravity, the most likely to be well-behaved.

For years the general belief has been that N=8 supergravity is non-renormalizable, based on the existence of possible counterterms at high enough order. The problem has always been that calculating the coefficients of these counterterms is too difficult, so one cannot be sure that one would not get zero if one actually did the calculation. Last year I wrote here about a talk by Zvi Bern in which he mentioned that twistor space methods for doing these kind of calculations were giving indications that these coefficients might be zero. Tonight there's a new paper out by Green, Russo and Vanhove suggesting the same thing. Their arguments involve M-theory and consistency conditions relating supergravity and the low energy limit of 10-d superstring theory.

It would be quite remarkable if it turns out that this work by Michael Green, using string theory and M-theory techniques, ends up shooting down the main argument for why one has to abandon QFT if one wants to do quantum gravity.

Update: Next month at UCLA there will be an entire workshop devoted to this question, entitled Is N=8 Supergravity Finite?

Comments

1. **anon.**
   October 29, 2006

   "It would be quite remarkable if it turns out that this work by Michael Green, using string theory and M-theory techniques, ends up shooting down the main argument for why one has to abandon QFT if one wants to do quantum gravity."

   I don't see that they would shoot down the argument; one has to be able to break SUSY without reintroducing nonrenormalizability. String theory allows one to have reasonable, realistic soft SUSY breaking. I'm not sure that N=8 SUGRA can do that.

   (Not that the question isn't interesting, and I would be happy to be corrected with pointers to references!)

2. **arnold**
   October 29, 2006

   Hi,
   a "naive" question. Why is it so important that there are no divergencies in a quantum theory of gravity?

3. **anon.**
   October 29, 2006

   arnold,

   That isn't precisely what's important — the technical property is "renormalizability", which means essentially that the theory is completely specified by a finite number of constants. Certain divergences are OK in a renormalizable theory, but in gravity they are usually too severe. One would need infinitely many parameters to quantize general relativity naively, and hence one would not really have a theory. You would always know at most finitely many parameters, and thus could never actually calculate anything.

4. **A.J.**
   October 29, 2006

   Arnold,

   One other reason that anon. didn't mention: The sort of divergences that appear when you try to quantize classical GR and supergravity have appeared elsewhere, e.g. in Fermi's theory of the weak interaction. (Although gravity is a considerably more broken theory than Fermi's ever was.) They usually indicate that the degrees of freedom we've chosen — in this case, gravitons — might not be valid at arbitrarily high energies.

5. **Kea**
   October 30, 2006

   I don't see much evidence of them taking the MHV twistor techniques seriously, so this paper can't have much to do with that excellent talk by Zvi Bern.

6. **MathPhys**
   October 30, 2006

   Why can you softly break SUSY in a string theory, but not in a finite supergravity theory?

7. **arnold**
   October 30, 2006

   thanks anon and a.j.

   Let me try to explain again my doubt : in any theory one has all possible operators allowed by symmetries, whose coefficients have to be fixed at some energy scale by experiments.

   Now, why does it matter if this coefficients are divergent or not?

8. **Gordon**
   October 30, 2006

I have about 8 papers on derivative corrections in IIB superstring theory and N=8. Including some matlab code that computes the coefficients. You might find this one interesting:

On the finiteness of N=8 quantum supergravity.

    November 30, 2006

    Gordon: *(reproduces my earlier arguments)*

    Yet, they don't seem to cite you.

12. **Gordon**
    November 30, 2006

    Well, Johny, it only took about 6 years and then sum.

    Lets cite it then. I do.

Some Early Criticism of String Theory

October 30, 2006
Categories: Uncategorized

From the “First Superstring Revolution” on, there have always been skeptics, even though they often were not very vocal. Perhaps the most well-known piece of such criticism was Paul Ginsparg and Sheldon Glashow’s [Desperately Seeking Superstrings], which appeared in the May 1986 issue of Physics Today. I recently became aware of some other similarly critical articles by Noboru Nakanishi, and copies of them have been made available to me. They are:

[Comments on the Superstring Syndrome] (also from May 1986)

[“Superstring Theory” Syndrome] (published in the popular magazine “Parity”, September 1986)

[Can the superstring theory become physics?] (January 1993)

This last paper claims that “the bubble of superstring theory has … bursted”, which, in 1993, was rather premature.

Comments

1. **D R Lunsford**
   October 30, 2006

   Nakanishi makes an extraordinarily accurate point!

   “I believe that any correct quantum theory should be able to be formulated in the Heisenberg picture. As long as one does not give up the idea of adding the interaction part to the free-field theory, one will never attain the fundamental theory.”

   There is so much truth in these two sentences!

   -drl

2. **Christine Dantas**
   October 30, 2006

   G. Borner, in his book “The Early Universe – Facts and Fiction” (1988), also cites Ginsparg and Glashow on page 223:

   Let us hope that from its phase of floating around in the imagination, superstring theory will be able to find some connection with reality. Let us wait and see whether it succeeds or whether it ends up as the kind of thing that Pauli would have characterized as being “not even wrong”.

   Christine

3. **Conrad**
   October 30, 2006

   Speaking as an interested layman with a degree in philosophy, I have never understood how it came to be that superstring theory became so entrenched as THE theory. I always knew that the theory made no testable predictions. I always suspected it to be something like Alfred North Whitehead’s theory of gravity(anyone out there there ever hear of this- but it was once a big deal)- an elegant theory written by a brilliant mathematician that ultimately goes no where.

4. **Chris Oakley**
   October 30, 2006

   DRL – agreed. Also known as “Haag’s theorem”. In between progamming bouts for the client, this is what I am looking at now.

5. **Kea**
   October 30, 2006

   This last paper claims that “the bubble of superstring theory has … bursted”, which, in 1993, was rather premature.

   Does that mean you think it has burst *now*?

6. **Peter Woit**
   October 30, 2006

   Kea,

   I don’t know. There’s certainly a lot of noise, but is it the noise of a bubble bursting or something else? Time will tell…

7. **hack**
   October 30, 2006

   There’s a saying that goes something like “Bubbles always last longer than you think is possible, even after taking into acount for the fact that they always last longer than you think is possible”.

8. **ralf**
   October 30, 2006

   Couldn’t one say that superstring theory has never been a part of physics as a (once) serious science, but has rather always been a phenomenon of the sociology of physics and the politics of academia and science funding? The exact moment of the bursting of its “bubble” may have been/be (hopefully) different for different people. For me there never was a “bubble” in the first place.
   I think nobody who even considers the mere possibility that the entire physical reality is a consequence of the super-Virasoro algebra should be considered a serious physicist.

9. **King Ray**
October 30, 2006

String theory is a compendium of failed ideas… Kaluza-Klein, string theory of hadrons, supersymmetry, supergravity, etc. Why would you expect to get the correct theory by combining so many failed theories? I never found any of those ideas aesthetically pleasing anyway, and all mixed together they are even less so.

10. **Thomas Love**
October 30, 2006

Are we now replacing string theory with bubble theory?

11. **Kea**
October 30, 2006

Are we now replacing string theory with bubble theory?

Exactly! By showing that string theory is merely a moduli space technique for doing rigorous QFT one removes the necessity of landscapes, higher dimensions, KK and all that.

12. **JC**
October 30, 2006

I vaguely remember the early 1990's being a slump for string theory. Besides the people who were working on mirror symmetry stuff, it looked like a number of the hardcore string people were banging their heads on the heterotic string (attempting phenomenology) without much success.

At the time I wondered whether the string bubble had actually bursted. I never thought that string people would become interested in 11d supergravity or supermembrane theory again. (In the mid-late 1980's, some string folks thought supergravity was a dead end).

13. **D R Lunsford**
October 30, 2006

King Ray – agreed! It always struck me as curious that something that appeared so physically ad-hoc could generate so much interest. My conclusion was that the interest was not coming primarily from physicists, rather mathematicians. I've always thought that the popularity of string theory may have derived simply from creating a large number of mathematicians during the Cold War, in a world short on things remaining to be proved – and so they fell on string theory because it was a fertile playground for mathematical speculation.

-drl

14. **dark-matter**
October 30, 2006

Amazing predictions from Ginsparg/Glashow and Nakanishi, 20 years ago.

Conrad:
For a philosophical essay see: http://www.arxiv.org/abs/physics/0610168

ST will proceed by sheer momentum and the power of denial. Maybe there are Miracles. LQG, having successfully dealt with quantization of GR (see http://www.arxiv.org/abs/hep-th/0605052) is now engaged in developing couplings to matter fields and taking a crack at unification. It may or may not produce something in the next few years. The best guide to developing a replacement for ST is the LHC, gravitational waves experiments, and satellites/telescopes. In another words, let the experimentalists take the baton and bring in some much-needed facts.

15. **arnold**
October 30, 2006

The article by Glashow and Ginsparg is really good.
Thanks Peter.

I always wondered how a theory which makes no conceptual breakthrough (it is just a naive hypothesis that matter is made out of strings) can have anything to say about the world 16 orders of magnitude smaller than what we know!

If you think about it, special relativity was a conceptual earthquake, as general relativity, and quantum mechanics.

String theory is just some naive generalization of Feynman diagrams to extended objects. And in order to even hope to make sense it requires so many adjustments (supersymmetry, more dimensions, some funny
compactifications to cure problems that were created by the theory itself,…) that it becomes almost ridiculous.

16. **King Ray**
October 30, 2006

DRL,

Someone once told me to beware of people that mathematicians think of as physicists and physicists think of as mathematicians.

I think also a lot of people have invested a lot of their careers in these failed ideas and want to see them survive in some way, so they have jumped on the ST bandwagon.

The string theorists just lack the nose for beauty and truth that Einstein had, that tells one if one is on the right track or not. Going from the SM to ST is like trying to deduce the shape of the whole iceberg from the part above water; it is extrapolation, and that rarely works well. Maxwell only added one term to one equation when he unified E&M, he didn't add hundreds of more forces. Likewise with EW theory.

17. **The Anti-Lubos**
October 30, 2006

Conrad: *Speaking as an interested layman with a degree in philosophy, I have never understood how it came to be that superstring theory became so entrenched as THE theory.*

Read Peter's book. Seriously!

18. **Tony Smith**
October 31, 2006

Noburu Nakanishi is professor emeritus at Kyoto University and co-author (with Izumi Ojima) of a well-known book, "Covariant Operator Formalism of Gauge Theories and Quantum Gravity" {World Scientific, 1990).

His most recent paper is hep-th/0610090 "Spacetime in the Ultimate Theory" in which he is critical of both non-commutative geometry and superstring physics models, saying:

"… Recently, the quantized spacetime has been revived owing to the fashion of the non-commutative geometry. But the quantized spacetime seems to be investigated in favor of the mathematical interest rather than the physical requirement. … Hence the calculations concerning it often become no more than mathematical exercises. Of course, one may claim that the quantized spacetime is an approximation of string theory, but such an assertion implies that the quantized-spacetime theory itself is not a candidate of the ultimate theory.
…
Some of the superstring people believe that it is fruitless to consider any other theory because the superstring theory is the unique candidate of the ultimate theory. I believe, however, that such an assertion is too much prejudiced, because there are several fundamental difficulties in the superstring theory and nothing of them have yet been resolved … there are absolutely neither theoretical nor experimental evidences which justify the huge extension of the theoretical framework done in the superstring theory.
…
utterly no superpartner-like particles predicted by SUSY are discovered. It is quite unnatural
to assume that all superpartners have a mass so large that no present-day accelerators can
produce them without exception … If NATURE does not adopt SUSY, supergravity and superstring must be abandoned, and many people researching them will become greatly embarrassed. …".

His paper is NOT merely criticism of non-commutative geometry and superstring models,
since
in it he propose a concrete model for spacetime (although not, in that paper, extended to describe all the particles and fields of the Standard Model). You should read the paper hep-th/0610090 and the book mentioned above for details, but here are a few excerpts that might give an indication of his ideas:

"… The quantum theory of gravity thus constructed turns out to have a 16-dimensional supersymmetry … based on the "16-dimensional supercoordinates" x^mu, b_nu , c^r, c'_p , where c^r and c'_p denote the Faddeev-Popov ghost and anti-ghost, respectively
…
More precisely, its superalgebra is the (8+8)-dimensional inhomogeneous orthosymplectic superalgebra consisting of 144 generators. Of course, the affine algebra is its subalgebra
…
In the framework of indefinite-metric quantum field theory … many unbroken symmetries are available without predicting the existence of extra physical particles, so that one can construct the action having a large (super)symmetry which may unify the spacetime symmetry and internal symmetries without contradicting the no-go theorem for the extension of the Poincare symmetry …
…
both the physical spacetime and the Lorentz symmetry of particle physics are the
secondary concepts appearing as a consequence of the spontaneous breakdown of symmetries … the Nambu-Goldstone boson corresponding to the symmetric-part generators of general linear transformations is nothing but the graviton. This fact guarantees the exact masslessness of the graviton. …".

The final sentence of his abstract in hep-th/0610090

"Any criticism on my opinion is welcome."

is a welcome contrast to some of the attitudes seen in the USA high energy theoretical physics community.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

19. **Jeff**
October 31, 2006

Peter,

Nice links. 🙂

String theory – for all its grandeur – is still a work in progress, even though you validly claim that 30+ years is a long time for a theory to be in development. Ofcourse, maybe the unspoken understanding may be that so long as Edward Witten thinks strings are a viable approach to QG and unification, the program will continue on unhindered.

But my post is not on strings per se; I wanted your view on what 'twistor theory' has to offer for QG (or even unification). Roger Penrose writes in his latest work (rather convincingly) that twistor theory has deep relations to physics that has not been fully explored as yet (due in large measure to string theory's dominance of hep-th research). Do you think twistor theory might have good potential in the future?

Regards,
Jeff

20. **1995**
October 31, 2006

Things started going wrong in 1995.

Around 1985, string theory seemed to be what we need: a theory of quantum gravity able of predicting its low energy QFT limit. Strings correctly become the mainstream.

But in 1995 people working on string physics had achieved nothing, while people working on string theory gave interesting results, showing that the theory was more rich than initially envisaged. This complication was a bad news, but many people were happy. Indeed, at this point the community was large enough to allow a self-referential study of the mathematical aspects of a theory that was loosing the initial physical motivation that turned it into mainstream.

String theorists now understood that they must start delivering truly good physics. Either this happens within a few years, or will not happen.

21. **D R Lunsford**
October 31, 2006

King Ray – Smolin says that ST is probably a consequence of the Feynman/Dyson "hard-nosed" approach to physics, where calculational virtuosity is the main skill, and contemplation of fundamental issues is secondary. Naturally, physical mathematicians are going to have a bigger role in such an enterprise than mathematical physicists. And I agree on your comments RE beauty – that is, beauty is a good guide, but you have to be able to see it first!

-drl

22. **Bert Schroer**
October 31, 2006

D R Lunsford
I don't think it is quite that simple because for a long time (up to the early 80s) ST did not have a mathematical attraction. It was Witten who showed that it can be used as a vehicle which carries metaphoric physical ideas into interesting mathematical conjectures.
Physically it had no historical connection; its birth was a shot from the hip, a strange combination of the most crude phenomenology (of saturating the intermediate state completeness property by an infinite tower of intermediate one-particle states) with Beta-function engineering. It unfortunately happened at a time when the success hubris from the standard model (see Phil Anderson's criticism) was in ascend and the conceptual control of of speculative proposals out of the blue were on the decrease. Only in this way one can understand that the result of a prescription was called S-matrix without ever checking whether it even satisfies the most crude properties (e.g. multi-particle clustering) without which that physical name is completely undeserved.
Feynman's and Schwinger's computational power was conceptually controlled and not rampart.

23. **Alejandro Rivero**
October 31, 2006

Amusing coincidence that the criticism of Ginsparg/Glashow were published in the "Reference Frame". I guess that this article substantiated some of the gossip about why hep@xxx was divided in hep-th and hep-ph (yep, and hep-lat, but that can be more obvious). And actually it is the first physics/… paper, is it?

24. **anonymous**
October 31, 2006

a posteriori one should now admit that crackpot Noboru, crackpot Paul and crackpot Sheldon correctly guessed many of the present problems. Still, I think that their criticism was too early and that strings had been a very good attempt, altough unfortunately the criticism of crackpot Peter and crackpot Lee might be close to the end of the story.

25. **D R Lunsford**
October 31, 2006

anonymous – I don't see how you can maintain this position in the light of Nakashini's extremely pointed criticisms. His essay is wonderfully to the point and succinct and hits the main issues of *principle*, without even going much into the technical details that Peter stresses. The paper linked by Tony Smith is also very much to the point and filled with physical insight. His insistence on having a Heisenberg representation for any final quantum theory is the best point in physics I've seen made in public for a long time. It should be pointed out that quantum theory was born this way. I think students should get a history course taught out of "Sources of Quantum Mechanics" by van der Waerden.

-drl

26. **Chris Oakley**
October 31, 2006

Anonymous,

I am surprised that you failed to mention that crackpot Popper, who required that physics should be based on mathematical models that are open to being proved wrong by experiment.

27. **Chris Oakley**
October 31, 2006

Oh, and another thing, in case non-native English speakers are getting confused: "burst" is the same in the past tense, and is therefore not a regular verb.

28. **D R Lunsford**
October 31, 2006

Chris – it is too bad the crackpot Dirac died in the same year as the Green-Schwarz coup. I wonder what lame comments he would have made?

-r

29. **Eamon**
October 31, 2006

I don't think that the bubble, if you can indeed call it that, will burst. I mean – how would such a thing play out? Too much reputation, energy, and money has gone into this.

What these older articles prove is that the shortcomings of string theory were already observed and noted long ago. They were ignored then, and will probably be ignored now. It even *took off* without a good connection to experiment. Why would that hurt it now?

30. **Chris Oakley**
October 31, 2006

Here is an exercise for the reader. Subtitute one the following for "the bubble" in Eamon's first sentence:

(i) Enron
(ii) LTCM

(iii) Ptolemy's epicycles
(iv) Alchemy
(v) Communism
(vi) Star Wars SDI
(v) The Hindenberg
(vi) Sony Betamax

31. **Chris Oakley**
October 31, 2006

… and finally

(xlci) my ability to count in roman numerals

32. **Bert Schroer**
October 31, 2006

Eamon
I agree with your pessimistic assessment.
Unless the most charismatic updater of ST returns to particle physics, i.e. to that what he was doing before he met Atiyah, and hence through this very act renounces ST (which we all agree is not particle physics) there will be no change. However I doubt very much that ST will survive the passing of its protagonists and Nobel supporters. As a result of its predictive vagueness it will most probably survive LHC, especially if new data resist satisfactory theoretical interpretation for a longer period of time. According to Phil Anderson one should expect that the duration of ST is direct proportional to the hubris in the aftermath of the unmerited success of the SM, but it is difficult to quantify hubris apart from registering (looking at its aggressive supporters) that it is still going pretty strong.

33. **Ari Heikkinen**
October 31, 2006

Yes, exactly, there's always been critics of string theory since its very beginning, yet many researchers have found it interesting enough to continue working on it over the years.

As far as I can recall, initially string theorists were called crackpots by physicists, not vice versa.

I still don't quite understand what's the big deal about the critism now. There's, for instance, Glashow's critism of string theory even in popular books about string theory like Greene's that's been there long before Lee or Peter wrote their books.

My point is, the critism is nothing new.

34. **Bert Schroer**
October 31, 2006

Can anybody explain why the title "crackpot" is so popular around Harvard? In an earlier reaction of Peter to anonymous he suggested that there may be something in the water around Harvard.

35. **egbert**
October 31, 2006

It's not just Harvard. It seems to have become a fundamental part of the string culture that, since nobody really understands what's going on, reputation is everything. When a string theorist meets some physicist, he rushes to judge that person's intelligence, and if that person says things that coincide with what the string theorist has heard from people he respects, then the person is intelligent and if he says the opposite he's a crackpot.

In the KITP video where the journalist in residence talks about Lee's and Peter's books, somebody in the audience proposes "taking a vote" about whether Lee Smolin is a crackpot. The vote didn't go ahead, perhaps because they knew they were being recorded and broadcast on the internet. But from the general hostility the audience was showing (even though they hadn't read the books), I think there can be little doubt about what the result of a vote would have been. The grad students learning string theory at UCSB will develop their opinions of who is an actual scientist and who is just some crazy crackpot in this environment.

Susskind does something similar in his review of the books. He tells stories about shipbuilders and explorers but in the end all he does is attack reputations.

36. **Bert Schroer**
October 31, 2006

Ari Heikkinen
I think there is a big difference if some individuals were called crackpots by the particle physics mainstream (I don't recall that this expression was in use in those days, probably the majority used to think that this was "crazy stuff" or something similar) or if string theorists think that everybody else is a crackpot. The last situation reminds one of a group of ghost drivers who drive down the highway in the wrong direction and shout at everybody who is driving the right way because they are not yet aware of their mistake.
And by the way, this is one of the few instances where the majority was right.

37. **Energex42**
October 31, 2006

In my mind, this round of String Theory criticism is more credible. LQG is making rapid progress, and creating a set of predictions. String Theory still have nothing to say about predictions.

Ironically, String Theory may be saved one day because LQG manages to see strings in an effective field theory.

38. **Bert Schroer**
October 31, 2006

No, please, it is not very effective.

39. **steve**
October 31, 2006

As an interested outsider (not a natural scientist), it has fascinated me how strong the social policing within physics (and to an extent astronomy and cosmology) is about crackpots. The structural reason for this is obvious–there are a lot of people who don't know what they are talking about who want to participate in the conversation and/or fantasize themselves as the new Galileo. In order for the conservation to be useful, the idiotic stuff has to be filtered out.

But the policing of crackpotism seems to me to go well beyond that. Even well-credentialed people who go off the reservation get cast into the outer darkness. It looks like most fields of science have foundational weak spots that everyone agrees to leave alone while working on superstrucural puzzles (if you'll pardon the metaphor). Everyone in the field has some existential worry that those weak spots will fail and bring down the whole structure, and they don't like people reminding them and pushing these issues to the foreground. So they declare anyone who worries about these matters to be a crackpot as a way of eliminating the cause of their anxiety. And by "shunning" these critics (in much the same way closed religious communities like some Mennonite sects do) they can exorcise the threat to communal well-being. Out of sight, out of mind. The shunned are rendered powerless to influence anything during their lifetimes.

Objectively, the shunners may well be correct in their scientific beliefs more often than not. But given a) the importance of the results if the "heretics" are in fact correct, b) the stimulus to mainstream theory created by the heretics, and c) the self-censorship that must cripple creativity when people want to avoid being shunned, I think a bit more tolerance for others' crazy ideas would be good right now. Personally, if the core theory in my field had problems like getting the vacuum energy wrong by 120 orders of magnitude, I'd be open to creative suggestions, even if they seemed a little bit cracked.

40. **TheGraduate**
October 31, 2006

steve:

I like what you said. Of course, what you say is just a general scenario that may or may not apply in individual circumstances. But I think it is a scenario that does seem to play out often.

However, I am surprised that so few physicists are willing say, "Yes there is no absolute proof of what I believe but I'm going to work on it anyway and since I believe it's the best idea, I am going to tell everybody else to work on it too."

They seem to prefer quarreling over the subjective value of the inconclusive evidence.

41. **Chris W.**
November 1, 2006

[*My apologies; it looks like I neglected to properly close an <a> element in the previous comment. Let's try again…*]

Steve,
I think one can interpret the tendency to label people crackpots in economic terms, especially these days. It *costs* something to sympathetically and carefully consider someone else's ideas, including time taken away from pursuing whatever research agenda one happens to be interested in. There is a strong incentive to latch onto reasons for quickly dismissing an idea, if only to save time for investigating other options, any of which may demand considerable effort. Like most successful and ambitious professionals, scientists hate to waste time, and look askance at (erstwhile?) colleagues who appear to be investing their time carelessly.
In contrast, Michael Nielsen quotes Freeman Dyson, speaking of J. Robert Oppenheimer:

> … we can see the nature of the flaw which made his life ultimately tragic. His flaw was restlessness, an inborn inability to be idle. Intervals of idleness are probably essential to creative work on the highest level. Shakespeare, we are told, was habitually idle between plays. Oppenheimer was hardly ever idle.

In this context, one should recall Aaron Bergman's repeated references to (and laments on) the relentless pressure to produce substantive research output, especially for younger scientists, and the general antipathy that most working scientists have to philosophical discussion, which they regard as mostly fruitless, if not altogether sterile and pedantic.
What I think many people are looking for at this stage in quantum gravity is a galvinizing idea—something that is both original and clearly relevant, ie, appears to be getting at the heart of the matter. (They also fear the paralyzing effect of knowing too much, ie, tending to immediately think of convincing reasons to suppose that any new idea couldn't possibly work.) Until such an idea appears there will be a lot of simmering frustration and some short tempers.

42. **Garbage**
November 1, 2006

Peter,

This is why this blog misses the oportunity to be a good place to discuss physics. You have an interesting post on finiteness of N=8 SUGRA, which if true would certainly produce a (though unrealistic) more *traditional* finite theory of gravity, that doesnt count more than 8 comments. In the other hand, this one on early critics of ST clicks 40 in a few days. It seems to me like you keep repeating yourself over and over, and even though I agree ST has grown perhaps way too far it should have ever been, and also particle physics needs to hit a *refresh*, I dont see the point of constantly hammering the same nail to get a swarm of mostly pointless comments. Do you really think that by doing that anything is going to change by doing that? I guess it is fair to say there is a lot a ST hype out there but jumping into the anti-hype wagon isnt going to help much.
I, as many physicists do , expect the LHC to clear the way for science soon.
And btw, the articles are fun reading 🙂

G

43. **Jeff**
November 1, 2006

Garbage:

You hit the nail! :-)) with your remark. The problem is that with excess time to spare, and not enough data to process, there really isn't much else to discuss except the latest gossip on our favorite blogs; everything else lies suspended in animation. Only when LHC gives experimental results will the field move forward.

As regarding string theory, I've heard rumors that even Ed Witten is beginning to have doubts (I can't exactly pinpoint where I heard this from; maybe it was from Peter himself – referring to conversations between L. Susskind and Witten).

Continuing, if you believe ST is a dead-end (or overhyped) then perhaps you may want to have a look through 'twistor theory'. Roger Penrose, in his new book 'The Road to Reality' quite elegantly argues that physicists have grossly overlooked [and sometimes undervalued] the twistor approach in favor of strings (citing similar reasons as others, i.e. Witten's overarching impact on current hep-th research, the sometimes unethical behavior of some string theorists when advocating the theory to lay audiences, string theory's lion share of research funding – frequently at the expense of other meaningful approaches, the media hype over string theory, etc.); he also adds that twistor theory has some fairly deep and robust properties – grounded primarily on physical! (NOT mathematical) considerations – to uncover new insights into fundamental

physics.
[Penrose, as many may know, is twistor theory's progenitor; however, given that he has spent more than 40+ years working on the topic, and given his calm and objective approach to writing on physics (as evidenced remarkably accurately in 'Road to Reality') I would not dismiss his claims as merely self-promotion; anyway, this *is* Roger Penrose we are talking about.]

I guess if you are a serious grad student (or young researcher) and want a clearer understanding of the current (theory) research landscape, Penrose's viewpoint may well not be an altogether bad start.

Regards,
Jeff

44. **Bert Schroer**
November 1, 2006

Garbage and Jeff
I agree with you that there is to much gossip and not enough scientific substance in weblogs including this one.
But I think that N=8 Supergravity is not a good illustration of this point. Why should a social construct like that be the subject of a meaningful discussion? Rumors about its possible renormalizability appear cyclically as reports on the sight of Nessy. Perhaps if somebody really succeeded to show nth order renormalizability it is worthwhile to talk about the physical significance of such an result but not in this stage.
The monomaniac preoccupation with quantum gravity siphons power away from post SM innovative research and at the end also harms progress about gravity.
If you look at my contributions of the recent weeks you will notice that I have been trying to get people interested in conceptual issues of actual research such as
Is KK consistent with QFT (and ST for that matter)
Why the CC computations of adding energies contradict local covariance
Why the alleged connection of holography with QG is misleading and how this led to wrong conjectures about AdS—CFT (a la Maldacena)
Why the objects of ST cannot be string-localized in any quantum-intrinsic sense
I admit that all these points require a certain amount of conceptual sophistication and mathematical knowledge. But is this the reason why nobody took them up or even asked meaningful questions?
I tried to adapt myself to the typical small talk on this blog with the subversive intention to lure people into more serious questions which could be the starting point of interesting discussions.
I do not see any point in repeating the lack of observational content of ST over and over again. Most participants and readers know this deadly flaw and the ST community has developed a thick skin.

45. **JC**
November 1, 2006

Bert,

Many folks I knew over the years felt that the biggest barrier to understanding algebraic QFT, even on a "qualitative" level, is the level of mathematics involved. Even with some knowledge of the mathematics involved, I've found that I still don't have a good understanding of it.

46. **Tony Smith**
November 1, 2006

Garbage said that Peter has "… an interesting post on finiteness of N=8 SUGRA, which if true would certainly produce a (though unrealistic) more *traditional* finite theory of gravity, that doesnt count more than 8 comments.
In the other hand, this one on early critics of ST clicks 40 in a few days … a swarm of mostly pointless comments. …
This is why this blog misses the oportunity to be a good place to discuss physics. …".

Garbage fails to note that the first comment on this thread was NOT "pointless" with resepect to substantive physics, but in fact dealt with Nakanishi's view of the fundamental status of the Heisenberg picture.
Also, other substantive physics points have been mentioned in this thread, such as:
Penrose's twistor theory;
Nakanishi's use of indefinite metric;
the consistency of Kaluza-Klein with QFT; and
soft predictions from spin networks of deformed special relativity, elementary particles as coherent excitations of quantum geometry, and disordered locality, all discussed in hep-th/0605052 which was mentioned in comment 14 by dark-matter.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – I note that Garbage him/herself has NOT submitted a comment to the thread on the finiteness of N=8 SUGRA, and HAS submitted a comment to this thread, and, further, posted the above-quoted comment as an AC.

47. **Bert Schroer**
November 1, 2006

JC
This is not the whole truth. The mathematical prerequisites are certainly not more demanding than those in string theory where these days people use category theory, gerbs, algebraic geometry, noncommutative geometry…..
I think the basic difference is that in ST you do not have to know their deeper mathematical content; the metaphoric physical nature of ST allows you to operate with a basically verbal knowledge and the rest can be done by improvisation and massage.
AQFT continued von Neumann's tradition on the mathematical side (but on a meanwhile infinitely refined level) and tries to implement the Jordan plea of disconnecting a more fundamental theory (QFT) from its classical bonds (the AQFT as conceived first by Haag). Its mathematics consists only of refinements of concepts which in their mode crude version you are certainly familiar with: bounded and unbounded operators, operator algebras and their spacetime encoding. It is the only setting of QFT in which there has been an independent development on par with mathematics on a very deep level of conceptual coalescence (the modular Tomita-Takesaki theory with an independent development from the center of QFT: the thermal theory of open systems by Haag Hugenholz and Winnink and the concept of modular localization which started with Bisognano and Wichmann). Using metaphors of physics for the advancement of mathematics or using existing mathematics to expand metaphors of physics is not the same thing.
The distance which people maintain from AQFT has little to do with its high demands on mathematics; it is more related to sociology and history. The same people who have to take responsibility for the post SM hubris are also those who consider it as a superfluous distraction from their grand design.

48. **Particle Physicist**
November 1, 2006

"The same people who have to take responsibility for the post SM hubris are also those who consider it as a superfluous distraction from their grand design."

It is also the people who developed the SM who consider AQFT as a superfluous distraction, and fortunately so. Otherwise, we wouldn't have QCD and a theory of electroweak interactions today but were still stuck in the 50's, roughly speaking. Or can you point to any insight into the SM that was provided by AQFT?

49. **Bert Schroer**
November 1, 2006

I was not talking about the ideas which led to those important discoveries, the hubris started afterwords. I never felt any antagonism before but rather a division of labor. There are those who go out and find our truffles and there are others who like to clarify and secure these findings in order to build a reasonable trustworthy basis for starting new discoveries and this has never had a stifling influence on the truffle seekers. The discovery of gauge theories was very important but the situation is a long way off from being in the possession of a trustworthy basis for the conquest of new phenomena (and I am reluctant to say this, in the present conceptual quicksand even the future results of LHC may not indicate the way out).
The point of view you are presenting is part of that post SM hubris. I suggest to you to read what Phil Anderson has said about this problem.

50. **Particle Physicist**
November 1, 2006

Let me repeat the question: what insights related to standard model physics, and beyond, would we miss if no one ever had dealt with AQFT?

51. **Bert Schroer**
November 1, 2006

What one is missing has more to do with how to get out of the present crisis which already lasts for more than 3 decades. There are indeed suggestions of how to get some conceptual progress on gauge theory in general and the Higgs issue in particular. Some ideas you find in the last section of my Samizdat essay. But the only presently already worked out innovations are in the area of QFT in CST and black hole issues in particular the entropy of the quantum state which causes the entropy associated with the Hawking radiation (also explained there).
But from the way you phrase your question it seems that you think of particle physics in terms of a sport match with winners and losers (this seems to be your attitude with respect to AQFT) or even worse in terms of a eliminationist anti-conceptual ideology. Perhaps if there would be more than a handful of researchers in algebraic QFT you would not still find yourself in that already 30 years discovered best quasiclassical straitjacket for the physical reality behind the SM (from which all the globalized communities of enormous size have not been able to get away).
It has been my experience in more than 40 years of professional activity that particle physics needs many different talents to make progress.

52. **Tony Smith**
November 1, 2006

Bert Schroer compared Superstring Theory with Algebraic Quantum Field Theory, saying:
"… in string theory … people use category theory, gerbs, algebraic geometry, noncommutative geometry…. I think the basic difference [from AQFT] is that in ST you do not have to know their deeper mathematical content; the metaphoric physical nature of ST allows you to operate with a basically verbal knowledge and the rest can be done by improvisation and massage …
AQFT continued von Neumann's tradition on the mathematical side … and tries to implement the Jordan plea of disconnecting a more fundamental theory (QFT) from its classical bonds … It is the only setting of QFT in which there has been an independent development on par with mathematics on a very deep level of conceptual coalescence … ".

With respect to AQFT and Standard Model model-builders, Bert Schroer went on to say that he " … felt … a division of labor.
There are those who go out and find our truffles … gauge theories ….
and
there are others who like to clarify and secure these findings in order to build a reasonable trustworthy basis for starting new discoveries …
The distance which people maintain from AQFT has little to do with its high demands on mathematics; it is more related to sociology and history …".

It seems to me that it would be a good thing to build bridges across the "division of labor" between AQFT approach and the "truffle hunter" model builder approach in which models are often built from gauge theory Lagrangians using path integral quantization.

In a comment to another thread on this blog, Bert Schroer said "… hyperfinite Type III_1 von
Neumann algebras … are the heart of local quantum physics …",
but
I don't see a road-map for exactly how the various parts of the von Neumann algebra correspond to the various parts of a gauge Lagrangian / path integral model.

Maybe a reason that ST people seem to have more political influence than AQFT people might be that the ST people (even if by "improvisation and massage") take pains to describe purported connections between their ST models and gauge Lagrangian / path integral models.

Without a road map to connect gauge Lagrangian / path integral models with the relevant von Neumann algebras, it is understandable why the model builders would feel distant from the AQFT people,
especially
if the main voice that the model builders hear from AQFT people is harsh criticism of basic model builder tools such as path integrals, as opposed to discussion of what kind of limiting processes etc might connect the two approaches.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

53. **woit**
November 1, 2006

I kind of agree with Garbage that I wish people would post more substantive comments, especially ones relevant to the more technical postings. I recognize that this may be too much to expect; the number of people out there really knowledgeable about some of these subjects is vanishingly small and undoubtedly they have better things to do than contribute to this blog.

But, please avoid posting repetitive comments that just add to the noise level. It's true that many of the postings here deal with the same issue, the current status and problems of string theory. This is largely because this is an active story and new material keeps coming in, but the same general comments about what's wrong with string theory are not enlightening. I'm already deleting quite a few of these, and will delete more in the future.

54. **Ari Heikkinen**
November 1, 2006

Peter,

It's interesting that you encourage people to post more technical comments instead of purely philosophical, yet the very first of the links to the papers you posted (Glashow et al.) about early criticism of string theory is purely philosophical without a single equation or proof. Yet they manage, in addition to the criticism of string theory in that very paper, call Einstein, probably the greatest thinker since Newton, incompetent (Quote: "He had to fail, simply because he didn't know enough physics.").

I'm sorry to say, but it seems more and more to me as if different standards are applied when evaluating the work of string theorists compared to evaluating work of non-string theorists.

55. **Peter Woit**
November 1, 2006

Ari,

My comment had absolutely nothing to do with string theory vs. non-string theory, other than noting that I'm already deleting a lot of repetitive comments people write in here criticizing string theory, and encouraging people to stop doing it. As far as comments here go, yes I do have a double standard: I virtually never delete anything people write in that is positive about string theory, and/or critical of my point of view on it, but often delete things that are negative about string theory or just endorsing my criticisms.

Also, when I link to papers, it is definitely not because I agree with everything in them. The ones mentioned here were mentioned for historical interest, just because I only very recently became aware of the Nakanishi ones.

56. **Bert Schroer**
November 1, 2006

Particle Physicist
I think that there has been a misunderstanding, my statement should have been:
…..who consider it as a superfluous distraction from their grand new designs"…."The word new was missing. If there was some hubris to their achievements to discover the SM this is human, understandable and did not cause any harm. I meant the hubris that one could get much more without any additional conceptual physical investment. I think it is clear by now that those ideas which were involved in the discovery of the SM and which people have used for 30 years to get beyond are sapped.
Tony Smith
All these things you mention have been discussed in previous blogs of mine. They have appeared in a specific context and taking them out of this context does not move me to explain things for the nth time again just because weblogs do not seem to have a memory for more than one week. I have got to know your point of view (basically use the old ideas perhaps with slight updating) and I am not trying to proselyte. There is a high entrance fee for AQFT and I am not offering a cheaper rate to anybody (and answering all your questions and statements for the nth time does not help anybody).
It is strange that you remind me of the only thing which I have in common with ST, namely the conviction that more of the QFT as it is in the books is not taking us out of our present misery.

57. **TheGraduate**
November 1, 2006

Peter,

It's unfair of you to blame other people when you're the one who hasn't been clear in a prominent place about what you want on your blog.

You said "But, please avoid posting repetitive comments that just add to the noise level."

What is 'noise' supposed to mean? If you have not defined it in an easy to find place on your blog, how are people supposed to know? And on the issue of repetitiveness … so agreeing with people is disallowed?

"As far as comments here go, yes I do have a double standard: I virtually never delete anything people write in that is positive about string theory, and/or critical of my point of view on it, but often delete things that are negative about string theory or just endorsing my criticisms."

This approach is very, very curious indeed. I am not how sensible it is to make insulting you the easiest way of making sure a comment is not deleted but to each his own.

58. **Peter Woit**
November 1, 2006

TheGraduate,

I probably should post somewhere some kind of "policy", but the problem is that it isn't so easy to precisely formulate such a thing. In practice the main problems have always been people who don't know what they're talking about, people who want to change the topic of discussion to their pet interests, and people who think it is a good idea to post comments that repeat others or their own, adding nothing new. The best way I know of characterizing what I'm trying to achieve is keeping the signal/noise ratio as high as possible. Sure, what I consider "noise" someone else may consider signal and vice-versa. But if you're writing a comment that is adding nothing new to the discussion that people are likely to find interesting, you shouldn't do it, it's that simple.

59. **TheGraduate**
November 1, 2006

Peter,

This may not seem plausible to you but asking others to live up to a standard which you refuse to articulate truly is the definition of 'unreasonable'.

60. **Arun**
November 1, 2006

Ari writes:

"Yet they manage, in addition to the criticism of string theory in that very paper, call Einstein, probably the greatest thinker since Newton, incompetent (Quote: "He had to fail, simply because he didn't know enough physics.")."

Ignorance is not the same as incompetence. Unless you mean to say that the discoveries since 1955 are irrelevant to producing a theory of everything (e.g, anomaly cancellation), Einstein certainly did not know enough physics. And it is very likely we still do not know enough physics to produce a theory of everything, despite all the ST claims to the otherwise.

Think about it – how would you express the fact that Einstein did not know about quarks and QCD, among a great many things? "He did not know enough physics" is certainly a legitimate expression of Einstein's ignorance.

61. **Peter Woit**
November 1, 2006

TheGraduate,

I just articulated it as best I can: don't post comments unless they're adding something new to the discussion that will be interesting to other readers (who you should assume are smart and well-informed…).

And the only reason I'm not deleting your last comment arguing with me about this is that you're insulting me by describing me as unreasonable…

62. **TheGraduate**
November 1, 2006

Peter,

Well I certainly did not get into posting on your blog to insult you or any one else. I only aim to accurately describe. I apologize. (You may delete this post after you have read it, as it will have served its purpose.) I will try my best in the future not to add to the noise. You may also delete the 'unreasonble' comment if you wish. Although, it may not seem like it, most of my comments are aimed at promoting better conversation.

Cheers.

63. **Tony Smith**
November 1, 2006

In my comment 52, I asked Bert Schroer "… exactly how the various parts of the von Neumann algebra correspond to the various parts of a gauge Lagrangian / path integral model. …".

Bert Schroer, in reply said "… All these things you mention have been discussed in previous blogs of mine. … I have got to know your point of view (basically use the old ideas perhaps with slight updating) …".

I agree that my point of view is to stay close to "the old ideas" of a gauge Lagrangian / path integral model,
but
I do not see where Bert Schroer has in "previous blogs" explained "exactly how the various parts of the von Neumann algebra correspond to the various parts of a gauge Lagrangian / path integral model.".

However,
I HAVE seen a dialogue in the thread in Peter's blog "Schoer's Samizdat" in which:

Arun in comment 106 said something substantially equivalent to my present question:
"… It seems to me [Arun] that AQFT practitioners find the Lagrangian path integral method of QFT to be unreasonably successful.
Well, if AQFT is indeed the way to do QFT,
then the success (and limitations) of the Lagrangian path integral should be explainable within AQFT.
Presumably the successful Lagrangian formulations are taking care automatically somehow the setting up of the unique hyperfinite type III_1 factor algebra, the modular positioning of a finite number of abstract monades, etc., etc. …"

and

Bert Schoer replied in comment 108:
"… "… arun,
this is all deja-vue, we (maybe without you) discussed this in this blog in April/May. … I [Bert Schroer ' will ignore this and answer it to the best of my [Bert Schroer's] knowledge
1) Funct5ional integrals are extremely limited …
2) you cannot solve any 2-dim. massive system, even in case it admits a Lagrangian presentation …
3) Most free fields cannot be characterized as being of Euler-Lagrange type (above spin 2 I [Bert Schroer] do not know any) but their use is perfectly legitimate in causal perturbation theory (where you only use interaction polynomials in free fields) although the most important ones can

4) The Lagrangian approach where it works in your sense is an artistic device:
you write something on paper in good faith, develop it in perturbation theory,
see that it does not make sense (the integrals diverge) and
use your hindsight and good physical sense to repair it (renormalization) and
at the end you realize that you have a perfectly reasonable result which however (if you try to check whether it its into your original functional representation) fails to satisfies your original functional representation. …
The artistic device of functional integrals (in QM it is mathematical) works because the whole idea of locality is so strongly incorporated that you cannot fail to extract the right result (if you have a good covariant formalism which was not available before 1949). …".

In my view, Bert Schroer's reply is only a negative attack on "the old ideas", and is NOT responsive to the issue raised then by Arun and now by me:

If the von Neumann algebras of AQFT describe physics as well as "the old ideas" of the Lagrangian / path integral Standard Model,
then
what are the exact correspondences between von Neumann algebra and the structures of "the old ideas" ?

Or,
does AQFT in its present state suffer from an ailment similar to that of the numerous vacua of superstring theory, that is:
are there a lot of von Neumann algebras and nobody in AQFT can identify a single one that corresponds to the Standard Model ?

From reading Bert Schroer's hep-th/0610225, it seems to me that the latter is the case, as he says there:
"… the physical reality of relativistic local quantum matter in Minkowski spacetime originates from the (modular) positioning of a finite number of copies of one abstract monade …
The rich content of a quantum field theoretical model including its physical interpretation (particles, spacetime and inner symmetries, scattering theory….) is solely encoded in the relative positions of a finite number of its monades …

The requirement is that the positioning should be natural within the logic of modular operator theory (using the concept of modular inclusions and modular intersections). For higher than 3 spacetime dimensions the presently known descriptions still look somewhat
concocted …
there are some still rather vague ideas of how the fact that the S-matrix has the interpretation
of a relative modular invariant … may be used in model constructions.
They are based on … the hope that its use (i.e. in a perturbative bootstrap-formfactor program) could have a chance to improve this situation. I [Bert Schroer] expect that by combining some ideas of the old S-matrix approach with this recent
framework of modular wedge localization one will obtain new insights into the
construction of QFT.
It is my [Bert Schroer's] intense impression that … it is not possible to make progress in
particle physics without a new problematization of the bootstrap-formfactor idea. …".

Bert Schoer's appeal to bootstrap ideas to try to construct models in more than 3 spacetime dimensions indicates to me that AQFT suffers from a problem similar to that of the many solutions of Superstring Theory:
a large and poorly described Landscape / Swamp of solutions,
with no known correspondence of any of them with the Standard Model.

In the absence of a concrete answer to the question raised by Arun in comment 106 of the "Schroer's Samizdat" thread and my question in comment 52 of this thread,
I will plod along using "the old ideas perhaps with slight updating".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

64. **A.J.**
November 1, 2006

Bert,

I think what Tony was suggesting is that it's time for someone to write up an "Introduction to Algebraic QFT for Particle Theorists", showing how the essential ideas of effective field theory (regularization, renormalization, anomalies, gauge symmetries, and perturbative expansions) are interpreted in the "local quantum physics" framework, in a language suitable for particle physicists. I don't mean that one shouldn't use Tomita-Takesaki theory, of course, but that one should treat it as something within the grasp of most particle physicists, rather than claiming that "there is a high entrance fee" to AQFT. The essentials of factors can be explained to anyone with a basic grasp of Hilbert spaces.

65. **steve**
November 1, 2006

Chris W: I like your formulation of the crackpot-policing issue in terms of time allocation. From an econ background, it makes a lot of sense.

If passive ignoring were the only behavior directed at well-credentialed heretics, though, it wouldn't be such a striking phenomenon. The aggression or venom involved in ridiculing, cutting off the funding of, and otherwise ostracizing the people who keep picking at anomalies almost seems to take as much time as would be required to address their concerns. I guess the number of active persecutors relative to passive ignorers is pretty low, though, so your theory still has a lot of power.

66. **Chris W.**
November 1, 2006

I, as many physicists do, expect the LHC to clear the way for science soon. (from Garbage)

To the extent that one wants the in question science to be about quantum gravity and unification, I wonder how much it will help. If the current theoretical situation allows for millions of potentially applicable models, and fundamental assumptions remain up in the air as one or the other of the models is refuted by the data, then we'll still be groping for a way to narrow the field on other than purely empirical grounds. (I'm assuming here that the individual models will be of limited interest by themselves.)

On the other hand, if one is mainly interested in taking the next small steps beyond Standard Model, with some interesting anomalies to chew on, then a return to doing science seems more likely…although that depends on what the LHC turns up.

67. **Bert Schroer**
November 2, 2006

Dear contributers and readers
When I actively participated in the weblog for the first time in April this year, the problem of alternatives to ST was an issue of considerable common interest. It was in that context that I started to mention the algebraic approach to QFT which most participants have only met (if at all) in the context of chiral theories or factorizing models (since in both cases there is no Lagrangian Lagrangian construction of such models) and whose contributions to 4-dim QFT are meanwhile very impressive and everytime mor constructive and concrete.
I tried to convey a bit about its content but as time went on it got a bit out of hand and I now realize that a weblog is not the right place. What caused me to write these lengthy contributions was the lack of a good reference; the book of Haag which was written in the late 80s as a nice motivating text (and it still continues to be) which however does not intend to connect readers to the technical level which would be necessary to reach a working knowledge (not to mention the impressive progress during the last 2 decades).
I think the lack of a textbook which includes in addition to a presentation of the concepts also sufficient technical-mathematical details makes any discussion on a weblog very difficult. Even though there are only very few people working with these methods, one would hope that this will change in the not so distant future. Since weblogs are not the right place I will stop right here admitting: mission not accomplished.

68. **Sailor Moon**
November 2, 2006

Ha! It looks like Ginsparg will let you make trackbacks to ~his~ papers!

69. **Arun**
November 2, 2006

While waiting for a up-to-date AQFT textbook, I'd just point out that the nature of successful scientific theories is that they explain the apparent success and limitations of previous scientific theories. Thus,in this sense, Special Relativity contains Newtonian mechanics, General Relativity contains Newtonian gravitation, and so on.

Anything that claims to supplant the Lagrangian/ path-integral/ perturbation-theory Standard Model of electro-weak & strong interactions, which is our most successful theory so far, needs to show how, in the appropriate limit, the Standard Model emerges.

70. **Tony Smith**
November 2, 2006

Arun said that if AQFT (or anything else) "… claims to supplant the Lagrangian/ path-integral/ perturbation-theory Standard Model of electro-weak & strong interactions, which is our most successful theory so far,
[then it] needs to show how, in the appropriate limit, the Standard Model emerges. …".

Alain Connes is certainly very knowledgeable about von Neumann algebras etc
and
he does take pains to connect his Non-Commutative Geometry (NCG) models to the Standard Model (although I don't think that he seems to be opposed to using Lagrangians etc in his model-building).

In his paper with Chameseddine and Maroclli at hep-th/0610241, Connes says
"… The input of the model is extremely simple. It consists of the choice of a finite dimensional algebra … a direct sum C + H + H + M3(C)
… geometric considerations on the form of a Dirac operator … lead to the identification of a subalgebra … of the form C + H + M3(C) …"
(where C = complex numbers, H = quaternions, and M3(C) = 3×3 matrix algebra).

Is there a way to show how that particular choice of algebra, in the context of that NCG model,
would correspond to
a particular "(modular) positioning of a finite number of copies of one abstract monade" from which, according to Bert Schroer's hep-th/0610225, "the physical reality of relativistic local quantum matter in Minkowski spacetime originates"
??

If there is, then it would help me to understand AQFT.

If not, then it might still be helpful to know why not,
and what are the difficulties in making such a correspondence.

If Bert can shed any light on that, I would appreciate him making at least one more appearance on this blog thread to do so.
In any event, I thank Bert for a lot of interesting comments, which I have enjoyed reading, although I regret that my understanding (although expanded from what it was before I read) is limited.

Tony Smith

November 3, 2006

Bert,

You commented:
I think the lack of a textbook which includes in addition to a presentation of the concepts also sufficient technical-mathematical details makes any discussion on a weblog very difficult.

Given your wealth of knowledge and experience, have you considered writing something like a review article of the "state of the art" of AQFT, complete with sufficient mathematical content to offer a path for those who might consider it a serious subject for study? The advantage of an in-depth summary of this kind is that you would have complete editorial control over the content and style. Publishing costs are free, and so is the cost to the student…

This would be a significant undertaking, but it would be a potentially lasting contribution, and one which would have far greater potential to interest the wider community in the possibilities of AQFT than anything a weblog could offer. Plus, even if you didn't have time to finish the article you could post whatever you have, and that would still offer something of substance to a potential student of AQFT. Anyway, it's just a thought…

72. **Bert Schroer**
November 3, 2006

The situation in the absence of a good pedagogical text is not that desperate as it appears in my last blog. Different from ST talks and articles often start with simple historically well-known results and problems. I have never seen a paper or participated in a talk on AQFT which started with hyperfinite type III_1 factor algebras, but I already found myself lost in talks (when I missed an early chance to get away) which started with type II_1 superstrings (with most of the audience nodding their heads approvingly). So it is not surprising that there are some very good reviews of some central concepts in AQFT (modular localization, charge confinement/liberation, local covariance of QFT in CST,…), but reading them outside the reach of experts may be frustrating because there is nobody whom you can ask if you get stuck. Certainly a normal weblog like this is not the right place and it may be worthwhile to think about a better solution.
Concerning the question of writing a book about algebraic methods, I once started to write some notes but then concluded that a time of rapid changes is perhaps not the right one. I do intend to return to this project next year (after having cleared up some pending problems as well as my desk).
What has been a bit frustrating to me is that that people always try to construct an antagonism between the functional integral approach and the perturbation theory resulting from AQFT ideas. In my earlier contributions (April-June) I took great pains to clarify this issue of AQFT being inclusive; renormalized physical correlation functions just don't care about the (even mathematically illegitimate) way you obtain them because you can check their correctness independent of the sins you committed on the way to obtain them. The number of renormalizable Lagrangian field theories is quite limited, there is a finite number of abstract actions and the rest is obtained in terms of families by playing around with varying numbers of field components (the last classified family was the gauge theory family which was the only one which possesses the asymptotic freedom property). But the number of non-Lagrangian families is infinitely larger as the studied 2-dim. factorizing setting shows. In that case you classify your theories by its simplest algebraic structure (as in case of chiral theories). I don't see any sense in craving for Lagrangian in 4-dim. while living quite comfortably with algebraic classifications and constructions in lower dimensions.
Concerning contributions to particle physics of people with great mathematical rigor, insight and talents like Connes and Witten I prefer to be silent because anything critical I say, as objective as it may be, will be misconstrued as regicide (whereas in reality I have an immense admiration for their mathematical knowledge and skills). The furthest I went was in a weblog discussion in (I think) May at this weblog with an anonymous participant named "the great inquisitor". He understood precisely what I wanted to convey and did not misuse it, neither did anybody else (perhaps I have been just lucky).

73. **N. Nakanishi**
November 4, 2006

Looking at the discussions between Bert Schroer and the outsiders of Algebraic QFT, I would like to comment that there is a standpoint in between theirs. I emphasize that any of non-superstring, non-path integral formalism, and non-perturbative approach does not necessarily implies Algebraic QFT, that is, there is the most traditioinal approach, canonical operator formalism of Lagrangian QFT. Recently, Abe and myself have developed a method for finding the solution to the canonical operator formalism of QFT in the Heisenberg picture. I believe that this method is quite natural, and several models have been explicitly solved by this new method. For a review, see N. N., Prog. Theor. Phys. 111 (2004), 301-337.

74. **Chris Oakley**
November 5, 2006

Nakanishi-san,

I am not aware of your work, but it sounds interesting and will look it up when I am in the library next.
I agree with the approach you describe above, although I would like to see the Lagrangian formalism replaced by something that emanates entirely from quantum considerations. I am (sort of) working on it…

75. **Bert Schroer**
November 5, 2006

Noburo
AQFT is a different method of implementing QFT it is not a different theory which modifies any of the underlying principles of QFT (as ST or LQP). There is no antagonism and I have tried (without much success) to get this message across. Fortunately QFT is a totally intrinsic theory (it even contains the concepts of its own interpretation) and the correctness of a result can be checked without using the same methods which were used to derive it, it is definitely not just a bunch of recipes as ST.
There are however problems for which the standard canonical quantization methods fail. Take e.g. chiral theories, factorizing models, QFT in CST or the question of computation of localization entropy (which I addressed in two of my publications). If you know how to deal with those problems in a canonical setting go ahead and do it; people on this weblog who are reluctant to learn trans-canonical methods will be thankful.
I think we both are conservative. You are conservative about the formalism whereas I am extremely conservative about the principles but care less about what formalism you use to implement them. I have no problems to agree with your critique of ST , supersymmetry and the so-called noncommutative theory.
all the best
Bert

76. **N. Nakanishi**
November 5, 2006

Bert:

I do not understand the contents of what you mean by "problems for which the standard canonical quantization method fails". In the method of Abe and myself, the representation of the operator algebra is given by constructing the set of all Wightman functions for the fundamental fields. If your problems can be discussd in the Wightman framework, I guess that they can also be dealt with my method.
The important characteristic common to both canonical operator formalism and Algebraic QFT is the existence of the operator level analysis. Izumi Ojima, my colleague, who previously established canonical operator formalism of the Yang-Mills field and is presently working in Algebraic QFT, has recently emphasized the fundamental importance of avoiding the theories in which the representation level is directly considered (such as path-integral formalism). I expect that he makes some comments in this debate.

(By the way, my first name is Noboru.)

77. **Bert Schroer**
November 6, 2006

Noboru
For the three problems I mentioned previously I do not know how to compute without using the setting of algebraic QFT.
The Wightman framework may be a nice way to present the structure of QFT, but I am not aware of any model computation which has been carried out in terms of them. The nonlinear positivity requirements are just too hard for any explicit construction and all successful calculations I know start with a Hilbert space and operators therein.

Particle Physics in Hawaii

November 2, 2006
Categories: Uncategorized

This week in Honolulu there's a major particle physics conference going on, a joint meeting of the Division of Particles and Fields of the APS, and the Japanese Physical Society, called the Joint Meeting of Pacific Region Particle Physics Communities. Slides from the talks have started to appear here.

The conference is huge, with hundreds of talks (for some reason, attending a conference in Hawaii seems appealing to many people), and I haven't had time to look at more than a few of them. Barry Barish gave a talk on international cooperation in HEP, Dave Schmitz one about the status of MiniBoone, which is "in the endgame" of a blind analysis of their neutrino experiment, with the black box containing their results to be opened in the not too distant future.

Lots of talks about string theory, including a plenary talk by Polchinski partly about AdS/CFT and attempts to use it to get information about QCD, partly about the landscape and string vacua. There was also a remarkable talk by Wati Taylor entitled Can String Theory Make Predictions for Particle Physics? Taylor begins by noting that "If we could do experiments at greater than 10^{19}Gev, answer would probably be Yes". "Probably" is different than the usual claims about this… His summary of the current state of string theory and particle physics goes like this:

- String theory need not make predictions for particle physics below 100 TeV
- We can't define string theory yet
- The number of suspected solutions is enormous, and growing fast
- Nonetheless, constraints on low-energy physics correlated between calculable corners of the landscape may lead to predictions
- If not, probably need major conceptual breakthrough to have any possibility of predictivity for low-energy particle physics
- *Raison d'etre* for string theory: quantum gravity

I don't know why he chose 100 TeV here, presumably just because it is probably an upper-bound on the likely energy scales particle physicists will be able to explore during the lifetimes of anyone now living. He could just as well have picked a much higher number. The only hope he sees for getting any kind of prediction using current versions of string theory is by finding correlations between things like numbers of generations and gauge groups when you examine large numbers of string vacua (this is similar to the conclusion reached by Michael Dine, described here). In work with Michael Douglas, he has found no evidence for this. Taylor also explains that the standard 10^{500} number often given for the number of string vacua seems to be a dramatic underestimate, and that it is even quite possible that the number is infinite when one takes into account non-geometric compactifications. Fundamentally, his conclusion seems to be that there is only a vanishingly small hope remaining of getting any predictions about particle physics out of string theory, so it has to be sold purely as a theory of quantum gravity, unless a miracle happens.

Taylor does make the case that string theory has found potential uses not in unification, but in studying strongly coupled gauge theory (AdS/CFT) and in suggesting new structures to try out in model-building. But at this point, he characterizes low energy physics predictions from string theory as unlikely, their appearance would just be an "unexpected bonus". So, I guess the answer to the question of his title is basically "No". Despite this, he does end by advertising the String Vacuum Project and listing the 17 prominent theorists who are asking the NSF to fund it.

Comments

1. **relativist**
   November 2, 2006

   Taylor has an excellent summary of the state of string theory on his webpage at

   http://web.mit.edu/physics/facultyandstaff/faculty/washington_taylor.html

   He starts off by saying "String theory is currently the most promising candidate for a framework in which to understand quantum gravity. It is still not possible, however, to define string theory in a space-time background compatible with the physics we see around us, and string theory cannot yet be used to make specific predictions".

2. **JC**
   November 2, 2006

   Peter,

   (slightly offtopic)

   Was there ever any "landscape" type thing in the days of supergravity, before string theory (ie. late 70's and early 80's)?

   (I looked up some old supergravity review papers the other day, and couldn't find much resembling the "landscape" silliness).

3. **Alejandro Rivero**
   November 2, 2006

   Due to a happy cumulation of circumstances, including or starting from the fact of the mass of the tau lepton being 1.78 GeV, we happen to have one of the outsiders of physicsforums giving a talk during a paralell session there. He went to Polchinski's, and did a brief comment here

4. **King Ray**
   November 2, 2006

   I agree that string theory is currently the most promising candidate for a framework in which to understand quantum gravity; it keeps promising and promising, but never delivers.

5. **Kea**
   November 2, 2006

   One of the speakers is blogging from the conference here:

   http://www.physicsforums.com/showthread.php?t=140402

6. **woit**

November 2, 2006

Kea and Alejandro,

If people want to discuss this speaker's talk, they're encouraged to do so with him over at PhysicsForums.

JC,
No, there never was anything like the Landscape back in the 70s or 80s. If anyone had suggested working on classes of models that complicated and unpredictive I doubt anyone would have taken them seriously.

7. **Ralph Q.**
November 3, 2006

No, there never was anything like the Landscape back in

I don't think people knew how, or had the motivation, to study non-susy vacua back then. Maybe the thrust in that direction came from the definitive astronomical evidence that the CC is not zero.

8. **Carl**
November 3, 2006

After the talk by Washington Taylor , one of the questioners started out her query with "I noticed that you avoided using the "A" word …"

Of course my mind leapt to the possibilities. Antimatter? Axion? Anomaly? Asymmetry? Atheism? Astronomy? Angular momentum? Algebra? Accuracy? Adultery? Ab initio? Aardvark?

Apparently the locals knew what was being talked about and the author, dared by the questioner, used the word "anthropic" in his response. I guess that that's a bit of a dirty word among the stringers. This (parallel) talk was well attended with standing room only.

The Polchinski (plenary) talk had two questions. The first was a request to comment on Susskind's alleged suggestion that we could be at the end of physics in that we are at the "end of the reductionist paradigm". The speaker wisely avoided commenting on Susskind, but said he himself does not have a paradigm, and that serious cosmologists have been worrying about this for >30 years, that is, what is it that allows life.

The second question was about the abilitiy of a large extra dimension allowing solving of the hierarchy problem. He speculated that maybe someone in the audience knew the answer to this but he didn't call on me by name (LOL), and mentioned the embedding of 5-D theories in 10-D.

9. **Matti Pitkanen**
November 3, 2006

For some mysterious reason Susskind equates the lack of predicitivity with giving up reductionism. Giving up reductionism in standard sense (reducing physics to Planck length scale) need not mean lack of predictive power. For instance, a loss of reductionism in the sense that there exists a hierarchy of scaled up variants of standard model realized as dark matter hierarchy, does not mean the loss of predictivity since fractality allows precise predictions using scaling arguments.

The additional bonus is that there is no need to continue repeating that there is no empirical input to guide the theoretician. Consider only biology: it serves as fantastic gold mine of effects if one accepts the possibility that biology is something more that mere complexity. I dare guess that the historians of physics will see the dogmatic belief in reductionism as the deepest reason for the recent crisis in theoretical physics.

10. **Tony Smith**
November 4, 2006

A potentially useful result that is contrary to conventional wisdom of the physics community appeared in the Hawaii DPF meeting in a section on Low Energy Tests of the Standard Model.

A contribution by Goran Senjanovic entitled "Grand unification and proton decay: fact and fancy" has an abstract that stated:
"… I review the minimal grand unification based on SU(5) and SO(10) groups, with and without supersymmetry. I discuss the predictions for the proton decay and show how they depend crucially on the fermion (and sfermion) masses and mixings. …".

Since the conventional view has been for years that proton decay experimental observations have ruled out SU(5) GUT,
and since I saw no full copy of Senjanovic's Hawaii contribution,
I looked up his arXiv postings, and found hep-ph/0204311 by Borut Bajc, Pavel Fileviez Perez, and Goran Senjanovic with an abstract that stated:
"… We systematically study proton decay in the minimal supersymmetric SU(5) grand unified theory. We find that although the available parameter space of soft masses and mixings is quite constrained, the theory is still in accord with experiment. …".

A couple of years later, coauthor of hep-ph/0204311, Pavel Fileviez Perez, wrote a paper (with Ilja Dorsner) at hep-ph/0410198 whose abstract stated:
"… We investigate model independent upper bounds on total proton lifetime in the context of Grand Unified Theories with the Standard Model matter content. … Our result implies that a large class of non-supersymmetric Grand Unified models, with typical values alpha_GUT = [about] 1/39, still satisfies experimental constraints on proton lifetime. …".

In an even more recent paper, hep-ph/0601023, Pran Nath and Pavel Fileviez Perez say in section 5.6:
"… In this section we discuss the possibility of finding an upper bound on the total proton decay lifetime … one may focus on the gauge d = 6 contributions since all other contributions can be set to zero in searching for upper limits …
any non-supersymmetric theory with alpha_GUT = 1/39 is eliminated if its unifying scale is bellow 4.9 x 10^13 GeV regardless of the exact form of the Yukawa sector of the theory.
Further, a majority of non-supersymmetric extensions of the Georgi-Glashow SU(5) model yield a GUT scale which is slightly above 10^14 GeV.
Hence, as far as the experimental limits on proton decay are concerned, these extensions still represent viable scenarios of models beyond the SM. …
For example in a minimal non-supersymmetric GUT based on SU(5) the upper bound on the total proton decay lifetime is …[less than or equal to]… 1.4 x 10^36 years …".

If non-supersymmetric SU(5) and SO(10) GUT models ARE consistent with experimental observations,
and
if N=8 supergravity might indeed be finite (see the thread in this blog citing the UCLA workshop on 11-15 December 2006 described at
http://www.physics.ucla.edu/tep/workshops/supergravity/index.htm)
then
maybe they could be useful in building a physically realistic unified theory/model.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – The proton decay ideas of Senjanovic, Perez, et al seem to be independent of the ideas of Adarkar, Krishnaswamy, Menon, Sreekantan, Hayashi, Ito, Kawakami, Miyake, and Uchihori expressed in hep-ex/0008074 that experimental backgrounds in proton decay experiments may have been incorrectly defined, and that different (and possibly realistic) background definitions would render experimental results to be consistent with SU(5) and SO(10) etc GUTs. If Adarkar et al are also correct, then the case for such GUTs is even stronger.

PPS – The UCLA workshop abstract says in part: "… The intimate connection of N=8 supergravity to N=4 super-Yang-Mills theory will also be discussed. …".
As is well known, quaternionic structure is key to the special properties of N=4 super-Yang-Mills theory,
and
N=8 supergravity has octonionic structure that may be useful in studying finiteness of it and related physics models.

11. **Not A Nobel Laureate**
November 4, 2006

"The first was a request to comment on Susskind's alleged suggestion that we could be at the end of physics in that we are at the "end of the reductionist paradigm".

It's not the end of physics, just the end of Susskind.

12. **dir**
November 4, 2006

100 Tev may come from the ultra high energy cosmic rays. their energy can be as high as 10^{19} electron volts, or above, which means a center-of-mass energy 100 Tev when they hit on protons in the air.

Events

November 4, 2006
Categories: Not Even Wrong: The Book

Because of the book, people have contacted me with various requests to do one sort of event or another, and I've agreed to do a few of these. Here's a list in case any readers of the blog are interested in showing up and saying hello:

- Monday November 6, 7pm, Princeton University Store. This one is coming up soon, and it will be interesting to be back at the location of my graduate student days, doing something I never would have believed was possible if you'd told me back then that this would happen.
- Thursday November 16, 7pm, University of Minnesota, Campus Atheists and Secular Humanists.
- Tuesday February 6, 7:30pm Cafe Scientifique, NYC.

Comments

1. **anon**
   November 4, 2006

   Very prudent not to do a book signing at Harvard or Stanford 🙂

2. **Alejandro Rivero**
   November 4, 2006

   Princeton seems risky enough to me 😀

   Btw, Peter, if during your signing tours you are pressed by Squarers of the Circle and they have some kind of formulae beyond 1% experimental agreement, remember I collect such, do not hesitate to pass them my email (sounds as a good excuse to get free of them, too).

3. **Peter Woit**
   November 4, 2006

   I encourage people with the kinds of interest Alejandro describes to, in the interest of efficiency, bypass me and contact him directly…

4. **anthropologist**
   November 4, 2006

   The book signing on Monday sounds like it could be worth attending. Is that gonna be just about the book, or other things as well that have transpired since that time?

5. **Peter Woit**
   November 4, 2006

   anthropologist,

   I'll probably be talking a bit about what's in the book, but mainly about how the book came to be and what is going on now. Also, it depends a lot on the audience. I'll try and discuss whatever they seem most interested in.

6. **M**
   November 4, 2006

   for Alejandro from M-theory: g2^2 = sinThetaW cosThetaW

7. **luke**
   November 5, 2006

   so atheists are against strings

8. **Who**
   November 5, 2006

   luke: *so atheists are against strings*

   I expect you're joking, and it's ridiculous to generalize that broadly but
   to make the obvious point: it is also possible that atheists are
   interested in knowing **how things actually are** and want
   to make up their own minds about it.

   Peter's book was #3 on the UK amazon physics bestseller list this morning
   when I looked just now. It often is near top among all physics books, still after being out in UK market for over five months. The book clearly has sales potential and should be worth doing some talks and signings to promote.

9. **Alejandro Rivero**
   November 5, 2006

   to M:
   :-DDD. Nah, you probably mean the criteria in formulae (10.6) of the pgd review.

   But indeed if someone likes to indulge in such games, email directly me, not to Peter, at al.rivero in my gmail.com account.

10. **Thomas Love**
    November 5, 2006

Recieved a mailing from Scientific American Book Club which has NEW on the list of available books. TWP was in last month's mailer.
It is cheaper than what I paid, but I've already read it so the extra money was worth it.

11. **M**
November 6, 2006

maybe sW cW = g2^2 seems too good to be true, but has nothing to do with the usual definition of the weak angle as function of the *ratio* g2/g1 (reexpressed in (10.6) of PDG in terms of observables).

To avoid that this gets deleted as off-topic numerology, let me try a strategy that was quite successful in the old good pre-Woit era:

The prediction sW cW = g2^2 is conjectured to result (in the Neveu-Ramond twisted formalism) from the Suguwara-Witten affine Lie algebra developed by generalized super-M theory compactified on toric varieties of weighted complex projective spaces associated with reflexive polyhedra.

12. **Tommaso Dorigo**
November 7, 2006

Hi Peter,

as far as events are concerned: I'm sure you know this already, but just in case you don't, there is a Discover.com online chat with Lisa Randall next Thursday 11/9 at 2pm,
"and the focus is string theory. Your insights would be valuable to this dialogue" recites the email I just got from a Coco Ballantyne, inviting me to participate.

Can't help laughing at my "insight" into string theory. But I will give the chat a look!

Cheers,
T.

13. **Peter Woit**
November 7, 2006

Tommaso,

I got the same e-mail. Not sure if I'll have time to tune into this, we'll see.

14. **whoman**
November 12, 2006

Peter,
I'm a sciambookclub.com memeber and at last they have your book in the club magazine. Below are the last two lines of the magazine review:
"String theorists, who have invested most of their careers to the topic, are loath to abandon it – and some have criticized Woit in distinctly unprofessional terms."
"In the face of many books from enthusiasts for string theory, NOT EVEN WRONG presents the other side of the story."

Of course I have put in my order.

15. **Thomas**
February 19, 2007

Hi

after reading your great book, it is absolut clear that string theory is a religion, with the "flying string monster", formerly known as flying spaghetti monster (www.venganza.org), as their good 😉

Regards

String Wars, Part Deux

November 4, 2006
Categories: Uncategorized

Yesterday at the KITP in Santa Barbara, George Johnson gave a second talk and led a discussion on the subject of the "String Wars". The rather remarkable first session was discussed here, here and here. This time people were much better behaved, and the main topic was the media coverage of physics in general, and the past history of the media interest in string theory, and what effects this might have had.

Johnson has put on his web-site copies of various articles from the NYTimes about string theory. The first mention of superstrings was in a piece by Walter Sullivan back in May 1985, just a few months after the "First Superstring Revolution" really got going. This piece included cautionary comments from C.N. Yang about the lack of even "a single experimental hint" and from Michael Green that "I've seen many bandwagons come and go." Interestingly, already at this time the main suggested test of string theory was astrophysical or cosmological, with the Times referring to a recent Nature article about the possibility of seeing effects of the "shadow matter" that one gets from the other E8 in the E8 x E8 model popular back then (and still popular to this day).

Much of the KITP discussion concerned what effect news stories and popular books promoting string theory have had, with several people noting that they think they have been responsible for the large number of students they have seen wanting to do graduate work in string theory. Someone in the audience also pointed out that the continual use of the modifier "super" seems to get people's attention, with students showing up wanting to study "supersymmetry" even though they didn't know what it was, and it was much harder to get them interested in, say, "diffractive scattering."

The latest Nature Physics has a fairly sensible editorial (Tied Up With String?) about the string theory controversy. Popular promotion of string theory continues today at Stanford, where the Wonderfest Festival of Science is featuring Raphael Bousso and Leonard Susskind discussing "Is the World Made of Strings?"

Comments

1. **Kea**
   November 4, 2006

   The second Johnson talk was positively dull compared to the first. I found myself nodding off. And what's the big deal with a 1000ft vertical of ice? That's not that high.

2. **Kris Krogh**
   November 5, 2006

   ". . .the continual use of the modifier 'super' seems to get people's attention, with students showing up wanting to study 'supersymmetry' even though they didn't know what it was. . ."

   That's how you win in the "free marketplace of ideas." Advertising.

3. **Bee**
   November 5, 2006

   Hi Kris,

   exactly. 1000ft or not, Steve Giddings made a very important comment. Founding agencies care about media coverage. That's not good but likely true. I also find public outreach an essential part of science, but its not good to distribute *research* grants according to the efforts invested in advertisement. Something is going wrong there…

   Best,

   B.

4. **Kea**
   November 6, 2006

   No offence to Steve Giddings intended. In reality, he is quite a nice guy.

5. **Tony Smith**
   November 7, 2006

   The blog of Christine Dantas now contains only format material, and this statement

   "Monday, November 06, 2006
   The end.
   I'll only leave the post by Daniele Oriti on his upcoming book on Quantum Gravity and on his current research."

   and the post by Daniele Oriti which discusses, inter alia,
   "… Group Field Theory … as field theories describing the quantum dynamics of the fundamental discrete building blocks of (quantum) space … they offer an altogether new perspective on the issue of the continuum approximation and on the emergence of a continuum spacetime. … It is the problem of showing that in certain situations (to be identified) the fundamental 'atoms of space' described by some GFT -condense-, so that a continuum spacetime emerges as a sort of liquid …",
   which ideas sound very interesting to me.

   Christine, thanks very much for leaving up the interesting ideas of Daniele Oriti,
   and also thanks for an interesting blog as well as comments to other blogs.
   I also liked very much Pedro's "Outer Space".

   Your contributions will be missed, and I hope that you will come back when you want to.

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

6. **urs**

November 7, 2006

> the continual use of the modifier 'super' seems to get people's attention, with students showing up wanting to study 'supersymmetry' even though they didn't know what it was

Are students also lured into solid state physics this way? By superconductors? Or by superfluidity? Maybe by the desire to learn about the supersolid state of helium? Maybe even by studies of superconducting superfluids?

7. **Who**
November 7, 2006

> Christine, thanks very much for leaving up the interesting ideas of Daniele Oriti,

I share Tony's sentiments.

Thanks for a beautiful and informative blog, Christine. Sorry it got too troublesome. I hope we continue seeing you here and at physics forums.

8. **Peter Woit**
November 7, 2006

Christine explains why she closed up her blog here:

http://www.physicsforums.com/showpost.php?p=1153475&postcount=13

and a copy of Schroer's latest that she mentions is here:

http://www.math.columbia.edu/~woit/schroer2.pdf

I'm sad to see what happened here. Her blog was an excellent example of a positive contribution and one of the best in this are. The fact that the controversy over string theory made it so difficult for her to keep doing what she was doing, mainly about LQG, without getting caught up in an environment she didn't have the temperament for, is very unfortunate.

9. **Bee**
November 7, 2006

Hi Peter:

Thanks for the link to PF, it makes me feel slightly better. I just sent Christine a long email apologizing for my last comment. I feel really bad about it since it seems I did upset her quite a lot. I can't even remember exactly what I wrote, just that I didn't like the insulting side remarks in Schroer's paper, that this is not going to solve any problem, and that it surprised me she would post this writing. 1/2 hour later there were several other comments whose exact content I can't recall, and a last comment from Christine saying it's been enough, or something.

It makes me very sad to see her go, since her blog has been very balanced on various topics, and I've always liked to read it. On the other hand, I can relate to her problem with the journalist… – and I guess most of you around here know that at some point it just takes too much time, and effort, to set every misconception straight, and one wonders whether it's worth it.

I also want to add for those of you who follow the so-called string wars only via the media and the internet: the picture you get from what is actually happening is badly distorted. There is some truth in what is written, but for most of the time we get along pretty well and peacefully, and just do our research. How it comes across in journal articles, or blogs, is like putting magnifying glasses on a spot on your nose and then getting obsessed about it.

Yes, there's some discussion about where the money goes and how to hire people, but that discussion has always been there, and probably will always be there, unless some government realizes that theoretical physics needs a grant increase of at least two orders of magnitude. Yes, there are reasons not to like string theory, there are also reasons not to like LQG, but there's no reason to retreat to name-calling and insults. If anything, I'd wish we'd focus on our similarities, the scientific goals that we want to achieve, the reason why we went to study physics in the first place.

I think, this was roughly the last sentence of my comment on Christine's blog.

Best regards,

Sabine

10. **Bert Schroer**
November 7, 2006

I have participated in this blog for a couple of month always trying to stick to physics, I think almost all my contributions had a physics content. Having been insulted by anonymous bloggers and by you know who, I have nevertheless stuck to the scientific content.
Please will anybody let me know where in my last contribution I insulted somebody? I break taboos (but so does the owner of this blog), but this has nothing to do with insults. Bee, you have all the advantages of anonimity on your side which I do not enjoy, please let me know the insult I committed so I can correct this or appologize.

11. **Tony Smith**
November 7, 2006

Peter linked to Christine's explanation of why she ended her blog. In it, she said that she
does "… not have the right temperament for "living in the blogosphere".. …".

It reminds me of a scene in the movie Batman in which Joker (Jack Nicholson) says about Gotham City:
"Decent people shouldn't live here. They'd be happier someplace else.".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Bee said "… most of the time we get along pretty well and peacefully, and just do our research …". That does not apply to those of us who are blacklisted by arXiv, unless Bee considers blacklistees to be outcast nonpersons.

12. **Bert Schroer**
November 7, 2006

I sent a corrected version of my paper to Peter, and I am sure that if he will be back from his book presentation tour he will do the change. According to my best knowledge neither version contains insults. The new version has some more remarks about the history of the recent great profound discoveries of the implementation of diffeomorphism covariance and the sufficient condition for obtaining diffeomorphism invariance. The story starts with the construction of the local covariant energy-momentum tensor by Wald and reaches its present culmination in the two papers I cite (unfortunately not my own!). I am a particle physicists and the advanced particle physics methods have impressed me more than anything else. Is that insulting to the Perimeter or to KITP?

13. **Bee**
November 7, 2006

Dear Bert,

Yes. I did not say your paper had no physics content, and I am aware of your contributions, which are interesting in many regards.

I made it explicitly clear that I was not referring to the scientific part of your text. What I can't approve of are general and unbalanced accusations of 'mass psychosis', 'mass cult', 'the scientific version of Stalinism' and 'faith based mantra', etc. This is just plain insulting for many string theorists, who are highly qualified serious researchers. A picture of string theorists being blind worshippers of some mass cult is as far off of reality as that of 'alternatives' eating muesli and reading Faust. Both of which are prejudices that I don't want to see distributed, no matter what reason you have to justify your claims: it's not going to help matters — if anything it will increase the gap that I sense dividing our community (meaning: theoretical physicists). If we are going to disagree, we should stay on scientific ground.

Dear Tony,

There are definitely things at odds in the way science is pursued today, and the arxiv policies are a mystery not only to you. Regarding the question whether the community today does too easily 'outcast nonpersons', Lee Smolin makes some good points in his book there. Yes, these are issues that we should work on, but not by calling other's theories crackpotism or faith based science. This is not constructive. My remark above referred to the fact that the string theorists I have met are not more or less weird, aggressive, naive or stubborn than theoretical physicists of other research directions (and I should add, there is more to theoretical physics than strings and loops).

What bothers me, and you can already see this from this comment section, is that name-calling gets far more attention than any kind of constructive criticism. E.g. to come back to the original topic of Peter's post: how come there's been so little discussion of this second part, but an enormous fuss about the first one? In this second part there were some important (though hardly new) points raised: as I wrote above, Steve pointed out that founding agencies might care about the media coverage – this is certainly of some concern. Someone mentioned (what I've also pointed out before), that the 'string wars' currently are a very US-centered phenomenon. Then there was a very interesting contribution about whether or not such media coverage as on the string-issue today does influence young students. And if it does influence, in which way, etc.

Best,

B.

PS: *Bee, you have all the advantages of anonimity on your side which I do not enjoy,*

My name is Sabine Hossenfelder, as you can easily find out from my blog. You get plenty of details about me by googling my name. In fact, I do think that anonymity is one of the big problems in this equation. E.g. it seems to me that there are only a hand full of people echoing always the same silly sentences (it's quite ironing that George Johnson began his first talk trying to make that point but nobody was really listening, they were all too busy echoing).

14. **Kris Krogh**
November 7, 2006

Hi urs,

The "supers" you cite are not theories, but physical phenomena that are actually above others. The theories for these things have not-so-exciting names like "BCS."

I think marketing considerations do go into the naming of some theories, a classic example being "quintessence."

15. **Christine Dantas**
November 7, 2006

There is one thing that I would like to point out in this discussion. Bert Schroer was absolutely *not* responsible for the ending of my blog! I encourage everyone interested to read his paper. It is a polemical paper, yes. But it does have important scientific comments that are deserved to be widely read and studied.

I pointed out over at PF that one of the reasons that I decided to end the blog was that I was not having a good time dealing with polemics. So after posting Bert's paper over at my blog, this feeling that I just was tired of dealing with polemics came out and I decided it was time to stop. This was a process that was already happening for some time.

So, my last word on this issue here is: *I appreciate Bert Schroer's criticism on string theory and his paper should be read with care. I do think there are some points that he could have written differently, but that's not what matters here.*

I publicaly apologize to Bert Schroer in the case that this was the impression I have given (that he was responsible for my decision to end my blog). Not at all.

Best wishes,
Christine

16. **Bee**
November 7, 2006

and isn't it ironic…

17. **Bert Schroer**
November 7, 2006

Dear Sabine,
Now I know who you are (inasmuch as this is possible from weblogs). There is a generation gap between us. I have seen impressive progress in particle physics when there was no necessity to think about sociological aspects of science and nobody (myself included) would use the style of communication as nowadays in weblogs but even in papers, whereas you have grown up already in this deep crisis of particle physics in the times of market values.
I spend 6 years under Stalinism (my neighboor in school was Helmut Karasek). When we use the adjective “Stalinist” nowadays we mean total reality denial coupled with the internalized belief that the worse things get so much the better the glorious destination. I know that we have entered such a situation in physics, I am not saying this to insult you or anybody else. People can be very intelligent and serious and nevertheless being misled. Seriousness and intelligence are of course necessary but by themselves no guaranty for innovative insights. You misunderstood me completely if you think that I am denying the intelligence and dedication to people in ST or LQG for that matter.
I used to think that hype, mass psychosis and collective delusion can only occur outside of science (Nazism, Stalin ism.. can be updated) but never in science. Well this is not true; we were only lucky that it hit us so late (see the remarks of Phil Anderson). If you feel that this does not concern or affect you that is fine, then just forget it and look at the scientific aspects. Maybe you can see that the scientific world is not yet completely dominated by those communities which are doing their best to steer particle physics into their barren mono cultures, but there are still some concrete individuals (which Smolin describes abstractly), which are not only in the possession of an underlying philosophy, but also have very balanced harmonizing conceptual and technical skills (as in the good times of Feynman. Schwinger…), but maybe not for long anymore; they cannot be globalized and they cannot have descendants.

18. **Christine Dantas**
November 7, 2006

Hi Bee,

Yes, it is ironic… That’s a *blogostuff fever* I suppose….

And again, to make it clear: **No one is responsible for the ending of my blog, except myself.** I openly apologize to anyone who believe that I have damaged them for some reason, and that includes you, Bee.

I have created the blog and I have destroyed it. It was just a blog. It was useful, nice, interesting? Good, I am happy I did something useful in this life! Now it’s gone, like many things in life I suppose…

All the best,
Christine

19. **Bee**
November 7, 2006

Dear Bert,

Thanks for this statement. Please understand that in my perception your writing can easily be misunderstood as being insulting, even if you didn’t mean it to.

whereas you have grown up already in this deep crisis of particle physics in the times of market values.

Well, there will always be parts of science that flourish and others that people loose interest in because it doesn’t seem to go anywhere. So far I haven’t considered myself as growing up in a scientific crisis. As you also say, if there’s a crisis then it is not simply one of scientific research, but a much more general one. Many of the concerns about ethic values, or competition on the ‘marketplace of xxxx’, people blindly following fashions, etc definitely aren’t specific for string theory, just apply them to any other field you can think of, from politics to the cosmetic industry.

If you feel that this does not concern or affect you that is fine, then just forget it and look at the scientific aspects.

It does certainly concern and affect me, otherwise I wouldn’t be here spending my time writing this comment. I just think it would be better to disentangle the sociological criticism from the actual research.

Best,

B.

PS: My comment from above overlapped with yours, so I hadn’t read your comment when I wrote mine.

20. **Arun**
November 7, 2006

Of the three – “hype, psychosis and collective delusion”, I think the only one applicable to string theory is hype. Since Stalinism and Nazism involved physical coercion of their opponents, they are utterly inapplicable and inappropriate to physics. Perhaps a more appropriate analogy, if one needs to be found, is that of a stock market bubble. It is not necessary to elaborate on the analogy.

This : http://www.floor.nl/ebiz/gartnershypecycle.htm
is an even better analogy, in my opinion.

It is a pity that Christine Dantas decided to end her blog. But, Bee, don’t feel badly.

21. **Bee**
November 7, 2006

Dear Christine:

My rather cryptic line from above referred to a typo in my earlier comment — obviously, it didn’t mean to write ‘ironing’… 😉 There’s no need to apologize, and I don’t feel specifically damaged. I hope this is the right decision for you, and you’ll be around. Best,

B.

22. **Christine Dantas**
November 7, 2006

Hi Bee,

I am alleviated that you are OK. I am also OK, and I believe Bert Schroer is OK as well. Peter Woit, are you OK? Good! So everything and everyone seem to be in their proper places. Good!

Now you can continue. 🙂

Christine

23. **Bert Schroer**
November 7, 2006

Arun
O.K. Stalinism killed people, whereas in particle physics only careers but not opponents of the dominating fad are destroyed. I think hype alone could not do that, but let us get back to work.

24. **TheGraduate**
November 7, 2006

Bert,
One of the sad but unavoidable things about science on a limited budget is that someone's career is going to get 'destroyed'. Someone, somewhere, is going to have to quit and leave science. It might happen in high school, or graduate school or somewhere along the tenure track. But it more or less has to happen somewhere.
Given that physics jobs are neither being created nor destroyed but only transformed from one form to another, I have often been confused about what element of this string theory debate isn't just a isolated power struggle between different physicists. On the one hand you have string theorists who are presumably trying to make advances in theoretical physics. On the other hand, you have other non-string theorists who feel the same way and are doing the same thing. Where is the symmetry broken?
You could call what the string theorists are doing similar to Stalinism (ie organization for malicious purposes) or you can call it Fordism (after Ford of Ford motor cars, or organization for positive and effective purposes).

25. **Tony Smith**
November 7, 2006

Bee said "… What bothers me … is that name-calling gets far more attention than any kind of constructive criticism. …".

Maybe the lack of constructive criticism is a direct consequence of the validity of Feynman's criticism:
"… I don't like it that they're not calculating anything. … why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations …".

If superstrings predicted a quark mass and LQG predicted a different quark mass,
then
the old physics process of comparison with experiment (which old process did lead to the last Big Thing in theoretical particle physics, the Standard Model) could settle the question of which (if either) model is realistic.

In the absence of what Feynman wanted, the only thing left for superstrings and LQG in their fight for funds is to engage in "name-calling".
Further,
if an alternative model DOES produce realistic numbers, the only way they can fight for funds against it is to "outcast" alternative model-builders as "nonpersons".

Therefore, it seems to me that, given human nature,
and the present state of superstring and LQG models (which get about 90% and 10%, respectively, of the theoretical particle physics funding in the USA),
it is inevitable
"… that name-calling gets far more attention than any kind of constructive criticism. …"
and
that blacklisting exists.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

26. **nontrad**
November 8, 2006

An unfortunate turn of events….

With repeated mention of the 'good old days' (calculation and so forth) it seems that this situation reiterates, in a round about way, the argument we've heard many times before: Data!

My 2 cents, physics has always been about data; data historically drove the most remarkable results…and I, for one, am convinced that it will again. Maybe not tomorrow, but one of these days.

In the mean time, I suppose it's a question of waiting this situation out. Hopefully, we won't let the tension get to us. The waiting room can be so boring.

In any event, all the best and best regards to you Christine.

27. **Tony Smith**
November 8, 2006

nontrad said "… physics has always been about data …".

That is true, and experiments are still providing relevant important data.
For example,
as Tomaso Dorigo said on his blog at http://dorigo.wordpress.com/ by post dated 26 October 2006:
"… WZ production discovered!
… Yesterday the CDF collaboration blessed a new result on electroweak physics: the measurement of cross section of the production of WZ pairs. …
we want to test the Standard Model … in [all] the available realm of predictions it makes. The rarer a process, the better the chances that something does not agree with the theory …
Now that we start seeing the very rare standard model processes yielding multi-leptons … we still see no new physics …".

In short,
new data is coming out, and it confirms the Standard Model,
with no non-Standard-Model-stuff like the supersymmetry of superstring theory.

The superstring and LQG models are not failing to meet Feynman's standards for want of data.
They are failing to meet Feynman's standards because,
even after decades of work by many very smart people,
they have failed to produce calculations that describe ANY of the particle masses, force strengths, Kobayashi-Maskawa parameters, much less to predict the WZ results stated by Tomaso Dorigo.

That indicates to me that alternative approaches should be given substantial support.

I would prefer that superstring and LQG funding remain level on the chance that maybe somehow those workers might some day figure out a way to do some of the calculations that Feynman wanted,
and
that new money be appropriated for alternative approaches.

The quest for new money for high energy physics theory alternative approaches
should (in my opinion)
be as important as the quest for new money for high energy experiments such as the ILC.

Since the amounts of new money needed for theory are far less than the amounts needed for such things as the ILC,
it should be at least as easy to get additional theory money as to get ILC money.
Perhaps the theory increase could be folded into ILC proposals.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Now that the Democrats have won control of the USA House of Representatives,
Dennis Hastert (Illinois Republican) will probably be replaced as Speaker of the House by Nancy Pelosi (California Democrat).
The USA high energy experimental community has strongly advocated an Illinois (Fermilab) site for the ILC, in large part to get support of Hastert as Speaker of the House.
Maybe the USA high energy experimental community should rethink its advocacy of an Illinois site in favor of a California site, which is not only the home of Speaker-to-be Pelosi, but is also on the Pacific Coast and therefore possibly more acceptable to other Pacific nations such as Japan.

28. **M**
November 8, 2006

TheGraduate,

speculations about quantum gravity have been fruitless: this causes struggles among physicists. In healthy fields (like cosmology, neutrinos and hopefully particle physics in 2010) struggles are about physics.

29. **urs**
November 8, 2006

> The "supers" you cite are not theories, but physical phenomena

The "supers" I cited were names for properties. So is the "super" in "supersymmetry".

> I think marketing considerations do go into the naming of some theories, a classic example being "quintessence."

I agree, that's a good example (since it is such a bad example: what a horrible term).
Whether similar considerations made people say "super" instead of "graded" back in the old days I can't say. But I am somehow doubting it.

I know that, as a a student, I found the plethora of "supers" in physics appaling. (But then, that's also my reaction to most kinds of advertisement, so maybe there is a point 🙂

30. **Bert Schroer**
November 8, 2006

The "super" in superconductivity and superfluidity has the meaning of "ultra" (trans, alem) whereas in supersymmetry it is hegemony, arrogance and domination; this was its only purpose and everybody knows that. It in no way goes beyond symmetry and contains it in a limit or by a phase transition. Once such a misleading name has been given and used for some time it cannot be changed (the word "string" in string theory is another case, from the point of view of quantum localization it still continues to be point-like localized, it has many more degrees of freedom as the irreducible object of QFT which is a free field). I wish Urs would stop posting such nonsense on this weblog which after all is dedicated to a critical evaluation of string theory and not about stupid names.
Peter, can you please finally exchange the first version of my draft (the one which I sent to yesterday); on a server I could make a replacement on my own, but here I cannot do it. My original purpose (when I dedicated it to the anniversary of Christine's weblog) was to present a profound analysis of all the claims in ST (I think I did not forget any) in order to get a scientific discussion going and I thought that this would have been a good place because it is also visited by LQG researchers. All the people who bothered her should address me directly after having red the corrected version (which I again kindly ask Peter to post).

31. **anon**
November 8, 2006

Bert,

"but there are still some concrete individuals (which Smolin describes abstractly), which are not only in the possession of an underlying philosophy, but also have very balanced harmonizing conceptual and technical skills (as in the good times of Feynman. Schwinger…), but maybe not for long anymore; they cannot be globalized and they cannot have descendants."

Could you give us some names please just to make things concrete?

32. **TheGraduate**

November 8, 2006

As far as I know, Smolin named names but maybe I don't know quite what you mean … he had names like Penrose and Rovelli and others.

33. **Bert Schroer**
November 8, 2006

Anon
you just have to look at the updated last section of my paper (which Peter hopefully will substitute today). A fascinating story started at the beginning of the 90s by Bob Wald's work about how to define the correct energy-momentum tensor in QFT in CST and culminated tentatively in startling results about diffeomorphism- covariance and its expected quantum invariance. The story is certainly continuing and I (as somebody with a particle physics background) am very excited about it. It is completely within an (albeit advanced, you may not like this) particle physics (QFT) setting and does not create those large distances with particle physics as we know it from the other approaches. It is certainly closer to LQG than to string theory (that was the reason why I thought that Christine's weblog would have been a good place) if only the LQG people would notice it. Just be patient for a couple of hours.

34. **Bee**
November 8, 2006

oh no! I lost my comment… what a waste of time… what was I about to say? … I'll try again…

Dear Tony,

high energy particle physics just might not be the way to proceed. Imo it's currently much more promising to focus on cosmology/astrophysics. We already have evidence for physics that can't be explained within the standard model, the data is good, and getting better every year. If you think about it, collider experiments aren't exactly the smartest thing do to. It's like examining leftovers of a car accident and trying to figure out what the driver ordered for dinner the evening before. Yes, that might not be good news for particle physicists, and yes, everything was better in the old days, when we were all younger, when the gasoline was less expensive, and the music was still music, but that's the way life goes.

it is inevitable "… that name-calling gets far more attention than any kind of constructive criticism. …"

It is not. Name-calling is a cheap and easy way to get attention, whereas constructive criticism requires time and thought. Blogs seem to favor an atmosphere of fast and unreflected comments and reward upsetting statements far more than qualified opinions. Unfortunately, this is more and more used by the media – in print as well as online – to strongly polarize discussion and to artificially enhance disagreements that otherwise wouldn't excite anybody. This then feeds back into the discussion in an upward spiral.

You decide for yourself what you pay attention to. That's a good starting point I'd say.

Best,

B.

PS: If that comment vanishes again in virtual Nirwana, I give up.

35. **Bert Schroer**
November 8, 2006

Maybe Bee, but I do not see how you can base your Astrophysics/Cosmology on such a shaky particle physics basis as we have now (i.e. how you can live with everytime more precise astrophysical observations and a shaky basis of fundamental interactions which according to you does not need improvements).
I like your comparisions with car crashes but none of the big car-manufacturers would sell anything without the security improvements of controlled car crashes. The LHC may not do miracles expected by ST (perhaps less so by LQG), but at least the hope to close some of the open ends seems to me realistic.

36. **Tony Smith**
November 8, 2006

Bee quoted me out of context as saying "it is inevitable "… that name-calling gets far more attention than any kind of constructive criticism. …""
and
then hit the out-of-context straw man by saying "It is not. …".

The very important omitted context was
"given human nature,
and the present state of superstring and LQG models (which get about 90% and 10%, respectively, of the theoretical particle physics funding in the USA),
it is inevitable
"… that name-calling gets far more attention than any kind of constructive criticism. …"".

In that context, I stand by my statement because:

1 – Human nature in fights over funding in the present-day USA, where money is GOD, is that anything goes. Just as in political campaigns (for example the Tennessee Senate race), name-calling etc can be very effective. In fact, the physics funding fights look a lot like political campaigns.

2 – The present state of superstring and LQG models is that neither of them can make any substantive particle physics predictions, so that "constructive criticism" fails because neither class of models has any concrete particle physics calculations that can be constructively criticized. As John Baez said in a blog comment on Ars Mathematica:

"… The unpleasant nature of the whole extended argument can be seen as a collective cry of agony on the part of physicists trying and – so far – failing to find a theory that goes beyond the Standard Model and general relativity. Both string theorists and their opponents are secretly miserable over this failure. …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

37. **Bee**
November 8, 2006

Dear Bert,

how you can live with everytime more precise astrophysical observations and a shaky basis of fundamental interactions which according to you does not need improvements).

I never said that our basis of fundamental interactions does not need improvement. This is not my opinion. I said that I find it very possible that astrophysical/cosmological data can give us the clues that collider physics hasn't yet delivered.

The LHC may not do miracles expected by ST (perhaps less so by LQG), but at least the hope to close some of the open ends seems to me realistic.

Yes. There's a reason why I've worked on LHC physics for the last years.

Dear Tony,

sorry for cutting your sentence in a confusing place. I still disagree with you. *Human nature in fights over funding in the present-day USA, where money is GOD, is that anything goes. […] the physics funding fights look a lot like political campaigns.* . Indeed, but there's no reason to throw hands up and say: well, it's in the human nature to adore money as GOD, and its inevitable to retreat to name-calling, that's just how we are. Maybe my picture of humankind is just much more optimistic, or call it naive, but I don't believe it's actually money that we are searching for — Instead, it's what we think it represents. Especially in the scientific community we should be able to realize that on the long run the winner won't be the one who has the best rhetorical skills. Everything else is shortsighted, and hinders progress. Think future. Sadly enough, I agree on what Baez said.

Best,

B.

38. **r hofmann**
November 8, 2006

Sabine, I agree with Bert when he says that particle physics is in a deep crisis considering the huge industry that went into virtually no gain of robust knowledge and deep understanding over the last twenty years. Your present opinion reminds me of my first three postdoc years when I didn't see anything wrong either in scientifically dealing with extra dimensions, susy and the like. In my case I only slowly started to develop a belly ache about what was happening around me, slowly but steadily. I would say people like Bert naturally have a more global view on things because of their richer experience. My opinion is that in Bert's case this experience serves constructively and courageously to change things for the better, he has demonstrated his scientific and social integrity in a number of ways …

Viele liebe Gruesse von Ralf

P.S.: Schon mal was mit selbstdualen Yang-Mills-Feldern, Donaldson-Invarianten, der Poincare-Vermutung, oder dem dreidimensionalen Ising-Modell zu tun gehabt?

39. **Tony Smith**
November 8, 2006

Bee says that her "… picture of humankind is just much more optimistic …".

I hope that Bee is right and I am wrong.

I would like very much to see (especially in the scientific community) that

competition is among IDEAS (all relevant ideas being considered) with the outcome being decided by comparison with experiments

rather than

among people saying things like "You know, if you know Lee [Smolin], it's because he wants our money. It's because he doesn't have it that he wants to cut us down. …" (quote from a KITP person in the first Johnson String Wars talk) with the outcome being decided by dictates of authority / political power.

Maybe my relatively dark view is colored by my experiences.

Tony Smith

Bee, what is the "evidence in cosmology/astrophysics for physics that can't be explained within the standard model" (apart from dark matter and cosmological constant)?

41. **Bee**
November 8, 2006

Hi Ralf,

Sabine, I agree with Bert when he says that particle physics is in a deep crisis considering the huge industry that went into virtually no gain of robust knowledge and deep understanding over the last twenty years. Your present opinion reminds me of my first three postdoc years when I didn't see anything wrong either in scientifically dealing with extra dimensions, susy and the like.

I see a lot of things going wrong, and I do agree that there's been an unfortunate pursuit of research directions that didn't pay off. However, I don't see this as reason to get depressed, and proclaim a crisis in physics. If the LHC doesn't fulfill our dreams, well, then lets look elsewhere. E.g. in the CMB.

Even though I've worked on extra dimensions, that's been mostly politically motivated. I admit that I'm not particularly proud of that, but at least I still have a job. As far as I am concerned, that is what's going wrong. I don't see a crisis in high energy particle physics, I see a problem with the way research directions and people are chosen and supported, for all further details, read Lee's book, he writes roughly what I also think, just skip the first three parts (and take off the cover).

Ralf, Ralf, Ralf… give me a hint, have we met?

Best,

B.

PS: 1. Yes, 2./3./4. No.

42. **Bee**
November 8, 2006

Hi Tony,

I am genuinely sorry to hear about your bad experiences. I was stupid enough to listen to the first talk, so I've heard all that crap. *I would like very much to see (especially in the scientific community) that competition is among IDEAS (all relevant ideas being considered) with the outcome being decided by comparison with experiments*

So would I! I encourage you to make proposals at to how the present situation can be improved in your opinion, or to distribute suggestions made elsewhere. If we have to echo something, then that's what we should echo.

Anonymous,

Isn't that enough to begin with? I think one shouldn't mix up the diverse data that lead us to postulate DM/DE, I find that very dangerous. E.g. the evidence for DE from high redshift supernovae, and that from WMAP. Then there's (with some statistical significance) the alignment of the low multipol moments ([Joao's axis of evil]()), evidence for DE from structure formation, rotation curves of galaxies (yes, it's handy to explain both by the same stuff, but do we actually know that?) and why is DM clustered in which galaxies how, do we understand that? Then (if I recall that correctly) there's a problem with the voids between visible structures (they are too large), what about the Pioneer anomaly, the missing GZK cutoff (okay, data isn't too good here, but should become better soon)? I also think there are some mysteries about the WMAP data, see e.g. [the north-south asymmetry…]() Hey, I am not even a cosmologist and can come up with all that!

Best,

B.

43. **Bert Schroer**
November 8, 2006

The corrected version of my article ST "deconstructed" is now available where Peter yesterday placed the previous version:
http://www.math.columbia.edu/~woit/wordpress/?p=489#comment-18997
For starting a critical evaluation of its content (a critical evaluation of all claims ST made which I am aware of) this may not be a good place, so I should perhaps ask Peter to post it at a more visible and accessible place.
There is of course no insult there since you can only insult individual persons and not areas of research as ST or LQG. When the subject of critique is an area of research (and naturally the associated monoculture of a globalized community) then one may be breaking a taboo, but this could hardly be called an insult. Critique and even taboo breaking is the oxygen of science (not only particle physics) and anybody who wants to regiment this may as well close down physics departments and research institutions. Nobody is served by acting according to the maxim: Friede, Freude, Eierkuchen (I do not know how to translate this into English)
My formulation is sometimes a bit shrill, but it is my experience that if one does not penetrate the elevated noise level of the globalized market, the message will not be noticed, as interesting and important it may be (I gave an illustration of this in the epilogue of my article). Of course the level must be proportioned to the content of the message, and I hope that I did not trespass this elementary rule.
It would be very productive if one could get a discussion about those 7 or 8 claims from ST which I exposed as being flawed in the above paper. This would give me the chance to (in a later stage) post something onto the hep-th server which has been brought to a public test. If the details of my arguments are to scars or unclear I can try to be more explicit. Of course string theorists are very welcome, especially in case I misunderstood any of their claims.

…morphed…

46. **Bert Schroer**
November 8, 2006

Dear Christine,
we had several email exchanges and there was at no time a problem or tension between us. Nevertheless I think it is nice to mention this also publicly and to express my sadness about having lost the most informative and equilibrated Brazilian weblog.
Already before you closed down your weblog you mentioned the problems outside your control which caused doubts whether the effort is worth it. You told me that you are not located at one of the great scientific centers in Brazil and that your have virtually no contact with the national physics community. I advised you to only continue as long as you get some satisfaction and enrichment of knowledge but that you should not do this for years only because your weblog became institutionalized. I also mentioned that Brazil as a result of the large distances between places of scientific activities and the grown number of researchers should have 3-4 weblogs and it would be nice if you could continue up to the appearance of others. Nevertheless, considering the circumstances a couple of days later, I think that your decision was the right one. I of course still have the hope that your example may animate other Brazilian physicists, although they would have to work very hard to build up those connections you had to the leading LQG people (or to other groups for that matter). But I also have the advice that if you should find yourself ever in a situation of "saudade" for your past activities then please return. It is not necessary to become enslaved by a weblog, it is not like a pet which needs to be constantly fed.
com um beijo e um grande abraco
Bert
ps. I just saw that you have a new post which I will look at immediatly after sending this one

47. **anon.**
November 8, 2006

"Especially in the scientific community we should be able to realize that on the long run the winner won't be the one who has the best rhetorical skills. Everything else is shortsighted, and hinders progress." – Bee.

It is not shortsighted but PERFECTLY LOGICAL for leading physicists to simply rename the concept of "shortsightedness" as "TAKING ONE DAY AT A TIME", ie, rely on name calling of alternatives (crackpots, cranks…), which enables them to keep what they perceive to be the "noise" level down (any alternative to M-theory = noise, by definition).

Similarly, the rulers of the church on 17 Feb 1600 burned the monk Brother Bruno to extinguish the noise he was making about astronomy. They weren't shortsighted, they didn't pay any penalty! They were long dead and burned by the time things changed. The censors only profit.

48. **Christine Dantas**
November 8, 2006

Dear Bert Schroer,

You told me that you are not located at one of the great scientific centers in Brazil

Well, I am, but I am not working in a physics department.

Thanks for the blogging advice. Blogging is not for me. Not for the faint of heart.

Why don't you set up your own blog?

Best wishes,
Christine

49. **Bee**
November 8, 2006

Dear Anon,

It is not shortsighted but PERFECTLY LOGICAL for leading physicists to simply rename the concept of "shortsightedness" as "TAKING ONE DAY AT A TIME", ie, rely on name calling of alternatives (crackpots, cranks…), which enables them to keep what they perceive to be the "noise" level down (any alternative to M-theory = noise, by definition).

What do you think these 'leading physicists' are searching for? It is money, is it fame? Or is it wisdom, knowledge, insights into the mysterious ways our universe works. And what is the way to a fulfilled life? It is my believe that many researchers have just lost track of their original motivations to become a scientist. And it is awfully easy to loose out of sight what you were really looking for if you are faced with what I like to call 'reality constraints' : you need a job, a place to sleep, income to get your family through. It hurts me if I talk to my colleagues and many, too many of them, tell me they'd rather work on this and that, but they are sitting on that boring grant number xyz, and they need to come up with a publication on a topic that's completely outdated since at least a decade. This IS unnecessary, and it is due to a mismanagement in our community, which can be improved. And if we don't do so, it IS shortsighted on every level you can think of: start with Bush's prime concern, the international competitiveness. It's not going to be helpful in any regard if theoretical physicists call each other names, and all advertisement in Nature, Discover or Physics Today isn't going to make a promising and promising theory into reality.

There is something at odds with the values in our society, more seriously though in the US, and it reflects not only in science. It is not logical to follow this path. Do I really have to point out that money and a high citation index doesn't make you happy?

Best,

B.

50. **Tony Smith**
November 9, 2006

Bee says that she "… believe[s] that many researchers have just lost track of their original motivations to become a scientist …
There is something at odds with the values in our society, more seriously though in the US …".

As to my opinion about "how the present situation can be improved",
I am (in my dark view) pessimistic,
but
here is my best guess at a course of action:

Some institution (not an individual) should set up a program (maybe for 3 to 5 years duration) to study and compare and evaluate ALL approaches to constructing unified physics models.

All the really obviously wrong ones should also be evaluated. Since it is easy to specify flaws in obviously wrong models, not much time would really be wasted doing that, and it would guarantee that EVERY approach got some consideration.

The only rules would be:
the evaluator should not be a worker on the approach being evaluated (thus eliminating self-praise)
and
the evaluator should actually listen to (or read) and understand the approach (at least enough of it to be accurate in making an objection to an approach)
and
an approach advocate should be allowed to append a supportive statement (the only limitations being as to length and being in a reasonable format such as pdf or LaTeX).

The evaluations (including statements etc) should then be put up on an evaluation web site for the world to see and make comparisons.

Such a project would create some physicist jobs, which is good.
It should be made clear that an evaluator gets as much credit for working on a flawed approach (and showing its flaws) as for "discovering" some approach that turns out to be useful and realistic.

I don't have enough experience in the world of grants to know how much it might cost,
but here is a rough guess:
50 jobs at $200,000.00 per year total cost including overhead, taxes, benefits, etc, would be $10 million per year;
for a 5-year program, that would be $50 million.

Since JoAnne Hewett said over at Cosmic Variance about the HEPAP committee on which she serves:
"… our committee is only charged at looking at experiments that cost $20 Million or more. …".
it seems to me that $50 million over 5 years is a reasonable, even cheap, amount to spend to get some sort of objective evaluation of the various approaches to unified theory models.

Of course, if the dominant paradigms of superstrings and LQG were really successful now, such a program would not be necessary,
but
as John Baez said (and Bee agreed): "… Both string theorists and their opponents are secretly miserable over this failure … to find a theory that goes beyond the Standard Model and general relativity. …"
and
such a program might uncover a realistic prospect that is currently off-the-radar of the physics community.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – As to what institution might be good to do such work, I don't know.
A problem with the biggest and richest North American universities and institutes (Harvard, Stanford, Institute for Advanced Study at Princeton, Kavli Institute at Santa Barbara, Smolin's Perimeter Institute)
is that their theoretical physics groups seem to be effectively monocultures for Superstrings (or
Loop Quantum Gravity / Spin Foam in the case of Smolin's Perimeter Inst.),
so they may be unable or unwilling to undertake a fair comparative evaluation.
Maybe the work could be done outside North America, say in Brasil or Japan or Europe … ???

PPS – As an example of current interesting results that seem to be ignored by most of the physics community,
that might be picked up and evaluated by such a program,
consider a contribution in the recent Hawaii DPF meeting in a section on Low Energy Tests of the Standard Model by Goran Senjanovic entitled "Grand unification and proton decay: fact and fancy" whose abstract stated:

"… I review the minimal grand unification based on SU(5) and SO(10) groups, with and without supersymmetry. I discuss the predictions for the proton decay and show how they depend crucially on the fermion (and sfermion) masses and mixings. …".

Since the conventional view has been for years that proton decay experimental observations have ruled out SU(5) GUT, and since I saw no full copy of Senjanovic's Hawaii contribution, I looked up arXiv postings for him and his coworkers (fortunately they are not blacklisted) and found hep-ph/0601023 in which Pran Nath and Pavel Fileviez Perez say in section 5.6:

"… For example in a minimal non-supersymmetric GUT based on SU(5) the upper bound on the total proton decay lifetime is …[less than or equal to]… 1.4 x 10^36 years …",

so, it seems that neutrino proton decay measurements have NOT in fact ruled out SU(5) GUT,
thus
contradicting a statement in the 2006 Particle Data Group Review 15. GRAND UNIFIED THEORIES (Revised October 2005 by S. Raby (Ohio State University)):
"… Recent Super-Kamiokande bounds on the proton lifetime severely constrain … with [lifetimes for varous decay paths greater than]… 5.0 x 10^33 yrs …[and]… 5 x 10^33 yrs …[and]… 1.6 x 10^33 yrs …[and]… 1.7 x10^32 yrs … These constraints are now sufficient to rule out minimal SUSY SU(5) …"
and
thus making even non-SUSY SU(5) GUT a viable component for building unified physics theory models.

PPS – Nothing in the above is intended to be an attack on S. Raby or Ohio State. The above-cited Review by Raby is very interesting and important. Even so, it should be possible for civil people to "agree to disagree", and any disagreement over how such things as dimension-6 operators work should be seen as furthering understanding, NOT personal competition.
Also, I like Ohio State and hope they win the USA football national championship (oh dear, now I have to say that I really don't fundamentally dislike Michigan, Louisville, Rutgers, Boise State, etc).

51. **JC**
November 9, 2006

Bee,

Most people don't know what they want out of "life".

By default, many people end up choosing obvious things like money, power, etc … In general, it tends to be things which can be "measured", and which have a "currency" in a particular group of peers, such as citations. Outside of physics, or academia in general, a person's citation numbers has very little to no meaning. The average anonymous person walking by on the street does not care about how many citations a particular physicist has.

I don't have any idea as to what the "meaning" of life is. For me, it is certaintly not string theory nor physics/math these days. I suppose if I still had a "fanatical" mindset, I probably could make something like string theory the "be all and end all" of my life. When I was younger, I was fanatical about all kinds of stupid things like rock bands (ie. Pink Floyd, the Scorpions, KISS, the Michael Schenker band, etc …).

52. **Chris Oakley**
November 9, 2006

Bee,

What you describe is unfortunate, but is hardly inexplicable. It follows from the fact that most academic research is, indeed, academic: in other words, society does not really care about the result. You will notice that when it does – e.g. semiconductors, or some kinds of medical research, a system more based on results and innovation emerges. The fact that research in theoretical physics is infinitely kind to useless, tenured old fossils and infinitely harsh to bright, young, sceptical people is because the first group have been allowed to dictate the terms.

Until about 1850 Oxford did not allow dons to marry: when they married they would leave, typically becoming country parsons or lawyers. This was healthy for the research environment, as it kept the average age of researchers down. Whilst I am not recommending a similar system for theoretical physics – which would exclude you already (and I doubt in any case that anything will really change) I have no doubt that a system that gave the whip hand to young people like yourself would produce better research.

I am only sorry that I am not in a position to do anything about it.

53. **r hofmann**
November 9, 2006

Dear Sabine,
but I like the cover of Smolin's book, and in particular 't Hooft's
comment, and I started reading the book as soon as it became
available. Otherwise I stand in awe of your honesty.

Gruesse von Ralf

P.S. Wir sind uns kurz ueber den Weg gelaufen, als ich anfing, von Frankfurt Geld zu beziehen und Du nach Arizona (?) gingst.

54. **Chris Oakley**
November 9, 2006

Apologies in advance for my rotten German, but …

Ich suchte ein anderes String theory Wortspiel hier, aber war enttäuscht.

55. **Bee**
November 9, 2006

Hi Chris,

Thanks for the link. I think I've just learned a new word: to denigrate. I should try to memorize it, it might be useful at some point. Totally off-topic: My first association to 'strung out' was this song (which nobody else seems to know). Which is not a bad song, but maybe explains why I find the title totally whack.

I actually agree that the society mostly doesn't care about what we do or don't. I think G. Johnson made a comment like this in the first part of his talks which went like: the public doesn't care one way or the other. Which caused quite some laughter, he looked pretty puzzled. I don't think this was meant as a joke.

But if you look on the 'large scale structure' of our daily struggles, and forget about the nasty details, the 'society' does of course care about our aims, trying to find questions to answers like: where do we come from, where do we go to, what are we made of? Of course that more general part of our work has to be communicated, that's why I think Peter Woit, Lee Smolin, Lisa Randall, Brian Greene, etc do a very important job with their books.

On the other hand, this 'not caring about the details' gives us fortunately room to organize our own community, set our standards, and ensure quality – which is hard for the public to judge on. Just that we haven't payed sufficient attention to that lately.

Dear Ralf,

AAH 🙂 🙂 Jetzt faellt der Groschen! Klar, Du hast mal an Stabilization of RS models gearbeitet und in Frankfurt irgendwas ueber Kinks erzaehlt (und keiner von den Heavy Ion Fritzen wusste wirklich worums geht)? Spaeter waren wir zum Nach-Colloq Dinner im Bastos? Bist Du noch in Frankfurt? Gibts das Bastos noch?

Best,

B.

56. **anonymous**
November 9, 2006

Various people here complain that the job market is too tough. But this is the same as complaining that salaries are too high: the two things are linked. Positions that would allow joung scientists to do long-term research without worrying of being competitive must have a salary a few times lower that what Tony Smith suggests. Otherwise people would start competing for these positions.

57. **Who**
November 9, 2006

Ralf Hofmann says
but I like the cover of Smolin's book, … Otherwise I stand in awe of your honesty.

the color is the blue of links. If you look at the date underneath the poster's name—right here—the book is that blue.

about things that matter, I admit she is awesomely honest, but if it doesn't matter she is able to feign insults for reasons of diplomacy and vocal balance.

when you point out 't Hooft's mention of "the sweet vagueness of quantum mechanics" you cause me to admire your ear for English style

high regards

58. **Bee**
November 9, 2006

Hi JC,

Most people don't know what they want out of "life".

By default, many people end up choosing obvious things like money, power, etc …

Yep. Many people go where money goes. That's why there's a discussion about the funding in theoretical physics… I don't know what I want out of life either, but I think that many scientists have a pretty good idea what they want out of science. Just that they don't have the opportunity to realize that. And sometimes just are afraid to speak out, in order not to appear naively idealistic, unrealistic, philosophically biased, or – well, maybe "pot-smoking hippies" 😉

I don't have any idea as to what the "meaning" of life is.

Maybe its better this way. What if you knew the meaning of life but didn't like it?

There is a theory which states that if ever anybody discovers exactly what the Universe is for and why it is here, it will instantly disappear and be replaced by something even more bizarre and inexplicable. There is another theory which states that this has already happened. ~ Douglas Adams

Hi Who,

the color is the blue of links. It's not. It has a definite green shade, I think its close by RGB#009dfc. In fact, I think there's an oil color that comes close: Coelinblau (sorry, don't know the English translation).

Best,

B.

59. **TheGraduate**
November 9, 2006

The internet says this is Coelinblau:

http://www.schmincke.de/media/images/news_ac_struktur/farbflaechen/coelinblau.gif

60. **TheGraduate**
November 9, 2006

further update: it means "Cerulean blue" (a greenish blue pigment)

61. **a.k.**
November 10, 2006

to quote Bee:

"Just that they don't have the opportunity to realize that. And sometimes just are afraid to speak out, in order not to appear naively idealistic, unrealistic, philosophically biased, or – well, maybe ''pot-smoking hippies."

I remark that I disagree to the implicitly given perspective that the main problems of modern physics root in the problem of formally preventing scientists to transform their original ideas of what 'life' should be into ideas of what 'science could be'. The search for an answer to 'large scale questions' of life or existence by using the method of 'exact sciences' could in itself be the germ of corrupting both the method and the aims. I tend to cite Horkheimer and Adorno in these respects who already objected 50 years ago a tendency of 'modern rationality', of the phenomenon 'Aufklärung' itself, to contain in a sense self-induced and inevitable regression, the point where it is undecidable where science turns into mythology and mythology turns into science. I strongly support the viewpoint that high energy physics today, i.e. string theory have an inherent tendency to represent mythological symbols of human existence in a quasi-rational language and that it is to a large degree undecidable where the scientific methods being constrained by falsifiablity and predictiveness, turn into belief. In this sense, I support the more radical view of Bert Schroer in his judgement of the state of string theory or JC's viewpoint of identifying a 'fanatical mindset' to judge the borders of what can still be called science and believe at the same time that these borders will define what was originally meant to be 'progress'.

62. **Bert Schroer**
November 11, 2006

Fortunately the "perfect" world of Bee never took hold of physics, not now and certainly not in those days of great progress in particle physics of Pauli, LSZ et al.
The big difference from pre- ST times and now is that irony, sarcasm and good polemics served the course of particle physics. When my boss Harry Lehmann told us (at the time when the Heisenberg nonlinear spinor theory entered the media): great news, the spinor theory was able to successfully compute the relative sigma-lambda parity up to a sign. Pauli was know for his acid humor, his own personality included. 4 weeks before his death, after a beautiful colloquium he gave in Hamburg, when he worn out and tired sat in his rotating chair which he used in the 20s (called the Pauli chair) and fell into his swaying movement like an orthodox Jew (the Pauli eigen-frequency) obviously in physical pains (4 weeks later he died of stomach cancer) he said: "I think that Heisenberg lies still heavily in my stomach". This was the condensed form of his previous withdrawn support of Heisenberg's spinor theory which he still presented and defended during a previous lecture tour through the US and it had more scientific content than 1000 words.
In the times of ST this has been substituted by foul language ("crackpot") void of any meaningful content. Can you imagine Witten using irony? Even Lee Smolin's "bel-esprit" soft-spoken style is a new phenomenon. Contrary to the pre-ST ways it is verbose and often repetitive. No Bee, I prefer not to be part of your nice new world.

63. **Bert Schroer**
November 11, 2006

I forgot to add:
without the information-laden irony of Pauli, the title of Peter's book would be at least as long as that of Lee Smolin's. There is nothing in the ST nomenclature which could match this, even the new ironic use of "a theory of everything" does not quite match the old style (and runs the risk of being misunderstood by the young ideologues).

64. **Bee**
November 11, 2006

Oh, great, I see you've promoted me into proclaiming the perfect world. I should maybe go and sympathize with the pot smoking hippies?

Dear Bert,

Fortunately the "perfect" world of Bee never took hold of physics,

*The big difference from pre- ST times and now is that irony, sarcasm and good polemics served the course of particle physics. […] Pauli was know for his acid humor, […]In the times of ST this has been substituted by foul language ("cra*kpot") void of any meaningful content. Can you imagine Witten using irony? Even Lee Smolin's "bel-esprit" soft-spoken style is a new phenomenon. Contrary to the pre-ST ways it is verbose and often repetitive. No Bee, I prefer not to be part of your nice new world.*

I completely fail to see how our personal sense of humor influences the way science works. I hate to point it out, but did it ever occur to you that sense of humor, and the way to lead arguments, differs from country to country? Your problem might just be that the particle physics community has changed in its composition. E.g. if you considered your text to be ironic, I am afraid I've been in the US for too long. On the danger of distributing prejudices, in my opinions Americans are just POLITE (in capital letters), and if I should describe their sense of humor, I'd call it nice and naive. I definitely do prefer British humor. Imo *Lee Smolin's "bel-esprit" soft-spoken style* isn't so much a new phenomenon, but an American phenomenon. You wouldn't believe how many times I stepped on somebody else's toes trying to make a joke I considered to be fairly innocent, but which was perceived as plain offending (or not a joke at all).

I'll give you another example where cultural differences play a big role. As I had to learn some while ago (correct me if I'm wrong), it's apparently not polite for a Japanese to say 'No'. So, they'll try to get around saying so in a straightforward way. If you don't know how to interpret that, you'll get a completely different impression of their way to answer questions, which might come off as incompetent. On the other hand, they'll likely be pissed off because they feel misunderstood.

Another point: yesterday there was a seminar here, which I missed, but several people excitedly reported to me that X had a fairly loud argument with Y. So. Back in Frankfurt that happened all the time. I've seen Russians working together, which apparently just wasn't possible without yelling at each other, and occasionally slamming doors. Go try that with an American, and say good bye to your paycheck (alternatively, you might end up in therapy, not a joke, I know a case where that happened).

I would summarize it by saying that globalization has changed the scientific community. If we don't take cultural differences into account, it won't work. In that respect, scientific research isn't so much different from the industry. Again, this is another point where our community needs a management that's missing (how about giving seminars on cultural differences to your international coworkers and how to acknowledge these).

But that's definitely not the problem I tried to point out, and it seems to me you're talking about something different altogether.

I agree with you that our community suffers from a lack of criticism. The reason for which I see in the necessity to advertise the own work as good as possible, to make a big fuss about successes, and keep silent about problems. Read a randomly picked abstract of a paper. How likely will you read a sentence like: We've tried the approach zing-zong to the problem soundso, and show that it doesn't work for the reason blahblahblah. Trial AND ERROR is a big part of science, but in times of short funding it's become common practice to just not mention any drawbacks (or if so, then not in public) .

That is a problem. And it's a big one. I agree on that. It is necessary to have constructive criticism. But it's definitely not necessary to do that in a specifically 'Paulian' way.

Best,

B.

65. **Bee**
November 11, 2006

Bert, regarding humor, see also The Stupid Title List. Maybe we're not such a hopeless case, eh*?

*trying to feel Canadian

66. **Bee**
November 11, 2006

Hi a.k.

I remark that I disagree to the implicitly given perspective that the main problems of modern physics root in the problem of formally preventing scientists to transform their original ideas of what 'life' should be into ideas of what 'science could be'. The search for an answer to 'large scale questions' of life or existence by using the method of 'exact sciences' could in itself be the germ of corrupting both the method and the aims.

Did I say that? If it came across as such, this is a misunderstanding.

What I tried to communicate is that I strongly oppose to shoulder shrugging when one faces a mismatch between 'that what is' and 'that what could be', by attributing it to an undefined concept like 'human nature'. Thereby one implicitly assumes that the own opinion is a minority opinion, and as a single person one can't do anything about it one way or the other. It's like cursing capitalism because the health care of low-income families sucks, but then shrugging shoulders and saying 'that's the way it is, and capitalism is in the human nature', instead of remembering that democracy means you can do something about it.

To come back to science, when I talk to colleagues I notice that there is a broad consensus that 'what is' is not 'what could be', but then again, who does something about it? This applies to issues raised in Lee's book (eg. who hires whom how, and are the presently used criteria optimal? why has it become necessary to work on 'hot topics' with somebody-famous), but in every day's work also e.g. to the peer review problem, or the completely ridiculous requirement that research proposals essentially have to explain what results you will have after 5 years. The recurring question about what the citation index actually says. Or, to come back to what Bert has addressed: that the importance of constructive criticism isn't sufficiently acknowledged.

It is in this context that I think most scientists do indeed have an original idea that is currently in conflict with reality, and I want to encourage them to do something about it. My remark above referred to the way science is pursued, not to the content of actual research fields (in which I agree that a scientist's original idea can very well be in conflict with reality, and that matching the one with the other would mean *corrupting both the method and the aims*)

Best,

B.

67. **Bert Schroer**
November 11, 2006

Well Bee, that's really funny especially in those cases where the humor is involuntary. In Sid Coleman's case it is probably functional humor related to the content, one remembers very nice titles of his work in the 70s like "the double well done doubly well". In Susskind against Laughlin it is probably an attempt to ridicule an unloved detractor of ST (but I did not open the article).
In your previous blog you put to much weight on US hypocritical behavior. Although you do not use this term it is precisely this what you have in mind. That is of course quite singular because it is such a normal everyday behavior in the US that it almost goes unnoticed. When Bush says after Abu Ghraib in front of international cameras with this slight cough in his voice: "we don't torture, the US does not torture" and the surprised rest of the world asks itself: well if the US did not do it, who was it? Didn't they have the supervision over Abu Graib?
this is an illustration of hypocrisy driven to perfection; the guy does not even notice the contradiction between his claim and the facts. However this sort of behavior I have never experienced during my 10 year stay within the academic surrounding in the US; and although one may criticise string theorists in the way of Phil Anderson, I do not think they can be accused of hypocrisy this is not part of the US academic cultural traditions. Japanese politeness is a cultural trait which includes academia but it has nothing to do with hypocrisy. Russian academic discussion tend to be a bit more rough than German, but as a result of the long reign of the Soviet system there was always a private political frankness. During the time of the Russian Afghanistan campaign it would have been inconceivable to be told by a Russian conscript in private that he fights in Afghanistan for the protection of his country or any other "just" course. But when the preemptive war in Iraq started probably most of the GIs internalized that they were bearers of freedom and democracy; even Witten believed that the war was justified by the argument of regime change.

68. **Bee**
November 11, 2006

In your previous blog you put to much weight on US hypocritical behavior. Although you do not use this term it is precisely this what you have in mind.

I don't. I think I made quite clear that I was pointing out there are different ways to argue, and I am not willing to start a discussion about George W and torture here, which doesn't have to do anything with my concerns about theoretical physics. Best, B.

69. **Bert Schroer**
November 17, 2006

Dear fellow physicists
I stop and say good by to all who engaged me in interesting discussions. It is not only the spam-filter which irritated me but I find this whole enterprise unworthy, regimented to rules which never were spelled out, and at the end and plainly ridiculous.

70. **Benni**
November 25, 2006

Edward Witten admits indirectly that string theory is in trouble:
He writes:
http://schwinger.harvard.edu/%7Emotl/witten-nature-letter.pdf

He Writes about, what scientists can answer to critics of science, indirectly referencing the case of string theory.
He writes, that he cannot answer the critics because this would add fuel to the discussion (maybe because he has no arguments). And explains that he thinks scientists should keep doing what they are doing and he hopes, some kind of science may might even be useful one day. He is clearly indirectly referencing to stringtheory here. And the case that "it even might be useful one day" is not an optimistic one.
The words from wittel below could be understood as a confession of failure. Or at least, as a not optimistic at all.

He writes:

The News Feature concerns radical environmentalists and
animal-rights activists, but the problem covers a wider area, often involving more enlightened criticism of science from outside the scientific establishment and even, sometimes, from within.

Responding to this kind of criticism can be very difficult. It is hard to answer unfair charges of élitism without sounding élitist to
non-experts. A direct response may just add fuel to controversies. Critics, who are often prepared to devote immense energies to their
efforts, can thrive on the resulting 'he said, she said' situation.
Scientists in this type of situation would do well to heed the advice in Nature's Editorial. Keep doing what you are doing. And when
you have the chance, try to patiently explain why what you are doing is interesting and exciting, and may even be useful one day.

71. **Peter Woit**
November 25, 2006

Benni,

I saw the Witten letter. Hard to know what exactly to make of it, since he's leaving it very unclear what this all has to do with the string theory controversy. In particular, the argument I'm making against string theory is not that the problem is elitism. I'm actually all in favor of elitism myself.

72. **Benni**
November 25, 2006

I think the sentences on elitism are simply because he seems a little bit depressed on what others say on his beautiful theory. They are simply because he is in bad mood.

I further think Witten says clearly what he wants. He says that string theorists should not discuss with critics like Smolin (this is the one who makes criticism from within science, because he has published actively on Quantum Gravity).
String theorist should, according to Witten, not discuss with critics because then, the situation for their subject would even go worse.

Witten answered to this nature article, because there was advice on scientists what to do with critics. Witten seemingly feared, that some string theorists would answer Smolin…..

All in all, when the only thing you can do is: proclaiming that "what you do might even be usefull at one day"…
You are actually saying (with the phrase "even might be") that there is a very good possibility that it won't be usefull at all. The man who writes here has clearly lost the last bit of optimism and admitts that he does this only becauese he likes the math.

73. **anon.**
November 26, 2006

"I'm actually all in favor of elitism myself."

Indeed.

74. **ScienceLover**
November 29, 2006

How can someone be elitist who leads a widely known public weblog? These media are exactly what blurr the distinction between a small elitist, self-selected community and a public audience delivered by press-speakers and mass media journalists. The silent readers as well as the participant form a new kind of public. I wonder a little about Wittens paternalistic attitude. What is science becoming after abandoning the englighted reader? A secret society with clan tattoos and corporatist ideals that tries to fascinate the people by the high fence they are living behind?

75. **Who**
November 29, 2006

ScienceLover you make several good points in a short post. I look forward to seeing more.

"…paternalistic attitude…abandoning the enlightened reader…fascinate the people by the high fence…"

To try to answer your rhetorical first question, perhaps one can distinguish between open-debate elites and sheltered inscrutable elites.

In both cases, the top people get to guide policy and influence how the money is spent, but in the open case top scientists recognize they have a responsibility to discuss differences of opinion in public—to educate the public, to explain, to reason honestly in the open.

Someone who says he favors the research establishment being run by elite, but who also has a blog that spotlights valid differences of opinion within the expert community and in a sense forces more open discussion, may be acting consistently.

Starting tomorrow there's a workshop in London entitled M-theory in the City, in some sense celebrating the 11th birthday of M-theory. There will be a reception on Thursday evening, and the organizers of the workshop are noting that:

Recently there have been a variety of publications presenting a sceptical view of string and M-theory. These have been reported extensively in both the national press and various popular science journals.

and encouraging journalists interested in this topic to attend the reception and use:

the opportunity to discuss with the participants and question where string theory is heading and address the recent criticisms string theory has faced.

Various and assorted quantum gravity news:

The latest Physics Today has an article by Lee Smolin entitled Quantum Gravity Faces Reality (available only to APS members). People concerned about open access to the scientific literature should note that sometimes professional societies like the APS are among the worst offenders. It appears that Physics Today is one of relatively few scientific publications that universities and other institutions are not even allowed to buy electronic access to. I've been told that this restriction of electronic access to subscribers is an intentional tactic of the APS to keep up its circulation figures and thus advertising rates.

The latest Nature Physics has a report from Ashtekar about recent developments in loop quantum gravity.

There's a new paper on the arXiv by Baratin and Freidel that looks quite interesting. It's too bad that Christine Dantas has given up her blog that provided an excellent location for discussion of this kind of quantum gravity research. I hope someone else will pick up where she left off. Blogger Sabine Hossenfelder has a recent arXiv preprint on Phenomenological Quantum Gravity.

I heard from my sister-in-law that NPR yesterday ran a segment on string theory, but it was mostly about soccer. I found this hard to believe, but she was right, the story is on-line here. NPR's Richard Harris covered a soccer game in Santa Barbara between visiting string theorists and laser physicists. The string theorists were trailing much of the game, but finally won on a penalty kick they got due to a misunderstanding by the laser physicists. The story does have some remarkable quotes from string theorists about the prospects for the theory. Steve Giddings "is actually feeling somewhat more optimistic about the fate of string theory these days", arguing that maybe the LHC will start producing strings (the article does note that "even most string theorists say this is a real long shot"). David Gross says that the reason to do string theory is that "…there's nothing else. There's no other game in town." He acknowledges that string theorists don't even know what the theory is, and are out on a limb and trusting in faith:

Even those of us who work in the field aren't really sure what string theory is or what it's going to be, Gross says. *So when you're in this kind of speculative, exploratory science, it's important to have faith because you're out on a big limb. So I think it's really a question of whether we believe this is the right direction; and that I do believe rather firmly.*

Update: Lee Smolin has put up a letter on his web-site in response to queries and criticisms he has received in response to his recent book.

Comments

1. **Jonathan Vos Post**
   November 8, 2006

   Hard to keep score. I'm not sure I understand the relationship between the icosahedral symmetry of soccer balls, Lie groups for glueballs, and the apparent confusion between theory and GOOOOOOoooooAAAAALLLLL!

2. **Bee**
   November 8, 2006

   Hi Peter,

   thanks for the link to my paper. It's not really a paper though, but just a writeup of a talk I gave at the SUSY06. The full paper is hep-th/0603032, and there's also a brief summary of it's content on my post The Minimal Length Scale. Best,

   B.

3. **anon**
   November 9, 2006

   The fact that Physics Today follows such restrictive circulation policies shows. It's sooo umbearably dull.

4. **M**
   November 9, 2006

   a criticism for Smolin, about physics.

   He carefully explains why unification is in trouble with proton decay. Later, when discussing "phenomenology of quantum gravity", he does not mention the Crab nebula constraint (astro-ph/0212190 and later works), that forbids some "quantum gravity" effects suppressed by one power of the Planck mass.

   I would say that both scenarios start to have trouble with experimental data. And of course in both cases one can avoid trouble in the standard way: if the simplest realization has problems, add complictations.

5. **Ejjay**
   November 9, 2006

   you know Peter, the string theorists are like these dilluded pot smking hippies, thinking they have this beautiful theory that will one day cure cancer and bring world peace. And you are like this nasty party-pooping right wing bastard, who slaps them around and telling them that their dreams are unrealistic and silly.

6. **Matti Pitkanen**

November 9, 2006

I have been wondering for more than two decades when people start to take the absence of proton decays seriously and be ready to consider separate conservation of B and L. I am also still wondering why the huge discrepancies in mass scales of fermions (think of top/neutrino mass scale ratio) do not raise the question whether mass scale might be a discrete dynamical variable. The attempt to force quarks and leptons into same multiplets might have looked natural when theoreticians discovered gauge groups but not anymore. In light of proton stability and huge mass scale differences for leptons, I am really amazed hearing people to claim that there is no data to guide theory building. What is data if this is not it?

7. **Tommaso Dorigo**
November 9, 2006

Good point, Matti…
There is indeed tons of data to speculate on. I see a tendency of self-constraint in the theorists in this respect. Why lepton and quark masses are what they are ? Why the values of the CKM ? Oh, sure, the landscape…
T.

8. **Lee Smolin**
November 9, 2006

Dear M,

Thanks for mentioning that. I agree I did not give a complete survey of the field of Planck scale phenomenology in either TTWP or the Physics Today article. My own view, which is consisstent with what you say, is that order l_P effects comingn from Lorentz symmetry breaking are already constrained by existing data, especially the lack of a polarization odd variation in the speed of light with energy. (The Crab nebula constraints are impressive but purists argue that there could be loop holes due to the modeling required.) However, as I hope I've made clear, the experiments leave room presently for possible order L_P effects coming from deforming special relativity.

Thanks,

Lee

9. **data lover**
November 9, 2006

To Tommaso and Matti:

A lot of well known theorists work on/have worked on models attempting to explain masses and mixings of the fermions out there. For instance to name a few, barbieri, hall, murayama, etc… High energy theory is a fast moving field based on what are the most promising and interesting directions at the time, so one shouldn't generalize that theorists aren't interested in these things just because you aren't seeing a whole host of flavor symmetry papers at the current time. However theorists are still interested and well aware of the shortcomings of the SM, however from EFT reasons there are more pressing issues to be solved in the SM, and presumably any succesful mechanism that explains the value of V_{cs} won't be able to be probed at the LHC.

As to the whole point of theorists not having data to guide them, this is a matter of perspective. There of course is a lack of data saying this is what physics there is beyond the SM, because up until now every experiment has always agreed with the SM. On the other hand we have tons of data and everything agrees with the SM which does inevitably guide model building in many ways. What most people outside of the theory community(and some theory savy experimentalists) don't realize is that it is very hard to solve your favorite issue in the SM without already having your solution be completely ruled out by other existing experiments if it predicts new phenomena at energies the LHC will probe!

10. **Tommaso Dorigo**
November 9, 2006

Datalover, I think I do know a little bit about those studies of mass generations. My point is that it is a minor branch of current theoretical effort, while it should by all means be a major one.
And I know it is very hard to formulate things that fit something without being at odds with some other data point. That, in fact, is the whole heart of the matter. The standard model rulez! I bet we will not break it in ten years (I have already, actually). But theory should try to fit the data, try and try. Present-day attempts appear a bit like philosophy to me.

Cheers,
T.

11. **Peter Woit**
November 9, 2006

Ejjay,

Funny, I thought I was the pot-smoking hippie telling the up-tight right-wing bastard string theorists that they needed to see the light, give up their uncool and unworkable rigid ideology, let a thousand flowers bloom, loosen up and try something new and different…

I do like the idea of Lubos as the pot-smoking hippie though.

12. **Mahndisa**
November 10, 2006

11 09 06

Well thanks for linking to Lee's letter, Peter. Although I found it a bit verbose, I was happy that he took the time to clarify his positions. As a student who has learned a lot of this stuff from personal study, it was rather difficult to figure out whose opinions I should listen to or not, as I relied upon more advanced persons for input. After seeing many of his comments on other blogs and reading a few of his papers, I appreciate the sanity of his approach, and his willingness to say that stringy options aren't a total impossibility, but that limiting our minds to only string theory isn't a good idea. Sounds reasonable to me:)

Have a nice day

13. **Pindare**
November 10, 2006

In the meantime Witten is still working on the Langlands program
http://math.berkeley.edu/index.php?module=announce&ANN_user_op=view&ANN_id=63

14. **Pot Smoking Hippie**
November 10, 2006

Maybe if we all got together and got high we'd get along better.

15. **anon.**
November 10, 2006

16. **Tommaso Dorigo**
November 10, 2006

There you go guys, if you put yourself into it you can create a hilarious thread for once! (Of course I read and love all threads here, but I laughed at the last few comments…)

And whoever was it that signed himself as a "pot smoking hippie" I bet it was not what he faked to be… Good try at peace on earth, buddy, but we prefer to keep fighting 🙂

T.

17. **Pot Smoking Hippie**
November 11, 2006

Actually, I'm not a he but a she, and I don't fake anything. 😉

18. **Mahndisa**
November 11, 2006

11 11 06

Hello Peter:
I wanted to bring something to your attention that has been bothering me. You have made a crusade out of pointing out the flaws in string theory methodology and even dedicated threads to Motl. But I have not seen you address his posts which are more pernicious than any 'wrongness' with string theory. If I am mischaracterizing you, or am incorrect, pls forgive. But I am sick of visiting blog sites where people are linked to this guy and his is spewing this racist nonsense. As a physicists, I am really offended that more people haven't delinked him or taken him to task. How in the world can he mentor anyone with these attitudes?

I think that tunnel vision is a bane to science at large, which is why I can appreciate this blog. However, tunnel vision in scientific ideas doesn't even compare to the evil of saying that one racial group is inherently more intelligent than another. If any of the physicists who read this comment have heart, they will consider what I have said because by linking to him, they are tacitly endorsing his screwed up positions.

Lastly, to keep in line with the thread, LQG's newest loopy oscillator by Corichi is quite interesting and gives us some insight into regulating and approximating the fundamental rep.

19. **Benni**
November 11, 2006

Peter, I agree with mahndisa. I also think it is time to delink him…

20. **Peter Woit**
November 11, 2006

Mahndisa,

Lubos is a grotesque racist, and his views on almost every topic are completely idiotic. He does however occupy a very prominent position as someone that string theorists have judged to be among the best young scientists in their community, and many continue to support him. I suggest you discuss his appalling behavior with them, not here.

The fact that I have a link to something in no way indicates any sort of approval of it, in many cases quite the opposite.

21. **Mahndisa**
November 11, 2006

11 11 06

Peter thanks for the response. I left the comment here because I knew it would be read. Also since you link to him I had no issue bringing this up to you. As to the position he occupies among string theorists, I will be leaving another comment on other blogs about this.

Take Care.

22. **anonymous**
November 11, 2006

Mahndisa,

As a very junior string theorist, I can't help but laugh at the contrast between what peter said and what I hear from real string theorists. Lubos is widely viewed as a lunatic in the string community, and people think it was only gross midjudgement that got him a (relatively undesirable, non tenure track) juniorjob at Harvard. I'm sure his colleagues there find him an embarassment. He hasn't been even a junior leader in this field for many years now.

23. **Peter Woit**
November 11, 2006

To correct “anonymous”

Lubos may be “widely viewed as a lunatic in the string theory community”, but this doesn’t appear to be true at Harvard.

As for his job, I believe it is technically tenure-track, although Harvard does rarely tenure people from these positions. The “gross misjudgement” appears to be an on-going one: Lubos was hired as a Junior Fellow (not a job I’ve ever seen referred to as “relatively undesirable”), then after dealing with him for a few years, they promoted him to a junior faculty position, and seem to be keeping him on.

Doubtless many string theorists do consider him an embarassment, but it’s remarkable how hard it is to get any of them to say so publicly and put their names to it.

Remarkably, the publicity material on Amazon for the forthcoming book by Michael Dine about string phenomenology contains a blurb by Lubos. Evidently Dine and the people at Cambridge consider him not to be a “lunatic”, but instead a leading member of the community.

Please though, enough about Lubos here.

24. **TheGraduate**
November 12, 2006

The connection between science and marketting is getting so strong. I can just see the thinking behind this soccer game story. Perhaps I am cynical but it comes across as an ad for string theory. It is not unusual for a company being maligned to then want to humanize itself.Think oil company executives hugging their kids and watering plants.

Apparently now scientists have wised up about this. There was a similar story with Yau in the Times “The Emperor of Math”. It was again basically a sort of soft piece meant, I think, to prop up Yau’s maligned profile. It’s potentially a good cause but is this the right method?

25. **rumor**
November 12, 2006

> ..then after dealing with him for a few years, they promoted him to a junior faculty position, and seem to be keeping him on.

During one of Lubos’s rants he mentions that he only has a few more months left to endure in the Republic of Cambridge.

I think his time at Harvard is done. I’m curious to see what department will be willing to take on such a polarizing figure.

26. **Who**
November 12, 2006

Though age from folly could not give me freedom,
It does from childishness: can Fulvia die?

*
[Antony and Cleopatra Act I scene 3]

27. **William**
November 12, 2006

Pot-smoking hippies? I thought all the string theorists were getting high on LXD (Large eXtra Dimensions).

28. **Tony Smith**
November 12, 2006

Peter, about the cover of the UK edition of your book:

Isn’t the cover particle physics event
the same event
that is shown on the cover of Freeman Dyson’s new book “The Scientist as Rebel” ?

Since Dyson’s book is not (according to Amazon USA) to be released until Tuesday 14 Nov 2006 (2 days from now), I have not yet read it,
but
the Amazon book description says in part:
“… An illuminating collection of essays …
His topics fall into four groups.
The first takes up contemporary issues in science, from cosmology to nanotechnology to global warming.
The second group deals with questions of war and peace, particularly questions of nuclear weapons and disarmament.
The third group is concerned with the history of science, especially physics, with essays ranging from Isaac Newton, to Sir Ernst Rutherford and the discovery of the structure of the atom, to Einstein and Raymond Poincar, to Norbert Wiener, Richard Feynmann, and string theory.
The final section contains more personal and philosophical essays, dealing with such questions as the differences between science and religion, and the relation between science and the paranormal …”.

With respect to the “third group … essays ranging from … to … string theory”:
a 2003 web page at http://www.thirteen.org/bigideas/printable/about.html says:
“… Freeman Dyson returns to provide an alternate, skeptical assessment of string theory. …”.

Since both you and Dyson have “alternate, skeptical assessment”s of string theory, I wonder:

Does the common cover photo event on the two books signify that Dyson regards you as one of the constructive rebels of science ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

29. **Peter Woit**
November 12, 2006

Thanks Tony,

Yes, the two covers ultimately are based on the same source, although I kind of doubt that Dyson was trying to make the point you suggest. One reason this happened is probably just that that image is in the public domain and easily accessible. Look at the interactions.org ImageBank, it's at

http://www.interactions.org/imagebank/search_detail.php?image_no=CE0057

The UK cover of my book was the third try. The first one involved a drawing of a piece of string and seemed a bit too silly, the second one I vetoed since it looked too much like the cover of "The Elegant Universe". At that point I suggested that they forget about strings and Calabi-Yaus and find a purely particle physics image, since that would be more appropriate for the theme of the book. I pointed them to the interactions.org ImageBank web-site, and that's what they came up with.

30. **Who**
November 13, 2006

There is now even a third book cover that has appeared this year with the same image!

http://backreaction.blogspot.com/2006/11/not-even-zong.html

31. **Anonymous 17**
November 13, 2006

I see Lubos Motl's racist comments have been removed from his blog … there are apparently some things that his colleagues (or possibly his administration) at Harvard are unwilling to tolerate.

32. **Who**
November 13, 2006

NEW and TTWP have been #3 and #2 on the UK amazon physics bestsell list whenever I looked today. It's nice to see them doing well. #1 on the list is a new book by Paul Davies called "The Goldilocks Enigma" about why the universe is "just right" for life. Hard to beat a title like that.

33. **Eric Dennis**
November 13, 2006

I am no fan of Lubos, but I've seen no evidence that he is a racist. (Linking to a psychometric study and stating simple statistical facts does not make one a racist. In Lubos' case, his target is not black people but rather leftist intellectuals. Despite much incredulity on the part of the latter, it is in fact possible to disagree with a leftist intellectual for reasons other than that one hates black people.)

This issue is obviously way off-topic but the charge of racism is probably the single most fear-provoking and consequential one in the modern acadamy, and it should not be made lightly.

34. **Peter Woit**
November 13, 2006

Eric,

I don't think Lubos hates black people, just that he thinks they're stupid. He also thinks women are stupid, Democrats are stupid, LQGer's are stupid, environmentalists are stupid, anyone who doesn't believe in string theory is stupid, and that I'm stupid.

But please, enough about him, on the whole it's a really stupid topic, and the last thing I want here is to have to deal with a stupid discussion of racism and "leftist intellectuals".

35. **woit**
November 13, 2006

I'm shutting off comments on this posting due to the behavior of "TheGraduate", who insists on repeatedly reposting the same comment about Lubos, using different names, no matter how many times I delete it. Sometimes dealing with the comment section here is just incredibly annoying due to the obnoxious behavior it attracts.

For some insight into the difficulties associated with being an untenured professor and trying to get an NSF grant in astronomy, see this post (and comments) by Rob Knop. For those innocent of the ways of academia, there's a post by Doug Natelson on what a well-organized faculty search is like (both of these via Angry Physics).

This week Witten will be giving two series of talks on gauge theory and geometric Langlands, one at Berkeley, and one at Harvard. Unfortunately I won't be able to make it to either, perhaps someone who does attend some of the talks can report on what Witten has to say, in particular on what might be new since his long paper with Kapustin on the subject earlier this year.

Some of the talks from last month's workshop on axions at the Institute for Advanced Study are now on-line.

Honeywell is sponsoring an educational program involving Nobel Laureates in chemistry and physics, called the Honeywell-Nobel Initiative. They already have material on-line from Leon Lederman and Horst Stormer, and from one of their promotional ads it looks like Frank Wilczek will also participate.

The Perimeter Institute has a new, improved web-site, with many online talks, both scientific seminars and talks for the general public.

The Templeton Foundation also has a new web-site. This month the featured "Life's Big Question" is Do we live in a multiverse?

The European Mathematical Society has a newsletter.
