– now the TNO (Trans Neptunian Objects), Kuiper Belt Objects, etc
Michael Brown/Caltech's numerous discoveries of objects beyond Pluto

All the above "data points" were totally unexpected & beyond predictability.."it is what it is". The whole idea of cosmological predictions from such localized data is absurd!

"I'm locally pessimistic, but globally optimistic"
— Dr. Jordan Pollack, Brandeis Univ/CS Dept

Their "global optimism" is overstating the reality of the data..way too localized.

It's beyond the wildest imagination of a science-fiction author (after copious amounts of alchohol). "The universe is WEIRDER than you can imagine". I guarantee you, that the results will be surprising & suggest new questions (this always seems to be the case, unwrapping the successive "shells" of information seem to go on endlessly)

LHC is breaking into new energy domains, so expect new data points.

"In order to Push the Limits, sometimes you have to EXCEED THE LIMITS"
— Formula 1 Australian GP (2003)

LHC is pushing the limits, & like a Formula 1 race car (aka "knife edge car"..very unstable), it will be at the performance envelope of Technology/Science. Should be interesting!

"May you live in Interesting Times"

— Chinese proverb

12. **mitchell porter**
September 9, 2008

    I once mailed Arkani-Hamed to ask if he was serious about betting a year's salary, because I might be interested to take him up, but I wanted to know the details. No reply.

13. **Chris Oakley**
September 9, 2008

    James,

    I was making a serious point. Physicists used to be taken seriously because people knew that if they did not give us what we wanted, we might just destroy the planet. But if senior physicists start bullsh*tting on about metastable particles that will solve all our energy problems then we will eventually just be regarded as a bunch of delusional, harmless hippies, no longer deserving of respect or fear. This could only harm funding prospects.

14. **Haelfix**
September 9, 2008

    Umm its a pretty damn good bet to wager a years salary on the detection of the Higgs (suitably phrased to allow for instance a doublet or somesuch). The scenarios where you would not see it (after a suitable time), are ugly and contrived and it really is an essential ensemble of probably the best tested theory in all of physics history. Its as close to a sure thing as anything in physics.

15. **David B.**
September 9, 2008

    Chris,

    The history of these `exotic particles' goes back to the days where nuclear physicists were studying muon catalized fusion. In principle, if you have a muon factory, you can use it to produce energy. A single muon could produce about 200 such reactions of combining deuterons into helium . The process would be stopped because there is a finite probability of capture of the muon by one of the helium atoms produced. After that happens, there is no time to recover the muon, since the muon decays. You are jut short of breaking even in terms of the energy cost to producing a muon, and the energy you extract from fusion.

    The reason that scenario has been put forward is because surprises happen in physics and that is one that has not been ruled out experimentally, yet. If it is there, however unlikely that is, wouldn't you want to know?

    I also object to your mischaracterization of physicists being funded because if they didn't give us what we wanted we would blow up the planet. The physicists did not hold the world hostage at any point. Technological applications for war purposes were a big deal during the cold war, that is why physics got such huge support: we could build the most destructive devices of all. Physicists were not feared. As a matter of fact, fear of technology is one of the most dangerous trends that can run against physics funding. All this hoopla about the LHC destroying the earth suggests that it will only get worse from now on, not better.

16. **DB**
September 9, 2008

    Hawking is on record as betting against the discovery of the Higgs Boson, although he hasn't exactly gone out on a limb – his bet is $100.

17. **James Robson**
September 9, 2008

    Chris,

    As you said, you were trying to make a serious point, and I respect that, and quite clearly I wasn't, so my apologies there if required. However, in a faint echo of David B's comment – do you really aspire to be "feared" by the general public for being a physicist?

    I think you should have chosen dentistry 🙂

    (Should have a smiley with teeth!)

18. **mike**
September 9, 2008

    Is there a good upper limit for the Higgs boson mass? It's disconcerting that without strong upper limits we will continue to search for something that might be a dead-end. I do think what we will see will hint at the existence of some scalar field, but it's characteristics might be much simpler than we think.

19. **bpz**
September 10, 2008

    "Is there a good upper limit for the Higgs boson mass?"
    In the MSSM it's about 200 GeV, in the pure SM it's about 800 Gev.

20. **Jimbo**
September 10, 2008

    BPZ,
    If you visit the link in my comment, you will find the number you seek. It is the 95%CL upper bound established by the Tevatron last Aug, of 144 Gev:
    http://www.physorg.com/news96040503.html

21. **Peter Woit**
September 10, 2008

mike,

There are two kinds of upper limits on Higgs masses:

1. In the SM, the Higgs mass is determined by the Higgs field self-coupling. To increase the mass, you have to increase this coupling constant, and beyond a certain point, there is no reason to trust perturbation theory. This is in conflict with the fact that the predictions of perturbation theory work very well.

2. Precision electroweak measurements provide indirect constraints on the Higgs mass, because it appears in the higher-loop theoretical predictions.

22. **Ellipsis**
September 11, 2008

Here's a prediction from last year that came true precisely (delay of two months beyond the at-that-time July scheduled start date):

http://www.math.columbia.edu/~woit/wordpress/?p=600#comment-28785
http://www.math.columbia.edu/~woit/wordpress/?p=608#comment-29531

So, I'll make a few more predictions:

3-sigma Higgs announced on July 28, 2010 simultaneously by CDF/D0 combination and by a shotgun combination of ATLAS and CMS data requested/required by CERN management.

Anomalies from ATLAS and CMS also announced in 2010, 2011, 2012 — all of them different and eliminated / made less significant by the following year's data (anomalies within the collaborations will fly continually, but 2010 will be the first year they are "vetted" and get through to public announcement, but still wrong).

First real anomaly that sticks will occur in 2013. This one will be a real one. There will be much heated debate as to whether it is from SUSY or not. The answer to that question will not be clear all the way until 2017.

Unlike Nima, Tommaso, Gordy Kane, etc., etc., I don't gamble, though, so no money.

23. **Peter Woit**
September 12, 2008

Thanks Ellipsis,

Your predictions look much more plausible to me than just about any others I've seen. Now, all you have to do is tell us what the 2010 Higgs mass will be….

24. **Ellipsis**
September 12, 2008

115.5 GeV

LHC Startup Tonight

September 9, 2008
Categories: Uncategorized

There's a media storm about the LHC building up as CERN makes last minute preparations to circulate a first beam in the machine. Cosmic Variance has live-blogging about this by a group of theorists, and Tommaso Dorigo will be in the CMS control room. He just might blog about this. For up-to-the-minute news, try the LHC beam commissioning site. Here's the plan for tomorrow, and the latest news: they're ready to get started at 6am tomorrow Geneva time. I'll be asleep.

Starting tomorrow, daily news reports about progress should appear here. They've got a very detailed plan for steps to go through, here's where they are now, here's where they hope to be Thursday and Friday.

Comments

1. **Kea**
   September 9, 2008

   I like how they arranged it so it was September 10 everywhere. I'm guessing the main event is scheduled for just before midnight here.

2. **Jason Starr**
   September 9, 2008

   The Boston Globe has a story today about how Frank Wilczek received death threats because of the LHC. Here is the URL,
   http://www.boston.com/news/local/breaking_news/2008/09/mit_physicist_g.html

3. **Yatima**
   September 10, 2008

   Well, this is more exciting than a Y2K upgrade of a billing system for sure. Will the threatening fantasy-literature-inspired ones realize that they have to keep the death threats coming until at least first collision (end of this year?), and possibly continuously afterwards, with exponentially decreasing threat level, then do it again when the machine is upgraded in 2010 or so?

4. **Steve Myers**
   September 10, 2008

   Read the affidavit of Luis Sancho concerning LHC dangers. It's at Harpers website.

5. **Peter Woit**
   September 10, 2008

   Everyone,

   Please, don't post anything on this blog about the supposed dangers of LHC-produced black holes. The way this issue dominates stories about the LHC is an excellent example of the sad phenomenon of attention-getting claims driving out intelligent discussion. I've heard way too much about this from too many people (including from the person discussed in the Wilczek story, who has also harassed me). Just stop, it's a waste of good brain cells.

6. **a quantum diaries survivor**
   September 10, 2008

   Peter, thank you for the link but, as you probably read already, my shift in the CMS control room got canceled late yesterday evening, because they wanted "experts" on site for each subdetector. For my own shift, which is attending the tracker, this is hilarious, since the tracker has been kept off for the entire day, given the unstable beam conditions one expects at startup.

   Sorry for the disappointment of your readers – I tried to post some useful information anyway today. Your link alone brought to my site about 500 people…

   Cheers,
   T.

   September 10, 2008

   Sorry for posting the story.

Science in the 21st Century

September 10, 2008
Categories: Uncategorized

This week the Perimeter Institute is hosting an unusual conference on Science in the 21st Century. One of the organizers is Sabine Hossenfelder, who has a posting discussing the conference here, and may have some more about it at her blog later.

Many of the talks are now available on-line here. I've only had time to watch a couple of them, but one that I found worth paying attention to was Lee Smolin's. He covered some of the same issues discussed in his book, including the question of what science is, the ethics of how it is pursued, and the difficulties of encouraging new ideas. The discussion with the audience was also quite fascinating, including an exchange about differences between the American and British academic systems, with a British participant describing his shock at seeing how much the "American academic system is a training in sycophancy".

The topic of blogs came up mainly in a section where Smolin discussed the ethical importance of scientists putting their name and reputation behind what they have to say about their science. He characterized anonymous criticism as one of the main reasons for the low signal/noise ratio and nasty environment of the comment sections of many blogs, describing this as far worse than anything he had encountered in his professional career, and something that is giving science a bad name. The theoretical physics group at Harvard in the 1970s was given as an example of about the worst it could get in academia. At the end of the discussion session, Paul Ginsparg took him to task about this, saying that he had been there too and it wasn't that bad. I was there at the same time as both of them, and remember it as a rather unfriendly environment with a quite high arrogance level. But, with faculty like Coleman, Weinberg, Glashow, and postdocs like Witten, the talent and accomplishments of the people involved seemed to justify quite a bit of arrogance.

Ginsparg went on to agree with Smolin about anonymity on blogs, comparing trying to have a serious discussion in such an environment to trying to do so in a Fellini movie, being attacked by dwarves wearing masks.

Update: One talk I highly recommend is that of Eric Weinstein, with the title Sheldon Glashow Owes me a Dollar (and 17 years of interest): What happens in the marketplace of ideas when the endless frontier meets the efficient frontier? Eric's talk includes a wide variety of thought-provoking and entertaining attempts to bring ideas from economics and finance into thinking about how science gets done and whether it can be done more efficiently.

Comments

1. **srp**
   September 10, 2008

   Smolin seems to contradict himself, since he makes a big deal about the importance of reputation and accreditation but then goes on to say that authority shouldn't matter in deciding issues. Attacks on anonymity don't sit well with a commitment to judging arguments on their merits. The real issue with reputation and authority (from a functional point of view) is the tradeoff between effective attention allocation, on the one hand, and objectivity in assessing arguments on the other.

   If we had limitless attention, then ideally arguments would be evaluated independently of who makes them, which is why many journals require double-blind anonymity. Even if we stipulated that X is an idiot and a bad person, if X's argument A is correct and novel then we gain from understanding it. Because most people have trouble being that objective, separating the argument from the X label–making it anonymously–is often a good idea.

   The countervailing values to objectivity are not wasting your time reading things which are likely to be boring or wrong, and being able to rely on others' arguments as building blocks without personally auditing them. Here, we really want to know if argument A came from X or from Y because we can never get back the time lost from reading or relying on a defective A and we'd like to play the odds based on reputation. Anonymity weakens the likelihood of our taking an argument seriously, and, if it is prevalent, makes the entire discussion less useful.

   If people want to be taken seriously, or they want their arguments to be taken seriously, I don't see that there is a problem of incentive compatibility. The maker of an argument can weigh and balance the greater objectivity with which his or her contribution will be treated if it is anonymous against the impact on how much attention is paid to it. If they make a mistake in deciding this, they bear most of the cost. The Invisisble Hand, so to speak, will take care of the problem. (Of course, this analysis appies to scientific contributions, not personal rumor-mongering where the costs and benefits are distributed very differently.)

2. **Peter Woit**
   September 10, 2008

   srp,

   There's a difference between "reputation" in the sense of knowing about someone through their work and writings, and "reputation" in the sense of knowing where they stand in the academic hierarchy. I think Smolin is not arguing that you should judge whether to pay attention to someone's arguments based on "authority", but rather on your own knowledge of the quality of their previous arguments.

3. **Tony Smith**
   September 11, 2008

   Lee Smolin said (page 11 of 51 of the pdf of his talk):
   "… without a Ph.D. from a reputable research department or group
   (or in very rare cases i.e. Freeman Dyson, the equivalent)
   someone cannot make useful contributions to a scientific community.
   Scientific communities function well only because discussions among experts are restricted to those with a Ph.D. or at least those far along in a Ph.D. program …
   this is essential and not incidental …".

   Back in the 1980s when I was beginning to formulate my physics model, I asked Yuval Neeman to discuss it with me. He agreed to meet me in his office at U. Texas Austin, and we discussed what I was doing.
   He pointed out some problems with my model as it was back then (since then I have worked through those problems)
   and I asked him about getting a Ph.D. working on the model.
   He knew that I did not need a Ph.D. for a job (my law practice gave me both reasonable income and spare time in which to work on physics), and told me (a quote to the best of my recollection):

   "If your model turns out to be right, then it is important enough that you do not need a Ph.D.
   If your model turns out to be wrong, then no matter how many Ph.D.'s you have, it will still be wrong."

Until recently, I have felt that Yuval Neeman's advice would eventually be proven correct, and that my model would be evaluated on its merits.

Now, in light of the above statement of Lee Smolin, who seems to me to be the most liberal member of the physics community with respect to unconventional ideas,
I see that Yuval Neeman's advice will never be effective,
as my model will never be evaluated by the physics community.

Tony Smith (no physics Ph.D. or "the equivalent")

4. **Mark van Akeren**
September 11, 2008

My impression is that the frustration of many (but by far not all) theoretical particle physicists over the lack of a predictive model in particle physics is getting on their nerves. That should not be the case. Physics is much too interesting for this kind of resignative attitude.
The aim of physics is to find out how the world works, not to prove that it works following certain preset mechanisms.

There are sycophants in every community, from business to politics to science, and at every level.

A colleague of mine remembers how a Nobel prize winner (now dead) once abruptly stopped to talk to him at a dinner and turned away when he suggested that time might not be continuous.

In Italy and other countries, the sycophants in the community of historical science have managed to spread the idea that Galileo (victim of an anonymous denunciation, by the way – blogs did not exist then) did not have enough arguments for his astronomical statements. Look at what they have done to one of the greatest historians that Italy has ever had, Pietro Redondi.

For the situation in Russia, read the new book from Springer Verlag which tells how in the 1970 and 1980s in Moscow, Jewish math students were given math problems that were impossible to solve correctly, in order to keep them out of university.

I wonder how Smolin and Distler get along. The British comment that the "American academic system is a training in sycophancy" might be exaggerated, but a few people at the conference do embrace that rule, such as Distler himself. (Motl at least is an entertaining sycophant, Distler is not even that…)

Sycophants are at work everywhere. One has to live with them, and find one's own way.

Mark

5. **Christine**
September 11, 2008

Children are great scientists, the best. Carl Sagan noticed that very well. But when they grow up into adults, most of them loose their once genuine curiosity to really understand how the world works. They stop doing the right questions (usually on the mark) and the instinctive use of the scientific method through testing their ideas and hypothesis against what they observe. All the naturalness of the understanding process that encompasses a genuine scientific activity is somewhat lost.

What happens during the growing process of children into adults is quite complex, but should be taken into serious consideration, because something very essential and important is lost. Is it just innocence? If so, then we should be more "innocent". We should be more uncorrupted and pure. Science should be an open activity for all, and the level of exploring it only dependent on one's technical knowledge, honesty, wisdom. The merit of one's work should be evaluated against those qualities. PhD titles should be only marks that certifies that you have those qualities and that you have made contributions to the field. But someone without a PhD should not be dismissed from the scientific endeavor.

Of course, what I see in reality is many PhDs that are a complete distortion of what a scientist should be. And conversely, I know people without a PhD that would make honest scientists.

6. **Bee**
September 11, 2008

Hi Peter,

Thanks for the link. I will write some more about the conference if I find the time. The British participant is Harry Collins, who also gave the first talk yesterday morning. It is too bad that the recording of Steve Fuller's talk failed. It was a very interesting argument about how metascientific measures such as e.g. the citation index are invasive to science. Best,

Sabine

7. **Peter Woit**
September 11, 2008

Mark,

I've never seen anything to indicate that Distler is very far from the median of the sycophancy scale of American academia.

He was trained by the Harvard theory group, a few years after the period that Smolin and I were there. As I noted before, during this period this was a group that measured high on the arrogance scale, but at a time that they had quite a lot to be justifiably arrogant about. Unfortunately being convinced that you are always right and that people who disagree with you must be stupid goes from being annoying to seriously dysfunctional when you devote yourself to a research program that turns out not to work.

I'd suspect Smolin gets along fine with Distler, since he's not known for having trouble interacting with people he disagrees with, and his training at Harvard should stand him in good stead.

8. **Gil Kalai**
September 11, 2008

The utility of blog science-discussions for promoting various aspect of science – popularization of science, explaining scientific advances to professionals, evaluating various scientific theories and claims, discussing philosophical, sociological, and ethical aspects of science, and not the least blogs as a tool to conduct scientific research, is a very interesting question.

The norms and ethics of blogs themselves is also a very interesting topic, and so is the specific issue of anonimious contributions. Of course, there is a huge data to try to evaluate the quality of blog discussions and the role of anonymous comments. (One can compare, for example, blogs which allow anonymous participation with those which do not allow it.) Overall, I tend to agree with ‘spr”s comments on this issue.

I think that the main difficulty with blog science-discussions is the quick paste and huge volume. I do not see an easy way around this difficulty.

9. **Terry Hughes**
September 11, 2008

As many readers of this blog probably know, Oded Schramm just died in a fall while climbing:

http://www.nytimes.com/2008/09/11/science/11schramm.html?_r=1&oref=slogin

Reading the report of his death I was struck by how genuine his contribution as a pure mathematician to physics really was. I was especially struck by the comparision to the bloated claims of physical relevance of Singer, Witten and the rest in connection with Yau’s birthday conference. I see no mention of string theory in connection with Schramm, for example, just illumination of “a multitude of physics problems from the percolation of water through rocks to the tangling of polymers.” Actual, testable physics, not junk food for the mind. Even Yau’s interesting and charming contribution to general relativity is rather marginal to physics in the end. I mean no criticism of Yau, Singer, Witten or anyone else as pure mathematicians, but their claims to having created methematics that has central significance to real physics seem vastly overblown. Schramm seems to have been the real thing. May God receive him in peace.

10. **Christine**
September 11, 2008

I think scientific blogs should be like a virtual place for discussions, somewhat an extension of those discussions that usually take in real life coffee breaks among colleagues, but with the advantage of storage of what have been discussed, as well as other resources, like the use of latex for formulas (of course you may have that as well in real life, like a blackboard in the coffee room). And of course, links to the relevant sources, etc.

Although storage is a very nice resource, the problem is how to make the information in a blog useful and organized. I often see Sabine and Peter repeating themselves (on their point of views) many times, although their blogs are reasonably organized.

Regarding anonymous comments, I have mixed feelings. I have received in the past useful and reasonable anonymous comments, as well as rants from them. So it is a question for the owner of the blog to have a great effort to moderate.

Evidently, in real life one will not attack people during a scientific conversation, whatever the informal level of it, except if he/she is out of his mind (at least, he/she would be considered that way by some). I’ve never seen people attacking each other in such conversations if they don’t agree about a scientific question. In blogs, human aggressiveness is free to act.

I think that blogs in their present format are not the best tool for providing an informative, educational, scientifically sound environment for discussions, although these can be carried out at a certain extent in some carefully managed blogs. A better tool for that is still missing, but what is missing mostly is honesty, empathy and collaborative posture.

11. **Christine**
September 11, 2008

Ah, and of course, people should try to increase their attention spans. Blogs tend to train you the other way around.

12. **ht**
September 11, 2008

“What happens during the growing process of children into adults is quite complex, but should be taken into serious consideration, because something very essential and important is lost.”

Money (funding), ego, and power can get in the way of doing good science. Whereas children naturally ask a lot of “why” questions out of curiosity, if a junior researcher tries to do that in a science seminar, depending on the speaker, it could be taken as a challenge to his/her authority or competence rather than a genuine desire to understand. Who wants to offend unnecessarily in an already difficult academic environment? I’ve noticed that this tends to happen less often in mathematics, probably because of the requirement to prove every result regardless of your position in the hierarchy.

13. **Gil Kalai**
September 11, 2008

Anonymity can be quite useful if you would like to explore an idea without commiting to it.

14. **Peter Woit**
September 11, 2008

Gil,

…and really annoying to the people whose time you are wasting by trying to start a discussion about something that you haven’t bothered to think through yourself…

15. **Gil Kalai**
September 11, 2008

Peter,

in my opinion, science is a lot about the ability to explore ideas without commiting to them; so not commiting to an idea does not mean you haven’t bothered to think about it.

Anyway, the issue of blogging and science/mathematics is something which I did think about quite a bit and even tried to explore in various ways (including having my own blog). I am still not sure if scientific blogging is a good idea to start with (do you?). It can be a waste of time. But I think it is an interesting enough idea for me to explore, and to spend some time on. (In any case, on my blog, people are welcomed to contribute thoughtful comments that can be anonymous.)

16. **Michael Bacon**
September 11, 2008

Gill,

Would you support a practice that you only post anonymously on your own blog — solves your problem and Peter's.

17. **Eric Habegger**
September 11, 2008

There was one key statement in Lee's talk in which he said, and I'm paraphasing, that a person should be certified in the skills as a scientist to show that his "experiments" or "calculations" should have attention paid to them. This seems applicable to the technical requirements for being a scientist, which I have no argument with. But there is a very untechnical requirement for being a GOOD scientist and that is critical thinking. The ability of seeing the forest for the trees.

I've been fairly disappointed in Lee lately. I read his book and was quite impressed with the apparent openness to new ideas and with his differentiation between technical and visual skills. I sense that he has reconsidered those ideas and now counts the technical skills as being the main thing of importance. His new stance seems to eliminate the probability of giving access to science to those with more critical thinking and visual skills. I'm really sorry to see him going in that direction.

18. **Chris W.**
September 11, 2008

Eric,

Insofar as Lee's primary concern is with theoretical physics, your emphasis on visual skills seems misplaced. Certainly a capacity for critical thinking is essential (in every field!!). But what is meant by visual skills? Visual representations—of necessity in 2 or 3 dimensions in ordinary physical space—are at best a kind of language or symbolic scheme. Admittedly they can be powerful, but they can also be profoundly misleading. They must be engaged in a dialogue with formalism; at the one throws light on the other.

A more general comment on Christine's observations: Unfortunately, the ongoing professionalization of science brings into science the small-mindedness of adult professionals protective of their turf and livelihoods and intent on building careers. Ambitious and energetic young people can be every bit as guilty of this as older scientists.

I. I. Rabi observed (in John Rigden's biography of him) that a sort of religious attitude or selflessness is essential to great scientific work—something that goes beyond simply finding science fun or rewarding in a conventional professional sense.

(See this 1999 article about Rabi by John Rigden in *Physics World*.)

19. **Eric Habegger**
September 12, 2008

Chris,
I won't go too far into this to avoid annoying Peter. Visualizations are good things, and there are also mathematical formalizations that cannot be visualized. I was speaking of visualization in terms of Lee's idea of "seers" in which one can have a holistic vision. He seems to be moving away from that idea to the idea that those kind of people must pass muster just the way an accountant must pass technical equivalency tests. The fact that those two different types of scientists could have "equal" value seems now to be abandoned by him. He seems to be saying now that those square pegs must be pounded into the round hole to have any credibility, which I don't happen to agree with. In reality no scientist is completely one or the other but are shades of both. But the current system completely capitulates to encouraging just the one side.

20. **anonymous fool**
September 12, 2008

It seems to me that most of the noise on this blog comes from non-anonymous posters, though of course it would be a bad idea to name them.

I have no idea who is srp, but his/her post is probably the most interesting on the thread.

21. **Christine**
September 12, 2008

Chris W. wrote:

"Ambitious and energetic young people can be every bit as guilty of this as older scientists."

Well, I see ambition positively if you have the right amount of it. Life is too hard; if you do not have some ambition then you are lost. In any case, I came to observe that ambition generally develops more after/during teenage years, because of competitiveness in school or based on behaviour of parents. I believe that you are referring to youngs of that age or a little above. I have the impression that this competitiveness imprint and the need to develop a high level of ambition in order to deal with it is specially true in American society.

But as far as I could observe, young children in general are not naturally ambitious, in the very strong sense above. However, I may be biased because my observation is mainly from Brazilian children.

In any case, it appears to me that kids below ~10-12 years old or so preserve the very desirable characteristics of what makes a good scientist, from the aspect of making good questions, being critical and making observations, etc. Very young kids are usually great in that respect (~5-7 years old). If you have made a outreach science presentation in class to kids at that age, you know what I mean.

22. **M. Wang**
September 12, 2008

Mark van Akeren Says:
"There are sycophants in every community, from business to politics to science, and at every level."

This is certainly true. What sets academia above all the rest in terms of sycophancy, however, is the unchecked level of arrogance and the narrow career path.

In politics, it is very hard to get truly arrogant when one has to beg and/or bargain for votes every few years. In finance, the masters of universe know in their hearts that luck plays a big element in their success because every single trade in the market reminds them of the fact. in Academia, and theoretical particle physics in particular, such reality checks are sadly lacking in recent years.

Arrogant people expect sycophancy. The single file career progression in academic disciplines then amplifies the pressure to become a sycophant by many folds.

Confucius once said, "It is shameful to be a sycophant, but doubly so to force your subordinates into sycophancy." Tenured professors will do well to keep this in mind.

Peter: You make a distinction without a difference. Regardless of whether authority is a matter of an individual's formal position or the quality of his previous arguments, the tradeoff I described still holds with respect to evaluating the NEXT argument offered. But there is more to the story if we think about the asymmetric information equilibrium.

If the argument is offered anonymously, it can be evaluated on its merits more easily but is less likely to get attention paid to it (assuming a high-authority individual). But for a low-authority individual, both incentives point in the same direction, so low-authority individuals should be more prone to adopt anonymity. Unfortunately, in equilibrium, this means that anonymous comments on average will come from lower-authority people and audiences will realize that and pay less attention to the substance of anonymous arguments. In turn, the anonymous arguer may be tempted to attract attention by being more sensational, caustic, or otherwise colorful.

I suppose these remarks apply self-referentially, as well, except that I'm not very colorful.

Anonymous fool: Thank you. I'm nobody in particular (an economist at a business school who thinks a lot about science and technology).

24. **Chris W.**
September 12, 2008

Thanks, Eric. I see what you're getting at now. I basically agree with you, although I'm not sure I would have chosen the word "holistic". Never mind that; it has often been observed about Einstein that as a young man he had an unmatched breadth as well as depth in his grasp of physics as it was known then. He truly embodied John Wheeler's injunction that a physicist should not be a specialist.

For our own time, I guess that implies that a willingness to attack deep problems may require taking greater risks of being dismissed as superficial or technically ill-equipped than in the past. In that context one could excuse Smolin for conceding that one ought to *at a minimum* secure a Ph.D. (Consider the case of Julian Barbour.)

25. **John Baez**
September 13, 2008

srp wrote:

> If we had limitless attention, then ideally arguments would be evaluated independently of who makes them…

Not clear. Our estimate of how often someone has been right is a useful piece of information in trying to guess if they're right this time. It's not obvious why we'd ever willingly give this up, except perhaps in unusual circumstances like refereeing an academic paper, which is presumably supposed to be completely lay out all the evidence for the claims it makes. Most arguments are not so fully laid out.

26. **Eric Weinstein**
September 13, 2008

Thanks Peter for the nice review. Part of the talk was actually informed by this blog; watching the reputational attacks between physics PhDs had been quite puzzling to me as a market enthusiast.

If you ever want to try to tease some of these issues out using the blog in an effort to improve the level of discourse, I'd be game to try.

Appreciatively,

Eric

27. **Carl Brannen**
September 17, 2008

Bee writes that Harry Collins is at the conference.

His book Gravity's Shadow is about the search for gravity waves but it is also a great introduction to the sociology of physics.

I think that most of the complaints about "my theory won't get a fair hearing" (because I don't have a PhD) are highly exaggerated. The professionals have the same trouble getting attention to their work. I am a very lucky amateur in that regard.

28. **De Bunker**
September 30, 2008

Having just started an anonymous physics blog…I feel compelled to react.

First, anonymity has an important place in science: that of peer review. In fact I wish peer review were double-blind, to eliminate some of the politics. I think it's totally appropriate for people to anonymously criticize each other, even in public and even on blogs.

In my experience when people first encounter the drivel that fills the comments section of any blog, they're substantially taken aback. The dynamics of anonymous conversation are different than the dynamics of face-to-face conversation. People get inflamed more easily, and are more likely to post hostile comments. They are also off-the-cuff, so one can't expect much in the way of scientific rigor, even on blogs run by scientists. (But I'm new to this game, maybe Peter feels differently)

But distaste for the different dynamics is not sufficient, in my view, to deny people the right to say what they *really* think without fear of retribution. Let's face it, young people won't criticize older more established physicists…unless they can do it anonymously. And they should still be able to get a job afterwards.

Why am I anonymous? Because I didn't want my blog to be seen as an an "official" CERN blog. I wouldn't have any problem attaching my name to the things I've written there. But then I think I may be bolder than some, and physics should able to use the work of great minds who are more timid.

29. **Eric Weinstein**
September 30, 2008

"Let's face it, young people won't criticize older more established physicists…unless they can do it anonymously. And they should still be able to get a job afterwards."

Fascinating. I had a completely different view of science in general and physics in particular. I can't fit this with what I hear of Feynman, Pauli, Yang, Schwinger, Weinberg, Dyson and others as young people. Can you elaborate?

More importantly, what do you require in terms of security that you would feel comfortable doing your job as a (non-anonymous) scientist?

30. **Peter Woit**
September 30, 2008

De Bunker,

The problem with your analogy with peer review is that

1. a referee is not anonymous to the journal editor who chose him/her. Acting unprofessionally here carries a real cost in one's reputation, since the editor knows who you are, will judge you accordingly, and may even discuss your behavior with his or her 100 closest colleagues.

2. a referee report is not a public document, findable with a Google search. If a referee chooses to say "the author is incompetent, an unpleasant asshole, and is known by his friends to have sex with barnyard animals", the only people who see this are the editor and the author. In a blog entry or comment, the whole world can see, and someone can easily find that one of the top entries on Google that appears if one searches on their name is something like this.

You might see this issue a bit differently if you were to experience the phenomenon of someone trying to destroy your professional reputation by posting on blogs things that are not true while hiding behind anonymity. Unfortunately, this is not unheard of.

I'm not an absolutist, sometimes there are good reasons for anonymity. On the whole though, it is over-used, and this does damage to the overall level of discussion on the internet. My bottom line is that I think people should be discouraged from using anonymity, but allowed to do so as long as they behave professionally. Attacking someone else unfairly in public while hiding behind anonymity is the kind of thing that I see as way out of bounds. I do my best to stop it from happening on my blog.

The use of anonymity by you and "Jester" is a bit unusual though, since I and presumably many others know who you are; you're not trying hard to hide yourselves. I actually don't believe it's possible for a scientist to write a regular blog about their field while staying completely anonymous. Scientific fields are just too small communities: if you write enough, sooner or later your colleagues will guess who you are. Anonymous comments are different, there one can hit and run…

31. **De Bunker**
September 30, 2008

> Fascinating. I had a completely different view of science in general and physics in particular. I can't fit this with what I hear of Feynman, Pauli, Yang, Schwinger, Weinberg, Dyson and others as young people. Can you elaborate?

My statement is one about humans, not about physicists in particular, and I think it's rather obvious. People do not tend to rock the boat. They do what the herd is doing, most of the time. Opposition to the herd should be possible, and should be possible by smart people who are not as outspoken as e.g. Feynman.

> On the whole though, [anonymity] is over-used, and this does damage to the overall level of discussion on the internet

It certainly does damage. People must learn to treat anonymous comments like a bathroom wall.

Sometimes, anonymity is sorely needed. When it is not needed it is difficult to see why one would want it. (Indeed, making my blog anonymous certainly was not necessary) These times are exceptional, but important. They always involve a weak person challenging a strong person.

Reputation attacks can be dealt with…most civilized societies have slander and libel laws, and these kinds of attacks existed long before the internet, and don't necessarily have anything to do with anonymity.

Don’t Buy Into the Supercollider Hype

September 13, 2008
Categories: Uncategorized

Some wag at the Wall Street Journal put the headline [Don’t Buy Into the Supercollider Hype] on today’s Op-Ed piece by Michio Kaku about the LHC, which describes its significance as follows:

> The LHC might shed light on the “theory of everything,” a single theory which can explain all fundamental forces of the universe, a theory which eluded Albert Einstein for the last 30 years of his life. This is the Holy Grail of physics. Einstein hoped it would allow us to “read the Mind of God.”
>
> Today, the leading (and only) candidate for this fabled theory of everything is called “string theory,” which is what I do for for a living. Our visible universe, according to this theory, represents only the lowest vibration of tiny vibrating strings. The LHC might find something called “sparticles,” or super particles, which represent higher vibrations of the string. If so, the LHC might even verify the existence of higher dimensions of space-time, which would truly be an earth-shaking discovery.

If I were an experimentalist or accelerator scientist working on the LHC, I might have a problem with the fact that the biggest media outlets are having theorists, often string theorists, be the ones to tell the public about the LHC (yesterday was Brian Greene’s turn, in the New York Times). Many such stories imply that the LHC will somehow tell us something about string theory, while even one of the blogosphere’s most enthusiastic string theory supporters puts the probability of this at about half of one-percent.

For some hype-free LHC predictions based on serious science that I fully endorse, see Resonaances, where the probability of seeing anything relevant to string theory isn’t even listed, and supersymmetry is given a one-tenth of one percent chance, on the grounds:

> 1% is a typical fine-tuning of susy models, and the additional factor of .1 is because it makes me puke.

which seems about right. The probability of the LHC producing black holes is given as something exponentially small, somewhat less than the probability of producing dragons.

Comments

1. **Aaron Bergman**
   September 13, 2008

   I think the reason for the op-eds is that theorists are the ones who write books and, consequently, have a higher media profile. If you’re an editor, wouldn’t you rather have an op-ed by someone the public has heard of rather than someone closer to the experiment but a total unknown?

2. **Susy Q**
   September 13, 2008

   Actually, anyone who’s really objective would asses the probability of observing supersymmetry at LHC as more like 70%. And regarding the Higgs mass, the most likely value is mH = 117 +/- 2 GeV, a result which one gets from the MSSM with radiative electroweak symmetry breaking, when combined with other experimental constraints.

3. **helvio**
   September 13, 2008

   You’re right, maybe they should have invited LQG theorists to write the op-ed’s, about the search for particles they don’t even have in their theories 😉 If evidence for extra-dimensions is found, than I see it as a full victory of string theory, not of Kaluza and Klein, or of a particular phenomenological model. The reason is that any phenomenological model with extra-dimensions imposes the additional dimensions as a working hypothesis, while in string theory it’s a consequence, an absolute necessity! Same with supersymmetry. The Higgs might be less clear that it is a direct consequence of string theory, but it’s also much less exciting theoretically as if you find evidence for the other two.

4. **joe**
   September 13, 2008

   > You’re right, maybe they should have invited LQG theorists to write the op-ed’s,

   Most definitely not. If I understood correctly, the point is that the experimentalists should be the stars here, since it’s they who are most closely related to the machine. I thought exactly the same thing yesterday when I read Greene’s article. Quite a good article, by the way, but could well have been written by Aymar, or someone else in direct contact with the LHC.

5. **joe**
   September 13, 2008

   > Similarly, once the hyperventilating critics get bored with the LHC and find something else to pounce on, science will move on to unlock the secrets of Genesis.

   Reading this final sentence of Kaku’s article, I wonder what hype we shouldn’t be buying according to him. The idea seems to be to replace all the Apocalypse crap by Genesis crap.

6. **bpz**
   September 13, 2008

   Wow, Jester just put $10000 in a bet with LM. I do admire people who are willing to put the money where their mouth is, unlike some other critics of SUSY.

7. **woit**
   September 13, 2008

   bpz,

   Betting with Lubos has its problems, including that of counterparty risk. I was tempted for a while by the idea of contacting Kane or Raby to offer a bet, but two things stopped me:

1. While I think any of the known SUSY extensions of the SM is worth betting against (because if they had anything to do with the electroweak breaking scale, we'd have seen evidence already, and the need for SUSY breaking makes the things ugly), there is some beautiful underlying mathematics, and I wouldn't want to bet against the existence of some still-uninvestigated "twisted" form of SUSY.

2. As ellipsis and others have noted, just about any experimental anomaly can be explained by invoking some SUSY model or other. I think there's a pretty high probability that at some point there will be a claim of seeing something that doesn't agree with the SM coming out of the LHC experiments. This may turn out to be something that goes away on closer investigation, or it may survive and be very interesting, but in either case we'll see all sorts of claims that this is "evidence of SUSY" and it may take a long time to sort these out.

One thing I'd be definitely willing to put some money down about would be string theory unification. But the problem with this is that it predicts nothing at all one way or another about what the LHC will see…

8. **Susy Q**
September 13, 2008

Peter,
You said, "because if they (the superpartners) had anything to do with the electroweak breaking scale, we'd have seen evidence already.."
I have to strongly disagree with this statement. Whether or not we see evidence of it or not depends on the exact masses of the superpartners, which we don't know. The only thing we do know is that they should be near the TeV scale if supersymmetry solves the hierarchy problem. It should be noted that this scale will only fully be explored by LHC, and so the superpartners should be seen there. In truth, superpartners are probably being created as we speak at the Tevatron, but not at a sufficient rate to generate a definite signal above the standard model background. On the other hand, the recent constraints on the Higgs mass being in the range 114-135 GeV strongly hint towards supersymmetry.

9. **woit**
September 13, 2008

Eric Mayes (=Susy Q = Victor),

Please stop posting the same argument using different pseudonyms, and ignoring my response. You're wasting my time.

10. **R.A.H. (anon)**
September 13, 2008

this quote is from the cosmic variance blog cited above:

Evidence for or against String Theory: 0.5%. Our current understanding of string theory doesn't tell us which LHC-accessible models are or are not compatible with the theory; it may very well be true that they all are. But sometimes a surprising experimental result will put theorists on the right track, so who knows?

So, basically, the worlds greatest high energy physics experiment has a 0.5% chance to say anything abut the "leading" high energy physics theory of everything …

Maybe more is being said (by Sean Carroll) about this ToE than he realizes. This is an unbelievable admission of failure.

11. **a quantum diaries survivor**
September 13, 2008

Aaron, what you say sucks, unfortunately it is also probably true.

Cheers,
T.

12. **nbutsomebody**
September 13, 2008

How long will it take to observe Higgs and Susy in LHC ?(in case they are at all present)

13. **woit**
September 13, 2008

Aaron and Tommaso,

I agree. The answer is for more experimentalists to start writing books.

nbutsomebody,

There should be a FAQ somewhere…

I'll recommend these predictions:

http://www.math.columbia.edu/~woit/wordpress/?p=882#comment-43559

We don't know the mass of either the Higgs or the supposed superpartners. How hard it is to recognize these things depends on their mass. Many supersymmetry enthusiasts like models where the Higgs is low mass, and hard to see (a couple years or so required), whereas some superpartners are much easier, maybe could even be seen in data collected this fall (but probably not understood until some time next year).

14. **Experimentalist**
September 13, 2008

We're too busy doing physics

15. **muxu**
September 13, 2008

> How long will it take to observe Higgs and Susy in LHC ?

From the June issue of APS Physics,

> Abraham Seiden of the University of Santa Cruz presented a timeline plotting the data to be collected at the LHC as a function of time, pointing out where key expected discoveries are most likely to be made. Potential milestones include discovery of the Higgs particle around 2009, assuming it is around 200 GeV in mass. Should the Higgs be closer to 120 GeV in mass, the chart indicates discovery around 2011, since it is harder to detect at that lower energy because it decays into a key signature involving photons that is very similar to other decay signatures.
>
> LHC data should also provide evidence for supersymmetry in 2009 if the energy scale for supersymmetry breaking turns out to be 1 TeV. Should the appropriate energy scale be 3 TeV, that discovery would more likely show up much later, around 2017. If there are extra dimensions of space, scientists might be able to detect them when energy scales reach 9 TeV in 2012. Evidence for a new type of Z\' force, assuming it exists, is unlikely to be observed until at least 2019.

16. **James Robson**
September 13, 2008

I guess this is a bit obvious: but the days of being able to do significant fundamental physics experimets in your personal lab (or shed in the garden) seem to be gone. The LHC cost bilions. So, it is not suprising that theorists were/are involved in the PR for the LHC, and are needed to be vocal to gain funding: since it's (suspected) benefits are purely theoretical.

17. **Spear Mark**
September 13, 2008

Theorists are always the publicity seekers… Rutherford actually made contributions comparable to Einstein… Rutherford might even have contributed more… transmutation of elements, the structure of the atom, the proton, the scale of nuclear energies; also founding of a school that gave Chadwick, Cockroft, Walton, etc. But Einstein ends up being the man of the century, and Rutherford is forgotten (by the public).

The truth is that experimentalists are a little suspicious still of publicity seekers. George Smoot got hammered for `the face of god', and Rubbia and Lederman long ago stopped being truly influential.

18. **Shantanu**
September 13, 2008

Peter or others, Now that LHC has started is the Tevatron still going to
continue running? Also does anyone know if people made bets about tevatron and what it would find

19. **Peter Woit**
September 14, 2008

Shantanu,

The US HEP budget situation is extremely unclear. The new fiscal year starts soon, and it may not be until half-way through it that there actually is a budget. As far as I know, plan is tor run the Tevatron through the next fiscal year, future after that depends on the budget and how the LHC does. As long as continued running makes it possible the Tevatron will see the Higgs before the LHC, I doubt it will get shut down. I don't know of any Tevatron bets.

20. **H-I-G-G-S**
September 14, 2008

Of course Kaku is full of it in claiming that the LHC will find evidence of string theory, but what is really amusing is that he gets the physics of string theory wrong. The sparticles do not arise as higher vibrational modes of the string. If they did, they would be extremely massive and the LHC would never see them. The sparticles and particles of the Standard Model all arise as the lowest modes in superstring theory. Oh, and Kaku doesn't make a living doing string theory. He makes a living writing popular science books full of wild ideas and outrageous claims.

21. **Internets Was Yes!**
September 14, 2008

Does this mean there is a small chance of the LHC producing Dragons? Won't the black holes destroy them?

22. **jpd**
September 14, 2008

that sounds like an awesome movie.

23. **saiko**
September 14, 2008

> Oh, and Kaku doesn't make a living doing string theory. He makes a living writing popular science books full of wild ideas and outrageous claims.

The guy was writing papers on string field theory already in 1974, and got several hundred citations for them. He definitely has earned the right to call himself a string theorist, and a pioneer. There's no point denying that.

But no matter what his credentials are, his predictions for the LHC are going to be as hard tested as anyone else's. We'll see…

24. **Karla**
September 14, 2008

Wouldn't we consider either supersymmetry or large extra dimensions to be supporting evidence of string theory if either of them is observed at LHC? I know they wouldn't prove string theory by themselves, but both supersymmetry and extra dimensions are central to strings.

25. **Chris W.**
September 14, 2008

The US HEP budget situation is extremely unclear.

The US *federal* budget situation isn't so clear either. Let's hope China and Japan don't call in their chips.

26. **Aaron Bergman**
September 14, 2008

Supersymmetry is important in string theory, but I'd say at this point that the connection between TeV scale supersymmetry and string theory is far from decided. Extra dimensions, on the other hand, are such a bizarre idea from a purely phenomenological standpoint, that I would consider them evidence for string theory although many extra-dimension theories these days are not obviously embeddable in string theory.

27. **Peter Woit**
September 14, 2008

Karla,

Supersymmetry and extra dimensions at the LHC scale just aren't predictions in any sense of string theory so can't provide evidence for it. If either one is discovered, it won't tell us whether string theory is right or wrong. On the other hand it will be a massive revolution in fundamental physics, with a huge amount to be studied and understood. If this happens, string theorists will try and see if string theory has anything to say about what exactly is observed and is able to make testable predictions. If they can do this, string theory will be revived, if not it will continue on its path to irrelevance.

28. **Tom W.**
September 14, 2008

Karla,

The discovery of extra dimensions would be a much bigger story itself than any confirmation of string theory . Extra dimensions would be a paradigm shift beyond even the Copernican revolution, IMO. There would be big questions opened up about
the universe ranging from the smallest to the largest scales.

So your question is ironic. But it does also hint at the extent to which the string theory people have warped the fabric of modern thought…..that is they have somehow established the "tacit" acceptance of extra dimensions as a "given" and proceeded to
build castles of sand upon that compacted nonsense.

Perhaps I'm just so old fashoned, but shouldn't we first require the
string people to prove the existence of *one* extra dimension, followed by the verification of *eleven* dimensions, before anyone
would waste time to listen to their baroque ideas about what happens in those new dimensions?

What ever happened to doing science one step at a time?

29. **Tom W.**
September 14, 2008

Peter,

Sorry my post says essentially the same thing you posted….didn't see your words until I hit submit. Anyway, thanks for your
continued important work and belated birthday wishes.

TW

30. **Haelfix**
September 14, 2008

Supersymmetry at .1% confidence is surely low. Its still the simplest and most natural solution to the hierarchy problem that we currently know off. Yes its bizarre that it hasn't already shown up (either directly or indirectly), but it still has a nice parameter space to live in, and one which still leads to a satisfying solution as well as giving a dark matter candidate.

Putting it above 50% confidence is perhaps a little optimistic (nature loves tricking us), but something like 33% is still where i'd imagine most phenomenologists/theorists would end up averaging out too.

31. **Kay zum Felde**
September 14, 2008

Hi,

yes, I think this hype could be really a problem. The successful start of the LHC has been broadcasted on 'Phoenix' (a TV broadcaster in Germany). A physicist from Bonn has been a guest in the studio of 'Phoenix'. He mentioned again, that LHC will not be able to mimic the Big Bang. However the moderator didn't ask further about this issue. What has been pointed out by the physicist was that the technology behind the LHC has been and will lead to valuable technology spin-offs. This seems to be really important.

When I talk with people about the LHC project, they are interested but often they want to know about the economic outcome of the experiments. I usually ask them, if they are not eager to know how the universe was born, or in other fundamental questions. I receive distinguished answers. I think people become somehow confused, since they obviously have other issues they are much more concerned about. No one can blame them for that, but this bothers me often. That's because I often prejudge them, since I guess financial issues are these other issues. They seem not knowing that the technology behind the LHC is almost entirely extremely challenging and new, and that the knowledge that society is gaining through such a project is worth much more valuable than the money that this project costs.

Kind regards

Kay zum Felde

32. **chris**
September 15, 2008

haelfix,

for my taste susy at 0.1% is just right. after all, it does not really solve the hierarchy problem, it merely ammeliorates it (or shift the fine tuning to other parameters as others might say).

saiko,

yes, that was in 74 and what exactly did he produce since then? i do not mean to be disrespectful, but there are a fair number of theorists even who would have much more of a standing to oped on a prestigeous journal than kaku. how about weinberg, gross or glashow? or yes, even greene for that matter, but who is kaku?

33. **Mikael**
September 15, 2008

Peter,
I think you are obsessed too much with testable predictions. Surely this is what we want from a theory of physics which we regard a success. String theory is, as I think everybody would agree, work in progress. And so the only question is whether it is promising. The problem is that the answer to this question is subjective, although not arbitrary, because any opinion on that has to be qualified.
Surely discovery of supersymmetry and even more extra dimension would let string theory look more promising than today.

34. **Chris W.**
September 15, 2008

What would constitute evidence for extra spatial dimensions, as opposed to evidence (confirmation of) a prediction of a theory that happens to incorporate extra spatial dimensions? Is there anything like an unambiguous phenomenological characterization of evidence for extra dimensions, with little or no model dependence?

It would seem that compactified extra dimensions complicate the question considerably.

35. **Peter Woit**
September 15, 2008

Mikael,

The problem with string theory is not that it doesn't make testable predictions, but that the more we learn about it, the more it becomes clear that it can't ever lead to testable predictions. If that's an "obsession with testable predictions", I guess I'm obsessed…

36. **Mikael**
September 16, 2008

Peter,
what do you think of the work of Vafa presented at string 08?
He is trying to get at some phenomenolgy.

37. **Peter Woit**
September 16, 2008

Mikael,

This is getting completely off-topic, but see

http://www.math.columbia.edu/~woit/wordpress/?p=697

38. **Coin**
September 16, 2008

What would constitute evidence for extra spatial dimensions, as opposed to evidence (confirmation of) a prediction of a theory that happens to incorporate extra spatial dimensions? Is there anything like an unambiguous phenomenological characterization of evidence for extra dimensions, with little or no model dependence?

Actually– and this is just my understanding from what I've read, so if I mess this up someone please let me know– yes:

The "mini black holes" prediction you see batted around as a long-shot possibility at the LHC is actually specifically a confirmation of "large extra dimensions". The thing is that the LHC is not, in fact, running at high enough energies to create black holes; however, if there were large extra dimensions (where "large" just means "noncompact") then there would be an effect where gravity is massively stronger over extremely short distances. This is because in a >4-dimensional universe gravity would follow not the inverse square law, but an inverse cube law or an inverse-256 law or something; however, it would also be the case that gravitons would be free to leak out into the above-4 dimensions, so past very very short distances this would smooth out into the normal inverse square law*. If this effect exists, then the difficulty of creating microscopic black holes is much lower, maybe low enough that the LHC would create them.

So if we see microscopic black holes at the LHC, then as I understand things this tells us there are extra noncompact dimensions; but it doesn't by itself tell us how many dimensions there are**, and it doesn't by itself tell us whether string theory is true. Of course since string theory provides us with a relatively rich working model of how and why our universe could be a 4D sliver in a higher-dimensional bulk, and nobody else I'm aware of in physics is predicting such a strange thing, then mini black holes would tend to be interpreted as proof of string theory.

* It isn't clear to me whether this detail– the leaky gravitons thing– is something specific to and/or required by LED string theory, or if it's just a general property of large extra dimensions scenarios.

** Although there's been at least one paper suggesting that if a mini black hole *were* seen in a particle accelerator, observations of that mini black hole and its evaporation could be used to tell you various things about the extra dimensions that allowed that black hole to form. And of course being able to take observations of an actual black hole, ever, would probably tell us about quantum gravity in a few instants than we've figured out in a century…

News From All Over

September 16, 2008
Categories: Uncategorized

There are two new particle theory blogs that I've noticed recently: Shores of the Dirac Sea, where David Berenstein and Moshe Rozali are blogging and the Physics Anti-Crackpot Blog, by an anonymous author at CERN. I don't know who this last blogger is, but he joins his (or her) colleague Jester at Resonaances (who is anonymous, but not hard to figure out) in skepticism about supersymmetry. Maybe things at CERN-TH are such that anonymity is a good idea if you hold such opinions….

Also at CERN, news of progress on the LHC commissioning is here. It seems that after some initial quick successes, there's no beam at the moment as they fix various problems with the machine.

Frank Wilczek doesn't have a blog (although his wife Betsy Devine does), but he does now have a web-site, as well as another web-site for his new book The Lightness of Being . Here's a summary of the book, and a sample chapter, which gives you an idea what he's trying to do with the book.

The IAS has started to put some lectures on-line, including the latest summer school on string theory and the memorial for Selberg.

The Harvard physics department now is running a video archive. It includes video of their recent Colloquia, Loeb lectures, and Sydney Coleman's quantum field theory course.

For the latest on INSPIRE, SCOAP^3, and potential changes in how the on-line physics literature works, see this interview with DESY's Annette Holkamp (via Travis Brooks at Symmetry Breaking).

Update: There seems to have been some sort of problem in Sector 34 triggered by powering tests for operation at 5 TeV. This caused a large helium leak in the tunnel, an investigation is under way. More here.

Update: The news from the LHC is pretty bad. A failure during a powering test will require warming up the entire sector to fix the problem, then cooling it back down. This means that it will be another two months before beam commissioning efforts can start again, likely pushing physics collisions off until next spring, after the winter shutdown. There's a press release here.

Comments

   September 16, 2008

   Gosh, those are some great resources, Peter. Thank you!

2. **Chris W.**
   September 16, 2008

   See this rather good popular exposition on the Higgs boson in Slate, by doctoral candidate James Owen Weatherall.

3. **Moshe**
   September 16, 2008

   Thanks for the link Peter.

4. **James Robson**
   September 16, 2008

   On a slightly different CERN topic, and given that I believe you have some responsibility for mantaining your department's computer network, even if the LHC produces no evidence for new physics, do you think we'll get cool new technologies in computer networking spinning off as has happened before?

5. **Peter Woit**
   September 16, 2008

   Moshe,

   Good luck with the blog, I look forward to following it.

   James,

   My great achievement in computer networking this summer was to get the university to replace the math building's 25 year-old wiring by something more modern. LHC-scale networking is something way beyond my expertise, but my understanding is that they are pushing the boundaries of some technologies. Unlikely to be a new development like the world-wide web, but maybe some new technology of wider use will come out of it.

6. **De Bunker**
   September 17, 2008

   My blog (anticrackpot) is not anti-SUSY. I'll withold my private beliefs for now… I set up the SUSY Prediction Market because of Jester's (RESONAANCES) bet (which I feel was a bad bet, not for the subject of the bet but for the terms — negligible upside and huge downside, and he's betting against the crowd which normally has a small downside and big upside). I set the SUSY market to start at 50%, and I'm barred from trading on it since I started it. The movement downward from there is not due to me. 😉

   All you out there who think you know the answer, place your bets!

   My anonymity so far has more to do with the fact that I wanted to combat "LHC disaster" nutters, and didn't want this to look like an "official" CERN publication. Also "anticrackpot" is rather confrontational. I think I will change the name if I keep blogging for long, besides I'm really burning out on combating nutters.

7. **Marcus**
   September 17, 2008

Better check spelling of the name Betsy. Thanks for the links!

8. **Peter Woit**
September 17, 2008

   Marcus,

   Thanks, fixed.

   De Bunker,

   Sorry for misrepresenting your views. I was going by a comment of yours at Resonaances that you would bet strongly against SUSY.

   An anti-crackpot campaign I fear is an endless and thankless task., Good luck with it though, someone should be doing it. I've tried to just ignore the LHC/black-hole nonsense thinking that starving it of attention is the way to go, but there do need to be some people out there dealing with it. I'll stick to complaining about creeping crackpotism in the mainstream….

   Best wishes for the blog, the more non-crackpot ones about physics the better!

9. **Aki**
September 17, 2008

   "Unlikely to be a new development like the world-wide web, but maybe some new technology of wider use will come out of it."

   Whether they find what they're looking for or not, the LHC gives a boost to Linux crusaders.

   http://blog.internetnews.com/skerner/2008/09/large-hadron-collider—powere.html

10. **All rights reversed**
September 17, 2008

    You can try to guess who Jester is by checking his reflected image off the glass CERN main entrance in the picture he took of the one and only protester during Day Zero.

11. **De Bunker**
September 17, 2008

    "I was going by a comment of yours at Resonaances that you would bet strongly against SUSY."

    Shit, you found me out. The interwebs is following me! Now if only I hadn't written all those SUSY papers…

12. **Yatima**
September 17, 2008

    > the one and only protester during Day Zero.

    Actually "first beam day", thus a no-black-holes-for-sure day. Good this is not the olde USA otherwise the protester would have come bearded & armed.

    The Economist has a review of Frank Wilczek's book, basically saying that it needs some additional editorial work. Still, I gotta check it out.

13. **James Robson**
September 19, 2008

    Well you can't build a fancy network without decent infrasrucure – or wiring – so well done!

    Incidentaly, I had a look at previous articles on this blog, and also at the comments, but couldn't find any mention of the fact that string theorists seem to have been let into the fold: no longer segregated, just part of the general physics links…

14. **Peter Woit**
September 19, 2008

    James,

    I reorganized things since there seemed to no longer be such a thing as a string theory blog. Other than Lubos, few if any string theorists seem to want to write about the subject anymore. Blogs written by string theorists these days are pretty much about anything but string theory.

15. **Moshe**
September 19, 2008

    I don't know about others, but I am sure we will have a lot of string theory content. Since I think there is a continuum between string theory and the rest of high energy physics, having one list is probably less confusing.

16. **Coin**
September 19, 2008

    This caused a large helium leak in the tunnel, an investigation is under way

    Hmm, isn't this something the detector folks would have been actually hoping for a year ago? 😛

17. **Jonathan Vos Post**
September 19, 2008

    Thank you for the hotlink to the sample chapter of Frank Wilczek 's new book The Lightness of Being. I printed it, and handed out photocopies to my 10th and 11th graders (and a few top 9th graders) to read over the weekend. Wonderful stuff!

18. **Marcus**
September 19, 2008

Wonderful stuff!
I agree with you on that. It"s a great book.

19. **a quantum diaries survivor**
September 20, 2008

Hi Coin,

the helium leak was in the tunnel, not in the beam pipe… At this point, with the detectors fully commissioned, this incident is a real curse. We were putting lots of hope in the small datasets we would collect this fall: even 5 inverse picobarns, even at 10 TeV, would still allow some important tunings and the determination of several important parameters. We would measure W,Z,top quark production, and do new physics searches. Enough to keep us busy during the winter!

Maybe the LHC is indeed cursed by backward causality, the same way two folks have claimed the SSC was killed.

Cheers,
T.

20. **outsider**
September 20, 2008

Why does CERN have this seasonal schedule? Why can't it run year round, once it's up and running? This "Fall run" is being portrayed as if it is a limited window of opportunity, but I don't understand why they can't just keep going with whatever they wanted to do later anyway.

21. **woit**
September 20, 2008

outsider,

My understanding is that CERN is committed to not operating its accelerators during the winter months because the demand they make on the power grid is so large that power needed for heating homes and businesses would not be available.

22. **Fred**
September 21, 2008

Thanks for the links, and the anti-susy movement 🙂
About the LHC crackpot someone (I don't know who?) bought a nice domain name:
hasthelhcdestroyedtheearth

23. **Coin**
September 22, 2008

Dorigo, thanks for the explanation!

By the way, a question about the LHC's winter shutdowns to save power: Is this normal, or is this just a quirk of placing one's accelerator in Switzerland? Does the Tevatron in Illinois do something similar, for example?

Far Off-topic

September 20, 2008
Categories: Uncategorized

This posting will quickly veer far off the usual topics of this blog into political issues that I normally avoid like the plague. For once, the issues involved seem important enough to interrupt your regularly-scheduled programming. I hope to not ever repeat this in future postings.

Over the last 20 years I've seen an increasingly large number of colleagues, students and friends leave academia to go to work in the financial industry. Many were hired as "quants", working on mathematically sophisticated models for valuing various financial instruments. During the same period, I've watched New York City change in dramatic ways, driven by the vast wealth flowing into the financial industry here. I've seen recent estimates that half the personal income on the island of Manhattan has been going to the 20 percent or so of the population that work in finance-related jobs. The effects of this wealth include something like a five-fold increase in apartment prices, with a modest two-bedroom apartment now selling for a million dollars. In many neighborhoods, a majority of the people on the sidewalks have a net worth above a million, and annual incomes of many hundreds of thousands of dollars. Not surprisingly, the streets are clean, buildings shiny and beautifully renovated, restaurants excellent and street crime non-existent. Banks have opened huge branches on every street corner.

For many years I couldn't figure out where all this money was coming from. When I'd ask people about this, I'd get a list of some of the things generating investment banking fees, but none of these seemed to add up to something that could provide the profits necessary to pay million-dollar bonuses to tens of thousands of people. Over the last year or so, the so-callled "credit crisis" has started to make clear what has been going on, and I (like many others, I suspect) have spent more time than is healthy following the story as it has unfolded.

It's a very complicated subject, but the most important part of it is relatively easy to understand, and there's not much disagreement about this. Starting about 10 years ago, housing prices in the United States began to increase dramatically, fed by low interest rates, and easy credit. A classic financial bubble developed as people borrowed ever-increasing amounts of money to invest in housing, sure that prices would keep going up. You can make a lot of money very fast this way. In 2006, housing prices nationwide had increased by a factor of 2.5 over the past ten years. This was the peak of the bubble and since then prices are off by 25%. They will still have to come down another 25% or so to get back to pre-bubble levels (inflation-adjusted).

The fall in prices has made a lot of housing worth less than the loans secured by it. More and more people have mortgages that cannot be refinanced and that they sometimes cannot afford, leading to foreclosure, or to a strong incentive to just leave and give the housing back to the bank. It turns out that one of the things the quants had been doing was developing pricing models for complex ways to market the risk associated with these loans. One of the sources of the huge income coming into Manhattan was the fees that this generated. The models being used turned out to be highly flawed, dramatically underestimating the fall-out from the all-too likely end to the bubble.

Since more than a couple ex-string theorists were involved in this, there's a temptation to make an analogy with the complicated failed models that they were trained in working on during their years in academia, but that would be highly unfair. Most of the flawed models were developed by people whose training had nothing to do with string theory, with the flaws coming from certain built-in assumptions. These assumptions were chosen because they allowed a lot of money to be made in the short-term, making many Manhattanites quite wealthy.

Now that the bubble has burst and it has become clear that the financial instruments created are worth far less than anyone had expected, the fundamental problem is that, absent some optimism about a turn-around in prices, it is likely that many US financial institutions are insolvent. Their assets may be worth less than their liabilities (depending on exactly how low housing prices go). As a result, their stock prices have collapsed, and no one is much interested in investing more money in them. The situation has gotten so bad in recent weeks that the normal operation of the credit markets is in danger of coming to a halt, as institutions stop trading with others out of fear that they will soon be bankrupt.

Today the Bush administration put out draft legislation to deal with the problem (see here). The solution proposed is strikingly simple: the Secretary of the Treasury will be given $700 billion to hand over to financial institutions in return for mortgage-related financial assets, as he sees fit. On news of this possibility the stocks of these institutions rose dramatically late Thursday and yesterday. Assuming that this is enough to make most of the insolvent institutions solvent again, this will allow them to return to business as usual and get the credit markets working smoothly again. If it's not enough, presumably Congress will just be asked to increase the amount.

Of course the devil is in the details, especially those concerning how Secretary Paulson will distribute the $700 billion. The plan seems to be to bring this legislation to a vote within days, unlinked to anything that would change the way the finance industry operates, or change the incentives that led to the current disaster.

Personally I think that, as economic policy, this is a really bad idea, for a host of reasons I won't go on about. But I'm no expert on these issues, so that opinion isn't worth very much and it's besides the point of this no-business-as-usual posting, which is the following:

The response to this that I have seen from Obama and the Democrats is extremely disturbing. Obama seems to be inclined to go along with this, as long as some aid to people who can't afford their mortgages is tacked on. This also appears to be the attitude of the Democratic congressional leadership, which includes senators Schumer and Clinton, acting in their roles as representatives of the largest industry in New York City. On the other hand, McCain appears to be choosing to take the populist position of ranting against Wall Street. It is now a few short weeks until the election, and I believe this will be the defining issue that decides it. If Obama and the Democrats support this bailout of the financial industry and McCain resists it in populist terms, I think we're in for four more years of irresponsible leadership. McCain has already done a good job of painting his opponent as an Eastern "elitist", and I can't believe he's too stupid to take advantage of the opportunity the Democrats will hand him if they vote for this legislation.

So, call and write your congressional representatives and the Obama campaign now.

For good sources to follow this story, there are some excellent blogs, including Calculated Risk and Naked Capitalism. This is also the kind of story on which some of the mainstream media shines, so read the New York Times, Wall Street Journal, and Financial Times.

Update: I hope Obama is reading not the Sunday New York Times which seems to indicate that this bailout of New York's main industry is essential, but Krugman's blog instead.

Update: Maybe Krugman is reading Not Even Wrong….

My reading now of what is going on is that Obama and the Democrats are starting to get a clue, based on seeing a firestorm of oppostion to the bail-out. The danger that they would go along with it seems to be receding. They can read polls too….

Comments

1. **Eli**
   September 20, 2008

   First you observe, "If Obama and the Democrats support this bailout of the financial industry and McCain resists it in populist terms, I think we're in for four more years of irresponsible leadership. " Then you suggest to lobby and support the presidential candidate and the party that just demonstrated irresponsible leadership on what you regard as the defining issue of the coming election. Where is logic?

2. **Little People**
   September 20, 2008

   Nationalizing corporative debts… where have I seen that before? This kind of scam used to be orchestrated by US corporations (and, probably, governments) in foreign countries. Now they are doing the same thing to their own people. I never thought I'd live to see this.

3. **Zeynel**
   September 20, 2008

   In one of the local newspapers here in Turkey a pandit wrote that "people who claimed that the Big Bang experiment will create a black hole that would swallow the world turned out to be right. They were only wrong in the place (or space) and the responsible parties. Big Bang did not happen in European Union's CERN but in the world's financial center Wall Street in the United States. And the people responsible for this were not physicists but bankers and institutions that evaluate credit worthiness. But as a result black holes resulting from the Big Bang happened and they swallow everything they encounter."

   I think that if the pandit I quoted knew that the bankers were using models developed by physicists he would have seen that his analogy is even better than he thinks. And isn't one of the reasons that string theory is so spectacularly popular in the academia even though it is a "complicated failed model" is because it allows physicists quick academic returns "in the short-term?"

4. **mario**
   September 20, 2008

   The banks were bailed out so that the black hole created by the Quants (not the guys at the LHC!) doesn't swallow the planet. I'd say this administration did the right thing – for once (although it was pretty much on gunpoint). Things will be bad, sure, but not nearly as horrible as they would have been.

   It is rather unfortunate that people do not understand this.

5. **Derek Teaney**
   September 20, 2008

   Dear Peter

   I enjoyed this last post quite a lot. I am not a financial
   expert either and do think that it is "Far Off-Topic"
   but I do think that it is right on topic discuss how many
   theoretical physicists have gone into the financial industry
   and the extent to which the complex financial instruments
   they have created (through confusion) the current financial
   situation. It is also should be realized that these very highly
   paid positions do not create real wealth the way that experimental
   physicists who invent the laser or invent the web do. I also
   wonder to what extent the malaise in theoretical physics,
   the general lack of funding, and lack of oppotunities in
   real industries, leads these individuals to enter the financial
   service sector.
   these individuals

6. **imho**
   September 20, 2008

   Hi Peter,

   Don't confuse the "correct policy" with the "correct politics". They are two completely different things. It is in no way clear to me, with the media screaming "the sky is falling", that McCain is in the better political position.

   Regarding the correct policy. You seem to want to punish wall street for their recklessness by letting the global financial system freeze up. That probably isn't a good idea.

7. **P**
   September 20, 2008

   I think this crisis was partially created by the government-both the Clinton and Bush administrations-pushing bankers to issue risky loans in order to promote the common good:

   http://www.openmarket.org/2008/09/19/trillion-dollar-bailout-will-lead-to-future-bubbles/?disqus_reply=2501529#comment-2501529

8. **Chuck U. Farley**
   September 20, 2008

   It's quite interesting how the Feds didn't seem to have a trillion to rebuild New Orleans but now the water is rising in Wall Street the money magically appeared over a weekend.

9. **Belizean**
   September 20, 2008

   You're right, this is a complicated issue. But it hardly makes sense to expect effective reform from the candidate who is the #2 Congressional recipient of Fannie Mae and Freddie Mac campaign contributions over the last 10 years (Democratic Sen. Chris Dodd is #1). Senator Obama achieved this dubious distinction despite only joining the Senate in 2005, well under 4 years ago. Also note that the primarily responsibility for oversight of banking operations belongs to the Congress, not the executive branch (Barney Frank, another Democrat, chairs the House Banking Committee).

   As usual, we don't get to choose between the Good and the Bad, but between the Bad the Worse.

10. **Emailc**

September 20, 2008

The Republican conservative philosophy caused this crisis. It's that simple. They deregulated the investment banks, which then naturally took extremely large risks to maximize short term profit.

Voters may not be very bright, but there's no way they are going to see McCain as being separate from the Republican party that is to blame. And McCain's support of the bail out is tearing the Republican Party apart.

So far, Obama and the Dems have been quick to place blame on McCain and the Republicans, to point out the need to help the middle class, to regulate the investment banks, and to control the size of the golden parachutes going to very bad CEOs. I think this is the correct response.

11. **Hall**
September 20, 2008

> Since more than a couple ex-string theorists were involved

I find this argument rather far fetched. I don't know how many ex string theorists work in finance. But it's pretty obvious that many more particle physicists (phenomenologists, latticists, etc) do. After the SSC collapse there were many more jobs in academia for string theorists than for particle physicists, so the latter flocked to computing and to finance.

12. **bane**
September 20, 2008

Actually, I think Peter is wrong with his remark "These assumptions were chosen because they allowed a lot of money to be made in the short-term". From what I've read, that's ascribing the results to poor motives whereas I think the quants were attempting to do their best to "remove the variance" from variable financial instruments and a fair degree of both analysis and simulation goes into verifying that these aims have been acheived in the simulated case that, eg, mortgage defaults follow a specified probability distribution. From what I understand, these tests are genuinely and stringently applied until some modification of the model passes them. The difficulty is that the tests aren't the right tests.

The problem stems from the fact that these are physicists who by the nature of the subject are very used to considering elements to be independent rather than "colluding" or "cooperating" and just didn't consider possibilities such as that almost all loans packaged in a given financial instrument might be liar loans, that every realtor would co-operate with "house price worth" inflation, that most lenders would get "spooked" at the same time, etc, etc.

So I don't think it was ill-intent so much as picking in researchers who in their previous careers never had any reason to get experience with an important aspect of the financial world. I've said in the past that I can see why finance houses would want the best people, but why it should be the best physicists rather than population biologists, epidemiologists, network researchers, etc, (who have much more experience of systems of colluding and non-independent components) never made sense to me.

13. **Cplus**
September 20, 2008

Your account of the state of play, although not inaccurate, is incomplete. For a bit more than the last 20 years, unfounded debt has been created globally in most economic zones and has been hidden in opaque government and corporate balance sheets worldwide. The housing sector in the US is only one of many manifestations of this phenomenon, although it has been the first to receive public scrutiny.
The global markets have been correcting and will most likely continue to do so until all this fictitious capital has been destroyed. Since it is hidden, probably more than the worthless paper will be incinerated in the process.
Eventually when all this has taken place, transparency will be in everyone's interest, and probably will be the way forward at that time. Until then,every effort is being made to conceal the lack of value and shift the losses to other parties. This is the function of Paulson's piecemeal proposals.
None of this is surprising. NYU's Noriel Roubini has analyzed in broad terms this entire unfolding process, by way of addition to the sound sources you cite.
Some ironies of the situation are striking. Eleven years ago, the Long Term Capital blow-up took place under the direction of a Nobel Prize winner in Economics, and John Meriwether, who subsequently started another fund which is reported in the Wall Street Journal today to be about to blow up for the second time.
This process will not be without consequences for some major US Universities which today receive more income from endowment (ie Hedge) funds than from tuition, and for public Universities as government funding and debt become more difficult to generate.

14. **Kea**
September 20, 2008

It is rather unfortunate that people do not understand this.

People understand perfectly well. The issue is how you manage the debt. Many assume that the only way to do this is throw money at the banks to buy back as much debt as possible. That's bullshit. Every new dollar that goes into the pockets of those overpaid twads is a dollar wasted.

15. **capitalistimperialistpig**
September 20, 2008

Peter,

I'm not sure I understood your final paragraphs. Are you advocating that Dems be persuaded to oppose the bailout or that we trust McCain to fix it?

I do think the bailout deserves tough scrutiny, and I think we need to insure that those who perpetrated this disaster get, at the least, a severe haircut, but I'm not sure that we can afford the alternative – an international financial meltdown.

16. **stevem**
September 20, 2008

It looks like quants, "financial engineering", and the science of "risk management" could finally lose all credibility. It's probably going to be finally seen now as modern alchemy and snake oil. But anyone really could have seen that this rediculously overblown credit and real estate bubble was going to explode. The massive bailout package has a real air of desperation about it. I've got a bad feeling about the whole thing but I guess there is no other choice. I'm reminded of Towering Inferno where Steve McQueen has to blow up the tanks at the top of the building in the hope that they release enough water to put out the raging fire that won't otherwise stop. But bailouts are part of the problem.

Exactly 10 years ago hedge fund LTCM was bailed out but that then seemed to set a trend: financial institutions and hedge funds then realised that they could borrow massive and take on monster risk/leverage and the government would bail them out if it all went totally awry, in order to safeguard the global economy and the normal functioning of the markets; the principle of too big to be allowed to fail and too connected to be allowed to fail. This has proven to be case with recent events although

Lehman was especially unlucky.

But how many hedge funds have imploded this week and how many will continue to implode, especially with the ban of short selling, and what effect this will have? The short selling ban could turn out to be a bad idea too. I'm especially interested to see how James Simons and Renaissance will come out of this. The consistency of their past performance suggests they are probably the only ones who have any real mathematical/statistical grasp of markets and their underlying dynamics. Will their strategies withstand everything?

Finally, it's worrying that neither of the candidates in the election race seem to have any real clue.

17. **nige cook**
September 20, 2008

'It turns out that one of the things the quants had been doing was developing pricing models for complex ways to market the risk associated with these loans. One of the sources of the huge income coming into Manhattan was the fees that this generated.'

It's interesting that ex-string theorists are deemed expert enough in real-world social dynamics to model credit risks. In the 90s I worked for the credit control/debt collection industry, dealing with defaulting mortgages in England near the tail-end of a recession that had begun in the early 90s. As inflation drives house prices ever higher, the average cost of mortgages gets bigger, people struggle more to pay with both partners working long hours, so any problem sends them into default.

Banks can't collect money from people who literally can't pay (back in 1997 many banks – our clients – were happy for us to accept from debtors as little as 5-10% of a mortgage in a lump sum 'final settlement' – writing off the remainder – rather than wasting time and money getting fruitless court orders for token payments that were hardly worth the effort to try to enforce).

As a result, banks increase interest rates to compensate for the money they lose in writing off uncollectable debt, and this increase in interest rates means fewer property buyers can afford mortgages, so the property market slows down. Eventually, people trying to sell property have to cut prices in order to secure a sale, so there is a slump in prices, which devalues the equity people have in their owned homes. Many people who bought property at high prices end up with 'negative equity', a home worth less than the mortgage they have outstanding to pay back.

If a bank repossesses such property (after expensive legal costs to do so), it can't recover most of the money because the property isn't worth as much as was paid for it. Property is only 'worth' what somebody else is prepared to pay for it, which is partly a psychological consideration. If you think there is a risk that the value will drop in the future, you lose confidence in buying. So it's a very complex risk analysis situation with a lot of interdependence between different factors once a recession kicks in. No matter how many credit rating checks a bank does before lending money, people will still default *en masse* if there is a major economic recession that drives prices beyond their wages or which leads to a lot of business closures and unemployment. (One suggestion I have for investors fearful of a recession is to invest in debt collection companies, which do great business and profit greatly during bad recessions. We got big bonuses in 1997!)

18. **woit**
September 20, 2008

CIP,

I'm advocating that the Democrats oppose the bailout. I believe that McCain is fundamentally another W, an irresponsible and incompetent person, and if he gets elected we're in big, big trouble. However, I suspect that he and his advisors are not so stupid that they won't see the opportunity Obama and the Democrats are putting in front of them to portray McCain as the Maverick real American determined to save people from the "elite" intent on taking all their savings and giving it to the New York bankers.

As for Paulson's claims that the financial system will melt down if Goldman Sachs, Morgan Stanley, and the banks are not bailed out, I think one should keep in mind that the guy is someone who made a better part of a billion dollars at Goldman Sachs, and so far what he has done to address the credit crisis has just continued to make things worse. A complete melt-down of some parts of the financial system such as the CDS market might actually be desirable, allowing the wreckage to be cleared and something new to be built. The plan now seems to be to keep the current dysfunctional system limping along, with new lubrication provided by the $700 billion from the taxpayers.

September 20, 2008

My understanding, far from complete, is that the so called quants saw that there were huge numbers of individuals and families who would like to own homes, but hadn't yet been able to do so. The problem in any society is that there always seems to be a fair proportion of people that, for any number of reasons, can't qualify to come up with the down payment or can't qualify for the mortgage payments. But these people would love to own homes.

What the quants did was split mortages for these non-qualifying individuals into two parts. There was a "good" part that had low risk to the lender because they were first in line to get paid if the debt holder defaulted. And the poor part of the loan was sold as sub-prime loans with high risk, but also high interest.

The reasoning went like this: As long as wall street knew the risk of each half of the loan then individuals could take the proper precautions, i.e. have only small proportions of the high risk loans. But, as is usually the case, they packaged it differently and didn't sell it has high risk. Instead they packaged the debt with less risky debt so that everyone got invested in it to pump up their interest rate and nobody realized the loans would never have been made had they not been split into a "good" half and a "bad" half.

Now the chickens have come home to roost and their is an avalanche effect that is spreading into loans that are above sub-prime as homes are put into foreclosure and prices collapse. There is a very real analogy to what has been going on in physics during this housing crisis. Though I wouldn't it put on string theorists exactly, I would say the problems in both come from too much faith in manipulating numbers to get the results you need and too little heed to fundamental, or foundational, research.

September 20, 2008

If indeed a cascading global crisis was imminent, Obama acted responsibly by not interfering with efforts to avert it. McCain banged on the operating room door and screamed at the surgeons.

At present the election looks to be close. McCain's demagoguery costs him support (votes, donations and/or advocacy) from economic conservatives and libertarians. It's not clear to me that he gains more than he loses.

September 20, 2008

Senator Bernie Sanders has a proposal:
http://www.sanders.senate.gov/news/record.cfm?id=303313

In my view, we need to go forward in addressing this financial crisis by insisting on four basic principles:

(1) The people who can best afford to pay and the people who have benefited most from Bush's economic policies are the people who should provide the funds for the bailout. It would be immoral to ask the middle class, the people whose standard of living has declined under Bush, to pay for this bailout while the rich, once again, avoid their responsibilities. Further, if the government is going to save companies from bankruptcy, the taxpayers of this country should be rewarded for assuming the risk by sharing in the gains that result from this government bailout.

Specifically, to pay for the bailout, which is estimated to cost up to $1 trillion, the government should:

a) Impose a five-year, 10 percent surtax on income over $1 million a year for couples and over $500,000 for single taxpayers. That would raise more than $300 billion in revenue;

b) Ensure that assets purchased from banks are realistically discounted so companies are not rewarded for their risky behavior and taxpayers can recover the amount they paid for them; and

c) Require that taxpayers receive equity stakes in the bailed-out companies so that the assumption of risk is rewarded when companies' stock goes up.

(2) There must be a major economic recovery package which puts Americans to work at decent wages. Among many other areas, we can create millions of jobs rebuilding our crumbling infrastructure and moving our country from fossil fuels to energy efficiency and sustainable energy. Further, we must protect working families from the difficult times they are experiencing. We must ensure that every child has health insurance and that every American has access to quality health and dental care, that families can send their children to college, that seniors are not allowed to go without heat in the winter, and that no American goes to bed hungry.

(3) Legislation must be passed which undoes the damage caused by excessive de-regulation. That means reinstalling the regulatory firewalls that were ripped down in 1999. That means re-regulating the energy markets so that we never again see the rampant speculation in oil that helped drive up prices. That means regulating or abolishing various financial instruments that have created the enormous shadow banking system that is at the heart of the collapse of AIG and the financial services meltdown.

(4) We must end the danger posed by companies that are "too big too fail," that is, companies whose failure would cause systemic harm to the U.S. economy. If a company is too big to fail, it is too big to exist. We need to determine which companies fall in this category and then break them up. Right now, for example, the Bank of America, the nation's largest depository institution, has absorbed Countrywide, the nation's largest mortgage lender, and Merrill Lynch, the nation's largest brokerage house. We should not be trying to solve the current financial crisis by creating even larger, more powerful institutions. Their failure could cause even more harm to the entire economy.

September 20, 2008

Peter and some commenters have modestly deprecated their econ credentials, but it's not scholarship that's required here. It's a commonplace that when it comes to debunking spoon benders, spiritualists, and various other fraudsters of that kind, physicists perform poorly in comparison to stage magicians, who can easily spot the deception.

In this case, the 'rescue' itself is the crime, with the politicians stampeded by the antecedent theatrics. For example, twice last week Charlie Rose had on Hank Greenberg, who built AIG and ran it for 30 years or so. He and his people had wanted to set up a bridging loan, far short of the government's $85 billion final solution, but they couldn't get a seat at the table. Charlie Rose kept saying he didn't understand why. Then Friday's hystrionics came along and cleared-up the mystery: Paulson needed a Reichstag fire to stampede the pols into the biggest raid on the U.S. Treasury in history, and AIG was it.

I trust everyone has noticed the part of the proposed plan that makes it non-reviewable by the courts? What does that tell you? I just emailed my senator and congressman, and told them to stop it. I suggest you all do the same.

24. **vespasian**
September 20, 2008

They aren't paying $700bn for nothing; provided the price is right (pennies on the dollar) this could actually make a large profit for Uncle Sam.

However the government should ensure banks are forced to hand over well performing derivatives as well as bad ones, and then regulate to just prevent these things from being created and traded. Contrary to popular opinion, the actual structure of CDOs is very simple to state mathematically – any first year undergraduate in a numerate subject could pick it up. What is genuinely difficult isn't the instrument itself but the risk modelling of it – which is true, though to a slightly lesser degree, even for simple shares and options. This is where the quants failed.

A slow liquidation of CDOs seems far more sensible than a fast panic driven one. Provided the plan commits to a selloff over a period of say, 10 years, I see no real problem with it.

That said, the deliberate lack of oversight being built in is extremely disturbing. This is the part people should be complaining about. It is scandalous that no elected official will be responsible for the management of this programme.

25. **D.**
September 20, 2008

Just to inject a professional perspective here, it's not quite right to say that "flaws coming from certain built-in assumptions" caused risk pricing error. In actual fact, total reliance upon private rating agencies, who had insufficient information to price nearly unregulated non-exchange-traded instruments, was the immediate culprit.

The underlying problem, a combination of irrational monetary policy and total lack of political will to tighten loan & credit regulation over the last 13 years, has been widely understood for a very long time, and many people are doing quite well; just look at the massive pre-collapse short interest on Lehman.

Of course, if you're sitting on a $1m Option ARM for some pasteboard monstrosity you saw on *Flip This House*, better leave the keys on the table now.

26. **Walt**
September 20, 2008

While quants I'm sure deserve some of the blame, the key failure was that the ratings agencies and banks essentially colluded to get around banking regulations. Banks need to hold investment-grade debt (such as AAA rated corporate bonds) as collateral. The ratings agencies obligingly gave certain kinds of mortgage bonds AAA ratings (the quants' inadequate risk analysis probably helped with this step). The bonds had higher returns than ordinary AAA bonds, which allowed the banks to make more money on their collateral.

Now much of the collateral isn't worth much, so the banks all have to raise more money, and some are probably already insolvent. Nobody wants to lend to the banks because nobody knows which banks are going to go under. If the victims of the crisis were just hedge funds, it wouldn't be nearly as big a deal.

27. **Eric Habegger**
September 20, 2008

"While quants I'm sure deserve some of the blame, the key failure was that the ratings agencies and banks essentially colluded to get around banking regulations."

Walt, while I think there's room for blame to go around, it was obviously the quant's who set the thing in motion and who oversold it to their employers as the best thing since sliced bread. What you're saying reminds of the pirate who says to his crew,
"Tie me to the mast before I do somethin 'orid, arrrghhhhh!"

28. **helvio**
September 21, 2008

The best introduction to the credit crisis I've heard until now is the program called "The Great Pool Of Money" presented in the radio show "This American Life" (Chicago Public Radio). It is very clear!

29. **Cplus**
September 21, 2008

It may be of help to review the state of play.
On one hand ,there is a congressional leadership of both parties which is well aware of its culpability in creating these problems over many years, and terrified of facing elections in a few weeks in the midst of crisis, and a financial leadership typified by Paulson, who helped to create the subprime debacle when CEO of Goldman, is now at risk of accountability and financial consequence, and until now has a remarkable almost 100% negative correlation with the unfolding financial realities. He appears to have contempt for the petty corruption prevalent in Washington, in comparison to the larger scale activity to which he was accustomed as an investment bank chief, and intends to bulldoze the Congress into rubberstamping another ill conceived and costly scheme. There is so much fear and weakness that his gamble may be won, but it is far from certain. If not, expect a degeneration into serious finger pointing on all sides.
On the other hand, there are the markets, which have an enormous number of degrees of freedom to come to terms with reality. There are currency markets, energy markets, grain markets, precious metal markets, short term money markets, commercial paper markets, government debt markets, corporate debt markets, municipal debt markets, interest rate swaps, mortgage debt markets, credit default swaps, and other derivatives in addition to all the markets directly related to equities. All of these have played a part in slicing through a good deal of the pretense in a little more than the past year since Paulson assured all that the problems were " well contained ". Of course their timing does not follow anyone's schedule. As Keynes, who made an enormous fortune for his college as its treasurer and knew a bit about it, put it, the markets can remain irrational longer than you can remain solvent. But eventually what has value will be valued, and what does not will not.

30. **Kea**
September 21, 2008

I suggest you all do the same.

But we're not all American.

31. **Tom K**
September 21, 2008

No, the basics is quite simple, while the details are quite complicated.

When the Greenspan era began, he changed how the fiat money system, which is used by just about all countries, worked. (The fiat money system is one which a sovereign state issue money 'out of thin air',without any material wealth backing them.) There are 3 types of money. First, the Federal government prints paper money and mint coins. Second the Federal Reserve creates money in the form of credit (i.e. debt for those who use it), which only commercial banks can use under strict regulatory control. One such key control is: a commercial bank can re-lend same amount of credit it borrowed from the Fed up to 10 times to businesses. Such 10x multiplier permits such credit to make up 95% of all money created. So far so good.

But there is a third form of money – money which the Fed does not create directly – called shadow credit. Shadow credit is created, out of thin air of course, by the shadow banking system – so-called investment banks. You know, Goldman-Sachs, Morgan Stanley, ex-Leyman Brothers, etc. They create shadow money by inventing things called derivatives and trading them. The type of derivative invented is a function of their 'innovation', how the trading work is unregulated, and the resulting financial credit generated is unlimited. It is in fact the 'perfect' money machine – private money that can be created out of thin air, outside of the government, outside of the Fed, outside of regulatory control, and which can be converted to real money (Fed credit or notes) with a click of a mouse.

When the US began to loose competitiveness around the world back 20 years ago, industries were 'forced' to outsource the industrial base in order to maintain a high profit return. While this takes care of the business side, the working people side will create trouble as good jobs disappear.

Greenspan needs to create a situation where the good life can be pumped into the economy without doing the real and smart hard work, with a downsized industrial base. He found the perfect 'free lunch' machine – unlimited money creation by the shadow banking system – to finance unlimited growth. But there is also a side beauty – details of such activities are secret, unregulated, so that very few people knows how the magic works. (Greenspan the magician knows!) So he arranged things so as to give the shadow banks a regulation-free reign – confident that the 'smartest guys in town' will know how to manage things.

Soon, investment banks realized they can do anything they want – invent any financial instruments, trade anything in any manner, brand their quality in any manner (since they control the rating agencies) and sell unlimited 'securitized' bonds to the world. The 'perfect' fake money machines was put into over-drive and trillions upon trillions of fake wealth thus created – to fund wars, security, and unlimited importation of goodies for the good life. The executives and traders pay themselves bonuses so great it make kings and queens blush with envy.

The fake-money machine works great for a decade – as long as the population can be convinced to keep on buying the fake credits (i.e. go into debt) without end. But when just about everybody is up to their eyeballs in debt, the executives at the Double-Word houses need to find ever more fools to keep the machine, thus their bonuses, running. Desperate, they turned to the poor class who has no wealth nor credit. Thus began the sub-prime mortgage con game. Bear Stearns was the one who invented the fake subprime mortgages to sell to fake buyers, collect them back in Wall Street and turn them into fake bonds to sell to unsuspecting pension funds and world banks. And the rest is recent history we all know.

Why did I bother to write this story in this blog. Because I want to point out one thing – Knowing about the real story of America's shadow banking system, whose function has been to create fake money to any amount they wish without transparency and regulation, who did operate in the most reckless of ways that resulted in destroying much of the fake wealth (along with much real wealth of the innocents), do you wish to maintain this shadow bank system?

Hank Paulson, ex-CEO of Goldman-Sachs, obvious does. He is asking the Fed to create (out of thin air of course) a trillion dollar worth of real money to buy up the fake zero-worth wreckage of the investment banks so that they can continue doing what they have done. When an addition $1T is created and added to the existing USD money supply without any corresponding economic activity, every dollar is thereby depreciated. In this way the taxpayer indirectly pays for it.

Now there's a reason why Congress might go along. See, the fake money machine also finances a great deal of politics and pork in DC.

September 21, 2008

Thus, all that money to make Manhattan a shiny bauble and give many people an Ali Baba lifestyle came from the future, in the form of the current raid on the taxpayer's pockets, augmenting the US national debt by possibly >>1 trillion or so. Nicely done.

I shudder to think what will happen to the "wonderful budget" promised for HE physics this year.

34. **Phil Warnell**
September 21, 2008

Hi Peter,

Both the strength and weakness of capitalism is that the buyer determines the value of things by what they are prepared to pay, which of course to a large degree is subjective. The problem here is when this extends to things that are necessities such as housing and food, which are not optional, things can be manipulated in this way. Perhaps it is time that in terms of economic policy there is a distinction made and that greater regulation of prices and supply in such areas should be considered to be both permanent and necessary. This of course is not true capitalism, yet when governments are forced to bail out banks and financial institutes, who are we kidding anyway.

Best,

Phil

35. **Chris Oakley**
September 21, 2008

So – we have the most right-wing government in recent US history, along with their proposed successors, advocating the biggest nationalization in history, with their left-leaning opponents, who go along with this, being chastised by a left-wing mathematics professor for not embracing the laws (and accompanying brutality) of the free market.

Or have I missed something here?

Personally, I do not see how the bail out can be avoided. The banks do not just comprise of Porsche-driving spivs earning multi-million-dollar bonuses; they also have savings of you, me and millions of others. The failure of a major bank would be a catastrophe. It may even turn out that even Lehman was too big to fail … we will see. Governments are well aware of all of this and hence the tight regulation of the financial industry. What I think recent events have demonstrated, though, is that the regulations need to be even tighter, and the "every man for himself" attitude that investment banks have needs to be replaced by something a little more responsible. We could start by looking at remuneration – if a trader is paid a percentage of gross profits as his bonus, but does not participate in losses – the usual practice – then *of course* his inclination will be to take on more risk. What is is the worst that can happen? He gets fired. No problem – he can get hired by a rival where he can do the same thing all over again. In technical terms, the trader owns a free call option on his own profitability. Many of my former trader colleagues, who are now setting up Hedge Funds, are now discovering just how nice it was when someone else (i.e. their employer) would pick up the bill for losses.

36. **Bee**
September 21, 2008

Hi Peter,

An interesting post – if you plan on writing more off-topical threads of that sort, go ahead. I too have a couple of friends who became 'quants'. Given that postdoccing sucks big time I've thought about going that same way, but it seems to be mutually incompatible with my political orientation.

Anyway, the way I see the problem is that the system (I mean the economical combined with the political) wasn't able to learn fast enough and to adapt in order to avoid a major crisis like this. Too many people doing their own planning to increase profit, too few people asking whether that's a sensible behavior in the long term. It's a classical mismatch of micro-interests with a desirable macro-behavior.

If you look at it from the system perspective, the problem is strikingly similar to those of the academic system. Too many people working for their own immediate advantage, dismissing thinking about the long-term consequences, too few people who pay attention to what science is about and under which circumstances it can flourish. It supports the formation of bubbles of nothing that eventually have to burst.

The problem in both cases is that the noticing of the mismatch between personal incentives and the desirable long-term large-scale trend does not feed back into the system – other than through a major breakdown. It's the case in which people working in the system are aware its setup does not make sense, but are unable to change something about it (and unwilling since it won't be of advantage for them either).

Best,

B.

37. **David H. Miller**
September 21, 2008

Peter,

I very seriously considered majoring in economics rather than physics, and, in fact, had an offer to do a post-doc in econ after getting my physics Ph.D. Sadly, I turned it down: I could have been one of those Wall Street gangsters making millions by defrauding the public!

Seriously, since I actually did know a good deal of economics (and since I'm honest), I would have been the naysayer pointing out the lack of reality in the models: my refusal to be a "team player" would no doubt have curtailed my career rather abruptly and I would not have made those millions anyway.

I remember some decades ago reading some stuff by Fischer Black on monetary policy and realizing that, for all his fame (this is the Black of the quants' famous Black-Scholes equation), he had almost no knowledge of real economics. That knowledge would not have endeared me to Wall Street.

Here for example is a quote from Black, courtesy of the wikipedia:
>In the U.S. economy, much of the public debt is in the form of Treasury bills. Each week, some of these bills mature, and new bills are sold. If the Federal Reserve System tries to inject money into the private sector, the private sector will simply turn around and exchange its money for Treasury bills at the next auction. If the Federal Reserve withdraws money, the private sector will allow some of its Treasury bills to mature without replacing them.

That betrays incredible, breathtaking ignorance of the monetary system, obvious to anyone who knows basic economics.

I think your own summary of the current crisis is generally accurate, but rather ignores two long-term issues.

First, there is the matter known in the literature as "moral hazard." In simple terms, bailing out bad behavior today sets a bad example for the future, encouraging people to engage in such behavior in the future, believing that they too will be bailed out.

The bailout of the S&Ls in the eighties and the implicit and widely believed (and true, through long officially denied) government guarantee of Fannie and Freddie are two examples of moral hazard that helped produce the current crisis.

Second, there is the issue of the "flexible" monetary policy followed for nearly a century by the Fed.

The Fed was created because, back in the bad old days of the gold standard, irresponsible behavior by the banks and the investment community led to repeated, sharp monetary crises that damaged the economy in general. The gold standard is inherently inflexible and there was no "lender of last resort" to bail out irresponsible financial actors.

However, exactly because of that lack of a flexible monetary regime, unsound financial practices could not be concealed for very long: crises and the resulting correction tended to be sharp, deep, but usually of fairly brief duration.

The monetary flexibility for which the Fed was created changed all that. By inflating the monetary supply ("adding liquidity to the system"), the Fed could delay the day of reckoning for some years, allowing the bubble to grow much, much bigger. And the Fed could similarly drag out the correction period for a rather long time, leading to periods such as the "stagflation" of the 1970s (the model, I'd guess, for the next ten years).

A side effect of this flexibility has been the huge inflation of the last century: from 1914, when the Fed went into operation, until 2008, the dollar has lost more than 95 percent of its value according to the Bureau of Labor Statistics (http://www.bls.gov/data/inflation_calculator.htm). By contrast, between 1800 and 1900, back in the bad old days before the Fed existed, when the monetary supply was "inelastic," the value of the dollar actually increased (see, e.g., http://www.measuringworth.org/uscpi/); the data for the nineteenth century are incidentally much rougher than for the twentieth.

All of this is old stuff, known since the early twentieth century: Friedrich Hayek won the Nobel Prize in Economics in 1974 for analyzing and explaining this in great detail (see, e.g., his "Prices and Production" and "Monetary Theory and the Trade Ccyle"), building on earlier work by Mises, Wicksell, etc.

Incidentally, I am not making any sort of claim that the Fed is some sort of secret conspiracy by the Illuminati, the Elders of Zion, or whatever. It's basic purpose and function are quite clear and have been publicly announced since it was founded. Unfortunately, carrying out that function, i.e., providing an "elastic' currency, has certain predicable results: intensifying and lengthening financial bubbles is one of those predictable results, a result that we are all observing as we write.

Despite my own lack of confidence in economic predictions, I will make one here: the monetary and financial system as we know it will not be (and for obvious political reasons cannot be) seriously reformed during the lifetime of anyone reading this. Any new regulatory agencies will simply be "captured" in a few years by the regulated industry (this too is a standard result in economics); no one who wishes to preserve his political viability will dare touch the system of "elastic" currency created early in the last century; and the bailouts, no matter how well-intentioned, will simply lay the groundwork for even greater acts of financial irresponsibility in the future.

Dave Miller in Sacramento

38. **Eric**
September 21, 2008

After the 1929 crash, we had 10 yrs of 20% unemployment because the government response was:
(1) raise taxes, particularly on the wealthy,
(2) protectionist,
(3) strong laws to favor unionism, which raised costs and according to academic research, lowered productivity, and also had the effect of preventing wages from falling to clear the labor market, and
(4) eat the rich mentality, prosecutions, etc.

Obama favors every one of those things and so do most of his backers and the interest groups pushing him.

Is it your opinion Peter, that this policy mix will work out better this time around?

39. **Peter Woit**
September 21, 2008

Eric,

You're trying to take a far off-topic discussion farther off-topic.

Please folks, take the standard right/left Democrat/Republican arguments elsewhere. If you have something interesting to contribute about the current financial crisis and the proposed bailout, please do so.

40. **Arun**
September 21, 2008

Chris Oakley finds the bailout to be inevitable.

Not so fast.

Sebastian Mallaby in the WaPo:

Within hours of the Treasury announcement Friday, economists had proposed preferable alternatives. Their core insight is that it is better to boost the banking system by increasing its capital than by reducing its loans. Given a fatter capital cushion, banks would have time to dispose of the bad loans in an orderly fashion. Taxpayers would be spared the experience of wandering into a bad-loan bazaar and being ripped off by every merchant.

Raghuram Rajan and Luigi Zingales of the University of Chicago suggest ways to force the banks to raise capital without tapping the taxpayers. First, the government should tell banks to cancel all dividend payments. Banks don't do that on their own because it would signal weakness; if everyone knows the dividend has been canceled because of a government rule, the signaling issue would be removed. Second, the government should tell all healthy banks to issue new equity. Again, banks resist doing this because they don't want to signal weakness and they don't want to dilute existing shareholders. A government order could cut through these obstacles.

Meanwhile, Charles Calomiris of Columbia University and Douglas Elmendorf of the Brookings Institution have offered versions of another idea. The government should help not by buying banks' bad loans but by buying equity stakes in the banks themselves. Whereas it's horribly complicated to value bad loans, banks have share prices you can look up in seconds, so government could inject capital into banks quickly and at a fair level. The share prices of banks that recovered would rise, compensating taxpayers for losses on their stakes in the banks that eventually went under.

Congress and the administration may not like the sound of these ideas. Taking bad loans off the shoulders of the banks seems like a merciful rescue; ordering banks to raise capital or buying equity stakes in them sounds like big-government meddling. But we are in the midst of a crisis, and it shouldn't matter how things sound. The Treasury plan outlined on Friday involves vast risks to taxpayers, huge complexity and no guarantee of success. There are better ways forward.

http://www.washingtonpost.com/wp-dyn/content/article/2008/09/20/AR2008092001059.html?hpid=opinionsbox1

41. **Thingumbob esq**
September 21, 2008

Bravo, this shows your sense extends well beyond debunking pseudo science. However, as far as your claim that you really know little about the situation, that is false modesty, I think. It is high time that the American people do a little reading about our nation's founding principles in regard to credit, etc. I urge you to read Alexander Hamilton's report on the Subject of Manufactures, ASAP.

42. **Boo Radley**
September 21, 2008

Dear Peter,

As before, I will not identify myself except for the following, which might give away my identity to those who know me.

I dabbled for sometime in string theory and am seriously dissatisfied with the subject. I have found some holes in some claims by certain string theorists which I have been prevented from publishing, and I do not have a future in academia. Consequently, I support myself and my family by taking up a job in finance.

From whatever little I know of these quant models, I would say they are seriously outdated. They need improvement, and perhaps the correction requires deep study. More than this I refuse to say.

There is a redeeming feature about the world of finance though. It is always possible that some guy like Robert Merton wins the Nobel one year, and within two years his hedge fund goes bust. However smart you think you are, you just can't beat the market.

In the world of high energy physics that does not seem to be the case. I don't see any Nobel laureate in physics biting the dust as easily, and that creates the illusion of infallibility. And any young unknown who comes along has a hard time. But all we do in physics really is glorified curve-fitting, you know. Nothing all that great.

In economics, people know very well that the prediction itself can affect the system's behavior. In that way, these people are more realistic than physicists.

Don't blame it on the quant geeks. It is blind faith in any mathematical paradigm that leads people into error. In the world of finance, there are plenty of skeptics, so it will correct itself faster. There are not enough skeptics in the world of physics, but the string bubble is also going to burst pretty soon, if it already has not.

There are some simple arguments that can kill off string theory -or at least suggest modifications to its present form – but you seem to be averse to physics discussion in the comments section here (you deleted some of my posts in the last fortnight), and seem intent to criticize string theory and also opine about quantitative finance without any real understanding of either subject. Is that fair?

Anyway, to borrow a few words from Robert Frost,
"Why hurry to tell Belshazzar
What soon enough he'll know."

Why don't you forget string theory and find something better to spend your time on? I would not say it is not even wrong. It is not the right model, and nothing will come of it. Trust an ex-"insider".

Robert Jungk once compared the lot of a physicist with that of Hamlet, so perhaps rephrasing a few lines from there would help.

There are more things on heaven and earth
Than there is in Green, Schwarz and Witten,
Or Polchinski, for that matter, or even in this blog.

Boo

43. **Andre**
September 21, 2008

As one of those who did not benefit from the various bubbles, all I want to feel is schadenfreude, baby!

But the problem is that my taxes will now go to the rescue of those who did so irresponsibly benefit from them, no matter who wins the election. I rent a crappy apartment in a crappy city, yet my dollars will now help pay for the emergency penthousing of the golden people you describe filling the sidewalks of Manhattan. People like me are left behind whoever is in power. Is it any wonder then that I will not vote for either candidate?

September 21, 2008

Bee:
"Anyway, the way I see the problem is that the system (I mean the economical combined with the political) wasn't able to learn fast enough and to adapt in order to avoid a major crisis like this."

Incorrect. Read my post. The shadow banking system is a deliberate business creation that has operated many years. The repeal of legal constraints on their operations were deliberate moves by Congress, Fed and Treasury. They wanted to free up the investment banks to create unlimited amount of money outside of the regular commercial banking system. The investment banks are completely independent, outside of the Federal Reserve system. They don't take deposits and have no insurance. They make their 'wealth' purely out of thin air, by creating financial derivatives, mostly of such complexity (thanks to the quants) that even upper execs do not fully understand the consequences. But for a decade they brought in obscene profits and that was good enough.

Chris Oakley:
"The banks do not just comprise of Porsche-driving spivs earning multi-million-dollar bonuses; they also have savings of you, me and millions of others."

Incorrect. What's being bailed out is not, *not* the commercial banks like Citi of BoA. These banks accept your deposits in saving and checking accounts, are under strict regulations, protected by the FDIC insurance, and are pretty safe. (But many smaller commercial banks are in trouble due to downturn of the housing market.) What's being bailed out is the investment banks (in truth, they are not even banks, just trader/broker). The investment banks accept no deposits from consumers. They make their money by trading other people stocks, finance business takeover, sell bonds. All these are fine. But what blew up is their derivative activities. Derivative as highly complex, high risk financial bets and insurance. They have little capital behind it (frequently, $1 of capital is used to fund up to $40 of betting). The derivatives have turned the investment banks into world's biggest gambling houses, with a total of around $100T, that's trillions, bets have been wagered on the table, but backed up only by a few hundred billions of real capital. It is easy to see how the slightest wrong moves can destroy the house. That's exactly what have happened.

Since this shadow banks are not insured by the FDIC, they have to be rescued by special acts of the government or go bankrupt.

September 21, 2008

I can say after reading these posts that most of you should stick to your day jobs. The discipline admits armchair quants just as easily as theoretical physics does. That is to say, it doesn't. So, as one former physics/math type turned quant to (I'd assume) mostly physicists, I'd caution on dimensional reductions that that boil this down to one aspect. Like many areas of specialization this takes years to learn, is rife with pitfalls, conundrums, and counter-intuitive solutions. While it has been 8 years since I studied physics, I don't pretend to be able to make sound arguments on the current state, despite the fact that I still follow it, and perhaps could still work out some problems in qft. That being said, while many can't tell you exactly what it is, I can tell you what it is not, and that it is not just because of models and opaque mathematical finance. Certainly the fall of Glass-Steagall led to tremendous securitization which facilitated unprecedented lending for reasons that were purely economic/accounting. The lending is clearly suspect, if not outright unethical or, even, criminal. These off-balance sheet transactions were bundled up and sold as MBS or in CDO's. Yes, this required modeling. There were no market observed prices for these CDOs and required complex modeling. Further, insurance wraps and arcane structuring did make these seem very safe. The massive amount of these "level 3" type assets, and their subsequent mark downs in illiquid environments whereby they could not be traded, did cause much of what we see. That being said, this is a very small part of the market, and a very small part of the theatre that "quants" work in. There are many people that get up and go to work each day and do it because they enjoy problem solving. They provide liquidity and risk management on a global scale with millions of transactions every day for decades without issue. They are not super wealthy. They are not usually poor, but they are not the 1:10,000 that the news likes to sensationalize. Quants are a small part of a big system, they often still have ties to academia, and many still publish (people who report to me still work in areas of mathematics and physics doing active research).

Before making broad brush-stroke generalizations, do your homework. I assure you it takes longer than a day, though, as this one former-physicist-turned-credit-turned-equity-derivatives-quant sees it.

46. **Arun**
September 21, 2008

That being said, this is a very small part of the market, and a very small part of the theatre that "quants" work in.

Then why cannot the market (say via a tax) bailout the "very small part of the market" that is in trouble? Why are taxpayers being asked to fork out?

47. **Quant**
September 21, 2008

Arun: I assume you were not being rhetorical? There was significant leverage, it was tied to the financial health of the larger institution, and you'll hear this word "contagion" thrown around. There is a great graph that Jim Reid at Deutsche has been showing in his research. It plots GDP, profits of non-financials, and financials. The first two basically track one another. Financials deviate in about 2000-2001 and just spread away. So, either they were printing money, or they were leveraged selling financial claims. I think the leverage works out in average to be about $1 to $2.50 according to a study I recently read (UBS, George Magnus, Financial stability) as it pertained to mortgages. There was just a ton of subprime origination and too much CDS written on it to get you AAA super senior structures, which stayed on book, and was marked down as it corrected (read: delevered=no liquidity) to put it in a nutshell. Go to bis.org and look for total outstanding notional of all derivative contracts. The total notional amount of the OTC market is probably around $650tr now.

48. **Kea**
September 21, 2008

Dear Quant. I did actually work as a quant in the fixed interest market for 18 months when I was younger, and I hated every second. It was perfectly clear to me that the whole business stank. Time to change.

49. **Arun**
September 21, 2008

Quant, while you're on – is such massive leverage necessary to the market? That is, suppose by law, the institution is limited in its leverage, say 12-1 as a strawman. Would trading in derivative securities then be viable? Attractive?

50. **Quant**
September 21, 2008

Arun, there are limits in many markets. Where things get a bit opaque are in OTC (over-the-counter) markets where there are no exchanges or clearing houses. With this would come limits, collateral, price discovery, etc. In fact, this in one of the solutions being proposed in credit derivatives (it has been for years). I should mention that, in a way, derivatives are leveraged from the perspective of having non-linear payoffs. So, not to be overly semantic, but by leverage I mean leverage of illiquid-to-liquid assets under the constraint of poor marks on the illiquid stuff leaving the firm capital starved in a correction (like we see now). Also, for instance in the case of AIG, why were they selling credit default swaps? This was indicative of people operating outside of their forte.

One odd thing that will play out this week in equity markets will be for option traders. Given that one can't take short positions, it is therefore fuzzy in a Black-Scholes theory context in that the price of an option is contingent on continuous trading in the underlying. Many people aren't even going to trade this week because of the dislocation that is ensuing from these bizarre trading rules. What is the price of an option? What is the risk neutral density?

There are many very smart and ethical people in this field, and nobody wanted this. Like any profession, physics included, there are pockets, and cliques and areas of research go in and out of vogue. I know people that hate their jobs getting beat on my traders to build trading models, I know people that are in energy that trade weather derivatives and model rocky mountain snow packs on super computers in lofts in Manhattan, I know people that were doing computational E&M and now doe the exact same thing (same pde's), but just in finance. I know number theorists who went from working on L-functions at IAS to doing the exact credit structures you are reading about. Like anything, you have good eggs and bad eggs.

51. **Chris Oakley**
September 21, 2008

Tom K,

1. Derivatives profits do not appear out of "thin air". As Gordon Gecko rightly says, it is a zero-sum game. If you make money, then your counterparty loses and vice versa.

2. Citi and BoA both have trading desks. Successful traders here will earn multi-million bonuses. I have this on good information as I worked on the interest-rate swaps desk at Citi (for all of two weeks).

3. Any institution that takes investor money is subject to regulation. That includes investment banks, but not necessarily private funds.

Quant,

Yes – in other words quants helped provide smoke and mirrors to conceal bad loans on banks' books. Credit default swaps (CDSs) helped spread the misery.

52. **Cplus**
September 21, 2008

Chris, under existing accounting rules in US and international economies, vast sums of illiquid OTC derivatives and other transactions are marked independently and creatively by the owners without recourse to market price or review by auditors or regulators to assure that counterparties to the same transaction do indeed net to zero, even in those rare instances when the counterparties are audited by the same firm or regulator.
In other words, on the balance sheets of many countries and corporations today, capital does indeed appear out of thin air.

53. **saiko**
September 21, 2008

As an ignorant physicist I understand nothing about financial instruments. However, I find even the orders of magnitude difficult to digest.

According to newspapers, the amount of money the government is going to pour into the financial sector is of the order of \$1×10^12. I guess the amount of "bad" or "toxic" debt must be larger, say \$1.5×10^12 to be conservative. Now, according to the CIA factbook, the US GDP is about \$15×10^12.

How is it even conceivable that the government did not notice a long time ago that the bottom line was wrong by at least 10% of the GDP? That's just like going into an elevator and not seeing the elephant in there. How can the Treasury and the Federal Reserve claim not to be complicit? How could the government argue that they did not see this coming long ago and didn't do anything to stop it because they actually wanted it to happen?

54. **Eric**
September 21, 2008

Saiko,

The losses are substantial, but they are not just blowing a trillion \$. It is very possible the government will make a profit on its various investments, including the various Wall Street Houses it now owns big chunks of. The RTC made a profit. There is a liquidity crisis, money is freezing up, people are being forced to dump assets, but it is far from clear what the scale of actual losses will/would be when/if all is said and done and the markets are unwound in an orderly fashion, assuming that happens.

Soryn, according to reports there were \$500 Billion in sell orders against Money Market funds prior to opening on Thursday. That constitutes a real run on the system. Action was necessary. There really wasn't time for the President to vote "Present", and we still haven't heard Obama's opinion, even on the actions from last weekend.

However, what we can definitely not afford is, going forward, to repeat the mistakes of the Hoover/FDR admins and (a) raise taxes, especially on the rich, (b) promote protectionism, and (c) promote unionism by acts like ending right to work, card check, etc. all of which are likely under an Obama administration.

55. **saiko**
September 21, 2008

> It is very possible the government will make a profit on its various investments,

I hope you're right, and for very practical reasons, not just "humanitarian" ones.

Yet, this all looks like a huge transfer of federal money to private corporations, for free. Much like the Iraq war has been.

56. **Dave Miller**

September 21, 2008

Quant,

I don't think it is reasonable for you to assume that most people here place all the blame on you quants. Since Peter's blog is largely about physics, and many of the quants came out of physics, it was reasonable for him to discuss that issue, but surely his initial post was not simply a matter of blaming the quants.

If you read my post above, you'll notice that I put the largest blame on the "moral hazard" created by past government policies and on the "elastic" monetary policies followed by the Fed, in accord with its original mandate.

Of course, if all the people in the financial industry had been perfect angels – both in intelligence and in personal responsibility – all that might not have mattered. But I take it as a given that human stupidity, greed, and dishonesty will always be with us. Government policy served as an enabler and amplifier of that dishonesty, stupidity, and greed.

You also neglect the point I made about Fischer Black: the quote I provided revealed a man whose knowledge of economics was not simply overly abstract but rather stunningly, breathtakingly wrong, rather like those who think that the secrets to physics all lie in the I Ching.

I know that Black-Scholes is not disastrously and mind-bogglingly wrong in the sense that Black's views on monetary policy were. However, the drastic over-simplifications and unrealities in Black-Scholes should be obvious enough to anyone who seriously studied economics Am I mistaken in thinking that Black-Scholes is held in rather high regard among quants?

I think that a profession, such as the quants, that is willing to take such an attitude, and that is willing to honor an obvious crack-pot like Fischer Black, does indeed deserve more than a little public ridicule.

But, yes, it is not just the fault of you quants: there is plenty of blame to go around.

Incidentally, your implication that those of us who have not worked professionally as quants, even if we have studied a great deal of economics, are not entitled to pass judgment on you guys is eerily evocative of the superstring theorists saying that no one can criticize superstring theory unless he has made significant contributions to the theory himself. It's a very old rhetorical trick: theologians and psychoanalysts have been employing it for a long time, and I'm sure it goes back to phrenologists, astrologers, and the first guy to declare himself the tribal shaman.

Dave Miller in Sacramento

57. **Chris Hillman**
September 21, 2008

Imagine you're in an elevator car. Suddenly the cable snaps and you experience the sensation of weightlessness. Since this sensation is exactly the same as you would experience in an exilarating roller-coaster ride, your natural reaction should be to merrily scream "whheeeee!!"

Not very funny perhaps, but there's a point to my sardonic jest. In recent decades— particularly the last two decades— Wall Street has managed to sell the entire world on one of the biggest lies ever told, the notion that the -appearance- of wealth is exactly the same as "genuine" wealth. Now every mathematicians loves an abstraction, but we instantly recognize— or ought to— that this is at best a local isomorphism. An elevator accident might temporarily resemble a fun-fair ride, but these two scenarios end very differently. That's one of the perennial problems with trying to "draw lessons from history"— history is told by the lucky ones. And we here will probably all agree that the problem of predicting the future from the past— particularly the problem of coping with instances of bad luck— is ultimately what this crisis is all about.

So— let the blaming begin! There's plenty to go around. And you guessed it: I intend to join the ranks of those claiming to have foreseen it all along. While not, I trust, exempting myself from my share of responsibility (in my case, I think my failure has been that I haven't been sufficiently forceful or persuasive).

Over at the New York Times, Saul Hensell (echoing Peter Voit) asks: "So where were the quants?"

http://bits.blogs.nytimes.com/2008/09/18/how-wall-streets-quants-lied-to-their-computers/?dbk

And over at The Edge, Nassim Nicholas Taleb has a timely response:

http://www.edge.org/3rd_culture/taleb08/taleb08_index.html

While I take issue with parts of his analysis, I happen to think he's spot on when he argues that the bankers and other financial managers should never have listened to the quants in the first place, because not only was their modeling suspect, the flaws were easily apparent for decades. As Taleb puts it: "the pilot did not have the qualifications to fly the plane and was using the wrong navigation tools". That reminds me of an anecdote.

As it happens, some years ago a boom time in quantitative analysis happened to coincide with a bust time in mathematics, and I was approached by several recruiters. The conversations went something like this: "Don't you want to ask what I know about finance? Because the answer is zilch." "Doesn't matter, you just need to understand the models, which are absurdly simple— this is much easier than proving theorems and the pay is much higher." "Something troubles me. We've established that -I- don't know the meaning of money, but tell me something: how do -you- define money? Risk? Probability?" (Long pause.) "You don't really want to work in the financial services sector, do you?" They got that right— criminal enterprise has never held any attraction for me.

I've been urging the mathematical elite for years to recognize the fact that over the past two decades the single biggest failure by the universities, with regard to teaching mathematics to the masses, has been failure to inculcate decision makers in all sectors with the danger of relying upon poor statistical reasoning and poor mathematical modeling. I've pointed to appalling modeling errors enshrined in federal regulation of the vast biomedical industry, warning that "faulty math/stat KILLS, and in large numbers". I've pointed to fabulous misapplications of the fearful securitization functor, and I've cried that "this will destroy the world as we know it, in your lifetime". I've asked why the Millenium Problems fail to include Kolmogorov's Last Problem: "what is probability, that we are mindful of it?" (Most of you know that as a young man, he offered an answer involving measure theory. But he wasn't satisfied with that answer and the rise of information theory apparently convinced him it was wrong; unfortunately he died before he could formulate a better answer.)

Some of you may remember that I have long urged that professional societies such as the AMS should organize a massive emergency effort to raise public awareness of the dangers of making decisions and predicting the future using bad statistics and bad mathematical models. I have suggested that our math/stat departments should require graduate students to spend at least one day per week in seminars with biomedical students, law students, and journalism students. That faculty and students should spent 20% of their time engaging in expository writing, fielding questions from reporters and advising government officials at all levels. And they should d all this gratis, as a generally recognized professional service obligation. I have argued that our scientific societies should make a much greater and much better organized effort to track and debunk junk mathematics, junk sci/stat, junk sci/math journalism, and junk sci/math testimony in the courts. Because only a genuine expert can efficiently spot and discredit potentially dangerous distortions dressed in mathematical garb. (Taleb speaks of the "snake-oil facade of knowledge— even more dangerous because of the mathematics".) For example, graduate students could begin their service not simply by running a recitation section but by patrolling the Wikipedia for malicious sign errors— yes, they exist! And professors could look for deliberate distortions of the State of the Art— yes, those exist too. And for the longer term, leading experts could organize and construct a "closed edit" wikified but refereed encyclopedia addressing, above all, the intelligent citizen. (And -edited- in the strict sense, the sense in which the Brittanica is edited; my brief foray into the utterly mad world of Wikipedia, which I soon came to regret, taught me just how essential a role is played by the organizers of any encyclopedic enterprise.)

Tim Berners Lee recently faintly echoed, I think, something else I have long been urging: debunking websites set up under the aegis of universities, which may enjoy some special if almost entirely tacit legal protections under U.S. law, and which don't mince words regarding quacks and free energy frauds. (It's neither fair nor wise that at present Bob Park http://bobpark.physics.umd.edu/ and a few others serve as solitary individual citizens playing this critical role, out of a compelling sense of duty.) I have also tried to argue that our academic philosophers constitute a valuable debunking resource, and we ought to ask them to turn their attention from comparatively trivial pursuits like debating the philosophy of space and time to such serious matters as founding the philosophy of probability, or poking holes in quantitative analysis and biostatistics.

I still think these are good ideas, and they are still worth doing, but I won't attempt to claim that they can undo the damage which has already been done. And just how bad is that damage? Right now absolutely no-one yet knows (and the reasons why no-one knows are one of the major lessons of this crisis), but last week, when allegedly stronger institutions were compelled to swallow some poison pills (failed institutions), and then gingerly began to examine what they had just acquired at the point of the federal gun, I swear I could hear the screams of incredulous dismay all the way from a small dwarf planet on the outskirts of our solar system.

And as many commentators pointed out, there is a certain illogic in "addressing" a problem created in great part by an incomprehensible tangle of business relations by creating even -more complex- corporate entities.

To my mind, one of the scariest aspects of the current financial crisis is that with news of the huge bailout, Wall Street actually -rallied-. That's scary because it proves that the majority of investors remain utterly unable to grasp the awful truth. I suspect that when the dust settles, when regulators have had a chance to examine the books and follow all the ant trails (and this discovery process will probably take two years or more), it will turn out that up to last week the world thought it was half again as wealthy as it really was— perhaps more. Prominent financial commentators mentioned successive figures of 5%, 10%, then 30% of global net wealth as having vanished last week. But of course, it was only virtual wealth. If there were any justice, disclosing that embarassing fact would be literally valuable to more than a handful of disgraced executives who are running away with a few billions in severance pay. (It's telling, I think, that this is a tiny fraction of the recent estimate of the cost of the bailout, which has surely been lowballed.)

In an interview late last week with Bill Moyers, Kevin Phillips (who predicted the recent disaster in a series of books) argued that the United States has now irretrievably squandered its -genuine- wealth (in the "real economy") and has forever lost its empire (and the good will of the world), and he pointed to the experience of the United Kingdom in the last century as a guide to what the United States can expect in the new century. I don't think it's a bad thing that as the shape of the new order becomes apparent, the U.S. will prove unable to continue to bully the rest of the world, even that it will find itself decisively removed from the front rank of the wealthy nations, but as with the UK we must expect that resentments accruing from past transgressions will linger, harmfully, for another century. As Phillips put it, the next few decades will be very tough for most Americans.

Sadly, it seems to me that it really doesn't matter who is elected President in November, because the next president will most likely prove powerless to mitigate the damage which has already occurred. Even worse, he will be distracted from addressing other long-term problems where some preventive measures might still be accomplished. This is in part because the much touted "imperial presidency" has been merely a puppet of Wall Street for quite some time— the reason why our politicians have lied even more in recent decades than they are naturally inclined to do is that cultivating ever more sweeping and intricate deceptions is regarded as absolutely neccessary to the "well-being" of Wall Street— and in part because under our Constitution, genuine reform would depend upon an ineffective political body which has been utterly corrupted by bad money, the Congress. The best one can hope for now is that your grandchildren will live in a world in which the position of the U.S. is somewhat analogous to the current position of the Netherlands or Portugal: a fairly stable second choice vacation destination which almost everyone forgets was once the master of a huge empire.

And let's not let our collective shock at the events of last week obscure the regulatory mess evident in the biomedical industry. When I examine common practices in biomedical research, I can only conclude that you could not devise a system more dangerous to human health if you tried. To repeat an example described by David Salsburg in his book The Lady Tasting Tea, decades ago some tragically deluded bureaucrat decreed that the statistical analyis in any federally funded medical research must use unbiased estimators— because, you know, bias is bad. But it should be obvious that bias (in the statistical sense) can be -beneficial- when it comes to assessing the risks versus benefits of novel medical treatments in a manner consistent with the Hippocratic Oath. And as most of you probably know, the most -reliable- statistical estimators are usually -biased-. (That's just a fact of mathematical life.) If government officals (and reporters) were better educated in statistics, I doubt that such an insane policy would have become firmly enshrined in federal regulations. And let me add that innoculating innumerate commoners against various methods for lying with statistics is not very dissimilar with teaching the warning signs of bad mathematical modeling (for example in finance). Our task is enormous, but will made easier by recognizing that as educators and expert advisors on technical matters in our fields, we really have only one problem here, not many: combating golden-tongued sellers of snake oil and exposing scientific shibboleths.

I and a handful of others have pointed for some time at an apparently growing problem whose true magnitude has gone largely unexamined, mostly because our professional societies prefer to stick their heads in the sand. (Sound familiar?) I speak of the problem of plagiarism and other serious scientific misconduct. Writers like Tom Friedman never seem to mention this when they celebrate our newly steamrolled world, but interestingly enough, certain geographical areas (China, the Indian subcontinent, and the Middle East) seem to have a particular problem with rampant misconduct and corruption. However, Europe and America are by no means immune. And if there are any mathematicians out there who are sniffing "this could never happen in my house!", I can point to specific counterexamples— but since the malefactors have proven a litigious lot, let me just say here that with a little effort you can easily find ample information about some of these outrageous incidents in the Google cache. Because the universities and professional societies have studiously avoided calls to start collecting statistics, it is difficult to test my hypothesis that these widely publicized incidents represent the tip of the iceberg, but that fact that everyone I ask seems to eventually admit personal acquaintance with a case of misconduct which was covered up, I feel that the situation appears to be rather serious.

A related problem (in my view) is the exploding phenomenon of on-line degree mills. If you think this isn't a serious problem, I suggest you (1) obtain a list of known degree mills— which already far outnumber legitimate institutions of higher education— from one of several U.S. states which offer such a list on-line and (2) search sites like LinkedIn to see who claims such degrees and where they work. Surprise! You will find acute-care nurses at "reputable" hospitals, nuclear reactor operators, miscellaneous government officials, highly placed executives in various industries, and even faculty in some "bricks and mortar" colleges (whose chairs stoutly defend their unconventional departmental hiring practices). And what position is most prominently infected with bad degrees? You guessed it— vice principal. I also noticed that ex-military are overrepresented among the ranks of those getting by on fake degrees. Could this be because they feel that our nation has taken unfair advantage of them in various ways, and they are too frustrated to be willing to contemplate taking a more traditional and honest path back into civilian life than by claiming a fake degree?

For anyone who wants to estimate the magnitude of this problem, one pitfall to avoid is the fact that many degree mills take names very similar to legitimate institutions, or even take the former name of a legitimate institution which has changed its name. And you certainly can't distinguish legitimate institutions from illegitimate ones just by glancing at their websites— many degree mills display pictures of buildings which exist somewhere, but which have no relationship to their "college", whose actual physical manifestation is generally little more than a small front office in a shopping mall, or even a mailbox in the Cocos Islands. Incidently, I think I can descry connections between the operators of many degree mills and the spam kings— certainly they often seem to hire programmers using the same pseudonyms, working from the same locations in the former Soviet Union.

These operations resemble spam in another way: it should be perfectly obvious that such deceptions harm society. These practices should not only be illegal, but should carry a heavy penalty. But in the same breath, I must confess that the degree mill phenomenon is plainly driven in part by the insane cost (to American citizens) of a college education— fixing that ought to be part and parcel of health care reform, because in today's economy, you really haven't got a chance if you lack -either- a college education or a clean bill of health. (Many other countries have fixed both problems quite nicely.) And the problem of plagiarism seems to be part and parcel of a culture of self-deception which is surely not unrelated to the coercion and corruption of essentially all our mainstream media and political institutions. And I have been saying for years that scientific misconduct is not trivial– it can kill. A concensus appears to already be emerging that the recent financial crisis is due in part to mathematical incompetency, so if we all now accept that bad mathematics can cripple the economies of formerly great nations, perhaps we will be willing to recognize that deception in all its forms is potentially dangerous— and as Taleb says, particularly when dressed up in mathematical garb, because only a competent mathematician can efficiently spot mathematical nudity.

And our genuine institutions of higher education are not immune to the culture of self-deception. Can you say "grade inflation"? Professors: hand upon your hearts, when was the last time you uncovered a case of student plagiarism and -reported it-? When I look at rate-my-professor type websites, I see a goodly number of student comments saying something like "harsh but fair". When offered the opportunity, most students seem to recognize that nothing is more unfair than to condone dishonest practices by some students. Most students, I think, wish not to cheat. So why do we place them in a situation where, many say, they feel -compelled- to cheat in order to remain competitive, because "everyone else is doing it", and getting away with it?

I would second something else Taleb says: in my experience, statisticians (whom I suspect many mathematicians tend to regard as intellectually impoverished cousins whom one is embarrassed to invite to dinner) tend to be more articulate and honest than most mathematicians (or economists) in expressing the limitations of their understanding. The statistical societies even make a half-hearted effort to provide statistical consulting to reporters— but in my view, such ventures have been far too disorganized and underfunded, and AFAIK little effort has been made to liase with the medical, journalism, or law schools— or with the math departments.

And speaking of professional responsibility: I can think of more than one profession involved in our current problems which has long needed to adopt a formal code of ethics. One aspect of the current furore which I find most unpalatable took form last week in the strained voices and pinched faces of certain leading financial commentators who desperately pleaded for bailouts for this firm or that. Am I the only one who noticed that most of these arguments were unaccompanied by disclaimers of any personal stake in the topic under discussion? In truth— this "dirty little secret" is apparently in fact rather well-known— it has been true for decades that so many "talking heads" in the economics websites are themselves investors in the companies whose causes they promote that few media outlets bother to even -try- to issue disclaimers. Well, that right there is one very obvious candidate for legislative reform: media figures should not be permitted to editorialize about corporations in which they have any personal financial stake— that's simply common sense. Since the media have devolved into mouthpieces for various megaconglomerates, it is no surprise that they have failed to regulate themselves, so government must impose and enforce regulation.

This would also be a good time for antitrust actions severing media concerns from their corporate overlords. And a good time to sever the universities (do I hear howls of rage?) from those same overlords, by prohibiting university researchers from accepting funding from corporate sources such as biomedical companies or organs of population control such as Google. Such corrosive conflicts of interest have long been a huge problem in engineering and biomedicine, but in the past decade I believe they have become a growing problem even in "pure" mathematics. Faculty with unclean hands are in no position to complain when their students misbehave— maybe that's why so many seem so reluctant to tackle the issue of student misconduct.

Another point I have pressed for years, perhaps more controversial than anything I repeated above, is that humans are obviously obsolete as the smallest recognizable economic/political decision-making agents. Jean Luminet has remarked that "physics is always near the beginning of its history", and think that's valid for science and for Terran civilization too. But in each stage of development "near the beginning", one must rely upon exponentially brighter bulbs to drive progress. Inflating human population in order to access greater and greater portions of the tail of a Gaussian is not a viable solution. For one, that policy inherently promotes enormous social injustice. For another, the Earth has simply run out of room and resources, and we'll all surely starve if we inflate human biomass another decade simply in hope of finding the next generation of hominid leaders one more half deviation out on the limb of the bell curve.

A concensus seems to have emerged in recent days that the root cause of the recent market meltdown was that no human in the world is sufficiently intelligent to understand the financial dealings that various bankers and brokers were supposedly monitoring. I think that's also a large component of the inertia of our political institutions. Sufficiently many politicians— despite owing their living to their corporate masters— may be momentarily in a mood to contemplate turning on the puppeteer, but they are too befuddled by the complexities confronting would-be reformers to have any idea where to start. I suspect we will all have ample cause in coming years to rue the fact that in this crucial election, the closest advisors of both candidates are former lobbyists for the very failed institutions everyone currently loves to hate, instead of national resources like Terry Tao. (Is it a hopeful sign that he just announced that he will be busy for a time?)

Because I think the only option which might prove rational in the long term is revolutionary and thorough reform of all our political, legal, educational, and economic institutions, reform founded upon the principle that we must be governed by the best mathematics, rather than— as become apparent to all in recent weeks— by the worst mathematics, the kind which promotes self-deception. If I profess any article of faith, I suppose it would be this: deception is an ever present danger, which always proves a harmful and destablizing influence, and deception can never be indefinitely self-sustaining. The day of reckoning always comes, and usually at the worst possible time.

Here I must admit that Wall Street is ahead of the curve— all the real decisions, it seems, are taken by stock trading software. The problem is that, as many a Vista user knows, complex software often proves unstable. Perhaps we should add another to the candidates for addition to the canon of Millenium Problems: who (or what) should make decisions (political, scientific, economic, judicial) in our global society, and how?

Chris Oakley wrote:
>Derivatives profits do not appear out of "thin air". As Gordon Gecko [sic] rightly says, it is a zero-sum game. If you make money, then your counterparty loses and vice versa.

No, Chris. Gordon Gekko is not a reliable source on economics or finance any more than Dr. Who is a reliable source on spacetime physics.

This "zero-sum" fallacy is the same mistake that people make who suppose that, since a mortgage involves a transfer of money from the mortgagor to the mortgagee, it too is a zero-sum game. In fact, both mortgagor and mortgagee gain, assuming both act intelligently: the mortgagee earns interest and the mortgagor gets to have a house he could not otherwise have acquired at that time.

Quant can probably explain this better than I, but used intelligently and responsibly, derivatives need not be a zero-sum game. There is a whole complicated literature on this, but, essentially, everyone can get the same profits with substantially less risk via intelligent use of derivatives.

The problem comes when people take naïve models of the derivative markets, and aggressively push those models to the limit at which they are almost certain to fail.

Then, we have not a "zero-sum" situation but a "negative-sum" situation in which large numbers of people will pay very dearly.

And, as I keep emphasizing in my role as almost-was/might-have-been economist, the real problem is the institutional and incentive structure that encourages and rewards those who behave irresponsibly and that enables the continuation and prolongation of bubbles.

Incidentally, that is why I turned down the post-doc in econ. Quant may well be, as he claims, a perfectly decent and honest fellow: if so, I fully believe his claims that he has not gotten rich out of his profession. I realized that, since I am an honest person, if I had pursued a career in economics or finance, I would not have been one of the high-flying, irresponsible, and therefore wonderfully remunerated stars of the field.

The financial and monetary system, at the root of which is the Federal Reserve, is structured so as to reward not people like Quant and me but rather the sort of people who created this mess.

And the system will continue to function this way no matter what cosmetic changes are made by President McCain or President Obama.

Dave Miller in Sacramento

September 21, 2008

Quant:
You have tried to defend the Quants, that they played only a minor role, that they are honorable people. Don't. The Quants did play a major role, and they did take compensations far exceeding of similar professionals in academic and industrial research. They are asked principally to come up with models to analyze derivative revenue & profitability scenarios, even develop new products, and they did perform the work. Based on these executives made their business decisions. The current derivative blow up would not have reached the depth of crisis if it weren't with the total complicity of the quants. (I was an ex-quant back in the early 90's and know quite a few quants – so try not to say I'm a crackpot. Moved back to academia and worked on string theory. Now you may say I am a bit of a crackpot!)

Chris Oakley:
"Citi and BoA both have trading desks. Successful traders here will earn multi-million bonuses. I have this on good information as I worked on the interest-rate swaps desk at Citi (for all of two weeks)."

Quite right. Citi an BoA have brokerage/trade operations, while many smaller commercial banks don't. But these, such as futures, options, certain swaps are quite well understood and 'benign'. They've been around long time and are not responsible for what blew up. Most are also regulated – lightly. But what the independent shadow banks do is the most risky and toxic kinds – credit-default swaps, auction interest rate security, and of course subprime mortgage securitization with fake credit ratings. All are highly leveraged, some even infinitely leveraged (no capital), all unregulated.

60. **chimpanzee (aka "joe")**
September 21, 2008

Kea Says:

> "It is rather unfortunate that people do not understand this."
>
> People understand perfectly well. The issue is how you manage the debt. Many assume that the only way to do this is throw money at the banks to buy back as much debt as possible. That's bullshit. Every new dollar that goes into the pockets of those overpaid twads is a dollar wasted.

I agree & agree with Peter's statement that a bailout of the irresponsible companies (taking on bad risk investments)

"The best response to a Fool, is to LET THEM HAVE WHAT THEY WANT"
— Darwin Awards, "what goes around comes around"

Essentially, the failure of said lending institutions & buyers are a consequence of Darwinism. Let them fail, they go extinct. Lesson learned, newcomers don't make the mistake, & prosper.

It's just MIND BOGGLING that the Feds come in & bail out the "deadbeats" (I know, they are just interested in a near-term "save" to prevent a collapse of an entire system). "You never give an Idiot what they want..EVER"..& the US Govt just did!! 😮

"You can't fix STUPID!"
— popular colloquial phrase in USA

US Govt is attempting just THAT. Recall the COSMOS episode, where a Landsat image of Washington DC is shown, & Carl Sagan comments "No sign of Intelligent Life".

"Suppose you were a Congressman, suppose you were an Idiot, but I REPEAT MYSELF"
— Mark Twain

I don't see anything changing since the 1800's (the time of the above comment).

All that wealth Peter is talking about is called "Stupid Money". BTW, I saw primtime evening news coverage, where they mentioned Jim Simons & how he made 2 billion off the current crisis. You can make $$ off a market downside, even! I saw a dumbed-down demo on a newscast, of "short-selling", man did that make me sick! You borrow a million shares of a stock, pay that guy (friend) a courtesy fee, wait till the stock tanks (market downside), SELL ALL OF IT (make millions), give it back to your buddy. Whoala..you're a multi-millionaire! All because of a loophole in the system. (someone correct the details, I think I got most of it right)

The paradox Peter is referring to is a consequence of a FLAW in the system. Predators were feeding off it, to "make stupid money",

"Stupid is, as STUPID DOES"

Well, there's that saying "Cheaters never prosper"..sure enough, it came back at them. And, public taxpayers money is used to bail out the con-men. DOES THAT MAKE ANY SENSE??

"Kludge [makes-no-sense bailout] upon Kludge [stupid system to begin with]"
— software hacking

We are witnessing a government version of "institutional hacking". 😮

Quant, Dave – what do you think of Nassim N Taleb? For some time he has been writing diatribes like this one:

http://www.edge.org/3rd_culture/taleb08/taleb08_index.html

His point has always been that statistical analysis gets frequently mis-applied by quants – used on economic processes that are extremely hard to model correctly. In his view this has developed into a habit of wishful thinking and arrogance. Taleb is a disgruntled quant himself.

62. **Krugman's Right**
September 21, 2008

I think Dr Woit has the right idea in this case.

I am not convinced that this will stop the inevitable downslide. The reason the models failed was a misbelief that people were rational actors. The specific flaw (not discussed below in the link) was that the models expected that people would cut other expenditures in order to keep their homes.

Unfortunately, cutting other expenditures wouldn't even be a "rational" answer for the individuals faced with losing their homes in this market.

So now its being proposed that when the government comes in to rescue these companies, the companies will behave rationally.

Are they HIGH?

I think the additional requirement is that any company taking advantage of this deal needs to go into receivership (banks included). The company should be broken up and sold as appropriate.

For more about the models see the below link:

http://www.nakedcapitalism.com/2008/06/central-banks-use-flawed-macroeconomic.html

September 21, 2008

I don't know if I can add anything productive at this point. This topic is highly polarizing, esp. when it admits political and moral stances and, speaking as a tax payer myself, is certainly upsetting. I am not defending any aspects of anything that led to this, or trying to suggest that anyone here is not entitled to an opinion, but I will offer the following: Summing it up in quick bits, like the press tends to, is a bit like writing in the margin that one has found the answer, but the margin is to small to write it out. Also, as most everyone on this forum knows first hand, the solution always appears simple once you are told it. Additionally, saying any one member (save for executives, perhaps) are to blame is a gross generalization, akin to saying that all physicists are mass murderers because they invented the bomb. There is a quote, which I will mangle, and I can't recall with whom to attribute it to, but it says something like absolute black-and-white stances are for children and psychopaths. So, in sum, it is very easy after the fact to take a moral high ground, generalize, and make judgement calls because it puts it in a nice conceptual framework with which to throw stones. Tens of thousands of people, that have families, are out of work. Many are quants, lawyers, economists, traders, …. The bailout is not so much meant to save the banks or the executives, but the retirements and investments of Americans.

I am sure that everyone on this forum has above average intelligence(s) and has the ability to delve deep into this matter, should they choose, and assign blame ex post. My initial post was only meant to add some healthy and constructive balance from, what I would hope, is an informed perspective. In the end, as painful as this is going to be, it is actually progress, albeit by violent correction, not growth. Many of us for years sensed this needed to happen. But, much like a complex system, it is very hard to disentangle the individual parts from the ensemble when trying to see where the issues are and describe the system.

Milkshake: Nassim is an interesting one. I have met him, gone to dinner with him, and read his books. I am tempted to say he has found a niche (much like, say Kaku) whereby he can publish outside the rigor of peer review. I'd call his work observations rather than developed ideas. His Empirica blew up because he ran short positions waiting for his swan but bled out before any such large payoff. He generally has issues with his peers. I'd say he is a bit like Wolfram is to science (if that makes sense?), but a bit more accusatory towards others.

Regarding Black. I don't know if he is a crackpot. He was clearly intelligent, albeit a flawed man (who isn't?). I have read Mehrling's bio (and discussed it with him and Taleb at the same table, oddly enough). He wasn't very charismatic. Of course he has one more Nobel Memorial than I do, so I can't really comment about his intelligence 😉 Black Scholes is a theoretical construct intended to get one the price of an option. It was actually around for 100 years before Black, but nobody had made certain assumptions that permitted its solution. Black himself, just afterwards, is quoted as asking why anyone uses the silly theory. Of course after the rate rise of the 80's, the advent of rate options, and the emergence of quunts from physics, they loved to talk about how it is reall ythe heat equaton and how the Laplace-Beltrami operator is really the generator for Brownian motion….. my point being that physicists took to the theory because it was stimulating intellectually. Of course finance has no symmetries and conservation laws, unless you try to shoehorn the math in (which has been done). I have met Myron Scholes, and I felt he wasn't too imposing, but I have been present when someone tried to publicly take Merton to task and Merton eviscerated them. Again, simple in retrospect, but at the time, in the details, nothing seemed to amiss.

I am going to go back and lurk in the shadows of this blog. I don't read many blogs, but this is one of my regular physics/math stops for information and ideas. Maybe one day I'll return to physics and post here again!

As of tonight, the Investment Banks are no more. The Federal Reserve has just baptized them as bank holding companies, joining the company of the other saved financial institutions masquerading as banks.

66. **JC**
September 21, 2008

Nassim Taleb would be more readable if his writings were a lot less angry and/or less confrontational sounding. Though I can see easily as to why a lot of pessimists and curmudgeons genuinely enjoy his writings.

Despite the negative tone of Taleb's writings, his "war stories" on Wall St. do have some credibility. This is judging from the time I worked on Wall St. many years ago.

Bee said:

> If you look at it from the system perspective, the problem is strikingly similar to those of the academic system. Too many people working for their own

immediate advantage, dismissing thinking about the long-term consequences, too few people who pay attention to what science is about and under which circumstances it can flourish. It supports the formation of bubbles of nothing that eventually have to burst.

My Caltech CS prof friend phrases is as:

"People behaving in their own self-interest"

Acknowledge it as a necessary evil..as abhorrent as that is. Why good papers get rejected, bad papers get accepted, good people don't get hired, bad people get hired, good money gets wasted, bad money gets used, etc.

Here is a particle-physics related poem that seems relevant:

Of the Nature and State of Man, With Respect to the Universe
Alexander Pope

> Who sees with equal eye, as God of all,
> A hero perish or a sparrow fall,
> Atoms or systems into ruin hurl'd,
> And now a bubble burst, and now a world.

I got my 1st exposure to the above in a Hawaii Five-O episode

Quant wrote:
> Regarding Black. I don't know if he is a crackpot. He was clearly intelligent, albeit a flawed man (who isn't?). I have read Mehrling's bio (and discussed it with him and Taleb at the same table, oddly enough). He wasn't very charismatic. Of course he has one more Nobel Memorial than I do…

Actually, Quant, Black does not have one more Nobel than you. He did not receive the Prize. And, no, from what I have read of his stuff, I doubt that he was intelligent, and I very much doubt that you could make that judgment from a brief interaction with him.

What does concern me is that you are a professional in the field and you cannot see how horribly wrong the quote from Black, which I previously posted, is. Anyone who has passed a first-year macro course should be able to write an essay pointing out one fallacy after another in the Black quote. His description of what happens when the Fed creates new money is simply, factually wrong.

For example, the new money may not just go back to buying Treasury paper – the new money might, for instance, go into buying shady mortgage-backed securities, just to use an example of current high relevancy. And even if it does go to buy Treasury paper, that simply means it is displacing some other buyers that are now free to buy, say, shady mortgage-backed securities. And, the money used to buy Treasury securities does not simply disappear – the Treasury is not known for simply destroying money. Rather, the Treasury spends it, thereby spreading the new money through the economy and increasing stimulative pressures. As the new money sloshes around the economy, it is available to buy, say, shady mortgage-backed security.

Anyone who knows basic macro could write a lengthy essay along these lines pointing out the level of economic illiteracy required to make a statement such as Black's. Unfortunately, this is not just an isolated example: I've seen a great deal of nonsense from him.

I have read enough of Black's stuff to know that he honestly, sincerely lacked the intelligence to grasp any of this.

The real problem is not that there is one crack-pot in your field but that this economic illiterate is so honored by your profession. That indicates a larger, profession-wide problem.

This would be like a physicist taking seriously the claims of the various use-vacuum-energy-to-solve-the-energy-shortage scams. Any physicist who supports those scams proves that he is incompetent or dishonest.

Fortunately, most physicists don't support or admire those scams. I wish the same could be said for people in the finance field who are unable to see what was wrong with the views and claims of Fischer Black.

A field which honors a crackpot like that is a field which was heading for certain disaster. Yes, as I said before, we all know that this mess is not due solely to you quants. But, yes, many of you played a role and it appears to be because of a deep and pervasive problem in your profession: to put it bluntly, you guys have been playing multi-trillion dollar games with the world economy while remaining almost entirely ignorant of elementary principles of economics.

The results are not surprising.

I know it is considered rude and socially inappropriate to point out that a whole profession seems to be lacking in basic competence, but considering the situation the world economy is currently in, perhaps a bit of blunt honesty is more than overdue.

Dave Miller in Sacramento

69. **AngryPhysicist**
September 22, 2008

Hmm…well, there are two outcomes to this current situation we face: 1) we're doomed, 2) we're not. Either way, it doesn't really matter…if we're doomed, there's nothing we can do! We're doomed! On the other hand, if we're not doomed, then it doesn't matter! We're not doomed!

Interestingly, economists know only how to *break* the economy, they don't know a single thing about how it *works*. There's a number of serious methodological problems they have, and a number of serious (tragicomical) mathematical errors they commit…no, mathematical *sins*. (An infinitesimal isn't zero!)

A rather readable dissection of economics is perhaps preferred to me maundering on and on, so please be referred to Steve Keen's "Debunking Economics". It's a fun read.

Good luck surviving economic Armageddon… 😉

I don't get it. What makes people so sure that playing the populist card will do McC any good? Everyone with a retirement account will tell him to take his populism and stick it. And if Obama tries to follow him in such a blatantly cynical way, how many votes will that win him?

72. **Bee**
September 22, 2008

Tom K: I don't see how what you explained is in disagreement with what I wrote. You might call me naive but I believe that in the long run reason would have prevailed. The dangers could have been closer investigated, regulations could have been put into place etc. In fact, what's happening right now is that necessary learning process taking place, just that a major crisis was necessary to draw attention to the shortcomings.

Chimpanzee: *Acknowledge it as a necessary evil..as abhorrent as that is*. Oh, I do. The problem is not that people behave according to their self-interests, it's human nature. The problem is if the system is set up such that the self-interests don't match with a desirable long-term trend, as e.g. is the case in anarchy or free capitalizm. We have means to match both – the political system is meant to do that. Just that it typically operates way too slow to keep up with much faster trends caused by a large number of actors driven by self-interest and irrationality.

September 22, 2008

Respectfuly, the Quants really didn't have much of a role in the securitization of credit derivatives, which is what the current situation is about.

The Quants have played a large role in the construction of arbitrage strategies, some of which involved credit derivatives, but that market has been quite small for some time.

(As an aside, the idea that repealing Glass-Steagal had anything to do with this is bizarre. The banks that have had trouble (Lehman, Morgan Stanley, etc.) are the ones that were NOT associated with depository institutions, consistent with the rule when Glass-Steagal was in effect.)

The current plea for "regulation, regulation, regulation" is really not helpful, since no-one has a plan for _how_ to regulate this credit market, or _what_ regulations to put into place.

In addition, the new populist push to limit bank _executive_ compensation completely misses the point. It really doesn't matter (or make any sense) what the bank executives are making, when the people who were making the relevant decisions were 25 year old middle managers with multi-million-dollar annual bonuses.

Peter, if you actually are interested in any of this, please feel free to e-mail me. This is what I do for a living.

75. **Michael Bacon**
September 22, 2008

At the risk of over-simplifying this, I think that the basic problem is leverage, and this should be the focus of further regulation. There should be a reduction in amount of leverage allowed. In order to play, there should be a requirement to have more skin in the game. This would work wonders in terms of reducing the number of bad bets. Would it decrease upside potential — yes, by definition it would. However, that's a trade that's worth making in order to provide more stability and certainty in the markets going forward.

September 22, 2008

In a comment above, Arun posted a link to The Subprime Primer.

In light of some things that happened since February 2008, when The Subprime Primer appeared on google,

I added an alternate ending and put it on the web at
tony5m17h.net/SubprimeShanghai.pdf
and
tony5m17h.net/Subprime5hanghai.mov

The first is a 3.4 MB pdf file and the second is a 1.9 MB mov file.

The post-February 2008 events were:

1 – A 23 March 2008 New York Time web article by Nelson D. Schwartz and Julie Creswell said, about Credit Default Swap Derivatives:
"… Today, the outstanding value of the swaps stands at more than $45.5 trillion,
up from $900 billion in 2001. …".

2 – Joseph Coleman, in a 6 June 2008 AP news article about an International Energy Agency (IEA) report, said:
"…The world needs to invest $45 trillion in energy
in coming decades, build some 1,400 nuclear
power plants … in order to halve greenhouse gas emissions by 2050 ….".

3 – A Reuters web article on 17 Sep 2008 said:
"… the world must consider building a financial order no longer dependent on the United States, a leading Chinese state newspaper said …".

September 22, 2008

I am a CDO quant. I was somewhat surprised to see that Peter actually got the economic phenomenology better than a lot of others — low interest rates spurring a classical credit bubble that is now bursting.

However, it is wrong-headed to blame quants or anyone else in the industry for building the technology (CDS, ABS, CDOs) that played a role in distributing this bubbling credit into the wider economy. One might just as well blame the internet for making it easier to shop for mortgages, or blame auto-makers for making it possible to commute to work from more distant neighborhoods. All of this is just technology created to help satisfy a demand for credit.

Why was this demand not brought into line with the actual supply (real savings)? What normally keeps demand in line with supply? A price, set on a free market where buyers and sellers equilibrate. But the price of credit, encoded in interest rates, is not set on a free market. It is set by the arbitrary dictate of a board of bureaucrats (the Fed) with analytical pretensions. When you throw darts to set perhaps the single most important price in the entire economy — a price that should have been the result of millions of savers and borrowers coming together in the market — expect bad things to happen.

There is an additional confusion about what credit-related models actually do. They do not generally attempt to predict the overall credit condition of the economy. All these mortgage securitizations were not based on *projections* made by fancy models. The credit macro-state of the economy is actually reflected in the market prices of various traded indices (e.g. CDX, iTraxx). These market prices are *inputs* to the models. The primary function of the models is to translate these prices into valuations for related but non-standard securities (and to determine how to hedge them with the standard ones). This is a second-order kind of effect. But the problems in the credit world were already present at first order, i.e. already reflected in prices of the traded indices.

One caveat to this is the models used by the credit rating agencies themselves. *These* models are the kind that try to predict the global credit state from historical data. And that is why they are not used by people who actually make money, people who of necessity tend to have fewer pretensions about what they know and what they don't know. Incidentally, the ratings agencies are creatures of government, holding what is in effect a legally enforced oligopoly in the ratings business.

80. **Michael Bacon**
September 22, 2008

"Leverage had nothing to do with this. The banks are not in trouble because they BORROWED money for bad bets. They are in trouble because they LENT money to people who aren't't paying it back."

Amos,

I'm sorry, but they are in trouble because they "borrowed" money to "lend" to people who couldn't pay it back. If they couldn't have borrowed money so easily for this purpose (if they had to use more equity), they would have checked the credit worthiness of the borrower a bit better I think.

This is similar to what happened in Japan when banks and companies could borrower money so (relatively) cheaply that they made far too many bad investments. I lived there for seven years and watched it unfold in painful slow motion.

I recognize that there are other factors as well, but it's very clear that this played a big role.

81. **Amos**
September 22, 2008

"I'm sorry, but they are in trouble because they 'borrowed' money to 'lend' to people who couldn't pay it back. If they couldn't have borrowed money so easily for this purpose (if they had to use more equity), they would have checked the credit worthiness of the borrower a bit better I think."

That's just wrong. This market involved making loans, securitizing the obligation to repay the loan, and then selling those securities.

82. **Amos**
September 22, 2008

"What normally keeps demand in line with supply? A price, set on a free market where buyers and sellers equilibrate. But the price of credit, encoded in interest rates, is not set on a free market. It is set by the arbitrary dictate of a board of bureaucrats (the Fed) with analytical pretensions."

This is, again, wrong. The Fed sets the price of credit for certain borrowings by regulated banks. The price of credit at issue here — the interest rate charged for the mortgages that were packaged into CDOs/CMOs, etc. — was set by the markets.

83. **Michael Bacon**
September 22, 2008

"market involved making loans, securitizing the obligation to repay the loan, and then selling those securities."

Amos,

I really don't know where you think the money comes from in the first palce — I know that once loans are made they are securitized to get them off the books.

"Consider Lehman – or, more specifically, consider its barely controlled growth of the past half decade. Its assets more than doubled in size, to $691-billion (as of the end of '07), while revenues and profits grew even more quickly. It was a trading house and investment bank on steroids. The juice was borrowed money, most of it short term, which allowed Lehman to accumulate $31 in assets for every buck the shareholders had in the enterprise by the end of 2007, up from $23 per dollar of equity in 2003. At Merrill, the story was exactly the same – a doubling of the balance sheet in just five years, leverage piled on top of leverage, ever more assets heaped on a thin reed of equity."

84. **Amos**
September 22, 2008

Michael Bacon:

"I really don't know where you think the money comes from in the first palce — I know that once loans are made they are securitized to get them off the books."

Its true that there was (occasionally) short term bridge-loan type borrowing, to cover the time between the purchase of the mortgages and the issuance of the securities. But that isn't relevant to what's going on.

In fact, you've got the whole thing backwards. The reason there were so many CDOs and CMOs being sold (and so many mortgages issued at such low rates) was because there was demand for the securities. (Well, that was part of the reason.) Ultimately, it was the purchasers of the CDOs and CMOs whose demand for those products drove down interest rates. The securitization was THE REASON FOR THE LOANS TO BEGIN WITH–people issued mortgages so they had something to sell to the banks, which bought the mortgages so they could sell the securities–not an afterthought intended to clean up the banks' books.

I read the article you posted a link to, and its an editorial by someone who doesn't know what they're talking about.

85. **EricD**
September 22, 2008

Amos,

How do you think Fannie, Freddie, all the off-balance-sheet SIVs, and other credit funds were financing themselves to propagate this credit bubble? They were borrowing short-term (at low Fed-dictated rates) and lending long-term. They were taking advantage of the interest rate term structure arbitrage that the Fed set in motion by, e.g., artificially depressing short-term rates to absurdly low levels in the early 2000s. These credit players are the mechanism by which Fed meddling leaks into the rest of the term structure and the broader economy.

86. **Michael Bacon**
September 22, 2008

Yeah, I'm sure the guy is a complete idiot who wrote that. And so are the other 50 sources I could cite with the same basic analysis and numbers. At least now you've switched your argument some from leverage didn't exist to well, OK, it existed, but it wasn't very much, and it wasn't really a problem. 🙂

And you're right that the one of the reasons, apart from cheap money, that the mortgages were made is because they knew they could get them off the books quickly through securitization (although they often had to keep the "D" piece or some part of the offering).

Listen, if what you were trying to argue is that leverage didn't initially trigger the meltdown, then I think we might find some area of agreement. There were a number of factors that triggered the current events. However, once the markets began to lose confidence there was no one willing to provide short-term funds to keep the ball rolling.

87. **Amos**
September 22, 2008

EricD & Michael Bacon:

You are correct that there was (some) short term borrowing used to purchase the loans (made by others), which were then securitized. That was SHORT TERM borrowing that was PAID OFF when the securities were issued.

THAT IS NOT LEVERAGED TRADING!

Michael, I understand there are a 100 very confused sources out there who think what's happening here is a replay of Long Term Capital Management and some of the hedge fund collapses of the past two years.

They're all wrong. There was no borrowing spree by the banks. The problem is that the banks now hold on their books enormous assets that have been substantially devalued. The problem is NOT that they borrowed money they can't repay in order to create those assets. They were the LENDERS not the BORROWERS.

Is this really that confusing?

88. **EricD**
September 22, 2008

Amos,

All of these credit vehicles worked by continuously selling short-term paper and using the proceeds to buy mortgages that they tranched up and sold to investors (and partially retained for themselves). Their short-term funding was not one discreet event. It was the fuel for their business, constantly replenished by new paper being sold. Without the Fed's loose monetary policy, and the term structure arb, these vehicles would never have been profitable. Once people finally identified the bubble and short-term funding dried up, these vehicles were toast, and the banks housing them buckled.

89. **Amos**
September 22, 2008

EricD:

"All of these credit vehicles worked by continuously selling short-term paper and using the proceeds to buy mortgages that they tranched up and sold to investors (and partially retained for themselves). Their short-term funding was not one discreet event. It was the fuel for their business, constantly replenished by new paper being sold. Without the Fed's loose monetary policy, and the term structure arb, these vehicles would never have been profitable. Once people finally identified the bubble and short-term funding dried up, these vehicles were toast, and the banks housing them buckled."

Your first point is right, but you are essentially agreeing with me that this is not a leverage crisis and Michael is wrong.

Your second point is that this was triggered when "people identified the bubble" and "short term funding dried up," which is completely wrong. Short-term funding (which you identify as the fed, partially right) didn't dry up, and in fact its much more available now than it was. The Fed has tried to increase the amount of short-term funding by lowering rates, in fact.

What has dried up interbank landing was the decline in the value of the securities on the banks' books, which decline happened because people stopped paying their mortgages.

What caused the "buckling" of the banks was the decline in value of the securities, which was triggered by the decline in mortgage payments and increasing default rate.

The securities are marked-to-market, and as the market for the sale of these securities dissipated they had to be marked-down. The trigger for the last few weeks was that one bank sold a lot of the securities for a very low rate. When other banks learned of the rate, they were required to mark the securities on their own books down to that rate (this is a very rough approximation of what happened, but close enough for our purposes), which meant a large loss in asset value. This, in turn, has made banks reluctant to lend to each other, because for some banks if the assets get marked down much further then the banks' book liabilities will exceed their book assets.

Get it?

90. **EricD**
September 22, 2008

Amos,

I haven't been paying attention to your discussion with Michael. As to my "second point" about short-term funding drying up, it is irrelevant whether the Fed has kept rates low (which it has). Short term funding for these vehicles no longer exists; no one wants to provide it. That is simply a fact. That this stems from increased defaults (and increased expectations of future defaults) is true. Indeed increased expectations of future defaults is what it means for people to have identified the bubble.

I am not sure what the point of that tangent was, however. You originally seemed to deny the critical role of the Fed in causing the mortgage bubble by pushing down short term rates. I had simply wanted to correct that.

91. **Amos**
September 22, 2008

EricD:

"I am not sure what the point of that tangent was, however. You originally seemed to deny the critical role of the Fed in causing the mortgage bubble by pushing down short term rates. I had simply wanted to correct that."

Your argument is that short-term lending (a) was too available because the fed set rates too low and it was the fed banks were borrowing from, (b) is no longer available because no-one is willing to provide, and (c) is important.

The second step of you argument is contradicted by your first step. Fed lending is more available now than it was.

Short-term lending has not dried up leading to a collapse in the securitized credit markets. Rather, the collapse in the securitized credit markets led to a GENERAL decline in the availability of credit on commercial terms.

This has nothing to do with interbank rates being too low, or anything like that. There simply was no short-term lending collapse prior to the decline in the value of the credit assets on banks' balance sheets.

I'm sorry, but the short-term bridge loans that were used to create CDOs and CMOs just have nothing to do with this. What's dried up is the market for the securities themselves.

92. **John Baez**
September 22, 2008

Little People wrote:

> Nationalizing corporative debts… where have I seen that before? This kind of scam used to be orchestrated by US corporations (and, probably, governments) in foreign countries. Now they are doing the same thing to their own people. I never thought I'd live to see this.

In the [Savings & Loan crisis](), the US government spent about 125 billion dollars bailing out banks between 1986 and 1996. So, unless you're quite young or weren't looking, you actually *have* lived to see this sort of thing.

Indeed, that earlier bailout may have helped create a "moral hazard" that's part of the cause of the present one.

93. **Amos**
September 22, 2008

John Baez:

"Indeed, that earlier bailout may have helped create a 'moral hazard' that's part of the cause of the present one."

That's partially true, but the S&L deposits were Federally insured, so there was a justified expectation of a government bailout, which isn't true here.

What the two events have _most_ in common, though, is that they were both caused by collapses in the real estate market, the first one commercial (a consequence of the '86 tax code), the second residential.

The moral of the story is that real estate does not always go up and the real estate market is not a securities market–it is highly inefficient, illiquid, and difficult to hedge.

94. **EricD**
September 22, 2008

Amos,

Fed lending enabled the original short-term financing of the credit vehicles. That doesn't mean continued Fed lending is sufficient to sustain this financing once the cycle has turned. The boom is not sustainable because the lending was accomplished on the back of an inflating money supply rather than an increase in real capital. When the effects of the boom redound through the rest of the economy and capital prices are bid up, housing prices decelerate, suddenly people can't maintain their over-leveraged mortgages because they can no longer tap appreciating home value, defaults increase, ABS spreads gap out, no one wants SIV paper irrespective what the Fed is doing, and… bust.

That's the dynamics. This has nothing to do with bridge loans. It has to do with the effect of a dangerously low fed funds rate dragging down the short end of the yield curve, creating a term structure arb exploited by credit vehicles, and setting in motion an unsustainable credit boom.

95. **Amos**
September 22, 2008

EricD:
"Fed lending enabled the original short-term financing of the credit vehicles. That doesn't mean continued Fed lending is sufficient to sustain this financing once the cycle has turned. The boom is not sustainable because the lending was accomplished on the back of an inflating money supply rather than an increase in real capital."

The problem with this part of your argument is that the Fed's lending played a very small role in the creation of the instruments at issue.

"It has to do with the effect of a dangerously low fed funds rate dragging down the short end of the yield curve, creating a term structure arb exploited by credit vehicles, and setting in motion an unsustainable credit boom."

I'm not sure I get your argument anymore. Are you suggesting that the driver for credit expansion was an arbitrage between short term fed rates and higher longer term rates on the commercial market? If so, I don't get your point, since commercial rates are always higher than the short term fed rate. I don't think that implies the existence of an arbitrage, at least not in the usual sense of the term.

On the other hand, are you suggesting that the fed simply maintained interest rates too low for too long leading to excess expansion? Is this a Keynesian argument or a monetarist one?

Either way its wrong, because the market should have (but did not) accurately assessed the risk of default on the mortgages themselves and on the mortgage backed securities.

The error you're making is that the supply of money isn't really a function of the fed, its a function of the capital markets. The Fed's influence, limited to M1, has never been more than marginal, and the growth of new credit instruments made the fed even less important.

The whole point of what was happening was that banks created new sources of loanable money.

Think about it this way:

In the beginning, there were loans, and they came from banks who loaned depositors' money, and they were regulated by the Fed.

Then there were simple securitized loans, where the mortgage-lending banks sold loans to investment banks, who turned them into bonds that could be sold to qualified investors. This made the qualified investors' capital available for lending and reduced interest rates.

Then came credit derivatives, where the clever bankers figured out how to divvy up bundles of loans so they could get a high credit rating and a larger pool of investors could buy them. That made lots more money available for lending, and reduced interest rates further.

The Fed played little or no role in any of this — the whole thing was about making sources of money OTHER than the Fed available.

96. **Peter Woit**
September 22, 2008

Amos (and others),

Thanks for the informed comments that add a lot to my understanding of how all this came about. If I don't contact you or ask more questions about the details, it's because I suspect I'm already spending more time on this than I should. The question of how this happened is one that I'm sure will be debated extensively in the future.

While I don't understand exactly how we got here, I think I do understand where we are: a financial system full of institutions that are effectively insolvent. The Bush administration is trying to get Congress to agree to deal with this by printing $700 billion and allowing Paulson to give it to pretty much whoever he feels like.

John,

This is rather different than the Savings and Loan story. There, the institutions had failed, the government owned them, and had to decide what to do. The proposal here is to bailout the current owners.

97. **EricD**
September 22, 2008

Amos,

First, the theoretical basis for my position is neither Keynesian nor Monetarist but Austrian (Mises, Hayek). You are apparently unfamiliar with the Austrian theory, so I suggest you wiki it, but briefly it focuses on the inevitable distortions brought about in capital markets (and the inter-temporal structure of production) when the government controls the price of credit instead of letting it be determined freely on the market.

An important aspect of this is that the Fed is substantially in control of the short end of the yield curve. It is irrelevant that a given entity is not borrowing directly from the Fed. The Fed is continuously pumping new money into the economy when it buys treasuries, or soaking money out of the economy when it sells them, in the process of fixing short term rates to its arbitrarily chosen level. Short term corporate rates include a default premium above this level, but are still substantially influenced by it.

There is no arbitrage in the strict sense between the two ends of the yield curve, but over a decade long initial phase of the credit cycle, there is a huge incentive to put on this kind of carry trade.

The essential point of the Austrian theory is that exactly the mechanism that the market would have in correcting a faulty assessment of future defaults, namely the mechanism of market interest rates, is thrown out the window when the central bank assumes the role of credit czar. You can't have a price system and eat it too.

What your account is missing is the fractional reserve nature of our system. The money lent out in mortgages did not come from depositors' funds, it was created out of thin air and transferred off the balance sheets of banks (into SIVs) so that it ultimately did not even impair their reporting situation in regard to capital requirements. The loans were ultimately not backed by real capital and were made possible by the phony price signals (low rates) manufactured by the Fed.

One guy who called a lot of this in detail way before it came to fruition is Grant of Grant's Interest Rate Observer. Reading back issues would be informative.

98. **Boo Radley**
September 23, 2008

Actually, Peter, this question is relevant and one that is worth spending time on. You should not just walk away from it. Just look at the response you have generated, even though not all of us agree with you on all counts. (String theory is boring, indefensible mumbo-jumbo, and of no relevance to the real world, and inelegant, in spite of all claims to the contrary.)

99. **Peter Woit**
September 23, 2008

Boo,

My comment was a purely personal one about not having the time necessary to invest in learning enough about some things to have a sensible opinion about them. This doesn't at all mean that I think they're not worth thinking about.

100. **Chris Oakley**
September 23, 2008

I recommend *Liar's Poker* by Michael Lewis to anyone who is interested in the issues raised here. This book will also tell you what a "Coyote Morning" is. Although now 20 years old the only things that have really changed are

• Traders now are soft-spoken and have degrees, the traders making markets in the simpler instruments having long since been replaced by machines. The downside is that dealing floors do not have the "buzz" they had when I started in the business.

• The credit derivatives market has exploded, a case of the tail wagging the dog as on the back of it a whole lot of poor quality debt has entered the market, leading to the current crisis.

101. **imho**
September 23, 2008

Let me get this straight Amos,

I give my child gun parts. My child assembles a gun. My child loans the gun to his best friend. The best friend proceeds to shoot himself and my child…. but the problem has nothing to do with me giving my child gun parts??????

Now, i'm just a simple minded physicist, so there is a good chance i'm missing some important point, but it really seems like this is the argument you are trying to make.

102. **Boo Radley**
September 23, 2008

@imho:

Then does it follow that Einstein is solely to blame for THE bomb? I doubt it.

A quant can make an assessment of the situation which the person consulting him is free to accept or reject. What is important is, at least he/she has a chance of making a falsifiable statement (which even an astrologer might, but perhaps not a string theorist 😉)

The danger is when there is sycophancy (voluntary or otherwise), greed, hubris and herd behaviour, and when the problems encountered by lower level employees don't reach the top. (See Andy S. Grove's "Only the Paranoid Survive") And also when a large number of people adopt the same strategy, and the profit margins all vanish, almost coherently, almost like a system at a critical point….

103. **Amos**
September 23, 2008

Peter:
Yes, you basically have it. Except that the "insolvency" thing is a lot more complicated. The issue is, no-one really knows what the debt derivatives (the CDOs, the CMOs) are worth because there's no market for them. They may in fact be worth much more than currently shown on the banks' balance sheets–a price that reflects the minimal trading taking place in the current illiquid market. Also, the fact that the banks' balance sheet are so poor means that the value of OTHER credit derivatives involving those banks (such as credit default swaps, etc.) has radically declined based on the perceived greater credit risk of the banks. That was AIG's issue.

That, combined with the idea that its now hard to borrow large sums for major transactions (which used to come from investment banks or bank syndicates), and that the risk of the banks defaulting on existing obligations, is the "spiralling" through the economy that everyone is talking about.

EricD:

I am quite familiar with Hayek and Mises, thank you very much. I did not (and do not) see any reflection of their thinking in your analysis, which still strikes me as naively monetarist.

You say: "What your account is missing is the fractional reserve nature of our system. The money lent out in mortgages did not come from depositors' funds, it was created out of thin air and transferred off the balance sheets of banks (into SIVs) so that it ultimately did not even impair their reporting situation in regard to capital requirements. The loans were ultimately not backed by real capital and were made possible by the phony price signals (low rates) manufactured by the Fed."

I'm sorry, but that is just factually incorrect. The money lent in the mortgages came either from depositors money or short-term loans, but it was lent with the (correct) expectation that the short-term loans could be repaid by selling the mortgages to investment banks. The banks purchased the mortgages, principally out of their own capital, with the (correct) expectation that the mortgages could be combined into debt derivatives and resold to qualified investors.

The "real capital" behind the mortgages was thus a real, and for a long time thriving and quite liquid, credit market in which many, many people (high-net worth qualified investors, institutional investors, hedge funds, governmental investment funds, etc. etc.) paid real money ("real capital") to purchase loans.

The relationship between rates on that markets and the fed rate has been minimal.

Of course, it all became a bit more complex than this in the last few years as the derivatives themselves became complex (the invention of "Super Senior," banks holding some slice of the derivatives on their own books, etc. etc.), but that's basically it.

104. **John F. McGowan**
September 23, 2008

Some other good comments on the bailout:

Progressive Conditions for a Bailout

By Dean Baker

http://www.cepr.net/index.php/op-eds-&-columns/op-eds-&-columns/progressive-conditions-for-a-bailout/

I do not agree with all of Dean Baker's politics but he predicted and warned about the housing bubble for years and his editorial above has many good points.

105. **Amos**
September 23, 2008

IMHO:

"I give my child gun parts. My child assembles a gun. My child loans the gun to his best friend. The best friend proceeds to shoot himself and my child…. but the problem has nothing to do with me giving my child gun parts??????"

The credit markets aren't gun parts. They aren't inherently destructive. For decades, they've served the incredibly valuable economic function of making credit — the engine of growth in capitalist societies like hours — more readily available not just for consumers buying cars and houses, but also students taking out college loans, and most crucially companies investing in new technologies, new factories, new machines, etc.

"What went wrong?" is a serious question. It does not have an easy or obvious answer, and to be frank, I don't think anyone knows yet. Even people (like, I think, me and my peer group) who understand both the finance and economic aspects of what's taking place don't claim to have a ready explanation of "why?".

106. **mario**
September 23, 2008

I don't know if anyone here has made the point, but… either the banks are saved or bailed out by giving them money, say amount *X*, or they collapse, making an absolutely fantastic mess that costs about, hm, let's say, *MX* for a not so smallish *M*. The moralities of the issue are besides the point at the moment. There will be plenty of time for that later.

Maybe the good folks in the US government just want to save their face by not making it look like they will just fall over without pondering the issue, or maybe they really are about to let the thing detonate for some ideological reason. We will see. It makes me a little nervous, though.

107. **Amos**
September 23, 2008

mario:

"The moralities of the issue are besides the point at the moment."

There's a practicality here, too. Its not as thought our government (or any) has a great record as a commercial investor.

The plan isn't just to have Paulson authorized to buy depressed assets at above-market prices. These assets aren't simple like equities or bonds, they have to be managed by someone. Basically, the United States is about to turn into the world's largest asset manager and investment bank.

108. **imho**
September 23, 2008

> Boo Radley Says:
> Then does it follow that Einstein is solely to blame for THE bomb? I doubt it.

Interesting debate technique… Make up a completely outlandish analogy that's completely unrelated to any of my comments. Then attempt to mock my original comments as if they were somehow represented by this completely outlandish and false analogy… In my little world we call this a straw man.

It's almost as bad this logical masterpiece below:

> Amos Says:
> The credit markets aren't gun parts. They aren't inherently destructive. For decades, they've served the incredibly valuable economic function of making credit — the engine of growth in capitalist societies like hours — more readily available not just for consumers buying cars and houses, but also students taking out college loans, and most crucially companies investing in new technologies, new factories, new machines, etc.

Gun parts aren't really gun parts. Gun parts aren't inherently destructive. For decades, they've served the incredibly valuable hunting function of making dead food — the engine of growth in food eating societies like hours — more readily available not just for consumers eating goats and cows, but also students taking out cooked pork, and most crucially villages investing in new cooking techniques, new jerky manufacturing, etc.

Dude, that entire paragraph is content-less.

> Amos Says:
> "What went wrong?" is a serious question. It does not have an easy or obvious answer, and to be frank, I don't think anyone knows yet. Even people (like, I think, me and my peer group) who understand both the finance and economic aspects of what's taking place don't claim to have a ready explanation of "why?".

I just told you why… You gave you children gun parts. Your child used complicated mathematical techniqes to create a gun, which he then loaned to his best friend. The best friend then proceeded to shot himself and your child.

At this very moment, Paulson and Bernanke are trying to convince congress that removing the gunshot wound from your child will solve the problem…brilliant

Our best bet is to regulate the children.. err.. I mean wall street. This way we get maximum growth (without the gunshot wounds). I've been reading that this bust was coming since the late 90's. These events were completely forseeable. The problem was that unregulated, capitalistic markets, with their quarterly demands for profit, have no room for moderation or prudence.

109. **Peter Woit**
September 23, 2008

imho,

Enough, this has ceased to be an intelligent discussion of anything.

110. **EricD**
September 23, 2008

Amos,

The only real capital backing much of these securitized loans is capital held in money market accounts that invested in the commercial paper of credit vehicles, including Fannie and Freddie, spawned by the Fed's loose monetary policy. But money market accounts are not treated as capital reserves — they are treated as cash and they are now being insured by the government whose only collateral is its ability to print money. Thus notes for this real capital have acquired an independent monetary character; the capital is being double counted.

111. **Amos**
September 23, 2008

EricD:

"The only real capital backing much of these securitized loans is capital held in money market accounts that invested in the commercial paper of credit vehicles, including Fannie and Freddie, spawned by the Fed's loose monetary policy."

I'm sorry, I just don't understand that. The mortgagor issues a mortgage, and then sells it to a bank for cash. The mortgage is backed by the purchased property (assuming it is non-recourse). The bank puts the mortgage with a bunch of others into a special purpose vehicle, and then securitizes the revenue stream, which securities are sold to investors. So I just do not understand what you are trying to claim here.

"But money market accounts are not treated as capital reserves — they are treated as cash and they are now being insured by the government whose only collateral is its ability to print money. Thus notes for this real capital have acquired an independent monetary character; the capital is being double counted."

Again, I really don't get what you are saying. If a bank holds an investment in a money market account, why wouldn't that count as part of its capital reserves? Maybe you're right and it doesn't, but I still don't see how that would imply that reserve capital is being "double counted" or something has acquired an "independent monetary character."

To be frank, at this point I have no idea at all what you are talking about, and I am now convinced that you've been spouting gobbledygook all along. I'm sorry I didn't spot that earlier.

112. **Amos**
September 23, 2008

imho:

I wouldn't reply since Peter's put a kabash down, but you say "Our best bet is to regulate the children.. err.. I mean wall street," which just begs for a response.

It isn't enough to say "let's regulate Wall St." What is it exactly you want to regulate? What regulations should be put in place? In any event, financial companies are subject to pervasive regulation already.

Indeed, the reason CDOs worked is a regulation that limited certain investors to assets rated as "investment grade" by the credit rating agencies. The idea of the CDOs was to package lots of high-risk stuff together in a way that a slice of it became lower-risk and could get an investment-grade rating that allowed it to be sold to a wider range of customers.

I don't mean to suggest that some new regulation is not called for. But the question remains: What do we regulate? What regulation do we put in place?

Personally, my instinct is that we should strategically encourage investment banks to move toward a salary-based rather than bonus-based compensation system. But that's for complex reasons not worth getting into here.

113. **Jack Lothian**
September 23, 2008

My understanding was it was a Ponzi-game which works like this.

A financial intermediary representative notices that two fellows have significant assets, sitting there earning not much revenues. So this intermediary says to both guys let me manage your assets & I will make you rich & I will only change a minuscule transaction fee for each transaction that makes you richer. So he says to the 1st guy, that 2nd guy's assets are much undervalued so you should buy them & you will buy them by selling your current asset at an incredible profit. Of course, he says this to both asset owners & they exchange assets but they evaluate the assets at 10% higher value. They give 5% of the extra value in commissions & feel rich enough to buy extra goods with their extra profits. This goes on until all the value in the assets are spent & the intermediary is rich.

Of course, the game was very sophisticated in this case because the home buyers were given sub-par rate mortgages which meant the buyer paid below market level monthly payments for the 1st few years of the mortgage but the financial lender did not lose because this lost interest was added to the principal. As long as houses continued to gain value at 10% a year the game worked. Every few years the buyer would flip house, pay the commissions, & extract profits from the house without really putting anything into the house. The point that most people failed to get was that the 1st time house prices did not jump up 10% the game collapsed. An indefinite rise of 10% is not sustainable because it would eventually lead to 1 bedroom shacks costing millions of dollars. An indefinite 10% compounding leads to incredible price increases over short periods. Most people failed to recognize this fact. The few na-sayers were ridiculed. All the financial institutions felt they had to get in on the game or be left behind. Their shareholders all demanded the same returns as the front runners.

During the run up, the financial institutions made huge sums of money off the transactions costs so they seemed to be making money from nothing but in reality money was being extracted out of the housing sector by a Ponzi game. This money has to be made up somehow & I am not sure that we have seen the end of this yet. A lot of money has been extracted from the housing sector & I think house prices might tumble even further.

In my opinion, this was an issue of insufficient regulation of a basic human trait – greed. We are influenced by others & it is possible for us to rush into danger. Cogitative-dissidence causes us to lose track of real risk & we need laws that stop us from acting foolishly as a collective group. Most financial institutions have become incredibly leveraged & the so-called profits are being made are a very thin slice of these assets. It makes for huge profits on the way up but huge losses on the way down.

Salary levels for CEOs are a red-herring. As long as huge profits can be made by ignoring risk there will be those who follow this path. Once a few institutions start down this path and make incredible riches others are forced to follow even if it is obviously dangerous. Then, cogitative-dissidence sets in & we convince ourselves these inappropriate actions are justified.

We need a mechanism that allows risk to be evaluated properly or we need to prevent people from taking really risky actions.

114. **Jack Lothian**
September 23, 2008

PS: I think physicists were minor players in this game. The biggest problem with mathematicians/physicists is they see the economic world as a mathematical model. Unfortunately, people do not model so-well. There is strong evidence that collective human behaviour may be both chaotic and an unstable equilibrium.

115. **imho**
September 23, 2008

> It isn't enough to say "let's regulate Wall St." What is it exactly you want to regulate? What regulations should be put in place?…

What the hell, I'll take a stab and can you tell me where I'm wrong.

A long time ago, in a galaxy far far away, access to low interest capital became doctrine. The gods of capitalism demanded that these traders take this practically free money and invest more more more. So the "masters of the universe", running out of things to invest in, decided to invest in dirt, weeds, and poison ivy. But no one valued dirt, weeds, and poison ivy, so the "masters of the universe" decreed that we should mix beautiful artificial roses in with the dirt, weeds, and poison ivy. We will slice and dice our mixture and call these things CDOs. We will combine different CDOs and re-slice and re-dice to make even more CDOs. We will repeat until all CDOs are opaque black boxes filled with, what we believe is, some sort of greenish organic like material with small pieces of artificial rose. Ratings agencies will declare these organic material filled black boxes good. Exuberance will reign, we will flood the market with these black boxes and create a bubble. Time will pass, until one day some one will wake up and realize that these black boxes are filled of small pieces of artificial rose completely surrounded by fertilizer. The bubble will burst.

So how do we prevent this from occuring in the future? We start by turning the opaque black boxes into transparent boxes with detailed labels, and we require that the labels be updated frequently. Or in other words, we regulate risk management. Maybe it's the credit ratings agencies that need to be nationalized??? An independent agency (not on wall street's payrole) needs to analyze all of these securities products and appropriately label the risk. So maybe in the future there will be less exuberance over $hit filled black boxes.

116. **EricD**
September 23, 2008

Amos,

Follow along and you might begin to understand. Keep your eye on what's under the shell.

A loan is made. The capital for that loan comes from, say a bank. The bank sells the loan to a vehicle, which funds itself by selling commercial paper. The capital for the loan is now coming from the buyers of that paper, e.g. a money market fund. The money market fund is itself financed by owners of money market accounts, so the capital backing the original loan is now coming from these account owners.

Do these account owners regard their money market deposits as risky investments? No, they regard the deposits as cash. They write checks against the deposits. They reduce other cash holdings (e.g. conventional bank accounts) to fund the deposits because the deposits seem just as safe but higher yielding.

This is exactly parallel to fractional reserve banking, where deposits are loaned out and held simultaneously by the borrowers (or by the people who sold something to the borrowers) as independent cash accounts. Real capital is double counted by money. And this framework has set in motion the same credit cycle that Mises identified, enabled by the Fed's artificial suppression of short term rates, which made these credit vehicles profitable.

117. **Amos**
September 24, 2008

imho:

"We start by turning the opaque black boxes into transparent boxes with detailed labels, and we require that the labels be updated frequently. . . . we regulate risk management. Maybe it's the credit ratings agencies that need to be nationalized??? An independent agency (not on wall street's payrole) needs to analyze all of these securities products and appropriately label the risk."

You recognize the function the ratings agencies were supposed to perform. Why do you believe that a nationalized credit rating agency could do a better job than the existing ones?

EricD:

You have the structure of the credit derivatives completely wrong as a factual matter.

In any event, your complaint is not with credit derivatives but, apparently, with the idea of banking itself. I really don't see a point in responding to it further.

118. **imho**

September 24, 2008

> Amos said:
> Why do you believe that a nationalized credit rating agency could do a better job than the existing ones?
>
> Hmmmm, why would an agency that reports to congress be better than an agency that gets paid by the same people it should be regulating… Geee, I don't know.

119. **Zeynel**
September 24, 2008

Bee notices that the banking system is "strikingly similar" to the academic system. She puts it this way "If you look at it from the system perspective, the problem is strikingly similar to those of the academic system." Yes. And why? Because both bankers and physicists are professionals. Banking and physics are the same type of hierarchical bureaucracies. Organisms with the same structure behave the same.

Bee correctly identifies the strict hierarchical bureaucracy of both organisms. "Too many people working for their own immediate advantage, dismissing thinking about the long-term consequences, too few people who pay attention to what science is about and under which circumstance it can flourish." Bee notices that like bankers physicists too have just one thing in mind: their career. Physicists like bankers want to move up the hierarchy by abusing the system. All they think is their own personal profit. Personal profit for a banker means more money and for a physicist it means more academic authority.

Bee continues that the careerist behavior of the practitioners and that the only way to move up the hieararchy is by abusing the system for self-gain "supports the formation of bubbles . . . that evenutally have to burst." But the question is why is it that banking bubbles burst periodically but physics bubbles never burst? Does physics have a breaking point? No. The key to understanding this, and I think Bee fails here, is to understand that both the bankers and physicists sell debt. In finance this is how the system works. In order to make money bankers must split the debt into ever finer and riskier debt and move them i.e., sell them. When this pyramid scheme collapses a crash occurs. The financial crash is built into the system. And what looks to outsiders as disaster actually benefits the practitioners and the system. After the crash the debt system is set to zero and it can start all over again. In physics the debt is theories. Physicists must invent ever riskier i.e., ever more absurd, theories that are more and more distant from experiment or verification. Physicists eventually hope that their theories will be verified by the gold standard of experiment. In academic physics this doesn't happen anymore.

But why doesn't physics crash periodically when like in banking the debt pushed by careerist physicists reach new heights of absurd? The reason is that physics differs from banking in this respect. Physics studies physical quantities. These, despite the name "physical," are not physical quantities but arbitrary definitions of units. Anything can be defined as a physical quantity. So physicists define new PQs and continue to float ever riskier theories that never break the system. When the system gives an error that has a possibility of breaking the system physicists define the error as a new legal PQ and start to study its "physical" properties. Here physical means its relation to existing legal PQs. There is no requirement that a new PQ must be experimentally verified.

But when Bee writes that "in both cases … the mismatch between personal incentives and the desirable long-term large-scale trend does not feed back into the system – other than through a major breakdown" she is only partially correct because this is only true for banking. In physics, as I mentioned above, the risk, ie the absurd, is continuously fed back into the system through PQs and this is the reason why physics never crashes.

And Bee's observation that "people working in the system are aware its setup does not make sense but are unable to change something about it (and unwilling since it won't be of advantage for them either) " must be disturbing to physicists. This picture of physicists is not very flattering. I think every physicist needs to stop for a moment and think about this. Because physics should not be like banking. Physics is supposed to be science. The hierarchical system populated by careerist bureaucrats whose sole goal is to sustain the status quo so that they can abuse the system to move up the hierarchy to gain more authority does not look like the scientific environment physics profession projects to the outside world. The content of physics is defined by this rotten hierarchical bureaucracy and the result is theories like the String Theory. I believe this was not an off-topic but a very much on topic post. Thanks.

120. **EricD**
September 24, 2008

Amos,

If you see a specific error in what I've written, I'd be glad to have it pointed out. Up to this point, you have not done so, as a factual matter.

But if you are only now glimpsing the close micro and macro relationship between securitized debt markets and the conventional banking system, I suspect it is a chastening experience.

121. **David Nataf**
September 26, 2008

Peter,

That was a very nice post and thank you for writing it.

I'm wondering, do you see much difference looking back between the students you had who went to Wall Street and those who stayed in Academia? Were the pre-quants more theoretical? Were they as good as the pre-academics at doing science?

122. **Peter Woit**
September 26, 2008

David,

I can't say that I've noticed many differences between people who stayed in academia, and those who shifted over into finance. It's certainly not true that the best ones stayed in academia, less competent (or more theoretical) ones went into finance.

123. **Ned**
September 26, 2008

Dear Mr. Woit,

thanks for even trying to "figure out where all this money was coming from" – that's more than most people ever did …
(and so the present situation could merrily develop)

124. **Chris W.**
September 27, 2008

Two new articles in the New York Times flesh out the intertwined fortunes of A.I.G. and Goldman Sachs, which might have been a major factor in the government's bailout of the former.

Wall Street, R.I.P.: The End of an Era, Even at Goldman

Behind Insurer's Crisis, a Blind Eye to a Web of Risk:

> As the group, led by Treasury Secretary Henry M. Paulson Jr., pondered the collapse of one of America's oldest investment banks, Lehman Brothers, a more dangerous threat emerged: American International Group, the world's largest insurer, was teetering. A.I.G. needed billions of dollars to right itself and had suddenly begged for help.
>
> The only Wall Street chief executive participating in the meeting was Lloyd C. Blankfein of Goldman Sachs, Mr. Paulson's former firm. Mr. Blankfein had particular reason for concern.
>
> Although it was not widely known, Goldman, a Wall Street stalwart that had seemed immune to its rivals' woes, was A.I.G.'s largest trading partner, according to six people close to the insurer who requested anonymity because of confidentiality agreements. A collapse of the insurer threatened to leave a hole of as much as $20 billion in Goldman's side, several of these people said.
>
> Days later, federal officials, who had let Lehman die and initially balked at tossing a lifeline to A.I.G., ended up bailing out the insurer for $85 billion.
>
> Their message was simple: Lehman was expendable. But if A.I.G. unspooled, so could some of the mightiest enterprises in the world.

The pervasive role of credit default swaps is central to the story.

125. **mike**
September 28, 2008

Peter,

I know this is a little late, but I completely agree with your analysis and I think there are more parallels between the banking process and the current string model than most realize. Whether it's $700 billion dollars or 10^500 vacuum states, it's all the same and pure nonsense – shoving large numbers at a problem does not really solve it. An understanding of the problem and what is happening goes much further than the blatant assumption that "we need to stabilize markets with an infusion of capital". This is pure nonsense and oversimplification of what happened after the great depression, which after real analysis, may not even be a valid comparision today with our electronically-managed, multiple fund markets. Unfortunately, in an election season, it's more prudent to be on the side of the public than to analyze the situation and try to correct the disease instead of the symptom. The real tragedy is that this financial fiasco happens right before the election, where critical thinking will get thrown out and knee-jerk reaction will be the substitute.

126. **Chris W.**
October 6, 2008

Paulson picks a former rocket scientist (and Goldman executive) to oversee the bailout.

By the way, it turns out that the final bill does include a provision for use of a stock-injection plan, despite the opposition of the banking industry.

Meltdown at CERN

September 23, 2008
Categories: Uncategorized

Besides the meltdown in the financial markets, perhaps of more concern to physicists is a meltdown at CERN, specifically in the connection between two magnets during powering tests being conducted at 11:17 last Friday the 19th. Here's the daily report from that day on the LHC beam commissioning site. By the next day it had become clear that it would be necessary to warm back up the sector to deal with the problem, leading to this press release. It was immediately clear that doing this would take at least a couple months, and make it impossible to have physics collisions at the LHC this fall. Today, a new press release confirms this:

> The time necessary for the investigation and repairs precludes a restart before CERN's obligatory winter maintenance period, bringing the date for restart of the accelerator complex to early spring 2009. LHC beams will then follow.

The press releases refer only to a "large helium leak" and the failure of an electrical connection, making the problem sound rather minor. I tried contacting a physicist at CERN to find out if they had any more information, but was told that he or she was under instructions not to discuss anything about what had happened beyond what was in the press releases, and that CERN was specifically concerned that information might show up in blogs. This policy seems to be being unevenly enforced, since today the Everything Blog carries the following report:

> I was in a meeting at CERN when someone ran to the front of the room with a computer, then after letting the speaker finish and setting up the computer to project the press release/e-mail (agonizing moments: it was a Mac), they let us know. I was worried that the sector with the helium explosion had collapsed like an old mine — there were rumors going around that this is a weak point in the tunnel. (Of course there would be such rumors.)
>
> I have learned a few more graphic details about the event in the last few days. First off, it was two tonnes of helium, not one. But I've also learned that this was a more explosive and dramatic event than I had imagined— helium is fortunately an inert gas, but the temperature gradient caused it to explode violently, probably causing physical damage to the nearby components. And now that section of the LHC is an ice tunnel, maybe with stalagtites hanging down and a Yeti moaning in the distance.

Up until now, the policy at the LHC has been to be quite open about the commissioning process, with detailed technical information provided on web-sites that were freely accessible. For instance, there's detailed news about how beam commissioning was going up until the accident available here. Going forward, it will be interesting to see how CERN deals with the problem of letting not-so-good news out to the public. Just about one year ago, I wrote about some earlier LHC problems, and it has always worried me a bit that having a huge LHC publicity onslaught before the machine was actually ready and working might not have been a good idea. Going through the often painful process of solving the problems likely to show up in a project of this scale may provide a different education of the public than the one people were hoping for.

Update: Yesterday there was a LHCC meeting at CERN, broken up into an open and closed session. The slides from the talks are available here, and give a wealth of information about the state of the machine and detectors, and what they were able to accomplish during the short period that they had a beam. There's no info about the accident in the slides, but video of the talks is here, and at the end of the talk by Lyn Evans (9-18min into the video) he gave a report on the accident and answered questions. The problem has been traced to an electrical fault in the magnet busbar, and bizarrely occurred during the test of the last circuit of the last sector that was being commissioned for 5 TeV operation.

Evans says that the machine will be down until "early spring". Before the accident, the plan had been to bring the LHC back up in early June, after various work needed on the injection system. The current plan is to try and get this work done instead this fall, so that they can start up more quickly in the spring.

   September 23, 2008

   Obviously this is the effect of the anthropic principle! In all the universes that the LHC were functioning and crossed it's beams, black holes were created which swallowed the earth. Since we are all alive and see the LHC malfunctioning, this is evidence that miniature black holes can be created at LHC. This is really the first experimental data the LHC have produced. It's amazing how much new good science this anthropic prinicple makes possible!

2. **wb**
   September 23, 2008

   The failure was in an interconnect between two magnets that caused a fire. Ultimately more than 20 of the superconducting magnets quenched. The good news is that the quench protection systems operated properly at a scale never tested before. This gives good confidence about magnet protection. The unknown question is why the interconnect failed – a change badly done connection,a design flaw? What needs to be done is to warm the sector and inspect. Based on what one sees,one may decide to warm everything and inspect the entire machine.

   This not such a simple decision. Remember the rf-fingers that had problems. These fingers have a potential for damage every time the machine is cooled. Therefore one tries to avoid thermal cycles unless necessary

3. **Observer**
   September 23, 2008

   I wonder how cold it got when the helium expanded?

4. **Coin**
   September 23, 2008

   I am expecting serious questions in the press and worldwide demonstrations for accountability over the question of whether it is possible that the operation of the LHC could, in fact, create Yetis.

   *Remember: There is no scientific theory that can definitively prove that the LHC will **not** result in the production of Yetis.*

5. **calvin**
   September 24, 2008

   It is being rumored that the LHC in it's test run has already produced evidence of susy. In fact, it produced the susy partner of a black hole, which instead of swallowing up the world, swallowed up Wall Street. In fact, the susy black hole – also known as sblack shole – a.k.a. Black-Scholes, for convenience of pronunciation, with the 'c' added to confuse people – has been around for a while.

The rest is silence.

6. **csrster**
September 24, 2008

Eirik, that may be the best comment in the history of this blog.

7. **Marco**
September 24, 2008

… it will be interesting to see how CERN deals with the problem of letting not-so-good news out to the public…

Concerning this point, yesterday during a collaboration (ATLAS) meeting we were formally asked not to give to the press anything that is not a CERN official statement (and this is somehow bounding at least for the CERN employees, we sign something about information disclosure with the contract). I guess this says something about the way CERN plan to control the information leak in the next months…

8. **DB**
September 24, 2008

I can understand that they need to inspect the failed parts and precisely determine the cause, and that premature speculation on blogs by Cern employees could be used irresponsibly by the media. But then they need to be completely open and transparent. As soon as is practicable. Just as they were when the faulty Fermilab components failed last year.

I have no reason at this stage to believe they will act differently in this case.

9. **Jack Lothian**
September 24, 2008

The media will do what they always do. Thinking that one can control the media is extremely foolish. As word gets out that CERN is trying to "control" the media's access, they will get more aggressive & hostile. From the media's viewpoint this is a declaration of war & they will now go to greater lengths to root out the real story.

I see this as a serious management mistake. Some people higher up are getting very nervous about their job & prestige and they are panicking. It is a normal human reaction under such conditions to try to control everything. Clamping down like this occurs all too frequently when the shit-hits-the-fan. It usually makes things worse but we do it anyway because it makes us feel safer.

10. **Peter Woit**
September 24, 2008

Marco,

Thanks. The problem with the "nothing to the media except what is in a press release" policy that the LHC collaborations are instituting is that, taken literally, it basically shuts down all blogging by LHC scientists. Blog postings are, unavoidably, communications to the media, since they can read them. If the only thing you can put in your blog are CERN press releases, why bother blogging about your work?

Funny, but this policy either wasn't in place or wasn't enforced until there was some bad news. De facto, the policy seems to be that LHC bloggers can discuss good news as much as they want, but not bad news, Also, the collaborations are mixing one legitimate problem (their conventional concerns about discussion of preliminary data), with a very different one, that of the public perception of how well the LHC project is going.

I think it would be appropriate for CERN to make sure that bloggers working there clearly distinguish between when they are speaking for themselves and when they are speaking officially for the lab, but beyond that I don't think it's a good idea to do anything other than encourage the dissemination of accurate information about how things are going.

11. **Jim Pivarski**
September 24, 2008

No I am not releasing more than what is publicly available! (This is Jim from the Everything Seminar.)

Please see http://cornellmath.wordpress.com/2008/09/24/this-is-not-sensitive-information/

12. **insider trading**
September 25, 2008

I totally agree with Jack Lothian. This is indeed a management mistake, the way I see it. Compare it with a totally open view: everything open from day one after the incident. Where is the trouble ? They show what they are doing. If they do the best that can be done, things are okay. Instead, they really look like they have something to hide.

I stay anonymous but I am a CERN experimentalist. By the way, beam operations will not restart before the start of spring, most probably April. Then there will most probably be a longer-than-planned run at 10 TeV.

13. **Will**
September 25, 2008

Peter, Why are you always so negative? Why?

14. **Peter Woit**
September 25, 2008

Will,

This isn't a really good example to accuse me of negativity. There's no way to deny that this is a discouraging piece of news. Writing a positive posting about it would be kind of idiotic. As for whether I'm negative about attempts by people at CERN to shutdown discussions on blogs by physicists that they might find inconvenient, I guess I'm a pretty negative guy when it comes to that.

On the whole, one goal of this blog is to put out accurate information, especially in cases where there's a lot of hype going on. I guess that can be thought of as a "negative" activity, but I think it has its value.

Personally though, I can assure you that I'm mostly a quite cheerful and optimistic sort, very happy with life. Maybe I compensate for this with the blog….

15. **Sara**
September 26, 2008

@ insider trading: but do they really have anything to hide?

16. **Pessimist**
September 27, 2008

What if it emerges that CERN management cut some corners so they could have "Big Bang Day" on schedule?

Barring that, the whole incident has been poorly handled. If these guys had a clue, they would have called the BBC back to inspect the damage. It's rumored to be quite spectacular, and pictures will undoubtably hit the web. Instead of a media bonanza, with the public engaged in the discovery process, it could become a sleazy scandal. Perhaps Big Science needs a good house cleaning.

17. **amba**
September 27, 2008

Moral: do not announce your pregnancy until you're past the danger period for miscarriages.

18. **chris**
September 29, 2008

well, i would call this a first successful LHC prediction 🙂

http://arxiv.org/abs/0802.2991

19. **Steve Myers**
September 30, 2008

I'm confused: didn't any one test for faults before power up? Was that too difficult to do? I have been involved in many startups of high power & complicated equipment, malls, office buildings, and power was never applied without extensive tests. Phase to phase, phase to ground, bad connections, etc. faults should be caught in initial tests and inspection. Clearly there's something I don't get about this accident.

20. **Peter Woit**
September 30, 2008

Steve,

From what Evans said, this happened when they were ramping up from a current corresponding to 5 TeV to one corresponding to 5.5 TeV. This was late in the game, after extensive testing, some kind of problem that only showed up at high currents.

21. **Pessimist**
October 16, 2008

The official report is out.

https://edms.cern.ch/file/973073/1/Report_on_080919_incident_at_LHC__2_.pdf

Thirty magnets out, 6 tons of He lost, soot in the beam pipe, ++

The good news is " the official inauguration ceremony that will take place [ ] in the presence of the highest representatives from the
CERN Member States, representatives from other communities and authorities of the countries participating in the LHC."

22. **Covariant**
October 17, 2008

From the report

"These forces displaced dipoles in the subsectors affected from their
cold internal supports, and knocked the Short Straight Section cryostats housing the
quadrupoles and vacuum barriers from their external support jacks at positions Q23,
Q27 and Q31, in some locations breaking their anchors in the concrete floor of the
tunnel. "

Wow

23. **Benni**
October 18, 2008

At least, from what is in the report, it seems that one can take appropriate measures that such a chain reaction of events won't happen again.

I wonder if the whole LHC must be warmed up when they make the necessary modifications on the other magnets to prevent such an accident in the future,

Proof of Resolution of Singularities in Characteristic p?

September 23, 2008
Categories: Uncategorized

I've heard reports from Harvard that yesterday and today Heisuke Hironaka has been giving talks in the math department there, claiming to have a proof that singularities of algebraic varieties can be resolved for any dimension in characteristic p. This would be a major advance in the field of algebraic geometry. I don't know any details of the proof, but Hironaka is, at 77, an extremely well-respected mathematician, not known for making claims unless they are very solid.

Hironaka won the Fields Medal in 1970, largely based on his 1964 proof of the resolution of singularities, in the characteristic zero case. For an introduction to that proof, see this [article]() from the Bulletin of the AMS.

Update: From comments here it seems that the source of my information about Hironaka's talk was most likely overly optimistic about exactly what Hironaka was claiming. The current situation seems to be that several groups are working on this, with promising ideas of how to get to a proof, but with no definitive proof yet done. There will be a [workshop at RIMS]() in December, with the goal of sorting out the current situation:

> The aim of the workshop is to review recent advances in the resolution of singularities of algebraic varieties with special emphasis on the positive characteristic case. After many years of slow progress, this is now a rapidly developing area with several promising new approaches. Our aim is to keep the program flexible, in order to give the maximum opportunity to discuss and explore new developments. We expect a joint effort to understand characteristic p, and that the purpose is not that everybody exposes his/her own results.

Comments

1. **Daniel de França MTd2**
   September 23, 2008

   "singularities of algebraic varieties can be resolved for any dimension in characteristic p. "

   Can you explain, with an example, why is that a very important result?

2. **Charles Siegel**
   September 23, 2008

   Well, there are a lot of problems in characteristic zero (where resolution is known) which are solved by taking a resolution of singularities, proving the result (or defining the object, or the like) on the resolution, and then pushing forward to the singular object. The point of the resolution is that it's smooth, but as close as possible to the singular variety. So presumably the reason is that there are some conjectures that hold if resolution does, but we can't prove otherwise. I know that some stuff on alterations by deJong at Columbia has been used to chip away at some of them (positive char stuff isn't my subject, so I'm working from heresay mostly) and stronger statements can be obtained with full resolution.

   Of course, there's also the fact that it's been an open problem for decades, and so a proof would most likely involve powerful new techniques that could be used to solve problems.

3. **Terry Hughes**
   September 23, 2008

   Peter,

   It is a vast overstatement to say that Hironaka is claiming to have a proof that singularities of algebraic varieties can be resolved for any dimension in characteristic p. He outlined a new approach at Harvard, but made no claims that he solved the problem.

   In Argentina Orlando Villamayor of the University of Madrid recently gave a very nice talk in which he claimed he had reduced the problem to some very special cases. He will also speak at the Harvard meeting.

   And there are some others who are claiming progress.

4. **Peter Woit**
   September 23, 2008

   Thanks Terry,

   Were you at Hironaka's talk and do you know exactly what he claimed? The story some people at Columbia were told was that there had been a claimed proof, but our informant from Harvard was not an expert on the subject, and may have missed something about exactly what Hironaka was claiming.

5. **Terry Hughes**
   September 24, 2008

   Peter,

   I didn't attend Hironaka's talk. My information comes directly from a Harvard senior mathematics professor who did attend. I don't know any of the details of Hironaka's new approach.

6. **Peter Woit**
   September 24, 2008

   Terry,

   Thanks. My info also comes from a Harvard senior mathematics professor….

   If any of my readers did attend the talk or know someone who did, I hope they can help us resolve this disagreement amongst the Harvard faculty…

7. **Jabotinsky**

September 24, 2008

Recently people in that subject have started to think that the proof of characteristic p resolution is imminent, so I think people are sort of jumping the gun staking their claims, and their exact wording might affect the impression they give. I suggest waiting to see what happens before making these speculations.

8. **Terry Hughes**
September 25, 2008

Peter –

That's hilarious. I sent my Harvard math department informant an email asking about the inconsistency, but I haven't heard back yet. My informant has made considerable contributions to algebraic geometry, so he very much knows what he's talking about in that field. But he is not a singularity expert as such.

I'll keep you apprised!

9. **Terry Hughes**
September 25, 2008

O, and my informant did attend the Hironaka talk.

10. **postthis**
September 25, 2008

I don't think it makes much difference until there's a paper. About a decade ago one of Hironaka's students gave a lecture series at Harvard on his proof of resolution in positive characteristic. (or approach-to-proof or however it was described). It sounded promising. But the details didn't hold up and the claim was eventually withdrawn.

Hironaka may well have a proof, a usable strategy, or neither. Resolution is a very technical problem and, unlike with Wiles or Perelman's proofs, I don't think a quick provisional determination of correctness would necessarily be easy to reach.

11. **Terry Hughes**
September 25, 2008

Hi Peter,

My Harvard math department informant has responded, and he's pretty certain:

"Actually, I cannot imagine any of my colleagues spreading the word that Hironaka had solved the problem. Movement on it is in the air, but it's not all by Hironaka, nor is the program complete."

My informant has been to the talks and he definitely walks the algebraic geometry walk! I'm quite confident in him, for whatever that is worth.

Survivor

September 26, 2008
Categories: Uncategorized

Steve Hsu has a recent posting Survivor: theoretical physics, which links to data about the theoretical particle physics job market compiled by Erich Poppitz from listings on the Theoretical Particle Physics Rumor Mill web-site.

Back in 2001-2 I also spent some time looking at this data, and estimated that in recent years there had been typically about 15 tenure-track hires each year in particle theory, of which roughly half were going to string theorists. Starting around 2000, the number of hires started to increase, as it has increased throughout academia during a period of reasonably healthy university budgets and an increasing number of retirements (of those hired during the 60s when many universities expanded dramatically). Since 2000 the number of hires has typically been more like 20, anomalously high at 28 in 2007. The anomalously low number of 15 for this past year's hiring may be a fluctuation, but it also may be an indication of either university budget cutbacks or increasing unpopularity of particle physics in US physics departments. The fraction of string theory hires has gone down dramatically, to more like 25% over the last 5 years.

I don't have any data at hand about the recent total number of people getting particle physics Ph.D.s, and whether this number has grown with the number of faculty hires. I did find at one point a number of 78 for particle theory Ph.D.s in 1997, but I don't know if this included degrees in cosmology, which increasingly has become mixed with particle theory. Poppitz also lists numbers of hires by institution. Princeton comes out significantly ahead with 23 people getting jobs over 15 years. I'd guess there are typically about 3-4 people/year getting theory Ph.D.s there. So, traditionally, if you want to maximize your chance at a job, Princeton is the place to go. Not clear how this will work out in the future, given the very small number of string theorists getting hired.

To get some idea of the imbalance between Ph.D.s being produced and tenure-track jobs, in 2007 one institution, Harvard, produced 8 theory Ph.D.s. That's more than half the total number of tenure-track hires this past year. In the past a large number of these Ph.D.s ended up working in finance, but prospects in that industry are not looking so good either.

Comments

1. **JC**
   September 26, 2008

   They should also look at the folks who did not get tenure and subsequently left particle physics, and also the folks who got a faculty job but later quit of their own volition (and left particle theory).

2. **MathPhys**
   September 27, 2008

   Are the tenure track prospects of math graduates better?

3. **big vlad**
   September 27, 2008

   anyone know roughly what fraction of postdocs in theoretical particle physics will find permanent positions? what's the breakdown between 'theory' theory and phenomenology?

4. **Peter Woit**
   September 27, 2008

   MathPhys,

   I haven't looked into the numbers for math, but the situation seems to me to be very different, with job prospects a lot better. I know many people with particle theory Ph.D.s who have left academia because they saw no prospects of any kind of job at all where they could do research. Of the math Ph.D.s I know who left academia, almost always it was not because they couldn't get some kind of job if they wanted one, but they decided that the pay, working conditions, location, etc. were better outside academia.

   Big Vlad,

   There's also a more recent postdocs rumor mill, you could gather data from there. Then you'd also have to figure out the question JC asks, how many people getting tenure track jobs stay on and get tenure.

   As a very, very rough guess, my impression is that in recent years maybe half of the new Ph.D.s in theory get postdocs, and of these, maybe 1/5 end up in a permanent academic job where they can do research. So, if you're a new theory Ph.D., one chance in ten…

5. **Rien**
   September 27, 2008

   Remember that this is rather America-centered. Many people get their PhDs elsewhere and come to the US or Canada for postdocs and/or faculty positions. Europeans often do a couple of postdocs in the US and then go back to Europe for faculty positions, but Americans very rarely go outside of the US at all except maybe for CERN. The postdoc rumor mill has postdocs everywhere, so the comparison won't be perfect.

6. **steve hsu**
   September 27, 2008

   It's important to emphasize that your probability of getting a job varies dramatically as a function of where you do your PhD work. At best (Princeton, Harvard, Berkeley) it is 1 in 3 or 4. But at many departments in the top 10-20 range of traditional rankings the probability could be 1 in 10-15 (Yale, Columbia, Maryland each produced only 3 professors over 15 years), or even less than 1 in 40 (e.g., UCLA, BU, UIUC … produced 1 or fewer professors in the last 15 years!) Note these are positions in the US and Canada. If you include jobs in foreign countries the odds improve quite a bit, perhaps by a factor of 1.5 I would guess, but many Americans wouldn't take a job in, e.g., China or Chile.

   While it's widely known that the job prospects overall are poor in particle theory, I doubt people are familiar with this rapid drop off in the odds as a function of department ranking.

7. **ninguem**
September 27, 2008

MathPhys,

The Notices of the AMS publishes very detailed statistics about the job market in Math every year.
http://www.ams.org/notices/

8. **Peter Woit**
September 27, 2008

Steve,

Thanks, that's right, the dependence on department is dramatic. The rough "1 in 10" I had in mind is an average.

As Rien points out, this is just about the US market, but increasingly this is a globalized profession. Many of our students in recent years have come from China or other places outside the US, and there are now starting to be attractive job possibilities for them if they want to go back. The story of the next decade may be a rather weak US academic job market, but all sorts of opportunities in places like China and India. If you're a string theorist, a job in the US may be hopeless, but many possibilities in Beijing (actually I have no idea what the situation is with Chinese universities and string theorists…).

9. **a quantum diaries survivor**
September 27, 2008

Well, well. I did not get any royalties yet from Hsu's site. I wonder if they got lost in the mail.

The thing is, besides the name of my blog, which is there since January 2006, I am really looking more and more like a survivor myself. At the young age of 42 years and a half, I still have a temporary position as a INFN researcher.

True, when I won the 5-year researcher position I have now, in December 2005, the INFN was clear in explaining that winners would gradually get a permanent position.

True, in 2007 a procedure of stabilization of personnel with at least three years of employment was started. I received a letter which assured me that the INFN had no power to fire me after the expiration of the five-year contract. That meant I could only be hired permanently, at some point. But when ?

Then, early this year those who had won the position in 2005 were asked to pass a new selection. This new selection was presented as the way by which INFN could bypass some budget restrictions and finally hire us permanently without further ado. Needless to say, we all complied to the new request. Then, only a contract was going to have to be signed, and we would all be happy…

Six more months have passed, Berlusconi's government is ruling, and a law is being passed which stops all the stabilization procedures, preventing the hiring of people with temporary postions, regardless of whatever had been promised before.

I think there is still a chance that we do not fall in the category which is cut or fired. I worry not – I would continue doing my job even if I was fired. However, I cannot but smile at my sorry country and its contorsions.

So, here it is, from a true survivor.

Cheers,
T.

10. **JC**
September 27, 2008

steve hsu,

How much is the Princeton/Harvard/Berkeley factor a function of self-selection? (ie. The better folks prefer to attend the better graduate schools).

11. **steve hsu**
September 27, 2008

T: your check is in the mail 😉 Can I visit Trieste soon?

JC: It's certainly true that the quality of theory grad students at each school roughly correlates with the placement probabilities. But there are other effects, like having a powerful supervisor pushing for you in letters and phone calls. It also helps to learn from other smart students, and it helps to be part of a big bandwagon / fad like string theory.

But let's take the example of a less elite but still very strong physics department like UCLA. It's a big department with a large high quality theory group. During the last 15 years they probably produced 50 or so PhDs in particle theory and related fields. But only 1 of their PhDs got a faculty job at a research university in the US or Canada. Shocking, no? I bet those 50 people are all very smart. They're probably producing a lot of value and innovation on Wall St., in Silicon Valley, etc. I doubt they knew what odds they were facing when they started graduate school.

At U Oregon the typical student who ends up doing theory is either a Chinese / Indian kid with perfect physics GRE who graduated at the top of his class from a leading university, or an American kid who was at or near the top of his undergraduate class at a big public university or liberal arts college. At that stage in their lives all options are still open to them. Little do they know what they are getting into.

12. **postthis**
September 27, 2008

It's not so clear that the job market in, for example, math is any better. One would have to compare physics (all fields) versus math (all fields) or else particle theory versus some comparably theoretical area of math.

If you count research labs whose employees publish their work in some of the same places as research professors, then there would seem to also be more places for physicists than mathematicians (who tend to be crowded out by those with more domain-specific knowledge such as computer science PhD's).

13. **Jabotinsky**
September 27, 2008

The odds in math are a lot better. There's been an increase in the number of jobs to go along with the increase in number of PhDs. Generally, if you have a good thesis at a good university, you'll get some postdoc. Americans are favored to some extent due to VIGRE etc. Tenure-track is substantially harder, but it's not like in physics. People who publish interesting stuff generally can get a tenure-track job at some research place somewhere… but you might have to move to Undesirable State University. It's the trade-off to get paid to do your hobby, I suppose. There are of course a few who for some reason or another strike out on the job market, due to interviewing issues or just bad luck. And there are more than a few who end out teaching math in the myriads of liberal arts places. But I think at a Harvard or similar at least 1/2 of the PhDs would be able to continue a research career if they really want to, based on my knowledge of this.

14. **a quantum diaries survivor**
September 27, 2008

Steve, I am in Padova, no connections to Trieste. You are welcome to visit Padova however.

As a comment from somebody living and working outside US, I must say the situation in particle theory is not perceived to be so bad there from here. Probably we have a slow response and old inputs. In experimental particle physics the situation is so different that it probably also help confuse matters – more than a few of my colleagues have found a job in US universities after hitting a wall here. But of course, I am talking about Italy.

Cheers,
T.

15. **John Baez**
September 27, 2008

What about tenure-track physics positions that aren't specifically "in particle theory"? That is, positions where they just want someone with a PhD who can teach undergraduate physics. How many string theorists (or more generally, particle physics) take jobs like this? I wouldn't count this as the equivalent of academic death.

16. **postthis**
September 28, 2008

at most institutions whose math faculty have a chance to survive intellectually, there are similar faculty positions for physics. An Undesirable State University where a math professor has a chance to at least survive intellectually also has physics courses and a physics departments. If they have anything with labs or grad students the physics faculty size grows accordingly.

The observations about VIGRE and Harvard just illustrate that the math and physics job markets have different cycles. There was a time when Harvard math PhD's (in all fields) were in exactly the situation of particle theory today, with postdocs, even for North American graduates, being easier to find on other continents.

17. **anonmath**
September 28, 2008

Well, as a faculty member of Undesirable State University, I would note that most of our faculty have PhD's from Ivy League, Oxbridge, etc type universities, whereas our graduate students tend to get jobs at "four year colleges" which in turn have no graduate students.

So the numbers game works out when most people settle for stepping down a rung.

18. **Thomas Larsson**
September 28, 2008

In a steady-state situation, each advisor will on average give birth to one new advisor in the next generation. So if each advisor on average advises ten students during his/her career, only one out of ten PhD's can become advisors themselves. Assuming that the days of exponential growth are gone forever, I don't see how this can be avoided.

19. **AGeek**
September 28, 2008

I am reminded of Wilczek's [marriage optimization algorithm]. Just substitute "prospective Ph.D. student" for "suitor", "academia" for "courtship" etc.:

> You have to estimate the number N of suitors that you can expect to deal with over your career in courtship. We'll assume that you evaluate them one at a time, and that once you've broken up with one, then that one is gone forever. Then what you should do is this. Evaluate, but do not accept, each of the first N/e suitors. Here e is a number, the base of natural logarithms, approximately 2.7. Then accept the first subsequent suitor who is better than all the earlier ones. That is how to maximize your chance of getting the best possible mate.
>
> For example, if N is 10, then you should evaluate but reject each of the first 4 suitors, and accept to first one after that who is better than them. In my own case, I estimated N=3. I dutifully broke up with my first serious girlfriend, but the second was better, and I married her. It worked out fine.

20. **JC**
September 28, 2008

steve hsu,

In the case of Princeton folks getting particle theory jobs over the last 15 years, it would be interesting to see how many were grad students of Edward Witten and/or had Witten writing their reference letters.

In the case of Harvard and Berkeley folks, were there any particular "superstar" advisors who had a significantly large number of students who got particle theory jobs?

In contrast, do the "non-superstar" advisors at Princeton/Harvard/Berkeley have zero (or one) students who actually got a particle theory job?

It would be interesting to trace the lineage of physics professors from earlier time periods. For example, how many folks who got theoretical physics professors jobs during the 1920's and 1930's, were grad students of Niels Bohr, Arnold Sommerfeld, Max Born, Werner Heisenberg, Wolfgang Pauli, etc …? Did having a physics phd from Goettingen, Munich, Leipzig, etc … from the 1920's and 1930's, have a significant correlation to one getting a theoretical physics professor job?

21. **Jeff McGowan**
September 28, 2008

I've been on a bunch of hiring committees here at "Undesirable State University" in math, and the job market for math is certainly much better than for physics, but it is far from good. Last year we hired two new tenure track people, both with interesting research, one very new, one with a bunch of publications already. We had a couple of hundred overqualified applicants. For most of the 90's, the market in math was worse than it is now – people from good schools with good theses ended up in places they would not have thought of considering when they started grad school. At that time, math was much more tenure track oriented, unlike physics which had always from what I know been very postdoc driven. Vigre changed things a lot, and since those started most good people in math can graduate and get a postdoc, but the tenure track situation isn't great. Not to say you can't get a job, but getting a job at a Ph.D granting institution is really hard. I'm guessing it's going to get worse, since there was a bunch of hiring tenure track since many people retired in the early oughts, and I think that has mostly worked it's way through. In my department I am now basically the senior pure mathematician, and I think it is unlikely given the financial stuff going on that we will be adding any more lines anytime soon (we have added a few in the past 5 years). In any case I'm not going to complain on a physics blog, since I don't think math has ever been nearly as bad as physics. I would think Peter would know about this, as a physics grad. who ended up in a math dept. When I met Peter (what, 7 years after you got your Ph.D?) it was at a math conference and I assumed his doctorate was in math, as I remember he was trying to get me interested in Dirac operators in addition to the Laplacian.

22. **JC**
September 28, 2008

steve hsu,

In your example of UCLA, a keyword search at SPIRES

FIND AFF UCLA AND K THESIS AND DATE AFTER 1993

shows that there were around 20-25 folks who did a particle theory PhD there over the last 15 years. (You are off by a factor of 2).

Your estimate of around 50 particle theory PhDs over the last 15 years, is more consistent with Berkeley

FIND AFF 'UC, BERKELEY' AND K THESIS AND DATE AFTER 1993

In the case of Princeton, there's around 65-70 folks who did a particle theory PhD there over the last 15 years.

FIND AFF 'PRINCETON U.' AND K THESIS AND DATE AFTER 1993

In the case of Harvard, there's around 30-35 folks who did a particle theory PhD there over the last 15 years.

FIND AFF 'HARVARD U.' AND K THESIS AND DATE AFTER 1993

In contrast, a lesser known place like UC San Diego had around 10 folks who did a particle theory PhD there over the last 15 years.

FIND AFF 'UC, SAN DIEGO' AND K THESIS AND DATE AFTER 1993

(All these counts exclude the PhD theses in experimental particle and astrophysics areas).

If you poke around further with similar types of SPIRES keyword searches, you will notice many particle theory PhD folks who did not publish a single paper (besides their thesis).

23. **steve hsu**
September 28, 2008

Comments:

1) re: physics vs math, keep in mind that many smaller schools don't have *any* particle theorists, but all have math departments. Some liberal arts colleges don't have any theoretical physicists, only experimenters.

2) those SPIRES numbers do not sound correct to me. For example, I don't think there have been twice as many Princeton as Harvard PhDs in the last 15 years. I also doubt UCLA produced < 2 PhDs per year over the last 15 years, but I could be wrong. Are you sure everyone's dissertation ends up on SPIRES?

24. **JC**
September 28, 2008

If you want to check the Harvard numbers through a source independent of SPIRES, there's a list of Harvard physics PhD's sorted by year at

http://www.physics.harvard.edu/academics/phds.html

No idea offhand where similar lists (independent of SPIRES) can be found for other universities, short of going through the online library databases of particular universities.

25. **ninguem**
September 28, 2008

Steve Hsu

I don't doubt you, but why do liberal arts colleges prefer experimentalists? Wouldn't they save lab costs hiring theoreticians?

26. **steve hsu**
September 28, 2008

I don't understand the policy, although perhaps they think it is easier to get students involved in exptl projects than in theoretical projects. But of course the easiest projects for students are numerical simulations or writing code 🙂

27. **Matt**
September 28, 2008

Hi

I'm a new graduate student in cosmology-high energy physics, in a Canadian university. When I first met my supervisor, he was very clear about my job prospects; I should be ready not to work in academia and be willing to work in the industry. I was and I'm still fine with that (I'm not even sure I would accept a faculty position if I got offered one … I'm ok with working 70 hours per week, but I don't think I could do that all my life), but I got to admit that I didn't expect my odd to be so low.

Anybody know what most of the phd students who left academia end up doing ? How hard is it to get a teacher job in a small college (non-research) ?

28. **ninguem**
September 28, 2008

Matt,

Who the hell works 70 hours a week? Tenured faculty certainly not.

29. **Peter Shor**
September 28, 2008

Don't small liberal arts colleges need people to *run* the lab courses students take? While there are some theoreticians I would trust to do that, there are quite a few more that I wouldn't.

Also, in reply to Jeff McGowan, I can definitely say that the wave of retirements in math departments is still in progress at some schools, so the current grad students aren't completely out of luck. But I wouldn't expect it to last much longer.

30. **Matt**
September 28, 2008

Hi ninguem,

I think my current supervisor works about that much, and from what I have seen it's not a unique case (one of my undergraduate research supervisor worked during the weekends and on week evenings too, he basically lived in his office). It seems hard to really go home and stop thinking about your research, and I don't think it's a problem that applies only to students …

Not to mention, I don't know if that applies to every department, but in mine the professors are in competion with each other regarding their salary (based on the number of publications, the quality of teaching, outreach …). So that really encourages to do a lot of overtime.

Plus, everyone knows that what drives physicists is prestige, not money, and in order to be the best I doubt that 40 hours a week is enough.

31. **David**
September 28, 2008

This thread leads to my big gripe. A lot of people seem to equate theoretical physics with string theory. There's a lot more out there.

32. **chris**
September 29, 2008

somehow i don't get the point of this constant whining of hep theory people about the job market. somehow it reminds me of my days as a student, when fellow students would talk about which professor has the hardest exams etc. these students were not among the best…

when i got into the phd program (or even more generally into studying physics) i was perfectly aware that not everyone and her neighbor could be a physics professor. but hey, that's a challenge! if you would have told me at the beginning of grad school that the chances of finding a faculty position were about 10% after phd, i would probably have rejoiced that the chance is somewhat realistic. it should be made perfectly clear to all grad students that it won't be a safe and easy ride but honestly, who does not know that? you have to close your eyes really hard.

and finally, if you think that hep-theory is the most competitive field there is i suggest you to think again. i know a bit how things look like in liberal arts and humanities – specifically in linguistics. basically the situation there is that there is no job. period. a 10% chance for phds to get a faculty position would probably be considered paradise in these fields. and their backup options typicall are not as good either (at least here in europe i know that taxi driver is not an unrealistic option).

33. **Fabien Besnard**
September 29, 2008

Chris, who said the competion was fair ? With odds so low as 1/10, this is bound to be quite the contrary. Let me illustrate this. You see 3 people drowning : your child, Albert Einstein, and someone you don't know. If you are given 2 lifebelts, you'll probably save your child and Albert, but if you have only 1, so much for Albert… This is perfectly reasonable from your point of view, but the loss for the society is immense.

34. **Thomas Larsson**
September 29, 2008

Note AE had to take a job as a patent clerk, which is the academic equivalent of drowning. The real anomaly is that Max Planck hired an amateur as his assistent in 1910.

35. **Matt**
September 29, 2008

Chirs said :

" if you would have told me at the beginning of grad school that the chances of finding a faculty position were about 10% after phd, i would probably have rejoiced that the chance is somewhat realistic. it should be made perfectly clear to all grad students that it won't be a safe and easy ride but honestly, who does not know that? you have to close your eyes really hard. "

I'm sure it's easy to say that once you have your own faculty position, or if your confidence and ego was so big that you were already sure you would end up with a faculty position. But the truth is when you're not that confident, you do care about all those issues, and you also care about which teachers give the hardest exams (I did care about that and I graduated first of my promotion).

If for you it was just a big challenge, well good for you, but what if you would have end up spending 10 years at University with no job in the end, was the challenge worth it ? Perhaps then you should have considered your option from the beginning, and this is precisely what this post is for, it's a warning !

36. **Peter Orland**
September 29, 2008

I went into particle theory with my eyes open, fully aware of what the job prospects were (I finished in 1982, when it was just as bad or worse as today). I had help from a few friends, and wrote some possibly decent papers, but the main reason I got a job at a Ph.D. granting institution was determination. During this period, I kept trying to introduce myself to colleagues, despite doors being shut in my face (literally, in one instance).

My case is not very unusual. I know other people who applied every year for faculty jobs, spending their own savings to visit institutions and go to meetings, some being unemployed for a year.

Though luck is certainly a factor, one can improve the odds by persistence. That being said, I don't encourage students to do particle theory unless they can't be dissuaded.

37. **srp**
September 29, 2008

If we had more physicists working in the patent office, maybe we would have fewer stupid patents granted. I'd even pay for time off to do research–the gains in social welfare would be huge.

38. **estraven**
September 30, 2008

The job perspectives in mathematics are better than in physics, and have been for at least two decades as far as I know. Also faster: mathematicians have a nontrivial chance of landing a tenure-track position two or three years after PhD.

I wouldn't be a scientist now if I hadn't gotten tenure before my ovaries were ready for the trashcan.

39. **David McMahon**
September 30, 2008

These numbers are positively bleak, but what can one expect I guess. Physics is such an interesting subject but even with the LHC in operation, society doesn't really value theoretical physics if there are such small numbers of jobs available. However, something students should realize is there are some related positions in DOE laboratories. I have worked at Sandia labs where I was able to do some quantum theory related to quantum computing. There are people doing particle physics at Los Alamos. There are not many positions like this either, but the point is you don't have to go into academia to do physics. And the pay in DOE labs is very good. But despite this it almost seems like going into theoretical physics is like trying out for the NBA. I cannot honestly encourage a young person to consider an advanced degree in physics. The reality is you have to take care of yourself in life and getting a job happens to be central to that mission. I would guess that math is better. People need to learn math for all sorts of reasons so you probably face better prospects with a PhD in applied math.

40. **nbutsomebody**
October 1, 2008

Excellent article, a real eye opener. Is the situation same for other branches of theoretical physics like bio-physics or cond-mat?

41. **Thomas R Love**
October 6, 2008

ninguem asked: "why do liberal arts colleges prefer experimentalists? "

If the local situation (Cal State Dominguez Hills) is any indication, the experimentalists get more grant money. Two are with Super-K and one spends summers at the Jefferson Nat'l Lab. The only one without a grant is a theorist. I'm just a parttime lecturer and not included in the above data.

42. **Alexey A Petrov**
October 6, 2008

I think the data is incomplete — it's probably more relevant to look at
where the person did a postdoc before he/she was hired into that permanent position, not at the place where he/she got his/her PhD. In this case the situation would be even more startling… speaking as one of the "points" making up that study (as well as someone who's been on several search committees).

Also, liberal colleges take both experimentalists and theorists (and this is not reflected in that study too), it depends on a person and on college — last year a person I made an offer to for a postdoc position took a permanent job at a liberal arts college instead. What I mean is that colleges like to have their students to be involved in research. It's much harder to argue that a string theorist would work with sophomores on cutting-edge research problems…

43. **nbutsomebody**
October 9, 2008

In recent years we see another dangerous trend. Within string theory the people who are getting faculties are people who has topcited papers. That is well and good (although what is the relevance and scientific worth of citation in string theory is a big question itself, but lets not ask this at the moment.) However the well-cited papers are with already established names in the field and that helped the lesser known then postdoc/student collaborators to get a job.

Now if one sees the output of junior faculties after they get a job and what they are doing on their own (assuming he/she has not got in job in ivy leagues and not in the same place with his/her previous mentor), it comes out to be really pathetic! Off course there are few "noble" exceptions. But this seems to be a general rule., at least in string theory.

44. **JC**
October 9, 2008

nbutsomebody,

For these "pathetic" string theorists who had previously high citation counts and who later subsequently produced mediocre to dreadful work as junior faculty, what percentage were later denied tenure?

45. **nbutsomebody**
October 9, 2008

JC,
Surprisingly almost nobody !!!! and they seem to have a lot of clout too !!

Deal Breaker

September 30, 2008
Categories: Uncategorized

Discussion of quantum gravity at a level similar to that of parts of the professional physics community makes it to prime-time TV:

Update: I should have credited where I first saw reference to this (no, I don't normally watch this show…), it was at Capitalist Imperialist Pig. If you are having trouble with the embedded link to the video, you might have better luck following his link to the cbs web-site and seeing what you can find there….

Update: Lubos is claiming credit for this, implying that he's the model for Sheldon. He has a point. I always thought that the string theory community should worry about the implications of having Lubos represent them on the web, now there's prime-time TV to think about.

Comments

1. **Jeff McGowan**
   September 30, 2008

   OK, so I hope Lee and Peter get some royalties for this stuff 🙂 Actually, in relation to the previous post about the job market, I guess a lot of recent physics Ph.Ds are now writing for television?

2. **Per**
   September 30, 2008

   Not available….

3. **Peter Woit**
   September 30, 2008

   Hmm, works for me, not sure why some people are having trouble with this.

4. **Uncle Al**
   September 30, 2008

   Firewall must be set to allow embedded objects, mime objects, javascripts… mobile code in general through.

5. **JC**
   September 30, 2008

   Television writers are a dime a dozen. (Though one could argue the same for many other professions, including physics and math).

   All it takes is somebody reading several books (both pro and con) on string theory, to write it into a tv or movie script. Even an episode of CSI mentions string theory in a completely misleading and convoluted manner.

   http://en.wikipedia.org/wiki/The_Theory_of_Everything_(CSI)

6. **Anthony**
   September 30, 2008

   I think the link only works in the US ;-(

7. **Vince**
   September 30, 2008

   Peter,

   Can you please provide us with the link to that clip?

   Thanks!

8. **Kea**
   September 30, 2008

   The CBS site says that the content is unavailable outside the U.S.

9. **capitalistimperialistpig**
   September 30, 2008

   TBBT is probably the only television comedy ever that consistently gets the physics right. The physicist characters are broadly drawn comic stereotypes, but stereotypes we can recognize from our experience: The nut job you shared an office with in grad school, the slightly loopy prof down the hall, that wacko chick from Dabney.

   But not, of course, ourselves.

10. **capitalistimperialistpig**
    September 30, 2008

    (continued, sorry)

    Note, e.g., the DSR reference in Leslie's argument.

11. **Amos**

September 30, 2008

"TBBT is probably the only television comedy ever that consistently gets the physics right."

That's priceless.

12. **anon.**
September 30, 2008

Yeah, it's nice that Sheldon gives precisely the right response to the absurd claim that LQG calculates black hole entropy correctly. But what's with "Barbero-Immirzi parameter" being written on the whiteboard behind them? Was Leslie giving Leonard a lecture earlier in the evening?

13. **David McMahon**
September 30, 2008

I think the clip is hilarious. For the vast majority of the people watching the show, the discussion is going to sound like a bunch of nonsense but hey at least we're getting physics into the popular culture. Great timing with the LHC!

[off-topic material deleted]

14. **Fabien Besnard**
October 1, 2008

We I read this post and the comments I thought it was some form of elaborated joke (I could not watch the podcast), but I went to the CBS site and saw that there is really a show about theoretical physicists in the US ! Something like this would be completely unbelievable here in France. Does it mean that americans are better educated in science ? That would not surprize me. I also had this feeling by comparing books that popularize science : they tend to be of a much better quality in the US.

15. **Chris Oakley**
October 1, 2008

Expect more of this kind of thing. With very few jobs for particle physicists in academia, and now much fewer jobs in Wall Street, scriptwriting for TV may start to look very attractive (… god forbid that we should ever be required to do anything *useful*)

16. **quark**
October 1, 2008

This link works in Europe

http://www.youtube.com/watch?v=XOwS0N3sX_M

17. **a mathematician**
October 1, 2008

Wow, that clip was painfully unfunny. Maybe they really are hiring physicists to do their writing.

18. **Kea**
October 1, 2008

Heh, thanks You Tube!!! LOL! That was hilarious. And the script is simple enough that I'm sure anybody gets it – no physics knowledge required at all.

19. **MathPhys**
October 1, 2008

You can watch it on Motl's blog. Yes, it was written by physicists. Very stale.

20. **milkshake**
October 1, 2008

No amount of beer can make this show tolerable. Whats genuinely needed is a sitcom about Lubos' struggles with the confederacy of dunces.

21. **Will**
October 1, 2008

Dear Peter,

Why are you always concerned about public perception? Nobody is an authority in science and good scientists are not doing science to sway public perception. I honestly think your feud with Lubos Motl is nonsensical.

Motl does not represent string theory but his one views and prejudices.On the other hand, you have no better things to do than just rant against string theory and its public perception and so on. It

Together, you have done more harm to science by trying to sway public perception in one direction or the other.

Will

22. **Low Math, Meekly Interacting**
October 1, 2008

That was…interesting. I mean, on the one hand, I'm psyched something like this can even exist, but on the other, well, I'm with the "it's not very funny" crowd above.

Also, I thought the String Theorist's debate skills were uncharacteristically anemic. I mean, wouldn't the string theorist have mentioned sparticles showing up at the LHC, or RS resonances/KK towers due to large extra dimensions, or some other seemingly typical example, as a rebuttal to the LQG testability claim, rather than having such a weak riposte? Also, I should think an LQG theorist would know that ST can also be used to calculate the entropy of at least some varieties of black holes, and hence such a claim of superiority would have been entirely unimpressive to a string theorist. She seemed entirely ignorant of this.

If I can think of these things, I'm sure the writers could easily have. If you're going to make a stab at comédie vérité, going only halfway kind of kills the whole effort, IMO.

23. **Just a Note**
October 2, 2008

I sometimes like to poke fun at people, but in all honesty, most of the physicists and mathematicians I have encountered are not at all like the characters portrayed on this show.

Sure there are little quirks, and certainly some of the debate around LQG and String theory is juvenile (or at least passionate), but the community itself seems full of a lot of well-rounded, well adjusted, principled people (and Peter is certainly one of them).

Intelligence, by its statistical nature, is a rare gift, and I have come to understand that "nerds" get picked on more out of jealousy than any other reason.

So I think that at some level the fact that a show like this has managed to make it into the popular media should be viewed as a complement to the community derived from the underlying respect that most people have.

24. **capitalistimperialistpig**
October 2, 2008

Just a note –

Hey, it's called humor. Comic characters are always exaggerations. Sure there are lots of normal, well-adjusted, physicists and mathematicians – they aren't very funny, though.

But if you have spent a lot of time around physicists and mathematicians and not met people who remind you of the characters in TBBT, I'm surprised. I surely have.

To me, the humorous depiction of scientists in TBBT is not mean spirited. They are odd but human people dealing with the usual human problems in an odd and slightly exotic context.

Check out Motl's take on the show though, especially the fury he whips himself into against the physicist character who espouses LQG – simply because the writers chose to associate that characteristic with her for this episode. Now that's odd, human, and scary in Spanish Inquisition sort of way.

25. **Plank**
October 2, 2008

Not very funny but replace LQG and ST for 2 religions and be amazed.

26. **Shantanu**
October 6, 2008

Peter or others, any speculations on tomorrow's Nobel Prize?
Thanks

27. **diana**
October 7, 2008

Guys,

"really a show about theoretical physicists in the US ! Something like this would be completely unbelievable here in France"

My dear friend, the show isn't about theoretical physics. Since sarcasm doesn't work on the internet, let me give you a hint: the show is about sex. The vehicle is theoretical physicists.

I think it's a terrific show, very sweet and very funny. It no more puts down theoretical physicists than it puts down cute blondes. I can claim total objectivity because I am neither a theoretical physicist or a cute blonde.

2008 Physics Nobel Prize

October 7, 2008
Categories: Uncategorized

Half of this year's Nobel Prize in physics has been awarded to Yoichiro Nambu for his work on spontaneous symmetry breaking, the other half to Kobayashi and Maskawa for the CKM matrix as an explanation of CP breaking. A detailed explanation of the scientific context of the prizes is here.

The prize for Nambu is well-deserved and rewards one of the deepest, surprising, and most important ideas in particle theory, that of spontaneous symmetry breaking. In 1960 Nambu realized that non-invariance of the vacuum state under an axial symmetry could explain the existence of pions and determine many of their properties. He also realized that this phenomenon is closely related to what happens in various condensed matter models (including the BCS model of superconductivity), where the ground state is not invariant under a symmetry of the theory. Nambu has often been mentioned as a candidate for the award, and it's surprising that it has taken nearly 50 years for it to come about. I'm a bit curious about how often Nobel Prizes in other fields are awarded for work done a half-century ago. Unfortunately the rather difficult times particle physics has found itself in the last few decades may mean that the best way for a particle theorist to get the prize is to have been around during the field's heyday, and to remain in good health.

The Kobayashi-Maskawa award is a somewhat less obvious one, since it didn't involve a surprising breakthrough, and it is about something completely different than Nambu's work. In the early-mid 60s, starting with work by Nicola Cabibbo, it had been shown that (in modern language…) flavor mixing matrix for two generation models of the weak interactions is governed by a single angle, now known as the Cabibbo angle. In 1972, Kobayashi and Maskawa pointed out that for three generations the matrix is determined by three angles and a complex phase. The complex phase makes this a possible source of CP violation, and it seems to be the main if not only source of observed CP violation. The Nobel committee text makes the claim that:

> This is in fact a result known in mathematics since around 1950, but the contacts between mathematics and physics were not great around 1970.

This is a rather odd description of the situation, since the mathematical facts involved here are quite simple ones about which 3×3 unitary matrices satisfy certain conditions, and presumably could have been derived by mathematicians who first worked with such matrices in the 19th century if this particular condition had come up. I can't think of anything mathematicians learned around 1950 that is needed to solve the problem, and, once stated physicists could easily solve it without help from mathematicians (who perhaps would have been more likely to just have been a hindrance in this case…)

The quark mixing matrix embodies most of the unknown parameters of the Standard Model, and as such is a crucial object for experimental studies of particle physics. Because of this, the KM paper is the second most highly cited paper in particle physics (after Weinberg's "A Model of Leptons"), but this ranking doesn't reflect the depth or importance of the ideas.

Lots of other blogs are also covering this. Tommaso Dorigo points out that it's a bit anomalous that a Nobel Prize for the CKM (Cabibbo-Kobayashi-Maskawa) matrix doesn't include Cabibbo, who is still around. Lubos Motl thinks that what is important here is that Nambu is also a string theorist, and that one of the people on the committee making this choice was a string theorist, Lars Brink.

Update: Lots of coverage of this in the press. Michio Kaku has an editorial in Forbes, where, like Lubos, he sees the real significance as being that Nambu is a string theorist:

> And there may even be a theory beyond the Standard Model, a true theory of everything that can unify all forces. It's called string theory.
>
> Not surprisingly, one of the founders of string theory is Professor Nambu, a newly minted Nobel Laureate who has years of research ahead of him. The best is yet to come.

   October 7, 2008

   > it's surprising that it has taken nearly 50 years for it to come about. I'm a bit curious about how often Nobel Prizes in other fields are awarded for work done a half-century ago.

   van Vleck

2. **Peter Woit**
   October 7, 2008

   Thanks Warren,

   That's also physics, but it's true it was awarded at a time (1977) when particle physics was a lot healthier, and there were a lot of recent advances that could have been awarded prizes.

   I was a student at Harvard at the time, and from what I remember, the conventional department celebration was a bit impeded by the fact that van Vleck was long retired and gone, I heard rumors that no one even knew how to locate him and contact him….

3. **Pablo**
   October 7, 2008

   On his blog Lubos says: "Nambu, a Japanese-born American, is often described as one of the "fathers of string theory . . But the Nobel prize is formally given to him for a comparably famous discovery ", which implies that the REAL reason for the Nobel is not that discovery, BUT his work on string theory . . . interesting lecture of the events.

4. **helvio**
   October 7, 2008

   I don't agree with your opinion that the work of Kobayashi and Maskawa (KM) is not a breakthrough. As I see it, their suggestion was: 3 families => CP-violating phase => matter/antimatter asymmetry. Only 2 families were known by then, so adding a 3rd family is for me a very bold working hypothesis, albeit a very simple one. And this is because its consequences are not only physically relevant but also philosophically profound. I put this breakthrough in par with the proposal of strangeness (2nd family) to explain the pattern of particles in the 60's. It was also a very simple working hypothesis, but which makes a lot of sense theoretically when you see its consequences, and it fits the data when you later test it.

5. **Peter Woit**
October 7, 2008

helvio,

Sorry, I agree that postulating a strange quark (2nd generation) may have been a bold hypothesis, but once you have two generations, postulating a third just doesn't seem that bold.

6. **JC**
October 7, 2008

Didn't Chandrasekhar get his Nobel Prize (in 1983) for work he did in the 1930's?

7. **helvio**
October 7, 2008

What I mean is that the boldness is not just in the hypothesis, which is pretty easy to make, but in suggesting it and showing explicitly that it leads to a profound conclusion, like CP-violation. The mathematics of 3×3 matrices is very simple, indeed, but it's the chain of arguments in their paper that matter, and the insight of recognizing that it's a very important discovery and not a triviality. Even though Lorenz wrote down his transformations, it was Einstein who established the logical sequence of arguments that make them a consequence of a small number of very basic but profound principles. Even though 't Hooft claims to be the first to have calculated the beta function of QCD, he thought it was a triviality; but for Gross, Wilczek, Politzer it wasn't trivial, they recognized its physical relevance. Every first-year grad student is able to do the same calculation, it's a simple one, but the real physics is in the interpretation, and that even the best can miss. Kobayashi and Maskawa interpreted rightly the relevant physics behind such a simple hypothesis, that's why I think they fully deserve the prize!

8. **Steve Myers**
October 7, 2008

Isn't the problem for Cabibbo is that they won't give the prize to 4? Same with Dyson.

9. **Cormac O Raifeartaigh**
October 7, 2008

I absolutely agree – while a couple of colleagues are suspicious of a particle physics prize in an area that seems obscure to them, given the year that's in it (LHC), I think the prize for Nambu is well-deserved and decades overdue (compare with Saalam and Glashow for example).

10. **Cormac O Raifeartaigh**
October 7, 2008

P.S.
I mean I absolutely agree with the post above, not the comments. That said, I too think it's most unfair that the third musketeer of the CKM mechanism was left out – that damn rule

11. **JC**
October 7, 2008

By a similar argument, should Ludwig Faddeev have received the 1999 Nobel Prize (with 't Hooft and Veltman) in analogy with Cabibbo vs. K + M ?

12. **spear mark**
October 7, 2008

Well, the value of KM is related to the value you place on getting a better handle on why we are made of matter, and not some sort of thin gruel of photons, electrons, and positrons that would have resulted if matter and antimatter were completely symmetric.

Cronin and Fitch got the price in 1980 or so for the experimental discovery of CP violation, and it is very appropriate that KM get a piece of the prize for the phenomenology that most closely describes the experimental result. Their phenomenology led to more experimental work… the Fermilab and CERN experiments on direct CP violation and the Babar/Belle experiments. That pretty much proved that KM were right, and so the timing of the prize to them is just about right.

Of course, from a theoretical perspective, KM's math is trivial and so their work is not so impressive. But in contrast to string theory, KM's work is closely tied to the physical world, which in some people's mind is more important than impressive mathematics.

Cabibbo's work, I thought, was not easy to separate from other similar contributions, although he got the name on the parameter.

To me the surprise was Nambu. I'm sure he's a great guy, but there have already been prizes to Glashow, Weinberg, Salam, t'Hooft, and Veltman for similar work. Actually, there are way too many prizes to theorists for the Standard Model, and too few to experimentalists.

How about Prescott for polarized electron scattering? Or a group for 3 jet events? The long b lifetime? Unfortunately, in the current climate, there is a theology that nothing happened in experimental particle physics since 1974 or so. That is merely theology, however. The actual experimental work of the last 35 years is crucial and innovative, just undervalued.

13. **A**
October 7, 2008

The "Nobel prize that Kobayashi-Maskawa will get within 3 years" was announced in a my comment on NEW 2 years ago, see href="
http://www.math.columbia.edu/~woit/wordpress/?p=465#comment-16690.

The reason why Cabibbo is excluded is that two-generation mixing was already mentioned in a footnote in an earlier paper by other authors (unfortunately I forgot which paper).

14. **Meow**
October 7, 2008

Clicking on the Motl link displays a Woit-bashing page

15. **cyd**

October 7, 2008

Weird. Why were Goldstone and Cabibo left out? If it's due to the only-three-per-year rule, surely they can give it to, say, Nambu and Goldstone this year, and to Cabibo, Kobayashi, and Maskawa next year.

16. **cyd**
October 7, 2008

> I'm a bit curious about how often Nobel Prizes in other fields are awarded for work done a half-century ago.

Abrikosov and Ginzburg finally received their prizes only in 2003, for the profound work they did in the 1950s.

Incidentally, the 2003 prize would have been Landau's second Nobel prize—Ginzburg's prize was for the Ginzburg-Landau theory—if the committee had been a little more timely, and if he had live longer. As it turned out, Landau had his famous and tragic car accident 1962; the Prize was quickly given to him in that year, for his work on superfluidity, for fear that he would die without being honored.

17. **Coin**
October 7, 2008

Isn't the problem for Cabibbo is that they won't give the prize to 4? Same with Dyson.

I'm told that this was also a problem in medicine this year, with the Nobel Prize going to two members of the team that discovered HIV causes AIDS, and also the guy who discovered HPV causes cervical cancer; with some third guy who ran a separate team with a claim to have codiscovered HIV being left out. It's not entirely clear whether this choice was actually a determination that the third guy's claim to HIV priority was illegitimate, or whether they just ran out of slots.

18. **An italian**
October 7, 2008

CABIBBO:
NOBEL!!!
NOBEL!!!
NOBEL!!!

19. **dir**
October 7, 2008

the point of km's work is cp violation mechanism, they predicted the third generation fermions. this work is very important, but also a kind of easy, and km themselves are not comparable with nambu who is really great.

as for the work of quark mixing, not only cabibbo, gell-mann and levy had a similar work in 1960, their paper should be the following one, nuovo cimento 16 (1960) 705.

20. **Anonymous**
October 7, 2008

Increasingly these days I'm more and more skeptical of the Nobel prize's worth… I mean, if you do phenomenal work why shouldn't you be recognized for it (i.e. case of Cabibo)? what exactly does a (rule on) limitation on number of recipients have anything to do with the scientific value of the research?

And furthermore, the Nobel Committee seems to think the universe of academic research – perhaps less so literary – revolves around their validation… does it actually?! The Committee/s awarding the prizes have had a (seemingly unending) streak of pompousness on how they perceive themselves as 'judges of value' when they assign credit / value to other people's research.

Bottom line: A number of their decisions over the years haven't been as objective as one would hope to believe for so prestigious a prize; and some of their awards have been based on factor/s not directly associated with strictly intellectual / academic merit.

(I won't mention specific cases because would start a controversy which I don't particularly want to get into).

21. **anonymous fool**
October 8, 2008

The most rescent Bulletin of the AMS contains an interview with Atle Selberg, in which he comments about prizes.

http://www.ams.org/bull/2008-45-04/S0273-0979-08-01223-8/S0273-0979-08-01223-8.pdf

Here are some excerpts:

"Question. You have received the Fields Medal in 1950. You also have received the
Wolf Prize in 1986. Three years ago the Abel Prize in mathematics was established. What are your thoughts on these types of prizes in general—do you think they have a positive effect?
It does not advance science. No one does scientific work because there exist
prizes—I cannot imagine that. A prize will make one or more persons happy, but
it also gives rise to disappointment among many people, I would imagine.
Question. But do you believe it serves mathematics in the sense that it creates
publicity and thus raises the awareness of the public?
Whether it serves mathematics to get publicity is an open question.
Question. Coming back to the Abel Prize: what are your thoughts on the awards
so far?
I proposed Serre and Grothendieck as candidates for the first award in 2003, as
some people I would have preferred. I thought that Serre would get it, and that
also happened. Since then I have not made any proposals. Concerning the Abel
Prize, I have a somewhat ambivalent attitude. Let us consider the Nobel Prize:
I think it has caused some unintended harm by creating a strong distinction inprestige between those that get the prize and others, who certainly deserve it, but do not get it. There are, of course, some people that so clearly outshine others that the award is uncontroversial; in physics, for example, you have Einstein, Bohr,Heisenberg, Dirac, and a few others. However, since the prize is awarded yearly, it is inevitable that the distinction will not be so clear. . ."

22. **Thomas Larsson**
October 8, 2008

Coin:

– When it comes to figuring out who made seminal medical discoveries, we in the Nobel committee are the world experts, not a bunch of laywers, says Bertil Fredholm, chairman of the Nobel committee at the Karolinska institute.

23. **DB**
October 8, 2008

"It's not entirely clear whether this choice was actually a determination that the third guy's claim to HIV priority was illegitimate, or whether they just ran out of slots."

You're referring to Robert Gallo whose role in the discovery of the Aids virus was long the subject of major controversy. Anyway, not a very good day for Italians (Cabibbo) or Americans of Italian descent (Gallo).

24. **Christine**
October 8, 2008

At least two Brazilians physicists also "missed" receiving the Nobel prize:

-Mario Norberto Baibich in 2007 for the Giant Magnetoresistance effect, see here (he was the first author of the paper describing the effect).

-César Lattes: although he was the main researcher and the first author of the Nature paper on the meson pi, Cecil Powell was awarded the Nobel for it in 1950; see here.

According to an interview with Lattes:

Question: Do you think that the fact of being Brazilian contributed so that another researcher gained the Physics Nobel in the research where you have participated?

CL: Although the judge commission was formed by Englishmen, I believe that it was not my nationality that weighted in the decision of the winner. As much in the discovery of pion, in 1946, as in its artificial creation, in 1948, I had the contribution of the Giuseppe Occhialini. He was the one who should have received the prize. And, in 1950, who took the prize was the Cecil Powell, who also participated in the work. But forget about this. These huge prizes do not help science.

25. **Shantanu**
October 8, 2008

BTW this is the first time IIRC, that the names of the nobel committee
(at least in Physics) has been made public. Is that right? (or in previous years also the committee has been public?)

26. **Pankaj**
October 8, 2008

One could perhaps argue that KM deserved Nobel prize more than Nambu. KM showed how CP-violation could be explained. They gave a theoretical idea for an experimental fact. This idea could have been proposed by some else, but they were the first. This happens quite often in science. Even the experimental discovery of CP-violation could have been done by someone else. Their case is more like Glashow whose ideas have experimental support; while perhaps there is no experimental support for the ideas of Weinberg and Salam for which they got the Nobel Pize. Nambu's case might be more like Weinberg and Salam. However, it is also true that Nambu, Weinberg and Salam are held in higher regard generally for their multifaceted contribution to physics and perhaps because their contributions have been more mathematical. But in the end,
what may count is the discovery of the
secrets of nature rather than how
mathematically inclined your work is.

27. **Thomas Larsson**
October 9, 2008

Shantanu, the members of the Nobel committees have AFAIK always been public. That would be difficult to keep secret, given that the committee members can attend the Nobel ceremony and banquet, with TV survey and everything. However, the protocols from the committee meetings are kept secret for at least 50 years, so you have to wait to see who voted for whom.

28. **MathPhys**
October 9, 2008

So why not J Goldstone precisely? I thought it was always known as the Nambu-Goldstone mechanism. Maybe Goldstone didn't publish?

29. **Shantanu**
October 9, 2008

Thanks, Thomas. Do you or anyone else knows why S.N. Bose (of Bose-Einstein statistics) was not awarded the Nobel prize and if
he was voted ? (as I presume he would have been shortlisted more than
50 years ago that the protocols must have been made public)

30. **Thomas Larsson**
October 10, 2008

I don't know specifically about Bose, but an interesting account of the politics surrounding the early Nobel prizes for QM can be found here.

31. **Travis**
October 10, 2008

Just a nit to pick a few days late:

From SPIRES current citation counts, KM is the 3rd most cited paper in HEP, after Weinberg and then Maldacena. And of course the PDG's Review of Particle Physics dwarfs everyone with well over 20,000 to all versions.

I suppose this error is my fault, since we haven't posted new all time lists recently, and the "pass" happened recently. However, note that you can, for the most part, do this yourself live:

Find topcite 3000+ and sequence by citation count [SPIRES]

Which will give you _current_ papers over 3000 citations in order.

Mind you, this has nothing to do with the Nobel. Clearly the order of these papers, and the exact number of citations at this point, is more of a reflection of the community than saying anything too important about the papers. This high on the list there are, I hope, better ways of assessing the impact of a paper [this is probably true in general, but that's another story…].

32. **MathPhys**
October 10, 2008

There is some serious science fiction in the 3000+ list.

News From Various Fields

October 8, 2008
Categories: Uncategorized

The hypothetical field with one element (known as F_{un}) now has its own blog, ceci n'est pas un corps. Among the many things of interest, there's a link to a video of Alain Connes explaining his recent paper with Consani and Marcolli on the subject. This is part of a project at the Journal of Number Theory to get authors to produce video introductions to their papers.

Over at the n-category Cafe, there's a discussion of Alan Weinstein's new paper on The Volume of a Differentiable Stack. A stack is a sort of replacement of a quotient space, of a sort that allows one to keep track of the fact that different points may correspond to different stabilizers. One would like to naturally assign as many properties of spaces as possible to stacks, and one interesting question is how to count sizes, for instance how to define volumes. If everything is finite, it turns out the thing to do is to count points by dividing by the size of the stabilizer, but something much more subtle is required in the differentiable case, where the sets involved are all infinite.

The last year has seen a flurry of activity on hep-th that goes under the name of the "M2 mini-revolution", or maybe AdS4/CFT3. I'd been waiting for some expository accounts of this to appear to read more about it, and there's a new one here. It includes graphs that show a total of 157 papers on the topic with 223 authors. Things didn't really get started until this past spring, with the number of papers peaking at 40/month in July, with 53 new authors joining the game that month. Since then, the trend is downwards, with 21 paper in September. Thomas Klose does a good job of surveying the subject and what has been learned about it. The only applications mentioned are in the last line of the last page, which refers to possible future uses in condensed matter physics.

The 2009 fiscal year has started already, with no federal budget in the US. The idea now seems to be to wait until it's half over next March or so, then have the new administration put together a 2009 budget and a 2010 budget simultaneously. In the meantime, a continuing resolution has been passed, under which money can be spent at the level of the 2008 budget. This is pretty bad news for US HEP, since the relevant 2008 level was one involving serious budget cuts. The effect of these was mitigated by a later supplemental appropriation, and that can evidently be used to keep the Fermilab budget at a level such that layoffs can be avoided (see discussion from Oddone here). But it remains completely unclear what will happen to the lab a few short months from now.

This past weekend the Skeptics Society at Caltech cosponsored with the Templeton Foundation a conference on Origins: the BIG Questions. The afternoon session was devoted to discussing God, the morning featured physicists promoting anthropics. An account of the talks is here, including this about Lenny Susskind's talk

> The conference began with a real bang – the Big one of course, and a lesson on what preceded that singularity as best understood today by physicists. Susskind condensed his Stanford undergraduate cosmology course into a beautiful one-hour primer on the universal constants (Planck's, gravitational constant, speed of light…) that support life. It turns out that life can only evolve and survive in a narrow window of values for these constants, a fact that Christians have recently embraced as proof of an intelligent designer. But Susskind explained how quantum mechanics support the existence of a multiverse that regularly spawns new universes with different sets of constants, making it inevitable that our comfy universe should appear. (I asked him whether a future day Dr. Strangelove could create the conditions that spawn a new universe in our own – he said no, but without a compelling explanation.)

and this about Sean Carroll's:

> Caltech physicist Sean Carroll delivered a great talk on time's arrow – how time fits into the universe and how it cannot exist without fluctuations in entropy. He explained how the physical constants give our universe just the right amount of clumpiness so that time can flow, and he presented an alternative theory – consistent with quantum mechanics – on how universes can bear "babies" with differing constants.

After Carroll, Caltech biologist Christoff Koch explained how:

> consciousness may in fact entail a new force not yet discovered by physicists.

Update: Sean has a posting about the "Origins" conference, mainly devoted to explaining what was wrong with the presentation of a crackpot who was speaking as part of the religion segment.

   October 8, 2008

   Look at

   http://xstructure.inr.ac.ru/x-bin/theme3.py?level=1&index1=461794

   for papers on "m2 mini-revolution".

2. **Bee**
   October 8, 2008

   Gee, I didn't know Sean makes in baby universes too. This topic will eventually fly just because the name is so cute.

   A friend just mentioned he is at ahoop and I was wondering what on earth that's supposed to be. Seems it is the meeting you are referring to, probably an abbreviation of 'Ahrenshoop'.

3. **K.B.**
   October 8, 2008

   What could Christoff Koch possibly mean? I've taken one of his classes at Caltech, and he seems like a reasonable guy, but:

   "…consciousness may in fact entail a new force not yet discovered by physicists…"

   …seems like a pretty dangerous/irresponsible statement to me.

4. **Peter Woit**
   October 8, 2008

Bee,

Yes, those slides are from the Ahrenshoop conference, more here:

http://people.physik.hu-berlin.de/~ahoop08/program.shtml

although the links seem to be temporarily broken…

5. **Michael T.**
   October 8, 2008

   I attended the Origins conference over the weekend and I must say all of the speakers were quite good. If my recollection is correct, I do not think Dr. Koch made the claim that consciousness is a fundamental property but rather posed it as a question and also considered whether consciousness was an emergent property of brain structure and neurochemistry.

   Susskind was more into the baby universe thing and heavy on the Landscape. What did take me by surprise was the number of possible universes in string theory. Last time I checked it was 10^500 and in Susskind's talk the number seems to now be 10^1000! I think it's getting kind of out of hand.

   The whole "God" discussion was rather pointless in my view and science can offer very little insight really. You either believe or you don't, simple as that.

6. **K.B.**
   October 8, 2008

   "…I do not think Dr. Koch made the claim that consciousness is a fundamental property but rather posed it as a question and also considered whether consciousness was an emergent property of brain structure and neurochemistry."

   Sounds considerably more reasonable. Thanks Michael!

7. **Esornep**
   October 9, 2008

   Bee said: "Gee, I didn't know Sean makes in baby universes too. "

   See his beautiful and extremely clear paper with Jennifer Chen, in hep-th 2004 on arxiv.

   "This topic will eventually fly just because the name is so cute. "

   Err, it has been around for many years already, eg Farhi and Guth back in 1987.

8. **Harry**
   October 9, 2008

   "ceci n'est pas un corps" is a nice reference title to belgian surrealist painter Rene Magritte, I think.. quite f_unny

9. **Chip Neville**
   October 11, 2008

   Peter,

   Brian Greene was talking about string theory today on "Bob Edwards Weekend," a public radio show. The URL is http://www.bobedwardsradio.com/bob-edwards-weekend/. You might be interested in his take on verifiability, and whether or not string theory is a theory or philosophy.

   Best,
   Chip Neville

10. **Tyler**
    October 14, 2008

    Hi Peter,

    (This is my first post to this blog, hoooooray!)

    I've been reading through your blog and found this comment from you on http://www.math.columbia.edu/~woit/wordpress/?p=673

    "I'm working on some new ideas (involving representation theory) about the mathematics behind the BRST formalism and how to handle gauge symmetries. I have a partially written paper now, hope to get something finished and done this summer."

    So, what's the deal? Summer is over! 🙂
    Will we see any of this on the arxiv? I can't wait!

    All the best,
    Tyler

11. **Peter Woit**
    October 14, 2008

    Tyler,

    Well, it's still a partially written paper, I fear. The problem is that my understanding of this keeps changing, just when I have something nearly finished, I realize there's a better way of thinking about it…

    Next week I'll be giving a talk at Dartmouth related to this work, the title is "BRST and Dirac Cohomology". I'm making up some slides, and hope to put those on-line, may also try putting up some blog entries soon that would explain some of the physics and mathematics background.

12. **Cplus**
    October 15, 2008

    The Harvard Endowment Fund is trying to sell a portfolio including a variety of venture capital and buyouts funds which could be one of the largest secondary sales of all time. As reported by the NYT, unconfirmed by the University.
    University scholars, now might be a good time to prepare for some serious belt tightening, if not already done. With the trouble all state budgets have now, especially California, it is unlikely that academics at State Universities will fare better.

13. **Shantanu**
    October 20, 2008

    Peter, have you looked at the slides of Aspera (european priorities in astroparticle physics) meeting held recently in Brussels

14. **Peter Woit**
    October 20, 2008

    Shantanu,
    I did see that, but astro-particle physics is just not something I know much about. For informed commentary on this topic, you need to look elsewhere….

The Landscape at Princeton and Harvard

October 15, 2008
Categories: Uncategorized

String theory in general seems to have gone very quiet recently, but attempts to intensively promote the string theory landscape view of fundamental physics show no signs of slowing down at all. The Princeton Center for Theoretical Science is running a year-long program Big Bang and Beyond, partially funded by the D.E. Shaw hedge fund. Next month there will be a program on "String Landscape: Examining how the string landscape alters approaches to fundamental physics and cosmology", featuring a public lecture by Leonard Susskind.

A couple weeks ago at Harvard, Frederik Denef gave a colloquium promoting Landscape research. The talk concentrated on making an analogy between the string theory landscape and condensed matter phenomena, relating this to recent attempts to use duality to study 3d CFTs of interest in condensed matter physics. Frederik also described a web-site (2ndcheek.com) which explains how string theory proves the Bible is right. Unfortunately this web-site no longer seems to be in operation.

Also at Harvard, or at least across the street, landscapeologists and other string phenomenologists have taken over the Clay Mathematics Institute this week for a workshop on Stringy Reflections on LHC, yet another attempt to make the case that string theory has something to say about the LHC, despite strong evidence against this (see for instance David Gross's talk at Strings 2008). Some of the slides from the talks have begun to appear on-line, and Michael Dine's landscape talk is here.

Update: David Berenstein has a report from the conference in Cambridge here.

Comments

1. **Robert**
   October 16, 2008

   Of course, on the internet, nothing is ever lost:

   http://web.archive.org/web/20070507032956/www.2ndcheek.com/stringtheory.htm

2. **Jason**
   October 16, 2008

   > "Frederik also described a web-site (2ndcheek.com) which explains how string theory proves the Bible is right."

   As I read it (thanks for finding that, Robert) it's more about how the Bible proves string theory is right than vice versa. With such sites — and there are many of them — it's always the religious tract proving the science. The Koran purports to prove not only string theory, but dark matter; supersymmetry; big bang; black holes; worm holes; GUT/ToE…

3. **changcho**
   October 16, 2008

   "Examining how the string landscape alters approaches to fundamental physics and cosmology", featuring a public lecture by Leonard Susskind."

   I went to a popular talk Susskind gave at Foothill College here in the Bay Area a couple of weeks ago and he talked about the Landscape as if it were already a non-controversial, accepted fact.

4. **Peter Woit**
   October 16, 2008

   Thanks changcho,

   I'm curious what sort of reaction Susskind will get in Princeton to his efforts to promote the Landscape. Until recently, this wasn't at all popular there, but this year Witten is gone (at CERN), and an influential Landscape proponent (Arkani-Hamed) may now be the dominant personality.

   My impression is that views on the landscape among string theorists remain definitely mixed, with physicists who are not string theorists very much unconvinced. Susskind's promotional efforts seem to me to have had the effect of convincing many people that string theory has gone off the rails into pseudo-science.

5. **anonymous**
   October 16, 2008

   Dear Peter,

   It may be worth emphasizing that the Princeton
   workshop is not particularly focused on the
   landscape research you are criticizing.
   It started with observational
   cosmology, then covered inflationary theory, and later
   is moving toward more and more speculative subjects
   including measures on the
   landscape, spacelike singularity resolution
   and ekpyrosis, etc..

6. **Peter Woit**
   October 16, 2008

   anonymous,

   Thanks for pointing this out. Next month's symposium on the Landscape is only one part of a larger program. I'm curious if you or anyone else knowledgeable about that program would be willing to try and characterize to what degree its participants are sympathetic to the point of view Susskind is promoting. For instance, if changcho is right that he's claiming the Landscape is now accepted fact, to what extent does that correspond to reality?

7. **Princeton Undergrad**
   January 25, 2009

   I don’t know much about the larger ideological currents, but Susskind didn’t even mention the landscape in his public lecture. He talked about the cosmic censorship conjecture, and touched on the holographic principle. I would note that the Center For Theoretical Science is headed partly by Paul Steinhardt, who has been very critical of the landscape idea as “unscientific.”

Princeton Companion to Mathematics

October 15, 2008
Categories: Uncategorized

I just recently got my hands on a copy of the new Princeton Companion to Mathematics, and I fear that this is likely to seriously impact my ability to get things done for a while, as I devote too much time to happily reading many of its more than 1000 pages.

The book is an amazing document (and physically, a beautiful, if weighty object), unlike anything else I know of. Its coverage of mathematics and mathematical culture is very wide and sometimes deep, but it makes no attempt to be comprehensive. Thus, the accurate title “Companion to” rather than “Encyclopedia of”. The most remarkable aspect of the book is the extremely high quality of the contributions from a large number of different authors. It includes many wonderful long expository articles, mostly at a level that a good undergraduate math student could hope to appreciate, with much of the book accessible to an even wider audience. The articles are often written by some of the best researchers and expositors around. For example, one can find Barry Mazur writing on Algebraic Numbers, Janos Kollar on Algebraic Geometry, Cliff Taubes on Differential Topology, Ingrid Daubechies on Wavelets, Persi Diaconis on Mathematical Statistics, and many, many others of similar quality. The table of contents is available here.

The book also includes extensive articles on historical topics in mathematics and short biographies of a large number of mathematicians, as well as coverage of applications and a section largely devoted to describing the art of problem-solving and how mathematics really gets created. This section includes a beautiful set of five essays called “Advice to a Young Mathematician”, which give five different equally fascinating perspectives from some of the best in the subject about how they achieved what they did, as well as what they have learned from years of helping students become researchers. The authors of these pieces are Michael Atiyah, Bela Bollobas, Alain Connes, Dusa McDuff, and Peter Sarnak. Luckily for all young (and old) mathematicians, this chapter is freely available here.

The person most responsible for this is clearly the editor (and author of some of the pieces), Fields Medalist Timothy Gowers, who had help from many others, including fellow Fields Medalist Terry Tao. Gowers has a weblog, and he has written about the book in these entries (and there’s a podcast interviewing him on the book web-site at PUP). Terry Tao has a posting about the book here.

If you’re looking for a gift for someone with a serious interest in mathematics, no matter what their background, you won’t do any better than this.

Comments

1. **Serifo**
   October 15, 2008

   Is there any similar book in physics ? I’m just a math’ s undergraduate student with some curiosity in mathematical foundation of physics (Quantum mechanics in particular). By the way , may I ask your views on Hilbert’s sixth problem ? Sincerely

2. **Peter Woit**
   October 15, 2008

   Serifo,

   I know of nothing like this book in physics.

   To be honest, I never understood exactly what Hilbert was looking for in this problem (“axiomatization of physics”). There are certainly parts of physics that are mathematically well understood and could be axiomatized, others where we still don’t understand things well enough to sensibly do this.

3. **Tim May**
   October 15, 2008

   Thank you, Peter, for this news. I just placed an online order for a copy.

   As a former physicist (is there really such a thing?) who found GR and black holes the most interesting things in the world, circa the early 70s, I now am finding the “quantum measurement” constellation even more interesting. I recently did a demo of the “quantum eraser experiment” from a Sci. Am. article, the one involving some polarizers and a needle between two oppositely-polarized filters. Wow. The essence of the EPR/weirdness reality demonstrated in a darkened living room.

   Sorry that this isn’t highfalutin’ string theory vs. loop quantum gravity vs. whatever, but it’s the essence of physics for me.

   And math. I eagerly await the Gowers book.

   –Tim May

4. **Serifo**
   October 15, 2008

   Thank you for the reply, it’s a pty there isn’t such a book in physics. When I was a high school student sometime ago, my physics teacher said ” more maths you learn, more easier is to learn physics ” , well next time I see her, I will say ” more maths you learn, more you struggle to understand physicist’s thoughts ” ! Maybe the starting point should be to axiomatize first those mathematically well understood theories then try gradually to capture the rest. Anyway sorry for bringing this off topic subject, cheerse to Bourbaki! Sincerely

5. **Fabien Besnard**
   October 16, 2008

   Yummy ! I’ll get a copy as soon as possible. Thank you for this.

6. **Navneeth**
   October 16, 2008

   That seems wonderful. Thanks, Peter. Added to my want-list.

7. **Navneeth**
   October 16, 2008

Fabien Besnard said: “Yummy!… ”

That’s exactly my reaction on reading about the contents! 😀

8. **Serifo**
   October 16, 2008

   I really hope they will produce : Princeton Companion to fundamental physics ! 🙂

9. **Navneeth**
   October 16, 2008

   One for Physics will require revision much often than one for mathematics. Maybe a web-based service will suit it better.

10. **Thomas R Love**
    October 16, 2008

    A book which does similar work is

    A Panorama of Pure Mathematics (Pure and Applied Mathematics (Academic Pr)) by Jean A. Dieudonne

    While the articles are at a much higher level (suitable for a graduate student or PhD) so is the price (about $225).

    I read it while in graduate school and it gave me a taste of other fields of mathematics.

    Several of the articles from the Princeton book were once available on line and I read several of them. They were at too low a level to interest me.

11. **Coin**
    October 16, 2008

    I know of nothing like this book in physics.

    From what you’ve said here it kind of sounds a bit like Penrose’s “Road to Reality”, though it sounds like it may be operating at a deeper level than Penrose’s book.

12. **JJ**
    October 16, 2008

    As mentioned by Coin, Penrose´s “Road to reality” is somewhat similar, giving some sort of overview of modern theoretical physics. Another interesting book, a little more demanding is Lawrie´s “A Unified Grand Tour of Theoretical Physics” (Amazon link: http://www.amazon.com/Unified-Grand-Tour-Theoretical-Physics/dp/0750306041)

13. **theoreticalminimum**
    October 16, 2008

    While I agree there is no such similar book for Physics, may I however point out that there exists the comparatively bulkier 5-volume set “Encyclopedia of Mathematical Physics“, which covers to some appreciable extent topics in theoretical and mathematical physics. Springer will publish a “Modern Encyclopedia of Mathematical Physics ” in 2010 apparently.

14. **Thomas R Love**
    October 17, 2008

    theoreticalminimum recommended the “Encyclopedia of Mathematical Physics“, and it looks good (judging by the description) but the price is a killer:

    Price:
    EUR 1,240
    USD 1,495
    GBP 855

    That represents about one third of my monthly take-home pay.

15. **theoreticalminimum**
    October 17, 2008

    I am acutely aware of the huge price, to the extent that people who would actually like to read anything from Elsevier would have to dig deep in their savings (recall for instance the resignation of the editorial board of “Topology” as protest against the outrageous prices of the publisher – find more here, here and here). That’s why we have gigapedia (hint) to be thankful for ;-).

16. **F Borg**
    October 18, 2008

    Paul Davies edited a successful physics tome “New Physics” in 1989 which has got a follow-up edited by Gordon Fraser, “The new physics for the twenty-first century” (Cambridge UP 2006). While they do not quite parallel the Companion to Mathematics these books still give nice overviews of what’s going on in physics.

    Eberhard Zeidler is by the way responsible for “Teubner-Taschenbuch der Mathematik” whose first part has also appeared in English as “Oxford User’s guide to mathematics” (Oxford UP 2004). The second part goes a bit deeper into the subjects including math physics. Lots of math for the money! Nirmala Prakash has written a quite “friendly” book on “Mathematical perspectives on theoretical physics” (Imperial College Press 2003). This is math phys seen from a stringy perspective. Quite different emphasis from *classical* math phys employed in electrodynamics, hydrodynamics etc. A modern exponent of the Jeffreys & Jeffreys tradition is Michael Vaughn’s “Introduction to mathematical physics” (Wiley 2007).

    Finally, for someone picking up physics I would recommend John Walecka’s recent “Modern physics” (World Scientific 2008) before they, if hooked, may proceed to Lawrie’s grand tour mentioned in an earlier posting.

17. **F Borg**

October 20, 2008

I just got a posting from *Springer*. **E Zeidler's** vol 2 of his gigantesque 6 vol set on math physics is announced (this is what the Germans call an "introduction" … 1000 pages plus per vol so far). One can download an interesting historical outline of physics from ch 1 here

http://www.springer.com/math/dyn.+systems/book/978-3-540-85376-3?detailsPage=samplePages

Though Zeidler can be associated w/ the **Bourbaki** tradition Zeidler's writing may have a stronger pedagogical intent judging from the above excerpt. I can see the advantage of a single author oeuvre in terms of coherence and style — but this one is a truly daunting task both for the author and potential readers!

Zeidler's Einleitung:

Volume I: Basics in Mathematics and Physics
Volume II: Quantum Electrodynamics
Volume III: Gauge Theory
Volume IV: Quantum Mathematics
Volume V: The Physics of the Standard Model
Volume VI: Quantum Gravitation and String Theory

18. **Steve Myers**
October 24, 2008

There is an encyclopedia of physics which is pretty good but I think it's over 10 years old. (I don't have it to hand here so don't recall publisher.) I wouldn't recommend the Penrose book — I'm sorry I bought it.

19. **Steve Myers**
October 24, 2008

If anyone's still checking here: the book is edited by Lerner & Trigg. It's from 1990 (second edition). VCH publishers. I find it useful.

20. **Serifo**
October 24, 2008

I`ve got Penrose`s " The Road to Reality " ! Although the book is quite well organized in respect to the topics, I found lack of clarity in a lot of the ideas ! Maybe because I`m just a young outsider in physics ; but I`m convinced the main reason is :
He tries to write the ideas as simple as possible (maybe too simple and informal), then the ideas get mix up and so confusing ! Actualy, I found similar problem in most of the physics textbooks, the textbooks are too informal to be understood ! Maybe via axiomatic approach , it will be easier to learn physics !
To Hilbert and his sixth problem 🙂

21. **Kaloyan Todorov**
February 19, 2009

Something of an equivalent in physics would be The Feynman Lectures on Physics by (you guessed it) Richard Feynman. A worthwhile read indeed!

Quantum Physicist Offers Solution To Global Market Meltdown

October 16, 2008
Categories: Uncategorized

I briefly met John Hagelin when I was an undergraduate. At the time he was a Harvard particle theory graduate student, soon to get his degree and start a quite respectable career in the subject. His biography on his web-site claims that:

> His scientific contributions in the fields of electroweak unification, grand unification, super-symmetry and cosmology include some of the most cited references in the physical sciences. He is also responsible for the development of a highly successful Grand Unified Field Theory based on the Superstring. Dr. Hagelin is therefore at the pinnacle of achievement among the elite cadre of physicists who have fulfilled Einstein's dream of a "theory of everything" through their mathematical formulation of the Unified Field—the most advanced scientific knowledge of our time.

Hagelin moved on from doing physics research, first to help run the Maharishi International University (now the Maharishi University of Management) in Fairfield, Iowa, then to run for president as the candidate of the Natural Law Party (it seems that "Joe the Plumber" was a member of this). Nowadays, the Maharishi has passed away, and Hagelin has moved to New York, where he is Executive Director of the Global Financial Capital of New York.

Soon after Hagelin moved to New York, his organization bought an impressive building down near Wall Street (chosen because "It's one of the very few buildings in all of New York City that's oriented due east"), with the goal "to inspire financiers to come forth to support the creation of Heaven on Earth". They also are buying up land near Princeton "where, with the support of the township, a university for 5,000 Yogic Flyers is to be established." Part of the plan seems to be to raise $3 billion or so from the financial industry, by offering 10% interest on 15 year loans.

Last year they held a news conference to explain how the a "surging stock market" was one

> of the concrete signs of the success of the Invincible America Assembly in Iowa—the largest-ever scientific demonstration project to document the effects of large group meditations on the economic and social trends of the nation, according to Dr. John Hagelin, world-renowned quantum physicist, executive director of the International Center for Invincible Defense, and President of the Global Union of Scientists for Peace, who is leading the Assembly.

This year the story is a bit different, with a recent press release entitled Quantum Physicist Offers Solution to Global Market Meltdown explaining that:

> a group of nearly 2,000 advanced experts is now in place at Maharishi University of Management in Fairfield, Iowa. He said the influence of coherence generated by this group is helping to calm the nation in the midst of the global crisis, but a larger, more powerful group of 8,000 experts (the square root of one percent of the world's population) is needed to neutralize worldwide fears and re-establish confidence in the global markets.
>
> The cost to establish this group on a permanent basis, Dr. Hagelin said, would be negligible compared to what has been lost in a single hour during the current financial crisis.

In a recent Open Letter to the Yogic Flyers of the Nation, Hagelin, the Raja of Invincible America, urges them on as follows:

> I am writing you from Wall Street, where I am living and working with members of my national team at the Global Financial Capital of New York, one block from the New York Stock Exchange. We are starting to make remarkably good progress in our efforts to bring Maharishi's knowledge of enlightenment and invincibility to leaders here whose thinking and actions vitally impact the whole world. However, ultimately, our success is dependent on you. We will be successful when the leaders are receptive to our message. But their openness is 100% dependent upon the numbers in the Domes. Why? Because a rise in national consciousness directly translates into a rise in openness among leaders of business, health, education, defense, government, etc.
>
> At this critical time I urge everyone to fly together in large groups
>
> Maharishi said we need 2500 experts flying together to guarantee invincibility for America. This requirement is because the turbulence in the collective consciousness of one country can easily spread like a wildfire to create a similar turbulence in another country. And this is why, at this critical time, with the economic stability of the world hanging in the balance, I urge everyone in Iowa and everyone in the country to recommit to fly together in large groups.

Update: Today was a beautiful day, and on a bike ride downtown I stopped to take a look at 70 Broad Street, the headquarters of Global Financial Capital of New York. Looking in the windows of the below ground level and the lobby level, the place looked pretty much abandoned. The building has some floors upstairs, maybe there is some activity up there.

They did just put out this press release, announcing a press conference to be held in the lobby at 11am on Tuesday and webcast. Hagelin will be announcing a $1 billion plan to fund 1000 experts in New York and 8000 experts in Iowa who will "create coherence for the whole world—the basis of an invincible, prosperous global economy." No word in the press release about where the $1 billion was going to come from.

Update: Video of the press conference is here. The plan is simple: just give Hagelin and his followers $1 billion, and they'll have this financial crisis all sorted out soon, by means of experts using the unified field.

Comments

1. **Joe the Physics Student**
   October 17, 2008

   Hi Peter,

   How does this individual's activities have anything to do with current physics research?

   Thanks.

   Joe the Physics Student

2. **Boo Radley**
   October 17, 2008

   Simply hilarious!

(At least he is making a prediction, though.)

3. **Vishal**
October 17, 2008

Is this for real?? Seriously? Is our science education not doiing its job well?

4. **Chris Oakley**
October 17, 2008

Rather than committing to yogically fly together in large groups, I would recommend

(i) Not allowing banks to pay big bonuses to their employees. These seem to end up being funded from my and your pension fund.

(ii) Ensuring that there is no such thing as an "off balance sheet" transaction … anything that could harm the ability of a bank or investment institution to pay its debts is, AFAIC, on balance sheet

5. **chris**
October 17, 2008

hmm.. i guess the square root of one percent of the worlds population is more like 8000 sqrt(people). how can such a renowned quantum physicist not get the units correctly?

6. **Frank Quednau**
October 17, 2008

Funny stuff. Let him get his numbers, if it works, it's nice.
@Chris: Looks like the units are OK. If you square an expert you get a normal person. Sounds about right to me 😉

7. **ObsessiveMathsFreak**
October 17, 2008

If I have learned one thing about "invincibility" it is that it always wears off a few seconds after you get the star, and if you weren't thinking ahead you'll probably have landed yourself in a very sticky situation by the time this happens.

You cannot apply physics to economics. I think that the only reason physicists migrate to this field is hubris, thinking they can "solve" the stock market. Ironic considering they have been essentially unable to solve/resolve the existing problems in their original field.

8. **andy.s**
October 17, 2008

Jesus, these guys are loaded with cash. All of it from thousands of saps who think they can fly by flapping their legs.

I am in the wrong business.

9. **Thingumbob**
October 17, 2008

I believe that it might be possible to get the Boltzman brain to astral project into this corner of the landscape to overcome our financial crisis. Has Professor Hagelin considered this?

10. **Bee**
October 17, 2008

Needless to say, E8 explains the global financial crisis

11. **A**
October 17, 2008

Actually, quite sadly this is an example of where a physicist has become a crackpot and is now conning a bunch of spiritual people who try to understand meditation and consciousness through what appear to be honest means.
It's a disgrace.
Joe the physics student, the relevance here is that he has risen to a position of power because he has sold himself as the world expert on The Grand Unified Theory. He has sold his GUT research as being The solution. Frankly, the Maharishi people are being scammed by Hagelin and his ilk.

12. **Joao Leao**
October 17, 2008

Hum! I wonder what kind of golden parachute Global Financial Capital of New York will provide for Hagelin given that his flying days may be about to end soon and abruptly. On the other hand that 3 Billion raising proposal looks to me quite like an "airplane" (Ponzi) scheme…

13. **Aaron Bergman**
October 17, 2008

I think that the only reason physicists migrate to this field is hubris, thinking they can "solve" the stock market.

Hubris had nothing to do with it. The reason physicists migrated to finance is because they paid lots and lots of money.

14. **Yatima**
October 17, 2008

"The reason physicists migrated to finance is because they paid lots and lots of money."

I can feel that in my bank account.

Ok guys, you had a good laugh, now how about getting back to doing some serious, honest-to-god work?

15. **Covariant**
October 17, 2008

    I think I am beginning to appreciate Peter's opinions on things

16. **Sakura-chan**
October 17, 2008

    Thanks for the laugh Peter. You presented the info beautifully, and with a straight face. =)

17. **gasp**
October 17, 2008

    Imagine if we had to choose between Hagelin and Bush. I honestly don't know who I would choose.

18. **Peter Woit**
October 17, 2008

    Please, no more off-topic comments about quants and Wall Street,especially because no one seems to have anything new to say about that topic.

19. **David McMahon**
October 17, 2008

    I think assuming that John Hagelin is conning the group is jumping to conclusions. Never underestimate the power of belief, just because someone got a PhD at Harvard that doesn't mean they are susceptible to it. Spiritual belief is a powerful force, and although the ideas may seem nutty to some of you they speak loudly to lots of people. In fact spiritual beliefs are more powerful than science because it taps into emotions. Emotion is all to often stronger than logic. Think about it-emotion comes from the deep-seated more ancient part of the brain, the limbic system. Spirituality is something people feel in their gut, but analyzing something scientifically is something you do with your cortex. So what I am saying is I wouldn't be the least bit surprised if Hagelin believed every last word of this. Doesn't matter if he was a particle physicist or not.

20. **Covariant**
October 18, 2008

    David McMahon said

    "Spiritual belief is a powerful force"

    So should we quantize and study it? Who gets to be Yoda?

21. **Marty**
October 18, 2008

    Actually when you go beyond a natural gut reaction to be skeptical and dismissive, there is a lot of absolutely amazing (and published) research behind what John Hagelin is saying. Take a few minutes and check out http://permanentpeace.org/
    In more than fifty studies published in scientific journals, including the Journal of Conflict Resolution and the Journal of Mind and Behavior, the method of sustained large group meditations has been documented to powerfully reduce violence and criminal activity and even calm open warfare. It is a technique that is currently also being used in some of the most troubled inner-city schools in the country to defeat the stress and violence that plague the learning process.
    Please don't laugh at it. Inform yourself about it. Then decide whether it is hokum or a new paradigm that presents consciousness as a magnificent and unbounded existential frontier full of all possibilities. Practiced individually, Transcendental Meditation reduces mental stress and increases personal wellbeing, harmony, productivity, creativity, and happiness. When practiced together in a group, the "good vibes" radiate outward into the unseen field of collective consciousness, creating the same effects on a societal scale. The bigger the group the better, and the further the effects spread, like ripples in a pond. Another analogy is to think of radio or TV transmitters that beam signals through an unseen electromagnetic field. Instead of picture or sound signals, groups of meditators generate a strong wave of coherence and positivity through an underlying field of collective consciousness. Stress and tension diminish.
    Scientists are beginning to recognize a "non-local" field of global consciousness into which intentions can have effects at great distance. A field effect. We should explore this territory, for it may hold the secret for planetary peace and harmony. We'll never know unless we are bold and courageous enough to put it to the test.
    Obviously, I am one of Dr. Hagelin's admirers, and a practitioner of meditation. But I am also a professional medical writer who writes about many so-called "breakthroughs." Most are far from breakthroughs. This is the real thing.

22. **gasp**
October 18, 2008

    Marty, religious and cult-like memes are not transmitted by telepathy. They use more mundane forms of communication, such as you typing a reply on a blog.

23. **Thingumbob**
October 18, 2008

    This non-local TM stuff sounds like spooky action at a distance to yours truly. Ahem.

24. **gasp**
October 18, 2008

    David McMahon, emotional experiences exist. Spiritual experiences do not. So they should not be equated.

25. **Marty**
October 18, 2008

    Gasp and Thingumbob:
    I understand your reactions. Take a few minutes though to check out the science. It is very strong. So strong that public educators from around the country are introducing TM in their schools. If it was based on a religious or cult-like meme they would have none of it.
    Gasp…I like that word meme…hadn't heard it before.
    Meanwhile, the memes of the Wall Street cult have been a disaster.
    Cheers.

26. **Marty**
October 18, 2008

gasp
what's interesting about the subjective spiritual experiences in meditation is that they have measurable physiological effects. studies have shown, for instance, that cortisol levels improve through meditation and that high blood pressure is knocked down. In fact, the National Institute of Health has funded a number of studies showing how TM has been as effective, yet without any negative side effects, as medication in improving blood pressure among african-americans with refractory hypertension. One of the reasons that I am such a believer is that the practice normalized my blood pressure after a couple of months. The doc wanted to put me on medication. I said I would rather try something natural. It worked great.
Regards

27. **David McMahon**
October 18, 2008

You guys completely miss the point. Spirituality is a powerful force IN PEOPLES LIVES and the EMOTIONAL STATES they have. Spiritual experiences exist through the emotional experiences people have. There was an implication that Hagelin was conning the TM crowd because he had a PhD in physics and "should know better" and I am saying no, Hagelin probably really believes what he says. Spiritual belief (and the accompanying emotion) is more powerful that logical thought for most people.

28. **Marty**
October 18, 2008

David…you are correct. Spirituality is indeed a powerful force in peoples lives and their emotional states (e.g., symapthetic vs. parasympathetic mode).
The implication that Hagelin is conning us in the TM crowd is based on some outside speculation with no basis in fact. If I am being conned, so are a lot of Ph.Ds, doctors, lawyers, scientists, students, investment managers, principles, actors, writers, etc., who are a whole lot smarter than me. They ain't stupid and they ain't gullible. They see the results. They see the science.
Hagelin not only believes what he says, but he has participated in the published scientific studies that explain or validate very fascinating explorations into consciousness.

29. **Covariant**
October 18, 2008

David McMahon said

"Spiritual belief (and the accompanying emotion) is more powerful tha(n)t logical thought for most people."

I think that is a valid observation, but what happens when one group's beliefs are different from another's and both groups "know" they are correct in their beliefs?

I think Hagelin hasn't thought about that too much.

30. **Marty**
October 18, 2008

Covariant:
I think Hagelin has thought about that a lot and has attempted to prove the value of spirituality (and specifically a spiritual practice such as meditation) on personal and societal scales through science. Could it be that the fundamental basis of subjectivity (call it emotions, spirituality, belief) and objectivity (science, matter, the physical world) are one and the same: an unseen universal field of intelligence.
You folks ask great questions.
Why don't you invite Hagelin to speak to you. He lives in the neighborhood. You can throw all your implications, doubts, and questions. I am sure you would find it very informative and it would open your awareness to a very cool world that begs exploration by bright minds such as yours.

31. **a.k.**
October 18, 2008

..one should add that the intertwinement of obscure reasoning (I am not denying any effect of meditation etc. on physical and mental health) and financial power, especially the entanglement of irrational methods in physics and political and economic power manifested in one single person, seems to shed light onto some well-known 'dialectic' aspects concerning the role of quasi-religious movements, esoteric 'enlightment' opposed to those methods which were in europe once called 'enlightment', in the western society. 'Esoteric enlightment'- this also stands for non-rational analysis of the financial market (solving problems by 'flying together in large groups'), for ethnocentric views of human societes and for poorly reflected boundaries of the scientific method. To cut it short, Hagelin manifests one of the reasons why I quit thinking about physics a long time ago.

32. **Thingumbob**
October 18, 2008

I would invite him, sure, but just now I have brought back from other side Monsieur Mesmer, and he confides in me that I need beware: there may be many hoaxers who only want the great and mighty of this world to supply their unspiritual monetary wants. Of course, if all this could be done without any need for money…

33. **Covariant**
October 18, 2008

Marty

I have no doubt that meditation is great; I have no doubt that a lot of people of common beliefs meditating together is even better.

I also have no doubt that there are a number of people who absolutely don't feel that way, and some of those never will feel that way.

34. **Marty**
October 18, 2008

Thingumbob:
You folks are delightful to chat with. But my garden overfloweth with weeds and I must leave you.
Please look at the science. And then draw your conclusions and critiques. At least then you will be armed with more than mere opinion and suspicion. And then invite him.

35. **Marty**
October 18, 2008

Covariant
You are absolutely right about a lot of people never changing their minds, and never will. No problem.
One of the neat things about this whole concept is that MOST people are skeptical….it is some mystical hogwash…etc. That's what they thought about meditation when it first became popular forty years ago. Now doctors prescribe it for patients, and school principles are using it to transform the most stress-ridden schools into the learning facilities they were meant to be. Science has shown it is very valid and relevant for our modern conflicted society. It is not a matter of belief.
The greater concept of group meditation on a societal scale that Hagelin advocates is a exploration and exploitation of the unchartered and unbounded possibilities of consciousness. It is amazing to me that psychiatry and psychology spend so much time groping around in the darkness of mental illness, when there is this huge and untapped universe of consciousness and mental potential to explore.
Over and out.

36. **Vishal**
October 18, 2008

I am pretty sure the Buddha would have been "horrified" to hear people talk about TM and stuff like that. There is nothing inherently "spiritual" about meditation, which is a wonderful and beneficial way of exploring phenomenon and events from a phenomenological perspective. There is no doubt that meditation confers great benefits (physiological, mental) to the practitioner, but people like Hagelin, not to put too fine a point on it, simply delude themselves into believing the esoteric or anything that is out of this world. Frankly, with so many "gurus" coming out of India, it tends to create more often than not a wholly incomplete and distorted picture of that country.

37. **Marty**
October 18, 2008

Vishal
To speak for Buddha is purely speculative on your part.
In India, Maharishi Mahesh Yogi, the founder of TM, is revered for having put into motion a great revival and "cleanup" of the massive distortions that have crept into the vast body of Vedic knowledge.

38. **Peter Woit**
October 18, 2008

Enough with repetitious comments on the pro/anti meditation topic, which in any case seems to have little to do with Hagelin's venture into the financial industry.

39. **A**
October 18, 2008

David McMahon, I think in fact you missed my point. The fact that Hagelin may or may not believe in the beliefs of the Maharishi is by the way side. He is SELLING them grand unified field theories. He is using his status as a physicist, his PhD from Harvard in his position with them. It is not his spirituality that is relevant but rather the fact that he attained that position using physics. It is not that a physics PhD taught him to be well reasoned and solve problems and so he has gone into the world and applied general principles to other work, like for example physicists have in finance. He is telling the Maharishi people that grand unified theories and string theory are the solution to what the search for. Hence he has conned them. He has told that that the grand unified field is itself the field of consciousness (notice the trick by using the world field here). They are trying to understand consciousness which is a perfectly respectable goal. And they have tried to speak to scientists to describe their experiences in the hopes of understanding and recording more scientifically what they have done. Hagelin and his ilk have conned them – in that they use fancy physics words to convince these people that they are experiencing the string field of consciousness blah blah blah. They translate basic human experience into fancy vacuum landscape language that is frankly just junk.

40. **Vishal**
October 18, 2008

> In India, Maharishi Mahesh Yogi, the founder of TM, is revered for having put into motion a great revival and "cleanup" of the massive distortions that have crept into the vast body of Vedic knowledge.

Marty,
It is amazing to see how much people (especially non-Indians) buy into this whole "Vedas contain all knowledge" idea! They tend to miss the point that the resurgence of interest in the "Vedas" and other "ancient scriptures" of India is closely connected with right-wing politics and nationalist ideology, today. A lot of the Vedas contain purely speculative knowledge – now that sounds almost like an oxymoron. The Buddha had thoroughly and rationally debunked a lot of the core beliefs of the Vedas more than two thousand years ago, and the fact that those debunked beliefs are regurgitated again and again, to me, is an indication of how powerfully those ideas grip the minds of people throughout history and even to this day.

Peter,
Please forgive me if my comments are totally off-track. But I do want to point out that some of the huge confusion people have about modern physics, "field of consciousness" and so on, clearly spring from the misinformation that is spread *vis-a-vis* "Vedic knowledge". The fact that Indians themselves don't know what to make of the claims about Vedas but that quite a few non-Indians readily accept whatever is told them about the Vedas should immediately raise a red flag. Anyway, the end result, as A correctly pointed out above, is that a lot of ordinary people get conned in a subtle way without even their knowing what hit them.

41. **David McMahon**
October 18, 2008

If you are conning somebody, you are misleading them with something you know to be false. I don't necessarily buy that Hagelin believes these ideas are false but is selling them off on people anyway. So that is why I don't think Hagelin is necessarily a con.

42. **Covariant**
October 18, 2008

Well, its a free country, and as long as Hegelin and crew use the money they raise as intended, and as long as they make their payments to whoever feels inclined to invest, then there really isn't much one can do or say.

I will be curious if they can pay it all back in 15 years at 10%. I doubt they will raise $3 billion, not without posting some significant collateral. If they have market research that supports their claim about the amount of money they'll make, then I think they will have a number of businessmen interested.

43. **Steve**
October 18, 2008

it may be a challenging stretch (which is sometimes a very good thing), but it definitely isn't completely off base and unsupported:

"Consciousness & Superstring Unified Field Theory"

http://www.youtube.com/watch?v=OrcWntw9juM

http://www.youtube.com/watch?v=FSxluvq5HI0

…give a listen (or not) and then critique the substance, and not just the superficial notion

44. **David McMahon**
October 18, 2008

Thanks for posting the videos. I would say his claims about what string theory says are a bit of a stretch.

45. **David McMahon**
October 18, 2008

Hi Steve,
I think the videos are pretty good, and I don't think Hagelin is completely wacky (wish I could use italics). Who knows, there may be something to his explanations. Afterall consciousness is something hard to grasp for science as it stands now. I would say explanations that its an "emergent" property from the "complexity" of the brain are non-explanations when you get right down to it. The fact is no scientist alive has any idea how the brain gives rise to awareness. Its the biggest problem in science-far bigger and more complex than anything in particle physics. But it would be an interesting twist if Hagelin's musings (and lets call them musings, they are not much more) about string theory (or lets say any unified theory since string theory is frowned upon here) had something to do with why life is conscious. David

David

46. **David H. Miller**
October 19, 2008

David McMahon wrote:

Dave, I agree with everything I just quoted from you. And, so do many sensible scientists and philosophers: the late Nobel laureate in neural science Sir John Eccles and the philosopher Karl Popper (see their book "The Self and Its Brain," physicists such as Schrodinger and Penrose, serious contemporary philosophers such as David Chalmers ("The Conscious Mind") and Colin McGinn ("The Mysterious Flame"), etc.

At some level, this should not even be controversial: after all, no neural scientists that I've heard of claims to have fully explained consciousness. I myself won't be surprised if the full explanation of consciousness shakes science just as much as quantum theory or evolution did.

However, I see no evidence that Hagelin is moving us towards such an explanation. I suspect that he does believe his own nonsense, but most of what Peter quoted from Hagelin is, indeed, nonsense.

To use one's standing as a scientist to point out that there is much we do not yet know and, probably, some big surprises in store is perfectly fine. In a sense, that is what Peter is doing in theoretical physics: he maintains that the future of theoretical physics is much more open than some of the superstringers think.

But to claim to have answers that you do not have, as Hagelin does, is dishonest, even if it is the sort of dishonesty that consists of deceiving oneself.

Dave Miller in Sacramento

47. **Thingumbob**
October 19, 2008

I guess perhaps I need to be less satirical to attempt to bring home my point here. There have been all sorts of spiritualists that have used many different varieties of scientific sounding gobbledygook to gull rubes out of their fortunes. For instance, the Rosicrucians, Annie Besant, Aleister Crowley, and on and on. This stuff is as old as dirt. The problem today is when it comes to this or that variety of GUT, its very hard to know the difference. (As far as the notion that consciousness has a physically mechanistic causality, I would remind you that this quixotic idea led Descartes to the absurdity of believing that the pineal gland was the seat of the soul.)

48. **Jeff McGowan**
October 19, 2008

OK, why do so many scientists seem to think it is inevitable that scientists will one day "explain" consciousness. I have no doubt that consciousness is a physical phenomenon, but that doesn't mean that anyone is ever going to explain it (whatever exactly that might mean). It seems to me there might very well be a metalanguage problem here of the highest order.

49. **Covariant**
October 19, 2008

After watching the videos two thoughts struck me:

1) I am even less inclined to believe that there really is such a thing of self awareness or consciousness. As against the grain that might be; although I manifest thoughts, I can observe that those thoughts are not entirely dependent on me. (Or as a mathematician I know stated, similar people tackling similar problems tend to come up with similar solutions).

2) The "unified field" as described by Hagelin, really seems to leave out the observed randomness in nature. He seems to describe a unified and interlinked universe that has no room for independent random events. There is a lot of randomness in how our brains actually function, and this can best be captured by the observations of Ebbinghaus in 1885.

http://en.wikipedia.org/wiki/Forgetting_curve

50. **kuhn dog**
October 19, 2008

It is said above (by Dave): "…to claim to have answers that you do not have, as Hagelin does, is dishonest, even if it is the sort of dishonesty that consists of deceiving oneself."

Many of the posters on this blog make this heavy judgment and denouncement of Hagelin, but based on what? How do you actually know that he is wrong? (Really, how would you KNOW this? On what epistemological grounds?) Granted, it may be your personal belief, your knee-jerk reaction. But, what answers does Hagelin claim to possess that are counter to empirical evidence, or even counter to current physical theory? And specifically, what claims does Hagelin make that are not supported by empiricle evidence or physical theory? (not counting the theory in neuroscience that consciousness is an epiphenomenon of the brain, which, as mentioned above, is a non-theory anyway…)

Hagelin's fundamental assertions seem to be
1. that there is a unified field (a claim made by many physicists)
2. that the u.f. is, in essence, a field of consciousness (perhaps a surprise to many, but, not without precedence in Eastern and Western thought)
3. that the u.f. as a field of consciousness can be subjectively experienced and thereby validated. (again, not without extensive scholarly precedence…)
4. that large groups of people experiencing the u.f. together at the same time (i.e., "group practice of the TM and TM-sidhi programs") influences the environment in a measurable way through the "field effect" of consciousness…yes, spooky action at a distance (which seems to be something that physicists are no longer so spooked by…yes?).

This fourth point seems to be the crux of the matter, as far as empirical testing of Hagelin's theory. (Not that subjective experience of the u.f. is without merit—the Upanishads, Gita, Yoga Sutras, etc. uphold the necessity of directly experiencing the unified state of consciousness in order to truly KNOW the underlying reality.)

Can group meditation really influence the environment? Is there a level of life where we're all interconnected?

I remember reading years ago in Yale Journal of Conflict Resolution, which published one of the research studies on what Hagelin calls "the Maharishi Effect"—the proposed "influence of coherence" that results from large group meditation. (I know, some of you are wondering why such a topic as this is even being discussed on this blog—how "out there" can one get? But, please, bear with me..) The editors interjected a caveat, as if to justify why they, a highly reputable sociological journal, would publish a study on something so outside the box. I paraphrase the journal's editors: "While we consider this research study on the extended sociological effects of meditation to be worthy of publishing because of it is solid research with sound statistical analysis, we must also acknowledge that the theoretical explanations of the findings are well outside the current paradigm of current sociological research."

My thoughts were, no kidding. It's BECAUSE the research is outside the current paradigm that Hagelin's group may be on to something—perhaps they've found a far better way of improving society than anything we're currently doing.

If Dave or any of you haven't actually looked at the research, read through the studies, duly considered the theory that Hagelin is proposing, and determined scientifically whether or not any of the 50+ research studies on the Maharishi Effect are valid science, if you haven't considered the design and controlls of the experiments and looked closely enough to discern whether or not the data supports the findings, then how can you dismiss the theory out of hand? Just because it's "outside the current paradigm of sociological research"?

My man Thomas Kuhn has a word for those who refuse to examine the data and cling to their old paradigm, despite overwhelming evidence: NON SCIENTISTS. "They have ipso facto ceased to be scientists." —TK.

In all fairness, maybe some of you didn't even know there was empirical evidence to support Hagelin's approach. I've actually read through most of these research studies (there are dozens of peer-reviewed studies on the Maharishi Effect). The data and findings seem to strongly support the theory that group mediation can influence crime, violence, and yes, even the stock market. There may be people on this site more qualified than me to ascertain statistical significance; if so, perhaps you should examine the studies. People often say, why take the time, the theory is so outside the box… Why bother? Because everything else has failed, and these peer-reviewed studies support the theory. Because if it's true, it would alleviate much suffering.

Instead of ridiculing Hagelin, perhaps consider the possibility that this is all he's is trying to do—make our world a better place. Have we become too cynical to listen to such a voice of hope? Not all of us have. I'm not talking about gullibility, but mere open-mindedness. Rake it across the burning coals of scientific scrutiny, but first give it a chance.

Patanjali said thousands of years ago: "In the vicinity of yoga (unified awareness) hostile tendencies disappear."

Maybe he was right. There are many ancient texts, passed down from the Vedic rishis (scientists of consciousness. perhaps?) that record experiences of a fundamental, unified field at the basis of nature's functioning. They called it Atma, Brahman, Samadhi, and had many precise technical terms for various levels of the experience. But the experience is universal and is recorded in every culture.

And I'd like to hear from Vishal: what specifically was overthrown by Lord Buddha, as far as the fundamental principals of Vedic knowledge? I don't mean, what were the points of misinterpretation that Buddha debunked, but what actual expressions of Vedic texts did Buddha prove (didactically or through other means) to be invalid?

Just because fundamentalist Hindu nationalists have appropriated certain Vedic teachings does not invalidate the fundamental principles of Vedic knowledge that pertain to the development of consciousness. The Vedic tradition of knowledge and what today is known as Hinduism are two different things. The Vedic tradition and it's methodologies predates the Hindu religion by several thousand years. But this is another discussion that would probably take more explaining than people here have patience for, at the moment.

October 20, 2008

The idea that putting together a group of meditators can make things better for the entire society, and even the impressive formula of a squaroot of one percent of the population for the number of required meditators is quite old by now.

Interestingly, this have led to a paper that was published in a peer-reviewed scientific journal which describes the spectacular success of an experiment that took place, from all places, in the city of Jerusalem.

The first author of the paper have written many many papers on other rather spectacular (but not as much as this one) good effects of Maharishi meditation.

ORME-JOHNSON, D. W.; ALEXANDER, C. N.; DAVIES, J. L.; CHANDLER, H. M.; and LARIMORE, W. E. International peace project in the Middle East: The effect of the Maharishi Technology of the Unified Field. Journal of Conflict Resolution , 32(4): 776-812, 1988.

A rather small group of meditators seemed to have achieved: "Improved Quality of National Life as Measured by Composite Indices Comprising Data on War Intensity in Lebanon, Newspaper Content Analysis of Israeli National Mood, Tel Aviv Stock Index, Automobile Accident Rate in Jerusalem, Number of Fires in Jerusalem, and Maximum Temperature in Jerusalem; Significant Improvement in Each Variable in the Index (Israel, 1983). Decreased War Deaths (Lebanon, 1983)."

The strong correspondence between the number of Transcendental Meditation-Sidhi program participants in the group in Jerusalem and a composite index of all the variables above can only be described as amazing. The graph can be found here: http://tm.org/charts/chart_51.html.

October 20, 2008

"The strong correspondence between the number of Transcendental Meditation-Sidhi program participants in the group in Jerusalem and a composite index of all the variables above can only be described as amazing."

Or that they want to sell something. I hope you are kidding, because the index (if at all it was not just made up) is certainly rigged. If you scale/shift/rotate a generic sigmoid or some such curve, you can pretty much find reasonable fits for anything. The real index will only look like noise.

James Randi has gone after and done background checks on some of the claims made by TMers and debunked it. I remember in particular some claims about crime rates in a small town in Iowa where apparently a huge percentage of the population was TM practitioners. All lies.

I am willing to give the benefit of the doubt to vedic-medicine from the far east or some such. Who knows, maybe there is some empirical validity for them, even if we don't understand the details of why some of it works. But TM for world peace? Gimme a break.

Kuhn Dog wrote specifically to me:
>Many of the posters on this blog make this heavy judgment and denouncement of Hagelin, but based on what? How do you actually know that he is wrong? (Really, how would you KNOW this? On what epistemological grounds?)
[snip]
>Hagelin's fundamental assertions seem to be
>1. that there is a unified field (a claim made by many physicists)
>2. that the u.f. is, in essence, a field of consciousness (perhaps a surprise to many, but, not without precedence in Eastern and Western thought)
>3. that the u.f. as a field of consciousness can be subjectively experienced and thereby validated. (again, not without extensive scholarly precedence…)

Let me be blunt: the "scholarly precedence" and the "precedence in Eastern and Western thought" do not matter, not at all. Evidence matters, "precedence" does not.

Honest, intelligent people do not bow down before "precedence." They bow down before evidence and logical reasoning.

If Hagelin merely suggested this nonsense as vague speculation, well, fine. Consciousness does exist – I, at least, am conscious (though "Covariant" claims he is not, and I accept him at his word). Consciousness has to be explained by something, and, for all any of us know, perhaps it will turn out to be superstrings.

But Hagelin does not merely suggest this stuff as vague speculation. He claims to actually know, based on his position as a physicist, that, in his words:
>"…consciousness isn't created by the brain…we call it the unified field…this single universal field of intelligence…or superstring field…"

These are not facts that are now established by physics. Hagelin does not in fact know any of this.

To steal the phrase that Peter borrowed from Pauli, this stuff is "not even wrong." It is so vague that it is hard to see how one could ever test or refute it. But Hagelin throws in enough buzzwords from real physics to make it seem plausible to those who are ignorant of science.

No, I doubt Hagelin is lying in the simple sense: he has probably succeeded in bamboozling himself.

And, I certainly have no desire to question Hagelin's or anyone's right to ask the sort of questions with which he opens the YouTube clip: e.g., what is consciousness?

Questions are good. Pretending to have answers when you do not have answers, and using your authority as a physicist to bamboozle unsuspecting members of the public, is not good.

At the serious risk of being both off-topic and lowering the S/N ratio, how does one comment on-topic on a post like this?

Perhaps I could say that it has always been my ambition to do formation Yogic flying against global financial panic, but I have had a bit of trouble finding like minded people who can actually get off the ground.

Any advice?

59. **Gil**
October 21, 2008

The claims about the effect of Yogic flying on world peace and on the stock market and the paper describing a scientific experiment supporting these claims have the value that they can improve our evaluation of other scientific experiments described by Maharishi scientists on remarkable effects of meditation which are a priori not so absurd.

60. **Jeff McGowan**
October 21, 2008

Dave,

I'm a mathematician, I think that probably makes me one of "we scientists." 🙂

I tend to go with Stephen Jay Gould on the whole progress thing…

Peace,
Jeff

PS Thanks for the reference, I'll check it out.

61. **anon.**
October 21, 2008

Has Dr Hagelin used superstring theory to formulate a scientific theory of how Yogic flying can reduce the turbulence in the collective consciousness of one country, thereby producing economic harmony?

Is the turbulent group consciousness something that is manifested in spatial extra dimensions, and if so, would the success of Dr Hagelin's approach to achieving world economic harmony by Yogic flying be a good indicator that superstring theory is correct and deserving of yet more funding?

Peter, it's refreshing that you are taking Dr Hagelin's claims seriously in this post, instead of your usual hostility and ridicule. Presumably it's because of your personal contact with him, but it's a step in the right direction. Have you tried Yogic flying yourself? 😉

62. **Amos**
October 21, 2008

The sad thing is, the rate of progress in physics is so low right now that entries like this are able to draw in 60+ responses in only a few days. It would be better if physicists were producing more interesting new results so that Peter could post them and we could talking about them instead.

63. **somebody**
October 21, 2008

"The sad thing is, the rate of progress in physics is so low right now that entries like this are able to draw in 60+ responses in only a few days. It would be better if physicists were producing more interesting new results so that Peter could post them and we could talking about them instead."

I somehow suspect that the reason why a topic like this draws attention has nothing to do with "rate of progress in physics". A post about gay marriages, or God, or Obama also would draw a lot of attention. Mind you, I am not suggesting there is anything a-priori wrong with those topics, some of them in fact are very important. But popular vote usually goes for topics in which we can all have strong opinions.

E.g., the possible application of black holes to the understanding of superconductivity is a very interesting development that happened during the last couple of years, but it suffers from the problem that it is not easy to have strong opinions about it without being well-informed.

I suspect that if Peter were to write about technical topics, contrary to (the spitit of) what you suggest, the traffic here would be less, not more. Even during the period when the Standard Model was being invented, I suspect that the blog entries would have to be about flying yogis, not anomaly-free matter content.

64. **Peter Woit**
October 21, 2008

I agree that the number of comments on a posting correlates not at all with whether there's something scientifically significant under discussion. So, that has nothing to do with the pace of progress in physics.

That said, I am finding it remarkable how little is going on these days. It's not just my blog, but the others I follow seem to have very little to say about new physics. I'm busy with other things, so haven't written about a few things I could have discussed, but still.

As for claims of applications of black holes to condensed matter physics or nuclear physics, my philosophy is that the people to report on those and evaluate their significance should be condensed matter physicists and nuclear physicists.

65. **Dave Miller**
October 21, 2008

Jeff,

In my experience, mathematicians actually tend to have a substantially different perspective and mindset than natural scientists. I'm not being critical: I think the average mathematician I've known probably had a higher IQ than the average theoretical physicist I've known (admittedly, this is partly because of a handful of physicists who pulled down the physics mean IQ quite a lot!), and, of course, we physicists certainly need you mathematicians.

And, computer scientists seem to have a different perspective than either mathematicians or physicists.

Anyway, I think you and I and Peter and most of the regular readers of this blog agree on the central point: it is not possible to accurately predict the future of science, and people who think they can do so are fooling themselves. I'm sure that progress in neural science holds lots of surprises for all of us, which, of course, is a big part of the fun of science.

(Somehow, though, I don't think that successful yogic flying will be one of those surprises.)

Dave

66. **Dave Miller**
October 21, 2008

Gil,

You wrote:
> The claims about the effect of Yogic flying…[snip] … have the value that they can improve our evaluation of other scientific experiments described by Maharishi scientists…

Yeah, but perhaps not in quite the sense you mean.

Everyone has been bending over backwards to be polite, following the example of our gentle host.

But… a TM Website (http://www.permanentpeace.org/technology/yogic_flying.html) claims:
> During the first stage of Yogic Flying, while the practitioner sits in the cross-legged lotus position, the body lifts up and moves forward in short jumps. One branch of the Vedic literature, the Yoga Sutras of Maharishi Patanjali, describes this first stage as "hopping," and further defines a second stage as hovering for a short time, and a third as complete mastery of the sky.

Look, everyone knows that no human has ever gotten beyond the "first stage," i.e., the funny little lotus hops. The whole thing is a scam. No human has ever reached stage two or stage three.

No one ever will.

I'm being too cynical?

Fine. Let's have the TM folks get their half dozen best Yogic flyers, and, at a well-known public place announced well in advance, say Central Park or the Capitol Mall, demonstrate second or third stage Yogic flying.

If they choose a New York venue, maybe Peter can even be induced to take some video to convince all us skeptics.

All they need do is hover in the air for a couple minutes – no, even thirty seconds would do – continuously of course, and all of us skeptics will bow our heads in shame.

But we all know that this will never happen.

Gil, they cannot really fly.

To be skeptical of Hagelin's claims, you do not need to be a dogmatic materialist (I'm not), you do not need to have an opinion on the ultimate nature of consciousness, superstring theory, or anything of the sort.

You need merely note that Hagelin states:
>At this critical time I urge everyone to fly together in large groups…

And then remind yourself – they cannot really fly.

Dave

P.S. Peter, I know the game of this post is to leave it all implicit and let everyone figure it out for himself, just like a good joke – something is lost when you have to explain why the joke is funny. But sometimes, some things ultimately have to be said explicitly.

67. **Peter Woit**
October 21, 2008

Dave,

Hey, I've seen still photos of these people flying. Of course in the photos their hair was kind of standing up, like maybe they were coming down. Fast.

68. **somebody**
October 21, 2008

Peter: “That said, I am finding it remarkable how little is going on these days.”

The farther zoomed out you are, the less impressive the changes are. Anything short of an actual warp drive is not going to impress a layman, for example. To understand progress you need to understand what are the interesting questions and why. This usually requires getting your hands dirty and wading into the details. If you are looking for applications to agriculture, you will not be impressed, I agree.

Strominger and collaborators recently found a way to compute the entropy of astrophysical black holes. Is this exciting? To be honest, it is not THAT big a deal to the string theorists because we always knew astrophysical black holes are not that different from the idealized (or “unphysical” as the haters call it) black holes. But you should be impressed, because this is a real black hole, one that you can actually see in the sky.

But on the other hand, why would you be? Even Hawking radiation is afterall experimentally unverifiable. As I have said before (and you have denied), you care nothing for understanding, but only for “experiment”. Since experiments are hard, you will always have your moral superiority.

Last couple of years – holographic superconductors were interesting, looking at turbulence through Einstein’s equations was interesting, integrability of gauge theory was interesting, membrane theories were interesting, realistic and more precise black hole entropy computations were interesting. WHY were they interesting? Because they gave us understanding about various things, some of which (relating to condensed matter and nuclear physics) are even accessible to semi-quantitative predictions. But are they ALL immediately going to be seen at the LHC? No.

My point is that when you make the statement that hardly anything is going on, you are in fact passing a judgement, and not stating a fact. This is something that the average reader of this blog will fail to recognize.

Peter: “As for claims of applications of black holes to condensed matter physics or nuclear physics, my philosophy is that the people to report on those and evaluate their significance should be condensed matter physicists and nuclear physicists.”

I am sure you have seen Bill Zajc’s comments at backreaction (if not, google!). That there are at least SOME nuclear physicists who are impressed by black hole predictions and calculationss is not too bad for a theory about the Planck scale.

69. **somebody**
October 21, 2008

“Strominger and collaborators recently found a way to compute the entropy of astrophysical black holes.”

I should be more precise and say fast-spinning astrophysical black holes.

70. **Peter Woit**
October 21, 2008

Somebody,

Thanks for the snide anonymous insults. I don’t know who you are, but I do have some idea what the “interesting questions” in fundamental physics are and have spent a long career “getting my hands dirty” trying to understand them. I just happen to be getting my hands dirty in places that are not so popular. I’ve also spent a lot of time trying to understand and learn from what others are doing, and make a point of keeping my mouth shut about things I don’t understand.

String theorists on the other hand, seem to revel in overhyping anything even remotely related to string theory. I’m well aware of the often-pointed to Zajc comments; you might also want to Google “Pinocchio award” and Larry McLerran for another take on this. One thing I have noticed about the string theorists who go on about this is that few if any of them seem to know anything about nuclear physics.

The way you misleadingly characterize the recent Strominger results is just typical. String theorists can’t just accurately explain exactly what some result is, instead they have to overhype it (“Strominger and collaborators recently found a way to compute the entropy of astrophysical black holes”!). You should realize that the whole field now has a huge credibility problem because of this behavior.

There is objective data available about the “no progress” claim from citation counts, and I’ve gone over this elsewhere.

71. **Peter Woit**
October 21, 2008

As for the reasons for the “no progress” problem, there are several. One is that the remaining problems are hard. Another is that a large and influential component of the community refuses to admit there is a problem, instead attacking the professional competence of anyone who brings up the topic.

72. **Jeff McGowan**
October 21, 2008

Dave,

I agree we have a different perspective. My old undergraduate advisor has for years taught a course called “Math and the Other Arts” and there is something artistic about many mathematicians approach (to everything). Could just be that I’m married to an artist, and off the top of my head I can think of at least five other mathematicians among my close acquaintances who are also married to artists 🙂 I didn’t take it as a criticism. I can pass you the names of some mathematicians who aren’t the sharpest tools in the shed if you want to even things up…

Also, I agree completely about predicting the future of science. And I have a lot of fun as an interested outsider reading Peter’s blog. Can’t quite believe the vitriol sometimes, you get much less of that in math, unless I’m just completely out of that loop. Oh, and as a practitioner of yoga, gotta say the flying bit is really funny. Actual yoga on the other hand is great.

73. **somebody**
October 22, 2008

I will try to stay close to the science and try to avoid getting into the vitriol.

Peter says: “I’m well aware of the often-pointed to Zajc comments; you might also want to Google “Pinocchio award” and Larry McLerran for another take on this.”

McLerran’s papers speak differently from his public talks. It always gets laughter to say a few words about string theorists and their 26 or 10 dimensions in talks. I do that too. But in his PRL paper he says (and I quote):

An amazing theoretical discovery was made by Kovtun, Son and Starinets [9], who showed that certain special field theories, special in the sense that they are dual to black branes in higher space-time dimensions, have the ratio η/s = 1/4pi (we use units with h = kB = c = 1) where η is the shear viscosity and s is the entropy density.

But I am sure there is perhaps another quote somewhere where he again bashes string theory, because it is no secret that McLerran is not a fan. So instead of hunting for it, I would also look at the specific comments made by Zajc about the science behind McLerran's Pinocchio remarks. We have alrready established that string theory has many enemies, so McLerran's like or dislike hardly adds anything new.

The crucial point is NOT that string theory has no enemies (ha-ha!), but that there are some qcd/nuclear physics types who are into strings these days. In particular, it is incorrect to imply that Zajc stands alone. Rajagopal, Weidemann,… have even published many papers on this.

Now lets turn to your comments about the Strominger computation:
" The way you misleadingly characterize the recent Strominger results is just typical. String theorists can't just accurately explain exactly what some result is, instead they have to overhype it ("Strominger and collaborators recently found a way to compute the entropy of astrophysical black holes"!). You should realize that the whole field now has a huge credibility problem because of this behavior."

You make an accusation that I am overhyping Strominger, while NOT making any statements about exactly what he does. I will chew my arm off and show restraint.

Two facts:

1. What Strominger does is to compute the central charge of the Virasoro algebra and the temperature of the dual CFT of an extremal four dimensional uncharged Kerr black hole. With these two you can compute the entropy using the Cardy relation.

2. There are ultra-spinning black holes in the sky. Astronomers have even identified them and given them names.

I will let you draw your own conclusions from these.

74. **nbutsomebody**
October 22, 2008

somebody said,
1. What Strominger does is to compute the central charge of the Virasoro algebra and the temperature of the dual CFT of an extremal four dimensional uncharged Kerr black hole. With these two you can compute the entropy using the Cardy relation.said,

Well, this is indeed a hyped way to present what he has done. what he has really done is to extend a little already known property of a AdS_3 and its various squashed cousins. It is a pure gravity calculation and there are simple geometric reasons why so called "central charge" is related to the area of the black hole horizon.
It is indeed suggestive of a holographic interpretation. However this was more or less known and there is no microscopic description.

75. **Archimedes**
October 22, 2008

Coming back to the topic… Is any of the Maharishi followers who happen to be reading this thread able to point out any publication where an experiment concerning the Maharishi effect is described in such a way that would allow one to reproduce it by independent means?

This may be a bit unfair a request, since social sciences are not "hard sciences" in the sense of physics, whose experiments can be reproduced by someone else in another lab, or another time. But it doesn't hurt to ask, so if someone can point out such an experiment I will be grateful.

If experiments are not of that type, as I expect they aren't (I haven't gone through any of the papers already mentioned in this thread) then the only way to check the validity of the conclusions is to really look at the papers carefully, perhaps with the help of someone from a statistics department or such.

Even so, doubts will remain about the validity of the experimental data to begin with. I am not a sceptic, in fact I'd be delighted if the Maharishi effect does exist. But I feel the need to be reassured that the Maharishi effect is not a corollary of the "Sokal effect"…

76. **Kevin Dailey**
October 22, 2008

The time has come when the science of physics has come to the frontier of the non-physical. It is very inspiring to see such a renowned physicist taking the leap into the spiritual. Whether we like it or not the effect of consciousness on matter is real and now in this modern age it is being scientifically explored and validated.

http://www.mum.edu/m_effect/

New frontiers are always scoffed at, doubted, made fun of and then finally widely accepted. You can be ahead of the crowd or follow behind. The choice is ours.

77. **anonymous**
October 22, 2008

Archimedes,

"allow one to reproduce it by independent means"

Presumably one would have to replicate the extensive training these people have in meditation, etc. (http://www.permanentpeace.org/technology/tm.html) This would be difficult and time-consuming to replicate from scratch.

Regarding the initial post: Reality of the effect (or not) aside, it boggles my mind that nobody questions whether doing this is ethical. If it is a real effect, why do we assume that it's a GOOD thing and that Hagelin SHOULD inflict it upon us?

78. **John Gonsowski**
October 23, 2008

The idea of a place where both physics and esoteric ideas can be studied is not a bad idea though one can certainly do it incorrectly or be too one sided.

Discussed in the link below are Plato's Academy, Gurdjieff's Institute for the Harmonious Development of Man, Maharishi International University, Perimeter Institute, and the authors' Quantum Future Institute.

http://quantumfuture.net/quantum_future/institute.htm

It’s not favorable to the Maharishi University.

79. **Tim May**
October 23, 2008

Anonymous writes:

“Presumably one would have to replicate the extensive training these people have in meditation, etc. (http://www.permanentpeace.org/technology/tm.html) This would be difficult and time-consuming to replicate from scratch.’

I’ll be happy to _personally_ fund the second round of experiments, with completely unaffiliated researchers trained at Maharishi University, AFTER at least the first round of experiments–involving video cameras manned by independent observers, checks for wires by independent observers, and other very basic norms of experimental science have given strong weight to “yogic flying.”

Saying that a bit of hearsay about yogic flight cannot be discounted until we have trained independent observers in exactly the same ways is not the way science works.

Early in my career, I discovered an unexpected effect (bits in computer chips flipped by alpha particles from the surrounding package, and at lower levels from cosmic rays). I presented experimental data, proposed mechanisms, and so on. Others followed on the work, presenting their own “independent” experiments.

There was never any suggestion that my work could only be confirmed or invalidated after others had “replicated” my training, etc. Granted, the “yogic flight” is supposed to be based on training, mental state, etc.

But the “reproducing the training” can and should come AFTER apparent “flight” (not ambiguous little “hops” of a few inches) has been established. A yogi flying in through a window of a conference hall and hovering 5 feet above the podium for a few minutes ought to do the trick.

Perhaps Peter will consider this off-topic, but I don’t. Experimental confirmation and “refutation of theories” is not nearly as subjective as some claim. Nearly all physics results in the 1850-1950 period could be duplicated or refuted by many around the world…and they were. After the era of Big Science, of course, it got a lot more expensive to do so. But even in the Age of Accelerators, competing labs can and do try to confirm what other labs are reporting. Further, even in the coming age of the One Big Accelerator, I expect enough internal competition between groups will provide for checks and balances on results claimed.

“Yogic flight” would be vastly more significant that the Higgs Boson, don’t you think? And yet people are debating some phony-looking Polaroids of guys who like they’re being dropped from some height into their (OUCH!) lotus position.

This is, as others here have said, “not even wrong.” Actually, it’s more than not even wrong. (Though a part of me would love to see evidence for yogic flying, or UFOs, etc., strong claims require strong evidence.)

Speaking for myself, not Peter or anyone else, this is not even in the same _game_ as string theory is. Rightly or wrongly, string theory is not yogic flying, crystal healing, or psychokinesis.

(As the joke goes, “All those in favor of psychokinesis, raise my hand.”)

–Tim May

80. **Gil**
October 23, 2008

The claims that the groups of meditators improve matters regarding the stock market or world peace and the statistically-based “scientific experiments” supporting them are nonsense. But these absurd claims raise the concern that the hundreds of papers by (the same) Maharishi scientists regarding more believable medical effects of meditation are bogus as well.

Trying to figure out if something is wrong and what it is in empirical experiments like those describing some wonderful effects of meditation is not an easy task. When the outcome of an experiment matches the desires of the experimenters but look otherwise suspicious or even absurd, a simple possible explanation is that the outcomes were “tuned” or “rigged”. Useful statistically-based methodologies that will allow to examine tunning effects are not easy to come by.

81. **Covariant**
October 24, 2008

OK

I was trying to be open minded about all this, and I confess I thought “yogic flying” was some sort of metaphor. Here is a link to a film where they demonstrate “stage one yogic flying”

http://www.youtube.com/watch?v=NHwhGUo90jw

Hagelin explains why Newton’s Laws are false. What a hoot!

82. **Thingumbob**
October 24, 2008

Here is the type of empirically verifiable study conducted at MIT which should serve as a model to test the claims of “yogic flying” :
http://zapatopi.net/afdb/

83. **anonymous**
October 27, 2008

Tim May – Do you really think this is about flying? Actual FLYING? I thought the flying was either 1) a cute (and rare) by-product of the effect, or 2) some kind of metaphor for the target state of mind.

Either way, I doubt that actually physically leaving the ground is necessary to achieve the purported aims of this project. It concerns me more that someone claims to have found a force that can pacify the ‘collective consciousness’ and is willing and able to use it, unrestrained by any ethical considerations, while people sit around arguing about gravity. (Here, watch my right hand while my left hand picks your pocket.)

Forget the flying. Assume it’s a woo-woo diversion to ensure that no one pays close attention to what is really going on. Since when do scientists deploy the results of their research arbitrarily upon mankind without obtaining any kind of consent? Sure, it sounds like a good plan – less fear in the collective consciousness = more stable markets

= good economic times for us all – but if ‘less fear’ came in the form of a pill, you would question the person who is telling you ‘trust me, it’s for your own good’. You wouldn’t sit around arguing about the placebo effect.

Even if you don’t think that the Maharishi effects are real (and I don’t mean the flying), Hagelin does, and he appears to direct their deployment according to an unvetted agenda.

84. **Vishal**
October 27, 2008

Here’s how yogis actually have been levitating in India all along: http://www.youtube.com/watch?v=etSivpBHUmE

I couldn’t believe my ears when I heard Hagelin’s interpretation of Newton’s law of gravitation in the YouTube video provided by Covariant. Unbelievable! The man is clearly duping people.

85. **Dave Miller**
October 28, 2008

John Gonsowski wrote:
>The idea of a place where both physics and esoteric ideas can be studied is not a bad idea…

No, John, it is a very bad idea, and for a very simple reason: “esoteric ideas” – all esoteric ideas – are nonsense, plain and simple.

I’m not claiming this as an a priori truth, but simply as an empirical fact proven by millennia of experience. We’ve had a very long time to check out all of this “esoteric” nonsense, and, again, to use the phrase Peter borrowed from Pauli, it has proven sometimes to be clearly false, but more often to be “not even wrong.”

I know that numerous people, sometimes even technically trained people, have claimed to acquire deep knowledge into the nature of the universe through esoteric studies, meditation, etc.

But when you probe the details of this deep knowledge, it boils down, at best, to saying that the universe is a really impressive place.

Indeed it is. But I realized that when I managed to understand Bondi’s “Relativity and Common Sense” as a kid. No meditation or esoterica required.

Meditation no doubt helps some people relax and cool down. Great. Singing old Simon and Garfunkel tunes in the shower helps me relax. Whatever.

But, the only road to knowledge ever discovered by human beings is the scientific method broadly construed: tie your ideas down to concrete, easily observed and easily checked evidence; make your conjectures sufficiently clear and explicit that, if they are wrong, they can be refuted; look for little “insignificant” details (such as the anomalous behavior of Mercury’s orbit) that suggest shortcomings in your ideas; assume you may have made mistakes in your reasoning or observations and cross-check them with other humans; etc.

Or, in simple terms, as Feynman put it, try really hard not to fool yourself.

The methods pursued by a mathematician, an experimental physicist, or a serious historian all follow that broad approach, even though their methods differ greatly in detail as fits their different fields of investigation.

“Esoteric ideas” are designed to violate all of the basic canons of the scientific method.

Esoteric ideas are nonsense.

Dave Miller in Sacramento

October 31, 2008

As regards scientific studies on meditation, the following newspaper article (dated 2005) provides a rough description:

http://www.npr.org/templates/story/story.php?storyId=5008565

The science here is neuroscience, and meditation is mostly buddhist. As far as I know the kind of research alluded to is interesting and serious. It also seems to be the state of the art in the field, and it is concerned with studying what happens in the brain of those who meditate, both in the short and the long run. This looks like a pragmatic and justified research program. What is more, all along neuroscience is still science, and buddhism is still religion/philosophy, no matter how suggestive the links between the two sides may be.

However, the Maharishi type TM, yogic flying and the like (even if the latter is taken only in a metaphoric sense) seem to be a completely different story, namely one whose claims, especially those that get all dressed up in the colors of deep fundamental physics, seem to be non-scientific assertions that mix up science, ancient philosophy, conjecture, intuition, faith and gut-feeling into an inextricable mess. Incidentally, looking at the MUM web pages I also came across something on “vedic mathematics” which seems to suggest that pure math is being garbled in just the same way.

   Newton, Hawking were no Fields medalist or Nobel laureates (for Physics). Certainly they are going to change that? 😉

2. **chickenbreeder**
   October 26, 2008

   Thanks for the tip. I will apply.

   OK seriously, Hawking's predecessor James Lighthill was also neither a Fields Medal winner nor a Nobel laureate. Actually, he was a fluid dynamicist whose achievement would not qualify him for either. But he was a dominant figure in the applied mathematics circle in Britain. So, don't be surprised if someone comes out of left field to take the job. (Lighthill was not a left-field choice. He was highly regarded and was recognized as exceedingly bright. His work on aerodynamics is world class. Only that aerodynamics is not a particularly fancy subject.)

   Another interesting trait is that although it's called Lucasian Professorship "in Mathematics", the Math here is almost always "applied" math (which means theoretical physics, geophysics, fluid dynamics, even meteorology, in British terms). This would exclude prominent British pure mathematicians like Andrew Wiles or Michael Atiyah, who would otherwise be big enough to fill the chair.

3. **FP**
   October 26, 2008

   To "show some class",
   Dirac was Physics nobel winners and Lucasian professor.

4. **curious**
   October 26, 2008

   What's happening with the current occupant?

5. **Peter Shor**
   October 26, 2008

   According to Wikipedia, the current occupant is planning to step down, and become Lucasian Professor emeritus. I hadn't realized he was that old.

6. **Kea**
   October 26, 2008

   Excellent! I think I will apply.

7. **MathPhys**
   October 26, 2008

   He will be 67 soon. I thought he already has a position in the US.

8. **Peter Woit**
   October 26, 2008

   MathPhys,

   There were rumors that Hawking might move to Perimeter on his retirement, I hadn't heard any rumors about the US.

9. **chickenbreeder**
   October 26, 2008

   Sixty-seven is the mendatory retirement age at Cambridge (and all Britain?) that's why Hawking is stepping down. Dirac also retired from Lucasian chair at 67, then spent the rest of his life in Florida as we know.

   Speaking of which, both Dirac and Hawking were appointed the chair at a very young age, in their 30's, and held the position for a long time. Lighthill occupied the chair from his 40's to 50's before moving to other more administrative positions. The limited samples seem to indicate that the ideal candidate is someone who is relatively young but already a dominant figure.

10. **Jimbo**
    October 26, 2008

    ProtoBrits for Lucasian Immortality:
    Julian Barbour, Michael Green, Neil Turok, Michael Berry, Mike Duff,
    David Deutsch, Roy Maartens, to name a few.

Now the real question: Who is stuffy enough to fit in at Cambridge ?

11. **Chris Oakley**
October 28, 2008

I just got the forms.

There is a section on disabilities (which worried me at first as I am pretty much able-bodied), but upon closer inspection, it turns out that this is not a requirement.

As I liked the idea of being the Lucasian Professor of Mathematics at Cambridge University, I was thinking of applying. I was about to e-mail Lubos to see if he would be prepared to give me an academic reference when I decided against it.

Firstly, I did not fancy the heavy teaching load (40 hours per year).

Secondly, the remuneration £60-124K (US $95-200K) – is less than a contract programmer earns in (what is left of) the finance world.

Well … maybe next time. Or probably not, as it seems likely that I will be over 67 when the appointee retires.

12. **Mitch Miller**
October 28, 2008

Are there any rumors for the Lucasian professorship? I can't imagine there being that many qualified people who are also interested in changing jobs.

13. **David McMahon**
October 29, 2008

Figures Britain has a mandatory retirement law. People should require when they are no longer productive or when they want to retire, not when some socialist government says they must. Not everyone is the same, some people are still very productive at 67 and beyond.

14. **chickenbreeder**
October 29, 2008

David – Mandatory retirement in academia is not a bad idea. Retired scientists can still freely pursue their research. I am sure Hawking will. In the U.S., emeritus professors often keep an office and are eligible to solicite external funding just like regular faculty. The difference is, their retirement frees up new positions for young people, easing traffic jam at bottom. This is critically important considering that, in certain fields, the total number of permanent positions have remains steady for a long time.

The mandatory retirement age is 60 at University of Tokyo. In some other Japanese Universities it's 62 or 63. People over there seem to have no complaint with that.

15. **Covariant**
October 30, 2008

Peter,

If you weren't in your current position would you consider applying?

I wanted to add that I picked up "Not Even Wrong" again. I read something this morning that made me think that certain fields of physics are moving more and more into the absurd.

For some reason, there was something about it that made some of your observations begin to resonate.

I won't go so far as to question all of string theory, but I have the feeling that we have exhausted the legitimate predictive power of QM and GR and the desire for expediency is leading to a cascade of abominations.

I think their might be something to this Peter Woit character afterall.

16. **Peter Woit**
October 30, 2008

Covariant,

No, I'm not qualified for that position. Like many a researcher, in my moments of extreme fantasy, I think that maybe the ideas I am working on now will lead to a huge success, one that might make me qualified for such a position. At the moment, that is pure fantasy.

And, luckily for me I'm very happy in New York working at Columbia, with no desire to go anywhere else.

17. **JustAnotherGradStudent**
October 30, 2008

So, are we placing wagers?

Here's a wild guess—David Tong. Young, energetic, very intelligent, already a Cambridge guy, definitely a mathematical physicist.

Anyone else have any guesses? The criteria seems to be a mathematical physicist, >67 yrs old.

Discovery of a New Particle?

October 30, 2008
Categories: Experimental HEP News

Except for the excitement surrounding first beams in the LHC, particle physics has been an all-too-quiet subject recently. It looks like that may be about to change, with a dramatic new result announced by the CDF experiment this evening, in a preprint entitled Study of multi-muon events produced in p-pbar collisions at sqrt(s)=1.96 TeV.

The CDF result originates in studies designed to determine the b-bbar cross-section by looking for events where a b-bbar pair is produced, each component of the pair decaying into a muon. The b-quark lifetime is of order a picosecond, so b-quarks travel a millimeter or so before decaying. The tracks from these decays can be reconstructed using the inner silicon detectors surrounding the beam-pipe, which has a radius of 1.5 cm. They can be characterized by their "impact parameter", the closest distance between the extrapolated track and the primary interaction vertex, in the plane transverse to the beam.

If one looks at events where the b-quark vertices are directly reconstructed, fitting a secondary vertex, the cross-section for b-bbar production comes out about as expected. On the other hand, if one just tries to identify b-quarks by their semi-leptonic decays, one gets a value for the b-bbar cross-section that is too large by a factor of two. In the second case, presumably there is some background being misidentified as b-bbar production.

The new result is based on a study of this background using a sample of events containing two muons, varying the tightness of the requirements on observed tracks in the layers of the silicon detector. The background being searched for should appear as the requirements are loosened. It turns out that such events seem to contain an anomalous component with unexpected properties that disagree with those of the known possible sources of background. The number of these anomalous events is large (tens of thousands), so this cannot just be a statistical fluctuation.

One of the anomalous properties of these events is that they contain tracks with large impact parameters, of order a centimeter rather than the hundreds of microns characteristic of b-quark decays. Fitting this tail by an exponential, one gets what one would expect to see from the decay of a new, unknown particle with a lifetime of about 20 picoseconds. These events have further unusual properties, including an anomalously high number of additional muons in small angular cones about the primary ones.

The exciting possibility here is that a new, relatively long-lived particle has been observed, one that decays in some way that leads to a lot more muons than one gets from Standard Model states. It should be remembered though that this is an extraordinary claim requiring extraordinary evidence, and the possibility remains that this is some sort of background or detector effect that the CDF physicists have missed. It should also be made clear that this paper is not a claim by CDF to have discovered a new particle, rather it is written up as a description of the anomalies they have found, leaving open the possibility that these come from some standard model processes or detector characteristics that they do not yet understand.

The overwhelming success of the Standard Model during the past 30 years has meant that essentially all claims from accelerator experiments to see some new, non-SM physics have turned out to be mistaken. As a result, collaborations like CDF are now extremely careful about making such claims and will only do so after the most rigorous possible review. It's a remarkable event that this one has gotten out, signed off on by the entire collaboration (although from what I understand, people can drop their names from the publication list of a specific paper if they disagree with it, maybe one should check this author list carefully…).

What would really be convincing would be a confirmation of this from D0, the other Tevatron detector. The D0 collaboration would not only be working with a detector that has somewhat different characteristics, but would also have some motivation to find a problem with the result from their competition. If they also see it, that would be pretty extraordinary evidence. Another sort of extraordinary evidence would be to see evidence for the same kind of new particle in other channels.

This will undoubtedly unleash a flood of papers from theorists promoting models that extend the Standard Model in ways that would produce something with the observed experimental signature. This is not a signature characteristic of supersymmetry or any of the other known heavily-studied classes of models. If real, as far as I'm aware it's something genuinely unexpected. Perhaps phenomenology experts can point to some less well-known models with this kind of signature. The only such thing I'm aware of is a very recent paper from three weeks ago by Arkani-Hamed and Weiner, entitled LHC Signals for a SuperUnified Theory of Dark Matter. They discuss a theory of dark matter involving a new hidden gauge symmetry, broken near the GeV scale, saying that this is "motivated directly by striking Data from the PAMELA and ATIC collaborations". In these models there can be Gev-scale Higgs and gauge particles decaying to an anomalously large number of leptons. They discuss the question of whether the parameters of such models can be adjusted to give large decay lengths, and predict the observation of events that "contain at least two "lepton jets": collections of n > 2 leptons, with small angular separations and GeV scale invariant masses", pretty much just what CDF sees . Since the CDF paper undoubtedly has been the topic of intense discussion among the 450 or so physicists in the collaboration for many months now, the most likely explanation for the appearance of a new theory paper a few weeks ago discussing exactly the signatures in question is that news of what's in the paper got out to some theorists early. Even if this particular result goes away, this gives some indication of what sorts of things are likely to happen once LHC data starts being collected and analyzed.

The bottom line though is that for the first time in quite a while, there's some very exciting and potentially revolutionary news in particle physics. It's coming not out of the LHC, which is still a hope for the future, but from a currently functioning machine which is producing more data every day. If this result holds up, this data contains a wealth of information about some new physics which will likely revolutionize our understanding of elementary particle physics. Particle physics may already have started to move out of its doldrums.

Update: This evening I came across an unexpected source of information about this, one which might explain why news of this result may have leaked out a while ago. More about this later.

Update: The results from PAMELA mentioned here, and which are listed as motivation for the Arkani-Hamed/Weiner paper, are now officially out. For discussion of this from someone much better informed than me, see this posting at Resonaances.

Update: There's an excellent detailed posting about the paper from CDF's own Tommaso Dorigo. If you're interested in understanding exactly what is going on here, that's where you should start.

Update: For entertainment, there's always Lubos.

Update: I'm now free to explain what I was alluding to when I earlier mentioned an "unexpected source of information". Yesterday evening while I was trying to find out more about the CDF result, its relation to previously published experimental results, and to possible phenomenological models, I was running some Google searches on relevant terms. One of these turned up something very surprising: the first result was a summary of CDF's internal review of drafts of PRL and PRD papers on the subject, the second was the PRL draft. Both of these documents were from early July, and part of a publicly accessible directory containing all the materials from a review of the draft at that time. Investigating further, it became clear that the CDF web-server was seriously misconfigured, allowing directory listings and public access to a wide array of their work materials.

I wrote an e-mail to people at CDF warning them about the problem, heard back quickly, and have just checked that they have fixed it, so I don't think I'll cause them a problem other than embarassment by telling this story here. It seems likely that these materials have been publicly accessible and indexed by Google probably for several months now.

I confess to reading these documents, figuring that anything really interesting that is Googleable is fair game. Since they clearly were not intended for public consumption I won't disseminate information about them beyond this story about their existence and the fact that the PRL draft contained tentative material interpreting the data in terms of new physics, the sort of thing the released paper avoids. One thing I can say is that it is very impressive to see the amount of effort and very serious scientific work behind a review of this kind. A lot went into this, and presumably a lot more has gone into it since last July. I understand why CDF does not make this kind of thing public, but it actually would be a wonderful example for the public of how science is done to do so.

Update: See Resonaances for a discussion of the dark sector model building.

Update: Another CDF blogger heard from: John Conway.

Comments

   October 30, 2008

   Heh, heh, heh!!!

   And wow, Peter. Such a long blog post so soon after the paper appearing. One might think you knew this was coming.

2. **Peter Woit**
   October 30, 2008

   Kea,

   There had been some chatter on the intertubes indicating that it might be a good idea to check the arXiv this evening….

3. **Amos**
   October 30, 2008

   If this pans out, today is truly a day of joy.

4. **Neal Weiner**
   October 31, 2008

   I can tell you officially we had no word on this. This blog is, in fact, the first I'd heard of it. (But have now looked at the paper.) What we predicted was just what was needed to explain PAMELA we thought.

5. **a quantum diaries survivor**
   October 31, 2008

   Neal,

   that is pretty hard to digest. Lepton jets with lifetimes. Come on. I think you owe it to the physics community to let us know where the leak came from.

   Cheers,
   T.

6. **Daniel de França MTd2**
   October 31, 2008

   Halloween Particle!

7. **Daniel de França MTd2**
   October 31, 2008

   "This is not a signature characteristic of supersymmetry or any of the other known heavily-studied classes of models."

   But Arkani-Hamed/Weiner uses a SUSY model to explain that, in fact, with 2 aspects of a certain SUSY, which he calls, SUSY(I) AND SUSY(II). Check page 3.

8. **Daniel de França MTd2**
   October 31, 2008

   Maybe it's this other Arkani-Hamed's/Wiener article that you are thinking of: http://arxiv.org/PS_cache/arxiv/pdf/0810/0810.0713v1.pdf . It was published in that same day you cited before, and it doesnt use SUSY.

9. **onymous**
   October 31, 2008

   Some comments:

   On a sociological note, although the paper doesn't specify which people within CDF did the analysis, my understanding is that it is a group which has some history of finding difficult-to-understand anomalies in the data. Tommaso has documented some of these on his blog (search for "superjets"); they are an interesting story, which one might take into account when deciding what to think of this.

   In Nima and Neal's model, as I understand it, one only expects lepton jets in events with SUSY, which you would *think* would stand out in some other way.

   My take on this is that it's probably nothing. Maybe punchthrough of hadrons into the muon detector. They claim to analyze all these things and quantify them, and I haven't digested the 70 pages, but these sound like very difficult problems, and I wouldn't bet on them being fully understood. If you want exciting things in data right now, dark matter is where it's at.

   (And dark matter / positron excesses is clearly what motivated the "lepton jets"; it's offensive for Tommaso to publicly imply otherwise.)

   In short: calm down!

   — A phenomenologist who would love to see new physics and thinks this isn't it

10. **Matti Pitkänen**
October 31, 2008

Nothing new to me but two excellent birthday gifts at my birthday October 30;-).

TGD has predicted the existence of colored excitations of leptons explaining CDF anomaly already for fifteen years ago.

One of the basic predictions of TGD indeed is that leptons should have colored excitations. Already at seventeens a lot of evidence for colored electrons, or rather their pion like bound states, came from anomalous production of electron positron pairs in heavy ion collisions. For some mysterious reason it was put under the carpet. I have tried to tell about this in blogs but in vain.

For year ago evidence for muo-pions came. Again it was forgotten although Lubos saw the trouble of ridiculing the experimenters.

CDF gives evidence for tau-pion. The lifetime predicted for charged tau-pion obtained by scaling the prediction for pion life-time is correct if one scales down the parameter x in the parameter f(pi)= xm(pi) characterizing pion coupling to axial current by factor .41. To my opinion the case is now closed.

The positron and electron positron cosmic ray anomalies can in turn be seen as evidence for M_89 copy of hadron physics.

See my blog.

11. **a quantum diaries survivor**
October 31, 2008

Dear ominous (same as the one who left a comment in my blog a while ago, I guess):

punch through is a possibility, but it has been investigated in depth, by people not exactly enthusiastic about the signal, and found inconsistent with the signal, its size, and characteristics. I would rather lend towards secondary nuclear interactions instead, but it is a tough call. The fact that there is a chance – what, 1% ? 0.5%? – that it indeed constitutes new physics, is extraordinary to me nonetheless.

As for the theorists and their claims: we are adults and we know physics. We have read thousands of papers and published hundreds. We know the history of HEP. We know how people chats in the corridors. And I personally know that in this particular case some people in CDF have been less careful than they should have with this paper before publication.

On the other side, there is this pair of papers coming out of the blue, which casually get published a few months after the CDF analysis emerges from the authors' computers and is in internal review, and less than a month before that analysis sees the light in the arxiv. These two phenomenological -but I would rather call them phenomenal- papers discuss a signature almost never heard of before. It entails lepton jets. Many leptons, with small invariant masses. With long lifetimes.

I say, you can believe in SUSY or you can believe in the Yeti, or whatever you want. I can believe a lot of things, but I do not buy that it is their own cooking. Especially since the paper is rather handwaving in tone and conclusions.

So, to summarize: it may sound offensive to be inquisitive with respectable theorists about where the hell they got that idea, but it is no less offensive to act nonchalant and pretend we buy this incredible coincidence without a detailed explanation.

Finally, about the authors of the analysis: be very careful. They are among the best physicists I know in CDF, and I know all of them. They have the vice of searching for the unknown rather than being happy with measuring something with twice better accuracy than others. I would like it if there were more like them around.

Cheers,
T.

12. **woit**
October 31, 2008

Daniel,

The Arkani-Hamed/Weiner paper doesn't use SUSY in any crucial way. Their proposal is that the observed signature comes from a "Dark Sector", this can be embedded in a SUSY model, but that's not necessary. From their paper:

"While our discussion is framed within the context of low-energy SUSY, some of the conclusions hold in a wider class of theories for new physics. The signals associated with decays into the dark sector and back follow in any theory with a particle charged under the SM that is nonetheless stable in the absence of a small coupling to the Dark Sector, while the new colored states should be expected in any picture in which the Dark Matter is charged under the Standard Model and gauge coupling unification is taken seriously."

13. **Daniel de França MTd2**
October 31, 2008

Peter,

The article with Moose tries to argue for SUSY, since this new Sommerfeld force must be unified with a larger picture, that is, the SM through SUSY. What the other article, does the thing you want, that is, specificaly describing that phenomeny, but without saying that SUSY has anything to do with that, or trying to embed that phenomena in any bigger scheme…

14. **andy.s**
October 31, 2008

Didn't Willis Lamb suggest that anyone discovering a new particle be punished with a $10,000 fine?

15. **Yatima**
November 1, 2008

>> Didn't Willis Lamb suggest that anyone discovering a new particle be punished with a $10,000 fine?

That was before the quark model and QCD, right? These days, discovering new particles is what decade-in-building billion-dollar machines are all about.

I applaud this New Kind of October Surprise. Here's hoping something will come out of it.

16. **L. Carpenter**
November 1, 2008

This all seems very iffy, howver it still doesn't rule out SUSY,
You know, SUSY with R parity violation has displaced vertices, as per Dreiner, Grab, Banks, Carpenter, Kaplan, Rhee and probably many more etc and so on, you just make the coupling small enough and the intermediate sparticle heavy enough. However I'd bet that this might go away.

17. **a quantum diaries survivor**
November 1, 2008

"I would bet than this might go away"

Lol… This is rather careful, isn't it ? Of course odds are against the multi-muon signal being new physics! Would you bet 500 to 1 ? That would be a statement. For me, a >0.1% chance that this is new physics is a HUGE chance.

Cheers,
T.

18. **Covariant**
November 1, 2008

I'm just wondering where the boundary between new and old physics is defined. When do we know enough of the old physics to know its new physics?

This reminds of long range artillery in WWI, when for the first time the coriolis effect had to be taken into account in calculating trajectories (confirming the Earth was spinning).

http://en.wikipedia.org/wiki/Paris_Gun

Do we know all the environmental effects well enough?

19. **mike**
November 1, 2008

It's certainly wise not to call it a new particle until it's been peer reviewed, but it's also wise not to dismiss it immediately as a detector problem. It would be good to see the D0 provide some insight into the problem. Wouldn't they have characterized the Si detectors in CDF pretty thoroughly by now?

20. **chickenbreeder**
November 1, 2008

Covariant: Foucault's Pendulum (cir. 1850) was already definitive experimental confirmation of Earth rotation.

A question from a casual reader: Could all this hope and positive outlook on the new particle be the result of desperation, given that there has been no breakthrough in high energy particle physics in decades? Also, was the experiment specifically designed with the expectation of finding a particle of this characteristic, or is it serendipity (assuming that there's indeed a new particle in this story)?

21. **Peter Woit**
November 1, 2008

Covariant,

By "new physics" what is meant is something not in the Standard Model. One possibility is that what is being seen is due to some poorly understood effect of the Standard Model, e.g that this might somehow be just another bound state of quarks.

mike,

The paper has undergone very extensive review at CDF, I doubt that a referee will find problems not identified in their internal review, but it's not impossible. They are careful in the paper not to claim discovery of a new particle, just to be putting forward an anomaly in the data that is not understood, with a new particle one possible explanation. The behavior of these detectors and the data analysis are extremely complex, there's a lot that can go wrong. It will be very interesting to see what D0 finds when they look for this.

chickenbreeder,

The lack of new discoveries in particle physics certainly makes any anomaly get a lot more attention. The detector was not designed to look for this.

22. **Luboš Motl**
November 2, 2008

"This is not a signature characteristic of supersymmetry."

That's quite a breathtaking statement. The whole paper by Arkani-Hamed and Weiner is based on supersymmetry. There would be no lepton jets without it. The acronym LSP – lightest supersymmetric particle – appears 45+ times in their paper.

They obtained the model by taking the model by these 2 and 2 other authors meant to match the PAMELA, ATIC, DAMA, INTEGRAL observations. Because the latter requires light scalars, SUSY is needed for naturalness. So they added it. Then it follows that there are several LSP-like particles and the lepton jets come from them. The model without supersymmetry cannot predict any lepton jets (although all models can be fine-tuned to get one particular prediction right, but others are likely to fail then).

If this explanation were right, it would be a nearly complete experimental proof of SUSY as well as several other characteristically string-theoretical signatures, including a hidden gauge theory sector and a quiver spectrum of matter. It is likely that some compactifications of string theory predict exactly this thing and they will be located soon, leading to new predictions. This scenario was just unrealized by everyone because everyone kind of thought that all hidden sector particles have to be heavy.

It would become the most direct proof in decades that the notion that these concepts are "untestable" or untrue or "not even wrong" and blah blah blah is just a gigantic and very stupid lie, indeed.

23. **Covariant**

November 2, 2008

Peter,

I appreciate the answer. I think that was what I was unknowingly alluding to.

Chickenbreeder,

I was cognizant of that fact (hence the word confirm and not proof). I think my intent was misunderstood.

There is still a lot about our little blob of iron and mud that we are unsure about 🙂

24. **Peter Woit**
November 2, 2008

Lubos,

I think you missed this:

http://www.math.columbia.edu/~woit/wordpress/?p=1045#comment-44797

Your claim on your blog that this is "An experimental proof of most low-energy signatures of string theory", and speculation that Arkani-Hamed and Weiner will share a Nobel prize for this are among the funnier things I've ever seen on a physics blog.

By the way, have you or anyone else asked Arkani-Hamed whether he knew of the CDF result before it was published?

25. **H-I-G-G-S**
November 2, 2008

Lubos,

If you buy into the string landscape explanation of the cosmological constant, as you seem to, then complaints about fine-tuning and appeals to naturalness carry very little weight. Without these there is no reason you can't have a model with the main features of the Arkani-Hamed and Weiner model but without supersymmetry. Claiming this result, if it holds up, as nearly complete experimental proof of SUSY is absurd.

PH

26. **Shantanu**
November 2, 2008

Peter, did I read correctly on cosmicvariance that one third of CDF collaboration have dropped their name off the paper? Do you know the reason?

27. **Esornep**
November 2, 2008

"Peter, did I read correctly on cosmicvariance that one third of CDF collaboration have dropped their name off the paper? "

You did. And what makes this utterly astounding is that the paper makes essentially no claims whatever to have found anything! All they say is, "we saw this weird signal in our data. Make of it what you will." Or could it be that the recalcitrant 1/3 are protesting at this extreme wishy-washiness? 🙂

28. **Esornep**
November 2, 2008

BTW, Arkani-Hamed and Weiner have rushed out a second version of their paper. It raises many question marks. And I mean that literally!

29. **onymous**
November 2, 2008

What a circus! Anyone want to place bets on how long before we see the first "unparticle" explanation appear on hep-ph?

30. **witness**
November 3, 2008

to Esornep:
The exact reasons for not signing vary but most range from "CDF can do much better in investigating this" to "this is clearly correlated hadronic punch-through of jets".

31. **Axolotl**
November 3, 2008

Latest from Arkani-Hamed at Dorigo's blog: it's lies, all lies, and anyway our model does *not* predict anything like what has been seen. Lubos Motl's denunciation of NAH as a crackpot is expected momentarily.

32. **Covariant**
November 3, 2008

I think NAH is deserving of some sympathy.

I am slowly making sense of the CDF paper, and being ignorant of how Tevatron runs are scheduled, I was wondering if CDF has done any time analysis on the "jets" to see if there was any variation based on time of day.

33. **a quantum diaries survivor**
November 4, 2008

To whom may be concerned:

the fact that the CDF paper carries only two thirds of the usual author names is due to the particular publication process this paper withstood. The authors wanted to see it out soon, because of the possibility (quite real, in fact, if you have read Peter's update above) that it might leak out and be scooped by a quick parallel analysis by D0 (unlikely, given that D0 is under-manned these days, and the bounty of data on which to concentrate for several other important measurements so large). Some colleagues in CDF felt they wanted more analysis, and they decided not to sign. This is still a CDF publication, case closed.

Let me add that CDF has published over 400 papers in its illustrious, 25-year-long career, and that we are publishing many, many other important measurements on a weekly basis. So, please do not concentrate too much on this one paper, which, I am sure, will be seen in perspective in a few months, one of two very different perspectives indeed. If electrons do not confirm, and D0 disproves the multi-muon signal, this will be just a honest attempt to explain to the scientific community what we saw and what we did not understand of muons in our data -which has some impact in past measurements. If there are confirmations, then the story is different of course, and those 1/3 of authors who took their name off will reconsider the matter for the future publications on the same topic.

Cheers,
T.

The Circus Begins

November 2, 2008
Categories: Experimental HEP News

Friday's arXiv posting of the paper by CDF about the multi-muon anomaly they are seeing has already generated three different conjectural explanations of what physics might be responsible for this. Undoubtedly many, many more are on the way.

- Some members of the CDF collaboration have posted a paper entitled Phenomenological interpretation of the multi-muon events reported by the CDF collaboration. This explains the large numbers of muons with a rather baroque mechanism, conjecturing the production of a 300 GeV heavy particle decaying through a chain of 3 lighter particles, the last of which is supposed to be the long-lived (20 picosecond) one. This interpretation was part of the original draft PRL from last June/July. The CDF collaboration as a whole seems to have decided not to support the draft PRL and this interpretation, instead releasing just a PRD paper that describes the anomaly without trying to interpret its significance. It also seems that only two-thirds of the collaboration put their names on the PRD paper, and the interpretation paper was put out just by a small group. The whole story is somewhat reminiscent of the "Superjet" affair (see Tommaso Dorigo's multi-part discussion here), which also involved a PRD publication about an anomaly signed by the collaboration, and an interpretation (in terms of squarks) signed by a much smaller group led by Paolo Giromini.
- An hour or so after the Giromini et. al. paper came in on Friday, a group of string theorists had posted the 40-page Towards Realistic String Vacua on hep-th claiming to explain the CDF results with a class of string vacua:

> We also describe model-independent physical implications of this scenario. These include the masses of anomalous and non-anomalous U(1)'s and the generic existence of a new hyperweak force under which leptons and/or quarks could be charged. We propose that such a gauge boson could be responsible for the ghost muon anomaly recently found at the Tevatron's CDF detector.

If the Giromini et. al. explanation invoking 4 new particles is baroque, it's hard to know what the right word is for the far more complicated constructions that are described in this paper.

- There's a new version this evening of the 3-week old Arkani-Hamed/Weiner LHC Signals for a SuperUnified Theory of Dark Matter, in which they claim to have a new signature for supersymmetry, with a large fraction of all SUSY events looking exactly like what CDF described. Oddly enough, the changes to the paper don't include a mention of the CDF result. This paper also invokes a rather baroque mechanism, involving both the supersymmetric extension of the standard model and a whole new complicated dark sector.

This last paper is also supposed to explain the PAMELA data, and papers with other explanations of this are starting to flood hep-ph.

So far, all the explanations of the anomaly seen by CDF look suspiciously complicated, which may be one reason that many members of CDF are so skeptical about the whole thing that they were unwilling to sign on to the PRD submission. But I'm sure that many more proposals for how to explain the anomaly are being drafted at this very moment, and maybe one of them will be more convincing.

Update: Over at Tommaso Dorigo's blog there's a short posting about Giromini et. al., and an exchange with Nima Arkani-Hamed, who claims to have had no inside knowledge of the CDF "lepton jets" when he wrote his paper with Weiner predicting them. He also explains how the exact mechanism discussed in that paper is unlikely to explain the CDF result since their observed rate is too high for this.

Update: New Scientist has the story, emphasizing the possible relation to the work of Arkani-Hamed and Weiner:

> So what could it be? As it happens, Weiner and Nima Arkani-Hamed of the Institute for Advanced Study in Princeton, New Jersey, and colleagues have developed a theory of dark matter – the enigmatic stuff thought to make up a large proportion of the universe – to explain recent observations of radiation and anti-particles from the Milky Way.
>
> Their model posits dark matter particles that interact among themselves by exchanging "force-carrying" particles with a mass of about 1 gigaelectronvolts.
> The CDF muons appear to have come from the decay of a particle with a mass of about 1 GeV. So could they be a signature of dark matter? "We are trying to figure that out," says Weiner. "But I would be excited by the CDF data regardless."

CDF spokesperson Jacobo Konigsberg is quoted as saying:

> we haven't ruled out a mundane explanation for this, and I want to make that very clear

Update: Then there's Slashdot, where the hypothetical CDF particle is advertised as accounting for the Arkani-Hamed et. al. theory of dark matter.

Update: Another story, at Physics World, which has more from various people at CDF. Again, that Arkani-Hamed/Weiner "predicted a CDF–like signal", although the problem with the rate being too low is mentioned.

Also Nature, where one learns:

> Theorists are already coming up with ideas about what might be producing the excess muons. One possibility is that they stem from the decay of a heavier, yet-to-be-discovered particle — perhaps related to dark matter, an unseen material that is believed to make up some 85% of matter in the Universe.
>
> Another idea from string theory evokes seven-dimensional 'branes' — theoretical surfaces that are inhabited by exotic particles manifested as strings. These higher-dimensional branes might be home to force-carrying particles that interact weakly with our three-dimensional world and create a faint, but traceable, signal in the data.
>
> But Adam Falkowski, a theorist at CERN, Europe's particle accelerator laboratory near Geneva, Switzerland, says that the explanations need some work, and cautions against attempting to force the data to fit into particular theories.

Update: More press stories here and here.

   November 3, 2008

   A 300 GeV particle with a 100 nb cross section. That's… special.

(They don't need the 300 GeV particle; they need the 15 GeV particle, but with enough of a boost to have collimated decay products. Hence the ad hoc 300 GeV Higgs to fit the curves.)

2. **Coin**
November 3, 2008

So far, all the explanations of the anomaly seen by CDF look suspiciously complicated, which may be one reason that many members of CDF are so skeptical about the whole thing that they were unwilling to sign on to the PRD submission

Hm, maybe I don't understand what you're suggesting here… is it normal for experimental particle physicists to doubt experimental results to the point of not participating in their publication, just because they can't find a clean theoretical mechanism from which those results came?

3. **Roger**
November 3, 2008

Its very unusual for a collaboration member to remove his/her name from a paper though it does happen from time to time.

However, I have never heard of a third of a collaboration removing their names. This is very worrying.

4. **Peter Woit**
November 3, 2008

Coin,

If your experiment is seeing something confusing and completely different than what known theory predicts, the chances are quite high that the problem is with your experiment, and every experimentalist is well aware of this. On the other hand, if the 20ps state CDF is seeing evidence for had the right properties to be the SM or MSSM Higgs, I'd bet absolutely everyone in CDF would have signed on, the paper would be a PRL making a discovery claim, and CDF leaders would be ordering their outfits for a trip to Stockholm.

5. **James**
November 3, 2008

There's a quote I've heard attributed to Einstein that goes roughly like "A theory is something believed by nobody except its creator, and an experiment is something believed by everybody except the experimenter."

6. **Shantanu**
November 3, 2008

Peter or anyone else, does anyone know what this model predicts for proton decay? This might be a good way to test the consistency of these models.

7. **Peter Woit**
November 3, 2008

Shantanu,

Which model? I don't think any of the models discussed here is the sort of thing that would make a testable prediction about proton decay.

8. **Sumar Ongi**
November 3, 2008

My personal hunch —as if it mattered— is that this whole thing will fizzle out. This is not a criticism of CDF and of the theoreticians working on this issue (quite the opposite, I see their work with respect and even admiration). It's just how physics works: 99% blind alleys, 1% breakthroughs.

Now, a 300 GeV Higgs boson? I would love so much to see that!!!

9. **dragon**
November 4, 2008

"Then there's Slashdot, where the hypothetical CDF particle is advertised as accounting for the Arkani-Hamed et. al. theory of dark matter."

Taken literally, this statement means that the CDF observations explain the existence of certain papers, rather than the other way around. One suspects a typo at first, but in view of what has been going on over at Dr Dorigo's blog, perhaps this is the right ordering after all…….

10. **a quantum diaries survivor**
November 4, 2008

Lol dragon… I decided I will not investigate the matter further. We have heard from the theoreticians, we know the story, the documents are out there for anybody to make their own mind. And regardless of opinions, publications remain.

My own opinion is however the following:
1) the CDF signal is not NP
2) the NAH et al. papers discuss an interesting signature, which however does not describe reality
3) we are still in the dark and we will stay there for a while
4) I am going to collect 1000$ soon. How soon ? Depends when the LHC will deliver 10/fb of data.

Cheers,
T.

11. **Arnaud**
November 4, 2008

Hello,

I'm not a professional physicist so pardon my naivete: How can anybody have a theoretical explanation for what appears to be a quite unexpected experimental result, less than a week after its publication? I'm sure HEP is full of very bright people, nevertheless this looks a bit rushed to me, and suspiciously like a race to publish.

Personally, my only way of understanding this would be if either the news have been in the pipeline beforehand, or it was in fact expected. The blog hasn't mentioned either fact, I think?

Physicists like to mock the media and their rush to the "story" over scientific content, but from the outside this particular event looks like this story of pots, kettles and blackness… Or am I wrong?

12. **Peter Woit**
November 4, 2008

Arnaud,

There's plenty ot mock about the media's coverage of science, but my own point of view is that in recent years the blame for problems with media coverage of some parts of physics lies with physicists themselves rather than journalists.

This experimental result was not expected at all by theorists. It is not known how widespread knowledge of the CDF result was before it was released last Thursday evening. Back in July, people at CDF were already worried that the news had leaked out (how do I know this? because by mistake the documents of their internal deliberations were freely available on-line and indexed by Google.)

One of the papers mentioned above appeared within a day of the Thursday evening news. My own view is that the paper in question uses a typical string theory set-up that is capable of explaining anything. String theorists are hard-working and industrious, it's perfectly plausible that within 24 hours they could have drafted the section of the paper needed to "explain" the CDF result within the context of the string theory models they are working with. In the same 24 hours they undoubtedly could have come up with explanations of all sorts of different unexpected experimental results.

This all shows what is likely to happen if and when unexpected preliminary result come out of the LHC. String theory/supersymmetry explanations of the results will come fast and furious, no matter what they are.

13. **Peter Woit**
November 4, 2008

In case the above is unclear, I'm referrring to the second paper mentioned in the posting. The first is from within CDF, the authors have had many months to work on their analysis. The last one is a paper written before the results were announced, there is extensive discussion about it over at Tommaso Dorigo's blog.

14. **Chris W.**
November 4, 2008

This all shows what is likely to happen if and when unexpected preliminary result come out of the LHC. String theory/supersymmetry explanations of the results will come fast and furious, no matter what they are.

It will be a painfully protracted process of coming to see not ST/SUSY's inability to explain these results, but its inconclusive and ultimately sterile fecundity* in explaining them, along with a million other results we don't happen to see, for reasons that will receive their own convoluted explanations (if anybody cares).

[* or to use Kant's phrase, "accursed fertility"]

15. **Arnaud**
November 6, 2008

Thanks Peter & Chris. I am not participating constructively to the discussion here, but instead I have another question, sorry again.

You seem to imply that String theory is an elastic concept which can
be made to fit any new fact and sort of retroactively claim that some form of it predicted the result, right? I'm kind of an educated layman on this (I'm only an actual rocket scientist), but I read Lee Smolin's book, so I guess I'm convinced by your argument now 🙂

My question is slightly different here: People like you and Lee seem to argue that over the last 20 or 30 years, not much has happened in theoretical particle physics, due in part to the lack of experiments (like the LHC) probing deeper into the high-energy spectrum. This seems to leave plenty of time to researchers to analyse current gaps in detail and hone their predictive models or new theories.

When I match that to some papers and presentations I've seen where different explanations are proposed depending on different expected values or results of proposed experiments (such as the mass of the hypothetical Higgs Boson), It leads me to imagine that there are a bunch of -to caricature- "if-then-else" set of explanations and theories ready to be put out as soon as new results come in. Does that make sense, and would you say it's in any way correct, or is the picture not quite like that?

This was how I though one could explain fast turnover of papers, although you're clear in your response it doesn't apply here because the results are quite unexpected. I guess this is what makes fundamental physics interesting!

PS, I read Tomaso's futher post and loooong dialogue and comments on this. I can't claim to have an informed opinion, but it leaves me a sad impression that the discussion is as much about physics as it is about ego and politics.
I recognise though, it takes a strong dose of wisdom and character to stand up for scientific integrity in this world of inflated career expectations, performance-related-pay and short-term contracts. I guess they don't teach those in physics courses… (This comment could be made for a lot of disciplines, naturally).

16. **Thomas D**
November 7, 2008

It is actually very disappointing that experimentalists would effectively refuse to publish a 10 sigma deviation, even after all imaginable systematics and loopholes are investigated, just because it is difficult to find a theory (within conventional frameworks) to account for it. But I don't know the exact reason why the whole collaboration would not sign up to the long Phys Rev paper.

The quote about 'theory is believed by no-one beyond its creator' is not at all true nowadays. On the contrary, HEP experimentalists are very reliant on theorists to tell them what types of signals are 'likely' to emerge (meaning, likely given some popular model or theory). That means that if none of the popular theories are right, the experimental search will not be well set up to investigate what there actually is.

There are a few groups trying to put together a 'model-independent' search for new physics at LHC, which is a good insurance policy against all the theorists being wrong, but maybe not enough attention is being paid to this.

Any reporting that tries to link the muons to recent dark matter models is pretty much malpractice. Arkani-Hamed has written:
"even if the CDF anomalies are an indication of new physics–which I think in all of our views is _very_ far from obvious– it can not be due to the signal Neal and I talked about, arising from SUSY cascade decays. The rate of the CDF anomaly is absolutely enormous–you are talking about 70,000 "ghost" events! (…)"

I am not sure what Peter is blaming physicists for in media coverage. Is he saying the Quevedo group is too hardworking? I have to say also, they are relatively lucky, since contrary to what he is insinuating not all string models have these leptonic or 'hyperweak' U(1)'s readily available… and not all string theorists happen to have a 40-page paper ready to publish at the same time as experimentalists announce something.

Perhaps someone could take the elementary step of asking someone in that collaboration whether or not their models can always explain every possible signal, rather than taking this as a basic assumption.

And it's by no means certain that this model *can* explain the multi-muons, rather than just containing ingredients which could go some way towards it. On p. 30 they say:
"Notice that this proposal to explain the CDF data can be considered independently of string theory. While we have assumed U to be a gauge boson motivated by the D3-D7 brane models considered in this paper, the same basic phenomenological approach could apply for any bulk state with very weak couplings to quarks and no kinematically accessible 2-body decays. (…)
It remains to be seen if with these numbers it is possible to obtain the proper U lifetime. The above is clearly a phenomenological scenario and not yet a full model. More detailed model-building is necessary for a full analysis of the merits and further phenomenological and cosmological implications of the approach outlined."

So again, what is Peter's problem with this?

17. **Peter Woit**
November 7, 2008

Thomas D,

CDF is not refusing to publish anything, they have submitted a paper to PRD. Some of the collaboration aren't signing on to the publication for various reasons. For an experimentalist to be skeptical about a very weird signal, thinking it is likely to be a flaw in the analysis, so not ready for publication, isn't exactly unusual or surprising.

I don't think I'm the only one who finds laughable the spectacle of a group of string theorists putting out a paper in less than 24 hours "explaining" a very weird and unexpected signal using a very complicated "string vacuum".

Gazouille,

Thanks, fixed.

20. **Brandon Watson**
November 9, 2008

If the Giromini et. al. explanation invoking 4 new particles is baroque, it's hard to know what the right word is for the far more complicated constructions that are described in this paper.

I know that this was ironic, but the word for the step up from ordinary baroque is churrigueresque — 'frantically baroque', as it has sometimes been called. I bring it up just because it's sometimes a very good word to have on hand.

21. **Peter Woit**
November 9, 2008

Thanks Brandon, I'm always glad to learn a new word.

Notes on BRST I: Representation Theory and Quantum Mechanics

November 5, 2008
Categories: BRST

This is the first posting of a planned series that will discuss the BRST method for handling gauge symmetries and related mathematical topics. I've been writing a more formal paper about this, but given the substantial amount of not-well-known background material involved, it seems like a good idea to first put together a few expository accounts of some of these topics. And what better place for this than a blog?

Many readers who are used to my usual attempts to be newsworthy and entertaining, often by scandal-mongering or stirring up trouble of one kind or another, may be very disappointed in these posts. They're quite technical, hard to follow, and of low-to-negative entertainment value. You probably would do best to skip them and wait for more of the usual fare, which should continue to appear from time to time.

Quantum Mechanics and Representation Theory

A quantum mechanical physical system is given by the following mathematical structure:

- A Hilbert space $\mathcal H$, the "space of states". A state of the physical system is determined by a vector $|\psi\rangle\in \mathcal H$, with unit norm (i.e. $||\psi||^2=\langle \psi|\psi\rangle=1$).
- An algebra $\mathcal O$ that acts on $\mathcal H$. To each physical observable corresponds a self-adjoint operator $O\in\mathcal O$. Eigenvectors in $\mathcal H$ of this operator correspond to states where the observable has a well-defined value, which is the eigenvalue.

If a physical system has a symmetry group G, there is a unitary representation $(\Pi, \mathcal H)$ of G on $\mathcal H$. This means that for each $g\in G$ we get a unitary operator $\Pi(g)$ satisfying

$$\Pi(g_3)=\Pi(g_2)\Pi(g_1)\ \text{if}\ g_3=g_1g_2$$

i.e. the map Π from group elements to unitary operators is a homomorphism. The $\Pi(g)$ act on $\mathcal O$ by taking an operator O to its conjugate $\Pi(g)O(\Pi(g))^{-1}$.

When G is a Lie group with Lie algebra $(\mathfrak g,)$, differentiating Π gives a unitary representation $(\pi, \mathcal H)$ of $\mathfrak g$ on $\mathcal H$. This means that for each $X\in \mathfrak g$ we get a skew-Hermitian operator $\pi(X)$ on $\mathcal H$, satisfying

$\pi(X_3)=\ \text{if}\ X_3=$

i.e. the map π taking Lie algebra elements X (with the Lie bracket in $\mathfrak g$) to skew-Hermitian operators (with commutator of operators) is a homomorphism. On $\mathcal O$, $\mathfrak g$ acts by the differential of the conjugation action of G, this action is just that of taking the commutator with $\pi(X)$.

The Lie bracket is not associative, but to any Lie algebra $\mathfrak g$, one can construct an associative algebra $U(\mathfrak g)$ called the universal enveloping algebra for $\mathfrak g$. If one identifies $X\in \mathfrak g$ with left-invariant vector fields on G, which are first-order differential operators on functions on G, then $U(\mathfrak g)$ is the algebra of left-invariant differential operators on G of all orders, with product the composition of differential operators. A Lie algebra representation is precisely a module over $U(\mathfrak g)$, i.e. a vector space with an action of $U(\mathfrak g)$.

So, the state space $\mathcal H$ of a quantum system with symmetry group G carries not only a unitary representation of G, but also a unitary representation of $\mathfrak g$, or equivalently, an action of the algebra $U(\mathfrak g)$. $X\in \mathfrak g$ acts by the operator $\pi(X)$. In this way a representation π gives a sub-algebra of the algebra $\mathcal O$ of observables. Most of the important observables that show up in practice come from a symmetry in this way. An interesting philosophical question is whether the quantum system that governs the real world is purely determined by symmetry, i.e. such that ALL its observables come from symmetries in this manner.

Some Examples

Much of the structure of common quantum mechanical systems is governed by the fact that they carry space-time symmetries. In our 3-space, 1-time dimensional world, these include:

- Translations in space: $G=\mathbf R^3$, $\mathfrak g =\mathbf R^3$, Lie Bracket is trivial.
For each basis element $e_j\in \mathfrak g$ one gets a momentum operator $\pi(e_j)=iP_j$
- Translations in time: $G=\mathbf R$, $\mathfrak g =\mathbf R$. If e_0 is a basis of $\mathfrak g$, $i\pi(e_0)=H$, the Hamiltonian operator. The fact that this operator generates time-translations is just Schrodinger's equation.
- Rotations in 3-space: $G=SO(3)$, or its double cover $G=Spin(3)=SU(2)$, $\mathfrak g = \mathbf R^3$, with bracket given by the vector product. For each basis element $e_j\in \mathfrak g$ one gets an angular momentum operator $\pi(e_j)=iJ_j$. These operators do not commute, so cannot be simultaneously diagonalized.

Another example is the symmetry of phase transformations of the state space $\mathcal H$. Here $G=U(1)$, $\mathfrak g=R$, and one gets an operator Q_e that can be normalized to have integral eigenvalues.

This last example also comes in a local version, where we make independent phase transformations at different points in space-time. This is an example of a "gauge symmetry", and the question of how it gets represented on the space of states is what will lead us into the BRST story. Next posting in the series will be about gauge symmetry, then on to BRST.

If you want some idea of where this is headed, you can take a look at slides from a colloquium talk I gave recently at the Dartmouth math department. They're very sketchy, the postings in this series should add some detail.

Comments

1. **Tom**
November 5, 2008

   Thanks for this BRST post, and those to come! I'm going to enjoy reading some technical stuff. I know I haven't seen BRST symmetry treated in a really mathematical way before.

2. **anonymous**
November 5, 2008

Please do not use the > character for the ket when you typeset using TeX!
It is for the mathematical less-than symbol. As such, the spaces around > are automatically widened, which makes your kets super-ugly.
See p.170 of TeXBook about \mathrel, \mathop etc.
So please either use at least |\psi\mathclose>. I prefer |\psi\rangle, though.

3. **estraven**
November 5, 2008

Great post, I'm looking forward to the rest fo the series.

@anonymous at 10.03pm: My .tex files include the lines

\def\>{\rangle}
\def\<{\langle}

because I like good typesetting but am also very lazy.

4. **TSM**
November 5, 2008

I have to ask; which program did you use to make your talk slides? If it is powerpoint can you point me to the template used?

TIA

5. **anon.**
November 6, 2008

One interesting question which is hard to understand from the standard textbook treatments and limited reading of the literature: does the BRST action for gauge-fixed Yang-Mills theory break down nonperturbatively, due to Gribov copies? Claims in both directions seem to exist, but it seems it would take a great deal of effort and/or reading to settle the matter. (Also: are there Gribov copies for gauge-fixing diffeo and Weyl invariance? I don't think I've seen this mentioned in treatments of BRST quantization of the string.)

6. **anonymous**
November 6, 2008

That's a LaTeX class called beamer. See http://latex-beamer.sourceforge.net/.
PowerPoint and Keynote are for losers.

7. **Kurt**
November 6, 2008

Fantastic, I am looking forward to reading about BRST. There is something that has always bugged me about symmetry in QM: Surely we do not want to say that every time independent unitary operator is a symmetry, because then every quantum system with the same dimension Hilbert space would have the same symmetry group (i.e. U(N), where N is the dimension of the Hilbert space). There must be some input about the dynamics (i.e. Hamiltonian) of the system. Usually we say something like: a symmetry is any time independent unitary operator that commutes with the Hamiltonian. This guarantees that the symmetry preserves the Schrodinger equation, but rules out things like the boosts (either Galilean or relativistic), which are represented by unitary operators that depend explicitly on time, and which we would like to have as symmetries. Thus, we might want to say that a symmetry is allowed to carry explicit time dependence, so long as it preserves the Schrodinger equation. But this brings us back to the original problem of all quantum systems (of a given dimensional Hilbert space) having the same symmetry group: given any unitary operator S, we can give it time dependence in such a way that it preserves the Schrodinger equation (just take S(t)=U(t)SU(t)^{-1}, where U(t) is the time evolution operator). So where is the middle ground; what is a definition of symmetry, (using only the notion of Hilbert space and hamiltonian, no fair talking about classical concepts such as action, Noether theorem etc., or extra structure such as the S-matrix) that allows the boosts but does not allow an arbitrary unitary operator?

KH

8. **N. Nakanishi**
November 6, 2008

The problem of Gribov copies arises only in the path-integral approach. No such trouble is encountered in the BRS-formulated operator formalism.

9. **Peter Woit**
November 6, 2008

Tom and anonymous,

Thanks for the tex advice.

TSM,

The slides were made using the "beamer" latex class.

anon.,

One reason I'm interested in BRST is precisely that I don't think the problem of how to handle gauge invariance is fully understood in theories like the Standard Model. I'll write more about this later, and the Gribov problem is part of the story. I don't believe there is any agreement about what happens to it outside of perturbation theory. What I'm writing about is mostly the operator formalism, and this does not have the same problems that the path integral has (as Nakanishi mentions). It may have others…

In diffeo and Weyl invariance, you don't get the same topological phenomenon that forces the Gribov problem, so I don't think you see it in the quantization of the string.

Kurt,

Interesting question. I guess when I'm talking about a "symmetry", this can come from any group action on the classical mechanical system being quantized, whether or not it commutes with the Hamiltonian. These give operators on the state space, which may or may not commute with the Hamiltonian operator. Well-known examples include the algebra of at most quadratic operators in p and q (Heisenberg + symplectic algebra)

10. **A.**
November 6, 2008

Dear Peter and anon,

Interesting stuff. With regard to Gribov copies, they are not just some mathematical problem with overcounting in the path integral — they have physical implications. It's been known for a long time that they play a key role in confinement, so it would be really surprising if the operator picture didn't feel their effects at all.

A.

11. **anon.**
November 6, 2008

A. is right: there's a large literature about Gribov copies and confinement, with which I have only a superficial familiarity, but which seems very interesting. It's been observed, for instance, that the center vortex configurations that have been primary candidates for explaining confinement since at least the work of 't Hooft in the late 70s lie on the Gribov horizon in certain gauges (hep-lat/0401003).

Fundamentally, Gribov copies are telling us that the Yang-Mills configuration space has a complicated geometry and topology, and I don't see how that could go away in the operator formalism. (Are there references?)

I could imagine, though, that the ghosts somehow encode the gauge algebra in a way that allows the BRST action to get all of this right anyway. (To throw out another reference that I haven't properly digest, Reinhardt in hep-th/9602047 showed that in maximal abelian gauge the path integral with an explicit integration over the group with the correct Haar measure is equivalent to the path integral with a Faddeev-Popov determinant.)

12. **FNesti**
November 6, 2008

Dear Peter,
thabks for this good idea, it will be interesting and useful to read about BRST and Dirac. I'd like to ask whether you plan to mention the Dirac-Hodge operator (d+delta) and its properties. In my present understanding, this is the same of a standard dirac operator in flat space, while on a generic manifold it gives a different coupling of 'spinors' to gravity. I believe this would be a really interesting point to clarify, from your cross-discipline experience, from both the mathematical and physical point of view.

Cheers,
Fabrizio

13. **Peter Woit**
November 6, 2008

Fabrizio,

The point you raise is not one that comes up only tangentially in the BRST story, but it is an important one if you try and understand spinors.

Basically, the operator you mention operates on differential forms, not spinors, and at each point the differential forms take values not in the spinor space S, but in SxS*. In flat space you get just dim (S*) copies of what you want (this is related to why Kogut-Susskind gives you multiple copies of what you want on the lattice). In non-flat space there's a non-trivial covariant derivative for the spinors, so you get not just multiple copies, but something different.

14. **Peter Orland**
November 6, 2008

The problem of Gribov copies does not go away in the Hamiltonian formalism. If complete gauge fixing (such as axial or Coulomb gauge) is performed, Gauss' law needs to be solved.

As an example I have some familiarity with, if one solves Gauss' law on a Hamiltonian lattice, to get an axial gauge condition (say $A_{3}(x)=0$ or $U_{3}(x)=1$ on most of space, it is a messy problem to define the conjugate electric field variable (E_{3}, or l_{3} on the lattice) everywhere, if the boundary condition is periodic. With open boundary conditions in every direction (so space is a rectangular prism) the situation is much better, and it is possible to further fix the gauge, completely removing all gauge freedom. It is not a trivial task to do this, however.

Anyway, in the above example, the Gribov problem cannot be ignored, though it can be solved.

15. **Peter Orland**
November 6, 2008

P.S. In the BRST operator formalism, you need to construct an exterior derivative operator from constraints. You need to prove that the square of this operator is zero. I guarantee that there is a problem with this on the Hamiltonian lattice. That is because the degrees of freedom of links of the lattice lie in the group manifold, not a nice linear space.

16. **Chris Oakley**
November 6, 2008

Just to say that I approve of this kind of post. Not being a mathematician, I expect to be left behind soon, although this has not happened yet.

It is funny that with the existence of half-integral spin, SU(2) and not SO(3) is the symmetry of nature (equivalently SL(2,C) and not O(3,1)). It suggests that Minkowski space is not the fundamental thing, and yet theories that take advantage of this (I am thinking in particular of twistors here, where the fundamental objects live in SU(2,2), the double cover of C(3,1)), although elegant, never seem to help in describing the real world.

17. **FNesti**
November 6, 2008

Thanks Peter,

yes I also find this quadruplication of 'spinors' (e.g. in flat 4D) important, although it is completely unknown to physicists.

What I was (and is) curious about are the precise properties under possible symmetries (loocal frame rotations but not only?) of these copies. Probably one will have to go through the work of Benn, Tucker et al…

(Indeed there was a burst of activity on Kahler spinors around the eighties, while now people are much less imaginative (or should one say realists?)).

18. **Aaron Bergman**
November 6, 2008

It is funny that with the existence of half-integral spin, SU(2) and not SO(3) is the symmetry of nature (equivalently SL(2,C) and not O(3,1)).

The point is that physics deals with projective representations. The half-integral spin reps or SU(2) are perfectly good projective representations of SO(3). You can prove that for a (compact?) f.d. Lie group, any projective rep is an honest rep of the universal cover. This isn't true in general, however, and that can show up in certain situations.

19. **N. Nakanishi**
November 6, 2008

Concerning the definition of "symmetry"

The question raised by Kurt can be answered in the following way.
Suppose that the operator algebra of fields has been found. If a transformation U leaves it invariant, U is a symmetry.
In the canonical formalism, since the operator algebra is determinded by field equations and equal-time commutation relations, one can check the invariance without constructing the operator solution explicitly.

Concerning the problem of Gribov copies

In the BRS-formulated covariant operator formalism of gauge theories, there arises no problem concerning the topology of the
gauge fixing. The BRS generator can be proved to be nilpotent. The problem of topology is encountered in the path-integral formalism, because it is based on classical quantities. One should note that there is no justification of the non-perturbative path-integral approach; indeed, in that framework, one cannot discuss the unitarity of the physical S-matrix.

20. **anonymous**
November 6, 2008

@Prof. Nakanishi
I think you're the man who introduced the Nakanishi-Lautrup field in the quantization of the Maxwell field, is it correct? If so, it is a great honor to have you here!

21. **N. Nakanishi**
November 6, 2008

anonymous:

Yes. Thank you for your courtesy.

22. **Kurt**
November 6, 2008

Re: Nakanishi-

I wonder, however, if such a definition can be made without additional structure beyond a Hilbert space and a Hamiltonian. If we are dealing with a generic quantum system, not necessarily a field theory and not necessarily possessing an algebra of field operators, is there still a good notion of symmetry?

KH

23. **Domenic Denicola**
November 6, 2008

This is very cool; thanks Peter! So nice to have a mathematician doing the talking after half a term of a physicist teaching us "quantum mechanics" (i.e. linear algebra) here at Caltech :-|.

24. **Peter Orland**
November 6, 2008

It is not correct that Hamiltonian BRST quantization solves the Gribov problem. If the Hamiltonian gauge theory is ultraviolet-regularized in a gauge-invariant way (and the only way to do this, except in some special cases, is on a lattice), there is no nilpotent BRST operator.

From what I understand, Hamiltonian BRST is fine for dealing with theories perturbatively, but that's it.

25. **Coin**
November 7, 2008

Peter, thanks, this is actually really helpful. I have a couple of questions that I hope aren't too stupid.

When G is a Lie group with Lie algebra, (frac-g, [•,•]), differentiating ∏ gives a unitary representation (π, H) of g on H.

I'm a little confused as to why this is– I.E. why it is exactly that differentiating ∏ happens to produce this thing that you want, or exactly what it means to "differentiate" this ∏ object.

Examining the wikipedia article for lie algebras, they mention: "Given a Lie group, a Lie algebra can be associated to it… by endowing the tangent space to the identity with the differential of the adjoint map." In linked articles they describe the "adjoint map" as something that sounds extremely similar to the ∏ map you define and which they use to construct an "adjoint representation" of a lie algebra; and they define "differential" in this context as a particular operation they also call a "pushforward". Is this in fact what is happening here? I.E. is it the case that ∏ is the same thing as the adjoint map of your symmetry group G, and the reason why differentiating ∏ gives a representation of frac-g is because this is just the canonical way of getting a lie algebra's "adjoint representation" given the associated lie group?

(By the way, a minor thing– you say "a unitary operator ∏(g) satisfying [conditions], i.e. the map P from group elements to unitary operators is a homomorphism". Is the

"P" here a typo for ∏?)

An interesting philosophical question is whether the quantum system that governs the real world is purely determined by symmetry, i.e. such that ALL its observables come from symmetries in this manner.

Are there any known examples of quantum observables that are not specifically known to come from symmetries?

Thanks!

26. **Kasper Olsen**
November 7, 2008

Hi Peter,

In mentioning different groups of symmetries, you need to say what the group action is; just to be more precise..

27. **Chris Oakley**
November 7, 2008

Aaron,

I am not quite sure what you are saying here … a 2π rotation leaves Minkowski space invariant, but does not leave a spinor invariant, yet a spinor is a necessary part of physics as we understand it. It suggests that requiring a unitary rep of the isometry group of Minkowski space is not quite the right thing to do, and that there is something more fundamental lurking beneath.

28. **Marco Frasca**
November 7, 2008

Dear All,

About Gribov copies and Yang-Mills there is a quite interesting situation both from theoretical and lattice point of views. There are two ways people managed confinement and these were Gribov-Zwanzinger and Kubo-Ojima scenarios. Both scenarios, that imply that Gribov copies are relevant in the infrared, require the gluon propagator going to zero at lower momenta and the ghost propagator going to infinity in the same limit faster than the free particle one. Functional methods devised in the '90 seemed to support such a view.

Of course, several other people turned out to computers to see if these views are true. These computations, done on lattices having huge volumes (till (27fm)^4!), completely disproved above results showing as the gluon propagator goes to non-null finite value at lower momenta and the ghost propagator is the one of a free particle. Above confinement scenarios and functional methods that heavily rely on Gribov copies are blatantly wrong. The main conclusion to be derived from this is that Gribov copies do not play any role for Yang-Mills theory, not even in the infrared limit. Indeed, the concept of Gribov copies appears useless to our understanding of Yang-Mills theory.

About BRST symmetry and Yang-Mills theory one has the following conclusion recently drawn in

http://arxiv.org/abs/0810.1987 .

This symmetry is violated by the lattice solution that implies that the gluon acquires a mass. Indeed, lattice computations done so far show us the very existence of a mass gap and this mass gap has the effect to break BRST symmetry. This is rather a screening mass than a true pole in the propagator and this means that the true particles of Yang-Mills theory in the infrared are no more gluons but gluon bound states making the above mass a constituent mass (see also my blog

http://marcofrasca.wordpress.com/2008/10/14/a-new-point-of-view/ .

This is our current understanding about confinement and Yang-Mills theory. Some theoretical results have also been known that are in agreement with it (e.g. see my paper to appear in PLB

http://arxiv.org/abs/0709.2042

and refs therein).

This situation is quite interesting and shows clearly the dynamics of the understanding in physical science at work.

Marco

29. **N. Nakanishi**
November 7, 2008

Re: Kurt

Symmetry should be defined at the operator level, because symmetry may be broken spontaneously at the level of representation. Any quantum system is described by an operator algebra and its representation in terms of state vectors. Symmetry is the invaraince property of operator algebra. Hamiltonian is nothing more than a particular symmetry generator for time translation.

30. **Peter Orland**
November 7, 2008

Marco,

It simply isn't clear what the relevance of Gribov copies is to confinement and the mass gap. We won't know until confinement and the gap are understood.

No calculation or theorem indicates confinement at weak bare coupling (strong bare coupling has been understood since the mid-70's). Ruling out a proposed scenario invoking certain concepts does not mean those concepts are not relevant. We simply don't know whether they are relevant. None of the scenarios proposed to explain confinement have been successful (including some I have worked on). That doesn't mean that the ideas have no merit, just as it doesn't mean that they do.

The best that theorists can do on tough problems, is to study what they find interesting, follow hunches, prove or disprove hypotheses, etc. But we also have to be intellectually honest; we have to be prepared to abandon our most cherished ideas when they don't work.

But anyway, I don't think that Peter W. is after confinement per se, just a better understanding of gauge theories and BRST.

31. **Marco Frasca**
November 7, 2008

Peter,

This is the work of an entire community and I was thinking that some of these results were leaking out to a lot of people outside. By the way you are speaking it seems like all this people's work went out useless. Do not you believe on lattice results for Yang-Mills propagators? It seems to me that the a clear picture is emerging by the work of this people and its acceptance may be just a matter of time. Meanwhile, I am trying to let their (and mine) work widely known. But, of course, your considerations seem simply out of track.

Marco

32. **woit**
November 7, 2008

Coin,

Thanks for pointing out the typo.

Many quantum observables don't come in any known way from a symmetry. For example, in a gauge theory, take the field-strength operator (or some gauge invariant quantity constructed out of it).

The way I stated the relation between representations of the group and the Lie algebra is standard, if a bit abstract for most physicists. The point is that a very good way to think of a representation of a group is as a map of groups

[tex]\Pi: G\rightarrow GL(n,\mathbf C)[/tex]

that is a homomorphism of groups. For a unitary representation, the map is to a unitary group [tex]U(n)[/tex]..

Such a homomorphism is a differentiable map, its differential is a map from the tangent bundle of [tex]G[/tex] to the tangent bundle of [tex]U(n)[/tex]. Evaluating this at the identity of the group gives a homomorphism of Lie algebras, from the Lie algebra of [tex]G[/tex] (which can be identified with the tangent space at the identity) to the Lie algebra of [tex]U(n)[/tex] (which can be identified with both the tangent space to [tex]U(n)[/tex] at the identity, and the space of n by n skew-hermitian matrices).

The above applies to any representation, What you're quoting from Wikipedia is how one constructs a very specific representation, the adjoint represention of a group on its Lie algebra. One way to do this is to look at the conjugation map of the group to itself

[tex]g_0\in G \rightarrow gg_0g^{-1}\in G[/tex]

and take the differential of that. For each element [tex]g[/tex] of the group you get a linear map of the tangent space at the identity to itself, this is the adjoint representation of the group on its own Lie algebra.

33. **Peter Woit**
November 7, 2008

Marco,

Please, don't try and turn this into a discussion of your favorite ideas about confinement. Peter Orland is right that the question of confinement is not one that I'm trying to address here, it involves a whole host of very different issues.

My point of view the significance of BRST is that a better understanding of its mathematical context can lead to new ways of using it to understand physics. I don't have any particular reason to think that this will help with the understanding of confinement. More likely would be some new insight into electroweak symmetry breaking, where the issue of how gauge symmetry gets handled is more directly relevant.

34. **Peter Woit**
November 7, 2008

Nakanishi,

Many thanks for your comments. The point that the right way to think about symmetries of a quantum system is as the group of automorphisms of the algebra of operators was especially helpful to me.

35. **Marco Frasca**
November 7, 2008

Peter,

Sorry for my improper posting but some people turned your very fine argument into something about Yang-Mills and Gribov copies and for this there exist a lot of lattice computations. I just aimed to answer to this.

So, I turn back into my little corner.

Marco

36. **Peter Orland**
November 7, 2008

Hi Peter,

I had a minor question concerning your formalism. Are you concerned about unbounded operators and non-normalizable states in all of this? The reason I ask is that you are defining states the mathematician's way as Hilbert space vectors, which square-normalizable. Depending on the manifold you start with, you might need to deal with a spectrum defined more generally than eigenvalues on such states, e.g. by singularities of resolvents.

If you work on a bounded manifold (such as a Lie group), there is no need to worry about this issue since the entire spectrum consists of eigenvalues of Hilbert vectors.

But I assume you eventually want to consider field theory in the thermodynamic limit, which means the spectrum contains numbers which are not eigenvalues (or in the physicist's language, not eigenvalues of normalizable states).

I suspect you've already dealt with these functional-analytic considerations, or they are just not important. I was just wondering…

37. **Serifo**
November 7, 2008

Hi professor Peter,

I suppose the considered Hilbert space is a separable Hilbert space, right ? Or it doesn`t really matter ?!

I also suppose you are assuming the Hilbert space as a complex vector space (right ?), now since the field of complex numbers is an extension of the field of real numbers, the same Hilbert space can be viewed as a real vector space . Does it help when we view the space as real Hilbert space ?

Sincerely

38. **N. Nakanishi**
November 7, 2008

Peter Woit:

There is no nilpotent selfadjoint operator defined on a Hilbert space. If you discuss the BRS generator in your next presentation, I expect that you will introduce an indefinite-metric Hilbert space. Is that so?

39. **Hendrik**
November 7, 2008

Dear Peter, I agree that it is high time that there is some serious discussion on quantum constraints;- there is a wide spectrum of different methods, not all of them equivalent. A few reactions to specific points:

1) The initial framework which you propose, of operators on a Hilbert space, binds you to a specific representation. It is better to start with an abstract algebra (e.g. a C*-algebra) as your setting, and then to select the convenient representations. For instance, as Peter Orland pointed out, in some representations you cannot solve your constraints due to continuous spectrum problems. There is a discussion of these points here (Erratum here) In any case, a constraint algorithm constructs a different representation for the observable subalgebra, than the starting representation.

2) There is not one BRST-formalism, but several, of which the two major approaches are the BFV-approach (as in the book by Hennaux and Teitelboim) and the Kugo-Ojima approach. Whilst these are superficially similar, they are in fact inequivalent, i.e. produce different results for the same system (I have a PhD student whose thesis contains substantiation of this). Moreover, the BFV-approach is a general constraint algorithm (so does not need a gauge group action to be applied), whereas the KO-approach is specifically written for gauge theories, so we don't know how to apply it to general constraints.
It is not difficult to show that the BFV-approach produces different results than the usual Dirac constraint method (see Sect 7 of this old scanned preprint -11MB, sorry). On the other hand, for Quantum Electromagnetism (the only gauge QFT which we can handle explicitly in the C*-algebraic framework), the KO-approach to BRST produces the correct results.

3) A common problem of the BFV-BRST method is that it selects multiple copies of the physical state space (this has been noted all over the literature, e.g. p50 of Van Holten, and I also found it in my old preprint above). This should not be confused with the Gribov ambiguity problem, which as I understand it, is a classical and global result, stating that there is no continuous section of the gauge orbit space of the connections (as the set of orbits of the connections is a principal fibre bundle, I think this just means that this bundle is nontrivial). Since the operator theory with which BRST works is local, infinitesimal (not global) and "forgets" the smooth structures of the classical objects, I cannot see how it can detect a Gribov problem. Of course, it is a different matter for the path integral approach, which starts from the classical theory. Having said that, I know that McMullan did some work on BRST and Gribov ambiguity, using Mackey quantization and analogies (as the groups are infinite dimensional, Mackey theory does not apply directly).

4) Serifo's question is an interesting one;- if you want to avoid continuous spectrum problems, you may need to use representations which are discontinuous w.r.t. the exponentiated commutation relations ("nonregular representations") and these must be on nonseparable Hilbert spaces. However, the final constrained Hilbert space must always be separable.

40. **Peter Woit**
November 7, 2008

Thanks to all for the interesting comments. The questions about BRST that I'm interested in are independent of the analysis issues people raise, they occur even for toy models with finite dimensional state spaces.

The state spaces in question are complex vector spaces, QM requires this. Similarly in representation theory I'll be discussing complex representations. Representations on real vector spaces don't give the examples and structures I'm interested in.

The question Nakanishi raises is an important one: having a self-adjoint BRST operator with square zero requires an indefinite metric. The Dirac cohomology idea I've been working with evades this, since the analog of the BRST operator has a square that is not zero, but a central element in the operator algebra. So, it acts as zero on the algebra of observables, but is not zero on states. This is one of the main reasons I think there may be something new here.

Hendrik is right that there are multiple versions of "BRST", and I've always found keeping them straight and understanding the relations between them incredibly confusing. What I'll be writing about is yet a different variant. It's not one that can be applied to any constrained dynamical system, but is intended to work for gauge theories.

41. **Hendrik**
November 8, 2008

Dear Peter, if your BRST-variant is intended for gauge theories, then Krein representations (indefinite metric) are required for reasons other than BRST (unless you use the exponentiated C*-algebra version with nonregular representations). The reasons come from a whole swag of theorems:- (1) Strocchi, F.: Gauge Problem in Quantum Field Theory, Phys. Rev. 162, 1429-1438 (1967) – there is no representation of the vector potential (i.e. local gauge field) which is covariant w.r.t. the usual action of the Poincare group, having a vacuum and satisfying the Maxwell equations, in which the fields (i.e. local curvature) are nonzero. Also see Comm. Math. Phys. 35, 25 (1974), and other Strocchi papers at this time or earlier. (2) Wightman, A.S., Garding, L.: Arkiv Fysik 28, 129 (1964) a covariant representation of a vector potential which is weakly local, cannot be a normal Hilbert space representation, it must be done w.r.t. an indefinite inner product. (3) Barut and Raczka proved that the only zero mass representation of the Poincare group on tensor-valued functions (e.g. Fock rep) must necessarily have indefinite metric.

These theorems meant that everyone in Wightman Field Theory, did their gauge fields in the indefinite metric framework.
The only way in which you can avoid using indefinite metric, is by using the exponentiated (Weyl) fields in a C*-algebra framework. Then you can work with ordinary Hilbert space representations, but they must be necessarily nonregular to avoid the theorems above. Nevertheless, you still get sensible results after constraining. You can read about that approach here. Unfortunately, the only gauge field for which we have an explicit C*-algebra is the Electromagnetic field.

42. **Urs Schreiber**
November 8, 2008

> The point that the right way to think about symmetries of a quantum system is as the group of automorphisms of the algebra of operators was especially helpful to me.

By the way, the essence of this is extracted by the Doplicher-Roberts reconstruction theorem applied to the symmetric monoidal category of local endomorphisms of the net of local quantum observables:

the theorem proves that just from the net of local algebras alone the global symmetry group of the QFT can be reconstructed, hence in particular its particle content be determined.

The DR-reconstruction theorem is one of the earliest instances where physicists found in their application a fundamental purely category-theoretic fact.

43. **tomate**
November 8, 2008

I'm sorry for the down-to-earth question in such elevate discussion. Is every symmetry of a quantum system connected to a conserved quantity or charge (as in your first few examples)? If so, does the U(1) global symmetry uniquely imply conservation of probability and vice-versa?

44. **Chris Oakley**
November 9, 2008

Tomate,

Yes, every symmetry has a conservation law, a result known as Noether's theorem. This is a classical result, but it applies also to quantum field theory, and is the only thing I can think of in elementary QFT that is named after a woman. U(1) global symmetry, if present, may be connected with charge conservation but has nothing to do with conservation of probability. One of the reasons for requiring the inner product or metric of Hilbert space to be positive definite in the foregoing discussion is that these quantities sometimes have the interpretation of probabilities, and probabilities cannot be negative.

45. **Peter Woit**
November 9, 2008

Tomate,

The point Kurt was asking about and Nakanishi clarified, is that I'm thinking of a "symmetry" more generally, as any automorphism of the algebra of observables (i.e. any map from this algebra to itself that preserves the algebra structure). Of these "symmetries", some will commute with the Hamiltonian operator, some won't. The ones that commute with the Hamiltonian are the ones that correspond to conserved quantities. Ones that don't commute with the Hamiltonian are sometimes given names like "dynamical symmetry", or "spectrum generating algebra". A few seconds of Googling turned up this more detailed explanation:

http://eom.springer.de/S/s110230.htm

As Chris explains, conservation of probability comes from the condtion that the Hamiltonian be self-adjoint, generating a unitary time evolution. The U(1) action corresponds to a charge, which may or may not be conserved.

46. **Hendrik**
November 9, 2008

Dear Peter, I think the concept of "symmetry of a quantum system" is not an easy one to sort out:
In the literature the concept is defined in a number of inequivalent ways:(1) As a continuous map on the projective sphere of a Hilbert space, preserving (moduli of) inner products. The content of Wigner's theorem is that these are either unitaries or antiunitaries, and in the case of a continuous one-parameter group of them, then they must be unitaries.(2) As automorphisms of the *-algebra A of observables (where A can be either abstract, or concrete operators on a Hilbert space H – if they are unbounded, a dense invariant domain must be specified).(3) As superderivations, e.g. in the case of BRST or supersymmetry.

The mathematical structure of collections of symmetries vary, e.g. they can be groups (discrete, Lie, infinite dimensional) or they can even be quantum groups, which are not groups at all. In the case that they are Lie groups, then of course the infinitesimal generators (selfadjoint operators or *-derivations) encode the symmetry group.

A symmetry is relative, i.e. it is a symmetry of *something*, and that something must be specified. An algebra A of operators on a Hilbert (or Krein) space by itself is not a physical system (different quantum systems have isomorphic algebras of observables). Some extra structure must be specified, together with some map that takes you from the labels in your theory to something outside, which can e.g. be measured in experiment. That is why we use suggestive labels like "mass" or "charge" for our mathematical objects. Then a symmetry is a transformation of the system which leaves the defining structures of the system invariant. So for instance, a "dynamical symmetry" is a transformation which leaves some specified one-parameter time evolution group invariant, and a "relativistic symmetry" is something which e.g. respects causality requirements. Even elementary descriptions of symmetry, include such a requirement. I am very uncomfortable with a "radical" interpetation of symmetry as *any* automorphism of your algebra of observables (though it appears in the literature). This seems to me without physical content.

The discussion regarding Tomate's question above, is not quite complete:If you have a continuous one-parameter group of symmetries in the Wigner sense above (they preserve probability), then it is given by a continuous one-parameter group of unitaries t -> U(t), and by Stone's theorem this must be of the form U(t) = exp(itS) for some selfadjoint operator S. If you assume that you have a time-evolution which commutes with the symmetries, then S is a conserved quantity, i.e. does not change in time. However, if you start from a discrete group or a discontinuous action, then there is no such conserved quantity. This picture becomes much more problematic if you view your symmetries as automorphisms on the algebra. For instance, you need not have that it is unitarily implemented, so even if you have a continuous one-parameter group, there need not be a concrete generating operator. (At the most, you have a *-derivation of the algebra).

47. **Thomas Larsson**
November 10, 2008

It seems to me that this discussion is closely related to the eternal confusion about diffeomorphism symmetry in GR. From one POV, every model has a diffeo symmetry because it can be written in curvilinear coordinates, and hence the concept is empty. By the same token, every (massive or massless) model has scale symmetry; after all, the scaling group is a subgroup of diffeomorphism group, since the dilatation D = x^u d/dx^u is a particular kind of vector field.

From this viewpoint, the difference between massive and massless is that the representations of the scaling algebra are qualitatively different. In the massless case, the Hilbert space is a direct sum of one-dimensional reps, spanned by a vector |h>:

D |h> = h |h>.

In the massive case, we need to look at a family of models at different scales, and the reps act on an infinite-dimensional vector space with basis |n>:

D |n> = |n+1>.

Although this viewpoint on massive models is not necessarily wrong, it is not fruitful neither; unlike in the massless case, we don't learn anything about the model by pondering dilatations.

More generally, assume that we have a big group G, a subgroup H, and an H rep R acting on our Hilbert space. Then G also acts on the Hilbert space, possibly after we have completed it to include new states. The G rep is necessarily a suprep of the induced rep Ind R. If the G rep is all of Ind R, considering G is fruitless; all information is already encoded in H. OTOH, if the G rep is a proper subrep of Ind R, we learn something new, and this viewpoint is fruitful.

This suggest one definition of "symmetry". Let G be the full group of automorphisms on the Hilbert space, and let H be the biggest subgroup such that the rep of G is induced from H. Then H is a "symmetry", in the sense that it is the largest group that says something nontrivial about the Hilbert space.

48. **tomate**
November 10, 2008

Hendrick,

> However, if you start from a discrete group or a discontinuous action, then there is no such conserved quantity.

I know this is a typical statement about discrete symmetries, but couldn't we put it this way: symmetry is an unobservable degree of freedom (as assumed in Wigner's theorem) and conservation laws (of continuous quantities like momentum or discrete charges) are their observable realization. A discrete example: inverting spatial axis is unobservable but has a corresponding conserved quantity, parity, which you can infer from experiment (up to conventions) and might be conserved in a process if the theory has such symmetry. I know it sounds a little bit tautologic, but it seems to me like a coherent view. Does this make any sense?

Peter and Chris,

thanks for explanation.

49. **Peter Woit**
November 10, 2008

Thomas,

I'm confused. You're starting with an H rep, for H a subgroup of G. There's the induced G rep, but what's the other one you have in mind? Can you give an example?

50. **Thomas Larsson**
November 10, 2008

1. The above scale symmetry of a massive model, on the group level. G = scaling group, H = trivial group, R = trivial rep.

2. Give the massive model a conformal symmetry: G = conformal group, H = Poincare group, R = a Poincare rep.

3. Make a model diff symmetric: G = diffeomorphism group, H = Poincare or conformal, R = a rep.

The last example is similar in spirit to saying that any model has a diffeomorphism symmetry because it can be written without coordinates, but not exactly the same, I think.

51. **Shantanu**
November 10, 2008

Peter, this looks interesting.
Do you have any students or colleagues working with you on this?

52. **Hendrik**
November 10, 2008

Thomas,

I'm afraid I don't follow your reasoning;- it seems you are proposing a different definition of "symmetry" but I cannot see what job your symmetry is supposed to do:

> "This suggest one definition of "symmetry". Let G be the full group of automorphisms on the Hilbert space, and let H be the biggest subgroup such that the rep of G is induced from H. Then H is a "symmetry", in the sense that it is the largest group that says something nontrivial about the Hilbert space."

Is the "full group of automorphisms on the Hilbert space" all of U(H), or is it the unitaries which implements the largest set of aotomorphisms of your algebra of observables A? In short, given A how do you get G?

"…it is the largest group that says something nontrivial about the Hilbert space". Since all Hilbert spaces of the same dimension are isomorphic, I cannot imagine what such a nontrivial property might be. Do you mean the rep of A on it?

Maybe I was a bit unclear earlier on;- in a nutshell, I think a symmetry is a transformation of the algebra of observables with a job to do. That job is to preserve the defining physical structures of the system. These strucures can be external to the algebra, e.g. a distinguished group action, or some map from space-time regions to subalgebras encoding causality/covariance etc. In this case, not all automorphisms of A can be symmetries.

Tomate,

Let me first answer the mathematical side of your question:
A "conservation law" is an additive quantity;- e.g. you add up all the momenta of a set of interacting particles, and if the total set of particles is free, then the total momentum is conserved. That is why we take the generators S of the unitary groups U(t) = exp(itS) of the symmetry groups to get our conservation laws, since by the

exponential law we have U(t)U(t') = exp(i(t+t')S). Parity is a multiplicative quantum number, not an additive one, so not a conservation law in the usual sense. Of course, given a set of (anti)unitaries implementing a discrete symmetry, commuting with time evolution, then it is easy to make conserved observables (staying constant in time);-just take any selfadjoint element in the *-algebra generated by the (anti)unitaries. However, these do not give you a conservation law in the usual sense for your original discrete symmetries.

We need a philosopher to sort out "symmetry is an unobservable degree of freedom" but let me have a stab at it. I think "to observe" is relative, and one should be clear where your observer is. Moreover you should also distinguish between applying your symmetry to to subsystems from application of it to the full system.
E.g. translation of a subsystem is an observable transformation (and physical thing to do) for an observer in the full system, but it is unobservable for an observer inside the subsystem (who by definition cannot see anything outside his system). Hence we can measure momentum of subsystems of our world, but we cannot measure the total momentum of the universe.
Thus concerning parity, we can measure it for subsystems of our world, but (if it is a symmetry for those systems), of course it is unobservable from within those systems.
By the way, parity is broken by weak interactions, so perhaps that was not the best example for your point

53. **tomate**
November 10, 2008

Hendrick,

maybe this is just a philosophycal hence not scientific matter and this by definition is no place for unscientific stuff, so forgive me all. The sentence "symmetry unobservable" is uncritically stuck in my mind due to many sources none of which I'm able to mention at the moment (but could do with a little research): they might not be very authoritative (aside: can we think of a quantum experiment that tests time invariance without appealing to energy conservation? If so then I'm easily wrong). We can better say that symmetry is what leaves transition probabilities unaltered, as is in the spirit of Wigner theorem.
I just notice that symmetry is rather abstract (lagrangian invariant under such and such transformation), and conservation very practical (something calculable before experiment = something calculable after). I'm just not very comfortable with the idea that multiplicative quantum numbers are excluded from the Gotha of conserved quantities, yet sharing this very intuitive picture. You yourself put, for instance, parity and momentum conservation on the same footing in your example.
I guess it's just a matter of convention of no conceptual importance. It would just be be more practical to say: all symmetries lead to conserved quantities. But it doesn't seem to be worthy a referendum.
(I do know parity is an unfortunate example – but it's the only one I remember how to calculate)

54. **Thomas Larsson**
November 11, 2008

Hendrik

Symmetry is perhaps not a good word, since it has an established meaning (commutes with the Hamiltonian). But what I am saying is that it is a good idea to look at the action of ever bigger groups on the Hilbert space (or perhaps an enlarged Hilbert space), as long as this gives you new information about your system. You should stop at the largest group H such that the action is not induced from some subgroup, because for bigger groups all info is already encoded in H.

Main example: CFT in 2D. The infinite conformal symmetry G is generated by L_m = z^(m+1) d/dz. Denote by H the non-positive (m &lt= 0) subalgebra. One may argue that only H is a symmetry (note that the Hamiltonian is not known), because the positive generators diverge at infinity and thus violate boundary conditions. The Hilbert space carries a direct sum of one-dimensional reps of H, characterized by L_0 |h> = h |h>, L_-m |h> = 0.

We can extend this action to an action of all of G, at the cost of adding new states to our Hilbert space. If the action of G on the enlarged Hilbert space were induced from H, i.e. a Verma module, this exercise is pointless; essentially all info about the Verma module already lives in H. But for physically interesting systems (minimal models), the action is something different: the Verma module modulo singular vectors. This yields new info which is physically important: the discrete spectrum of critical exponents. So in this case, going from H to G is a good idea, even if it does not commute with the (unknown) Hamiltonian.

And yes, I have glitched over some details such as the central charge.

November 11, 2008

Aaron said : "The point is that physics deals with projective representations. The half-integral spin reps or SU(2) are perfectly good projective representations of SO(3)."

Couldn't we take the POV that (quantum) physics deals with algebra representations instead ? The natural/"real"/important object here would be the lie algebra of SO(3) = Lie alg of SU(2). This POV would also naturally leads to quantum groups as a possible generalization.

56. **Peter Woit**
November 11, 2008

Shantanu,

The BRST project is just me.

57. **Aaron Bergman**
November 11, 2008

Couldn't we take the POV that (quantum) physics deals with algebra representations instead ? The natural/"real"/important object here would be the lie algebra of SO(3) = Lie alg of SU(2). This POV would also naturally leads to quantum groups as a possible generalization.

Just looking at the Lie algebra doesn't go far enough. You need to look at central extensions of the Lie algebra. It so happens that central extensions of semisimple Lie algebras aren't particularly exciting, but there's more to life than semisimple things. Like loop groups, say.

58. **AM**
November 14, 2008

Thanks for the post. More posts along these lines would be great !

59. **Gen Zhang**
December 9, 2008

I realise I'm coming a bit late to this party, but:

You state, as most elementary texts do, that symmetries are implemented as a unitary representation of the group on the Hilbert space. However, it is important to realise that this is often not possible; as has been alluded to by Aaron, we really care about projective representations. Usually at this point the discussion veers off into the rough, but I'd like to bring up an elementary example: a single 2D electron in a uniform magnetic field. The system is obvious symmetric wrt. translations in the plane, but it is also easy to see (Aharonov-Bohm effect) that it is not a proper representation on the wavefunction.

I have rarely seen this issue being discussed — perhaps because the theory of projective representations is not as advanced yet. It is still surprising the number of physicists who are completely unaware of this issue though.

60. **Peter Woit**
December 9, 2008

Gen Zhang,

The point about projective representations is an important one, which I was avoiding for simplicity here. It will appear when I try and write something about affine Kac-Moody Lie algebras and their representations. Another way of dealing with this is to say that, instead of a projective representation, one ends up having a representation of an extension of the symmetry group one started with.

61. **Blair Smith**
January 24, 2009

No fair PW! You hang that philosophical comment (before "Some Examples") out there like a musical note in tension without providing a resolution 😉

Maybe I need to read further on to see where you are going, but might it be possible to give that idea more teeth by say associating (via some ontological-like constraints on possible models of reality) classes of theories that alternatively do (do not) have all observables arising from symmetry groups with unitary reps on H?

Short Bits

November 11, 2008
Categories: BRST, Experimental HEP News, Multiverse Mania

More about BRST is on its way, but in the meantime a lot of things have accumulated that might be of interest, so I wanted to do a quick posting about these.

One of them does have to do with BRST. A correspondent pointed out to me that the 2009 Dannie Heineman prize for Mathematical Physics has been awarded to the four people involved in the original discovery: Carlo Becchi, Alain Rouet, Raymond Stora, and Igor Tyutin.

Via Garrett Lisi, there's this collection of photos of the latest Threeasfour collection. It seems that E8 is inspiring not just physicists.

Over at the n-category cafe, John Baez has a posting about the remarkable publication record of M. S. El Naschie.

On the experimental HEP front, it looks like the LHC will not be trying again to commission beams until next summer. Minutes of a recent meeting about LHC work are here, an outline of a schedule here.

SLAC recently hosted an ICFA seminar, with talks available here summarizing the state of various current and proposed accelerator projects. Prospects for a photon-photon collider are discussed here.

For the latest on the CDF anomaly, Tommaso Dorigo has started a series of detailed posting on the analysis here and here. Matt Strassler has a new paper out about this, including some discussion of possible interpretation of the results in terms of the hidden valley scenario. For more about this topic, see a recent posting at Resonaances.

There's a new popular book out about particle physics, Nature's Blueprint: Supersymmetry and the Search for a Unified Theory of Matter and Force by Dan Hooper. It's a rather breathless account of how physics is about to be revolutionized by the discovery of supersymmetry at the LHC, very much like Gordon Kane's 2000 Supersymmetry: Unveiling the Ultimate Laws of Nature. In Kane's version the LHC was supposed to start up in 2005 and soon discover supersymmetry, in Hooper's the LHC start-up is moved to 2008. One change since 2000: string theory played a big role in Kane's book, Hooper pretty much ignores it.

The December issue of Discover Magazine is out, with Hawking on the cover for a story about the "50 Best Brains in Science". Terry Tao and Edward Witten are on the list, and the magazine includes a nice appreciation of Witten by John Schwarz, who writes about his experience co-authoring a book on string theory with Witten, explaining that:

> Witten is both deep and fast: After thinkings through the ideas, he can compose an essentially error-free 100 page manuscript, often describing breakthrough original research, on his computer in a day. His papers and lectures set a new standard for clarity of exposition. And he shows no signs of slowing down.

This year, Witten is working at CERN, and there's a talk by him scheduled in the string theory seminar there next week, topic TBA. Maybe Jester will report on this.

In other Discover-related news, Cosmic Variance has announced that they have "sold out to the man", and will now be going corporate, signing up with Discover to be one of their blogs.

Also in the new Discover Magazine is a long article promoting the multiverse entitled Science's Alternative to an Intelligent Creator: the Multiverse Theory. The author's take on the story is that we really only have two choices: believe in God and intelligent design, or believe in the Landscape. He seems to have gotten this from Susskind:

> The physicist Leonard Susskind once told me that without a multiverse theory, there may be no other explanation for life other than intelligent design.

The author's note reports that the article came about through Templeton funding:

> For this issue, he traveled to Cambridge, England, as a Templeton-Cambridge Journalism Fellow in Science and Religion to learn what physicists have to say about how the universe seems custom-tailored to favor life.

In keeping with his theme, Folger quotes many proponents of the multiverse, and only one critic: John Polkinghorne, an ex-physicist and current Anglican priest who has motive to want to keep a role for God.

There's some rather out-there stuff at the end from Andrei Linde:

> As for Linde, he is especially interested in the mystery of consciousness and has speculated that consciousness may be a fundamental component of the universe, much like space and time. He wonders whether the physical universe, its laws, and conscious observers might form an integrated whole. A complete description of reality, he says, could require all three of those components, which he posits emerged simultaneously. "Without someone observing the universe," he says, "the universe is actually dead."

The History Channel is running a series on The Universe. Next week the multiverse is being promoted, in an episode Parallel Universes. Here's the summary:

> Some of the world's leading physicists believe they have found startling new evidence showing the existence of universes other than our own. One possibility is that the universe is so vast that an exact replica of our Solar System, our planet and ourselves exists many times over. These Doppelganger Universes exist within our own Universe; in what scientist now call "The Multiverse." Today, trailblazing experiments by state of the art particle colliders are looking for evidence of higher dimensions and Parallel Universes. If proof is found, it will change our lives, our minds, our planet, our science and our universe.

I learned about this from Clifford Johnson's blog. He'll be one of the physicists featured in the episode, as well as in the following one, entitled Light Speed. The next episode, Sex in Space, which will explore the "physiological, psychological and cultural challenges of sex in space" presumably will not be starring any theoretical physicists.

Update: It seems that selling pseudo-science with the argument "it's either this or religion" works.

Update: The links above to the LHC Performance Committee's site have now been closed to outside access. For the last few years the web-sites of the groups responsible for getting the LHC working have been open to the public, but it looks like there now has been a change of policy. The tentative schedule now inaccessible to the public showed that it is repairs to sector 34 that will determine when they can get going again. The process of getting damaged magnets out of the tunnel, making repairs, getting replacements installed, then testing everything, is what may delay everything into next summer.

Update: For some commentary on the Strassler paper, see Tommaso Dorigo here. Slashdot features the Discover article, promoting the idea that the string theory landscape is "Science's Alternative To an Intelligent Creator".

Comments

   November 12, 2008

   Sorry to be a curmudgeon about the Dannie Heineman prize for Mathematical Physics for Becchi, Rouet, Stora and Tyutin (and without detracting from the impact of their work), but why is this *mathematical* physics? The context in which they did their work was nonrigorous QFT, and whereas classical BRST has attained rigorous status, quantum BRST has only very partially done so.

   The distinction between Theoretical and Mathematical Physics is an old bone of contention;- I remember a public debate some years ago at the IAMP meeting in Paris on exactly this point. My preference is for a definition I heard from Thirring: Mathematical Physics is mathematics but the problems are from physics. This is also in several articles of Jaffe, or in the section "the bad influence of physics on mathematics," on p146 of this book.
   Thus it had to be rigorous to qualify as mathematical physics. Unfortunately, the debate at the Paris ICMP went in a political direction: "we should not criticise our colleagues in physics," and since then the consensus has also shifted in this direction, and now we have no word for mathematics work on physics problems. There are many instances of (nonrigorous) theoretical physics being called mathematical physics. It is just a pity to see the prizes doing this too.

2. **Tony Smith**
   November 12, 2008

   Peter, you say that "… photos of the latest Threeasfour collection …" of fashion indicate "… that E8 is inspiring not just physicists …".

   A google search indicates that E8 has not only transcended math and physics, but even beyond fashion,
   to a high-financial realm where no Lie group has gone before:

   According to a 14 August 2008 marketwatch.com story:

   "… E8.com, Inc. today announced that it has successfully acquired six premium numeric domains from Marchex, Inc. …
   "We are pleased to add these domains to the ever expanding, digital asset portfolio of E8.com," said T.J. Demas, Founder and CEO of E8.com, Inc.
   "Equally exciting is the fact that the close of the acquisition coincided with E8.com's initial incorporation on August 8, 2008 (8.8.8) in the state of California."
   E8.com, Inc.'s initial capitalization structure includes a 99% ownership stake by Aspen Edge Research, LLC and a 1% ownership stake by Moover Toys of Copenhagen, Denmark. Moover Toys initial 1% equity investment in E8.com, Inc. totaled $88,888.88 valuing E8.com, Inc. at $8,888,888.88 at inception. …
   E8.com's mission is to provide the most advanced, intuitive, user interfacing platform in the world based upon the unifying supersymmetry of the exceptional Lie group E8 and its corresponding 248 dimensions. …".

   According to a dnjournal.com article:
   "… You may have seen a cryptic news release a few days ago from Marchex and E8.com about E8 buying six numerical domains from Marchex. The prices paid were not disclosed – but we are going to release them for the first time in this column.
   As it happens I know E8 Co-Founder and President, T.J. Demas, an Aspen, Colorado based investor …
   Demas is, to put it mildly, a mathematics fan. His company is named after an E8, one of the most complicated structures ever studied … In a nutshell E8 is all about symmetry and Demas is applying symmetry to a series of numerical domain purchases for a project he is not yet ready to fully reveal.
   With his focus on symmetry, his purchases have followed a certain pattern and the prices paid have been thought out down to the last cent. This past week Demas completed the purchase of 11 domains totaling $1,144,444.30. Six of those were bought from Marchex and five more were acquired in private transactions. …".

   Peter, how much do you think that BRST.com might be worth?

   Tony Smith

3. **Hendrik**
   November 12, 2008

   Further inspection of the list of previous Dannie Heineman prizewinners shows that this particular prize was always given to both (nonrigorous) theoretical physicists and mathematical physicists, with a fair representation of string theorists. It seems to have a ratio of about 2 theoretical physicists for each mathematical physicist. (Perhaps because it is administered by the APS?)

4. **mathematician**
   November 12, 2008

   Re: Discover Magazine article "Science's Alternative to an Intelligent Creator: the Multiverse Theory."

   Why do people fall for these ridiculous false dichotomies? They basically take the form of "It's either my theory, or else it's this straw-man" when in reality, there are many more than just two competing explanations.

   I've even seen theists turn the tables by comparing their theism favorably with their chosen strawman, the anthropic landscape/multiverse (e.g. on an episode of "closer to truth" which is really terrible).

5. **Me**
   November 12, 2008

   Regarding sex in space, those interested in some experimental results caught on video should search for "The Uranus Experiment" (filmed in free fall).

   The results are not very appealing and without knowing in advance I for one would have not found anything special about them.

6. **a quantum diaries survivor**
   November 12, 2008

   Hi Peter,

   thank you for your reiterated signs of appreciation for my reports – you know I value your opinion at least as much as I value your links.
   The series on multi-muons will continue at least for three or four more posts, and possibly more, becoming the longest series on my blog. The third part, about secondaries from nuclear interactions, is out now.

   As for the LHC schedule: the repairs of sector 34 are indeed complicated. Many magnets need replacement, but quite a few more need to be checked. Moving stuff around in the LHC tunnel looks pretty much like that game invented by Sam Loyd (the unrivalled chess problem composer), "15".

   I heard unofficially stated that we will most likely get beams in September 2009. That really sucks, but on the other hand we are not watching idly. People are busying themselves in various ways. No publications, and no data for grad students to build a career on: these are really nagging facts. But to many, more time to refine tools is not the end of the world. My main concern ? This is moving my cashing the 1000$ bet against new physics at LHC too much in the far future!

Cheers,
T.

7. **Serifo**
November 12, 2008

I agree with prof. Hendrik in some points. However, currently I find it hard to define the term ” mathematical physics ” . Sometimes I have the impression that mathematical physicists are divided in following two groups 🙂 :

1) Those (real mathematical physicists ?) who are concerned with the physics but also with mathematical rigour of their ideas.

2) Those (pseudo mathematical physicist ?) who know and use the most advanced mathematical tools for physical purpose, but are not at all concerned in the rigour of their ideas .
You may like to read the following article by Eric Zaslow on the idea of physmatics :

http://www.claymath.org/library/senior_scholars
/zaslow_physmatics.pdf

Ps – The use of advanced mathematical tools in nonrigorous way in physics, may be the reason for the lack of progress in physics. So, maybe Hilbert had a point when he said physics is too difficult for the physicists ! 🙂

8. **Peter Woit**
November 12, 2008

Hendrik and Serifo,

I think the term “mathematical physics” has always been rather vague, covering several different kinds of activity, and it has just become more so in recent years. The Heineman prize appears to have historically gone mostly gone to physicists, often ones without much interest in mathematics.

After spending a lot of my life among both mathematicians and physicists, I’ve seen that:

1. Mathematicians often see physicists as not only missing the importance of rigorous proof, but sometimes being unwilling to even formulate clearly what they are doing, and keep straight the distinction between what they do understand and what they don’t understand. From a mathematician’s point of view, this can make it very hard to make progress.

2. Physicists often see mathematicians as overly concerned with pedantic issues, focusing on technicalities needed to achieve absolute rigor, or on empty formalism.

I tend to often agree with both sides about this, but what happens is that the best people in each subject manage to rise above the problems of their subject. At the moment, it seems to me that mathematicians are in much better shape, making good progress, while maintaining high levels of rigor. Theoretical physics is not in such good shape, with even the best people making little progress. The problems are hard, and a lack of clarity about exactly what they are, what is understood and what isn’t, has a lot to do with this.

9. **MathPhys**
November 12, 2008

Thank you for the link to “The case of M S El Naschie”.

I searched around a bit and found an e-mail that Paul Ginsparg wrote re one of El Naschie’s collaborators, Carlos Castor. Highly recommended for entertainment value.

10. **MathPhys**
November 12, 2008

I meant Carlos Castro. A link to Ginsparg e-mail is here

http://www.archivefreedom.org/freedom/Cyberia.html

Can someone please take a look at these photos

http://www.ijnsns.com/conf/Photo-Gallery.pdf

Some seem to have been produced by photoshop

Look at the photo with Wilczek, ‘t Hooft and Gross

http://www.el-naschie.net/el-naschie-physicist.asp?site=249&lang=

Looks very suspicious to me.

11. **Serifo**
November 12, 2008

Hi prof. Peter,

Let me take your interesting observation : ” At the moment, it seems to me that mathematicians are in much better shape, making good progress, while maintaining high levels of rigor. Theoretical physics is not in such good shape, with even the best people making little progress. The problems are hard, and a lack of clarity about exactly what they are, what is understood and what isn’t, has a lot to do with this. ” Well , maybe theoretical physics is in crisis at foundational level as mathematics was in the early 20th century . Some Mathematician like Hilbert for example were not happy with the state of the subject itself, thus they started to put the subject in a firm (axiomatic) basis . So maybe theoretical and mathematical physicists need to do the same, specialy those who already have permanent academic positions and so are not concerned on spending 3 or 5 years to put the subject in a firm basis even if they fail ! 🙂 Now as in mathematics, where some fundamental concepts like Set had to be carefully formulated, maybe the same has to be done with some fundamental physical concepts !

12. **Peter Woit**
November 12, 2008

MathPhys,

I don't see any real evidence of photoshopping. El Naschie seems to have some sort of talent for getting ahead in the world, and I don't think that attending a conference featuring some Nobel prize winners and getting in a picture taken of them would be all that much of a challenge.

13. **Peter Woit**
November 12, 2008

Serifo,

I don't really think an axiomatic framework is what's important. But I do think the question of what the right fundamental ideas are, and what their best mathematical incarnation is, are still open questions for fundamental physics. In recent years I've started to think there's a lot more to BRST than just a solution to a technical problem…

14. **Kea**
November 12, 2008

MathPhys, your link to the Castro story is solid evidence AGAINST the photos being photoshopped. Perhaps you should read what you link to before you post something.

15. **Hendrik**
November 13, 2008

Dear Peter,
I have also experienced those contrasting views which mathematicians and physicists have of each other. I think the reasons for these (occasionally) hostile views are sociological and economical. Theoretically, there should be no conflict between the two fields;- physicists are good at discovering patterns in the physical world, and should not be slowed down by being chained to rigour. Mathematicians on the other hand, are good at sorting out the exact logical frameworks, extensions and applications for those patterns, and need rigour in order to have certainty in their results. These are complementary activities, you need both to create a mature reliable description of a physical system.

Unfortunately due to competition (for grants, territory, status etc) there is often conflict where there should be cooperation, and this competition is sometimes at the level of appropriation of names. So, it is that "mathematical physics" once was practiced mainly in rigorous frameworks, but now the term has been appropriated by the physics camp, and also denotes nonrigorous theoretical physics. (I disagree that it always had this general meaning;- from my small corner of the field, I have seen a definite 20yr drift in the meaning towards the nonrigorous). At the practical level, it means that both "types" of mathematical physicist now apply for the same grants and that e.g. Commun.Math.Phys. has the same rating as J.Phys.A. when these applications are judged, so it is not just a question of names.

16. **Tony Smith**
November 13, 2008

Hendrik said
"… physicists are good at discovering patterns in the physical world …
Mathematicians on the other hand … need rigour in order to have certainty in their results…".

Would it be fair to say that
physicists's work should be constrained by experimental observations
and
mathematicians's work is constrained by rigour of proof ?

If so, then "… there should be no conflict between the two fields …" so long as each is subject to its constraint system.

However, problems may arise if and when
physicists work without constraint of experimental observations
(which may be a source of concern about superstrings)
or
mathematicians work without rigour
(which seems, thankfully, not to be something that is a present source of concern).

I agree with Hendrick that the term "mathematical physics" was, up to the 1980s, "… practiced mainly in rigorous frameworks …"
(for example, look at the program of the 1981 Congress of the International Association of Mathematical Physics in Berlin (West)).
and
that since that time (temporally coincident with the rise of superstring theory) there has been, as Hendrik said, "… a definite 20yr drift in the meaning towards the nonrigorous … theoretical physics …".

Tony Smith

17. **Chris Oakley**
November 13, 2008

The question of whether what one does is rigorous or not should not even arise. Particular assumptions lead to particular conclusions and if any one of the steps in the derivation is not rigorous then it all falls apart and all one can then say is that the assumptions do *not* therefore lead to the conclusions. In this regard, I would "tone down" my comments about renormalization considerably if text books and QFT courses were honest about the non sequiturs … "effective" field theory has a self-consistency, but is a much smaller framework than the pedagogical materials would lead one to believe.

18. **Sandro**
November 13, 2008

I think all of you have read this

http://arxiv.org/abs/math-ph/0002018

but it never hurts to give it another look..
I agree that the reason for hostility between physicists and mathematicians are (most of the time) of economical species, and it is sad that we can't get the best of the two worlds, which I think is the only way towards progress in both fields, because of this.

19. **MathPhys**
November 13, 2008

Kea,

I have read what I linked and came up with a conclusion that's opposite to yours. Perhaps you should consider that others may reach conclusions that are opposite to yours before you type.

To my mind, a man who claims an affliation that dosn't belong to him (amongst many other petty acts along the same lines) is not above posting photoshopped pictures of himself with celebrities.

20. **Serifo**
November 13, 2008

I red the following story from somewhere □ : " professor X holds a joint position in physics and maths departments. Now in respect to his research , his colleagues in physic`s dept. say he`s not doing physics while in math`s dept. they say he`s not doing maths ! "So what is professor X doing ? Could it be a new and independent field of knowledge, that uses both physics and maths as a platform ?
Now I think among the mathematicians today, although there isn`t a general consensus on " what is mathematics ", there is a kind of consensus in all the fields, on how the practice of the subject must be done ! On the other hand, it seems to me that, there is a kind of consensus among theoretical physicists on " what physics is all about " but there isn`t a consensus on how the subject must be practiced !

21. **Jeff McGowan**
November 13, 2008

OK, couldn't pass up the opportunity – I'm sure most everyone has seen some variant of the following joke –

If you understand something and can prove it, publish it in a math journal.
If you understand something but can't prove it, publish it in a physics journal.
If you don't understand something but can prove it, publish it in an economics journal.
If you don't understand something and can't prove it, publish it in (fill in your least favorite subject) journal.

22. **Chris Oakley**
November 13, 2008

> If you don't understand something and can't prove it

… then get someone to make a popular science program showing that the only alternative to your idea is Intelligent Design.

23. **anon.**
November 15, 2008

'He'll be one of the physicists featured in the episode, as well as in the following one, entitled Light Speed. The next episode, Sex in Space, which will explore the "physiological, psychological and cultural challenges of sex in space" presumably will not be starring any theoretical physicists.'

Hawking is planning to go into space aboard Richard Branson's Virgin spacecraft, so maybe he'll be featured in the programme explaining his opinions on the physics of sex in space? See http://www.msnbc.msn.com/id/15970232/

24. **chickenbreeder**
November 15, 2008

The El Naschie story at n-Cc is pretty fascinating to read. It looks like El Naschie has adopted the same tactics of Bogdanoff brothers – using multiple aliases (all trackable to Cairo…) to defend himself.

A case like this is by no mean isolated. Quickly off my head I can think of a few people who share the trait of EN, though not so extreme as to publish 300+ papers in the journal edited by oneself. This is happening and is largely left untreated because the majority of "normal" scientists do not want to drag themselves into the mud by pointing fingers at their colleagues, however justifiable it may be. It could lead to law suits and other unpleasant things. You never know.

25. **st**
November 15, 2008

That's the problem, chickenbreeder. If scientists who know the type of pseudoscience he's been consistently producing don't speak up, then who will? If there is fraud like fabrication of data, should they not bring attention to that too? Why should they be afraid of lawsuits if their criticism is based on fact (e.g. the guy claims to have written a PhD thesis and has even cited it, but no thesis can be found at the university)? Folks, this is not a colleague doing poor work; it's an outsider claiming to be one of you and has succeeded in fooling even a reputable (albeit greedy) publisher for a long time.

Normally, it is best to ignore people who talk/write nonsense, but he has been draining the community's resources and has destroyed the name and reputation of a journal, which at one time was probably a decent publication.

26. **MathPhys**
November 15, 2008

I think El Naschie deserves a medal (to add to his extensive collection). Without him (and the Bogdanoff's and some of our colleagues who only go from high to higher) we would be lulled into the belief that the system works. It's pioneers like El Naschie (and Carlos Castro) that keep us on our toes.

27. **Shantanu**
November 17, 2008

Peter, this may be a bit off topic, but I watched a very interesting talk
by Robert Brandenberger on cosmology of the Lee-Wick extension to standard model
http://pirsa.org/08110032/ and in the first 10-15 minutes Robert
talks about the particle physics aspects and history of Lee-Wick standard model and apparently there were no papers on this subject for more than 35 years until recently.
This is the first time I am hearing about the Lee-Wick model.
Has this model been ruled out long time ago? Maybe you could post something about this model, as you are probably familiar with it

28. **Peter Woit**
November 17, 2008

Shantanu,

Sorry, I don't really know anything about the Lee-Wick standard model.

29. **MathPhys**
November 19, 2008

Peter,

Maybe you want to take a look at the Lee-Wick version of the standard model. Any alternative to supersymmetry is welcome. Brandenberger's talk is probably a good starting point.

30. **Math Phys**
November 19, 2008

El naschie using his own journal as
a stock for his endless uncountable papers.
Here is, one of his marvelous papers found in Chaos, soltion and fractals.

The title

"On the universality class of all universality classes and E-infinity spacetime physics"

M.S. El Naschie,

King Abdul Aziz City of Science and Technology, Riyadh, Saudi Arabia

Available online 18 October 2006.

Abstract
It is argued that E-infinity theory may represent the universality class of all universality classes of certain discrete dynamical maps which are at the root of relevant field theories. First we give a concise derivation of the basic equations of E-infinity and its ground state. Subsequently it is shown that the independence of the results obtained from the details of any equations of motion or Lagrangian is a clear indication that E-infinity may represent the universality class of all universality classes in the sense of Cantor with regard to relevant quantum field theories.

I'm quite amzed how this could be published.

In fact, for any one who knows little about particle physics realize that the results of any theory depend strongly on the particle content of the theory. For example in QCD, asymptotic freedom depends on the number of colours and flavors. The presence of CP violation in the quark sector depends on the number of generations. No CP violation for one and two generations, at least three generations is required for the presence of CP violation.

31. **Math Phys**
November 19, 2008

Almost one year ago we have sent to Elsevier about this issue concerning the "Chaos, soltion and fractl" Journal and his editor in Cheif El naschie

Here is the letter

Dear publishing responsible
We are writing you about the Journal of Chaos , solitons and Fractals and his editor in chief El Naschie. We are group scientists from different countries working in theoretical high energy physics and as a matter of fact we noticed that El Nashie the editor in chief the above mentioned journal has been publishing an incredible large number of papers in this journal, where he claims to have solved all the problems of particle physics using his E-infinity approach based on fractal geometry. We have looked at those papers very carefully and found them unscientific and meaningless, completely irrelevant to science and particle physics in particular. Moreover, those papers are not only without sense but complete junk. On the top of that El Naschie has published in 2008 (in one month and 5 days) 33 papers, that is one paper per day!!, which scientifically unacceptable. Not only that, we discovered that most if not all the papers published in this journal by different authors have no scientific sense and are really junk and rubbish. What most authors, who publish in this journal, do is either to refer to El Nashie works or invent a theory title and attribute to El Naschie, and then write anything, in many cases they just copy formulas from books and write them and publish the same article several times by changing the introduction and the conclusion.As an evidence we attached some papers published in this journal and we invite you to ask any respectable scientist to evaluate those papers. Indeed it is not even needed to have a big knowledge of physics and mathematics to realize that the content of those papers is complete non sense.This journal has become preferred place of scientific junk.We wonder how a respectable and leading publisher which publishes prestigious journals like Nuclear physics, physics letters.etc…accept such misconducting of this journal by his editor in chief El Nashie. In fact, it is very weired and strange that El Naschie publishes all his papers in his journal and this does not happen in any respectable journal. Indeed we have nothing personal against this guy, but this journal as we said has become sort of source of rubbish and junk and in our view a source of jokes. We are afraid that the publisher Elesvier will be participating and playing an unintentional role in fostering and delivering junk science in the globe, in contrast to supposed policy of Elsevier. Best Regards

Here is the reply:

thank you for your letter.
We shall review the issues that you raise carefully. Thank you for bringing your concerns to our attention.
Sincerely,
David Clark David Clark
Publishing Director, Physics, Mathematics, Computer Science and Astronomy
Elsevier B.V. Radarweg 29, Amsterdam 1043 NX
The Netherlands
Tel + 31 20 485 2451 | Fax + 31 20 485 2370 | david.clark@elsevier.com | http://www.elsevier.com

But at the end nothing happened

32. **Peter Woit**
November 19, 2008

"Math Phys" (who is not the same as "MathPhys")

If you want to use a pseudonym, please choose a different one than one being used by someone else here.

33. **st**
November 20, 2008

Yesterday, I sent an email to David Clark of Elsevier to ask him if he did indeed respond a year ago to a letter written by a "group scientists from different countries working in theoretical high energy physics". I included the addresses of blogs (including this one) that mentioned this letter, in case he would like to comment on it. It's only been 24 hours, but I haven't received a reply yet.

34. **MathPhys**
November 21, 2008

st,

I expect that Elsevier will respond by saying that it has already been decided that El Naschie will step down as Editor-in-Chief, but I think that that won't be good enough.

I think Elsevier has to explain what happened and how someone like El Naschie was let loose on a scientific journal published by them.

35. **st**
November 22, 2008

MathPhys,

I don't know when Elsevier will respond if at all. Perhaps the journalist mentioned here (see 11/22/08 comment) will have more luck. Apparently submissions to CS&F may now be sent directly to the (same) Editor-in-Chief at his newly announced e-mail address instead of an office in Elsevier, as was required until two days ago.

I wonder if it is common practice to send manuscripts directly to the publisher first instead of an editor.

36. **MathPhys**
November 22, 2008

"The latest electronic version of manuscripts for publication should be sent to the Editor-in-Chief, Professor M.S. El Naschie, Chaos, Solitons & Fractals via e-mail:Chaossf@aol.com. Alternatively manuscripts may be submitted to the nearest Regional Editor."

A professor at which university?

37. **An**
November 24, 2008

I think the case of El naschie is a scandal by all measures. This case opens the door for many questions: what are the organizations involved in this matter?

In the first place, one can mention Cambridge university which allowed him to publish his articles for nearly ten years 1993-2001 using its affiliation. It is far from reality to imagine that people in Cambridge have been fooled for that long time. According to the following data base

http://www.engineeringvillage2.org

One can find:
17 articles where the affiliation is DAMTP, Cambridge, UK.
72 articles where the affiliation is Dept. of Appl. Math. & Theor. Phys., Cambridge Univ., UK
40 articles where the affiliation is Univ of Cambridge

No prize for one who guesses at which journal those articles have been published.

In the second place, it comes Elsevier that has been the main stage for producing such a scandal bomb of heavy weight. It is clear that there have been many people behind that matter who got direct benefits (earning money, most probably from El Naschie himself).

38. **MathPhys**
November 25, 2008

I find it very strange that Elsevier allows for an editor-of-chief of a journal who uses professor as a title simultaneously with a POBox number as an affiliation and aol.com as an e-mail address. What's going on in Radarweg 29, Amsterdam?

39. **Stefan**
November 26, 2008

In this week's Nature, Quirin Schiermeier writes about the El Naschie story, Self-publishing editor set to retire (subscription required), including a quote by Peter.

40. **Felipe**
November 28, 2008

It is very clear to me, just in case someone ever had a doubt, that Elsevier is in the making money business. The company has no real commitment whatsoever to the scientific quality of its publications, as long as they can make some university's libraries pay for them. That is a very, very sad state of affairs.

41. **MathPhys**
November 29, 2008

Felipe,

This is no secret, in fact when they interview someone (with a degree in science) for a job, that's the first thing that they tell them.

In fact what I find strange is that Elsevier does not have the good business sense to know that to stay in the business requires a minimal degree of product quality control which is totally lacking in this case.

42. **Any one**
November 30, 2008

Looking for the numerous amazing articles of El naschie, I found a wonderful one whose title is
"P-Adic analysis and the transfinite E8 exceptional Lie symmetry group unification "
M.S. El Naschie
King Abdullah Institute for Nano and Advanced Technology, KSU, Riyadh, Saudi Arabia
Volume 38, Issue 3, November 2008, Pages 612-614

Just reading the first sentence in the introduction which is
"One of the most amazing results in high energy physics is the T-duality discovered in the context of superstring theories by Witten [1] "
But, for your surprise, the list of references you find no mention of any reference of Witten.
Reference [1] is just a paper of El naschie himself. Here is list

[1] M.S. El Naschie, A few hints and some theorems about Witten's M theory and T-duality, Chaos, Solitons & Fractals (2005), pp. 545–548.
[2] A. Leonovich, Comments on E8 unification and P-Adic numbers. http:/www.telegraph.co.uk/earth/main.jhtml?xm1=/eareth/2008/01/22/scieinstein122.xml (10/03/2008).
[3] M.S. El Naschie, Transfinite harmonization by taking the dissonance out of the quantum field symphony, Chaos, Solitons & Fractals (2007).
[4] M.S. El Naschie, High energy physics and the standard model from the exceptional Lie groups, Chaos, Solitons & Fractals 36 (2008), pp. 1–17.
[5] M. Kaku, Introduction to superstrings and M-theory, Springer, New York (1999) see p. 385 in particular.
[6] M.S. El Naschie, Infinite dimensional Branes and the E(∞) topology of Heterotic super strings, Chaos, Solitons & Fractals 12 (2001), pp. 1047–1055.

The first reference as already mentioned is El naschie paper. The big surprise about this paper is its tilte
"A few hints and some theorems about Witten's M theory and T-duality" here again we find no reference to any of Witten's papers . here is list of references of this paper ;

[1] E. Goldfain, Cantorian spacetime and unified field theory, Chaos, Solitons & Fractals 23 (2005), pp. 701–710.
[2] M.S. El Naschie, A review of E-infinity theory and the mass spectrum of high energy physics, Chaos, Solitons & Fractals 19 (2004), pp. 209–236
[3] M.S. El Naschie, Gödel universe, dualities and high energy particles in E-infinity, Chaos, Solitons & Fractals 25 (2005) (3), pp. 759–764.
[4] El Naschie MS. On the cohomology and instantons number in E-infinity Cantorian spacetime. Chaos, Solitons & Fractals, in press doi:10.1016/j.chaos.2005.12.019.
[5] M. Kaku, Strings, conformal fields and M-theory, Springer-Verlag, New York (2000).
[6] A. Khrennikov, Non-Archimedean analysis, Kluwer Academic Publishers, London (1997).
[7] V. Vladimirov, I. Valovich and E. Zelenov, P-Adic analysis and mathematical physics, World Scientific, Singapore (1998).

Something more peculiar about the list of references, of the first paper, is that one of the references is just a comment on an article published in the Telegraph, unfortunately the comment has been deleted. Also the address of the first paper raises another question about the so many false affiliation of El Naschie. The address seems not to be related to his activities.

It is obvious that there is no kind of peer review for these papers even at the fromal level apart from the content.
One can guess that papers may be generated using a program of language generation like n-moles or n-grams or whatever kind of program used. I think, at least for me, that the 'a b' of scientific writing should fulfill certain basic criteria:
1- If you mention a paper of Witten (or any name) [], then one should put reference for that person in the square bracket.
2- If you have a paper titled with theory of some one, then the list of references should contain at least one reference for that guy.

I hope, by now, El naschie has a plenty of time to fix the bugs in the program generating papers, implementing these two mentioned rules in the code and acknowledge this blog for drawing his attention.

43. **MathPhys**
November 30, 2008

On the positive side, El Naschie makes specific references to a standard textbook on string theory by one of the founding fathers of the subject

[5] M. Kaku, Introduction to superstrings and M-theory, Springer, New York (1999) see p. 385 in particular.

44. **st**
December 1, 2008

Earlier I commented that "no thesis [of El Naschie] can be found at the university". The comment was based on the fact that his name did not (still does not) appear in the University of London Theses Catalogue, a database known to contain titles dating back to the fifties.

Recently Stefan at Backreaction has apparently found a record in the Integrated Catalogue of the British Library.

I regret reacting prematurely.

45. **Any one**
December 20, 2008

To St

It is not important if El naschie is a phd holder or not.

The number of his papers is 350 or 1000 papers is also

immetrial. If one is allowed to write in his style without any

peer review one could publish 6000 papers in twenty years.

The main problems in his papers is they don't make sense

whatever mathematically or physicaly.

About the address "King Abdullah Institute for Nano and Advanced Technology, KSU, Riyadh, Saudi Arabia" on

his recent papers is very supicious as it has no relation to his activities.

On the Ninth International Symposium Frontiers of

Fundamental and Computational Physics 2008 had a lecture titled

“Average exceptional Lie group hierarchy and high

energy physics” where he claimed to be the director of

King Abdullah Al Saud Institute for Nano & Advanced Technologies

as evident from the affiliation mentoined below.

M.S. EL NASCHIE

King Abdullah Al Saud Institute for Nano & Advanced Technologies*,

Riyadh, Saudi Arabia.

*) Director

one can check

http://agenda.fisica.uniud.it/difa/getFile.py/access?contribId=52&sessionId=32&resId=0&materialId=slides&confId=9

But if you check the web page of King Abdullah Al Saud Institute for Nano & Advanced Technologies you don’t find his name listed in the Committee Members of Establishing King Abdullah Institute for NANO Technology and there is no mention for him at all. That

seems odd especially he is the director as he claimed.

One can check the web page for “Committees consultative sciencetisic”

http://www.nano-ksu.com/publish/article_46.shtml

web page for “Supervisory Committee to King Abdullah Institute for Nanotechnology”

http://www.nano-ksu.com/publish/article_63.shtml

Can the great man explain for us.

46. **Any one**
December 29, 2008

If El naschie is an honest scientist and not a fraud. He should mention the web link to the institute he claimed to have a position or related to it in his website.

I challenge him to put links which shows his claims and to assure his honesty for the others. Please give links to the following claimed position

1-He is the current advisor of the Egyptian Ministry for Science and Technology (High Energy Physics and Nanotechnology)

2- He is Adviser to King Saud University on Nanotechnology, and even more he claimed to be the director of King Abdullah Al Saud Institute for Nano and Advanced Technologies.

One can check the following link where he claimed to be the director

http://agenda.fisica.uniud.it/difa/getFile.py/access?contribId=52&sessionId=32&resId=0&materialId=slides&confId=9

If you check the webpage of of King Abdullah Al Saud Institute for Nano and Advanced Technologies. You find no mention for him at all

One can check the web page for “Committees consultative sciencetisic”

http://www.nano-ksu.com/publish/article_46.shtml

web page for “Supervisory Committee to King Abdullah Institute for Nanotechnology”

http://www.nano-ksu.com/publish/article_63.shtml

In fact it reflects badly on these countries if this was true.

47. **Any one**
January 5, 2009

Believe it or not

El naschie had four articles whose titles containing Witten. The articles are

1- A few hints and some theorems about Witten’s M theory and T-duality,

Chaos,Solitons and Fractals 25 (2005)545 û548

2- Using Witten’s five Brane theory and the holographic principle to derive the value of the electromagnetic structure constant alpha =1/137,

Chaos,Solitons and Fractals 38 (2008)1051 -1053

3- Fuzzy knot theory interpretation of Yang -Mills instantons and Witten’s 5-Brane model, Chaos,Solitons and Fractals 38 (2008)1349 -1354

4- On the Witten -Duff Branes model together with knots theory and E 8 E 8 super strings in a single fractal spacetime theory,

Chaos, Solitons and Fractals xxx (2008)xxx – xxx . The article is still in press, but you can get the pdf. file.

The amazing thing about the references of the first three articles is that they don't contain any research paper for Witten. Finally, the great man realized his mistake and put a reference for Witten in the fourth one (the most recent one). But the man didn't acknowledge who pointed out to him this bug in his program which he used to generate papers (Backreaction blog). Any way this a good step, at least the references are now correctly produced. Unfortunately you still need further improvement in your code that seems has a serious problem with E. Witten. Although you referred to a paper of Witten the program has produced a wrong title for it. In the reference list we find

[4]Witten E. Searching for a realistic Kaluza-Klein Theory. Nucl Phys B 1981;186:412 – 28.

While the correct title turned out to be, as you can check yourself:

Search for a realistic Kaluza-Klein theory

Nuclear Physics B, Volume 186, Issue 3, 10 August 1981, Pages 412-428, Edward Witten

As N. Eisfeld wrote on Mar. 26, 2008 @ 18:32 GMT, in this blog, http://fqxi.org/community/forum/topic/395, describing El naschie

"This man has never bad-mouthed, ignored or downplayed anyone or any contribution. He also acknowledged every single person who contributed to his work unless he genuinely did not know and then he will immediately apologize of the unintended omission."

48. **Any one**
January 7, 2009

I think that Elsevier is doing dirty jobs in scientific publishing. The CSF journal is owned by Elnaschie and Elsevier is getting money out of this apart from the journal subscription fees. El naschie pays for getting credibility of Elsevier and to have the chance to publish his great scientific ideas in journal hosted by a supposed reputable publishing house like Elsevier. There are other many similar cases in Elsevier.

El naschie keeps publishing junks in CSF for a quite long time and kept unnoticed by mentoring system of Elsevier which seems very odd. While it was so obvious from the far beginning that we have a crackpot.

The same applies to Cambridge university which allowed him to publish his articles for nearly ten years 1993-2001 using its affiliation, while, for sure, he wasn╝t a staff member there. It is far from reality to imagine that people in Cambridge have been fooled for that long time. According to the following data base

http://www.engineeringvillage2.org

One can find:

17 articles where the affiliation is DAMTP, Cambridge, UK.

72 articles where the affiliation is Dept. of Appl. Math. & Theor. Phys., Cambridge Univ., UK

40 articles where the affiliation is Univ of Cambridge.

No prize for one who guesses at which journal those articles have been published.

It is not enough for Elsevier just to step down Elnaschie , they should explain how these things happened and what their future precautions to prevent such a misusing of editorial power.

On the other side, Cambridge people should explain how it was possible for El naschie to use its affiliation for a quite long time, harming their reputation without charging him and any legal action.

The papers of El naschie would be a permanent black record for both Elsevier and Cambridge for too long time in the future.

49. **Any one**
February 2, 2009

Dear All,

There is an interesting article worthy to read.
The aricle is written in German about El naschie

Betrug in der Wissenschaft (Fraud in science) which
uncovers the reality of El naschie.

http://www.zeit.de/2009/03/N-El-Naschie?page=1

50. **Prego Senor**
February 27, 2009

The ZEIT article was removed, most probably due to pressure from El-Naschie. This is another scandal, since the article contained nothing but facts and opinions of other scientists bold enough to speak out. Many people underestimated Mohamed S. El-Naschie and hoped this would silently solve itself out somehow. They could not know that El-Naschie is a genius. Not by any means in the field of science, but the field of propaganda, defamation and filing law-suits.

Notes on BRST II: Lie Algebra Cohomology, Physicist’s Version

November 15, 2008
Categories: BRST

My initial plan was to have the second part of these notes be about gauge symmetry and the problems physicists have encountered in handling it, but as I started writing it quickly became apparent that explaining this in any detail would take me into various issues that are quite interesting, but far afield from what I want to get to. So, I hope to get back to this at some point, but for now will just assume that most of my readers know what gauge symmetry is, and that the rest just need to know that:

- The gauge group is an infinite dimensional Lie group. Locally (on space-time), it looks like a group of maps into a finite dimensional Lie group.
- The conventional assumption is that physics is invariant under the gauge group, so the gauge group and its Lie algebra should act trivially on physical states.

The actual situation is quite a bit more complicated than this, but for now we’ll focus on the simplest version of the mathematical problem that comes up here, and see how the BRST formalism deals with it. This posting will begin explaining one part of this story, starting with the simplest version of BRST cohomology, in a language familiar to physicists. The next posting will deal with Lie algebra cohomology in a more general mathematical context and work out some examples. For more about the material in this posting, see, for instance, Green, Schwarz and Witten, volume I, section 3.2.1, where they go on to apply this to the Virasoro algebra, or these lecture notes from Jose O’Figueroa-Farrill .

Physicists always begin by choosing a basis, in this case a basis X_i of $\mathfrak g$ satisfying $=f_{ij}^kX_k$, where f_{ij}^k are called the structure constants of $\mathfrak g$. A representation (π,V) is then a set of linear operators $K_i=\pi (X_i)$ on V satisfying $=f_{ij}^kK_k$. Let α^i be a basis of the dual space $\mathfrak g^*$, dual to the basis X_i.

Now, extend V to $\mathcal =V\otimes \Lambda^* (\mathfrak g^*)$, where $\Lambda^* (\mathfrak g^*)$ is the exterior algebra on $\mathfrak g^*$. On this space, define the “ghost” operator c^i to be wedge-product with α^i, and “anti-ghost” operator b_i to be contraction (interior product) with X_i. These operators satisfy “fermionic” anti-commutation relations

$$\{c^i,c^j\}=\{b_i,b_j\}=0,\ \ \{c^i,b_j\}=\delta^i_j$$

and one can get all vectors in $\mathcal H$ from linear combinations of decomposable elements of $\mathcal H$ (those given by repeated application of the c^i to the “vacuum vector” $V\otimes \mathbf 1$).

The ghost number operator $N=c^ib_i$ on $\mathcal H$ has eigenvectors the decomposable elements, with integer eigenvalues from 0 to dim $\mathfrak g$, given by the number of ghost operators needed to produce the eigenvector from a vacuum vector.

The BRST operator is given by

$$Q=c^iK_i -\frac{1}{2}f_{ij}^kc^ic^jb_k$$

which increases the ghost number by one, and has the crucial property of $Q^2=0$ (this comes from the fact that the f_{ij}^k satisfy the Jacobi identity). The BRST cohomology is given by considering the space $ker\ Q$ of elements χ of $\mathcal H$ that are “BRST-closed”, i.e. satisfy $Q\chi=0$, and identifying two such elements if they are “BRST-exact”, i.e. differ by $Q\lambda$ for some λ. So BRST cohomology is defined by

$$H^*_Q(V)=\frac{ker\ Q}{im\ Q}|_{V\otimes\Lambda^*(\mathfrak g^*)}$$

with $H^j_Q(V)$ the component of the BRST cohomology of ghost number j.

A vector $\chi=v\otimes\mathbf 1$ of ghost number zero satisfies $Q\chi =0$ iff and only if $K_iv=0$ for all i, so we can identify $H^0_Q(V)$ with the space $V^\mathfrak g$ of $\mathfrak g$ – invariant vectors in V.

The essence of the BRST method is to replace the problem of finding the invariant subspace $V^{\mathfrak g}$ of a representation V by the problem of finding the degree zero BRST cohomology $H^0_Q(V)$.

There are two different ways of putting an inner product on $\Lambda^*(\mathfrak g*)$ and thus getting an inner product on $\mathcal H$ ((π,V) is assumed to be unitary, so preserves a given inner product on V).

- Given $\omega_1,\omega_2\in \Lambda^*(\mathfrak g*)$, one can define

$$< \omega_1,\omega_2> = \int \omega_1\omega_2\equiv coeff.\ of\ \alpha_1\wedge\cdots\wedge\alpha_{dim\ \mathfrak g}\ in\ \omega_1\wedge\omega_2$$

(this uses the “fermionic” or “Berezin” integral $\int$, although I have not properly dealt with signs here.).
This inner product is indefinite, but it makes the BRST operator Q and ghost-operator c^i self-adjoint.

- Use an inner product on $\mathfrak g$, e.g. the Killing form for a semi-simple Lie algebra, to identify $\mathfrak g$ and $\mathfrak g^*$. This gives a Hodge operator $*_{Hodge}$ on $\Lambda^*(\mathfrak g*)$ that takes $\Lambda^i(\mathfrak g*)$ to $\Lambda^{dim\ \mathfrak g -i}(\mathfrak g*)$, and one can define

$$< \omega_1,\omega_2> = \int_G \omega_1\wedge *_{Hodge} \omega_2$$

(Note, here the integral sign is not Berezin integration, but the usual integration of differential forms over a compact manifold, in this case G)

With this inner product Q and c^i are not self-adjoint on $\mathcal H$. To get something self-adjoint, one can consider the operator $Q + Q^\dagger$ where $Q^\dagger$ is the adjoint of Q, but this operator does not have a definite ghost-number.

Comments

1. **MathPhys**
   November 15, 2008

   Peter,

   Can you make your BRST notes available as pdf files? That would make them easier to print.

2. **anon.**

November 16, 2008

MathPhys, use the free ‘Cute PDF’ print engine: http://www.cutepdf.com/Products/CutePDF/writer.asp

It installs as a printer, so you click print, choose Cute PDF as the printer, then it asks you where you want to save the PDF. I’ve just done it for this blog post, and it works perfectly (including all the mathematics).

anon.

I tried CutePDF and it was very useful. Thanks.

5. **Hendrik**
November 17, 2008

Dear Peter,
I know this is the physicist’s version, but as it seems so easy, let me point at some underlying technical difficulties, (mostly arising from the fact that the Lie algebra of the gauge group is infinite dimensional).

1) “The gauge group is an infinite dimensional Lie group. Locally (on space-time), it looks like a group of maps into a finite dimensional Lie group.”
Well, its topology is important, and there are actually quite a lot of choices (e.g. in terms of how much differentiability is needed). Usually it is given the k-Sobolev topology (w.r.t. a volume form on the base manifold M), but sometimes the smooth maps of compact support are taken too, or even Schwartz groups. It has an interesting structure;- see the thesis of Christoph Wockel on his website.

2) “Physicists always begin by choosing a basis, in this case a basis X_i of the Lie algebra g…”
Since the Lie algebra g of the gauge group G is infinite dimensional, the existence (and meaning) of a basis is not clear. If you mean that every element Y in the space has a unique expansion in terms of a convergent sum of multiples of the X_i (which is what your next expression suggests), then that means the set of X_i is a Schauder basis, and there are deep theorems in functional analysis stating that not every separable Banach space has a Schauder basis. So this is a point where the choice of topology on the gauge group G is important. In the case that you choose a Sobolev topology, then there are Schauder bases, but it is not clear that there are if you choose the smooth topology.

3) “….satisfying [X_i,X_j]=f_{ij}^kX_k, where f_{ij}^k are called the structure constants of g.”
If this is an infinite sum (over k), then a topology must be stated to get convergence of the series.

4) “A representation (\pi,V) is then a set of linear operators K_i=\pi (X_i) on V …..”
The type of representation appearing in physics, is where the K_i are unbounded operators on Hilbert spaces, and these cannot have full domains. There is always a dense invariant subspace of the Hilbert space (also in the domain of your observables).

5) “Let \alpha^i be a basis of the dual space g*, dual to the basis X_i.”
Here g* is a topological (not algebraic) dual I assume. As it is infinite dimensional, your assumption of a dual basis severely limits the type of space which g can be. It will work for Hilbert spaces, but very few other infinite dimensional topological spaces (if any).

6) “extend V to V \otimes \Lambda (g*)…”
Probably the space H below is the label for this. Topologies are not clear. I presume if g* is a Hilbert space, you will want \Lambda (g*) to be the antisymmetric Fock space, in which case you need to take completion of the space. Also, \otimes for (infinite dimensional) topological spaces involves choices (e.g. of cross-norm, if they are Banach spaces).

7) “..ghost number operator N=c^ib_i on H has eigenvectors the decomposable elements, with integer eigenvalues from 0 to dim(g),…”
The ghost number operator N=c^ib_i is written as an infinite sum;- convergence and basis dependence?

8) “BRST operator is given by Q = c^iK_i -(1/2)f_{ij}^kc^ic^jb_k”
Apart from the question on infinite sums (convergence?) in this expression, this is the formula of the BFV-BRST formalism which does not produce the right constrained theory (without ad-hoc adjustments), when you carry out your BRST prescription below the formula. The Q-operator which produces the correct one, is from the Kugo-Ojima approach where the field aspect has to be taken into account, and you have an integral over the space-time variables rather than a discrete sum.

9) “…uses the “fermionic” or “Berezin” integral”
How do you define a Berezin integral when you have infinitely many fermions? In the supersymmetric Taylor expansion, you need a “top term” which will not exist if there are infinitely many fermions.

10) “Killing form”….“Hodge operator”
Both of these are problematic in infinite dimensions.

Of course, most of these problems do not arise when the dimension of g is finite.

6. **Thomas Larsson**
November 17, 2008

Hendrik,

Perhaps we should refrain from rushing ahead. I am sure that Peter will eventually arrive at various problems associated with infinite dimensionality, but starting with the finite-dimensional case makes sense to me.

Having said that, I will rush ahead and emphasize that the type of infinities matter, already on the Lie algebra level. For Lie algebras that are linearly infinite-dimensional, i.e. possess a Z-grading by finite-dimensional vector spaces, and positive and negative degrees are isomorphic, things are not too bad; you just have to replace loop algebras by their central extensions, the affine Kac-Moody algebras. But for algebras of gauge transformations in d dimensions, you have a natural Z^d-grading rather than a Z-grading, and then things start to become interesting…

7. **Peter Woit**
November 17, 2008

Hendrik,

Thanks for the useful explanation of the many places where infinite-dimensionality can cause trouble. I should have made explicit that I'm just sticking to finite dimensions for now.

At Thomas mentions, for d=1 gauge groups there is some understanding of what to do, with the algebraic part of the story going under the name "semi-infinite cohomology", which I hope to get to at some point. For d larger than one, I'm not convinced that anyone knows what's even the right way to formulate the problem. One reason for investigating different approaches in finite dimensions is that they may suggest a more promising way to deal with the situation in higher dimensions.

8. **Hendrik**
November 19, 2008

Dear Peter and Thomas:
OK, if your lie algebra g and the representation spaces V (in your next BRST posting) are finite dimensional, then the functional analysis issues all disappear, and there is not much I can say. Then the theory at this point can only cover global gauge theories (though the observable algebra will still force your representation spaces to be infinite dimensional).

Point (8) above still remains, in that this approach will lead to multiple copies of the physical space, and give problems with positive definiteness when you add the usual inner products.

A last comment, is that the BRST-algorithm which you summarized for the constraint space is not yet complete, it also needs a (algebraic) part for the constrained observables. Is that coming later?

9. **Peter Woit**
November 20, 2008

Hendrik,

I'm not quite sure what you mean in your question. Part of the story is the Kostant-Sternberg formalism for BRST, where the Lie algebra cohomology idea is put together with a resolution of functions on the constrained surface, in a package using Clifford algebra techniques. I'll write about that, including about the problems with that. For the trivial case it doesn't work…

Another thing I plan to get to is work by various mathematicians about how "quantization and reduction commute" in certain contexts, and how to interpret this a la BRST. There are still some things about that though that I'm confused about.

10. **Hendrik**
November 21, 2008

Dear Peter,
To clarify;- the BRST algorithm, like any constraint enforcement algorithm, constructs not just the constrained representation space (V^g in your notation), it also gives a method for finding the constrained observables on V^g from the original given algebra of observables. In particular this piece of the BRST algorithm specifies the constrained observables through "operator cohomology" by

O_BRST := (Ker d)/(Ran d)

where d(A) is the supercommutatior of Q with A. It also shows how O_BRST is represented on the physical space V^g.

We found that this prescription produced an algebra O_BRST which is too large, i.e. it properly contains the physical algebra of a straightforward Dirac constraining.

I've also looked at the "quantization and reduction commute" papers, and look forward to see your take on those. As you know, there are huge problems with general quantization schemes;- there are always choices involved, and limitations of the algebras which can be quantized. Moreover, some quantum constraints (which can be generators of gauge groups) are purely quantum, i.e. with no classical counterpart, i.e. if you do a "classical limit" they become trivial.

11. **Maynard Handley**
November 30, 2008

Peter, for those of us who are not steeped in this subject, could you clarify a few points that you zip over (assuming that they are obvious):

First- At the start of your discussion, you refer to extending V to
V \tensor /\(g*) where /*(g*) …
Is there a typo here and you actually mean that you are extending V to
V \tensor /*(g*)
?
I could imagine some sort of weirdness that involves not just an exterior algebra of forms, but an exterior algebra of multi-vector valued forms, and that's what you mean by the notation, but it seems easier to assume a typo.

Second- when you get to discussing inner products, what do mean by the integral notation. You and commenters agree that, at this stage of the game we are discussing a finite-dimensional space (that presumably will become a fiber at some point). Presumably we are not (yet) discussing fields of forms and vectors. So what does this integral mean — is it simply meant to be some sort of notational convenience (but what convenience is it buying?)
Beyond that, there's still so much elided that I don't get.
– Is the second inequality in the Berezin inner product a result (this integral, defined however the hell it is defined, happens to equal this cofficient) or is it a definition?
– As for the second definition, should there not be another hodge dual outside the integral to convert the result from a (dim-g) form to a 0-form? Under normal (field) circumstances, the integral would take us from a dim-g form to a scalar, but in this context I've no idea what the integral means.
– Is there a good reason why, in both these integrals, we don't refer to the integrand as \omega_1 \wedge \omega_2 rather than the rather less obvious \omega_1 \omega_2. As far as I can tell in both cases (making allowance for the fact that I've no idea what the integral actually does) the result seems to be dependent on the omega1-omega2 ordering.

12. **Peter Woit**
December 1, 2008

Maynard,

Thanks for the questions. You're right about the typo, will fix.

The part about inner products was written in a very confusing way, I'll try and fix it a bit. One problem is that I was using the integral signs in two ways, one for the Berezin integral, the other for the fundamental class of the compact Lie group, i.e. the standard integral over differential forms. I'll rewrite this to make it clearer.

In the second, definite, way of defining the inner product, all sign problems can be buried in the definition of the Hodge dual. For the Berezin case, I don't have the signs straight, but that's not the inner product I want to use anyway.

13. **ramón**
February 13, 2009

    Can I get the pdf files on BRST cohomology?

14. **Peter Woit**
February 13, 2009

    ramon,

    There's a pdf file at

    http://www.math.columbia.edu/~woit/notesonbrst.pdf

    I'll be updating that with a new version soon.

Notes on BRST III: Lie Algebra Cohomology

November 16, 2008
Categories: BRST

The Invariants Functor

The last posting discussed one of the simplest incarnations of BRST cohomology, in a formalism familiar to physicists. This fits into a much more abstract mathematical context, and that's what we'll turn to now.

Given a Lie algebra $\mathfrak g$, we'll consider Lie algebra representations as modules over $U(\mathfrak g)$. Such modules form a category $\mathcal C_{\mathfrak g}$: what is interesting is not just the objects of the category (the equivalence classes of modules), but also the morphisms between the objects. For two representations V_1 and V_2 the set of morphisms between them is a linear space denoted $Hom_{U(\mathfrak g)}(V_1,V_2)$. This is just the set of linear maps from V_1 to V_2 that commute with the action of $\mathfrak g$:

$$Hom_{U(\mathfrak g)}(V_1,V_2)=\{\phi\in Hom_{\mathbf C}(V_1,V_2): \pi(X)\phi=\phi\pi(X)\ \forall X\in \mathfrak g\}$$

Another conventional name for this is the space of intertwining operators between the two representations.

For any representation V, its $\mathfrak g$-invariant subspace $V^{\mathfrak g}$ can be identified with the space $Hom_{U(\mathfrak g)}(\mathbf C, V)$, where here $\mathbf C$ is the trivial one-dimensional representation. Having a way to pick out the invariant piece of a representation also allows one to solve the more general problem of picking out the subspace that transforms like a specific irreducible W: just find the invariant subspace of $V\otimes W^*$.

The map $V\rightarrow V^{\mathfrak g}$ that takes a representation to its $\mathfrak g$-invariant subspace is a functor: it takes the category $\mathcal C_{\mathfrak g}$ to $\mathcal C_{\mathbf C}$, the category of vector spaces and linear maps ($\mathbf C$ – modules and $\mathbf C$ – homomorphisms). If, instead of taking

$$V\rightarrow V^{\mathfrak g}$$

one takes

$$V\rightarrow V^{\mathfrak h}$$

where \mathfrak h is a Lie subalgebra of \mathfrak g, one again gets a functor. If \mathfrak h is an ideal in \mathfrak g (so that \mathfrak g/\mathfrak h is a Lie algebra), then this functor takes \mathcal C_{\mathfrak g} to \mathcal C_{\mathfrak g/\mathfrak h}. This is a simple version of the situation of interest in the case of gauge theory: if V is a state space with \mathfrak h acting as a gauge symmetry, then V^{\mathfrak h} will be the physical subspace, carrying an action of the algebra of operators U(\mathfrak g/\mathfrak h).

Some Homological Algebra

It turns out that when one has a category of modules like \mathcal C_{\mathfrak g}, these can usefully be studied by considering complexes of modules, and this is the subject of homological algebra. A complex of modules is a sequence of modules and homomorphisms

$$\cdots\stackrel{\partial}\longrightarrow U\stackrel{\partial}\longrightarrow V \stackrel{\partial}\longrightarrow W\stackrel{\partial}\longrightarrow\cdots$$

such that \partial\circ\partial =0. If the complex satisfies im\ \partial=ker\ \partial at each module, the complex is said to be an "exact complex".

To motivate the notion of exact complex, note that

$$0\longrightarrow V_0\longrightarrow V \longrightarrow 0$$

is exact iff V_0 is isomorphic to V, and an exact sequence

$$0\longrightarrow V_1 \longrightarrow V_0 \longrightarrow V \longrightarrow 0$$

represents the module V as the quotient V_0/V_1. Using longer complexes, one gets the notion of a *resolution* of a module V by a sequence of n modules V_i. This is an exact complex

$$0\longrightarrow V_n \longrightarrow\cdots\longrightarrow V_1 \longrightarrow V_0\longrightarrow V\longrightarrow 0$$

The deviation of a sequence from being exact is measured by its *homology* $H^*=\frac{ker\ \partial}{im\ \partial}$. Note that if one deletes V from its resolution, the sequence

$$0\longrightarrow V_n \longrightarrow\cdots\longrightarrow V_1 \longrightarrow V_0\longrightarrow 0$$

is exact except at V_0. Indexing the homology in the obvious way, one has H^i =0 for i>0, and H^0=V. A sequence like this whose only homology is V at H^0 is another manifestation of a resolution of V.

The reason this construction is useful is that, for many purposes, it allows us to replace a module whose structure we may not understand by a sequence of modules whose structure we do understand. In particular, we can replace a U(\mathfrak g) module V by a sequence of free modules, i.e. modules that are just sums of copies of U(\mathfrak g) itself. This is called a free resolution, and more generally one can work with projective modules (direct summands of free modules).

A functor that takes exact complexes to exact complexes is called an exact functor. Homological invariants of modules come about in cases where one has a functor on a category of modules that is not exact. Applying such a functor to a free or projective resolution gives the homological invariants.

The Koszul Resolution and Lie Algebra Cohomology

There are many possible choices of a free resolution of a module. For the case of U(\mathfrak g) modules, one convenient choice is known as the Koszul (or Chevalley-Eilenberg) resolution. To construct a resolution of the trivial module \mathbf C, one uses the exterior algebra on \mathfrak g to make free modules

$$Y_k=U(\mathfrak g)\otimes_{\mathbf C}\Lambda^k(\mathfrak g)$$

and get a resolution of \mathbf C

$$0\longrightarrow Y_{dim\ \mathfrak g}\stackrel{\partial_{dim\ \mathfrak g -1}}\longrightarrow\cdots\stackrel{\partial_1}\longrightarrow

Y_1\stackrel{\partial_0}\longrightarrow Y_0\stackrel{\epsilon}\longrightarrow \mathbf C\longrightarrow 0$$

The maps are given by
$$\epsilon : u\in Y_0=U(\mathfrak g) \rightarrow \epsilon (u) = const.\ term\ of\ u$$

and
$$\partial_{k-1} (u\otimes X_1\wedge\cdots\wedge X_k)=$$
$$\sum_{i=1}^k(-1)^{i+1}(uX_i\otimes X_1\wedge\cdots\wedge\hat X_i\wedge\cdots \wedge X_k)$$
$$+\sum_{i<j} (-1)^{i+j}(u\otimes\wedge X_1\wedge\cdots\wedge \hat X_i\wedge\cdots\wedge \hat X_j\wedge\cdots\wedge X_k)$$

To get Lie algebra cohomology, we apply the invariants functor

$$V\longrightarrow V^{\mathfrak g}=Hom_{U(\mathfrak g)}(\mathbf C, V)$$

replacing the trivial representation by its Koszul resolution. This gives us a complex with terms

$$C^k(\mathfrak g, V)=Hom_{U(\mathfrak g)}(Y_k,V)= Hom_{U(\mathfrak g)}(U(\mathfrak g)\otimes \Lambda^k(\mathfrak g),V)$$
$$=Hom_{U(\mathfrak g)}(U(\mathfrak g),Hom_{\mathbf C}(\Lambda^k(\mathfrak g),V))$$
$$=Hom_{\mathbf C}(\Lambda^k(\mathfrak g),V) =V\otimes\Lambda^k(\mathfrak g^*)$$

and induced maps d_i

$$0\longrightarrow C^0(\mathfrak g, V)\stackrel{d_0}\longrightarrow C^1(\mathfrak g, V)\cdots\stackrel{d_{dim\ \mathfrak g -1}}\longrightarrow C^{dim\ \mathfrak g}(\mathfrak g, V)\longrightarrow 0$$

The Lie algebra cohomology $H^*(\mathfrak g, V)$ is just the cohomology of this complex, i.e.

$$H^i(\mathfrak g, V)=\frac{ker\ d_i}{im\ d_{i-1}}|_{C^i(\mathfrak g, V)}$$

This is exactly the same definition as that of the BRST cohomology defined in physicist's formalism in the last posting with $\mathcal H =C^*(\mathfrak g, V)$.

One has $H^0(\mathfrak g, V)=V^{\mathfrak g}$ and so gets the $\mathfrak g$-invariants as expected, but in general the cohomology will be non-zero also in other degrees.

This is all rather abstract, so in the next posting some examples will be worked out, as well as the relationship of all this to the de Rham cohomology of the group. Anthony Knapp's book Lie Groups, Lie Algebras, and Cohomology is an excellent reference for details on Lie algebra cohomology.

Comments

1. **Serifo**
   November 16, 2008

   Hi professor Peter , I think you forgot to index the homomorphisms of the complex in your first definition of complex . It may be convenient also , to specify over which ring R is the complex defined.

2. **Serifo**
   November 17, 2008

   Ok, you are considering the complex to be defined over the ring of complex numbers C (which is a field). Would it be relevant to your research if you consider complexes defined over another type of rings, for example the ring Z of integers ?

3. **Peter Woit**
   November 17, 2008

   Serifo,

   I'm trying to avoid over-generality here, just using what I need, and trying to get the basic ideas across. So, unless otherwise specified, everything is defined over C.

   I'm also trying to avoid explicitly dealing with some points that would require adding a lot of details that aren't so relevant, until the point at which they become relevant. An example would be the indexing question.

   In general, if someone hasn't seen any of this before, I hope they'll use what I write to get a general idea of what is going on, then go to a textbook like Knapp to see the details, and to see more general versions of the story.

4. **a.k.**
   November 19, 2008

   ..sorry if I am posing a stupid question, but: the above cohomology groups should be expressable as some sort of Ext-groups, that is as appropriate n-fold extensions of V by C, that is, they should be more or less the same as (an equivariant version of) Ext*(C,V), where C are the complex numbers. Is this true and if yes, is there a physical meaning of this correspondance?

5. **woit**
   November 19, 2008

   a.k.

   What I gave was basically the definition of Lie algebra cohomology as
   [tex]Ext_{U(\mathfrak g)}(\mathbf C, V)[/tex]

   This is an Ext for modules over a non-commutative algebra, I don't know of any physical meaning for such objects, curious if anyone else does…

The Complete Idiot's Guide to String Theory

November 17, 2008
Categories: Book Reviews, This Week's Hype

I recently acquired a copy of The Complete Idiot's Guide to String Theory, by Scientific American's George Musser, which has been out for a few months now. It's a popular-level treatment of modern physics, string theory and quantum gravity, much like many other such books, but now in the "Complete Idiot's" style of lots of cartoons, graphics, material set off in boxes, and short summaries of chapters. As such, I guess it does as good a job as any of putting this material in a form designed to sell it to as many people as possible.

Musser is an enthusiast for just about any and every speculative idea about space and time. Besides string theory, the book covers loop quantum gravity, causal dynamical triangulations, the idea that spacetime is a fluid or a giant computer, and even some ideas I'd never heard of (we live in 3 dimensions because "For the simplest particle, we can make three mutually exclusive measurements"????). The treatment is often breathless, continually going on about how "exciting" all this is. In many ways, the book reads like advertising copy, hyping the promise of ideas (with string theory getting the bulk of the attention) while mostly ignoring or minimizing their problems. For example, the chapter on symmetry contains more than two pages on the "Pros and Cons" of supersymmetry, but this turns out to be just about all "pros" until a short paragraph at the end that begins: "That said, supersymmetry raises some questions that physicists have yet to solve".

I think I'm tempermentally allergic to this sort of discussion of science, but can see that some people like it and I realize there are arguments in its favor (get those kids and taxpayers excited about science!). Within the limits of such a genre, much of the book does a reasonable job, until the later chapters, where it starts to go off the rails.

There's a chapter on "parallel universes" which promotes the anthropic multiverse, describing it as "the most promising scientifically" of all possible options. Despite the fact that many string theorists are extremely unhappy with seeing this kind of thing promoted as the received wisdom of their field, Musser claims that:

> String theorists originally expected everything to be hard-wired but now think that almost everything is accidental

The scientific advisor for the book was Keith Dienes of the String Vacuum Project, and the list of those most prominently thanked for their help is dominated by landscape proponents Dienes, Bousso, Carroll and Tegmark.

A late chapter entitled "Ten Ways to Test String Theory" goes beyond the overly enthusiastic into the realm of the misleading and the simply untrue. According to Musser, the LHC will test string theory, GLAST will test string theory, Auger will test string theory, Planck will test string theory, LIGO will test string theory, a successor to Super-Kamiokande will test string theory, all the various dark-matter experiments will test string theory, table-top measurements of Newton's law will test string theory, bouncing laser beams off the moon will test string theory, checking midget galaxies to see if their stars have planets will test string theory, and looking for variation of fundamental constants will test string theory. This is really egregious nonsense.

The next to last chapter is about "The String Wars", and I appear prominently as "the most persistent and forceful critic of string theory", paired with Lubos Motl for my "over-the-top" comments. One of the few explicit factual errors in Musser's book is the claim that my book grew out of this blog (the book was written earlier, but took a long time to get published). The chapter is quite a bit less than even-handed in its discussion of these "wars", and mainly devoted to shooting down the supposed arguments of critics of string theory. I come in for criticism as endlessly putting forward a "silly deadline" of less than twenty years for string theory to have succeeded in reaching its goals. This straw man argument is conclusively bested, while ignoring the real argument, which is that the huge investment in time and effort put into string theory research has just produced more and more evidence that string theory-based unification is an idea that doesn't work. The problem is not the magnitude of the rate of progress towards understanding unification, it's the sign. And, soon I can start going on about 25 years….

Comments

1. **Kea**
   November 17, 2008

   Oh, but you are familiar with mutually unbiased bases – for spin they correspond to the x, y and z directions. As operators they are the Pauli operators. In the modern bootstrap, these correspond to the three indices of the next higher MUB set, corresponding to mass. Very popular in Quantum Foundations these days. In fact, I just got a postdoc to study them.

2. **Roland**
   November 17, 2008

   How can a book with a chapter full of egregious nonsense contain only few explicit factual errors?

3. **tomate**
   November 17, 2008

   It has no errors: being a theory of everything, every experiments tests it, including Millikan, Michelson-Morley, etc.

4. **Marion Delgado**
   November 17, 2008

   It was that enthusiasm "for just about any and every speculative idea about space and time" that made me sour on the physics lectures and presentations I used to go to that were cutting edge string-theoretic.

   Tachyons, in particular. Nonetheless, I'll read the book.

5. **Gazouille**
   November 17, 2008

   Roland,
   I think it might be that nonsense can't [even] be wrong…

6. **Will**
   November 17, 2008

   I dont know what good it does to comment about a naive book.

7. **Peter Woit**
November 17, 2008

Will,

Actually I don't think it's a naive book. It reflects accurately the views of one segment of the theoretical physics community, that which thinks the multiverse is science, string theory is the way to get unification, and hyping this kind of research to the public is a good idea.

8. **Low Math, Meekly Interacting**
November 17, 2008

It took a while before I figured out that such treatments of relatively speculative ideas about high-energy/unification physics were skewed. In fact, it was in the process of trying to figure out just how skewed that I came across this blog.

That said, one of the best physics popularizations, in part, that I've read was "The Fabric of the Cosmos" by Brian Greene. Not because (any more) of the stringy content, but the great attention paid to the established stuff. The discussion of Bell's Inequalities in the notes was for me both demanding but very approachable and rewarding for the effort, and one of the best attempts at giving the layperson a reasonably rigorous understanding of what hidden variables are all about that I've encountered. In that regard, portions of that book seemed very much in the spirit of what is now my hands-down favorite popularization of science of any discipline, namely "QED: The Strange Theory of Light and Matter".

If you ask me, that must be the best "For Dummies" book ever written. I really wish someone would take Feynman's approach, modernize it a bit to reflect the current state of established particle physics and QFT, couple it with an equally clever and illuminating treatment of GR, and, well, actually be able to sell it as is. I fear that the only way to get something like that published is to make it an introduction to whatever TOS the author specializes in. It's too bad, because there are loads of people out there who really think they know something about quantum gravity, but have only the vaguest notion of what the modern, tested, firmly-established theories of quantum and gravity are really all about. They'll talk compactifications and Calabi-Yau manifolds with an air of completely unwarranted authority, but haven't a clue what a tensor or a Hamiltonian are.

Hell, I was one of those people. And that's a problem. I'm gaining a better appreciation of how ignorant I am with each passing day, but I fear these books, in their often well-meaning enthusiasm for the wonders of the frontiers of science, tend to (unintentionally, I hope) give people an utterly false sense of confidence about their true level of understanding. I never got that feeling with QED, because of Feynman's grounded introduction. I don't think the speculative stuff is all about profit, necessarily. I just wish there were more QED's out there, and that publishers and/or the public at large got excited about them. Maybe they don't because real understanding is too much work, and a real appreciation for one's lack of understanding isn't the American Way.

9. **Visitor**
November 17, 2008

". . . . real understanding is too much work, and a real appreciation for one's lack of understanding isn't the American Way."

If you are aware of any country in which an equivalent statement is not true, please enlighten me, so that I can seriously research the feasibility of going there to live.

10. **Low Math, Meekly Interacting**
November 17, 2008

It's the only book market I'm really familiar with. Sorry.

11. **Chris W.**
November 17, 2008

So, Visitor, are you saying Americans no longer have a monopoly on cocksure, smug ignorance? Maybe we've succeeded in exporting that, along with our sophisticated grasp of modern finance. 🙂

12. **csrster**
November 18, 2008

This is the complete idiot's guide to string theory:
http://abstrusegoose.com/78

13. **anon.**
November 18, 2008

Peter, I wonder if you have seen another popular book (on a less speculative topic than string theory), 'Quantum Field Theory Demystified', by David McMahon which was published in February by McGraw-Hill, http://www.amazon.com/Quantum-Field-Theory-Demystified-McMahon/dp/0071543821

It has some bad reviews for making mathematical errors, but I like the idea of popularizing this stuff. I'd appreciate any comments you have on that book, if you've read it.

14. **Peter Woit**
November 18, 2008

anon,

I took a look at the McMahon book once in a store. It's not at all a popular book, but a real textbook, one that tries to boil down some difficult material to help a serious student starting out in the subject. It might be a good place for some people to begin learning the subject.

The same author also has a similar book on string theory, which I also looked at, but I think that's less successful. The material is just so complex that trying to get it into a low-level, accessible form is not going to work out as well.

November 18, 2008

I realized upon re-reading that I typed "TOS" instead of "TOE". S and E are adjacent on the keyboard, and I'm a sloppy typist. It occurred to me one could potentially read into that typo some scatological hidden meaning, which was not at all my intent. Freudians, make of it what you will.

16. **Coin**

November 18, 2008

One of the few explicit factual errors in Musser's book is the claim that my book grew out of this blog (the book was written earlier, but took a long time to get published).

Huh. When was the book written in relation to that "String Theory: An Evaluation" article?

17. **woit**
    November 18, 2008

    Coin, my book was mostly written in 2002, after the 2001 article, before the 2004 start of the blog

18. **anon.**
    November 19, 2008

    Thank you Peter, I've just bought the McMahon QFT book, and it does look useful.

19. **Andrew**
    January 29, 2009

    Hi Peter,

    Do you have anything to say about John Moffat's new book "Reinventing Gravity"?

Science and Science Fiction

November 18, 2008
Categories: Multiverse Mania

I just set my DVR to record this evening's broadcast on the History Channel of Parallel Universes, and noticed that the summary information about the show reads:

> Some of the world's leading physicists believe they have found evidence proving the existence of parallel universes.

One participant in the program is Clifford Johnson, who writes on his blog about how he's gotten a bad feeling about the project after seeing a rough cut:

> I'm a bit worried, if I'm honest, since this is a topic that is so easily seized upon by nutcases and sensible people alike, and is, in various forms, the fodder of so much charlatanism and mystical mumbo-jumbo. Any program in a science series on this sort of material has to be doubly careful -triply- to not give people an excuse to say that "the scientists have verified this".
>
> Why am I slightly worried? Well, I did not see a final cut of the show and so don't want to go over the top here, but an early rough cut I saw did seem to potentially suffer from a problem these shows can sometimes have: A collection of practicing scientists are very carefully making comments about what is known, unknown, likely, and unlikely, and so forth, and then much of that care can be undermined by the interspersing of their remarks with clips of every physics documentary filmmaker's favourite go-to guy who can be relied upon to say wild and wonderful things – Michio Kaku…
>
> I also did notice in the rough cut that there were a couple of places where I'd have preferred a bit more of a reminder that string theory (a framework where some of these speculative ideas about parallel universes has recently been re-discussed in scientific -but yes, still speculative- circles) is itself an unestablished and under-developed theory that could well be cast aside one day in favour of something else. I stressed this point in the course of our shooting, but don't know how much this got through.

One odd thing about this TV show is that it has already been done, in our universe, with the same name, featuring Michio Kaku, by the BBC back in 2001:

> Everything you're about to read here seems impossible and insane, beyond science fiction. Yet it's all true.
>
> Scientists now believe there may really be a parallel universe – in fact, there may be an infinite number of parallel universes, and we just happen to live in one of them. These other universes contain space, time and strange forms of exotic matter. Some of them may even contain you, in a slightly different form. Astonishingly, scientists believe that these parallel universes exist less than one millimetre away from us….
>
> For years parallel universes were a staple of the Twilight Zone. Science fiction writers loved to speculate on the possible other universes which might exist. In one, they said, Elvis Presley might still be alive or in another the British Empire might still be going strong. Serious scientists dismissed all this speculation as absurd. But now it seems the speculation wasn't absurd enough. Parallel universes really do exist and they are much stranger than even the science fiction writers dared to imagine.
>
> It all started when superstring theory, hyperspace and dark matter made physicists realise that the three dimensions we thought described the Universe weren't enough. There are actually 11 dimensions. By the time they had finished they'd come to the conclusion that our Universe is just one bubble among an infinite number of membranous bubbles which ripple as they wobble through the eleventh dimension.

In his posting, Clifford asks sensible questions about what scientists can do to keep science fiction from taking over science programs. I've heard that one mediagenic physicist who was offered a role in this program told them he would only participate if given the right to veto any segment involving him that misrepresented his views. He's not in the program.

From the opposite end of the science/science-fiction issue, tomorrow in LA there will be an event to launch a new project called The Science and Entertainment Exchange. This is a program (directed by Jennifer Ouellette, who blogs about it here), aimed at improving the portrayal of science by the entertainment industry. There seems to be an increasing amount of media-interest in science-related story lines, and the goal of translating this into getting some higher-quality science out before the public is a worthy one.

One goal of this organization I guess will be to improve the science in science-fiction programs. Since, at least as far as fundamental physics goes, the battle to keep science-fiction out of science appears to have been lost, maybe there should also be an effort to improve the quality and accessibility of the fiction now spreading throughout the physics literature. Some organization could get together creative artists and other media professionals to work on this, helping out programs like "Parallel Universes" as well as popular science books and journal articles. One can't deny that, at the moment, all of these are pretty sophomoric as creative art, as well as typically not very successful at reaching a mass audience.

There's a lot of room for advice from visual artists about more appealing string theory vacua for use in particle physics and string cosmology. Surely a good novelist or playwright could come up with a better pre-big bang story line than "colliding branes". As physics journals like Nuclear Physics B fill up with articles on Boltzmann Brains and the multiverse, with some help from the entertainment industry they could be marketed to a much wider audience, bringing down their cost to university libraries. A lot could be done on the marketing front: for instance it might be a good idea to include some 420 with each issue to help ensure that "mind-blowing" ideas don't just bore people, but really do blow the mind of the target audience. The possibilities really are limitless…

Update: Just finished watching "Parallel Universes". Wow. Almost completely free of any real scientific content, and definitely deserves an award as the most idiotic and ludicrous TV show ever made that pretends to have something to do with science. Deep into "what the bleep" territory. The problem is not just Michio Kaku. Everyone involved in the thing should be deeply ashamed of themselves.

Comments

1. **Chris Leonard**
   November 18, 2008

   Peter – what does this mean?

   for instance it might be a good idea to include some 420 with each issue

2. **Peter Woit**
   November 18, 2008

   Chris,

It means that this nonsense about "Parallel Universes" is making me get rather silly and vindicate those who describe this blog as sometimes "over the top". If you're unaware of what "420" is, you could try Google…

3. **Chris Leonard**
   November 18, 2008

   Right – gotcha now. I agree in that case!

4. **IGPNicki**
   November 20, 2008

   I've just been posting on another forum about how I feel strongly that while yes, I would appreciate better science in science fiction, I feel strongly that since the words "science" and "fiction" share equal billing, it shouldn't be a prerequisite for enjoying a show. However, have to totally agree that we need to keep scince science and not science fiction. I definitely see this trend for science lite (the spelling was on purpose). And not just science either. There's very little on the history channel which actually pertains to history. Pretty scary!

Notes on BRST IV: Lie Algebra Cohomology for Semi-simple Lie Algebras

November 18, 2008
Categories: BRST

In this posting I'll work out some examples of Lie algebra cohomology, still for finite dimensional Lie algebras and representations.

If G is a compact, connected Lie group, it can be thought of as a compact manifold, and as such one can define its de Rham cohomology $H^*_{deRham}(G)$ as the cohomology of the complex

$$0\longrightarrow \Omega^0(G)\stackrel{d}\longrightarrow \Omega^1(G)\stackrel{d}\longrightarrow\cdots\stackrel{d}\longrightarrow\Omega^{dim\ G}(G)\longrightarrow 0$$

where $\Omega^i(G)$ are the differential i-forms on G (note, we'll use complex-valued forms), and d is the deRham differential.

For a compact group, one has a bi-invariant Haar measure $\int_G$, and can use this to "average" over an action of the group on a space. For a representation (π, V), we get a projection operator $\int_g \Pi (g)$ onto the invariant subspace V^G. This projection operator gives explicitly the invariants functor on $\mathcal C_{\mathfrak g}$. It is an exact functor, taking exact sequences to exact sequences.

The differential forms $\Omega^*(G)$ give a representation of G in two ways, taking the induced action on forms by pullback, using either left or right translation on the group. If $(\Pi(g), \Omega^*(G))$ is the representation by left translations, we can use this to apply our "averaging over G" projection operator to the de Rham complex. This action commutes with the de Rham differential, so we get a sub-complex of left-invariant forms

$$0\longrightarrow \Omega^0(G)^G\stackrel{d}\longrightarrow \Omega^1(G)^G\stackrel{d}\longrightarrow\cdots\stackrel{d}\longrightarrow\Omega^{dim\ G}(G)^G\longrightarrow 0$$

Since elements of the Lie algebra $\mathfrak g$ are precisely left-invariant 1-forms, it turns out that this complex is nothing but the Chevalley-Eilenberg complex considered last time to represent Lie algebra cohomology, for the case of the trivial representation. This means we have $C^*(\mathfrak g, \mathbf R)= \Lambda^*(\mathfrak g^*)=\Omega^*(G)^G$, and the differentials coincide. So, what we have shown is that

$$H^*(\mathfrak g, \mathbf C)= H^*_{de Rham}(G)$$

If one knows the cohomology of G, the Lie algebra cohomology is thus known, but this identity is normally used in the other direction, to find the cohomology of G from that of the Lie algebra. To compute the Lie-algebra cohomology, we can exploit the right-action of G on the group, averaging over the induced action on the left-invariant forms $\Lambda^*(\mathfrak g)$, which again commutes with the differential. We end up with a complex
$$0\longrightarrow (\Lambda^0(\mathfrak g^*))^G \longrightarrow (\Lambda^1(\mathfrak g^*))^G\longrightarrow\cdots\longrightarrow (\Lambda^{\dim\ \mathfrak g}(\mathfrak g^*))^G\longrightarrow 0$$

where all the differentials are zero, so the cohomology is given by

$$H^*(\mathfrak g,\mathbf C)=(\Lambda^*(\mathfrak g^*))^G=(\Lambda^*(\mathfrak g^*))^{\mathfrak g}$$

the adjoint-invariant pieces of the exterior algebra on $\mathfrak g^*$. Finding the cohomology has now been turned into a purely algebraic problem in invariant theory. For $G=U(1)$, $\mathfrak g=\mathbf R$, and we have shown that $H^*(\mathbf R, \mathbf C)=\Lambda^*(\mathbf C)$, this is $\mathbf C$ in degrees 0, and 1, as expected for the de Rham cohomology of the circle $U(1)=S^1$. For $G=U(1)^n$, we get

$$H^*(\mathbf R^n, \mathbf C)=\Lambda^*(\mathbf C^n)$$

Note that complexifying the Lie algebra and working with $\mathfrak g_{\mathbf C}=\mathfrak g\otimes \mathbf C$ commutes with taking cohomology, so we get

$$H^*(\mathfrak g_{\mathbf C},\mathbf C)= H^*(\mathfrak g,\mathbf C)\otimes \mathbf C$$

Complexifying the Lie algebra of a compact semi-simple Lie group gives a complex semi-simple Lie algebra, and we have now computed the cohomology of these as

$$H^*(\mathfrak g_{\mathbf C}, \mathbf C) = (\Lambda^*(\mathfrak g_{\mathbf C}))^{\mathfrak g_\mathbf C}$$

Besides H^0, one always gets a non-trivial H^3, since one can use the Killing form $< \cdot,\cdot>$ to produce an adjoint-invariant 3-form $\omega_3(X_1,X_2,X_3)=$. For $G=SU(n)$, $\mathfrak g_{\mathbf C}=\mathfrak{sl}(n,\mathbf C})$, and one gets non-trivial cohomology classes ω_{2i+1} for $i=1,2,\cdots n$, such that

$$H^*(\mathfrak{sl}(n,\mathbf C))=\Lambda^*(\omega_3, \omega_5,\cdots,\omega_{2n+1})$$

the exterior algebra generated by the ω_{2i+1}.

To compute Lie algebra cohomology $H^*(\mathfrak g, V)$ with coefficients in a representation V, we can go through the same procedure as above, starting with differential forms on G taking values in V, or we can just use exactness of the averaging functor that takes V to V^G. Either way, we end up with the result

$$H^*(\mathfrak g, V)=H^*(\mathfrak g, \mathbf C)\otimes V^{\mathfrak g}$$

The H^0 piece of this is just the $V^{\mathfrak g}$ that we want when we are doing BRST, but we also get quite a bit else: $dim\ V^{\mathfrak g}$ copies of the higher degree pieces of the Lie algebra cohomology $H^*(\mathfrak g, \mathbf C)$. The Lie algebra cohomology here is quite non-trivial, but doesn't interact in a non-trivial way with the process of identifying the invariants $V^{\mathfrak g}$ in V.

In the next posting I'll turn to an example where Lie algebra cohomology interacts in a much more interesting way with the representation theory, this will be the highest-weight theory of representations, in a cohomological interpretation first studied by Bott and Kostant.

Comments

1. **Anon**
   November 20, 2008

   I'm a bit confused by the step where the De Rham complex of differential forms on the group G is found to have the same cohomology as the complex of left-invariant differential forms. Did I miss the step where this was explained above?

2. **Peter Woit**
November 20, 2008

Anon,

I guess maybe I'm skipping some steps there…

The argument is that:

1. Because the averaging functor is exact, the cohomology of the complex with terms [tex]\Omega^*(G)^G$[/tex] is [tex]H^*(G)^G[/tex]

2. But [tex]H^*(G)[/tex] is [tex]G[/tex]-invariant, since it is homotopy-invariant, and [tex]G[/tex] is connected.

Shouldn't Something Be Done?

November 19, 2008
Categories: Multiverse Mania

The sheer awfulness of last night's History Channel program on physics is hard to exaggerate. Here's some of what Clifford Johnson (one of the participants in the program) wrote on his blog while watching it:

> Oh, right… I remember "there are dinosaurs in your living room" thing. Oh dear. It is coming on in 8 minutes here, and so I guess I'll pour myself a long single malt and prepare myself. I've still got faith in Andy, though…
>
> Got to first commercial break. Er… need more whiskey. There's some good science embedded in there somewhere (e.g., Tegmark talking about inflation, and WMAP results and flatness and so forth (but the laser beams!?)), but the voice-over (among others) is taking serious liberties (like claiming right at the beginning of the show that scientists have evidence that there may be parallel universes…sigh. No, No, No, No. That was really not necessary.)…
>
> Need. More. Whiskey*.
>
> Ok… That's it. I had a lot of fun shooting my stuff for this, and while I know that it is maybe really not polite to say this, and I really like Andy and the crew who put this together…but I can't really defend this. They really really should have sent this out in time for us contributors to comment on. By time I saw the rough cut and sent in suggestions it was too late… I presume other sensible people contributing to this such as Ovrut, Lykken, etc, would have liked to have seen a rough cut of this and made remarks. It is really clear that the VO and script was written without a very good understanding of some of the basic concepts in place, and certainly not a careful regard for what's accurate and what is blatantly misleading. Anyone watching this would think that string theory or M-theory is experimentally verified and a working tool used to study the early universe… I spilled my whiskey when they showed pictures of people working in (what looked like optics) laboratories while talking about "years of research into string theory…".
>
> I have never ever heard of this "level x" business. I don't know who says that. But what was with the laser beams?! Where did that come from? Not the burning a hole in the fabric of spacetime and escaping a dying universe to go to another (WHAT?!), but the shooting them out from WMAP in order to measure the flatness of the universe. What was that?! And did you see the red struts between the blue branes that were supposed to be the "extra dimensions holding the branes in place"? What was that?!
>
> This is all so sad because there's so much, as we say above, good TV that could be made of this material if done right.
>
> Ok. I'm done with this. It's very sad.

One would like to just ignore something like this and let it fade into obscurity, but the problem is that the History Channel is likely to keep rebroadcasting it for years and years, doing continuing damage to the public understanding of science and the public image of physicists. I don't really see how an intelligent person can watch this thing and not come away with the impression that theoretical physicists are a bunch of idiots. It seems to me that it would be a good idea for people in general, and the scientists involved in this in particular (Clifford Johnson, Max Tegmark, Michio Kaku, Joe Lykken and Alex Filippenko) to contact the History Channel with a polite request that this program not be rebroadcast, and that steps be taken to avoid creating more disasters of the same kind.

Update: Chad Orzel also saw the program and has some comments about it one of its dumber aspects, beginning with:

> Yeesh. That was so actively irritating that I don't know where to start.

Comments

1. **Academic Lurker**
   November 19, 2008

   It seems like scientists (or, more specifically, physicists, since this seems to happen to them in particular) are in a bit of a bind here.

   It's one thing to avoid charlatans like the makers of "What the Bleep…", but this was a documentary for the History Channel. Folks like Clifford Johnson & co. had every reason to think that this would be a respectable production. And from your post below:

   "I've heard that one mediagenic physicist who was offered a role in this program told them he would only participate if given the right to veto any segment involving him that misrepresented his views. He's not in the program."

   it's clear that scientists are allowed little influence on the production once they've given their interviews. Is the only option to just avoid involvement in these projects?

   It seems like that would be doubly unfortunate because a) public outreach & getting people excited about what physicists do is good, and b) it leaves the stage to folks like Kaku.

   I'm not sure what the answer is.

2. **Low Math, Meekly Interacting**
   November 19, 2008

   I agree, it's a pickle. Over on CV they're talking about improved outreach and media representation, but the main paradox, I think, is that it's extremely difficult to make accuracy/edification entertaining to the general public, and producers of such programs are in the business of entertaining and making lots of money, not providing a public service that there's no demand for. It's a problem all school teachers struggle with on a daily basis: How do keep the average student interested, and actually give them a high-quality education? On the one hand, it's vitally important that scientists remain engaged, but on the other, they lose control over the message as soon as it leaves their mouths. As Lurkee notes, when the interviewees make unentertaining demands, the producers simply move on to someone with fewer scruples. How do you win?

3. **Bee**
   November 19, 2008

   I recently learned that Discovery Channel will be airing some of PI's public lectures. I generally think it is a better idea if movie guys help scientists to get a message across than if they ask scientists for help to get their own message across.

4. **milkshake**
November 19, 2008

I remember watching a PBS-NOVA program few years back, about Andrew Willes, Galois representations and Fermat's last theorem, and I thought it was entertaining enough for the lay audience – and it even provided some taste of a life spent working on an esoteric problem. The documentary had some annoying parts (repeated annoying song and animations) but given the dry subject they did a decent job popularizing the historic background and the story of the proof itself.

So its not like "it's extremely difficult to make accuracy/edification entertaining to the general public" if one actually cares about the subject he is trying to popularize.

5. **Peter Woit**
November 19, 2008

I think physicists should continue to get involved with media projects, even ones like this. But, at the same time they need to be wary about what they have gotten themselves into and behave accordingly. In this particular case, the topic should have set off a lot of red flags.

Once the damage is done, in egregious cases like this one, I think it really is the responsibility of those who participated, and of the physics community to at least try and do something about this. If the only complaining is a bit of grumbling on blogs, it will keep happening.

6. **Low Math, Meekly Interacting**
November 19, 2008

Hi, Milkshake,

I don't doubt you were entertained, but you may have more discerning tastes than the average viewer, for lack of a better way of putting it. Public Television is not immune to the need for ratings, but they don't have the same business model as a commercial cable channel like Discovery or History, and likely cater to broadly different audiences. I'd frankly be shocked if the numbers and demographics of the eyeballs either network grabs bore much similarity, and I'd be flabbergasted if PBS' market was more representative of the general viewing public than DC's or HC's.

All this said, protests, both formal and informal, do make a difference. I'm reminded of the outcry generated by "The Great Global Warming Swindle". Granted, that execrable excuse for a documentary was motivated more to influence policy than to simply earn advertising revenues, but it used the same sorts of distorting tricks to hook the audience, it sounds like.

So, yeah, I agree, speak up loudly, for what it's worth. I doubt it will solve the overall problem, though. Just dampen this particular fire, which is a worthy enough goal.

7. **Michael Bacon**
November 19, 2008

I favor an 'Everettarian' MWI, but even I had to switch the show off after a few minutes — really, breathless, content free viewing.

8. **changcho**
November 19, 2008

Peter, I think you meant to write the History Channel, not Discovery Channel. Other points:

* The History Channel's treatment of science is a mixed bag. I do recall watching at least one very good show ("How the Earth was Made") there.

* NOVA on PBS is, in general, much more careful and accurate with their science shows.

*I have seen M. Kaku on several science shows (mostly on Discovery Science Channel, History Channel) talking about extremely speculative ideas (parallel universes, string theory) as if they were commonly accepted by most scientists. This is clearly a disservice (except for him, of course).

9. **Peter Woit**
November 19, 2008

changcho,

Thanks for catching the mistake, fixed now. My apologies to the Discovery Channel…

10. **milkshake**
November 19, 2008

Discovery and History are both full of X-files-level rubbish – all presented with the utmoust seriousness by a team of independent experts.

11. **Serifo**
November 19, 2008

I think the media (specialy private media) are more concerned with the number of the audience than to inform the audience in a honest way ! Well , general public seems to enjoy ideas that are not part of the orthodox scientific thinking. I think the basis for this , is in the history of science . See, people (general public) learned with the history that, in their time , Scientists like Galileo challenged the orthodox (scientific or religious ?) thinking about universe. So , these days whenever somebody comes up with non orthodox ideas about universe, people normally start to have pictures of Galileo and others who were rejected , which is actually something positive in my view, as long as they are aware that " Galileo and others also had incomplete or even wrong ideas about universe " !
Now , I think the media has the responsibility to inform the people on " what is currently the orthodox and non orthodox scientific thinking about universe " otherwise the general public will end up ………

Ps – I just hope the research funding agencies (specialy the private ones) don`t make decisions based on TV programs ! 🙂

12. **rick**
November 19, 2008

I watched this and the whole while I was thinking, maybe there's a parallel universe where Michio Kaku still has his dignity, but probably not.

13. **Chris W.**
November 19, 2008

As a child I came to the conclusion—semiconsciously—that wanting to *really* understand almost anything is viewed in mass society as a vaguely subversive and perverse attitude. If you manage to maintain this desire while meeting other people's expectations it is tolerated, and with luck even encouraged. If not, difficulties often ensue.

Let's face it, as a joint venture of Hearst, Disney, and NBC, the History Channel (like the Discovery Channel) is a commercial enterprise, and it aims to draw and hold viewers. In the contemporary media environment that inevitably devolves to pandering and efforts to titillate and offer shallow diversions. When people sit down to watch TV at night they are rarely prepared to concentrate deeply or be intellectually absorbed by something, and frankly, *broadcast* television has never been a good medium for that. (I think video on the internet is—at least potentially—a different story, notwithstanding the vast quantities of vacuous garbage on YouTube.)

Many professional scientists seem to be too easily taken in by flattering invitations. Think about the context, folks, and get a clue.

14. **Janne**
November 20, 2008

    There are vast quantities of solid material on youtube aswell. For example MIT and Stanford physics lectures and some researchers have contributed computer animations from their research. I've watched some interesting lectures on Googletalks as well. I think the scientific community could do a lot more with youtube.

15. **Low Math, Meekly Interacting**
November 20, 2008

    There's certainly good stuff to be had via YouTube, but it's not easy to find if you don't know exactly what to look for. I bet, though, that somebody more educated and obsessive than myself has compiled a clearinghouse of links to freely-available content that has both accessibility and integrity. If not, I'd be willing to kick in a few bucks to make it worth their while

16. **Hun**
November 20, 2008

    I found that the History Channel often sends out biased documentaries just like the Fox Channel, using interviews to deliver the message 'they' like. PBS seems to be much more careful.

17. **Charlie C**
November 20, 2008

    It's useful to look at this from a different perspective. What we have been talking about here is how to turn entertainment into education, a tough row to hoe. Following Janne's lead, maybe scientists should be asking how to we use modern tools to explain our ideas clearly. The scientists should take the lead, as has started to happen with YouTube. However, so far, most of the YouTube scientific lectures are pointed at fellow professionals. The REAL challenge is how can modern animation, graphic packages, YouTube video clips, etc be combined, by scientists, to CLEARLY yet ACCUATELY explain basic and sometimes profound concepts. Maybe some scientists should be taking the lead and forming small teams of media experts in order to create professional, accurate, and yes, maybe even exciting expositions intended for the non-pro. You don't have to talk down to your grandmother, but you do have to really understand how to describe your topic clearly and simply. And, of course, to teach is to learn. Win-win.

18. **Mitch Miller**
November 20, 2008

    "I don't really see how an intelligent person can watch this thing and not come away with the impression that theoretical physicists are a bunch of idiots." [PW]

    This is too harsh of a statement, but there is a danger here. We have all probably seen programs on the history channel with PhDs talking about how aliens built the pyramids who are clearly idiots. While this program was no were near that level (most of the experts came of as very smart people trying to explain speculative ideas to lay persons) it is concievable a physics show in the future could approach alien/pyramid if the experts aren't careful.

19. **Coin**
November 20, 2008

    What confuses me is why we don't ever seem to have a situation where they just hire one of these physicists to *write the program script*. It's not like real scientists are magically incapable of writing for a popular audience; they let scientists write *books* for a popular audience all the time (and more than one of the participants in this program has done exactly that), so why not let scientists write tv programs? Why relegate the science people to "consultant" at best– Clifford Johnson etc were expressing concern that they weren't able to view and give feedback on the program before it aired, but why is it that people like Clifford Johnson are being kept so far away from the production of the program in the first place that "request minor changes once the thing's done" is the best they can hope for?

20. **Heineken**
November 20, 2008

    the FLT video was called The Proof. it was a very good Nova episode. there are also 2 (?) NOVA episodes on Einstein's work. very good stuff for the lay audience.

    i had some questions about the symmetry with modular forms, how to find an E series, etc.

    some of my favorite books combine equations and history, and are geared to the lay audience with a year or two of calc background. Prime Obsession being a good example.

21. **Chris W.**
November 20, 2008

    From Coin:

    > What confuses me is why we don't ever seem to have a situation where they just hire one of these physicists to *write the program script*.

    What I said previously:

    > [The History Channel] is a commercial enterprise, and it aims to draw and hold viewers. In the contemporary media environment that inevitably devolves to pandering and efforts to titillate and offer shallow diversions.

    Why would the producers of a History Channel program let a physicist muck up their efforts to target the audience they're trying to reach? They are media professionals, and they figure they know better than anyone how to reach the audience that upper management wants to reach. That includes controlling how the script is written. Consider what professional scriptwriters, let alone academics moonlighting as script consultants, often have to contend with when they write for film or television. Stories of scripts butchered at the behest of producers and directors are legion.

22. **lcs**
November 20, 2008

By the way, I stopped watching PBS/NOVA science programs years ago because of the obnoxious introduction of MTV style editing, background music or drums (always completely unnecessary) and other concessions to the 10 second attention span of today's under 50 audience. The last good PBS show was about Feynman.

23. **Peter Woit**
November 20, 2008

I'm not so sure this is such a simple story of "bad TV people ruin good physics". There's a lot of pseudo-science in the multiverse to begin with and precious little good physics. The physicists participating in this all seemed willing to, on camera, go on about how cool it is that there is some other universe out there with people exactly like you, but slightly different. It's not too surprising that the film-makers took this kind of thing and ran with it.

Clifford Johnson seems to have gone into this without having any idea of what many of his colleagues (e.g. Tegmark) have been promoting, writing:

"I have never ever heard of this "level x" business. I don't know who says that."

You don't need to have followed much of the multiverse mania to have run up against Tegmark's 4 levels of multiverse. And any exposure to multiverse mania should make one very careful about getting involved in a program promoting it.

Again, at least one physicist had no trouble recognizing this, insisting that he wouldn't participate unless he could be sure his words would not be used to promote this kind of pseudo-science, and dropping out when he couldn't get convincing assurances. Of those who participated in the program besides Clifford, I have no idea whether they feed betrayed by the program, or whether they actually think it made sense. Fillippenko is listed in the credits as "scientific consultant".

I tried to contact the History Channel about this, got nowhere. Maybe other people might have more luck. I'm curious whether any of the physicists involved have complained to anyone there about the program.

November 20, 2008

And we wonder why the general public (not to mention politicians) is virtually scientifically and mathematically illiterate. Whenever I catch the occasional NOVA, I'm always hoping that it will really be about science this time. But alas, it always seems to be more boring historical reenactments and other renaissance faire fluff more appropriate to something that should be shown on the History Channel. It's essentially like a glorified version of Wishbone (the dog that reenacts classics like Romeo and Juliet, and Treasure Island, with the neighbohood kids). Oh well. Just my two-cents worth on this stuff.

25. **Chris W.**
November 20, 2008

For some modest relief, BBC2 offers *Einstein and Eddington* [Physics World blog review]. The science is apparently lightweight, but at least it seems to be a well-done drama on an interesting historical period; the producers show a modicum of taste.

26. **abbyyorker**
November 20, 2008

The public loved "What the bleep do we know" (I guess – didnt it have a sequel?). That movie was not only nonsense – it was boring. Public has no clue about physics – even physics from the 20's. Some great science communicators can give a whisper of understanding but it is of little consequence. So let the theorists run wild – the wilder the better because the public will not (cannot) call them to account.

27. **csrster**
November 21, 2008

"I'm always hoping that it will really be about science this time. But alas, it always seems to be more boring historical reenactments and other renaissance faire fluff more appropriate to something that should be shown on the History Channel."

The dearth of good history broadcasting and it's replacement with costumised puff is a topic for another day …

28. **Chris Oakley**
November 21, 2008

FYI: *Einstein and Eddington* is on in the UK, BBC2, tomorrow night (November 22) at 9:10pm.

I didn't see *Parallel Universes*, at least not in this one. Although one of my body doubles in a parallel universe may have watched and enjoyed it, this strand of Dr. Oakley probably won't bother.

29. **trond**
November 21, 2008

Anything broadcast on History/Discovery Channel is mostly infotainment and it's unreasonable to expect peer-reviewed content (no pun intended on Chaos, Solitons & Fractals). As mentioned by the other posters, there are only two broadcasters, BBC and PBS, that still occasionally produce quality productions.

30. **Visitor**
November 21, 2008

"I tried to contact the History Channel about this, got nowhere. Maybe other people might have more luck. I'm curious whether any of the physicists involved have complained to anyone there about the program."

Perhaps it might worthwhile, and more productive, to contact the physicists involved. It would be interesting to know, not only their opinion of the show, but if they feel that they have any duty to do anything about it, or if they can just wash their hands of the matter.
If these people are sufficiently dissatisfied with the show's treatment of the subject, and if they could ante up enough money to put an ad in a magazine, trade journal, or some publication of that sort, it is – and let me make this statement sufficiently conditional – it is not impossible that the resulting bad publicity could serve as a caution to other tv producers considering traipsing down the same road as was done in this show.

31. **bane**
November 21, 2008

To Serifo,

Whilst funding bodies generally don't consider media appearances, unfortunately many career important committees like hiring, promotion or other-university-responsibility boards often consider only the volume of a scientist's media work (via the pile of clippings and lists of TV work they attach to the CV) and not their quality. In all honesty I can't say considering media profile in these kind of things is wrong per se, it's just that if you're going to consider it you really should evaluate it properly rather than just "weigh it".

32. **Tom Whicker**
November 23, 2008

This program was really terrible, but sadly just standard operating
proceedure for the History Channel. I had the misfortune of seeing
"The Earth's Black Hole" not long ago on the HC. This one was so
astoundingly absurd that even non-technical fans of the channel were
calling for a boycott. There were plenty of mis-quoted scientists
in this one also. Here is a list of those that appeared if anyone
wants to contact them and maybe get some kind of group action going:

http://en.wikipedia.org/wiki/Decoding_the_Past

33. **GR**
November 23, 2008

CUNY has a new NYC subway train poster with a life size color photo of Dr. Michio Kaku. It describes him as "co-founder of string field theory" & "international authority on theoretical physics".

34. **db**
November 24, 2008

The "Einstein and Eddington" drama on BBC 2 wasn't all that bad. It focused more on the political and social consequences of corresponding with "the enemy" than the physics, but what physics they did include wasn't outrageously mangled.

They took a fair number of liberties with the characters, but they were largely forgivable with the exception of one cringeworthy speech toward the end.

Overall it did a better job than most of the pop sci stuff out there, but the science was almost entirely incidental.

35. **WP**
December 11, 2008

As a writer-producer-director with a strong background in the sciences, I can see the validity of the points brought up. I personally thought the program was entertaining, but thought someone reached way up to pull out some of the stuff showcased on the show.

Now, I've always been a proponent of the idea of a 'multi-verse' yet some of the theories like 'well there may be other identical universes, they're just too far for us to see' should get the 'plasticman' award for reaching. That and the 'burning a hole in space-time with lasers' was way too sci-fi even for me.

I do agree with the poster who mentioned that once the script is in the network's hands its a done deal. I'm sorry to say that it's all 'infotainment' including NOVA which I thoroughly enjoy and respect. So at best, production personnel and scientists will strive to get in and keep in as much solid info as possible.

One good thing about all of this is there are young people watching this stuff and are building an interest in how all these things (i.e. physics, math, science in general) work and want to know more. I know that NOVA, Jaques Cousteau, Wild Kingdom and a host of other shows made the sciences very attractive to me. I'm sure it is having the same effect on others.

The good news is; those who end up exploring these disciplines will soon discover the 'smoke and mirrors' whipped up by these programs and one day they'll say, "Hey, there really wasn't a lot of good math in this program…."

36. **P**
January 20, 2009

The history channel tends to be pretty sensational in many of its programs. Sometimes, late at night, they have had programs about the illuminati and alien conspiracies. Their religion programs like to focus on the gnostic gospels. If a real historian would laugh at some topic as total bull, they will probably do a special about it on the history channel.

The Map of My Life

November 22, 2008
Categories: Book Reviews

Springer has just published an autobiography of Goro Shimura, entitled The Map of My Life. Shimura's specialty is the arithmetic theory of modular forms, and he's responsible for a crucial construction generalizing the modular curve, now known as a "Shimura variety". The book has a long section at the beginning about his childhood and experiences during the war in Japan. The rest deals mostly with his career as a mathematician, including often unflattering commentary on his colleagues. One of those who comes off the best is André Weil, who encouraged and supported Shimura's work from the beginning. They both ended up at Princeton, with Weil at the Institute, Shimura at the University.

The book contains extensive discussion of the story of what Shimura calls "my conjecture". This is the conjecture proved by Wiles and others that implies Fermat's Last Theorem. In the past, it has conventionally been referred to by various combinations of the names of Shimura, Taniyama and Weil, although more recently the convention seems to be to refer to it as the "modularity theorem". Shimura also claims credit for conjecturing the "Woods Hole formula" that inspired Atiyah and Bott to prove their general fixed-point theorem.

To get a flavor of the unusual nature of the book, here are some extracts from one section:

> Jean-Pierre Serre, whom I had met in Tokyo and Paris, was among the audience, and kept asking questions on the most trivial points, which naturally annoyed me…. Somebody told me that he had become frustrated and even sour. Much later I formed an opinion that he had been frustrated and sour for most of his life. As described in my letter to Freydoon Shahidi, included as Section A2 in this book, he once tried to humiliate me, and as a result gave me the chance to state my conjectures about rational elliptic curves. I now believe that his "attack" on me was caused by his jealousy towards my supposed "success" — my conjectural formula and lectures — at Woods Hole….
>
> In spite of the fact that my mathematical work was little understood by the general mathematical public, I was often the target of jealousy by other mathematicians, which I found strange. I can narrate many stories about this in detail, but that would be unpleasant and unnecessary, and so I mention only one interesting case…
>
> (*he then describes an encounter in which Harish-Chandra compares favorably Apery's result on the irrationality of ζ (3) to Shimura's work*.)
>
> Clearly he thought he finally found something with which he could humiliate me: To his disappointment, he failed. Did he do such a thing to other people? Unlikely, though I really don't know. But why me? To answer that question, let me first note an incident that happened in the fall of 1964. As I already explained, Atiyah and Bott proved a certain trace formula based on my idea. Bott gave a talk on that topic at the Institute for Advanced Study. In this case he clearly acknowledged their debt to me. In the talk he mentioned that Weyl's character formula could be obtained as an easy application. Harish-Chandra, who said, "Oh, I thought the matter was the other way around; your formula would follow from Weyl's formula." Bott, much disturbed, answered, "I don't see how that can be done." After more than ten seconds of silence, Harish-Chandra said "It was a joke." There was half-hearted laughter, and I thought that his utterance was awkward and did not make much sense even as a joke.
>
> It is futile to psychoanalyze him, but such an experience may allow me to express some of my thoughts. He was insecure and hungry for recognition. That much is the opinion shared by many of those who knew him. He did not know much outside his own field, but he was not aware of his ignorance. In addition, I would think he was highly competitive, though he rarely showed his competitiveness. From his viewpoint I was perhaps one of his competitors who must be humiliated, in spite of the fact that I was not working in his field. Here I may have written more than is necessary, but my concluding point is: He did so, even though I did nothing to him.

The book contains quite a few other unpleasant characterizations of other people, together with assurances that everyone else shared his view of the person in question. I know for a fact that in at least one case this is untrue:

> A well known math-physicist Eugene Wigner was in our department, and so I occasionally talked with him. He was pompous and took himself very seriously. That is the impression shared by all those who talked with him.

Wigner was still around when I was a student at Princeton and often came to tea. My impression of him was not at all that which Shimura claims to have been universal.

Update: An exchange between Shimura and Bott about the Woods Hole story can be found here.

Comments

   November 22, 2008

   Interesting. I will probably buy a copy of the book if it's not expensive.

   A book like this is not unprecedented. Andrei Sakharov's memoir has a lot of moments when he pointedly accused his colleagues of character flaws. Those include at least one for Zeldovich, who had been supportive of him most of the time and was considered by AS as a friend. In fact, I think this is exactly what a good memoir should be: Honest recollection of one's thoughts and feelings, at the end of one's career when there's nothing more at stake. This also serves as a release, or else one would have to bring those thoughts and feelings alone to the grave.

   (In the revised version of his memoir, Sakharov mentioned that he and Zeldovich eventually reconciled.)

2. **Coin**
   November 22, 2008

   Maybe not the most appropriate question to ask, but I cannot help but wonder– does Shimura's book have anything of detail to say about Taniyama, or attempt to offer any insight into his suicide?

3. **Neville**
   November 22, 2008

   It sounds like a rather sad book. Life should be a happy adventure.

4. **mathematician**
   November 22, 2008

Is there any reason to doubt the general picture portrayed by Shimura of a not always pleasant sociology. I would tend to take him at his word (with an appropriate grain of salt). Surely there are at least others in that circle who could confirm the existence of this kind of negative atmosphere.

I know nothing of this group, but I have seen and experienced negative things in my own circles, and I am acutely aware of how much people resent being informed of it.

5. **anonymous**
November 23, 2008

One is obviously reminded of Grothendieck's "Recoltes et Semailles", where similar "score settling" sadly occurs.

When I've got a grudge against someone, I take it up with him/her, not with the general public.

6. **MathPhys**
November 23, 2008

I know that Grothendieck's accusations of a certain person in R et S were completely unfounded.

Grothendieck was a very great man, but when he wrote R et S, he was too angry to see that others may have perfectly valid explanations for their actions.

In any case, the people that he attacked were all still around and active when R et S was distributed.

In Shimura's case, the situation is different as many of the people that he talks about are no longer in a position to defend themselves.

7. **Peter Woit**
November 23, 2008

Coin,

There's a bit in the book about Taniyama, no insight into the reason for his suicide.

mathematician,

I gave one reason to doubt Shimura's portrayals of other people's failings, based on my own personal experience. I've never met Serre personally, but Shimura's claim that he was jealous because of the Wood's Hole conjecture is hard to believe. The currency of renown among mathematicians is theorems, not conjectures….

8. **Per**
November 23, 2008

If the text above is true, then it is a bit sad that excellence in mental achievements does not imply growth of other aspects of personality.

Egomaniacs seem to roam the halls of famous mathematics institutions also.

9. **mathematician**
November 23, 2008

Peter, okay you have a point that Shimura's claims of the form "everyone agrees with me" are easily refuted by people disagreeing with him.

But his claims of the form "person X has certain negative characteristics" are not so easily refuted by people disagreeing with him. People may not like hearing such things, but if they know nothing of the people involved they should just remain agnostic on the issue. I object to people automatically rejecting his claims, just because they are negative.

I have personal experience of being severely mistreated by someone who is viewed positively by many people and who has received awards and recognition for being something completely different to what I am describing. Several years ago I was almost driven to suicide by this person, and I believe there is another case where the word "almost" does not apply. And yet I just have to keep my mouth shut about it, because of the backlash that there is to such negative claims.

10. **st**
November 23, 2008

The academe in previous decades was not nearly as open-minded as it is today. I am sure as a foreign Japanese scholar working in the US back then, he must have felt at least some form of subtle prejudice or discrimination. From the excerpts and letter to the AMS, it appears that Shimura has felt that his ideas were often ignored or belittled and would like proper credit for his work. Although he may come across as a bit paranoid in his writing, that doesn't mean his observations about his colleagues were inaccurate or baseless, though the assertion that "all" agree with his opinion is exaggerated.

11. **woit**
November 23, 2008

st,

If Shimura felt discriminated against by anyone for being Japanese, he doesn't mention that in his book.

12. **st**
November 23, 2008

Peter,

I mentioned discrimination because it was well known at the time. For example, in his paper *A History of Mathematics at Princeton University* (available here), Michael Seip writes:

> Gian Carlo Rota was an undergraduate mathematics major at Princeton in the early 1950's, a period marked by growth of the department and political upheaval in academia. He describes another, more ugly, notion of the times; nationality prejudices in academia. Many notable professors from Europe and the Far East were allowed to visit American universities, but not many were granted tenure. This bias was expressed at Princeton in several notable instances. The geometer Kunihiko Kodaira, from Japan, was appointed to a six-year term but was not awarded tenure. Though Kodaira, "whose work in geometry was revered by everyone in the Princeton main line", (Rota, p. 226) was an accomplished and productive researcher, several members of the Princeton faculty were opposed to his award of tenure on the basis of his nationality and he was voted down.

On a different note, the paper continues with this observation:

> "Bias also existed towards those men who studied subjects considered intangible at the time…"

This type of bias, unfortunately, is still pretty much alive today.

13. **Kea2**
November 24, 2008

Over the years, Shimura has increasingly isolated himself from other mathematicians. Like Grothendieck, he can write very well about nonmathematical things — for example, his memoir on Taniyama (BLMS 1989) is very moving — but I wouldn't give any more credence to his characterizations of other mathematicians than I do to Grothendieck's.

14. **Jean-Paul Billon**
November 24, 2008

Whatever the domain, to push one's ideas leads to be shot at will by people you were trusting to be fair great minds. Mathematicians are not outside of the current universe under this aspect. Having been a mathematicinas in a former life, I was hurt by the buzz that a very obvious fundamental theorem I was using to base on a new method of theorem proving was wrong. No luck for my detractors, it was a well known theorem proven by Shannon. Since I have been moving to industry and now to politics. Same game. But you learn how to get a thick skin. Whoever believes that fundamental science is clean from any blow under the belt is a naive. Novertheless, sciens is moetimes progressing, which is great. BTW, did you know that Einstein was barred from tenure in France when seeking asylum…?

15. **N. Nakanishi**
November 24, 2008

My impression of E. Wigner is common to P. Woit's one. In 1961, at Princeton I met him and reported that I had translated his famous essay entitled "The Unreasonable Effectiveness of Mathematics in the Natural Sciences" into Japanese. He was extremely polite to such a young Japanese as me.

16. **sz**
November 25, 2008

Mathematicians always behave like children, even great ones like Shimura are no exception. In this book Shimura portrayed himself more like an aged Tom Sawyer than a matured adult. I don't see anything wrong about it, I believe his words are sincere and truthful.

In my naive psycho-analysis, I think sometimes when a person describes another person, he unconsciously projects his own shadow over the others' image. In Shimura's opinion about Harish-Chandra, I very much see an image of Shimura himself.

But I do think this is different from Grothendieck's "Recoltes et Semailles", because Grothendieck is not a traditional mathematician. What he did in mathematics is, in some sense, not mathematics at all, but rather like mythology of Ramanujan…it's like he hits the weakness of standard mathematical thinking in some way. His anger towards the others maybe come from the fact that even those closest to him can not or would not follow his way of thinking.

17. **a.k.**
November 25, 2008

..discrimination was not only 'well-known at that time', it certainly influenced the mathematical community not only in those days. In difference to any other subclass of society, the existence of discrimination by race, class or gender among mathematicians is not a 'valid' subject of discussion, is is assumed to be non-existent due to the general 'level of civilisation', which one presupposes for mathematicians. This is -without any doubt- the (conscious or subconscious) reason why Shimura did not explicitly mention the term of discrimination in his book, although it seems to be clearly implicit. It is a common phenomenon for people experiencing discrimination to react in a way which seems 'paranoid' to the observer, even or especially if the actual formulation of the term 'discrimination' is, for some reason, not an accepted way to choose for the person in case, for personal or 'external' reasons.

18. **former mathematician**
November 30, 2008

I can't resist the opening to report a Shimura anecdote from the 50's or 60's, when it seemed that he was publishing at least one 45-page paper each month.

A mathematician was browsing through typewriter ribbons ath the university store. Shimura approached him and said, "Don't get that brand; get this brand. You will find it helps write better papers."

19. **Peter Woit**
November 30, 2008

fm,

Funny, typewriter ribbons seem to be a big concern of Shimura's. In his book, he describes one city in Japan where he worked as kind of a wasteland, with the main evidence being that he had trouble finding a place to buy typewriter ribbons.

20. **anonymous**
December 6, 2008

Jean-Pierre Serre was probably the greatest mathematician of the second part of this century. He remained very creative over the years. Of course there were very creative new comers, who started at the right time. But the fact that Jean-Pierre Serre lasted so long must be irritating to some…

21. **Betsy Devine**
December 9, 2008

What a strange characterization of Wigner, who was shy and so European-polite as to seem quite formal.

I remember in the mid or late 1970s when the talk of Princeton physics was Wigner's courting Pat Hamilton, the widow of another physicist who was soon to become his third wife. Joan Treiman told me that on summer evenings you could see them out strolling together, holding hands. I never saw this phenomenon, but it was a real pleasure to see them at physics parties looking both so, so happy. My impression was that Wigner's colleagues loved as well as admired him.

22. **st**
December 10, 2008

I wonder whether mathematicians, in general, are always aware of how they come across to others especially in social situations. I would imagine that this awareness is probably below average as a group, although there are some with average to superb social skills. This is because we're trained to be direct, specific, and honest in our communication. There's little room for "spinning" when proving a theorem. As Gian-Carlo Rota once observed, mathematicians have "bad personalities," make "terrible salesmen," and are "totally devoid of common sense."

To give an example from my own experience, I've pointed out several relatively minor mistakes to a speaker in public without realizing at the time that that might have been offensive. For us, it is almost an instinct to correct. So I can understand how someone "asking questions on the most trivial points" might just be trying to understand the material rather than to intentionally annoy. What is "trivial" to one expert may be puzzling to others not directly working in the area. Coupled that with the extra-sensitivity of a person who might have experienced discrimination, it is easy to give birth to a "grudge" without the other party being aware of any wrongdoing. Such misunderstanding is unfortunate indeed.

23. **Anonymous**
    February 7, 2009

    Goro Shimura recently published this book too:

    Link can be found here:

    http://www.tenspeed.com/store/?main_page=pubs_product_book_jph1_info&products_id=2465

24. **anon smith**
    February 27, 2009

    Professor Goro Shimura, one of the greatest mathematicians of our day, has written a wonderful book about something well outside of mathematics: an aspect of Japanese culture that should be of great interest for anyone interested in Japanese civilization. I congratulate him for writing so eloquently outside the field of mathematics and for showing his sincere passion for an art form that is unique to historic Japan and its tradition. This book will enlighten and delight any reader with interest in Japan, in fine porcelain, and in ancient traditions.

Notes on BRST V: Highest Weight Theory

November 23, 2008
Categories: BRST

In the last posting we discussed the Lie algebra cohomology $H^*(\mathfrak g, V)$ for $\mathfrak g$ a semi-simple Lie algebra. Because the invariants functor is exact here, this tells us nothing about the structure of irreducible representations in this case. In this posting we'll consider a different sort of example of Lie algebra cohomology, one that is intimately involved with the structure of irreducible $\mathfrak g$-representations.

Structure of semi-simple Lie algebras

A semi-simple Lie algebra is a direct sum of non-abelian simple Lie algebras. Over the complex numbers, every such Lie algebra is the complexification $\mathfrak g_{\mathbf C}$ of some real Lie algebra $\mathfrak g$ of a compact, connected Lie group. The Lie algebra $\mathfrak g$ of a compact Lie group G is, as a vector space, the direct sum

$$\mathfrak g=\mathfrak t \oplus \mathfrak g/\mathfrak t$$

where $\mathfrak t$ is a commutative sub-algebra (the Cartan sub-algebra), the Lie algebra of T, a maximal torus subgroup of G.

Note that $\mathfrak t$ is not an ideal in $\mathfrak g$, so $\mathfrak g/\mathfrak t$ is not a subalgebra. $\mathfrak g$ is itself a representation of $\mathfrak g$ (the adjoint representation: $\pi(X)Y=$), and thus a representation of the subalgebra $\mathfrak t$. On any complex representation V of $\mathfrak g$, the action of $\mathfrak t$ can be diagonalized, with eigenspaces V^λ labeled by the corresponding eigenvalues, given by the weights λ. These weights $\lambda\in\mathfrak t_{\mathbf C}^*$ are defined by (for $v\in V^\lambda,\ H\in \mathfrak t$):

$$\pi(H)v=\lambda(H)v$$

Complexifying the adjoint representation, the non-zero weights of this representation are called roots, and we have

$$\mathfrak g_{\mathbf C}=\mathfrak t_{\mathbf C} \oplus ((\mathfrak g/\mathfrak t)\otimes\mathbf C)$$

The second term on the right is the sum of the root spaces V^α for the roots α. If α is a root, so is $-\alpha$, and one can choose decompositions of the set of roots into "positive roots" and "negative roots" such that:

$$\mathfrak n^+=\bigoplus_{+\ roots\ \alpha}(\mathfrak g_{\mathbf C})^\alpha,\ \mathfrak n^-=\bigoplus_{-\ roots\ \alpha}(\mathfrak g_{\mathbf C})^\alpha$$

where $\mathfrak n^+$ (the "nilpotent radical") and $\mathfrak n^-$ are nilpotent Lie subalgebras of $\mathfrak g_{\mathbf C}$. So, while $\mathfrak g/\mathfrak t$ is not a subalgebra of $\mathfrak g$, after complexifying we have decompositions

$$(\mathfrak g/\mathfrak t)\otimes \mathbf C=\mathfrak n^+ \oplus \mathfrak n^-$$

The choice of such a decomposition is not unique, with the Weyl group W (for a compact group G, W is the finite group N(T)/T, N(T) the normalizer of T in G) permuting the possible choices.

Recall that a complex structure on a real vector space V is given by a decomposition

$$V\otimes \mathbf C=W\oplus\overline{W}$$

so the above construction gives |W| different invariant choices of complex structure on $\mathfrak g/\mathfrak t$, which in turn give |W| invariant ways of making G/T into a complex manifold.

The simplest example to keep in mind is $G=SU(2),\ T=U(1),\ W=\mathbf Z_2$, where $\mathfrak g=\mathfrak{su}(2)$, and $\mathfrak g_{\mathbf C}=\mathfrak{sl}(2,\mathbf C)$. One can choose T to be the diagonal matrices, with a basis of $\mathfrak t$ given by

$$\frac{i}{2}\sigma_3=\frac{1}{2}\begin{pmatrix}i&0\\0&-i\end{pmatrix}$$

and bases of $\mathfrak n^+,\ \mathfrak n^-$ given by

$$\frac{1}{2}(\sigma_1+i\sigma_2)=\begin{pmatrix}0&1\\0&0\end{pmatrix},\ \frac{1}{2}(\sigma_1-i\sigma_2)=\begin{pmatrix}0&0\\1&0\end{pmatrix}$$

(here the σ_i are the Pauli matrices). The Weyl group in this case just interchanges $\mathfrak n^+ \leftrightarrow \mathfrak n^-$.

Highest weight theory

Irreducible representations V of a compact Lie group G are finite dimensional and correspond to finite dimensional representations of $\mathfrak g_{\mathbf C}$. For a given choice of $\mathfrak n^+$, such representations can be characterized by their subspace $V^{\mathfrak n^+}$, the subspace of vectors annihilated by $\mathfrak n^+$. Since $\mathfrak n^+$ acts as "raising operators", taking subspaces of a given weight to ones with weights that are more positive, this is called the "highest weight" space since it consists of vectors whose weight cannot be raised by the action of $\mathfrak g_{\mathbf C}$. For an irreducible representation, this space is one dimensional, and we can label irreducible representations by the weight of $V^{\mathfrak n^+}$. The irreducible representation with highest weight λ is denoted V_{λ}. Note that this labeling depends on the choice of $\mathfrak n^+$.

Getting back to Lie algebra cohomology, while $H^*(\mathfrak g, V)=0$ for an irreducible representation V, the Lie algebra cohomology for $\mathfrak n^+$ is more interesting, with $H^0(\mathfrak n^+, V)=V^{\mathfrak n^+}$, the highest weight space. $\mathfrak t$ acts not just on V, but on the entire complex $C(\mathfrak n^+, V)$, in such a way that the cohomology spaces $H^i(\mathfrak n^+,V)$ are representations of $\mathfrak t$, so can be characterized by their weights.

For an irreducible representation V_λ, one would like to know which higher cohomology spaces are non-zero and what their weights are. The answer to this question involves a surprising "ρ – shift", a shift in the weights by a weight ρ, where

$$\rho=\frac{1}{2}\sum_{+\ roots} \alpha$$

half the sum of the positive roots. This is a first indication that it might be better to work with spinors rather than with the exterior algebra that is used in the Koszul resolution used to define Lie algebra cohomology. Much more about this in a later posting.

One finds that $dim\ H^*(\mathfrak n^+,V_\lambda)=|W|$, and the weights occuring in $H^i(\mathfrak n^+,V_\lambda)$ are all weights of the form $w(\lambda +\rho)-\rho$, where $w\in W$ is an element of length i. The Weyl group can be realized as a reflection group action on $\mathfrak t^*$, generated by one reflection for each "simple" root. The length of a Weyl group element is the minimal number of reflections necessary to realize it. So, in dimension 0, one gets H^0(\mathfrak n^+, V_\lambda)=V^{\mathfrak n^+} with weight \lambda, but there is also higher cohomology. Changing one's choice of \mathfrak n^+ by acting with the Weyl group permutes the different weight spaces making up H^*(\mathfrak n^+, V). For an irreducible representation, to characterize it in a manner that is invariant under change in choice of \mathfrak n^+, one should take the entire Weyl group orbit of the \rho – shifted highest weight \lambda, i.e. the set of weights

\{w(\lambda +\rho),\ w\in W\}

In our G=SU(2) example, highest weights can be labeled by non-negative half integral values (the "spin" s of the representation)

s=0,\frac{1}{2},1,\frac{3}{2}\2,\cdots

with \rho=\frac{1}{2}. The irreducible representation V_s is of dimension 2s+1, and one finds that H^0(\mathfrak n^+,V_s) is one-dimensional of weight s, while H^1(\mathfrak n^+,V_s) is one-dimensional of weight -s-1.

The character of a representation is given by a positive integral combination of the weights

char(V)=\sum_{weights\ \omega} (dim\ V^\omega)\omega

(here V^\omega is the \omega weight space). The Weyl character formula expresses this as a quotient of expressions involving weights taken with both positive and negative integral coefficients. The numerator and denominator have an interpretation in terms of Lie algebra cohomology:

char(V)=\frac{\chi(H^*(\mathfrak n^+, V))}{\chi(H^*(\mathfrak n^+, \mathbf C))}

Here \chi is the Euler characteristic: the difference between even-dimensional cohomology (a sum of weights taken with a + sign), and odd-dimensional cohomology (a sum of weights taken with a – sign). Note that these Euler characteristics are independent of the choice of \mathfrak n^+.

The material in this last section goes back to Bott's 1957 paper *Homogeneous Vector Bundles*, with more of the Lie algebra story worked out by Kostant in his 1961 *Lie Algebra Cohomology and the Generalized Borel-Weil Theorem*. For an expository treatment with details, showing how one actually computes the Lie algebra cohomology in this case, for U(n) see chapter VI.3 of Knapp's *Lie Groups, Lie Algebras and Cohomology*, or for the general case see chapter IV.9 of Knapp and Vogan's *Cohomological Induction and Unitary Representations*.

   Well what did you ever determine intuitively about the bifurcation of the world represented by W direct bar W? There are many candidates, but they come down to matter vs. antimatter. I mean how did you come to think about it? This issue comes up again and again.

   -drl

2. **Peter Woit**
   November 24, 2008

   drl,

   This is just the completely conventional way mathematicians think of what it means to put a complex structure on a real vector space.

   I should have commented somewhere about the fact that the whole highest-weight theory set-up is very much analogous to quantum field theory, with the highest weight vector playing the role of a the vacuum vector. You get something just like the particle-anti-particle business.

   In the case of affine Lie algebras, the analogous construction is exactly one that comes from 1+1 d QFT.

   for another way of avoiding the ρ-shift without using spinors.

The Landscape at Princeton

November 24, 2008
Categories: Multiverse Mania

The Princeton Center for Theoretical Science has been having a mini-symposium on the string theory Landscape, and as part of this today hosted a “panel discussion” on the topic. It turns out that there’s not a lot of support for the Landscape in Princeton.

Michael Douglas was the only real Landscape proponent in evidence. He gave a presentation on the state of Landscape studies, beginning by noting that landscapeologists keep finding more possible string vacua. Evidently the 10^500 number always quoted for the number of semi-realistic vacua is no longer operative, with latest estimates more like 10^(10^5) or higher. Douglas acknowledged that this pretty much removes any hope of making predictions by using experiment to fix this freedom and end up with non-trivial constraints. All that’s left is the idea of doing statistical calculations, but there the problem is that you don’t know the measure. He ended up mainly talking about cosmology, partly about the hope that maybe cosmology would constrain the possible vacua, as well as going over various ideas for putting a measure on the space of vacua. None of this really seems to lead anywhere, with all proposed measures having a rather ad hoc character. Douglas advocated just trying to count all vacua with the same weight, since at least one might hope to calculate that.

Tom Banks began by claiming that the effective field theory picture used in the landscape is just not valid. He also pointed out that if the landscape arguments were valid, the landscape would be disconfirmed by experiment, since 10-20 of the Standard Model parameters are unconstrained by anthropics, but take unusually small values, not the random distribution one would expect. Banks takes the attitude that the CC probably has an anthropic explanation, but not particle physics or the SM parameters. He also attacked the usual claims that different vacua are all states of the same theory, arguing that they instead correspond to different theories. Finally, he pointed out that the one prediction that landscapeologists had claimed they would be able to make, the scale of SSYM breaking, hadn’t worked out at all (Douglas now acknowledges that this can’t be done).

Nati Seiberg then argued that, as one gets to deeper and deeper levels of understanding of particle physics, one might reach a level where the only explanations are environmental and have to give up. He sees no reason for that to be the case now, with the main problem that of EWSB, and nothing to indicate that anthropics has anything to do with the problem. Rather, the problem is there because we haven’t had high enough energy accelerators (the LHC should change that), and the problem is hard. He ended by saying that the appropriate response at the present time to anthropic arguments like the Landscape is to just ignore them.

The last speaker was Nima Arkani-Hamed, who I suppose was chosen as a proponent of anthropics. He didn’t live up to this, saying that he pretty much agreed with Seiberg. Like Banks, he finds the anthropic explanation of the CC a plausible reason for why no one has come up with a better idea. He did say that thinking about anthropics and the Landscape has led people to look at some possiblilities for particle physics that otherwise would not have been examined. About the cosmological issues brought up by Douglas, his opinion is that there’s probably no point to thinking about these questions now, doing so might be like trying to come up with a theory of superconductivity in 1903. As far as EWSB goes, he believes the LHC will show us a non-anthropic explanation for its scale.

He explicitly attacked the discussion of measures that Douglas had engaged in as “not fruitful”, saying that he didn’t see any “endgame”, that it was wildly improbably that these could predict anything about particle physics. He also doesn’t see why our vacuum should be typical, joking that some of the least typical people in the world (Linde was mentioned) are most devoted to claiming that our universe is typical. He went on to argue for the currently fashionable enterprise of studying S-matrix amplitudes, arguing that looking at the local physics embodied in Lagrangians was no longer so interesting, that instead one should be trying to understand questions where locality is not manifest.

Finally, Arkani-Hamed ended with the statement that string theory is useful as a way to study questions about quantum gravity, but “unlikely to tell us anything about particle physics”. This is an opinion that has become quite widespread among theorists, but news of this has not gotten out to the popular media, where the idea that string theory has something to do with the LHC keeps coming up.

So, all in all, I found myself in agreement with most of the speakers. On another positive note, the math and physics book collection at Labyrinth (which has replaced the U-store bookstore) has improved dramatically.

Comments

1. **anon.**
   November 25, 2008

   “Evidently the 10^500 number always quoted for the number of semi-realistic vacua is no longer operative, with latest estimates more like 10^(10^5) or higher. Douglas acknowledged that this pretty much removes any hope of making predictions by using experiment to fix this freedom and end up with non-trivial constraints.”

   But isn’t the mainstream string theorist argument now the exact opposite, i.e. “the bigger the landscape, the better”? See:

   http://motls.blogspot.com/2006/06/top-twelve-results-of-string-theory.html

   According to Joe Polchinski (who is has done research in string theory and written a large textbook on the subject as you are aware), the twelfth top result of string theory is precisely:

   “The existence of the landscape, a *large enough set* of metastable solutions that the cosmological constant can adjust to a value small enough as to allow organized structures (which require many bits and many cycles). [hep-th/0603249]” (Emphasis added.)

   Therefore, the bigger the size of the landscape, the higher the probability that it can be somehow adjusted to fit observed physics, in principle. If the landscape size was really small, string theory could be falsified easily, and these experts (who appreciate a really big landscape over a small one) wouldn’t waste their time on it.

2. **Peter Woit**
   November 25, 2008

   anon.,

   Landscape proponents want at least 10^120 vacua, so as to anthropically solve the CC problem. They would like to get a prediction about something else, and for this the much larger numbers being considered now are a problem.

3. **Shantanu**
   November 25, 2008

   Peter, can you post a link to the conference site/talks if available?
   thanks

4. **Peter Woit**
November 25, 2008

Shantanu,

The only info about the conference available on-line that I know of is here:

http://pcts.princeton.edu/pcts/bigbang/Program-11-21-08.pdf

at the panel discussion, Douglas has quite a few slides, Banks just a few, Seiberg and Arkani-Hamed made informal remarks. I don't think anything was recorded, or that more will be available on-line.

5. **Tony Smith**
November 26, 2008

Peter, the PCTS conference link you gave was interesting in what was omitted:
Witten was not listed as being involved.

Has Witten taken a clear position on the Superstring Landscape,
or
does it appear that he is just letting it hang itself and drift slowly in the wind ?

Tony Smith

6. **Aaron Bergman**
November 26, 2008

Witten is on sabbatical at CERN.

7. **Peter Woit**
November 26, 2008

Tony,

As Aaron points out, Witten is not in Princeton this year. My impression is that he, like just most of the theorists in Princeton, is no fan of the landscape, and even if he were around, might steer clear of much involvement in this kind of program. What I find remarkable about the landscape story is how its proponents have managed to give the public the impression that it is the dominant point of view among string theorists. In actuality, I think most string theorist's attitude toward it is that of Seiberg: it should just be ignored.

8. **M**
November 27, 2008

ignoring the string landscape implies ignoring string theory

9. **Sumar Ongi**
November 27, 2008

I may be wrong, but I think not too long ago Arkani-Hamed was actively working with landscape-inspired models. (I even vaguely remember his calling this kind of work "staring the monster in the face", or something like that, in an interview.) If so, his change of opinion about those models (and about the relationship between ST and Particle Physics) is quite remarkable. More generally, it seems to me that all the opinions quoted above from well known theorists about these matters reflect a tidal change of mind in the string community.

10. **Arun**
November 27, 2008

I think it is a sign of progress that 10^500 has morphed to 10^100000. It is much more effective in keeping more people from wasting their time on it. Let a small contingent of researchers keep working on this and improving the intractability results of the landscape.

11. **Tony Smith**
November 27, 2008

Sumar Ongi said "… Arkani-Hamed was … calling … landscape-inspired model … "staring the monster in the face" …"
and
Peter said "… Nima Arkani-Hamed … went on to argue for the currently fashionable enterprise of studying S-matrix amplitudes, arguing that looking at the local physics embodied in Lagrangians was no longer so interesting …".

Is Arkani-Hamed's "landscape-inspired model" that is "the currently fashionable enterprise of studying S-matrix amplitudes"
actually
his MARMOSET approach described in hep-ph/0703088
and discussed in a RESONAANCES blog entry dated 1 July 2007 entitled "Nima's Marmoset" ?

In view of the success of the Standard Model Local Lagrangian,
is it reasonable to say that "local physics" of "Lagrangians" is "no longer so interesting" ?

Tony Smith

12. **Peter Woit**
November 27, 2008

Tony,

You're mixing up three completely unrelated things (landscape-inspired models, studying S-matrix amplitudes, and MARMOSET), with nothing much in common except that Arkani-Hamed has worked on them.

13. **hmmm**
November 27, 2008

What exactly is it that there are N=10^{many} of? (What does "possible string vacua" mean?) How are they counted? Does each one of these N "vacua", have their own continuously variable parameters (like the standard model has), in which case, why don't they say there are infinitely many and be done with the counting?

Finally, is there any sense in which string theory "predicts" that these "vacua" actually exist in physical reality, or is it just that some people choose to add the separate and additional hypothesis that things that might be theoretically possible, are guaranteed to actually exist as part of physical reality? (And couldn't you just make a "landscape" out of the standard model and its own continuously variable parameters, or out of whatever variable model you like?)

It just seems that some of these theorists are taking their models way too seriously, and have too narrowly focused on a limited range of possibilities.

14. **Peter Woit**
November 28, 2008

hmmm,

For the answers to you first questions, see review articles by Douglas and others. Plenty of string vacua do have continuous parameters, but these are supposed to correspond to massless fields. We don't see these, so you ignore those vacua. The 10^500 or larger number is a counting of vacua that aren't in obvious conflict with experiment.

Whether these "vacua" are legitimate metastable ground states of the full non-perturbative string theory is controversial. No way to resolve the controversy, since no one knows what the full non-perturbative string theory is.

I've gone on at length elsewhere why this is different than the standard model, but the obvious point is that the string landscape is thoroughly non-predictive about anything, whereas the standard model makes a vast number of detailed, testable (and tested) predictions.

15. **dan**
November 30, 2008

PW,
Do you support research aimed at writing down "full non-perturbative string theory"?

What can full non-perturbative string theory tell us that current perturbation series can't?

regards,
dan

16. **Peter Woit**
December 1, 2008

dan,

Sure, some people should continue thinking about this. The problem right now is that, besides gauge/string duality, no one has any very promising ideas. There are a long list of things that people would like string theory to do (provide a predictive TOE, a full quantum theory of black holes, a string dual to QCD, etc, etc.), but no one can tell whether this will work, because no one is sure what string theory "is", outside of perturbation theory. If that question had a definitive answer, one could start getting agreement on what string theory is good for, and what it isn't good for, which would be very helpful.

17. **Gordon McCabe**
December 5, 2008

Do anthropic explanations include cosmological natural selection (a la Lee Smolin)?

18. **hmmm**
December 5, 2008

Gordon McCabe Says: "Do anthropic explanations include cosmological natural selection (a la Lee Smolin)?"

No. Definitely not. They are completely different.

Anthropic explanations are more akin to postulating that the universe generates a huge number of random configurations of matter, some of which happen to be elephants.

Cosmological natural selection is more akin to the usual natural selection and its explanation for elephants.

19. **Highspin**
December 6, 2008

10^500 might be "the number of semi-realisitic vacua in ST usualy quoted", but this is the number of vacua in a more or less typical KKLT flux compactification senario. There are a possibly infinite number of Calabi-Yau's etc. that you could use to play that game. The question is then what are the superselection sectors, but no one knows that I guess…

Two years ago in Les Houches Summer school, Nima was still a very strong proponent of anthropic argument, and not only for the CC. It was fun listening to him, even a 3 in the morning, and it got me thinking a lot. I'm glad if he changed his mind though.

20. **Gordon McCabe**
December 7, 2008

I recognize that cosmological natural selection (CNS) is distinct from the anthropic principle (AP); in CNS, a life-permitting universe is a typical member of the universe population, whilst according to the AP, it is a very special member of the population.

However, I wondered if CNS falls under the aegis of anthropic explanations for the purpose of the arguments in this article. I'm thinking of the following:

"He also pointed out that if the landscape arguments were valid, the landscape would be disconfirmed by experiment, since 10-20 of the Standard Model parameters are unconstrained by anthropics, but take unusually small values, not the random distribution one would expect. Banks takes the attitude that the CC probably has an

anthropic explanation, but not particle physics or the SM parameters."

Can cosmological natural selection explain those Standard Model parameters, or does it leave them unconstrained, just like the anthropic principle?

21. **hmmm**
    December 7, 2008

    To Gordon McCabe:

    Good question, I don't know. You would have to go to the original source. I would guess there is much less written on CNS than (various versions of) AP.

    But I would think that for Standard Model parameters that are unconstrained (or loosely constrained), it wouldn't matter. Their values could drift (between generations) with neutral effect, and so CNS would not "explain" their specific values, nor would those values falsify or confirm CNS. (Just like selection-neutral genes.) There are still plenty of (SM and cosmological) parameters that could falsify CNS.

    I'm not an expert. I just read some things and formed my own conclusions.

Latest From the LHC

November 25, 2008
Categories: Experimental HEP News

A talk at CERN today by Jorg Wenninger gives an update on the problems at Sector 34 and more information about what the prospects are for restarting the machine next year.

The cause of the accident has been identified as excessive resistance in a busbar interconnection between two magnets. Looking at logged data from before the accident, evidence for this excessive resistance was seen. Checking all the other sectors, a hint of a similar problem was found in one other cell, and that dipole will be replaced.

50 magnets are in the process of being removed from Sector 34, all to be out by Christmas. To avoid future similar accidents, the quench protection system is being upgraded, and the commissioning procedures will include a systematic search for excessive resistance problems. These measures can be implemented before next summer. There is also a plan is to add pressure release valves on every dipole cryostat, but this is highly problematic since it will require warming up all the sectors and likely would not allow the LHC to run with beam during 2009. The summary for 2009 plans reads:

> Plan A:
>
> - Restart in (late) summer of 2009 with beam.
> - Beam intensity and energy limited to minimize any risk.
>
> Plan B:
>
> - No beam before a complete 'upgrade' of the pressure relief system is implemented on all sectors.
> - Excludes beam in 2009.
>
> Final decision in February?

On a more cheerful note, tonight PBS will be broadcasting a documentary about the search for the Higgs at Fermilab called The Atom Smashers. It looks like this program should be about 10^(10^5) times better than a recent one featuring theorists. One of the filmmakers has a blog here. With the LHC out of commission for a while, the Higgs search at the Tevatron is where the action is, and the experimenters there may be the ones to find the Higgs or rule it out.

Update: Two more recent presentations with information (including pictures!) about the LHC accident, repairs and plans for the future are here and here. For now, the plan is for the machine to be cold again next July.

Comments

1. **Thomas R Love**
   November 25, 2008

   Peter, Thanks for mentioning "The Atom Smashers". I checked the local listings and it is not playing, but it is available on DVD, so I shelled out $27.05 and hope to have it in a week.

2. **observer**
   November 25, 2008

   I tought that The Lorentz force and its consecuences (quenching, resistance and of course heating to name a few)were a solved problem, looks that it is not, well we have to wait how the upgrades go, is getting interesting now.

3. **Patrick**
   November 26, 2008

   The sentence "the experimenters [at the Tevatron] may be the ones to find the Higgs" could probably be rendered more acccurate by adding "or to confirm the LEP hints at a mass around 115-116 GeV/c2". Actually, if the Higgs boson mass *is* at 115 GeV/c2 (as current insignificant Tevatron excesses seem to point to;-), it is only through a combination with LEP that the TeVatron might be able to confirm the observation (with a combined significance of 3 sigma). It actually turns out that many of the Tevatron current experimeters were LEP experimenters in 2000, so it's probably what would happen in this happy situation!

4. **Roger**
   November 26, 2008

   If the Higgs were to be discovered by the Tevatron or Tevatron+LEP this would not be a happy situation, especially if no exotic physics was found at the LHC.

   We sold the idea of the LHC as a means of discovering the Higgs – for the sake of future funding it would be best if the LHC find it or disprove its existence.

   I realise, however, we live in the real world and I would be thrilled if the Tevatron picked the Higgs up first but this would cause problems later down the line when we ask for money for big projects.

5. **A.**
   November 26, 2008

   Sigh. I thought a bonus to landing another postdoc this year was that, as the LHC was coming online, I might still be in academia when the fallout of "we found/didn't find the higgs/susy" etc etc started up.

   Also, the incoming director general of Cern, Rolf-Dieter Heuer, gave a talk on the LHC, this week, in Dublin. You can now stream it from http://www.rds.ie/cern.

6. **Bont**
   November 27, 2008

   I couldn't find what is quoted here from 'talk at CERN today.' Was it updated recently?

7. **Peter Woit**
   November 27, 2008

Bont,

The information quoted was from around page 45 on that document. Right now it appears to be having trouble loading, presumably because it has been slashdotted

http://science.slashdot.org/science/08/11/26/2135203.shtml

8. **Bont**
November 27, 2008

Mr. Woit,

When I loaded it yesterday, that page didn't exist 🙂 Anyway, now it is available. Thank you very much.

9. **observer**
November 27, 2008

Off-topic but I am sure interesting. I just read in the news (canadian television) that Stephen Hawking is coming to the Perimeter Institute by January of 2009.

10. **Patrick**
November 28, 2008

To Roger:

If the LHC were not to discover anything new, I agree entirely that we would not be in a happy situation ! It would probably mean the end of particle physics, irrespective of anything else.

I disagree, however, on the fact that the LHC was sold to discover the Higgs. It was sold as an extraordinary step in energy towards discovery of TeV new physics. Let's put it right: as repeatedly demonstrated in the past 15 years, an e+e- collider with energy of the order of mH + mZ + 30 GeV would be in much better a position to discover and finely study the Higgs boson than any hadron machine ever. In this perspective, the sooner the discovery is confirmed, the better !

(Note: I am not a TeVatron experimenter, but an LHC experimenter, former LEP experimenter)

11. **Logan**
November 28, 2008

Hey I just found your blog and am pleasantly surprised. Thanks for letting me read your thoughts and ideas!
Good to know that the cause of the accident was found and that steps to prevent it from occurring again are being taken. It would be unfortunate if we didn't see another beam in 2009, but they gotta do what they gotta do.
Hahaha 10^(10^5) better? – looks like I should find a video of that broadcast! Thanks for the heads up.

12. **Clayton**
November 28, 2008

Hello — I'm one of the co-directors of "The Atom Smashers." Thanks for the link to my blog about the making of the film! I'm not sure about "10^(10^5) times better" than the other film you mentioned (that's quite a tall order), but I hope our film was enjoyable to those of you who watched. If you missed it, or are interested in buying a copy (the dvd for sale is the 73-minute "director's cut" with some extras, including the video Leon Lederman's made to try to convince Ronald Reagan to support the Superconducting Super Collider), you can do that by visiting our site at http://www.theatomsmashers.com. Also the film will be shown again on PBS on January 27.

We struggled with depicting many of the complexities of the fascinating search for the Higgs from the standpoint of Fermilab — it was a great story to tell with many interesting people and complex issues. We're interested to hear your thoughts.

13. **mike**
November 28, 2008

Maybe CERN can be convinced to double their efforts in bringing the LHC online sooner. An argument can be made that if landscape theory is proven with the LHC, we can then transport ourselves to a parallel universe where our trillion $ debt suddenly becomes a trillion $ surplus which will then pay for the additional time spent on the LHC. I think this is referred to in political circles as a self-fulfilling investment plan (or alternatively a scientific bailout)!

14. **SpaceTime**
November 30, 2008

Mini-blackholes http://www.aip.org/pnu/2008/split/871-1.html

The Atom Smashers did broadcast on our local OTA (Over the Air) PBS station here WPBT in South Florida but it played on an OTA digital only channel (2.2) so if your using cable/dish you may not get it. PBS often repeat shows on other digital channels and they also run on a sister station channel 17 WLRN.

This was an excellent show and pointed out the chronic anti-intellectual trend.

15. **Paul Collins**
December 3, 2008

It looks like access to the second presentation is restricted. The first one was very informative, however.

16. **woit**
December 3, 2008

Thanks Paul,

Linking from here to a previously public CERN source of technical information about the state of the LHC seems to often lead them to shut off public access. This is too bad. In the past, their policy was mostly to be very open with technical information about exactly what was going on at the LHC. It appears that this has changed, in response to the huge amount of press attention they are getting, and because of the accident this past September.

17. **Paul Collins**
December 5, 2008

Looks like the second one is available again.

From Quarks to Strings

December 2, 2008
Categories: Uncategorized

There's a new preprint on the arXiv from Polyakov, entitled From Quarks to Strings, in which he tells the story of his involvement with string theory over the years. He begins:

> In the sixties I was not much interested in string theory. The main reason for that was my conviction that the world of elementary particles should allow field theoretic description and that this description must be closely analogous to the conformal bootstrap of critical phenomena. At the time such views were very far from the mainstream. I remember talking to one outstanding physicist. When I said that the boiling water may have something to do with the deep inelastic scattering, I received a very strange look. I shall add in the parenthesis that this was a beginning of the long series of "strange looks" which I keep receiving to this day.
>
> Another reason for the lack of interest was actually the lack of abilities. I could not follow a very complicated algebra of the early works on string theory and didn't have any secret weapon to struggle with it.

After the asymptotic freedom breakthrough, Polyakov quickly saw that a non-perturbative understanding of gauge theory was needed. He (independently from Wilson) developed lattice gauge theory, but acknowledges that, unlike Wilson, he did not have the Wilson loop criterion for confinement. In 3d, he worked out the dual-superconductor picture, where monopoles are responsible for confinement, and he has interesting comments about efforts over the years to use instantons in 4d, something that works for the N=2 supersymmetric case (Seiberg-Witten, and Nekrasov), but not for QCD itself.

The strong-coupling lattice expansion was one thing that encouraged him to look for a gauge/string duality as a way to solve QCD. One idea was to write dynamical equations for the Wilson loop (later called Migdal-Makeenko equations) and find a solution to these as a path integral over surfaces, thus a string theory. About this he writes:

> This action is called now the Polyakov action, demonstrating the Arnold theorem,stating that things are never called after their true inventors.

He derived the critical dimension for the string, but was much more interested in trying to understand non-critical strings, especially the four-dimensional string as a tool for studying gauge theories, and the 3d string as a tool to solve the 3d Ising model. Later he realized that it was natural to think of the Liouville mode as a fifth dimension, and by 1996 was studying the idea of using warped 5 dimensions to get gauge/string duality. Here's how he describes what he was doing in the lead-up to the breakthrough by Maldacena which led to the AdS/CFT conjecture:

> At this point I was certain that I have found the right language for the gauge/ strings duality. I attended various conferences, telling people thatit is possible to describe gauge theories by solving Einstein-like equations (coming from the conformal symmetry on the world sheet) in five dimensions. The impact of my talks was close to zero. That was not unusual and didn't bother me much. What really caused me to delay the publication () for a couple of years was my inability to derive the asymptotic freedom from my equations. At this point I should have noticed the paper of Igor Klebanov in which he related D3 branes described by the supersymmetric Yang Mills theory to the same object described by supergravity. Unfortunately I wrongly thought that the paper is related to matrix theory and I was skeptical about this subject. As a result I have missed this paper which would provide me with a nice special case of my program. This special case was presented little later in full generality by Juan Maldacena and his work opened the flood gates.

He goes on to make some intriguing comments about the questions of integrability, and that of how to truly understand and derive gauge/string duality from first principles:

> The problem of reproducing gauge perturbation theory from the string theory side remains unsolved (and extremely important).
>
> Why should we care about the derivation from the first principles ? After all, in physics we value not so much the proved theorems but correct and powerful statements. However, in this case the lack of the derivation really impedes progress. We do not know how far the gauge /string duality can be extended and generalized. The enormous accumulation of special cases has been useful but not sufficient for deeper understanding. This is why I think that establishing the foundations is one of the most important problems in the field.

Polyakov seems to have always been a skeptic about the idea of using the 10 dimensional superstring to construct a unified theory, instead hoping that some understanding of the 4d non-critical string might lead somewhere. Like most string theorists, he takes the attitude that we need to wait for the results from the LHC and hope that a new clue will emerge and tell us how to make progress along these lines:

> As for the problem of string unification, it seems to me that non-critical strings may have some future. However, it may be wise to wait for some more information about Nature (specifically about supersymmetry) which we expect to get from the LHC.

Comments

1. **Shantanu**
   December 3, 2008

   Peter, do you know of or have you read anywhere about Polyakov's views/opinions about LQG?

2. **Peter Woit**
   December 3, 2008

   Shantanu,

   No, I've never heard anything about what Polyakov might think of LQG.

BRST News

December 2, 2008
Categories: BRST

I should finish writing the next installment of the Notes on BRST series soon, but thought I'd post here about two pieces of BRST-related news, concerning the "B" and the "T".

- The "T" in BRST is I.V. Tyutin, whose Lebedev preprint N. 39 from 1975 is considered to be one of the first uses of what was later to become known as BRST symmetry. This paper was never published and the preprint has not been widely available (in particular, I've never seen a copy of the original). This evening one of the new preprints in the arXiv hep-th section is a copy of the 1975 preprint, making it now available on the web.
- The "B" in BRST is Carlo Becchi, who together with Camillo Imbimbo has written an article on BRST for Scholarpedia entitled Becchi-Rouet-Stora-Tyutin symmetry. Scholarpedia has the interesting feature of making available (here) the discussion between reviewers and authors of the article, which can be enlightening.

   «in particular, I'd never seen a copy»

   typo?

2. **Peter Woit**
   December 2, 2008

   More like bad grammar or something… Will improve.

3. **pedant**
   December 4, 2008

   `I had never seen' is good grammar, since you did see a copy before writing this post. 🙂

4. **N. Nakanishi**
   December 5, 2008

   Previously, I discussed the literature concerning the names of BRS and BRST. See Opening Address — "BRS" OR "BRST" ? — of "BRS Symmetry, Proceedings of the International Symposium on the BRS Symmetry on the Occasion of Its 20th Anniversary Held in Kyoto, Japan, September 18-22, 1995" edited by M. Abe, N. Nakanishi, and I. Ojima. Stora's paper in this volume also contains his comment on Tuytin's work.

Notes on BRST VI: Casimir Operators

December 3, 2008
Categories: BRST

For the case of G=SU(2), it is well-known from the discussion of angular momentum in any quantum mechanics textbook that irreducible representations can be labeled either by j, the highest weight (here, highest eigenvalue of J_3), or by $j(j+1)$, the eigenvalue of $\mathbf{J\cdot J}$. The first of these requires making a choice (the z-axis) and looking at a specific vector in the representation, the second doesn't. It was a physicist (Hendrik Casimir), who first recognized the existence of an analog of $\mathbf{J\cdot J}$ for general semi-simple Lie algebras, and the important role that this plays in representation theory.

The Casimir Operator

Recall that for a semi-simple Lie algebra $\mathfrak g$ one has a non-degenerate, invariant, symmetric bi-linear form $(\cdot,\cdot)$, the Killing form, given by

$$(X,Y)= tr(ad(X)ad(Y))$$

If one starts with $\mathfrak g$ the Lie algebra of a compact group, this bilinear form is defined on $\mathfrak g_{\mathbf C}$, and negative-definite on $\mathfrak g$. For a simple Lie algebra, taking the trace in a different representation gives the same bilinear form up to a constant. As an example, for the case $\mathfrak g_{\mathbf C}={\mathfrak{sl}(n,\mathbf C)}$, one can show that

$$(X,Y)=2n\ tr(XY)$$

here taking the trace in the fundamental representation as n by n complex matrices.
One can use the Killing form to define a distinguished quadratic element Ω of $U(\mathfrak g)$, the Casimir element

$$\Omega=\sum_iX_iX^i$$

where X_i is an orthonormal basis with respect to the Killing form and X^i is the dual basis. On any representation V, this gives a Casimir operator

$$\Omega_V=\sum_i\pi(X_i)\pi(X^i)$$

Note that, taking the representation V to be the space of functions $C^\infty(G)$ on the compact Lie group G, Ω_V is an invariant second-order differential operator, (minus) the Laplacian.

Ω is independent of the choice of basis, and belongs to $U(\mathfrak g)^{\mathfrak g}$, the subalgebra of $U(\mathfrak g)$ invariant under the adjoint action. It turns out that $U(\mathfrak g)^{\mathfrak g}=Z(\mathfrak g)$, the center of $U(\mathfrak g)$. By Schur's lemma, anything in the center $Z(\mathfrak g)$ must act on an irreducible representation by a scalar. One can compute the scalar for an irreducible representation (π,V) as follows:

Choose a basis $(H_i, X_{\alpha},X_{-\alpha})$ of $\mathfrak g_{\mathbf C}$ with H_i an orthonormal basis of the Cartan subalgebra $\mathfrak t_{\mathbf C}$, and $X_{\pm\alpha}$ elements of $\mathfrak n^{\pm}$ in the $\pm\alpha$ root-spaces of $\mathfrak g_{\mathbf C}$, orthonormal in the sense of satisfying

$$(X_{\alpha},X_{-\alpha})=1$$

Then one has the following expression for Ω:

$$\Omega=\sum_i H_i^2 + \sum_{+\ roots} (X_{\alpha} X_{-\alpha} +X_{-\alpha}X_{\alpha})$$

To compute the scalar eigenvalue of this on an irreducible representation (π,V_{λ}) of highest weight λ, one can just act on a highest weight vector $v\in V^{\lambda}=V^{\mathfrak n^+}$. On this vector the raising operators $\pi(X_{\alpha})$ act trivially, and using the commutation relation

$$=H_{\alpha}$$

(H_{α} is the element of $\mathfrak t_{\mathbf C}$ satisfying $(H,H_{\alpha})=\alpha(H)$) one finds

$$\Omega=\sum_i H_i^2 + \sum_{+\ roots}H_{\alpha}= \sum_i H_i^2 +2H_{\rho}$$

where ρ is half the sum of the positive roots, a quantity which keeps appearing in this story. Acting on $v\in V^{\lambda}$ one finds

$$\Omega_{V_{\lambda}}v=(\sum_i\lambda(H_i)^2+2\lambda (H_{\rho}))v$$

Using the inner-product $< \cdot,\cdot>$ induced on $\mathfrak t^*$ by the Killing form, this eigenvalue can be written as:

$$< \lambda,\lambda>+2< \lambda,\rho>=||\lambda+\rho||^2- ||\rho||^2$$

In the special case $\mathfrak g = \mathfrak {su}(2),\ \mathfrak g_{\mathbf C}=\mathfrak sl(2,\mathbf C)$, there is just one positive root, and one can take

$$H_1=h=\begin{pmatrix}1&0\\0&-1\end{pmatrix},\ X_{\alpha}=e=\begin{pmatrix}0&1\\0&0\end{pmatrix},\ X_{-\alpha}=f=\begin{pmatrix}0&0\\1&0\end{pmatrix}$$

Computing the Killing form, one finds

$$(h,h)=8,\ (e,f)=4$$

and

$$\Omega=\frac{1}{8}h^2 + \frac{1}{4}(ef +fe)=\frac{1}{8}h^2 + \frac{1}{4}(h +2fe)$$

On a highest weight vector Ω acts as

$$\Omega=\frac{1}{8}h^2 + \frac{1}{4}h=\frac{1}{8}h(h+2)=\frac{1}{2}(\frac{h}{2}(\frac{h}{2} +1))$$

This is 1/2 times the physicist's operator $\mathbf{J\cdot J}$, and in the irreducible representation V_n of spin $j=n/2$, it acts with eigenvalue $\frac{1}{2}j(j+1)$.

In the next posting in this series I'll discuss the Harish-Chandra homomorphism, and the question of how the Casimir acts not just on $V^{\mathfrak n^+}=H^0(\mathfrak$

n^+,V), but on all of the cohomology H^*(\mathfrak n^+,V). After that, taking note that the Casimir is in some sense a Laplacian, we'll follow Dirac and introduce Clifford algebras and spinors in order to take its square root.

Comments

1. **Tony Smith**
   December 4, 2008

   Peter, will you be discussing the physical significance of all the Casimir operators of all groups used in physics model-building,
   or will your discussion be restricted to the quadratic Casimir ?

   Tony Smith

2. **woit**
   December 4, 2008

   Tony,

   The next topic, the Harish-Chandra homomorphism, deals with the story of the higher-order Casimirs. But after that, what I'm writing about deals with Dirac operators. In some sense, from then on, the story is about the square root of the quadratic Casimir, not the higher order ones.

3. **Coin**
   December 5, 2008

   Woit: Small note, looking at the listing for your BRST category I find that BRST IV got left out, you may want to fix that.

4. **James**
   December 8, 2008

   I'm sorely missing my usual fix of "scandal-mongering or stirring up trouble of one kind or another", and after some months of cold-turkey and BRST treatment, I wonder if you could explain the motivation, and long-term prognosis, of all of this group-therapy?

   As an outsider I would ask: is this some technique for creating new potential QM theories, or a way of quantising classical models, or to try to put existing QM theories on a surer maths footing, or is it just cute maths in itself?

5. **Peter Woit**
   December 9, 2008

   Coin,

   Fixed.

   James,

   I'm back from a trip, and have tried to do a bit more stirring up of trouble. Unfortunately, it's getting harder to stir up trouble in this area. Nothing much new is happening, and I and pretty much everyone else is tired of the same old topics.

   Now that I'm back, and classes are over for the semester, I'll try to pick up the pace, and get to the point with the BRST postings, ending with some more explicit speculation about what all this might be useful for. Still in the realm of speculation, it might be useful for getting some sort of new insight into the non-perturbative quantization of gauge theories such as the standard model, as well as useful in purely mathematical problems about representation theory.

6. **D R Lunsford**
   December 15, 2008

   Peter, am I right that SO(3,3) has Casimirs of rank 2,3, and 4? Looking forward to the next installment.

   -drl

7. **woit**
   December 15, 2008

   drl,

   The Lie algebra of SO(3,3) is a real form of the Lie algebra of SO(6,C)=SL(4,C). Just finished writing up the next posting, where I at least mention that the higher Casimirs of sl(n,C) are of degree, 2, 3, etc. up to n, so, yes in your case they are of degree 2,3 and 4.

Educational Malpractice

December 9, 2008
Categories: Uncategorized

According to the New York Times, Scarsdale High School has decided to get rid of their Advanced Placement classes, including AP Physics, replacing them with a new curriculum that cost "$40,000 to bring in 25 professors from Harvard, Yale, New York University and other top colleges."

> "We have the luxury of being able to move beyond the A.P.," John Klemme, Scarsdale's principal, said in a recent interview. "If people called it a gold curriculum in the past, I refer to this version as the platinum curriculum."

What's the change in this new "platinum curriculum" as far as physics is concerned?

> Physics students now study string theory — a hot topic in some college courses that is absent from the Advanced Placement exam.

Comments

1. **rrtucci**
   December 9, 2008

   It's a smart move. By the time these kids graduate, investment banking will be in vogue again.

2. **Charles Siegel**
   December 9, 2008

   …I assume this is an "ideas in physics" type of course they're running, with no math? Because if they aren't even doing AP Physics, how the hell are they doing String Theory? Even the simplest non-popular accounts require quantum mechanics…

3. **A.J.**
   December 9, 2008

   The NY Times article doesn't really offer enough information to draw any firm conclusion. I'd guess that the regular physics course is spending a few weeks at the end sketching contemporary topics, and that this has been sexed up to "studying string theory" for the purposes of the article.

4. **Thomas R Love**
   December 9, 2008

   Like this site, the high school classroom is not "a place for people to promote their favorite ideas about fundamental physics."

5. **Peter Woit**
   December 9, 2008

   Charles and A.J.,

   I couldn't find a syllabus on the Scarsdale site for the physics class, so I don't see support for either of your conjectures. It seems that what this is all about is that many high school teachers are unhappy with being forced to teach to a rigid syllabus set by the AP exams. These new courses are meant to replace AP courses, with the students often taking the corresponding AP exams anyway. So, presumably this is not a "no-math" course. No idea how much time they devote to string theory, hard to believe it's a huge part of the course.

   One does wonder whether teaching string theory in a high-school AP-level class is the idea of the Scarsdale physics instructors, or the consultants hired by the school district.

6. **Rob**
   December 9, 2008

   Folks, I think teaching "string theory" – whatever that might mean in high school – is really besides the point. Scarsdale deserves praise for phasing out the ridiculous AP curriculum and actually teaching kids something meaningful beyond how to, you know, memorize facts and best use practice exams. Besides, pretty much every reasonable university has 'exposure' courses in something like string theory/complexity theory/what have you.

7. **Peter Woit**
   December 9, 2008

   Rob,

   If Scarsdale wants to abandon the set AP curriculum and do something better, that's fine. But, if their idea of something better is to feed trendy hype to their students instead of solid science, which is what they are doing if they are replacing conventional topics with "string theory for high school students", then that is educational malpractice.

8. **Rob**
   December 9, 2008

   Peter,

   If I had to guess, I'd say that they offered up "string theory for high school students" as a sound bite for the usual bad reasons. If they are indeed teaching a 'Scientific American-esque' course on string theory, rather than a fancy sounding low-level physics or mathematics course – yes, that's a serious issue. That said, I don't see a problem with something like an optional lecture series on the topic (not that kids are going to get anything out of it).

   They should teach a good course on quantum mechanics or stat mech. It (1) – would sound catchy, (2) – would be accessible enough for high-schoolers, and (3) – would be really useful for most future scientists and engineers.

9. **Rob**

December 9, 2008

Rather, the knowledge in those areas would be "…really useful for most future scientists and engineers." I have some doubts about a class for high school students.

10. **GR**
December 9, 2008

I can't imagine this working, at least not without some serious changes to the whole curriculum. As I recall, AP Physics was a constant struggle for the teacher to teach the calculus the students should have received in their math classes.
I don't really understand the scorn that is heaped on the AP curriculum, especially in physics. It seems that a lot of it comes from people who never actually took an AP class? In my view, it's a fairly solid curriculum which covers basic mechanics and E&M. And it was a challenge to fit all that in one school year. The exam isn't bad either, and unlike the dreaded GRE actually has some questions which aren't multiple choice.
I think a lot of it has to do with the quality of the instructor, and the lack of high school teachers with dedicated physics backgrounds. I was fortunate enough to go to an excellent (public) high school, which had one of the only two teachers in the STATE who were certified to teach actual physics, not just "science". I was also fortunate enough to take an International Baccalaureate (now that really ought to be the "beyond the AP" curriculum, but that's a whole other discussion) physics class after AP which went over waves, stat mech, and some basic quantum.
That's the sort of thing students need: an AP class to teach the basic fundamentals and only after that classes that teach more contemporary topics.

11. **D.**
December 9, 2008

I doubt they're getting more than a day or two of string theory.
Just for background, Scarsdale is one of the best public high schools in the country, and has long employed PhDs to teach their math & science classes.
Students there have structured their lives to be attractive to good schools, so if this change somehow harms test scores or admissions rates it will immediately vanish.

12. **Jack Lothian**
December 9, 2008

As an aside, at different times my wife has been a director of a neighboring school board and the chair of our local school board. Her experience is that many parents are obsessed with high math & science marks for their children but most do not actually value what their children learn in these classes. There is constant pressure from parents, teachers and students to dumb down these subjects so students can get better grades. In her experience, individual weak teachers are not the focus for most parent complaints. As long as the students get good grades everything is OK with most parents. Tough teachers or tough exams are the flash point for almost every crises my wife has faced concerning these subjects. I am sure there are some over-the-top teachers & exams but it is strange that my wife has never received a complaint about a teacher or exam that doesn't challenge the students enough. How relevant this point is to the discussion I do not know but I do know science and math is constantly under attack in our public schools.

13. **JC**
December 10, 2008

Jack Lothian,

This exact same thing has been happening in community colleges too. Students and their "helicopter parents" will revolt and try to get the tough instructors fired. Frequently the tough instructors will get several reprimands from the administrators, before eventually being fired for being "too tough".

Though back to the subject, string theory has not been mentioned at all in the physics courses taught at community colleges. (Not even by instructors who are believers in string theory).

14. **Jake the Snake**
December 10, 2008

They are teaching string theory to high school students? Oy! What is the woild comin' to?

The string theorists are really getting desperate. I always thought that contemporary theoretical physics was beyond the grasp of even many of the brightest high school students. To truly understand and appreciate Newtonian physics, one needs a background in calculus, and most American high school students do not learn calculus until senior year if at all. (The concepts of Newtonian mechanics are simple enough that calculus or any higher math is unneeded. Entry-level algebra would suffice, but to get a good working understanding requires analytical geometry and calculus and the like.) Not to mention such 20th century theories as quantum mechanics or relativity theory.

To truly understand higher physics would require not only advanced algebra, analytical geometry, probability, statistics, calculus, etc. but discrete mathematics, matrix operations, linear algebra, differential geometry, and the like. High school students should be able to understand the basics of quantum theory, especially as it applies to chemistry, but relativity requires very advanced geometries! Relativity would not make sense within Euclidean geometry. To say nothing of string theories with the many warped dimensions…

As I understand it, AP type physics courses generally cover advanced Newtonian physics with introductory lessons on relativity and quantum physics. They might explain what special relativity postulates or the meaning of E=mc^2 for instance. A high school level course might be set up as "Fundamentals of Modern Physics" (i.e. quantum theory, relativity), but without the math and physics background, such courses would be pop-sci introductions. Such an approach would be acceptable for more established theories such as relativity or quantum mechanics, but it would be a bad idea to apply said format to controversial theories like string theory and its variants. If you ask me, assuming it is true that high school students study string theory, it looks like these kids are being indoctrinated into the string cult.

Regarding what Thomas R. Love said, it seems apparent to me that he is a disgruntled string theorist displeased with your blog. After all, he accuses you of censorship, claiming, "[this site] is not a place for people to promote their favorite ideas about fundamental physics," implying that you stifle dissenting viewpoints. While I support his right to comment, I would disregard that statement. Dr. Woit, your blogging does a great service to the physics community. Keep up the good work!

15. **woit**
December 10, 2008

Jake,

Thomas Love is not a string theorist. I certainly do stifle certain kinds of dissenting viewpoints, ruthlessly censoring comments that are off-topic and go on about the author's favorite ideas. On the whole, I think people appreciate this policy…

16. **Mitch Miller**
December 10, 2008

I don't think we can put too much stock in an article that describes string theory as "a hot topic in college courses."

17. **Thomas R Love**
December 10, 2008

Jake the Snake: the phrase: "a place for people to promote their favorite ideas about fundamental physics." occurs just below "Leave a Reply".

I was just quoting Peter. His book is a must read for any aspiring physicist.

To call me "a disgruntled string theorist" is an insult. I do mathematical physics. String theory is not physics. It is not even sound mathematics.

18. **somebody**
December 10, 2008

I agree that it would be horrible to feed the kids Kaku-style nonsense. But if at all they are to hear *anything* about the frontiers of theory, it is reasonable that they hear about string theory. The most reliable judge here is the consensus of the scientific community (NOT consensus among ignorant haters, like we have on this thread). Even if we believe that Peter is a messiah who could look into the future, at this point in time, the reasonable thing to teach kids is the consensus of the community, not the views of a minority of dissenters. The discussion here would have more content, if it focussed on the hype aspect rather than on teaching string theory altogether.

19. **Peter Woit**
December 10, 2008

somebody,

I agree with you that the consensus of the scientific community should be a deciding factor here. This is not the same thing as the consensus of the string theory community. From talking to many, many scientists, my impression is that the consensus of the scientific community is that the picture of unifying particle physics with strings in extra dimensions is a very speculative idea that doesn't seem to be working out. This is not what "dissenters" think, this is what most physicists who are not string theorists think. Even among string theorists, I see an increasing number who have given up on string theory for unifying particle physics, instead seeing it as a tool for studying strongly coupled qfts, and as a toy model for understanding issues in quantum gravity.

There are several different problems with the idea of teaching string theory in high school, but one of them is precisely that the speculative picture of unification still vocally promoted by an increasingly small number of physicists does not have support from the rest of the scientific community.

20. **Jake the Snake**
December 10, 2008

To Peter Woit and Thomas. R Love, I apologize for the misunderstanding.

Mr. Love, I'm sorry that I misunderstood your above comment. I was not aware of your meaning as you did not provide the context. I did not know it was a Woit quote. I thought you were insinuating that Woit CENSORS differing viewpoints (i.e. string theory), as opposed to applying skepticism to FILTER out bad ideas, and you were implying that he similarly wanted to keep string theory out of the classroom for ideological reasons.

I took you for someone on the side of Lubos Motl, not our side. As it turns out you are not a string theorist (thank you for clarifying) and, the quote in context means that the classroom, like this blog, should be "no-nonsense zones." What I took to be anger or displeasure at string theory being excluded was in fact agreement that certain ideas are not appropriate. Correction appreciated!

Dr. Woit, I appreciate the reply. First off, this is your blog and your right to moderate comments. I do not believe what you do is "censorship" so much as "filtering." I agree that irrelevant and off-topic comments, or messages that are disrupting are fit for deletion. I am sorry I did not understand Thomas' comment.

21. **David Metzler**
December 10, 2008

As a math Ph.D. who teaches math and physics in high school, I am curious about the proposed Scarsdale curriculum, and in what way it is supposed to be superior to the AP curriculum. I agree with various previous comments that the string theory part is unlikely to be more than a tiny part of the course, and was hyped in the article by someone who thought that it was a major selling point.

Rob, I wonder exactly why you think the AP (Physics) curriculum is ridiculous. I'm not wedded to it, and I do dislike the rigidity, but I can't say that it emphasizes simply memorizing facts…could you elaborate?

For those who don't know, I'll note that there are two AP Physics courses: AP Physics B is a non-calculus based course, which covers basic mech and E&M as well as a smattering of waves, fluids, and modern physics. I haven't taught that one. AP Physics C covers less material—just Mech and E&M—but uses calculus (which is usually taken concurrently—tricky but manageable) and makes students work deeper and more involved problems.

22. **MathPhys**
December 11, 2008

They may be using the words "string theory" in a very general sense. They may start with something on the electromagnetic interactions and gravitation. Followed by something on the nuclear forces, then the idea of unification (which would allow them to include some basic mathematics, group theory, etc). It doesn't have to be too bad.

23. **somebody**
December 11, 2008

Peter says: "This is not what "dissenters" think, this is what most physicists who are not string theorists think."

Looks to me like you are trying to do a statistics of the high energy community, AFTER excluding the string theorists. Isn't that the same thing as putting in your answer by hand? Besides, I am not willing to take your anecdotal evidence (that you know "many, many scientists" who are against string theory) at face value. A much more objective measure is the preprints that turn up on hep-th everyday. The overwhelming majority of them are string-inspired.

Also I want to emphasize that the relevant consensus here is that of the people who are competent enough to understand the problems and merits of the various ideas in high energy theory. NOT the generic scientific community. (nobody asks particle physicists about plasma physics, if you notice). And within the high energy community, it would be ridiculous to claim that string theory is not a major theme, because your blog itself is afterall a dissent against this consensus.

So again: if at all the kids are to hear *anything* about the frontiers of fundamental physics, it is reasonable that they hear about string theory. It is one thing to emphasize that the theory is tentative, quite another to turn it into a war against tentative ideas. It is precisely the ideas that are not fully understood that trigger the imaginations of both a seasoned researcher and a beginning student. People who are trying to make the curriculum "safe" are not getting what drives human curiosity. Me, I see nothing wrong with a little mention of string theory in school, as long as it is not hyped up drivel.

24. **Peter Woit**
December 11, 2008

somebody,

Despite what string theorists like to think, there are many physicists and other scientists competent to evaluate whether the idea of string theory unification has had any success or not. Even if one is not an expert in the technicalities of a subject, one can listen to the case made by its proponents, and see what evidence they put forward. Here, it is inarguable that 25 years of intense effort has led to absolutely zero in terms of predicting anything or explaining anything about beyond the SM particle physics. Any competent scientist can read books like Susskind's "Cosmic Landscape", and see that the subject is at a dead end.

This is the problem with promoting teaching string theory as the "frontier" of the subject. It may be be interesting, but it's not a good use of high school student's small amount of time studying science to be explaining a complicated speculative picture that doesn't work. The problem isn't just with the fact that if people do this, they will hype the subject, the problem is with the whole idea.

25. **somebody**
December 11, 2008

I gave you an objective way to measure the opinions of the hep-th (NOT string) community: papers everyday on the arXiv hep-th. You say that people n other fields of physics who get the story of string theory from popular science books should also count. I simply disagree. This is not how it is ever done in any other field, so why should high energy theory be a popularity contest? Expertise counts!

Once again: My claim is that if we plan to teach high school students something about the cutting edge of fundamental physics, the scientific consensus that string theory is relevant should not be ignored. You keep repeating your opinions as though they were facts, but that still does not make them the opinions of the community.

26. **Somebody else**
December 11, 2008

Somebody,

The consensus of the scientific community is that 'string theory' is just speculation until there is some experimental evidence for even a small part of it.

Here by 'scientific community' I mean something broader than 'high energy particle theorists', but not much broader than 'professional physicists' (surprisingly to some the preceding two categories are not the same).

There are thousands of scientific ideas that ought to be presented to high school students before they are exposed to something like string theory.

27. **Peter Woit**
December 11, 2008

somebody,

If you talk to your non-string theorist physicist colleagues, I think you'll find that their sources of information about string theory range from popular books to colloquium talks by string theorists to having taken a course on the subject to having worked on it and stopped. I also think you'll find a great deal of resentment about the way string theorists are dealing with their own failures by telling their colleagues that they are just too ignorant to appreciate what they are doing.

The bottom line here is that, after 25 years of intense work, there is zero evidence for string theory unification. You don't have to be an expert to understand that this is not a promising situation, or that this is not something you want to present to high school students, unless you're trying to teach them about the sociology of science, not science itself.

28. **anon.**
December 11, 2008

Now I'm tempted to start a blog dedicated to complaining about how, after 20-odd years of work, there has been no definitive success in building a theory of high-Tc superconductors. What are these condensed matter theorists wasting their time on, anyway? They better not try to tell me I don't have the expertise to judge them.

29. **Coin**
December 11, 2008

anon: One obvious difference here is that there is experimental proof high-tc superconductors actually exist.

30. **Peter Woit**
December 11, 2008

anon,

I haven't noticed condensed matter theorists with unsuccessful high-Tc superconductivity models trying to get them taught in high school…

31. **Thomas R Love**
December 11, 2008

This from Zwiebach's "A First Course in String Theory":

"When we think about teaching string theory at the undergraduate level the main question is "Can the material really be explained at this level?" …the basics of string theory can be well understood with the limited tools acquired in the first two or three years of an undergraduate education.

…A First Course in String Theory should be accessible to to anyone who has been exposed to special relativity, basic quantum mechanics, electromagnetism and introductory statistical physics.

While the mathematics for string theory is discussed at

http://www.superstringtheory.com/math/index.html

This includes real analysis, complex analysis, group theory, differential geometry, Lie groups, characteristic classes, homotopy, , fiber bundles and more.

I seriously doubt there is any high school student with this background in physics and math.

32. **Yatima**
December 11, 2008

I remember, 20 years ago, reading high-level overflight articles about string theory in "Science & Vie". Meanwhile: learning the basics of calculus, complex and real analysis in advanced math courses. Fighting english and french grammar. Studying the causes of WW1 (yes, really). Reading mandatory novels for literature classes. Cramming (really badly taught) economics 101 for the 'bac. … And our physics teacher frantically trying to give us a 1-hour overview of things not seen in the classroom before students left for exams and the wider world beyond — the ones seen being mechanics, heat, LCR electronic circuits (no memristor yet), simple Newtonian mechanics and the Compton effect – with the mathematics just starting to be useful. Ah, youth.

String Theory? Under these circumstances? Shurely not.

33. **srp**
December 11, 2008

I believe you could teach some real high-energy physics in high school if you cut into the subject the right way. In college (about thirty years ago) a visiting professor named Irving Reichert taught our "Physics for Poets" class out of his manuscript for an innovative introductory textbook. The main idea was to teach the correct physics at the particle level first by focusing on the basic known conservation laws (momentum, strangeness, charge, etc.). Special relativity was assumed from the outset. Typical problems were about particle collisions and what could go in or out from different interactions, how to interpret bubble chamber data, etc. (This was all handy when we took a field trip to Brookhaven–we had some idea what all that gear was for.) Lots of high-school algebra was involved, but nothing more advanced.

One of his pedagogical points was that he could do quite a lot without having to use any calculus (even though I was taking multivariable calculus at the time). Another was that students who had been excited by media reports of cutting-edge discoveries in high-energy physics were turned off by intro courses' usual diet of frictionless blocks sliding down planes and so on. A third was that the Newtonian stuff was an approximation so why start with that? (I should point out that he was not a high-energy guy himself–I think he told us he worked on the magnetic behavior of electrons in helium and could do his experiments on a tabletop.)

I've never been able to find his textbook, so perhaps it wasn't published. He was a heck of a teacher, though, and I appreciated his innovative spirit. In any case, he showed that you could teach high-energy topics in a more-than-superficial manner without advanced math.

34. **J.F. Moore**
December 11, 2008

David Metzler alludes to this above (and as an AP teacher he clearly knows), but I thought I would clarify since some people seem to have the wrong concept of what AP Physics C (the calculus-based one) is: There is no modern physics taught at all, certainly no quantum, no relativity, not even optics or stat mech. There's no time. It could be the students' first physics class, and half is devoted to mechanics and half to E&M. It is supposed to be the equivalent of a rigorous freshman college series, not some overview of 'exciting topics'.

While there may be room at some high schools for more advanced physics, it seems silly to replace a foundation class.

35. **AngryPhysicist**
December 12, 2008

Hmmm…yes, well, call me old fashioned, but wouldn't it be better to ditch the AP in favor of actual college undergraduate level physics? You know, the good old Lagrangian and Hamiltonian formulation of mechanics, thermodynamics, classical field theory, electromagnetism…the good stuff!

There really is no need to be teaching string theory at all (I think some of the comments above more or less overlooked that point of view — ditching the AP is not bad, but replacing it with string theory should be seen even by string theorists as nonsensical; why not teach them quantum physics before classical?).

36. **David Metzler**
December 12, 2008

Thanks to J.F. Moore for the expansion/clarification of my comment. I'm a bit confused by AngryPhysicist's comment; AP physics is intended to be (and, if taught well, is) equivalent to standard college freshman physics, not the more advanced treatment he alludes to, usually taken in the junior year. That would be quite a tall order for a high school class.

One thing that's very important to remember in discussing freshman/AP physics is that most people taking such a class are not going to be physics majors, much less physicists. The majority will be engineers, or other types of scientist. Hence there are two strong motivations for spending a lot of time on blocks and pulleys (which a previous commenter seemed to suggest was boring). First, even for future physicists, you have to start with familiar examples to build intuition about Newtonian mechanics, before you go to Hamilton/Lagrange, much less QM. Second, I really want the guy building the bridges to understand that stuff!

37. **AngryPhysicist**
December 13, 2008

The AP subjects don't handle things such as Lagrangian or Hamiltonian mechanics, much less classical field theory! Consider discussing symmetries of a classical system using diffeomorphisms much less! So why would you skip this to go to string theory? Especially since everyone acknowledges these subjects are fundamental to more advanced physics.

That's why I remarked "Why not teach them quantum mechanics before classical mechanics?" It makes no sense to teach them string theory without having them know the basics of quantization of gauge systems and general relativity, which requires knowledge of quantum theory and classical field theory, which requires knowledge of the Lagrangian and Hamiltonian formulations of mechanics. To just skip all this is nonsense.

So is it good to abandon the AP? Well, I think the entire public education system in the US needs to be completely redone…so it's a moderate step forward. Is it sensible to replace AP physics with lectures on string theory? Not in the least.

(By the by, the "intention" is to have the AP be "equivalent" to college work just like how eating out of a dumpster is "equivalent" to being inoculated.)

38. **somebody**
December 13, 2008

"The AP subjects don't handle things such as Lagrangian or Hamiltonian mechanics, much less classical field theory! Consider discussing symmetries of a classical system using diffeomorphisms much less! So why would you skip this to go to string theory?"

I think the purpose of teaching something like this is not to leave the students powerful enough to start computing, say, scattering amplitudes. It is merely to let them know that physics is not a finished business. You don't have to be able to talk string theory, in order to talk *about* string theory. The value is more inspirational, in order to emphasize that there are plenty of questions (that are not merely details), which we still don't understand. As a kid, I distinctly remember being fascinated by the idea that general relativity was not consistent with quantum mechanics and that resolving this puzzle might be at the heart of resolving the puzzles behind big bang and black holes. I think this is the kind of context where one could drop a line about string theory in a high-school curriculum.

Back to Peter and the blind-leading-the-blind debate:

THE overwhelmingly major candidate for the cutting edge of fundamental theory is string theory, despite repeated claims by Peter otherwise. You cannot simultaenously make the claim that departements all over are being hijacked by string theory, while at the same time claim that string theory is not popular. It is simply ridiculous, no matter how many of your devoted followers here agree with you. Facts are simply not decided on the basis of democracy. About whose consensus is relevant: I am old-fashioned with these things and have to stick with my claim – that high energy physicists are better qualified to judge high energy physics, than people who have learnt about it from popular books and expositions. Shrug!

39. **Pawl**
December 13, 2008

Somebody, Anon.,

You are correct that facts are not determined by democracy — but that also means they are not determined by which research groups have the most members, nor by how many arxiv papers there are. They are determined by nature.

String theory, despite its mathematical successes, and the extraordinary cleverness its researchers have shown at working on its internal problems, has very little to show about physics beyond the speculative.

There has also ben a considerable lack, until recently, of frank self-criticism within string theory. There are plenty of statements from prominent proponents of string theory which reflect very poor judgement in this regard. So the credibility of judgments by the in group has been seriously cast in doubt by their own actions.

If you want to defend string theory at this point, it would be best to explain exactly what you are defending, and what previous claims you think were excessive. Remember, most of us have in mind overblown prior claims, statements by prominent string theorists to the effect that nothing but string theory can possibly be right (and so work on other approaches ought to die out), that wherever string theory leads (e.g., the landscape) must be right, etc. — which many of us feel are indefensible positions.

40. **Jonathan Vos Post**
December 13, 2008

Meanwhile India and Pakistan and China and Iran are teaching according to a "Plutonium Curriculum." As someone planning on a second doctoral program, namely a Doctorate in Educational Leadership, I find the American position indefensible, in both scholarly and Pentagon senses of the word. India had a multiverse theory, in Sanskrit, a millennium ago. Now, instead, they have more computer programmers than does Silicon Valley, and an Indian flag on the Moon (with the Chandrayyan-1). China had the theory that there were innumerable planets in the universe, then moved on — and had their first "space-walk" this Fall. We do not have the luxury to gaze into our stringy navels. There is a real world, with real competition.

41. **themanwithaplan**
December 13, 2008

"and the extraordinary cleverness its researchers have shown at working on its internal problems"

You take out Witten, Vafa, and a few others, and their cleverness probably goes below the average in sciences!

42. **somebody**
December 14, 2008

Pawl says: "You are correct that facts are not determined by democracy — but that also means they are not determined by which research groups have the most members, nor by how many arxiv papers there are. They are determined by nature."

I am with you till here.

Pawl continues: "String theory… has very little to show about physics beyond the speculative. etc. etc."

Now you see, this is no nature's truth, this is merely your opinion, presented as a fact. And therein lies the rub. When we want to make a policy decision, like what to teach students etc., the closest thing we have to nature's facts are the collective opinions of the relevant group of specialists, not yours or my oipinion. ArXiv etc. are good objective measures of this collective opinion. Replacing that with a more coarse (unspecialized) form of democracy, is what I am against.

About your other comments: Since you have made an effort to be reasonable, I will return the favour and respond to them as reasonably as I can. I think these are precisely the kind of questions asked by people who are not directly involved with the premises and challenges of high energy theory, so it might be useful to answer them. But these are off-topic (in as far as any discussion of the string controversy can be off-topic on this blog), so I will post them as a separate message.

43. **MathPhys**
December 14, 2008

While all of us are painfully aware of the severe shortcomings of string theory on the experimental verification front, there is simply no denying its incredible attractiveness to intelligent young people, who are too idealistic to study anything that would prepare them for a job and want nothing other than to learn the most fundamental physics. Every teenager/20 something believes that maybe he/she will crack the problem.

Over and over and over again, young people keep on approaching me saying "I want to learn string theory. Where should I start?"

Under the circumstances, all I can do is to make them aware of its problems, aware of the job prospects, then tell them about the 5 or 6 basic textbooks on string theory and hope that at least they will learn some conformal field theory and/or get a global view of modern mathematical physics.

We can use string theory as an excuse to introduce an incredibly large amount of very good mathematics and mathematical physics.

44. **somebody**
December 14, 2008

Dear Pawl, you say that string theory is speculative. But what exactly do you mean by "speculative"? In my opinion, string theory is probably THE most conservative extension of well-understood physics. It contains only the most well-accepted ingredients of physics (like say Feynman diagrams), with a single extra piece: that particles are extended strings. Everything else follows automatically (if one is infinitely smart).

I think what you might possibly mean by "speculative" is not so much that the theory is full of ad-hoc constructions, but that some of the *solutions* of the theory could give rise to a lot of exotic physics, like branes and extra dimensions and what not. (Incidentally, notice how this question is subtle and requires some training to even pose correctly.). But having exotic solutions is not an unknown situation in physics. General relativity has them too. This is hardly a reason to discard it without further thought.

The way I look at it, the experimental difficulties with string theory are basically a problem that ANY theory of the Planck scale will have to face. The real question, which gets usually drowned in the caricatured attacks, is whether we know enough to extrapolate to Planck scale from what we know at low energies. I personally think it is NOT ad hoc speculation to extrapolate, but again, this is precisely the question that I think requires some expertise to form a fair judgement call.

Now, about self-criticism in string theory. Here I think you are confusing two closely related, but fundamentally different phenomena. I think you are conflating the public hype of string theory in the media with the workings within the community. Again, the hep community is a LOT more stringent than what one might think from reading about string theory in the popular media. I cannot think of even one idea that got popular, which was accepted without sufficient scrutiny. Every SINGLE valid criticism of string theory (and its resolution) has come from *within* the community, not from outside, as many people would like you to believe. In particular, I think Smolin and Woit did a good job of counterbalancing the hype, but scientifically, there were absolutely no surprises from either of them. There are even main-stream figures who are vocal against some of the widely held notions within the community. Like Tom Banks. They are not booed out of court, but that is because they have more than superficial things to say.

About previous excess claims by string theorists. This is again a hype issue and a phenomenon you can only see in the public media. Within the community, the amount of attention an idea receives has always been roughly correlated with the intrinsic value of the idea, and has never been dependent on the hype. Most of what goes as tall claims in the media, did not get much traction within the community. In fact I cannot think of even one example for that happening. For instance landscape statistics gets an inordinate amount of attention in the media, but most people within the community are not really into it, because they would like to have a better way to pose the problem. Landscape is something we still don't understand well in string theory, but usually not for the reasons that it gets bashed for, in superficial debates.

PS: By the way, Peter, I have to say that I respect your integrity when posting these comments. My previous message actually got stuck in the wordpress filter, and I was worried that maybe you censored it, but happily, you liberated it. Despite the fact that I disagree very much with you on much of your views on string theory (while agreeing very strongly with you when you fight the string hype), it is refreshing to know that you are not going down the easy path of censoring stuff – which is a trap very easy to fall into. Of course, this does not mean that I am going to go easy on you in the future, ha! Cheers and respect!

45. **ex AP student**
December 15, 2008

I'm a mathematician who took AP "Physics C" decades ago.

For those not in the USA, "AP physics" means a calculus-based one year class in Newtonian mechanics (no Lagrangians or Hamiltonians) and basic electromagnetism. The standard textbook was, and as far as I know still is, Resnick & Halliday.

The real problem with both the physics AP and whatever Scarsdale etc might replace it with, is that (1) the mathematical prerequisites are acquired concurrently rather than in the preceding year, and (2) the nominal prerequisite in physics (a qualitative, non-calculus one year class in physics standard in US high schools that offer AP Physics) is a joke and completely superfluous for the AP material. What works much better is to eliminate the year of joke physics entirely and replace it with a full year of calculus (in AP terms, "Calculus BC").

46. **Pawl**
December 15, 2008

Dear Somebody,

I very much appreciate your continuing this dialog thoughtfully. You raise quite a few points, and I will do my best to respond relatively briefly.

It's curious that you take issue with the statement that string theory has little to show about physics beyond the speculative, to the point you doubt whether we mean the same thing by "speculative." As I noted before, string theory does have mathematical successes, and it has internal successes — remarkable cohesions, etc. But it hasn't had any predictive successes, which is how we usually judge physics.

So I would say that all of string theory's contributions to physics are speculative — inspired guesses, which may or may not turn out to be right. (And the track record in science is of course that far more speculations — even beautiful ones — turn out to be wrong than turn out to be right.)

Your comments lead me to think you don't really think of string theory as speculative in this sense. (And that would explain much of the rest of what you have written.) So I am going to speak to that. I don't want to trash string theory as an approach to quantum gravity, because I do think it is a reasonable one to investigate. What I am arguing for is viewing its prospects reasonably.

To begin with, it is very rare in physics that fundamental theory can make much progress without experimental input. We simply are not clever enough to anticipate what nature will do most of the time. Moreover, it is very rare to be able to successfully guess what will go on many orders of magnitude from what has been experimentally investigated. There are simply too many ways nature can surprise us in the intervening regimes. So the fairest evaluation of **any** theory of Planck-scale quantum gravity would be considerable skepticism.

As to string theory particularly, again, reasonable people can work on it, but there are also good reasons for thinking that it may well be entirely misdirected. As you say, it is rather conservative in some respects. Its basic physical idea — moving from point to string (or brane) interactions — seems hardly to be the sort of profound insight that one would expect to be the lynch-pin of a successful theory of quantum gravity. (Compare, for instance, the sorts of wrenching new physical insights which went into creating quantum theory and relativity.) Too, its premise is that one can quantize gravity without centrally dealing with interpretational issues in quantum theory. That might be true, but it could also very easily be wrong. And the reliance on supersymmetry and extra dimensions — well, that just might be wrong, too.

The point here is not to discard string theory (although, again, the only fair assessment of **any** theory of quantum gravity at this point is that it is likely to be wrong). The point is that other approaches should be investigated. This has sometimes been acknowledged by string-theorists, but the demographics of the subject (who is hired, what the standards of review are) tell a different story. Very nearly all of the quantum-gravity eggs have been put in one basket, and that is simply the wrong strategy for the community to adopt. And they've been put in that basket because of aggressive actions from the top of the string-theory community. The effect may well be to have made the world safe for string theory, but to have retarded the prospects for getting the right quantum gravity theory.

The general mode of proceeding in string theory has been copied from particle physics, for obvious historical reasons. That is, write down Lagrangians, do path integrals, don't worry too much about foundational questions. That worked in particle physics, partly because it all turned out to be quantum field theory, but more because there was a continual confrontation with experiment which weeded out a lot of erroneous theories. (But even there, the weeding was slow, and at many times progress was very hard.) But it's not at all clear that that is the right way to proceed in trying to quantize gravity.

I've spent some time trying to give a down-to-earth view of string theory's prospects, because of your hesitation in accepting that it was speculative. I want to quickly address another point you make.

I do take your point that some of the hype from the string-theory community is for external consumption (or is simply self-serving), and I know string theorists who smile or cringe when they hear it. On the other hand, there are cases of internal hype (for example, the claims of "obvious finiteness," an argument which was made vociferously as one way of justifying the large amount of resources going to string theory).

But my main concern is not so much the minutiae of the arguments as the big picture. String theorists seem not to have taken seriously (by which I mean, as far as allocating funding, hiring, etc.) that it would be more important to try to encourage a diversity of work than to concentrate work on one theory.

47. **David Nataf**
December 17, 2008

When I was taking high school physics we studied topics like the inclined plane, the pulley, charged rods and the Bohr atom.

48. **ishi**
December 22, 2008

this has probably been said, but the web tutorial mentioned above (superstringtheory) and general articles by Witten in Physics Today seem to me as a nonphysicist (who took physics to do math biology, which uses alot of the formalisms, from cond-mat to wick rotation) seem actually to me to be pretty good introductions which could be used as a 'special topic' day (or a few) to generate interest and motivation to learn the required math ,which is pretty universal for any field, at least at the intro level. I was amazed to see string theory was based on basic ideas like the classical wave equation, and duality in e and m. You can even get your lagrangian and action principle, etc.

I think maybe wikipedia may be just as good for many things, maybe even better than MIT open courses.

49. **somebody**
December 25, 2008

Dear Pawl, I just saw your message but thought I will reply anyway since I have some time. Your arguments are really against high energy theory altogether (as you probably realize), and not specifically against string theory. You haven't really got the distinction I was trying to make between speculative constructions which are often quite arbitrary, and a solid, robust theory which builds from the fundamental ideas of physics and merely cranks the formalism (in some sense) and churns out extraordinary insights (like gauge-gravity duality).

This distinction is what makes string theory so extremely appealing to so many. And a lot of the critics merely brush it off as "speculation" (while often making some concessional words about the mathematics of string theory), and equate it in value to a lot of other cock-and-bull stories that theorists come up with. This incomprehending nature of the critics is the reason why it is a little hard to take them seriously.

The sociological ways in which theory and experiment interact need not always be the same. At least a few times in history, our problem was not so much that we took our theories too seriously, but that we didn't take them seriously enough. Quantum field theory was not trusted for a long time because of the infinities (from 40s to 70's almost) unttil the standard model was unravelled. Big bang was considered so speculative that nobody even cared enough to look for its signature.

My point is that it is merely your personal claim when you say that experiments and theory have to interact in a certain sequence. Of course, experiments are necessary in physics. But the challenges facing science will change qualitatively as generations come and go. It is quite likely that in the future, experiments are going to be hard and theorists will have to work very hard (and perhaps long) in order to relate theory and experiment. The light is going to be only at the end of the tunnel. This is just the way things are going to be. Does that mean that high energy theory has to be shut down? If there came a stage where it was provably impossible to connect theory and experiment, I would consider that possibility. But otherwise, I would vote for pushing forward, because I think theory is our last line of attack against the frontiers of our ignorance about the universe. Shutting it down will be the end of curriosity. If you think objectively about why exactly society sponsors things like mathematics, particle physics etc., I think you will find that it is not such a horrible thing to do, to support research in theoretical high energy physics of this kind.

It is in such a context that one has to really weigh the balance of judgement against a theoretical idea. How robust is string theory is the real question. Not cheap caricatures, like "no experiment, so string theory is useless". These are just another form of veiled hate against theoretical physics itself, the not so uncommon hate against the top of the food chain, if you know what I mean. It was there back when theory was still dealing with experimentally accessible things, but then the criticism took a different form. Then it was "no practical use", now it is "no experiment".

In the above two paragraphs, I was taking on your experiment-above-all-else argument: the claim that string theory is useless because there are no experiments. (This is actually not even fully true considering the recent RHIC etc. experiments.) The real problem with these shallow criticisms is that they *totally* fail to see that a good theory teaches us deep insights and understanding about the things that we already knew, but thought were distinct. String theory has taught us that gravity and gauge theory can be understood in terms of each other (notice that between the two they exhaust all of dynamics.) Then thereare things like black holes, etc. where string theory has truly found ways to get past previous challenges. Notice that none of these things have anything to do with the fancy math aspect. If you believe that this sort of understanding is without value, then you are correct that string theory is not for you.

50. **Pawl**
December 26, 2008

Dear Somebody,

Thanks for responding. However, I don't really think you've understood my points. I won't reiterate them, but I will try to sketch what seems to be preventing commuication.

Rather than take up what I have said, you are entirely misrepresenting me (saying I am against high-energy physics altogether) and shifting the discussion to a straw man (people who "brush off string theory as 'speculation'"). You spend your post discussing what "the critics" of string theory say without taking up with what I say.

It is also disturbing that when I raise some criticisms of string theory, you amplify this into a question of whether theoretical physics is worthwhile or not.

Please reread what I have written.

51. **somebody**
December 27, 2008

Sorry Pawl, I cannot concede that easily that I am misinterpreting you. Here is an exact quote from from your previous message:

"To begin with, it is very rare in physics that fundamental theory can make much progress without experimental input. We simply are not clever enough to anticipate what nature will do most of the time. Moreover, it is very rare to be able to successfully guess what will go on many orders of magnitude from what has been experimentally investigated."

So yes, you were against high energy theory, not merely string theory, as I claimed. Your whole message was predicated on the deep pessimism that we are probably not smart enough, so it is unlikely that we will understand the (remaining) mysteries of the universe. This argument has been valid and compelling for most of history, but curious people who are not intimidated by the unknown usually find a way around. Is this going to happen this time as well? I don't know. But I am not going to bet on the mediocrity of humans like you do. Experiments are hard, yes, but there might be possible experiments which we are missing because our theory is not well-developed. People could have probably done the Aharonov-Bohm experiment in the early 1900's. But they didn't. Why? Because there was no way anyone could have thought about it before quantum mechanics.

The bigger point, as I said before, is that experiment and theory can interact in many ways.

The reason why I did not dissect your claims point by point is because it didn't seem like a useful thing to do. So instead I took a few of your more interesting points and responded to them. The overwheleming impression I got from your message is that you have opinions about things you are not very familiar with (sorry, I am honestly not trying to put you down, but I fear this is relevant to our discussion!). Not just when you talk about the "hype" regarding finiteness of string perturbation theory, but also when you say how research should be diversified. In principle the latter sounds like a good idea, but I really do not know of a much better way to run the scientific process in HEP, than the way it is currently. Not that the current one is perfect, but I suspect any artificial redistribution of the limited resources is only bound to make it worse.

52. **Pawl**
December 27, 2008

Dear Somebody,

Your response is becoming unproductive and rude: to say you will not answer my points because of your "impression" I don't know what I'm talking about.

I am completely baffled as to how you interpret the paragraph you quote as me being against high-energy theory. (However you manage to do this, it reflects what is in your own mind and not what I have written.)

There is no point in continuing unless you are willing to answer my points, and to try to understand what I have written.

53. **Peter Woit**
December 27, 2008

Somebody,

You are just ignoring real issues and making up straw men to attack. Pointing out the difficulties associated with trying to do theoretical physics without experimental input is not exactly saying something controversial, nor is it "against particle theory". Despite the impression one might get sometimes from hep-th, much of particle theory is very much involved with the question of what might or might not be seen at experiments that are being done now, or will be in progress soon (e.g. the LHC).

Not all particle theory needs to be so directly related to experiment, but anyone who works on scientific questions divorced from the discipline of contact with experiment (I include myself here) needs to be very aware that they are out on a limb and think carefully about what this means. Group-think, hype-mongering, and an unwillingness to admit failure are a very real problem here.

As to "artificial redistribution of the limited resources", my point of view is that that's exactly what string theorists have been trying to achieve, by attacking anyone who points out the failure of the string theory unification program in hopes of avoiding the conventional implications of that failure for the the distribution of resources. This tactic is no longer working so well.

54. **somebody**
December 27, 2008

Peter: "Pointing out the difficulties associated with trying to do theoretical physics without experimental input is not exactly saying something controversial, nor is it "against particle theory". "

That was not the claim, and this is a strawman. Nobody disputed the difficulties. The question is when do you decide that a research program is fruitless.

Your second paragraph I agree with, but not the third.

Peter: "As to "artificial redistribution of the limited resources", my point of view is that that's exactly what string theorists have been trying to achieve, by attacking anyone who points out the failure of the string theory…"

You have a book written, you are invested in this thing, your name is built on the anti-string campaign. So I am not sure that the anonymous string theorist who is trying to while away a weekend in sickbed is the one with an agenda to protect. Scientists usually are passionate about what they think they know. I didn't realize that I was defending my funding when doing the blogospheric dogfights against random people who think ignorance is a point of view.

Again, you are translating what is really a scientific debate into a sociological thing.

There is nothing stopping teachers from doing some extra material along with AP, other than the capability and background of the students (which is unlikely to be quite college level in all respects). however my teacher in AP chem did particle in a box, point group symmetry and solid sphere packings. All of which I think are extra. She still had time to spend half the class talking about school politics and how to behave at football games. We loved her! And lots got 5s.

Ap Physics is a whole nother kettle of fish. My school did not have it. We had PSSC phsycis (science emphasis, but pre-calc) and had HPP physics (liberal arts slanted). I had taken PSSC and Calc BC and so took the AP exam anyhow. I placed out of one semester of mechanics (I had to horse up with rotational mechanics, but the eqyations are very analagous to straight line stuff…and calc based problems had already been touched on within the calculus class.) I tried to cram the E&M, but it was too tough. got a 4 on mechanics and a 2 on E&M.

In service academy, where I went, the entire student body had to take 'zoics and it was nominally in the sophomore year so that differential and integral calc were done before the start. And during the second semester (E&M), multivariable calc had just been covered and diff EQs were being covered. This seemed to work.

Physics majors and EEs took a harder 3 semester curriculum in place of that Halliday and Resnick style (think it was actually Giamoato or somehting like that) curriculum.

AP or any advanced class should be more for that mass of engineering students than for the 'zoics majors. They will be otrutued enough with classical E&M as they go through.

Status of Superstring and M-theory

December 11, 2008
Categories: Multiverse Mania, Uncategorized

A write-up by John Schwarz of his Erice lectures from this past summer has now appeared on the arXiv, with the title [Status of Superstring and M-theory](). In his second lecture, Schwarz provides a good review of the various attempts to do "string phenomenology" by trying to find a "string background" that doesn't conflict with known particle physics. He devotes particular attention to the newest of these backgrounds, so-called "F-theory local models", providing a summary of the rather complicated constructions involved. Schwarz doesn't describe any experimental predictions of such models, just noting:

> It will be very interesting to see what predictions can be made before the experimental results pour in and whether they turn out to be correct.

For more discussion of these models and the question of whether they predict anything, see here.

Schwarz begins with an account of his interactions with Sidney Coleman at Aspen and elsewhere:

> I recall him once saying that there are three things that he does not like, all of which are becoming popular: supersymmetry, strings, and extra dimensions. Obviously, my views are quite different, but this did not lessen my regard for him, nor did it harm our personal relationship. In fact, I respected his honesty, especially as he did not try to impose his prejudices on the community.

About the anthropic landscape issue, he has this to say:

> Perhaps the absurdly large number of flux vacua that typically arise in flux compactifications has discouraged people from trying to construct viable particle physics models. In fact, this large number of vacua has motivated the suggestion that various parameters of Nature (such as the cosmological constant) should be studied statistically on the landscape. I don't really understand the logic of doing this, since this approach seems to assume implicitly that Nature corresponds to a more or less random vacuum. This in turn is motivated by some vague idea about how Universes are spawned in the Multiverse in a process of eternal inflation. Then the story gets even more entangled when the anthropic principle is brought into the discussion. Some people are enthusiastic about this approach, but I find it fundamentally defeatist. It is not the way I like to think about particle physics.

Meanwhile, public promotion of the Multiverse continues, with the opinion pages of Britain's The Independent today featuring a piece by Bernard Carr entitled Fifth dimensions, space bubbles and other facets of the multiverse. Carr describes the "growing popularity" of the multiverse proposal, ending with:

> But is the "multiverse" a proper scientific proposal or just philosophy? Despite the growing popularity of the proposal, the idea is speculative and currently untestable – and it may always remain so. Astronomers may never be able to observe the other universes with their telescopes and particle physicists may never be able to detect the extra dimensions with their accelerators. So, although some physicists favour the multiverse because it may do away with the need for a creator, others regard the idea as equally metaphysical. What is really at stake is the nature of science itself.

Carr characterizes some multiverse proponents as atheists favoring something that doesn't seem to fit into the conventional scientific method because it gives an answer to the argument from design for a deity. For more about this all-too-common argument for the multiverse, being promoted by Susskind and others, see here. In answer to such claims about religion being promoted by physicists, New Scientist this week is running a sensible piece by Amanda Gefter entitled Why it's not as simple as God vs the multiverse. It makes the obvious point about the multiverse-God dichotomy:

> Science never boils down to a choice between two alternative explanations. It is always plausible that both are wrong and a third or fourth or fifth will turn out to be correct.

Update: For more multiverse mania, see today's colloquium at Perimeter here. The intense promotion of this pseudo-science continues, but I don't think it's getting any traction.

Update: Yet more media attention to the God vs. Multiverse debate, now from the Guardian.

Comments

1. **Shantanu**
   December 11, 2008

   Peter, I watched this nice talk on testing inflationary models
   http://pirsa.org/08110021/ and near 46th minute where the
   speakers talked about testing consistency of string theory, there was a lot of
   discussions. Do you think these tests are really testing string thoery?

2. **Peter Woit**
   December 12, 2008

   Shantanu,

   Because of the low audio quality, I found it hard to hear exactly what was going on in that discussion. But, as far as I can tell, what's going on is that the speaker and others are talking about their "dream" to "constrain string theory". So, in their most optimistic scenario, all they will ever be able to do is to, amongst the infinite complexity of the landscape, say that some regions of it are consistent with various string inflation scenarios, and some aren't. This can never actually produce any evidence for or against string theory itself, it just takes physics where some string theorists want it to go. String theory is accepted as the "best guess" as to how the universe works, taught to high schools students, and fundamental physics becomes reduced to just parametrizing observations with string vacua, vacua that are capable of parametrizing anything that is ever likely to be observed. Doesn't really look like science to me….

3. **Samuel Prime**
   December 13, 2008

   You wonder if the enormous advancements in physics (and science) are prompting researchers to delve into, speculate, and think about superquestions and more adventerous ideas that, by nature, go beyond the currently accepted methods of science. It's hard to imagine science not evolving in its methods. (Causality was an integral part of classical physics 100 years ago but now no longer—or rather is still part of relativity but not quantum theory.)

   Perhaps new and/or additional methods will need to be added in order for us to advance (or define) our 'knowledge' of such huge unknowns (and which are so intriging to us humans). (Perhaps string theory is a symptom of this trend to 'push' the methods of science.) Of course, as Socrates would say, I know nothing, but I do think it is safe to say that science in 200, or even 500, years from now will not be the same as it is today. Our perspective will change. Perhaps even our methods and manner of perception.

We are hitting the boundaries of experiment. (More specifically, experiment that can be humanly done.) These many superquestions and supercuriosities show that we are more curious by questions that now seem untestable by our current state of abilities, at least to a high degree of certainty. Nevertheless, the big curiosities could play a role how the methods of science develop.

I have wondered if the development science will become similar to that of mathematics. (Research in high energy physics is already beginning to look like that!) For example, even though the Axiom of Choice and the Continuum Hypothesis are unprovable from the other Zermelo-Frankael axioms of set theory, mathematicians generally feel free to assume them in their work (even though they are 'untestable'). So if in science we hit boundaries of experiment and the unknowable, we may have to find ways to penetrate such boundaries.

4. **Chris W.**
December 13, 2008

Samuel Prime: *(Causality was an integral part of classical physics 100 years ago but now no longer—or rather is still part of relativity but not quantum theory.)*

It sounds like you're confusing causality with strict determinism. Causal structure is very much a part of quantum theory. (By the way, see Scott Aaronson's latest post.)

More to the point: When delving into superquestions and more adventurous ideas leads a scientist—or someone who claims to be a scientist—to start regarding testability against empirical observation as fundamentally irrelevant, it becomes utterly self-defeating. Some theorizing about the multiverse flirts with that attitude. Metaphysical speculation is (in my opinion) an inescapable part of formulating scientific questions that seek deep understanding, but the ultimate goal is a challenging confrontation with observation, hopefully with a successful outcome for the theory in question.

5. **Esornep**
December 14, 2008

It's rather amusing that Schwarz can dismiss the nucleation of bubble universes ["This in turn is motivated by some vague idea about how Universes are spawned in the Multiverse in a process of eternal inflation"] just after his reverential remarks about Coleman, in view of the fact that Coleman, with De Luccia, was the author of the massively influential paper on which all current multiverse theorizing is based. Yes, Coleman, who was opposed to higher dimensions, etc etc etc, started the whole multiverse ball rolling. Coleman was quite explicit about the possibility that our own Universe is a bubble, and of course there is no reason for such a bubble to be unique.

6. **Samuel Prime**
December 17, 2008

Chris W., could you please tell me where I mentioned determinism so that it would be confused (by yourself) with causality? Any educated physicists who read my comment would know what I meant by causality in the contrasting contexts of relativity and QM that I stated.

As for the unhappy comments toward the multiverse idea, I would hardly consider Steven Weinberg as among those 'self-defeating' physicists. In his essay Living in the Multiverse, Weinberg notes:

> There is also a less creditable reason for hostility to the idea of a multiverse, based on the fact that we will never be able to observe any subuniverses except our own. Livio and Rees and Tegmark have given thorough discussions of various other ingredients of accepted theories that we will never be able to observe, without our being led to reject these theories. The test of a physical theory is not that everything in it should be observable and every prediction it makes should be testable, but rather that enough is observable and enough predictions are testable to give us confidence that the theory is right.

It seems that two standards are being applied. One standard to theories we don't like, where we raise the standards to too rigorous a level (and requiring each idea to be testable), and another standard to theories we like and where we do not pick on them for not being testable in every respect. One could have picked on the Big Bang theory for the idea of an infinitely small point or particle when it exploded, even though that idea by itself alone is untestable.

As for myself, I can't say I believe in the multiverse idea. However, I am open to the concept. It can't just be an idea that stands by itself, but along with a broader mathematical framework, coupled with other hypotheses, so that the whole theory (not just one single idea) can either be tested or related to other known or accepted facts or scenarios that may be worthy of examination and further study.

I don't know of any grand and successful physical theory in which all of its ideas and concepts are each testable. So let's not push the testability thing too far or it will haunt our efforts.

7. **anon.**
December 17, 2008

'The test of a physical theory is not that everything in it should be observable and every prediction it makes should be testable, but rather that enough is observable and enough predictions are testable to give us confidence that the theory is right.' – Weinberg, quoted above.

That's wishy-washy brane-washing, because there is no unequivocal definition of 'enough' and 'us'. It's easy for string theorists to find even today 'enough' ad hoc prediction of gravity, etc., in string theory to give *them* confidence (to the point of arrogance) that their pet theory or religion is the right one. The fact that they are confident that they are right isn't worth much, however. Try applying Weinberg's statement to flat-earth theory, Piltdown man, cold fusion, Phlogiston, Caloric, etc.

8. **Jake the Snake**
December 17, 2008

The God v. Multiverse issue is an amusing one. Intelligent Design types love the dichotomy because it "forces" atheists to accept their God or postulate a weird hypothesis about multiple universes as an alternative explanation for the apparent "design" or "fine-tuning." Likewise, some atheists might not like it because they do not understand the real nature of the God-Multiverse dichotomy and think they may be compelled to postulate a multiverse, while those who do believe in a multiverse think they have an answer to the arguments of intelligent design. The problem is that any hypothesis which appeals to either a supernatural entity or multiple cosmoses fails the test of Occam's razor. Fortunately, the dichotomy between God and Multiverse is simply not true.

There is no compelling to declare either of the two scenarios true, or, on the contrary one can combine the two. Bradley Monton considered the ramifications of doing this to resolve the so-called problem of evil.

http://bradleymonton.wordpress.com/2008/12/03/the-many-universe-solution-to-the-problem-of-evil/

Why would Monton, who claims to be an atheist, attempt the above argument? It seems to be a thought experiment. As Monton reveals, he did not come up with the proposed solution, but he analyzes it briefly and considers the multiverse proposal to be an unsatisfactory answer to the problem of evil.

9. **Samuel Prime**
   December 20, 2008

   > ” … there is no unequivocal definition of ‘enough’ and ‘us’. “

   Yes, there is a practical one: the general consensus of the physics community. I’ll grant you, though, that string theory has much more work to do before it proves its mettle (if it is the right approach). (I think they know that themselves, even if some are arrogant, just as arrogance can be found on any side of an issue.)

   I had an arrogant and mean math teacher in school, but for some reason I separated his arrogance from my fascination for math. After him there was a much kinder teacher, and that made it all the more sweeter.

10. **TCO**
    January 3, 2009

    Skepticism about string theory has penetrated the popular culture. Its days of supremacy in funding and tenure positions are numbered. You should not feel defeated or defensive. You’ve practically won already.

    Lubos is smart and young so he can find something useful to do, still. Though if he doesn’t have tenure yet, I would be rather worried. Harvard is bad enough but with his field falling out of favor…anyhow, it just means he’ll latch on at a less prestigious school after Harvard dings him in a couple years.

Notes on BRST VII: The Harish-Chandra Homomorphism

December 15, 2008
Categories: BRST

The Casimir element discussed in the last posting of this series is a distinguished quadratic element of the center $Z(\mathfrak g)=U(\mathfrak g)^\mathfrak g$ (note, here $\mathfrak g$ is a complex semi-simple Lie algebra), but there are others, all of which will act as scalars on irreducible representations. The information about an irreducible representation V contained in these scalars can be packaged as the so-called *infinitesimal character* of V, a homomorphism

$$\chi_V: Z(\mathfrak g)\rightarrow \mathbf C$$

defined by $zv=\chi_V(z)v$ for any $z\in Z(\mathfrak g)$, $v\in V$. Just as was done for the Casimir, this can be computed by studying the action of $Z(\mathfrak g)$ on a highest-weight vector.

Note: this is not the same thing as the usual (or global) character of a representation, which is a conjugation-invariant function on the group G with Lie algebra $\mathfrak g$, given by taking the trace of a matrix representation. For infinite dimensional representations V, the character is not a function on G, but a distribution Θ_V. The link between the global and infinitesimal characters is given by

$$\Theta_V(zf)=\chi_V(z)\Theta_V(f)$$

i.e. Θ_V is a conjugation-invariant eigendistribution on G, with eigenvalues for the action of $Z(\mathfrak g)$ given by the infinitesimal character. Knowing the infinitesimal character gives differential equations for the global character.

The Harish-Chandra Homomorphism

The Poincare-Birkhoff-Witt theorem implies that for a simple complex Lie algebra $\mathfrak g$ one can use the decomposition (here the Cartan subalgebra is $\mathfrak h=\mathfrak t_{\mathbf C}$)

$$\mathfrak g=\mathfrak h \oplus \mathfrak n^+ \oplus \mathfrak n^-$$

to decompose $U(\mathfrak g)$ as

$$U(\mathfrak g) =U(\mathfrak h) \oplus (U(\mathfrak g)\mathfrak n^+ + \mathfrak n^-U(\mathfrak g))$$

and show that If $z\in Z(\mathfrak g)$, then the projection of z onto the second factor is in $U(\mathfrak g)\mathfrak n^+\cap\mathfrak n^-U(\mathfrak g)$. This will give zero acting on a highest-weight vector. Defining $\gamma^\prime: Z(\mathfrak g)\rightarrow Z(\mathfrak h)$ to be the projection onto the first factor, the infinitesimal character can be computed by seeing how $\gamma^\prime(z)$ acts on a highest-weight vector.

Remarkably, it turns out that one gets something much simpler if one composes $\gamma^\prime$ with a translation operator

$$t_\rho: U(\mathfrak h)\rightarrow U(\mathfrak h)$$

corresponding to the mysterious $\rho\in \mathfrak h^*$, half the sum of the positive roots. To define this, note that since $\mathfrak h$ is commutative, $U(\mathfrak h)=S(\mathfrak h)=\mathbf C$, the symmetric algebra on $\mathfrak h$, which is isomorphic to the polynomial algebra on $\mathfrak h^*$. Then one can define

$$t_\rho (\phi(\lambda))=\phi(\lambda -\rho)$$

where $\phi\in \mathbf C$ is a polynomial on $\mathfrak h^*$, and $\lambda\in\mathfrak h^*$.

The composition map

$$\gamma=t_\rho\circ\gamma^\prime: Z(\mathfrak g)\rightarrow U(\mathfrak h)=\mathbf C$$

is a homomorphism, known as the Harish-Chandra homomorphism. One can show that the image is invariant under the action of the Weyl group, and the map is actually an isomorphism

$$\gamma: Z(\mathfrak g)\rightarrow \mathbf C^W$$

It turns out that the ring $\mathbf C^W$ is generated by $dim\ \mathfrak h$ independent homogeneous polynomials. For $\mathfrak g=\mathfrak{sl}(n,\mathbf C)$ these are of degree $2, 3,\cdots,n$ (where the first is the Casimir).

To see how things work in the case of $\mathfrak g=\mathfrak{sl}(2,\mathbf C)$, where there is one generator, the Casimir Ω, recall that

$$\Omega=\frac{1}{8}h^2 + \frac{1}{4}(ef +fe)=\frac{1}{8}h^2 + \frac{1}{4}(h +2fe)$$

so one has
$$\gamma^\prime(\Omega)= \frac{1}{4}(h +\frac{1}{2}h^2)$$

Here $t_\rho(h)=h-1$, so

$$\gamma(\Omega)=\frac{1}{4}((h-1)+\frac{1}{2}(h-1)^2)=\frac{1}{8}(h^2-1)$$

which is invariant under the Weyl group action $h\rightarrow -h$.

Once one has the Harish-Chandra homomorphism γ, for each $\lambda\in\mathfrak h^*$ one has a homomorphism

$$\chi_{\lambda}: z\in Z(\mathfrak g)\rightarrow \chi_\lambda(z)=\gamma(z)(\lambda)\in \mathbf C$$

and the infinitesimal character of an irreducible representation of highest weight λ is $\chi_{\lambda + \rho}$.

The Casselman-Osborne Lemma

We have computed the infinitesimal character of a representation of highest weight λ by looking at how $Z(\mathfrak g)$ acts on $V^{\mathfrak n^+}=H^0(\mathfrak$

$n^+,V)$. On $V^{\mathfrak n^+}$, $z\in Z(\mathfrak g)$ acts by

$$z\cdot v = \chi_V(z)v$$

This space has weight λ, so $U(\mathfrak h)=\mathbf C$ acts by evaluation at λ

$$\phi\cdot v=\phi(\lambda)v$$

These two actions are related by the map $\gamma^\prime: Z(\mathfrak g)\rightarrow U(\mathfrak h)$ and we have

$$\chi_V(z)=(\gamma^\prime(z))(\lambda)=(\gamma(z))(\lambda + \rho)$$

It turns out that one can consider the same question, but for the higher cohomology groups $H^k(\mathfrak n^+,V)$. Here one again has an action of $Z(\mathfrak g)$ and an action of $U(\mathfrak h)$. $Z(\mathfrak g)$ acts on k-cochains $C^k(\mathfrak n^+,V)= Hom_{\mathbf C}(\Lambda^k\mathfrak n^+,V)$ just by acting on V, and this action commutes with d so is an action on cohomology. $U(\mathfrak h)$ acts simultaneously on $\mathfrak n^+$ and on V, again in a way that descends to cohomology. The content of the Casselman-Osborne lemma is that these two actions are again related in the same way by the Harish-Chandra homomorphism. If μ is a weight for the $\mathfrak h$ action on $H^k(\mathfrak n^+,V)$, then

$$\chi_V(z)=(\gamma^\prime(z))(\mu)=(\gamma(z))(\mu + \rho)$$

Since $\chi_V(z)=(\gamma(z))(\lambda + \rho)$, one can use this equality to show that the weights occurring in $H^k(\mathfrak n^+,V)$ must satisfy

$$(\mu +\rho)=w(\lambda + \rho)$$

and thus

$$\mu=w(\lambda + \rho)-\rho$$

for some element $w\in W$. Non zero elements of $H^k(\mathfrak n^+,V)$ can be constructed with these weights, and the Casselman-Osborne lemma used to show that these are the only possible weights. This gives the computation of $H^k(\mathfrak n^+,V)$ as an $\mathfrak h$ – module referred to earlier in these notes, which is known as Kostant's theorem (the algebraic proof was due to Kostant, an earlier one using geometry and sheaf cohomology was due to Bott).

For more details about this and a proof of the Casselman-Osborne lemma, see Knapp's *Lie Groups, Lie Algebras and Cohomology*, where things are worked out for the case of $\mathfrak g=\mathfrak{gl}(n,\mathbf C)$ in chapter VI.

Generalizations

So far we have been considering the case of a Cartan subalgebra $\mathfrak h\subset \mathfrak g$, and its orthogonal complement with a choice of splitting into two conjugate subalgebras, $\mathfrak n^+ \oplus \mathfrak n^-$. Equivalently, we have a choice of Borel subalgebra $\mathfrak b\subset \mathfrak g$, where $\mathfrak b =\mathfrak h \oplus \mathfrak n^+$. At the group level, this corresponds to a choice of Borel subgroup $B\subset G$, with the space G/B a complex projective variety known as a flag manifold. More generally, much of the same structure appears if we choose larger subgroups $P \subset G$ containing B such that G/P is a complex projective variety of lower dimension. In these cases $Lie\ P=\mathfrak l \oplus \mathfrak u^+$, with $\mathfrak l$ (the Levi subalgebra) a reductive algebra playing the role of the Cartan subalgebra, and $\mathfrak u^+$ playing the role of $\mathfrak n^+$.

In this more general setting, there is a generalization of the Harish-Chandra homomorphism, now taking $Z(\mathfrak g)$ to $Z(\mathfrak l)$. This acts on the cohomology groups $H^k(\mathfrak u^+,V)$, with a generalization of the Casselman-Osborne lemma determining what representations of $\mathfrak l$ occur in this cohomology. The Dirac cohomology formalism to be discussed later generalizes this even more, to cases of a reductive subalgebra $\mathfrak r$ with orthogonal complement that cannot be given a complex structure and split into conjugate subalgebras. It also provides a compelling explanation for the continual appearance of ρ, as the highest weight of the spin representation.

This and That

December 17, 2008
Categories: Experimental HEP News, Uncategorized

This week's Nature has a nice cover story on Lyn Evans, who has been leading the construction of the LHC. The story mentions one of the problems of his high-profile job:

> Evans has found himself the subject of more than one ad hominem attack in physics chat rooms and blogs; he knows because he Googles to find out.

While beam commissioning won't start up again at the LHC until at least next July, at the Tevatron things have been going extremely well. Last week they set a new luminosity record, accumulating 74 pb^{-1}. For more about this, there's a posting at Symmetry Breaking.

The Boston Globe has an interview with Lisa Randall, who is writing the libretto for an opera to be entitled "Hypermusic Prologue: A projective opera in seven planes".

Lieven le Bruyn has a posting about David Mumford and the so-called "Red Book", the notes for his course on algebraic geometry. This includes a reproduction of Mumford's picture of Spec Z, together with explanations of what all the squiggles mean. From this posting I also learned about a wonderful book on the topic of "Five Centuries of French Mathematics", available here.

Taking a look at the Theoretical Particle Physics Jobs Rumor Mill, things are looking quite bad for tenure-track jobs in string theory or, more generally, any formal work on quantum field theory. It seems that what US physics departments most want now are cosmologists and "astro-particle physicists". One place that plans to do a lot of hiring in this area is Arizona State, which is advertising for 8-10 new faculty appointments in these areas, and a similar number of postdocs, to be hired over the next 5 years. All of a sudden the field of "string cosmology" starts to make a lot more sense.

One organization that may need a lot of string theory instructors is the Maharishi Central University which will offer "Unified Field Based Education":

> The groundbreaking curriculum of Maharishi Central University is based upon the most advanced scientific knowledge of our age: the discovery of the Unified Field. During the past quarter century, modern physics has explored progressively more fundamental levels of nature's functioning at the atomic, nuclear and sub-nuclear scales, culminating in the recent discovery of the Unified Field—a single, universal field of nature's intelligence at the foundation of the universe.
>
> This Unified Field, or "E8xE8 superstring field," is the crowning achievement of fifty years of advanced research in quantum gravity theory, and is expressed most concisely in the following, compact Lagrangian, or "super-formula," presented, for simplicity, in the super-conformal gauge…

The summary of the curriculum goes on to explain how the superstring field "provides the long-sought, mathematically rigorous, interdisciplinary foundation for all the sciences, and for the whole field of academic study," and that "Without such knowledge, the entire field of education is essentially baseless."

The plan seems to be to build 50 universities, one in each state, with a construction cost of $16 million each. They're looking for investors, who are told that each university will enroll 200 students who will pay $45,000/year, generating an income of $9 million per year, so "This will render financing completely risk free." This money-raising effort is related to the one discussed here.

The first such university is being built at the "exact geographic center" of the US, a point about 12 miles northeast of Smith Center, Kansas. The news from Raja Robert Wynne, Mayor of Maharishi Vedic City and Raja of Invincible New Zealand, Armenia, Kenya, Pakistan, Iraq, Vanuatu, Liberia, and Burundi for the Global Country of World Peace, is that there are 10 buildings now under construction. From an AP article about this, according to founding president John Hagelin

> "The ultimate vision is 40,000 students. We're probably not interested in something smaller than 10,000 students"… He said it would take more than $100 million to start up the university – which he had wanted to have open two years after construction began – and that kind of money isn't easy to find amid a national banking crisis. Because of that, he said, a more reasonable estimate would be that the university will open in five to 10 years.

The locals seem to not be very happy about all this, worried by the presence of a Mexican construction company with Mexican workers at the site. One such Kansan is the Rev. Dennis Lambert, whose church is nearby, who says "We consider them to be a cult". The AP article explains that

> Lambert was among a small group of people who in 2006 dug up what they believe to be a Hindu idol on a rural property that meditators had once owned about 10 years ago. The figure, a hollow metal animal, contained fake jewels symbolic of the nine planetary gods, he said.
>
> "The fake jewels were crushed and the metal deal was destroyed with heat," Lambert said. "It was believed to have demonic influence and that's the way we dealt with it."

“Because of the extraordinary significance to mankind of Dr. Nader Raam’s scientific breakthrough that consciousness is the basis of human physiology, he was awarded his weight in gold and crowned in October 2000 as “Maharaja Adhiraj Rajaraam, First Ruler of the Global Country of World Peace.” Shortly thereafter, Maharaja Adhiraj Rajaraam’s Global Administration honored Dr. Hagelin as Minister of Science and Technology (2001). ”

Are these guys for real?

5. **Arun**
December 18, 2008

It would be amazing if the ancient Hindus knew of the nine planets – but they didn’t. They knew the five visible to the naked eye. The other four are the sun, moon, Rahu and Ketu.

http://www.navgraha.org/

“”Nav” or “Nava” means “nine”. Graha is sometimes translated as “planet”, but the Sun, Moon, and Rahu and Ketu are not “planets” according to modern astronomy. “Graha” is sometimes translated as “celestial body”, but Rahu and Ketu are not celestial bodies either. A third translation is celestial god or demi-god, but again, Rahu and Ketu are Asuras not Devas. Rahu and Ketu are further believed to be only positions in the planetary paths. A fact common to all navagrahas is that they have relative movement with respect to the backgound of fixed stars in the zodiac belt.”

More precisely, two of the “planets”, Rahu and Ketu, are the lunar nodes (the two points where the moon’s orbit intersects the ecliptic). They “cause” solar and lunar eclipses.

The graha do not fit into the category of “demonic” or “godly” either, as noted above.

It is a conceptualization of the world outside the domain, beyond the grasp of Rev. Lambert.

December 18, 2008

This is something right out of Monty Python’s holy grail quest.

Peter, a question: do you know who funds these guys? Their hilariously-inept (and comical) invitations for multi-million dollar fundings surely don’t net anything, howcome they’ve been running for so long? Who’s giving them all this money, cause I also have some magical beans to sell…

7. **Peter Woit**
December 18, 2008

themanwithaplan,

I’m also quite curious about the finances of this organization. As far as I can tell though, their grandiose plans to raise lots more money aren’t working out.

8. **Sumar Ongi**
December 18, 2008

That Hagelin entertains those projects is nothing unusual, it seems he’s been doing so for at least a decade now. His sources of funding are admittedly a more interesting research topic.

But Randall? An *opera* ??!!! That’s … well…, surprising, to say the least.

9. **Markk**
December 18, 2008

The Tevatron info was interesting. The fact that they have bumped luminosity by a factor of six in the last few years by what seems to be process improvements means, to me, that we are still on the upslope of the learning curve in knowing how to mess with high power particle beams. Long term that is good news for LHC hopes as they will climb that curve too.

I think it is a reason to keep the Tevatron going. People always want the next thing, the Higgs or whatever, but this is new high energy physics data and a bunch of it. We aren’t getting stuff like this anywhere else and won’t for a while. It will be a good set of data to use as a check and to find little things that we don’t know to look for now. Maybe Fermilab could try to start pioneering an open standard format for this information and create an open archive, like CERN was looking at a while ago.

10. **Chris W.**
December 18, 2008

That Hagelin entertains those projects is nothing unusual, it seems he’s been doing so for at least a decade now. His sources of funding are admittedly a more interesting research topic.

Hmmmm. Maybe something interesting will come out of the impending litigation over Bernard Madoff’s Ponzi scheme. 🙂

11. **DB**
December 19, 2008

“But Randall? An opera ??!!! That’s … well…, surprising, to say the least”

She probably got the idea from John Adam’s Doctor Atomic (2005), about Oppenheimer and the Manhattan Project.

12. **A.**
December 21, 2008

A summary of news on the Tevatron from Beate Heinemann at the UK Annual Theory Meeting:

No deviation from the SM in diboson production, preliminary data for a CP violating phase measured in B_s -> J\psi\psi decay might not agree with the SM prediction, this will be watched, and there is still no concensus on whether the CDF results indicate new physics or a miscalculated background.

Dave Charlton gave a status on the LHC which just confirms what Peter said in his post.

13. **woit**
    December 21, 2008

    Thanks A.,

    Many of the talks at that meeting look quite interesting, and slides are available there.

    I found the perspective of the talk on String Phenomenology and the LHC to be kind of amusing. It ends with

    "LHC can give us important information on the structure of the MSSM string landscape!"

    The philosophy seems to no longer be that experiment can test string theory. All experiment can ever do is tell us "where we are" in the landscape, with string theory and the string theory landscape now having the status of untestable axioms of physics.

14. **Chickenbreeder**
    December 22, 2008

    I noted that you no longer have the link to Arizona State job announcement. Are those 8-10 jobs not real after all? They just seem too good to be true since all I have heard is hiring freeze.

    I believe the scarcity of jobs in theoretical physics is correlated with the ill wind of economic downturn that's blowing over elite universities. Even Harvard and Stanford announced major cutback and hire freeze due to endowment loss.

15. **Peter Woit**
    December 22, 2008

    Chicken Breeder,

    The ASU job announcement is still there. I have no idea if budget problems will cause them to cut back and hire fewer people.

    All of US academia is having budget problems, especially public universities since state and local budgets are having problems.

    Harvard has announced major budget cuts, supposedly because their endowment has gone down $8billion this year. Unclear to me why this is such a huge problem, since it went up $6billion last year…

16. **BlissCat**
    December 22, 2008

    I sincerely hope to see the opening of Maharishi Central Universities everywhere. The idea of an underlying interdisciplinary foundation in education is very appealing to me, but sorely lacking in academia today, so that we are often left with an unbalanced curriculum which cannot fully develop a student's brain. In contrast, students who befit from the sort of complete education Dr Hagelin is talking about, develop their inner potential through the practice of Transcendental Meditation, increasing creativity, learning ability, the ability to relate to others, and cultivating the total potential of their brain. That to me is the basis of success in life. Click here for a description of scientific studies on the benefits of Transcendental Meditation in education:
    Transcendental Meditation & Brain Potential

17. **Henriette Hagelin-Chandra**
    December 23, 2008

    Well, BlissCat, since you seem to have the secret of success, I don't doubt you'll be donating a couple million of your dollars to our Maharishi C.U. We appreciate your financial support.

18. **Kay**
    December 23, 2008

    The National Institutes of Health have granted $24 million to study Transcendental Meditation for the prevention and treatment of heart disease, hypertension, and stroke – they wouldn't do that for a money scam! The beneficial effects of TM have been studied by independent researchers at Harvard, Standford, Yale, UCLA Medical School, and literally hundreds of leading institutions, and published by the American Medical Association, the American Heart Association, the International Journal of Neuroscience, etc. So don't let these fear-based claims get to you. See for yourself: Transcendental Meditation : Ask the Doctors. TM is safe, effective, and affordable with scholarships.

19. **Damru10**
    December 24, 2008

    Where does the money come from? Good question. The money comes from wherever it is. You compose a proposal for your idea, locate funding sources, then make your pitch.

    Imagine the pitch the Visionary Physicists(VP) of CERN gave to the Banker(B) who represents the universities that funded LHC.
    VC: We want €500Billion.
    B: Why?
    VC: To discover the Higgs Boson.
    B: When you find it, can you show it to me?
    VC: No. It's intangible to the five senses.
    B: Intangible? Well, what good is it, then?
    VC: It will prove my theory of the universe is correct.
    B: Let me get this straight. You want €500Billion for philosophical reasons. Right?

    That's gotta be a tough sell. The LHC visionaries at CERN must have told a very convincing story to get that kind of money. Of course making a pitch like this is predicated upon the money people actually listening to you.

    The regular contributors to this blog are scientists. As scientists you have to be painfully aware of Galileo's plight. He offered a heliocentric theory of how the universe functions to the ecclesiastical power elite who were deeply entrenched in a geocentric view. The Vatican was so threatened by Galileo's ideas that they contained him under house arrest for the rest of his life. Scientists would not want to duplicate the mistakes of the past. Would they? They would listen with an open mind to new ideas and evaluate them based on the science. Right? No real scientist would dismiss a new idea based solely upon here-say.

If anyone wants to hear what Dr. Hagelin is actually saying, here are his lectures on Unified Field Based Approach to various topics, including Health Care, Education, Defense, Poverty Removal, Global Financial Bailout Plan, Architecture, Agriculture and Administration:
http://www.gfcny.net/video/

For a review of the science behind the technologies of consciousness that Dr. Hagelin is recommending, examine the more than 600 peer reviewed studies, performed by over 215 independent universities and research institutions, that have been published in more than 160 peer-reviewed scientific journals and edited books.:
http://www.TruthAboutTM.org/truth/Research/TMResearchPublications/index.cfm

Remember Arthur Schopenhauer's 3 stages of truth:
"First, it is ridiculed.
Second, it is violently opposed.
Third, it is accepted as being self-evident."

20. **Kay**
December 24, 2008

Wow, thanks, Damru10, for your thoughtful, intelligent reply. It brings this discussion to a whole new level.

21. **Shantanu**
December 24, 2008

Peter, there are 2 other string-related talks at PI
See

Introduction to string theory

http://www.pirsa.org/08110034/
(This one is about eternal inflation)

22. **archie**
December 24, 2008

Regarding Hagelin and Maharishi Central U.: Damru10's Schopenhauer quote bears repeating:

"All truth passes through three stages.
First, it is ridiculed. Second, it is violently opposed.
Third, it is accepted as being self-evident."

23. **me**
December 24, 2008

Bullshit that is (eventually) accepted by mainstream also passes by the exact same stages.

How interesting.

24. **anon.**
December 25, 2008

Pseudoscience indeed passes through Schopenhauer's 3 stages, but the order is reversed:

"First, it is accepted as being self-evident.
Second, it is violently opposed.
Third, it is ridiculed."

Think about flat earth, epicycles and the sun orbiting the earth, witchcraft, Caloric fluid heat theory, etc. In a primitive society, even simple natural phenomena like fire, magnets, and gravitation can be held up by priests as "evidence" of their secret wisdom and supernatural craptrap powers. As more evidence accumulates that such things might not need religious belief in uncheckable theories, they can be successfully opposed and finally ridiculed.

25. **ishi**
December 25, 2008

i do have to give credit to the maharishi types; they published a 2 page ad in the wash post for their theory of everything (maybe the standard model lagrangian—i forget). you rarely see any math in the paper (though recently on a math ed article they did have something from complex variable theory). soetimes you take it from whatever source (dumpster diving theory of education).

i actually imagine meditation in general is ok. somewhat like sleeping. they did try to stop crime in DC by meditating (you need the sqrt of the population to get it to stop. (presumably this follows from the LL#s). but we still got the bush administration.

26. **Kay**
January 3, 2009

Please, it's not helpful to speculate that Transcendental Meditation might be like sleep. The brain wave patterns during TM are extraordinarily different from sleep. Here is what actually happens: The technique allows the mind to settle inward beyond thought to experience PURE AWARENESS, the source of thought, also known as transcendental consciousness. This is the most silent and peaceful level of consciousness — one's innermost Self. In this restfully alert state, the brain functions with significantly greater coherence than in sleep or ordinary waking state.

The superior person settles his mind
as the universe settles the stars in the sky.
By connecting his mind with its subtle origin,
he calms it.
Once calmed, it naturally expands,
and ultimately his mind become as vast and immeasurable
as the night sky.
— Lao Tsu

For decades, John Hagelin has been a proponent of a complete unified field theory of all the known matter and force fields of nature. But he has gone much, much farther, by proposing that this unified field at the basis of matter and energy is the SAME as the field of pure awareness described above – the source of thought, experienced while transcending. That silent, transcendental, holistic experience has been described by the great minds of all civilizations, from ancient Vedic seers to Taoist masters, from Greek philosophers to Christian saints, from Renaissance poets to modern artists. It is a universal experience which connects all beings. Hence it has a measurable 'field effect' capable of calming violence and radiating peace in the environment.

Notes on BRST VIII: Clifford Algebras

December 21, 2008
Categories: BRST

Clifford Algebras

Clifford algebras are well-known to physicists, in the guise of matrix algebras generated by the γ -matrices first used in the Dirac equation. They also have a more abstract formulation, which will be the topic of this posting. One way to think about Clifford algebras is as a "quantization" of the exterior algebra, associated with a symmetric bilinear form.

Given a vector space V with a symmetric bilinear form $(\cdot,\cdot)$, the associated Clifford algebra Cliff $(V,(\cdot,\cdot))$ can be defined by starting with the tensor algebra $T^*(V)$ ($T^k(V)$ is the k-th tensor power of V), and imposing the relations

$$v\otimes w + w\otimes v = -2(v,w)1$$

where $v,w\in V=T^1(V),\ 1\in T^0(V)$. Note that many authors use a plus instead of a minus sign in this relation. The case of most interest in physics is $V=\mathbf R^4$, $(\cdot,\cdot)$ the Minkowski inner product of signature (3,1). The theory of Clifford algebras for real vector spaces V is rather complicated. Here we'll stick to complex vector spaces V, where the theory is much simpler, partially because over $\mathbf C$ there is, up to equivalence, only one non-degenerate symmetric bilinear form. We will suppress mention of the bilinear form in the notation, writing Cliff(V) for Cliff$(V,(\cdot,\cdot))$.

For a more concrete definition, one can choose an orthonormal basis e_i of V. Then Cliff(V) is the algebra generated by the e_i, with multiplication satisfying the relations

$$e_i^2=-1,\ \ e_ie_j=-e_je_i\ \ (i\neq j)$$

One can show that these complex Clifford algebras are isomorphic to matrix algebras, more precisely

$$Cliff(\mathbf C^{2n})\simeq M(\mathbf C, 2^n),\ \ \ Cliff(\mathbf C^{2n+1})\simeq M(\mathbf C, 2^n)\oplus M(\mathbf C, 2^n)$$

Clifford Algebras and Exterior Algebras

The exterior algebra $\Lambda^*(V)$ is the algebra of anti-symmetric tensors, with product the wedge product $\wedge$. This is also exactly what one gets if one takes the Clifford algebra Cliff(V), with zero bilinear form. Multiplying a non-degenerate symmetric bilinear form $(\cdot,\cdot)$ by a parameter t gives for non-zero t a Clifford algebra Cliff$(V, t(\cdot,\cdot))$ that can be thought of as a deformation of the exterior algebra $\Lambda^*(V)$. Thinking of the exterior algebra on V of dimension n as the algebra of functions on n anticommuting coordinates, the Clifford algebra can be thought of as a "quantization" of this, taking functions (elements of $\Lambda^*(V)$) to operators (elements of Cliff(V), matrices in this case).

While $\Lambda^*(V)$ is a $\mathbf Z$ graded algebra, $Cliff(V)=Cliff^{even}(V)\oplus Cliff^{odd}(V)$ is only $\mathbf Z_2$-graded, since the Clifford product does not preserve degree but can change it by two when multiplying generators. The Clifford algebra is filtered by a $\mathbf Z$ degree, taking $F_p(Cliff(V))\subset Cliff(V)$ to be the subspace of elements that can be written as sums of $\leq p$ generators. The exterior algebra is naturally isomorphic to the associated graded algebra for this filtration

$$\Lambda^p(V)\simeq F_p(Cliff(V))/F_{p-1}(Cliff(V))$$

$\Lambda^*(V)$ and Cliff(V) are isomorphic as vector spaces. One choice of such an isomorphism is given by composing the skew-symmetrization map

$$v_1\wedge v_2\wedge\cdots\wedge v_p=\frac{1}{p!}\sum_{s\in S_p}sgn(s)v_{s(1)}\otimes v_{s(2)}\otimes\cdots\otimes v_{s(p)}$$

with the projection $T^*(V)\rightarrow Cliff(V)$. Denoting this map by q, it is sometimes called the "quantization map". Using an orthonormal basis e_i, q acts as

$$q(e_{i_1}\wedge e_{i_2}\wedge\cdots\wedge e_{i_p})=e_{i_1}e_{i_2}\cdots e_{i_p}$$

The inverse $\sigma=q^{-1}:Cliff(V)\rightarrow \Lambda^*(V)$ is sometime called the "symbol map".

This identification as vector spaces is known as the "Chevalley identification". Using it, one can think of the Clifford algebra as just an exterior algebra with a different product.

Clifford Modules and Spinors

Given a Clifford algebra, one would like to classify the modules over such an algebra, the Clifford modules. Such a module is given by a vector space M and an algebra homomorphism

$$\pi: Cliff(V)\rightarrow End(M)$$

To specify π, we just need to know it on generators, and see that it satisfies

$$\pi(v)\pi(w) +\pi(w)\pi(v)= -2(v,w)Id$$

One such Clifford module is $M=\Lambda^*V$, with

$$\pi(v)\omega=v\wedge\omega - i_v\omega$$

where i_v is contraction by v. This gives the inverse to the quantization map (the symbol map σ) as

$$\sigma: a\in Cliff(V)\rightarrow \pi(a)1\in \Lambda^*(V)$$

$\Lambda^*(V)$ is not an irreducible Clifford module, and we would like to decompose it into irreducibles. For $dim_{\mathbf C}V =2n$ even, there will be a single such irreducible S, of dimension 2^n, and the module map $\pi:Cliff(V)\rightarrow End(S)$ is an isomorphism. In the rest of this posting we'll stick to the this case, for the odd dimensional case see the references mentioned at the end.

To pick out an irreducible module $S\subset \Lambda^*(V)$, one can begin by choosing a linear map $J:V\rightarrow V$ such that $J^2=-1$ and J is orthogonal ($(Jv,Jw)=(v,w)$). Then let $W_J\subset V$ be the subspace on which J acts by +i, $\overline W_J$ be the subspace on which J acts by -i. Note that V is a complex vector space, and now has two linear maps on it that square to -1, multiplication by i, and multiplication by J. W_J is an isotropic subspace of V, since

$$(v_1,v_2)=(Jv_1,Jv_2)=(iv_1,iv_2)=-(v_1,v_2)$$

for any $v_1,v_2\in W_J$. We now have a decomposition $V=W_j\oplus \overline W_J$ into two isotropic subspaces. Since the bilinear form is zero on these subspaces, we get two subalgebras of the Clifford algebra, $\Lambda^*(W_J)$ and $\Lambda^*(\overline{W_J})$. It turns out that one can choose $S\simeq \Lambda^*(W_J)$.

One can make this construction very explicit by picking a particular J, for instance the one that acts on the element of an orthonormal basis by $Je_{2j-1}=e_{2j},\ Je_{2j}=-e_{2j-1}$ for $j=1,\cdots n$. Letting $w_j=e_{2j-1}+ie_{2j}$ we get a basis of W_J. To get an explicit representation of S as a Cliff(V) module isomorphic to $\Lambda^*(\mathbf C^n)$, we will use the formalism of fermionic annihilation and creation operators. These are the operators on an exterior algebra one gets from wedging by or contracting by an orthonormal vector, operators a_i^+ and a_i for $i=1,\cdots,n$ satisfying

$$\{a_i,a_j\}=\{a^+_i,a^+_j\}=0$$

$$\{a_i,a^+_j\}=\delta_{ij}$$

In terms of these operators on $\Lambda^*(\mathbf C^n)$, Cliff(n) acts by

$$e_{2j-1}=a_j^+-a_j$$

$$e_{2j}=-i(a^+_j+a_j)$$

The Spin Representation

The group that preserves $(\cdot,\cdot)$ is $O(n,\mathbf C)$, and its connected component of the identity $SO(n,\mathbf C)$ has compact real form SO(n). SO(n) has a non-trivial double cover, the group Spin(n). One can construct Spin(n) explicitly as invertible elements in Cliff(V) for $V=\mathbf R^n$, and its Lie algebra using quadratic elements of Cliff(V), with the Lie bracket given by the commutator in the Clifford algebra.

For the even case, a basis for the Cartan subalgebra of $Lie\ Spin(2n)$ is given by the elements

$$\frac{1}{2}e_{2j-1}e_{2j}$$

These act on the spinor module $S\simeq\Lambda^*(\mathbf C^n)$ as

$$\frac{1}{2}e_{2j-1}e_{2j}=-i\frac{1}{2}(a_j^+-a_j)(a_j^++a_j)=i\frac{1}{2}$$

with eigenvalues $(\pm\frac{1}{2},\cdots,\pm\frac{1}{2})$. S is not irreducible as a representation of Spin(2n), but decomposes as $S=S^+\oplus S^-$ into two irreducible half-spin representations, corresponding to the even and odd degree elements of $\Lambda^*(\mathbf C^n)$.

With a standard choice of positive roots, the highest weight of S^+ is

$$(+\frac{1}{2},+\frac{1}{2}\cdots,+\frac{1}{2},+\frac{1}{2})$$

and that of S^- is

$$(+\frac{1}{2},+\frac{1}{2}\cdots,+\frac{1}{2},-\frac{1}{2})$$

Note that the spinor representation is not a representation of SO(2n), just of Spin(2n). However, if one restricts to the $U(n)\subset SO(2n)$ preserving J, then the $\Lambda^*(W_J)$ are the fundamental representations of this U(n). These representations have weights that are 0 or 1, shifted by $+\frac{1}{2}$ from those of the spin representation. One can't restrict from Spin(2n) to U(n), but one can restrict to $\tilde U(n)$, a double cover of U(n). On this double cover the notion of $\Lambda^n(\mathbf C^n)^{\frac{1}{2}}$ makes sense and one has, as $\tilde U(n)$ representations

$$S\otimes \Lambda^n(\mathbf C^n)^{\frac{1}{2}}\simeq\Lambda^*(\mathbf C^n)$$

So, projectively, the spin representation is just $\Lambda^*(\mathbf C^n)$, but the projective factor is a crucial part of the story.

The above has been a rather quick sketch of a long story. For more details, a good reference is the book *Spin Geometry* by Lawson and Michelsohn. Chapter 12 of Segal and Pressley's *Loop Groups* contains a very geometric version of the above material, in a form suitable for generalization to infinite dimensions. My notes for my graduate class also have a bit more detail, see here.

In the next posting we'll see what happens when one chooses $V=\mathfrak g$, and studies the Clifford algebra $Cliff(\mathfrak g)$

Comments

   December 23, 2008

   It seems only few years back that Clifford Algebras have been getting more attention…

   I'm wondering what their primary applications are.

2. **Peter Woit**
   December 23, 2008

   John,

   The primary applications of Clifford algebras have always been to construct spinors (and thus the spin representations of orthogonal groups, from which all other reps of these groups can be constructed) and write down the Dirac equation. Much more speculative has been the idea of trying to use them to understand internal symmetries. Lots of people have tried to do this, with varying results.

   In physics, whenever one works with anti-commuting variables, when one quantizes them, what one gets is a a Clifford algebra. So, the things really are everywhere.

   In mathematics, the use of Clifford algebras to do representation theory, more generally than just for orthogonal groups, has been getting more attention in recent years, and that's part of the story I'm trying to write about here.

3. **John**
   December 23, 2008

Peter, I'm sure you know of David Hestenes' works using Grassmann and (I think also, although I'm not sure) Clifford Algebras…

Aren't Clifford Algebras then used to reformulate some areas of physics? If they are, I'm wondering which areas and (perhaps) how?

Also, are the Clifford Algebra reps a key component of BRST quantization (Just wondering.)

John

4. **Peter Woit**
December 23, 2008

John,

Grassman algebra = exterior algebra

I haven't looked closely at the work of Hestenes. From what I've seen much of it exploits the relationship between the exterior algebra and the Clifford algebra explained in this posting.

Clifford algebras are a crucial part of the approach to BRST I'm explaining in these notes. If you look at standard treatments of BRST, you'll find that some of them crucially use Clifford algebras, others avoid this.

5. **John**
December 24, 2008

Thanks.

6. **andy.s**
December 24, 2008

Hestenes (and also Doran and Lasenby at Cambridge) rewrites basic physics using Clifford algebra to replace vector algebra.

So, for angular momentum $L = r \wedge p$ instead of $L = r \times p$, for example.

It's fun stuff. Doran and Lasenby use this to derive a gauge theory of gravity in flat space.

Physics Murder Mystery

December 27, 2008
Categories: Uncategorized

After the recent news that Lisa Randall is writing the libretto for an opera, there's further evidence that particle theorists in Cambridge are moving in the direction of creative writing. Today's Wall Street Journal has a feature article about various people's plans for 2009. One of these is Frank Wilczek, who writes:

> I'm writing a physics murder mystery. The idea is that two men and two women from Harvard and MIT collaborate and discover dark matter. It's clear that they should win a Nobel Prize, but according to the rules of the prize, only three people at most can share.

This is an entertaining idea for a plot, and perhaps it has some personal resonance with Wilczek. For much of his career, he was well-known to be one of the people responsible for a definitely Nobel-prize caliber discovery, but he did not have a Nobel prize. By some counts, there were four people (Gross, Politzer, 't Hooft, Wilczek) who had a hand in the discovery of asymptotic freedom back in 1973. It was only with the award of a Nobel for related work to 't Hooft and Veltman in 1999 that the numerical obstruction to an asymptotic freedom award was removed, with the award going to the other three in 2004. Over this quarter century or so, surely it did not occur to any of the four that it might not be an entirely bad thing if one of them didn't live to a ripe old age….

Next month I'll be spending a week or so in Paris, partly for vacation, partly to attend a conference about Grothendieck's mathematical legacy, to be held at the IHES, a place I've never before visited. There's a murder mystery about the IHES that I've heard about but haven't yet read, so I hope to get a copy in France. The author is Nicole Gaume, who worked for the IHES director, and was forced out when a new director (Marcel Berger) came on the scene. Under the pen-name Margot Bruyère she wrote a roman à clef featuring the mathematicians of the IHES and the murder of a new director. The book first came out under the title *Dis-moi qui tu aimes (je te dirai qui tu hais)*, but was republished in 2002 under the new title *Maths à mort*. For more information about the book, see here.

Update: I just noticed that Wilczek has posted on his web-site an essay about Hermann Weyl's Philosophy of Mathematics and Natural Science that will be the introduction to a new edition of the book appearing next year.

   December 27, 2008

   "Writing a book for a general audience connected Randall with a new set of people in fields outside of physics. One of them, the Spanish composer Hector Parra, intrigued Randall by asking if she would try writing a libretto for an opera about her work. The resulting piece, a collaboration with the artist Matthew Ritchie, is scheduled to debut in Paris at the Georges Pompidou Centre this summer, then travel throughout Europe in the fall. …

   "The piece has the puzzling title of "Hypermusic Prologue: A projective opera in seven planes," the seven planes referring to space and to the opera's seven acts. The work's broader goal is to suggest new approaches to both science and art. The old-fashioned form of opera, Randall and her colleagues hope, can become a vehicle for modern science, using sound and voice to re-create the many dimensions that physicists now explore."

   It's interesting that string theorists are so successful in popularizing their ideas that people *now actually ask them to convey the ideas by media such as opera*. Lisa can't be blamed, since she was asked to write it. But will anyone ever ask people working on alternatives to string theory to write operas to popularize those? Is it obviously the Matthew effect (Matthew 25:29), i.e. once an idea has attained a critical mass of publicity, nothing can prevent a media frenzy about it that ignores alternative ideas completely. Extra dimensions have so much buzz, they're in fashion. Does opera want to be fashionable, or is it really the best medium for exploring the physics of string theory?

2. **Coin**
   December 27, 2008

   Incidentally, if this question is sufficiently on topic: Has anyone read Wilczek's "The Lightness of Being", is it recommended? Does it do much to teach physics concepts or is it more a philosophy-of-science sort of thing?

3. **Peter Woit**
   December 27, 2008

   Coin,

   It's not designed for people who already know a lot about particle physics, but more aimed at (among other things) giving the general public some idea of the insights from the Standard Model about where mass comes from. I liked the fact that it's free of the kind of speculative hype and science fiction that too often characterizes popular books about physics these days.

   For a more technically sophisticated reader, I'd recommend Wilczek's "Fantastic Realities", which I wrote about here:

   http://www.math.columbia.edu/~woit/wordpress/?p=394

4. **Chris W.**
   December 27, 2008

   > It's interesting that string theorists are so successful in popularizing their ideas that people *now actually ask them to convey the ideas by media such as opera*. Lisa can't be blamed, since she was asked to write it.

   Lisa Randall is not a string theorist. Of course one can argue that Kaluza-Klein inspired models of the sort for which she has become known have become about as trendy (and problematic) as string theory itself, but the distinction should be maintained.

   December 28, 2008

   It was certainly eye opening to see in Wilczek's survey of Weyl such an emphasis on Leibniz' philosophy. I believe we would be hard pressed today to find a mere handful of theoreticians who comprehend the legacy and vector of method running through Leibniz, Gauss, Dirichlet, Riemann, Cantor, Hilbert to Goedel, et al.

6. **Cormac O Raifeartaigh**

December 28, 2008

Hi Peter, interesting post as always.
Lochlainn spent a year at IHES in the seventies, working with Louis Michel – that is also where his book on the group structure of gauge theories was written. All the family have happy memories of both Bures and the IHES.
Re Nobel, I've never understood hy the Swedish Academy have stuck to such a literal interpretation of the rules, it's really a pity..

7. **theoreticalminimum**
December 28, 2008

Maybe you could enquire how things are going with IHES' edition of "Récoltes et semailles" when you are in Bures-sur-Yvette? 🙂

8. **Jonathan Vos Post**
December 29, 2008

One should not be surprised by the subgenre of Physics Murder Mystery" given precursors such as:

(1)
"Special Topics in Calamity Physics"
by Marisha Pessl
ISBN13: 9780670037773
ISBN10: 067003777x
"is a darkly hilarious coming-of-age novel and a richly plotted suspense tale told through the distinctive voice of its heroine, Blue van Meer. After a childhood moving from one academic outpost to another with her father (a man prone to aphorisms and meteoric affairs), Blue is clever, deadpan, and possessed of a vast lexicon of literary, political, philosophical, and scientific knowledge"

(2)
Einstein Year – a year celebrating physics – Who killed Prof Jaeger?
"Rufus Jaeger, a world-famous physicist, is killed while demonstrating a live quantum experiment on stage – but was it an accident? Follow news@nature.com's murder mystery to track down the killer."

(3)
I. Goldhaber-Gordon and D. Goldhaber-Gordon, "Schrodinger's mouse- trap – Part 6: A cryptic response", Nature 433, 805 (2005). Chapter of a serialized physics murder mystery.

(4)
Innes, Michael The Weight of the Evidence. 1943, Harper/Perennial. A somewhat ordinary murder mystery, but the murder was committed using a meteorite in a university setting.

(5)
Preuss, Paul Broken Symmetries. 1983, Pocket Books. A novel of science, politics, and intrigue surrounding the building of a giant particle accelerator in Hawaii. (A 1997 sequel is entitled Secret Passages.)

(6)
Benford, Gregory "Matter's End" in Matter's End. 1994, Bantam. Physicists in India find that protons do decay as predicted by some Grand Unified Theories, with dire consequences for reality.

(7)
Egan, Greg Quarantine.1992, Harper Prism. A sophisticated detective mystery that addresses serious ideas in the interpretation of quantum mechanics.

(8)
Lem, Stanislav The Investigation. 1959, Avon. A novel that considers the philosophical implications of quantum mechanics: what if a mystery is unsolvable in principle?

(9)
Niven, Larry "All the Myriad Ways" in All the Myriad Ways. 1971, Ballantine. Works out some of the implications of the many-worlds interpretation for solving murder mysteries.

(10)
The Physics of Murder by Don Light.

I could go on at length, given my Physics training at Caltech , my coauthorship with Isaac Asimov (who wrote many Mystery stories and books, and several popular books of Physics and Chemsitry), and my father and myself having been Active Members of Mystery Writers of America. But I hope that these 10 data in an existence proof show that Lisa Randall, whether or not you can narrowly call her a String Theorist, is wiring in a grand tradition, and should be welcomed by scientists and the literati alike.

9. **Andrew Gelman**
December 29, 2008

Hi, Peter. This story is consistent with the finding that not getting the Nobel Prize reduces your expected lifespan by two years. The fited article frames it as that winning the prize increases your lifespan, but so many more eligible people don't get it than do (and the No comes year after year). I'd guess that it's a net reducer of scientists' lifespans. Even setting murder aside.

10. **Jon A.**
January 1, 2009

Peter, is the IHES conference open to the public, or do you have to be a registered guest?

I am a math PhD student, and will be traveling in the area. I would like to attend the talks on Monday.

11. **Jon A.**
January 1, 2009

I just found out that the registration is closed for the conference. Thanks.

12. **coolstar**
March 12, 2009

It's probably not well know to regular readers here, but there's a similar "4 person" problem in astronomy now. The four are Marcy & Butler and Mayor & Queloz for their work in discovering extra-solar planets. I strongly suspect that if THAT number was reduced by one (not that I'm hoping for that), then the survivors would have a good shot at the Nobel. Unlike the example given in physics, the chances of a "good" solution to this seems unlikely.

Notes on BRST IX: Clifford Algebras and Lie Algebras

December 29, 2008
Categories: BRST

Note: I've started putting together the material from these postings into a proper document, available [here](), which will be getting updated as time goes on. I'll be making changes and additions to the text there, not on the blog postings. For most purposes, that will be what people interested in this subject will want to take a look at.

When a Lie group with Lie algebra \mathfrak g acts on a manifold M, one gets two sorts of actions of \mathfrak g on the differential forms \Omega^*(M). For each X\in \mathfrak g one has operators:

- \mathcal L}_X: \Omega^k(M)\rightarrow\Omega^k(M), the Lie derivative along the vector field on M corresponding to X

and

- i_X:\Omega^k(M)\rightarrow\Omega^{k-1}(M), contraction by the vector field on M corresponding to X

These operators satisfy the relation

di_X+i_Xd={\mathcal L}_X

where d is the de Rham differential d:\Omega^k(M)\rightarrow \Omega^{k+1}(M), and the operators d, i_X, \mathcal L_X are (super)-derivations. In general, an algebra carrying an action by operators satisfying the same relations satisfied by d, i_X, \mathcal L_X will be called a \mathfrak g-differential algebra. It will turn out that the Clifford algebra Cliff(\mathfrak g) of a semi-simple Lie algebra \mathfrak g carries not just the Clifford algebra structure, but the additional structure of a \mathfrak g-differential algebra, in this case with \mathbf Z_2, not \mathbf Z grading.

Note that in this section the commutator symbol will be the supercommutator in the Clifford algebra (commutator or anti-commutator, depending on the \mathbf Z_2 grading). When the Lie bracket is needed, it will be denoted _{\mathfrak g}.

To get a \mathfrak g-differential algebra on Cliff(\mathfrak g) we need to construct super-derivations i_X^{Cl}, {\mathcal L}_X^{Cl}, and d^{Cl} satisfying the appropriate relations. For the first of these we don't need the fact that this is the Clifford algebra of a Lie algebra, and can just define

i_X^{Cl}(\cdot)=

For {\mathcal L}_X^{Cl}, we need to use the fact that since the adjoint representation preserves the inner product, it gives a homomorphism

\widetilde{ad}:\mathfrak g \rightarrow \mathfrak{spin}(\mathfrak g)

where \mathfrak{spin}(\mathfrak g) is the Lie algebra of the group Spin(\mathfrak g) (the spin group for the inner product space \mathfrak g), which can be identified with quadratic elements of Cliff(\mathfrak g), taking the commutator as Lie bracket. Explicitly, if X_a is a basis of \mathfrak g, X_a^* the dual basis, then

\widetilde{ad}(X)=\frac{1}{4}\sum_a X_a^*_{\mathfrak g}

and we get operators acting on Cliff(\mathfrak g)

{\mathcal L}_X^{Cl}(\cdot)=

Remarkably, an appropriate d^{Cl} can be constructed using a cubic element of Cliff(\mathfrak g). Let

\gamma= \frac{1}{24}\sum_{a,b}X^*_aX^*_b_{\mathfrak g}

then

d^{Cl}(\cdot)=

d^{Cl}\circ d^{Cl}=0 since \gamma^2 is a scalar which can be computed to be -\frac{1}{48}tr\Omega_{\mathfrak g}, where \Omega_{\mathfrak g} is the Casimir operator in the adjoint representation.

The above constructions give Cliff(\mathfrak g) the structure of a filtered \mathfrak g-differential algebra, with associated graded algebra \Lambda^*(\mathfrak g). This gives \Lambda^*(\mathfrak g) the structure of a \mathfrak g-differential algebra, with operators i_X, \mathcal L_X, d. The cohomology of this differential algebra is just the Lie algebra cohomology H^*(\mathfrak g, \mathbf C).

Cliff(\mathfrak g) can be thought of as an algebra of operators corresponding to the quantization of an anti-commuting phase space \mathfrak g. Classical observables are anti-commuting functions, elements of \Lambda^*(\mathfrak g^*). Corresponding to i_X, \mathcal L_X, d one has both elements of \Lambda^*(\mathfrak g^*) and their quantizations, the operators in Cliff(\mathfrak g) constructed above.

1. **Shantanu**
   December 31, 2008

   Peter this maybe a bit OT, But your thoughts about this paper by
   Mcelrath
   [http://arxiv.org/abs/0812.2696]() ?

Thanks

2. **lewallen**
January 1, 2009

   Thanks a lot for the pdf! It’s great and very convenient.

3. **Peter Woit**
January 2, 2009

   Shantanu,

   Sounds pretty implausible, but I know very little about it. For some discussion with McElrath, see the comments at

   http://blogs.discovermagazine.com/cosmicvariance/2008/12/27/gravity-emergesfrom-neutrinos/

   One problem is that of universality, raised by Bee, which McElrath acknowledges he doesn’t yet have an answer for.

Dis-moi qui tu aimes (je te dirai qui tu hais)

January 2, 2009
Categories: Book Reviews

A colleague has very helpfully provided me with a copy of the murder mystery set at the IHES that I wrote about recently here, and I've just finished reading it. Since I'm not much of an afficionado of this genre of fiction, I can't really evaluate how good a murder mystery it is. But as a memoir of the IHES during the 1980s, it is excellent. A claim at the beginning of the book that "any resemblance to real persons is just coincidence" seems to be one of the few things in it (besides the murder) that is fiction. As far as I can tell, the descriptions of all characters correspond precisely to someone at the IHES during that period, with only the names changed. I'm guessing that all or most of the anecdotes about these characters also correspond to reality.

It's a roman a clef, so here's the key for the major characters:

Andre Grusin = Leon Motchane
Henrik Dekker = Nicolaas Kuiper
Charles Bouleaux = Marcel Berger
Antoine Fleuret = Alain Connes
Jacob Zuram = Barry Mazur
Boris Grekov = Mikhael Gromov
Jacques Chevalier = Pierre Deligne

Among the minor characters, I suspect

Joe Bub = Dennis Sullivan
David Amir = Ofer Gabber
Albert Toudy = Adrien Douady

I don't think I'll be giving away too much of the plot to mention that, since the novel was written nearly twenty years ago, back when string theory was a hot topic, one of the plot twists involves string theory. There's a discovery that "superstring theory is renormalizable and predicts that gluonic interactions are colorless".

   January 2, 2009

   i know it's pathetic but the 'que' should be a 'qui'. Anyway, I'd love to read the book in whatever language (it's out of print), now that I've read Dixmier's testimonial :

   « Une partie du charme de ce livre provient de l'environnement psychologique inhabituel. Bien sûr, les passions classiques se déchaînent ; mais aussi des passions moins classiques. Margot Bruyère, à l'évidence, connaît bien le milieu qu'elle décrit. »
   Jacques Dixmier

2. **Peter Woit**
   January 2, 2009

   Thanks Lieven, typo fixed.

   Dixmier's blurb is accurate.

   Is it really out of print? It was republished in 2002 as "Maths a Mort", and that version still shows up on the publisher's web-site:

   http://www.aleas.fr/index.php?option=com_content&task=view&id=16&Itemid=2

   and FNAC

   http://livre.fnac.com/a1355591/M-Bruyere-Maths-a-mort?PID=1

   and amazon.fr

   http://www.amazon.fr/Maths-à-mort-Margot-Bruyère/dp/284301056X/

   Margot Bruyere has a web-site:

   http://www.margot-bruyere.fr/

   and the first chapter is online there:

   http://www.margot-bruyere.fr/en/docs/maths.pdf

3. **lieven**
   January 2, 2009

   thx peter. i did find the website and read the first chapter. the fnac-website sucks and amazon.fr says its unavailable. i'll try to get hold of it somehow. atb :: lieven.

4. **lieven**
   January 2, 2009

   my apologies to fnac.fr. they've promised delivery in 3 weeks…

5. **Margot Bruyère**
   January 4, 2009

Happy new year! Bonne année!
I just discover your website and the comments on my book “Dis-moi qui tu aimes” alias “Maths à mort”, and I am happy to state that most people enjoyed it.

I regret that my english is too poor to translate it. But if somebody thinks it’s worth to do it and have it print, I would be very gratefuf… but I do’nt know a translator (Mary Turner seems to have given up) neither a publisher.

6. **Peter Woit**
   January 5, 2009

   Margot Bruyere,

   I also definitely enjoyed the book, thanks for writing it!

   I know nothing about the market for murder mystery books, but perhaps a press that publishes mathematics books would be interested. Maybe Princeton University Press, perhaps Jacques Chevalier could help…

   Peter

7. **Margot Bruyère**
   January 7, 2009

   Thank you, Peter, for reading the book. I am happy that you appreciate it. Maybe I will try to have the book translated! But I am working now more on history than mathematicians.

   I enjoyed very much the time I worked at IHES, but I enjoy also very much the life I have now in Brittany.

New Year Links

January 5, 2009
Categories: Uncategorized

There's a conference going on in Jerusalem now on the topic of Particle Physics in the Age of the LHC. Some slides and other talk materials are here, video may start appearing here. Not clear when the "Age of the LHC" is; unfortunately we're still a ways away from first collisions, even farther from new physics. Next year, starting in May, the KITP will be running a program on The First Year of the LHC, which may also be jumping the gun a bit, at least to the extent that the topic is LHC physics results. Last year's LHC program, Physics of the Large Hadron Collider, has a web-site that still begins with the counter-factual "The Large Hadron Collider (LHC) will begin operation by the end of 2007."

Also next year, the KITP will be running another supposedly LHC-related program, entitled Strings at the LHC and in the Early Universe. I wonder what the KITP director thinks of this, since he's on record as thinking it unlikely that the LHC will have anything to say about string theory. A much less dubious KITP program about string theory is the one starting today, with the title Fundamental Aspects of String Theory. This program focuses on the current lack of understanding of what string theory really is:

> Over the last decade, string theory has seen important conceptual and technical advances on a host of long-standing problems involving non-pertur-bative and strongly-coupled physics. However, the fundamental ingredients of superstring theory and M-theory are still not well understood, and this five month program will be directed at these open questions.

The first week will be devoted to introductory talks about string field theory and the pure spinor formalism, two quite different attempts to give a new and different formulation of string theory.

Also starting today is the big annual meeting of the AMS, held this year in Washington, DC. One of the important features of this meeting is that many institutions, especially smaller ones, do their initial interviews for next year's jobs at the meeting. This coming hiring season promises to be an exceptionally brutal one for job candidates, with financial problems leading to freezes and reduced hiring at many places. One resource for young mathematicians on the job market is the web-site of the Young Mathematicians Network.

I wrote about Witten's talk on quantum Yang-Mills theory at the Yau birthday conference here. A write-up of the talk is now available as a preprint here.

There's a new book coming out this month that I'm looking forward to reading, Graham Farmelo's biography of Dirac, entitled The Strangest Man: The Hidden Life of Paul Dirac, Quantum Genius. Nature Physics has a review here.

This week's Science Saturday featured John Horgan and George Johnson discussing the state of science journalism and what it has to do with blogging. As science journalists, they take exception to the point of view common among scientists that their job is just to try and accurately transmit to the public the claims being made by scientists.

Comments

1. **MathPhys**
   January 5, 2009

   Thank you, Peter, for the link to Dirac's biography. There is another by Kragh and a number of biographical sketches by others, but I never thought they were adequate.

   Best wishes for 2009.

2. **John Armstrong**
   January 5, 2009

   To expand on the brutal hiring season: word on the street here at the Joint Meetings is that fully one third of the employers have pulled out of the job fair. And as for me: I quit.

3. **anon.**
   January 6, 2009

   Thanks for the link to Farmelo's book on Dirac. I'm surprised that you are keen to read about the guy, seeing how much he argued against mainstream QFT developments after his own work. (E.g., quotations from Dirac here and here.) Dirac also claimed that there was some argument for a physical Dirac sea of virtual particles in the vacuum:

   'Physical knowledge has advanced much since 1905, notably by the arrival of quantum mechanics, and the situation has again changed. If one examines the question in the light of present-day knowledge, one finds that the aether is no longer ruled out by relativity, and good reasons can now be advanced for postulating an æther. . . .

   'We must make some profound alterations to the theoretical idea of the vacuum. . . . Thus, with the new theory of electrodynamics we are rather forced to have an æther.' – P. A. M. Dirac, 'Is There an æther?', Nature, v168 (1951), pp. 906-7.

   'Infeld has shown how the field equations of my new electrodynamics can be written so as not to require an æther. This is not sufficient to make a complete dynamical theory. It is necessary to set up an action principle and to get a Hamiltonian formulation of the equations suitable for quantization purposes, and for this the æther velocity is required.' – P. A. M. Dirac, 'Is there an æther?', Nature, v169 (1952), p. 702.

   In addition, there was his large numbers hypothesis with the argument that G varies with time. In addition, he was an electrical engineer before studying mathematics. Surely all this crackpottery makes the guy unworthy of serious attention?

4. **Peter Woit**
   January 6, 2009

   John,

   Thanks for the report from the meeting. Good luck to you and others dealing with the job situation. About the only encouragement I can provide is to note that just about all of the many people I know who have left academia over the years look back on that as a good decision…

5. **Peter Woit**
   January 6, 2009

anon.,

Adopting the standard of ignoring any of the great physicists of the past if some of their ideas don't hold up well half a century later would make the study of the history of physics a great deal simpler…

6. **Thomas Larsson**
   January 7, 2009

   Scientists are not remembered for their mistakes and blunders, but for their successes. The list of great physicists doing fundamental mistakes is long. E.g., Lorentz and Poincare were leaders in ether theory, Kelvin ridiculed Einstein's discoveries, Einstein denied QM, Heisenberg's Urfeld theory, Witten promoted string theory 🙂 , and many others. The only safe way to avoid wrong ideas is to not have any ideas at all.

7. **theoreticalminimum**
   February 24, 2009

   Dear Peter,

   I was just wondering if you have had the opportunity to read Farmelo's book on Dirac yet. It would be nice to know what you think about it. I am very much looking forward to buy a copy of the book, since Dirac was so special a human being.

8. **Peter Woit**
   February 25, 2009

   No, haven't got a copy of the book yet. Hope to soon, and probably will write something about it after I get to read it.

Best Job in the US

January 6, 2009
Categories: Uncategorized

According to the latest JobsRated listing released today, the best job in the US is that of mathematician. Pay is good, stress is low, and you don't have to get your hands dirty, but can sit in front of a computer monitor all day. Nice work if you can get it. The job of physicist is significantly less desirable: down at number 13, not quite as good as working as a philosopher (number 12), but a bit better than being a parole officer (number 14).

Comments

1. **A.**
   January 6, 2009

   Cute! If you have tenure, sure, being a mathematician (or theoretical physicist, the day-to-day routine isn't very different) is a sublime job.

   A postdoc position, on the other hand, well I'd guess that would come much further down the list! Pay is OK, stress — mostly from agonising over where the next postdoc is coming from — is high, and you have to get your hands dirty working on trendy stuff you don't really care about in order to get noticed. I've got a heacache just thinking about it.

2. **Sandro**
   January 6, 2009

   "Pay is good, stress is low, and you don't have to get your hands dirty, but can sit in front of a computer monitor all day."

   They forget to say that there are high chances you get obsessed with what you are doing, and that actually what you are working on never leaves you alone…

3. **Cormac O Raifeartaigh**
   January 6, 2009

   Parole officer? I think that tells us a little about this study…

4. **John Armstrong**
   January 6, 2009

   Stress is low? Bull. Like A. points out, that only goes if you've got tenure. The job market is horrific this year.

5. **John Armstrong**
   January 6, 2009

   Looking into their methodology indicates that the mathematician's "mid-level" income is quoted as \$94K, with a "growth potential" (span from low to high income) of "160%", for whatever that means.

   I don't think this is intended as describing academic mathematics, but mathematics as a wider occupation. I'd say academics should be listed separately.

6. **Peter Woit**
   January 6, 2009

   For information on academic math pay-scales, see

   http://www.ams.org/employment/facsal.html

   \$94K would be a typical salary of a tenured person at a university with doctoral programs. Liberal arts and other colleges pay less. Math jobs in the financial industry pay quite a bit more,

7. **Nugae**
   January 6, 2009

   Being a mathematician sounds to me to be about the most stressful job around. Sure, you get paid, and you get to sit around in a nice warm office, but you risk spending years of your life on something that never works out. Or on proving something that someone else, with different tools and insights, proves in 5 minutes.

   Most jobs have a built-in worthwhileness indicator that gives you some sort of an answer to "have I been wasting my time today / this week / this month / this year?". Mathematics doesn't.

8. **Peter Woit**
   January 6, 2009

   Nugae,

   Mathematicians outside of academia are often working on things that quickly get evaluated as to their "worthwhileness". My friends who build models used by hedge funds in their trading strategies are an example. As for academics, you forget that a big part of the job is to teach students. And, with every test they take, you see whether you are doing a good job.

   Pure math research may not work out, or may be hard to evaluate, but one of the main reasons that people do it is that they enjoy the process. You learn new things as you go, even if you don't end up where you had hoped.

9. **st**
   January 6, 2009

   If you're a math major and want a secure high-paying job, be an actuary or a biostatistician. Mathematics research is not a job; it's a vocation, a calling — like monkhood.

10. **John**
    January 6, 2009

    Hi Peter,

    Does this mean that Quant jobs are no longer worth pursuing?

    Regards

11. **Sandro**
    January 7, 2009

    "Pure math research may not work out, or may be hard to evaluate, but one of the main reasons that people do it is that they enjoy the process. You learn new things as you go, even if you don't end up where you had hoped."

    I agree. The problem is when things don't end up anywhere, and it happens quite often…

12. **Peter Woit**
    January 7, 2009

    John,

    From what I hear, people are still getting quant jobs, but they are quite a bit harder to get. Then again, all jobs are harder to get right now….

13. **Steve Myers**
    January 8, 2009

    I was a math major who ended up doing all kinds of work (mostly in electrical field) & have ended up acquiring and analyzing data & writing technical papers with a job with good pay & benefits. (I dropped out of grad school.) My oldest son, who is very gifted mathematically (invented his own form of integral calculus) chose Computer Science & does well (very good pay). My brother became a high school math teacher. So there are many ways to go for math guys. And you can always do pure research on your own for the pure pleasure of it.

14. **John**
    February 5, 2009

    Many people love working in a work place. I appreciate your honesty in this blog.

Dyson on Birds and Frogs

January 7, 2009
Categories: Uncategorized

Next month's Notices of the AMS has an essay by Freeman Dyson entitled Frogs and Birds, which was written for his planned Einstein Public Lecture. In it, he divides mathematicians up into two species: birds, who "fly high in the air and survey broad vistas" (i.e. seek abstraction, unification and generalization), and frogs, who "see only the flowers that grow nearby" (i.e. study the details of specific examples).

Dyson himself is resolutely a frog, but writes that "many of my best friends are birds", and argues that both birds and frogs are needed to do justice to the breadth and depth of the subject of mathematics. Frog that he is, his essay covers a variety of quite different special topics that have drawn his attention, linked together only weakly by the bird/frog theme. These include a discussion of the roles of complex numbers and linearity in quantum mechanics, a proposed idea about how to attack the Riemann hypothesis (try and enumerate 1d-quasicrystals, since the zeros of the zeta function have this structure), and a collection of profiles and anecdotes about various mathematicians and physicists (Besicovitch, Weyl, Yang, Manin, von Neumann).

Personally I suppose I fit well into Dyson's bird category, but among the best mathematicians that I know, the frog/bird distinction is often unclear. Many of them make their reputation by proving rather abstract and general theorems, but these proofs are often the result of a huge amount of detailed investigation of examples. I agree with Dyson that both points of view are needed, and see the most successful cases of progress in mathematics coming from mathematicians who avoid the temptation to fly too high into arid abstraction, or sink too deep into irrelevant detail.

Dyson includes a long section on string theory, which I'll include here:

> I would like to say a few words about string theory. Few words, because I know very little about string theory. I never took the trouble to learn the subject or to work on it myself. But when I am at home at the Institute for Advanced Study in Princeton, I am surrounded by string theorists, and I sometimes listen to their conversations. Occasionally I understand a little of what they are saying. Three things are clear. First, what they are doing is first-rate mathematics. The leading pure mathematicians, people like Michael Atiyah and Isadore Singer, love it. It has opened up a whole new branch of mathematics, with new ideas and new problems. Most remarkably, it gave the mathematicians new methods to solve old problems that were previously unsolvable. Second, the string theorists think of themselves as physicists rather than mathematicians. They believe that their theory describes something real in the physical world. And third, there is not yet any proof that the theory is relevant to physics. The theory is not yet testable by experiment. The theory remains in a world of its own, detached from the rest of physics. String theorists make strenuous efforts to deduce consequences of the theory that might be testable in the real world, so far without success.
>
> My colleagues Ed Witten and Juan Maldacena and others who created string theory are birds, flying high and seeing grand visions of distant ranges of mountains. The thousands of humbler practitioners of string theory in universities around the world are frogs, exploring fine details of the mathematical structures that birds first saw on the horizon. My anxieties about string theory are sociological rather than scientific. It is a glorious thing to be one of the first thousand string theorists, discovering new connections and pioneering new methods. It is not so glorious to be one of the second thousand or one of the tenth thousand. There are now about ten thousand string theorists scattered around the world. This is a dangerous situation for the tenth thousand and perhaps also for the second thousand. It may happen unpredictably that the fashion changes and string theory becomes unfashionable. Then it could happen that nine thousand string theorists lose their jobs. They have been trained in a narrow specialty, and they may be unemployable in other fields of science.
>
> Why are so many young people attracted to string theory? The attraction is partly intellectual. String theory is daring and mathematically elegant. But the attraction is also sociological. String theory is attractive because it offers jobs. And why are so many jobs offered in string theory? Because string theory is cheap. If you are the chairperson of a physics department in a remote place without much money, you cannot afford to build a modern laboratory to do experimental physics, but you can afford to hire a couple of string theorists. So you offer a couple of jobs in string theory, and you have a modern physics department. The temptations are strong for the chairperson to offer such jobs and for the young people to accept them. This is a hazardous situation for the young people and also for the future of science. I am not saying that we should discourage young people from working in string theory if they find it exciting. I am saying that we should offer them alternatives, so that they are not pushed into string theory by economic necessity.
>
> Finally, I give you my own guess for the future of string theory. My guess is probably wrong. I have no illusion that I can predict the future. I tell you my guess, just to give you something to think about. I consider it unlikely that string theory will turn out to be either totally successful or totally useless. By totally successful I mean that it is a complete theory of physics, explaining all the details of particles and their interactions. By totally useless I mean that it remains a beautiful piece of pure mathematics. My guess is that string theory will end somewhere between complete success and failure. I guess that it will be like the theory of Lie groups, which Sophus Lie created in the nineteenth century as a mathematical framework for classical physics. So long as physics remained classical, Lie groups remained a failure. They were a solution looking for a problem. But then, fifty years later, the quantum revolution transformed physics, and Lie algebras found their proper place. They became the key to understanding the central role of symmetries in the quantum world. I expect that fifty or a hundred years from now another revolution in physics will happen, introducing new concepts of which we now have no inkling, and the new concepts will give string theory a new meaning. After that, string theory will suddenly find its proper place in the universe, making testable statements about the real world. I warn you that this guess about the future is probably wrong. It has the virtue of being falsifiable, which according to Karl Popper is the hallmark of a scientific statement. It may be demolished tomorrow by some discovery coming out of the Large Hadron Collider in Geneva.

I don't know where Dyson got the estimate of ten thousand string theorists; my own estimate would be more like one to two thousand (with the number strongly dependent on how you decide who is a "string theorist"). The large yearly Strings200X conferences that bring together a sizable fraction of active string theory community tend to draw roughly 500 people.

The Princeton-centric assumption that there are lots of string theory jobs embedded in his question "And why are so many jobs offered in string theory?" is quite problematic, as any young string theorist on the job market could explain to him. There actually aren't a lot of string theory jobs out there, and a lot of Ph.D.s in the subject being produced, leading to a lot of ex-string theorists now working in the financial industry and elsewhere. These days, if you are going to choose your field based on where the jobs are, you become an LHC phenomenologist or a cosmologist. If you want to be a string theorist, you better be a string phenomenologist or a string cosmologist. Also rather unrealistic is Dyson's "it could happen that nine thousand string theorists lose their jobs", due to tenure in the academic system. Even if a consensus develops over the next few years that string theory was all a big mistake, twenty years from now there will still be a cadre of (older) people working in the field.

Dyson's idea, that 50-100 years from now, a new revolution in physics will show how string theory fits in may be right. It also may be that this has already happened, as much of the field has moved into the study of gauge-string dualities, where string theory provides a useful approximation for strongly coupled systems, and the idea that it unifies particle physics is falling by the wayside.

Comments

   January 8, 2009

Dear Peter,

Thanks for pointing out that nice piece of an essay. As a stringy person myself I would however disagree with Dyson saying that string theorists are too narrowly trained to be useful in other parts of science. People who enter a PhD program in string theory in a reknown place (need not to be Princeton) are good physicists already from their undergrad time, as the students normally interested in string theory are interested in deep questions of physics in general, and for this they need to understand the basics of physics to a good extend, which in turn means they have done their homework already as an undergrad. This is at least my experience. So they are well-trained physicists, and can in principle with some preparation time work in any field of theoretical physics. Also, for understanding the implications of string theory one needs to be well-trained in nearly all subjects of basic theoretical physics, which there are mathematical methods, classical and quantum field theory, statistical physics and gravity/GR. The average string theorist is well-trained in all these subjects. What makes the change of subject away from string theory even to closely related areas like "quantum gravity" (for the purpose here just summarizing all attempts to quantum gravity except string theory), classical gravity or pure cosmology is, in my experience, rather the attitude of other communities towards string theory, which is often full of prejudices originating from hearsay, the failure to understand even the stringy basics and the dissatisfaction thus created. Its often a one-way road: String theorists understand what other people are doing, but the other people dont understand string theory. With such a structure, it is nearly impossible to change for a postdoc in a different field, as everybody takes only the people whose work he knows and understands. This is partly also true in string theory, of course.

Another remark: Not only string theory is cheap, whole theoretical physics is, if you dont need supercomputers. So poorer universities can higher also other people…

2. **somebody**
   January 8, 2009

   Thanks for Dyson's interesting article, Peter. The essay was overall balanced I think, so I will state a few issues with which I disagree.

   1. People don't go into string theory for jobs. I was very sternly warned that going into string theory is dangerous, careerwise, and no string theorist I know had any illusions about it when they got into it either. I suspect that Dyson is forgetting why he went into mathematics and theoretical physics back when he was an excitable young man, but thats just my guess.

   2. While agreeing with the possibility that string theory might be only part of the full picture, I would like to point out that since we don't have the benefit of hindsight, the only working strategy we have available for progress NOW is to push our current theories to their limits. Revolutions, almost by definition, cannot appear on demand. To give an example: It took almost twenty years of work on seemingly pointless things like gauged supergravities, many dimensions, superconformal algebras, large N gauge theories etc. before it all finally came together in gauge-gravity duality.

   3. String theory being superspecialized is also a weird claim. One of the challenges that an aspiring string theorist faces is in fact the ridiculous amount of physics and math they have to learn. I think the real problem is not that string theory is superspecialized, but that some string theorists are superspecialized to one subfield or even to one problem. But this is not just a feature of the string theory community …

3. **Peter Woit**
   January 8, 2009

   Rene,

   I agree that Dyson's explanation that string theorists get hired because they are cheap doesn't explain anything, since they are no more or less expensive than other theorists.

   As for the somebody's point that string theorists don't go into the subject because job prospects are good, that's certainly right, more so now than ever. The question though is a relative one. The job situation in theoretical physics in general has been terrible for a long time. If you decide you want to try for a career as a theoretical physicist, despite the odds, does going into string theory maximize your chances? I think now someone who wants to maximize their chances is more likely to go into phenomenology or cosmology. But if your interest is in fundamental, more mathematical and formal approaches, you still may not have any real alternative to string theory. The job situation for string theorists is bad, but jobs in formal theory that is not string theory are pretty much non-existent in physics departments, at least in the US.

   My impression of the background of string theorists is that it varies widely. Some do actually know a lot of physics and mathematics, and have a good chance of changing fields if they want to. Others don't, and suffer from the disability of not knowing how little they know, making it highly unlikely that they'll ever be able to do what it takes to move to another field.

4. **Jonathan Vos Post**
   January 8, 2009

   I love Dyson's paper. To me, though, the strong point is the detailed and insightful History of transdisciplinary unifiers in Mathematics, and the surprise that this is useful in understanding Physics. I feel that Context trumps Content here. But I agree with the comments that we'll have a batter idea in 50-100 years what this was all about, in the late 20th century. If I'm very lucky, I'll be here in 50 years (aged 107). Nobody yet has been 157, so I'm not going to invest much effort in what might be known in 100 years.

5. **Rene Meyer**
   January 9, 2009

   Dear Peter,

   I have to disagree on the job situation. I just applied for my first postdoc, got some offers, but it was a very competitive thing. Nowadays string community in Europe and the US/Canada is very competitive on the postdoc level already, not to speak about tenure track. I have a little bit of insight into other fields of theoretical physics, where people are handled around to their next postdoc until they are old enough for tenure track. They do not have to go through all the pain of applying worldwide without knowing whether they should get a job at all. Long story short: In my opinion the job market in the string community is more competitive and less connection-driven than in other fields of theoretical physics.

   But feel free to disagree.

   Best, Rene.

6. **Peter Woit**
   January 9, 2009

   Rene,

   I don't disagree at all that the job market for string theorists is now highly competitive.

7. **Haelfix**
   January 9, 2009

   I don't really understand why he thinks lie groups are a failure for classical physics, or why the analogy makes much sense =/

8. **anon.**
   January 10, 2009

   Dyson's 50-100 years guess is for a revolution is identical to the guess in his 1981 essay Unfashionable Pursuits:

   '… At any particular moment in the history of science, the most important and fruitful ideas are often lying dormant merely because they are unfashionable. Especially in mathematical physics, there is commonly a lag of fifty or a hundred years between the conception of a new idea and its emergence into the maintsream of scientific thought. If this is the time scale of fundamental advance, it follows that anybody doing fundamental work in mathematical physics is almost certain to be unfashionable. …'

   – [Dyson's 1981 essay, Unfashionable Pursuits]

9. **nbutsomebody**
   January 10, 2009

   The number 10000 may come from "Brief History of Time". Somewhere it is written that 10000 people are doing string theory world wide, at least that what I remember.

   About the job situation, it is really bad in string theory. There should not be any question about that. But the situation was probably a little different in late nineties.

10. **Grant**
    January 21, 2009

    Peter,

    You write "Personally I suppose I fit well into Dyson's bird category" which makes me wonder, which fields of mathematics/physics did you unify, generalize or abstracted to a higher level? By looking at your record on spires, it's not at all clear what you mean. It seems to me your research has been pretty focused on a single topic, topological aspects of non-abelian gauge theories, which to me seems to fit the frog category.

    Your thoughts?

    Thanks for reading,
    Grant

11. **Peter Woit**
    January 21, 2009

    Grant,

    My early research was on topological effects in lattice gauge theory, but my general area of interest is trying to find new ways of understanding the underlying structure of the standard model using modern mathematics and representation theory. One of my problems in life is that my bird-like tendencies have led me to spend a large fraction of my time flying around at too high altitude trying to learn about different kinds of mathematical structures that might be useful, instead of getting down to ground and working out details and publishing.

    The current ideas about BRST that I'm working on and trying to get down to detail with involve algebraic ideas that are very far from the topological and geometrical ideas that I started with. It has taken me a long time to start to appreciate the algebraic approach.

    In any case, I recognize my tendencies (if not my accomplishments..) in Dyson's description of birds, find his description of "frogs" much more alien (e.g. when he says that he had no interest in the relations between number theory and QM that were pointed out to him)

12. **Phil Harmsworth**
    January 26, 2009

    Peter,

    I'm not sure that I follow Dyson's analogy between Lie groups and string theory. As I understand it, Lie was trying to create a Galois theory for differential equations. The 'disappointment' to which Dyson refers stemmed from his perception of a lack of recognition for his work, and not so much from a lack of applications.

    I also don't understand his description of Lie groups as a failure in classical physics, although admittedly it took until the 1940s before Lie's ideas started to be applied systematically (to hydrodynamics). (Refer the CRC Handbook of Lie Group Analysis of Differential Equations for an overview of more recent applications.)

    I think that it may be more accurate to say that for both classical and quantum mechanics, Lie's ideas needed further development and refinement. For example, the theory of representations of Lie algebras (to which Dyson refers to as natural language of particle physics) was a considerable advance from Lie's concept of 'infinitesimal groups'. As 'Not Even Wrong' describes, it took a considerable period for these ideas to be understood and accepted.

    If there is indeed an analogy for string theory, perhaps it is that the necessary tool or tools for progress already exist in contemporary mathematics, but they may also need further development. And it may not be at all obvious at the outset that these tools are in fact useful at all.

13. **Academic Career Links**
    March 20, 2009

    A related but somewhat different kind of division can be found in the essay [Two Cultures of Mathematics] by W.T. Gowers.

Science Channel Inks Deal With Physicist Michio Kaku

January 8, 2009
Categories: Uncategorized

Fresh from his leading role in the History Channel's Parallel Universes (if you missed it on TV, the DVD is available here), according to a press release today, Michio Kaku will now be appearing regularly on Discovery's Science Channel:

> The Science Channel has signed a multi-year agreement with theoretical physicist Dr. Michio Kaku. As part of the deal, the Discovery-owned network will produce a 10-part series based on his New York Times bestselling book Physics of the Impossible and has exclusive television rights to Kaku's other works for adaptation in series and specials.
>
> In addition, Kaku will become the host of "Sci Q Sundays," the Sunday programming block that explores scientific news and topics.

The show has a web-site here, including instructions on how to build a time-machine.

Comments

1. **Sakura-chan**
   January 8, 2009

   He's great at the capitalism game.

2. **J.F. Moore**
   January 9, 2009

   I actually forced myself to read Physics of the Impossible, so I could legitimately criticize it. I dread having to be the killjoy when people watch this series and get excited about the absurd stuff. Not that I mind straightening people out, they just seem to dislike boring mundane reality.

3. **MathPhys**
   January 9, 2009

   Kaku is *"one of the founders of string field theory"*, but that's too technical, so let's not split strings and just say *"one of the founders of string theory"*.

   The title of a future TV series could be

   "From Veneziano, Susskind and Nambu to Green, Schwarz and Kaku."

   It rhymes!

4. **anon.**
   January 9, 2009

   It would be good to know if there are any surveys of what really motivates most students to become interested in modern physics. If it really is down to sci fi wormholes, Planck scale manifolds, and spin-2 gravitons in string theory, then Kaku is needed in a sense to continue inspiring student interest in physics (one can hope that some of those students will defect back to reality at some stage, instead of worshipping unchecked speculation).

   In some cases the best-scoring students of theoretical physics started off by scoring well in mathematics, and then found a lot of interesting applications for those skills in physics. This is a different line of approach from a deep desire to understand phenomena, which probably is the route taken by those majoring in experimental/applied physics. If you start off with phenomena that you measure and plot, then find an equation for, then develop a theory that explains the equation and predicts other things, you end up with real understanding.

   I hope that this will happen once experiments indicate what is really occurring with electroweak symmetry breaking. The big strength of the standard model is in its experimental basis and experimental checks, which so far haven't extended to the Higgs mechanism. Hopefully LHC experiments will this year focus attention on building theories to explain, and checkably extrapolate predictions from, real phenomena. This is the opposite of what string theorists do when they produce mathematical models of Planck scale speculations and then use those models to produce uncheckable predictions.

5. **D R Lunsford**
   January 9, 2009

   J. F. Moore,

   Yes I think a lot of us have experienced that. I have a friend who is all over these news releases and I'm almost embarrassed to tell him the truth.

   anon.

   No I think serious physicists start out with wall sockets and fire and such. 🙂

   Peter,

   Was hoping for some science news of the new large radio noise discovered by ARCADE (Absolute Radiometer for Cosmology, Astrophysics, and Diffuse Emission) beyond press release hype. Standard modelers will be discomfited.

   -drl

6. **Chris W.**
   January 9, 2009

   Michio Kaku is to physics what Kenny G is to jazz. (Kenny G majored in accounting in college.)

7. **MathPhys**
January 10, 2009

If Nambu has a Nobel prize, why not Kaku?

PS Plagiarized from *"If QED got a Nobel prize, why not QCD?"* which was the catch phrase of the Gross *et. al* lobby, or so have I been told.

8. **Ari Heikkinen**
January 10, 2009

That's funny, as I opened TV today there happened to be a document about CERN and LHC, which was (basicly) touted as a "time machine", "capable of looking into the creation itself", "creating conditions of big bang", etc. and those comments were (apparently) from people working on the project. Atleast in that "how to build a time-machine" piece there's a section that reads "practical problems with time travel".

9. **Will**
January 10, 2009

I dont think people should expect people like Edward Witten or Steven Weinberg to champion physics causes. They have better things to do. Michio Kaku is doing a descent job of trying to popularize fundamental science and it is not an easy job. He may not be anywehre near a top physicist, but he has done commendable work in physics. You cannot expect people to really appreciate ADS CFT or mirror symmetry or dualities. You have to view his shows as not a lecture that consist all facts (which would be impossible) but entertainment with descent amount of good science for people who are talented and interested to get enthused about great progress made by modern physics, string theory and mathematics.

10. **MathPhys**
January 11, 2009

Will,

Seriously speaking, I wholeheartedly agree with you.

11. **Jimbo**
January 11, 2009

In his attempts to popularize theoretical Physics, Kaku really creates a bad image for the field. It is very unpleasant when people hear what I do and say "oh, so you're like Michio Kaku?".

12. **MathPhys**
January 11, 2009

Okay, so we need someone to popularizes theoreticall physics without giving a nutty used car salesmanic impression.

13. **Will L**
January 11, 2009

I think TED presentations are much more effective at inspiring students to become scientists than these pop programs.

14. **trond**
January 11, 2009

Isn't most of his previous documentaries mostly speculations too (he label himself as a futurist), so I guess these are just a continuation of those.

Another one that have been profiling himself is Brian Cox with some BBC documentaries. The latest was "What time is it?". The documentary style is much more personal and I actually learned something from it (and speculative ideas were stated as such). With Kaku it's just no-holds-barred, but then again he has to work within the contraints of commercial media.

15. **J.F. Moore**
January 11, 2009

The problem is with the hyperbole and poor logic Kaku uses when he is popularizing science. I can't conceive of the likes of Carl Sagan being so careless and silly, even though they are both dynamic lecturers and are good at capturing the fantastic scope of science.

For example, Kaku regularly chimes in on a notoriously nutty AM radio show and feeds people's fantasies that there have been extraterrestrial visitors. The question is whether more harm than good is being done ultimately.

16. **MathPhys**
January 11, 2009

Kaku ***is*** an extraterrestrial visitor.

17. **D R Lunsford**
January 13, 2009

You know in India, they have instead of Kaku, Jayant Narlikar (some might remember his work with Hoyle on the steady-state cosmology). He's the soul of restrained reason, and holds a position of near veneration there while continuing his career, emeritus. I can't help but see something deeply disturbing about our culture in Kaku's goofy omnipresence.

JFM, yes the comparison to Sagan was apt. I heard Sagan issue some whoppers about relativity, but on the whole he was enthusiastic and sane at the same time.

-drl

18. **Amos**
January 13, 2009

Since there are more physicists than physics jobs, I don't understand why recruiting more students to the field is a net-positive.

In all events, the people who watch popular science programs (including, occasionally, myself) do so because (a) we want to understand nature, and (b) the accumulation of such an extraordinary understanding of nature makes us proud of the species.

It serves those people no purpose to have a popular science program that fails to educate and fails to illuminate.

19. **King Ray**
January 13, 2009

It sort of reminds me of L. Ron Hubbard, a science fiction writer who decided the best way to get rich was to create a religion, Scientology.

Here we have physicists creating a religion called string theory and profiting from selling it in schools and to the public.

20. **Jake the Snake**
January 13, 2009

In my opinion, Michio Kaku seems like a very nice person. He appears to be a perfect gentleman, but I have trouble taking him seriously as a scientist. As a pop-sci guy he is decent, but Isaac Asimov was WAY better in that respect! Having read through *Physics of the Impossible*, I couldn't help but think that Asimov would have written a book just like it, only a bit better.

Unfortunately, Kaku has become THE pop-sci guy. It would be great if he quit theorizing and became a sci-fi writer. In fact, most string theorists ought to look for work writing science fiction should their area of research ever be marginalized. (…Except maybe for Lubos. Any attempt at fiction by him might be disturbing.)

Then again, it makes sense that the **History Channel** of all channels would select Kaku as their science guy. The History Channel has been notorious for having more shows about UFOs, cryptids, Nostradamus, and other occultic or paranormal stuff than actual history.

21. **MathPhys**
January 14, 2009

Kaku does not just *seem* like a nice man. He *is* a nice man. He's also a very smart man. Too bad he decided to get into the UFO business.

22. **Christine**
January 15, 2009

Asimov and Sagan were not only skilled science popularizers. They represent *schools* of science outreach. I wonder who is doing the job today at the same level of quality.

23. **Peter Woit**
January 15, 2009

Jake,

The History Channel was responsible for the recent awful program about parallel universes, but it's the Discovery Channel that is involved here. Not clear there's much to choose from between them….

24. **smart and nice**
January 15, 2009

how "smart and nice" can one be to promote time machines at the expense of physics?

a physicist's "niceness" and "smartness" should be judged relative to how "smart" he is regarding physical reality, and how nice he is to his peers who are engaging physical reality.

there is a certain type of media-physicist who has evolved who is now doing more damage than good on multiple levels. they suck up all the attention and funding, at the expense of true physicists.

truly, what has kaku truly contributed to physics?

25. **Russ**
January 15, 2009

I don't often watch shows on Discovery or the History channel – but sometimes I do and I admit to hearing things that make me groan. These channels by their very nature are for a wide popular audience. Physics (hell, speaking as someone with an M.A. in history) and History for that matter , are difficult subjects for a mass audience to digest . Physics in particular utilizes mathematics that is way beyond college calculus. If Kaku can translate for a popular audience even a small portion of what we agree to be physics then I think he is doing a service. I challenge 'Smart and Nice' to quantify in dollars just how much Kaku has damaged physics funding? I grew up watching Sagan and he is still a hero in my mind, as far as popularizing astronomy. Who knew how much the guy liked refer? 😉

26. **Jake the Snake**
January 15, 2009

@ MathPhys:

Well, I can't say I know him personally. He *COULD* be a prick and I wouldn't know, I simply would not conclude something based on my impression, though he does seem like a good person. However, you appear to have known him and that he is indeed a nice guy does not surprise me. And he would have to be very intelligent to wrap his mind around higher physics concepts like string theory. The problem is when scientists like Michio Kaku use their brilliance and personality to act as PR for bad ideas. As long as string theorists have agreeable and intelligent spokespeople, they have PR.

@ Christine,

Isaac Asimov is probably the most logical person whose writings I have read. In fact, if Asimov had a time machine, he would totally own Aristotle in rational argument! The genius of Asimov lies in his ability to explain even the most esoteric concepts in relatively simple ways that make sense. Kaku, for all his intelligence, would have a tough time catching up to Asimov though he tries to fill his shoes.

Dr. Woit,
Actually, I naively believed that the Discovery Channel, History Channel, Animal Planet, etc. all came from the same corporate entity as if one company had a virtual monopoly on educational or informational programming on American Cable. I later learned that Discovery Channel and History Channel are not owned by the same

company.

Discovery Communications, LLC is the sole owner of the Discovery Channel (and Animal Planet, TLC, the Science Channel, Military Channel, Discovery Health, etc.) while the History Channel is part of A&E network, a joint venture of National Broadcasting Corporation, Disney, and the Hearst Corporation. Yes, *that* Hearst, as in William Randolph Hearst, the turn-of-the-20th-century propagandist infamous for his invention of yellow journalism and perhaps inspiring such notorious media figures as Joseph Goebbels and Rupert Murdoch. The heritage of the History Channel might explain its preference for sensationalist programming.

Between Discovery affiliated networks and History Channel, I could almost sense a world of difference. Discovery Channel actually has plenty of great quality shows, especially *Mythbusters*, which is an excellent exposition on how to apply the scientific method. The (ironically titled) History Channel, on the other hand, is much more eager to air programs about the Loch Ness Monster, Nostradamus, exorcism, or UFO. Perhaps it is not surprising that HC would retain Michio Kaku as their go-to physicist. A "serious" scientist willing to give serious attention to spooky topics. But what does asking Kaku to host a show on the Science Channel say about Discovery? Until I get to see the show, I really can not say.

27. **Christine**
    January 15, 2009

    Jake the Snake,

    I started reading Asimov at 11 years old (fiction and non-fiction) and I am certain that he was responsible for my formidable interest in science. Asimov is supreme.

    Best,
    Christine

28. **Marion Delgado**
    January 17, 2009

    On the one hand, he's one of the people that turned me off string theory before I ever heard of Peter Woit.

    On the other hand, I now think that he's simply more up-front about the seemingly fanciful results you can get from the landscape and the latest predominant ideas in string/etc. theory. So paradoxically I am less bothered by him than I was.

Quick Posting, European Edition

January 15, 2009
Categories: Uncategorized

It's semester break and I'm in Paris this week, but I have a few moments to post on some topics that may be of interest:

People here in Europe seem quite normal, but Lubos has just won an award for Best European Blog.

Some details of the proposed new US stimulus package have just been released. Science is one of the main beneficiaries, with the DOE getting:

> $1.9 billion for basic research into the physical sciences including high-energy physics, nuclear physics, and fusion energy sciences and improvements to DOE laboratories and scientific facilities.

This should dramatically change the situation at Fermilab, which has been operating so far this year under a low continuing resolution level of funding. For the immediate future, the funding situation in the US for HEP and science in general looks bright, although this presumably will come to a screeching halt whenever the federal government stops financing everything by printing a trillion dollars a year.

Travis Brooks of SPIRES has produced Top Cites lists for 2008. He has a blog posting about this here, and the list of most heavily cited papers during 2008 is here. For the first time in many years, a new hep-th fad is having visible impact, with Bagger-Lambert at number 37, and three other papers on the same topic in the top 50.

Over at the Edge web-site, there's an interview with Frank Wilczek.

Comments

1. **Tony Smith**
   January 15, 2009

   At Edge, Wilczek said "… The time is right for an assault on the process of aging. A lot of the basic biology is in place. …".

   Would it really be a good thing for every human to live forever (barring accident or homicide)?

   Maybe individual human auto-termination with an upper-limit life span of 120 years or so
   is something that is beneficial for human society ?

   Tony Smith

2. **Cormac O Raifeartaigh**
   January 16, 2009

   I'm a European blogger and I've never heard of this award!
   I had a look at the winners and two points spring to mind

   (i) Although I read his science, I think it's a pity Lubos won – his style of rubbishing those who disagree with him will do little to convince those who doubt the usefulness of weblogs

   (ii) Most of the other winning blogs seem pretty humdrum!

3. **anon.**
   January 16, 2009

   People here in Europe seem quite normal, but Lubos has just won an award for Best European Blog.

   And another climate-change denier won the "Best Science Blog" category. I hope these results just reflect excess zeal and/or cheating from the denialists, and not their actual prevalence in the population….

4. **James**
   January 16, 2009

   I had also not heard of the European Blog award, and groaned when seeing that Motl had won it. However, there was a sigh of relief when the link explained that neither the UK or Ireland were involved (I'm from the UK).

   Auto-termination, or Euthenasia as it's called round these parts, is often up for discussion in Europe. Some recent cases made the news, usually involving countries such as Switzerland which allow it, and questioning whether family members who assist in the travel of the (what's the right word?) 'subject' from countries where it is illegal are criminals. This is a non-trivial question to say the least.

   However, if the human lifespan was unlimited by our own genetics and other biological factors (so ignoring environmental hazards such as asteroid collisions with the Earth, the explosion of the sun, the ultimate demise of the Universe, or dodgy electrics in the shower unit) this would reposition the whole euthenasia issue: should somebody be allowed to end their life becuase they were just too bored after 4000 years of living, and can't stand hearing the same crap songs played over and over again?

5. **Chris**
   January 16, 2009

   It should be Bagger-Lambert.

6. **Peter Woit**
   January 17, 2009

   Chris,

   Thanks, typo fixed.

7. **cormac**
   January 17, 2009

   I should have said – it's not Lubos's writings on climate science I enjoy, far from it…

8. **Shantanu**
   January 17, 2009

   interestingly enough 6 out of the top cited 10 papers are in (observational) astrophysics.

9. **Charles**
   January 20, 2009

   Does any erudite person here entertain me about how to use Anyons to do quantum computing? I read the Frank Wilczek's interview. Does the collective bosonic behavior of electrons at low temperature is theoretically predicted by his QCD theory or just experimentally achieved a technically smaller scale of what called Bose-Einstein condensate but with electrons instead of liquid Helium?
   Any other Fermionic material demonstrates collective bosonic behavior?
   Any other theoretical guy currently plays with idea like Bosonic matter near blackhole hehaves collectively as Fermionic matter?
   When I was young I have fantasized that the Universe would be very dull if everything can be classified as "black or white". This kind of large scale collective behavior sounds more intriguing to me. Thanks.

   Charles Hui

The Worst Jobs in Science: Theoretical Physicist

January 19, 2009
Categories: Uncategorized

After the recent news that being a mathematician is the best job in the US, next month's Popular Science magazine has come out with a list of the worst jobs, not overall, but in the sciences. "Theoretical Physicist" makes the list, right in between "Monkey-Sex Observer" and "Vermin Handler". Here's the text about this:

> For much of the past century, physics was an exciting, wide-ranging exploration. But to be a theoretical physicist today, you pretty much have to stake your career on one incredibly popular but pretty much unprovable notion: string theory. Since the idea that the universe is composed of small vibrating "strings" gained a following in the 1970s, the theory, which in some forms posits 10 dimensions and seeks a unifying "supersymmetry," has captured the theoretical-physics community in the U.S. The easiest way to earn an appointment is to dive head-first into a branch of string theory, which dominates the top programs at Princeton, MIT and other influential institutions. The problem is, we simply have no idea if we're on the right track, because the theory isn't verifiable.
>
> Lee Smolin, a physicist at the Perimeter Institute for Theoretical Physics in Waterloo, Canada, who investigates quantum gravity and string theory, believes that the physics monoculture is stifling. "Science has become too risk-averse, and its progress is being hurt as a result," he says. When CERN's Large Hadron Collider restarts later this year, however, it could end the waiting, helping to confirm parts of string theory — or dash it altogether. If supersymmetric particles called sparticles are bashed into existence: yay! But if the W boson particle does not react as hoped, that damages a central pillar of the theory. Across the U.S., whole careers are boiling down to the chance that a big box comes up with something.

It's true that, for string theorists, a lot is hanging on the question of whether sparticles are found at the LHC. If none are seen, I suspect that will pretty conclusively finish off in most theorist's minds the idea that string theory unification can be connected in any way with observations. The business about string theory and W-bosons is utter nonsense, presumably coming from this.

As mentioned here repeatedly, claims that hiring in particle theory is dominated by string theory are behind the times. String theorists are now yesterday's fad, with terrible job prospects if they don't have a permanent position. Today's fads are LHC phenomenology and cosmology (news from the rumor mill about two new jobs is that UCSB wants "candidates with interests in phenomenological aspects of particle physics and related areas of astrophysics and cosmology", Rutgers wants "a focus on LHC physics, broadly conceived.") String theory is on its way out in American universities it seems, but the long-standing pattern of fad-driven hiring isn't. Which is one thing that makes the idea of trying for a career in theoretical physics these days about as appealing to many smart young people as the idea of going into the vermin handling business…

Comments

1. **Bourgeois Nerd**
   January 19, 2009

   This may be a stupid question, but from a non-academic who reads this blog, I've been dying to ask: what exactly IS a "phenomenologist"?

2. **Peter Woit**
   January 19, 2009

   Bourgeois Nerd,

   Phenomenology: theoretical work closely tied to experiment, e.g. computation from a given model of specific predictions about what a certain experiment will see.

   contrast to so-called "formal" theory, which is about trying to better understand theoretical ideas: investigation of toy models, unphysical examples, development of new calculational techniques, etc.

3. **steve newman**
   January 20, 2009

   String Theory R.I.P.
   Will Dark Energy and Dark Matter and Inflation be next?
   Why do dead ends have such a long life?
   Hoping for a re-birth of physics.

4. **csrster**
   January 20, 2009

   Humorous stuff, but obviously not quite accurate if you happen to be, for example, a theoretical condensed-matter physicist.

5. **chris**
   January 20, 2009

   @steve newman

   i think you will hear a lot about dark matter/energy in the years to come. main reason is that they are observable.

   "Why do dead ends have such a long life?"
   Some famous guy once said (i don't remember who) that obsolete ideas only die with their supporters.

6. **Cormac O Raifeartaigh**
   January 20, 2009

   Hmm… the implication of the excerpt is that if SUSY is seen at LHC, this is a victory for ST – this is not necessarily true, as you know.

   Conversely, Peter's comments seems to imply that if SUSY is not seen at LHC, that rules out ST – but that doesn't work either, as only low -energy SUSY can been ruled out at the LHC!!

7. **mr**
   January 20, 2009

@chris

“Some famous guy once said (i don’t remember who) that obsolete ideas only die with their supporters.”

I think it was Max Planck, wasn’t he? (Not sure about the exact phrasing, though)

regards.

8. **TheorPhys**
January 20, 2009

Theoretical physics is for sure beautiful, but the sad story is that (unless the LHC finds something radically new) we are almost at a saturation point in the knowledge that man can have about fundamental laws of Nature. Maybe I am too pessimistic, but at least in the last 30 years this seems to be the trend.

But the real problem is that the education system does not easily provide young people alternative careers and easy ways to transfer from one subject to another one…once they get stuck in some dead end.
After all physics is a very broad field and this would be definitely possible.
Once upon a time science and knowledge were broad concepts. If you were a scholar you could study very different topics, with reasonable freedom.
If you think of Enrico Fermi he has been working in almost all fields of physics, as a theoretician and an experimentalist too, for example.
Today even a young Fermi could be probably stuck in some dead end, or following some fashion just to get a job.

The reality is that nowadays competition and excessive specialization have introduced also in science an industrial logic….and this kills scientific creativity and flexibility and even the pleasure of doing science.

9. **Peter Woit**
January 20, 2009

Cormac,

Logically, low energy supersymmetry is pretty much independent of string theory. But, sociologically, it’s a very different story, and my comment was more a sociological one.

TheorPhys,

The fact that it is hard for theorists to change fields is a huge problem. The effects of it may be worse for senior people than for junior people, with many senior people getting stuck in a failed dead-end research program. This leads to a seriously damaged field, as it affects the training and job prospects for young people. Anything that makes it easier for people to move on to something else when the field they are trained in stops being fruitful would be a good thing. But the danger of faddishness is that everyone will just move to the same new hot topic….

10. **TheorPhys**
January 20, 2009

Dear Peter,
I completely agree with you.

However, I would say faddishness is not such a big danger. If somebody is having the feeling of wasting time and energies and being in the wrong track , I can understand insisting just for a few years, but not too much. If instead, you feel ok in some field you would not even think of changing. After all physics should be driven by passion, and I have seen many theorists (even very bright people) being frustrated by the wild speculations that they have to do nowadays.

I think everybody who is in charge of science policy and in the universities should be aware of this problem and think about solutions of this issue.
Otherwise the only alternative for a theorist would just be finance, which is a bit sad.

11. **terry**
January 20, 2009

this is so ridiculous it’s not even wrong. the world of physics is huge compared to the small number of self-promoting, self-indulgent particle “theorists.” most theorists are happily solving problems in condensed matter, nuclear, fluid mechanics, lasers …, real problems with real applications and real jobs. the fact that some research universities have been parasitized by string theorists is only really relevant to a few competing clans.

sadly, this type of coverage reflects badly on all physics, not just string theory. if you can do it, and you want to do it, there are few jobs that are better than being a physicist–even if you have to settle for being a theorist.

12. **TheorPhys**
January 20, 2009

Dear Terry, I disagree with you.
Not all fields in physics have real problems with real applications and real jobs.

There are many fields, apart from string theory, which do not meet these requirements. Mainly those related to theory, to mathematical physics, to experiments in fundamental physics (do experimental particle physics or experiments in astrophysics, gravitational waves… have always real applications?).

13. **David Katz**
January 20, 2009

This is what I’m hearing from fellow physicists in the UK too. A recent chat with a friend of mine lead to string theory being described as “going through a period of navel gazing”. Hopefully some of that wonderful string theory money can now be put towards condensed matter, or fields of particle physics such as lattice QCD that might actually stand a chance of telling us something about physics, rather than sometimes beautiful mathematical models that stand no chance of ever being proved.

14. **Bee**
January 20, 2009

Anybody looking for an LHC phenomenologist going cosmologist, here is one, and in addition I am looking for a job.

So, Lee has now turned from a researcher into an “investigator”. That’s an interesting twist.

15. **D R Lunsford**
January 20, 2009

BN, this is a good question and shows you are paying attention.

Phenomenology is not equivalent to "experimental" – for example, the original theory of electron spin proposed by Pauli was a phenomenological theory. Only when Dirac showed how it came from a basic idea could spin be said to have a firm theoretical basis. Essentially, phenomenological theories have terms in them that are only heuristically justified – this does not make them bad theories, but progress usually comes from giving a theoretical basis to what was formerly phenomenology.

-drl

16. **Cormac O Raifeartaigh**
January 20, 2009

Peter: Yes, apologies, I see you what you mean.
Bee: What's this about a new job? Wanna come to Ireland? Have a look at the Dublin Institute for Advanced Studies..

17. **mathematician**
January 20, 2009

As a mathematician, I sometimes get physics envy.

And physicists sometimes get mathematics envy.

Of course, string theorists get both.

18. **Aaron Bergman**
January 20, 2009

These days, string theorists get job envy.

19. **Ari Heikkinen**
January 20, 2009

Just tell young people to get an engineering degree, that way they'll be solving practical problems in the real world. Or even better, tell them to acquire good software engineering skills and they won't ever be unemployed for long.

20. **JC**
January 20, 2009

Ari Heikkinen,

Engineering jobs vary significantly between different areas. It can also be trend driven to some extent too, just like physics.

Also many engineering majors don't even get the opportunity to ever work as an engineer. No big surprise as to why many engineering majors ended up in computer programming jobs over the last 25-30 years. Though with that being said, outsourcing has been eating away at salaries and jobs for many years.

21. **banerjee**
January 20, 2009

Many tenure-track positions in engineering are going to physics graduates these days. If a string theorist (or any other type of physics theorist) feels the need to be in academia can can't get a physics position, one path is to get some post-doctoral experience in a good engineering department and then switch to that field.

We in engineering are always looking for people with good skills and ideas in subjects that are not well understood by engineers.

22. **Troublemaker**
January 20, 2009

Humorous stuff, but obviously not quite accurate if you happen to be, for example, a theoretical condensed-matter physicist.

Well, you have to bear in mind that on this blog, and every other string theory or anti-string theory blog, "physics" = "high-energy theory." I like this blog and I like Peter, but he, his friends, and his enemies are all very high-energy-theory-centric in their conception of what it means to do physics.

23. **Shantanu**
January 20, 2009

Peter or others, anyone know about the job prospects for those doing neutrino physics or neutrino phenomenology.
Also are there many papers connecting string theory
with neutrino physics for which we have lots of data and will soon have more?

24. **bob**
January 20, 2009

what fraction of physicists are theorists? what fraction of physicists are string theorists?

i don't think string theorist is a bad job, and even if so, i don't think "theoretical physicist" should be branded a bad job even if string theorist is a bad job.

25. **Cormac O Raifeartaigh**
January 21, 2009

Terry: "the world of physics is huge compared to the small number of self-promoting, self-indulgent particle "theorists." Most theorists are happily solving problems in condensed matter, nuclear, fluid mechanics, lasers …, real problems with real applications and real jobs"

I don't think that's fair. First of all, particle physics is a fundamental field that bears close examination, in the sense that everything is made up of atoms, but atoms are not made up of semiconductors (say). Secondly, it turns out to be a very difficult field, accessible by only the very best students – the maths of gauge theory is way beyond most physicists, and therefore commands a certain respect. Thirdly, how do you know what the future applications will be? There have been many stunning applications of discoveries in particle physics, from nuclear power to the use of accelerators in medicine

If the public show a disproportionate interest in subjects like quarks or strings, I think it's for the same reason that they find cosmology so interesting… human curiosity concerning 'fundamental' questions..

26. **Peter Woit**
January 21, 2009

Shantanu,

String theory has nothing to say about neutrino physics.

As for job prospects for theorists working on neutrinos, I think it's a small group of people and a small number of possible jobs. Prospects should be better than if you're a string theorist, but beyond that I don't know.

27. **somebody**
January 21, 2009

A few pointers –

1. Jobs are overall bad in particle theory, and if anyone here is implying that phenomenologists have a cakewalk, they are delusional.

2. About the increased focus on phenomenology (much of it string-inspired, incidentally) being a "fad". It makes perfect sense to me that on the eve of the LHC, people care more about the TeV scale than the Planck scale. Choosing the word "fad" to describe this, is again, another way in which a perfectly valid SCIENTIFIC judgement is being (consciously?) misinterpreted as a sociological issue.

3. A significant fraction of the current HEP faculty in big universities is composed of string theorists and string-inspired people. To claim that the focus in recent years on phenomenology is an indication that they are done with strings, is beyond ridiculous. As I said, there is a very real reason why we all should be concerned about phenomenology/cosmology: the LHC and WMAP.

4. Since the departments that hire phenomenologists contain a significant fraction of senior string theorists, can we at least have a consensus now that not all senior string theorists are blinded ideologues who try to "suppress" everything else?

5. Cormac's previous message was excellent.

28. **Thomas Larsson**
January 21, 2009

Secondly, it turns out to be a very difficult field, accessible by only the very best students – the maths of gauge theory is way beyond most physicists, and therefore commands a certain respect.

Come on, gauge theory is not that hard. And remember that it was a squalid state physicist who invented the Higgs mechanism.

Thirdly, how do you know what the future applications will be?

This can be answered be a simple energy argument. The original fields to which QM was applied – atoms and molecules, solid state, chemistry – typically deal with energy scales of order eV, i.e. scales found on earth, and the practical applications at terrestial energy scales are too numerous to list. Nuclear physics is at the keV scale, i.e. typical energies of the sun. Solar scales have far fewer applications than terrestial scales, but since the sun is rather close to us there are still a few important ones – nuclear power and weapons, NMR, and maybe something more. In contrast, 45 years after the quark model, HEP has very few practical applications. Off the top of my head, the only one that I can name is the use of synchroton radiation in medicine (muon catalyzed fusion didn't work out, did it?), and this is very low high energy – MeV physics rather than GeV or TeV physics. The energy scales that will be probed at the LHC are typical of supernovae and the big bang, and will remain irrelevant for terrestial phenomena in the forseeable future.

Any good physicist who makes such an energy considerations will realize that applications of GeV physics will remain in the very distant future. There might of course be spin-off effects, like CERN inventing the WWW, space science inventing cool materials, and military science inventing the internet. But such spin-offs do not have anything to do with the core science.

There have been many stunning applications of discoveries in particle physics, from nuclear power to the use of accelerators in medicine

Since when did particle physicists adopt nuclear physics? I remember a rather controversial talk 20 years ago, when a local string guru (let's just call him "Veneziano's advisor") argued that nuclear physics was unmodern and its funding should be redistributed to more modern physics.

Medical applications remain at the MeV scale.

29. **Peter Woit**
January 21, 2009

somebody,

You really like to argue against statements that no one has made…

No one claims that "phenomenologists have a cakewalk", just that there are more jobs out there per person for phenomenologists than for others kinds of particle theorist.

No one claims that string theorists "are done with strings". They're not. I suppose many of them will keep working on string theory until retirement, no matter what happens.

No one claims that "all senior string theorists are blinded ideologues who try to "suppress" everything else." Sure, many of them are now the ones agreeing to try to hire phenomenologists and cosmologists. Besides their openness to difference though, another consideration might be that other people in their department (who have a lot to say about tenure-track hiring) would not put up with hiring another string theorist, for various reasons, including perception that a phenomenologist is more likely to get grant funding these days.

WMAP data came out 6 years ago, the LHC was initially supposed to be producing data a couple years ago. These two experiments have a lot to do with the general trend that started quite a few years ago in the direction of cosmology/phenomenology, but nothing much to do with the dramatic acceleration of this trend (to proportions that I think make accurate the description of “faddish”) during the last couple years.

30. **Bee**
January 21, 2009

Hi Cormac,

Thanks. I checked the website, it says deadline was in December. Too bad, I would have sent my docs had I known. Best,

B.

31. **Cormac O Raifeartaigh**
January 22, 2009

Thomas:
Re ‘Gauge theory is not that hard’, rather than get in too a silly argument about what constitutes ‘hard’, allow me to point out that in physics departments the world over, only the very best and mathematically able students are pointed in the direction of particle physics, and there are good reasons for this..
Re applications, it is the spin-off effects that I’m talking about. It’s always a mistake to consider only the direct applications of new science as it is in the getting of the results that the technical breakthroughs occur..
Re nuclear power, how quickly we all forget the history of particle physics. The splitting of the nucleus using the Walton linear accelerator was the first hint of a new source of energy, as you know. More recently, I believe Carlo Rubbia published an innovative design for a modern reactor based on work he did at CERN…

32. **Sumar Ongi**
January 22, 2009

>HEP has very few practical applications.

To add one more application to “terrestrial” phenomena (not necessarily very practical, though): the theory of weak decays in nuclear physics. And, since about 10 years ago, the theory of few-body nuclear interactions has been based on QCD.

>Since when did particle physicists adopt nuclear physics?

There was an article in Physics Today some months ago about the new theoretical approaches to nucleon-nucleon interactions and the impact they have had on *experimental* nuclear physics. Very interesting stuff, I’m sorry I can’t give the exact reference now.

That whole business started with a couple of papers by Weinberg from the early 90s, showing how low-energy QCD effective theories could be applied to the nucleon-nucleon problem. The field has matured a lot since then. Besides, since some years ago, lattice computations are also being applied to those systems.

In fact, the field of low-energy hadron physics has been more or less merged with high-energy (or “relativistic”) nuclear physics since a couple of decades ago. Many particle physicists in those areas routinely publish in nuclear physics journals like PRC, NPA, EPA, etc.

On top of that, AdS/CFT – inspired models are also being applied to some nuclear physics problems, though I’m not sure how much has been done in that direction. Finally, let’s not forget that string theorists have adopted nuclear/quark matter as their favorite application of N=4 SQCD…

33. **Thomas Larsson**
January 22, 2009

Indirect spin-off effects can just as well be used to argue for increased military spending – after all, military science led gave us arpanet turned internet. This is very different from direct applications of low-energy physics such as transistors, lasers or nuclear power, where it is the physics itself that has applications.

Fair enough. I don’t see a problem with HEP (at least high energy HEP) lacking practical applications; knowledge can be valuable without increasing GNP. However, I see a problem with the statement that we cannot know whether HEP will lead to practical applications, when it hasn’t happened for 45 years and there are simple arguments why this has to be the case.

34. **Dan M**
January 22, 2009

>allow me to point out that in physics departments the world
>over, only the very best and mathematically able students are
>pointed in the direction of particle physics, and there are good >reasons for this..

This statement is false. The very best and mathematically able students of whom I am aware are directed to choose their own fields, since they are the ones who are presumably most qualified to do so. In my experience, they usually choose something other than particle physics. And there are good reasons for this…

35. **Cormac O Raifeartaigh**
January 22, 2009

“In my experience”
It would be interesting to know your position and experience. (Mine are on the link). Here in Europe, we generally try to give students the best advice, cognisant of individual inclination and talent, but also of which fields tend to be difficult to make an impact in..perhaps a different approach is employed in the US

36. **somebody**
January 22, 2009

Peter, the primary effect contributing to the recent interest in phenomenology is LHC. You suppressed that in your original post, but after I pointed it out, you now claim that you were talking about a secondary effect. You also claim that I “really like to argue against statements that no one has made.” I don’t have the power of hindsight that you have, Peter. If you keep qualifying your previous statements when a new point is made, I will always be chasing a moving target.

Sorry about the sarcasm, but the last paragraph of your original post was the worst propaganda-driven drivel I have read here in a while. It is a pity because there are so many things about the sociology and the public relations aspects of string theory community which I find appalling …

Unparticles would qualify for a “fad”, but not phenomenology in general.

The whole issue you raise is pretty much vacuous, because it is only you who see such easy boundaries between phenomenology and fundamental theory. Considering the fact that Seiberg and Vafa are both working on ways to connect with TeV scale physics these days, I would say that your straightjackets are designed for mediocrity.

37. **Ari Heikkinen**
January 23, 2009

JC: "Though with that being said, outsourcing has been eating away at salaries and jobs for many years."

Here in Europe firms don't generally outsource their best engineers. Is the situation in the US really that bad that they oursource even their best employees to save money?

38. **JC**
January 23, 2009

Ari Heikkinen,

It depends on the particular firm, and who is calling the shots in these firms. In firms run by management consisting of mainly folks who only have an accounting and/or finance background, they tend to be more into the outsourcing thing.

39. **Eugene Stefanovich**
January 23, 2009

Regarding outsourcing… (for those contemplating trading a "high-stress" job in theoretical physics for a "lucrative" employment in industry)

My company (USA, software for microelectronics industry) hired quite a few engineers in Shanghai last year. Mostly for quality assurance and for programming of peripheral features. When (if) economics goes south this year, the management will have a choice: either layoff their core developers in the US, or cut fat overseas. Although 1 engineer in the US costs as much as 3-5 engineers in China, something tells me that my bosses would prefer the latter option. (In similar circumstances a few years back, they decided to shut down a division in France, rather than touch their US employees). So, it may sound paradoxical, but I think that outsourcing, actually, increased my job security.

40. **mike**
January 24, 2009

The vermin handling business sounds like a safer profession. Although there are some vermin that can bite (ouch!) – the fangs that some string theorists exhibit towards scientists of differing opinions makes the theoretical physics field much more dangerous!

41. **Doug Natelson**
January 25, 2009

Cormac – I would agree that many of the most mathematically skilled students tend toward theory, often high energy theory. Still, I think it's borderline pejorative to assert that these students are, because of their mathematical sophistication, "the best". Your taste and bias are influencing your choice of words. Frankly, the implication that high energy theorists are inherently superior to other physicists (let alone other scientists) is an example of what many perceive as arrogance.

42. **Cormac O Raifeartaigh**
January 26, 2009

That is not what I said and I am not a particle physicist. What I actually said is that here 'only the best students the best and most mathematically able students are encouraged in the direction of particle physics' – not just because it is a difficult field but because it is very difficult to make an impact in this field as it has attracted a great many physicists over the years (this is also true experimentally).
I absolutely agree that there are many other important and rewarding fields – that's the point!

43. **Cormac O Raifeartaigh**
January 26, 2009

Re main topic of this thread, I keep meaning to say there is a very nice interview with Peter Higgs in the September issue of New Scientist at
http://www.newscientist.com/article/mg19926732.100-the-man-behind-the-god-particle.html

On the difficulty of the theory, he states "…there was a problem for me when the bandwagon started to roll in 1972. Because I'd written an influential paper, people tended to assume I understood far more about the subsequent theory than I did and I found it increasingly hard to keep up".
He describes then taking an interest in supersymmetry, but again found that tough going too. "I realised the only people who were producing anything that was worth doing was the generation that had just got their PhDs. After some years, I gave up"..
Of course, Higgs is a famously modest man, but it makes you think all the same..

44. **Shantanu**
January 26, 2009

Peter, any interesting or newsworthy from last week's PI conference on black holes and quantum physics http://www.pirsa.org/C09002 and from the string theory related talks in this meeting?
Getting the correct value of black hole entropy and information loss paradox
is supposed to be a triumph of string theory.

45. **King Ray**
January 27, 2009

Peter, what do you think of this?

http://www.foxnews.com/story/0,2933,483477,00.html

46. **anon.**
January 27, 2009

"Theoretical Physicist" makes the list, right in between "Monkey-Sex Observer" and "Vermin Handler".

That's because theoretical physics has lost glamour. It used to be dominated by interesting personalities and rapid progress. Now things have slowed down and you have the boring geniuses left.

“Men of genius are often dull and inert in society; as the blazing meteor, when it descends to earth, is only a stone.” – Henry Wadsworth Longfellow

47. **Cormac O Raifeartaigh**
January 28, 2009

King Ray: I think the only sentence we need bother with is:

“We conclude that … the growth of black holes to catastrophic size does not seem possible”.
What a clear example of a journalist paying no attention to what the scientists actually said. Hopefully, Obama will declare a fatwah on FOX news…

48. **Bruce**
February 4, 2009

Peter,

In your post you point out that the claim that hiring in particle physics is dominated by string theory is behind the times. I don’t dispute this, but I wonder if you can quantify this statement or is it simply obvious to folks like you who wander widely in the field?

49. **Peter Woit**
February 4, 2009

Bruce,

Up to the minute data on particle theory hiring into tenure-track jobs is available here:

http://particle.physics.ucdavis.edu/rumor/doku.php

You’ll find that job descriptions this year often explicitly ask for LHC phenomenologists or cosmologists, whereas a few years ago string theory was often specifically mentioned. You’ll also find very few string theorists on the short lists for jobs this year.

I think if you talk to any young string theorist who is on the job market, you’ll get more confirmation of the problem

50. **Just Asking**
February 9, 2009

So Regge and Veneziano weren’t doing phenomenology? And we haven’t all been waiting with baited breath for almost 30 years now to probe the TeV scale?

You know, Boltzmann committed suicide shortly after his contemporaries reclassified him from “physicist” to “applied mathematician.” His theory did, after all, rely on the reality of unobserved “atoms” and “molecules.”

Hey, I have a great idea, let’s further encumber the minds of young people in an already anti-intellectual cultural climate with a pop science “debate” which reduces untold billions of man-hours of careful thought into the credo of some “parasitic” cult.

That will surely prevent the Boltzmann’s of today from hanging themselves while on Summer vacation.

51. **woit**
February 9, 2009

Just Asking,

I don’t think the Boltzmanns of today are likely to consider hanging themselves because unification via a 10d superstring doesn’t seem to work. They might just work on something else.

As for who is doing anti-intellectual pop science, that’s something I tried to avoid in my book and here. It would be a good idea if those promoting string theory considered doing the same…

52. **Robert**
March 10, 2009

I just received my Bachelor of Science in Physics and have been reading about string theory. It seems to me that all the talk about string theory being unprovable or unverifiable is overstated. Many theories in physics are based upon indirect evidence. For example, no one has ever seen a proton or neutron or electron, yet much of 20th century science is based upon the assumption that these particles exist.

I don’t understand string theory fully- yet, but I have read enough to know that if a theory explains events in the universe accurately and the math works it is worth pursuing.

Personally I find it pretentious that some physicists have the nerve to tell other physicists what they should be studying. If string theorists want to study string theory what is wrong with that as long as they follow the scientific method?

53. **Peter Woit**
March 11, 2009

Robert,

Of course indirect evidence is acceptable in science. The problem is that there is no such indirect evidence now, nor is there any plausible proposal for how to get such indirect evidence.

Scientists all the time argue for and express scientific opinions about which scientific ideas are promising and showing success, which ones are not working and why. Evaluating what works and what doesn’t is an important part of what scientists do. This is different than “having the nerve to tell other physicists what they should be studying”. Other physicists can make up their own mind about what to study based on the arguments they hear.

If you are interested in string theory, I suggest you read and think about the arguments being made both by enthusiasts and skeptics, and make up your own mind. I don’t see the point of complaining that both sides of the argument are available to you.

54. **Puttputt**

March 20, 2009

It can be solved by outsourcing theoretical physics. PARTY ON AMERICA!

Lots of Unrelated Topics

January 27, 2009
Categories: Uncategorized

I'm trying to finish writing up something about equivariant cohomology for the BRST project, slowed down by realizing there was something interesting about this that I didn't understand. Soon that should be sorted out….

In the meantime, here are various other things that might be of interest:

The El Naschie/Elsevier saga continues, latest here.

There's a new book out from Cambridge University Press entitled On Space and Time, which has chapters from different authors stretching from solid physics to theology, with lots of quantum gravity in between. The editor, Shahn Majid, is blogging here, on a site run by Cambridge.

Evidence for time travel has appeared in the British newspaper The Independent, which recently published an editorial by Mike Duff about string theory that appears to have come through a worm-hole connected to about 13 years ago.

There really are good reasons that theorists who insist on devoting their lives to absurdly speculative models of extra dimensions which have nothing to recommend them other than not being obviously inconsistent should stop promoting these things in the press. One of these reasons is that doing this tends to lead to articles like this one on Fox News.

British theorists at Durham are getting some new funding.

American scientists are lobbying for their piece of the stimulus pie that should be cooked and ready to serve within the next couple weeks. An editorial by David Gross and Eric Kandel is here, a letter from 49 Nobelists here. The latest news indicates that the NSF and DOE are still in line for massive short-term budget increases.

In France, President Sarkozy argued in a speech that French scientific research needs to be reformed, with the economic crisis that originated in the U.S. a good opportunity for the French to modernize and do things more the way they are done over here. Many French scientists are reacting with "shame and anger", and planning on joining a general one-day strike this Thursday. I know little about the problems and virtues of the French research system, but perhaps scientists there should tell Sarkozy it's a deal if he is willing to put up the sorts of cash the current U.S. administration is discussing.

There have been a few physics arXiv preprints that seemed worth a mention recently, although all of them have been discussed extensively by Lubos, who seems to be saner these days:

- Smolin and Ellis argue here that if you take the landscape seriously you end up predicting a negative cosmological constant, falsifying the idea. This is along the same lines as other such wrong predictions (e.g. proton decay), and since their existence hasn't slowed down the spread of landscape ideology, I doubt one more will do the trick.
- Several authors here find 10^{668} as a lower bound when calculating the number of possible vacua in a certain class that might give the standard model at low energies. This is high enough to make getting any predictions (other than the wrong ones…) impossible, but along the same lines as previous estimates which didn't slow down the landscapeologists. No reason to think this one will either.
- Petr Horava has an interesting proposal for a new candidate sort of quantum gravity here, one with Lorentz breaking at short distances. I don't know if this is any more testable than other such proposals. Even though his proposal has absolutely nothing to do with string theory, it's rather amusing that the author finds it necessary to somehow invoke string theory:

> Given this richness of string theory, it might even be logical to adopt the perspective in which string theory is not a candidate for a unique theory of the universe, but represents instead a natural extension and logical completion of quantum field theory. In this picture, string theory would be viewed – just as quantum field theory – as a powerful technological framework, and not as a single theory.
> If string theory is such an apparently vast structure, it seems natural to ask whether quantum gravitational phenomena in 3 + 1 spacetime dimensions can be studied in a self-contained manner in a "smaller" framework. A useful example of such a phenomenon is given by Yang-Mills gauge theories in 3 + 1 dimensions. While string theory is clearly a powerful technique for studying properties of Yang-Mills theories, their embedding into string theory is not required for their completeness: In 3 + 1 dimensions, they are UV complete in the framework of quantum field theory.
> In analogy with Yang-Mills, we are motivated to look for a "small" theory of quantum gravity in 3+1 dimensions, decoupled from strings.

So, the idea seems to be that now string theory is a "logical completion" of qft, although not needed to describe any of the forces we know about.

For two new survey talks at UCSB by Edward Frenkel about geometric Langlands, see here. He also gave an interesting talk there as part of the KITP string theory program, on recent work (summarized here) that has relations to both geometric Langlands and to the pure spinor formalism.

Update: One more. The Chronicle of Higher Education has an article on SCOAP^3, the plan to make the entire high physics literature open access by coming up with \$14 million/year to pay off the publishers. I don't really see this. The idea seems to be that the money is needed to get peer review, and the size of the literature is about 10,000 papers/year. So, cutting out the publishers, referees could be paid \$1,400/paper to do peer review. This might dramatically increase the quality of refereeing, or at least the take-home pay of many physicists. Some quotes:

> But Mr. Mele says journals still play a crucial role in the professional life of scientists, even though readership has declined. "We do not buy journals to read them, we buy journals to support them," he said. "They do something crucial, which is peer review."
>
> Without journals, he asks, how would colleges evaluate the work of scientists to know whom to hire or whom to promote? And how would other scientists know which of the thousands of preprints contain the most important findings?
>
> "What we are really paying for here is for a service of peer review," he said.

but here's the problem, at least in the U.S.…

> The librarians praised the goals of the project, but some asked whether it was sustainable. After all, if the journals make their contents free online, why should college libraries use their shrinking resources to pay for them?
>
> Some librarians at public institutions say they cannot participate even if they want to. "Most states require that public funds allocated for purchasing have to be used to actually purchase something," said Dennis Dillon, associate director for research services at the University of Texas at Austin. That is certainly the case in Texas, he said. "They can't be used to pay for something that everyone already has for free."

Update: For more LHC-related hysteria generated by publicity-hungry academics, see this. It originates with a group at the Institute for the Future of Humanity, last seen promoting the idea that we live in a simulation.

   January 28, 2009

   '… by coming up with $14 million/year to pay off the publishers. I don't really see this. The idea seems to be that the money is needed to get peer review, and the size of the literature is about 10,000 papers/year. So, cutting out the publishers, referees could be paid $14,000/paper to do peer review. This might dramatically increase the quality of refereeing, or at least the take-home pay of many physicists.'

   $14 million divided into 10,000 is $1,400, not $14,000. It will help those who are peer-reviewers, but will it help those trying to publish unfashionable ideas? I'd imagine that putting such a price tag on peer-review will make for a lot of the 'I'll review your paper if you review mine' culture, great for the mainstream but not so good for backwaters.

2. **Eugene Stefanovich**
   January 28, 2009

   "journals … do something crucial, which is peer review"

   Wrong. Scientists peer review each other. The contribution of journals is limited mostly to a technical work of sending e-mails back and forth. This job can be easily performed by a not-so-sophisticated web application. Paying $ millions to publishers is just beyond ridiculous.

3. **Peter Morgan**
   January 28, 2009

   Journals also provide an archive of their papers. If my library has a subscription, I go to the journal web-site for the paper, instead of writing to the author for an offprint. My library doesn't have an on-line archive of their own, whereas they used to have their own carefully maintained paper copy archive.

   Journal editors also act as doorkeepers, a task in which they are scrupulously supervised. Editors are expected not to pass papers to peer review if they are obviously substandard. I've seen at least one nasty blast at an editor for sending one of my early papers to a referee. You have to pay for your doorkeeper.

   Journals also apply minimal copy editing and standardization of format. Over time, new technical developments sometimes require changes to such policies, a process that requires expertise, time, and resources. The move to the web was a major such transformation of the process, which was handled well or badly by different journals, but it certainly cost money.

   There are numerous administrative tasks associated with any large-scale organization, which do not go away by the application of fine sentiment. It's not just peer review that is provided by journals, it's organization of peer review, knowing who can be sent any given new paper, knowing how to deal with new ideas well in the journal environment, etc. There is still the printing process to take care of, even if many fewer copies are printed and offprints have become almost a memory.

   I presume that a journal editor could list a significant number of other tasks that scientists themselves would be loath to spend time on. I am not associated with journals in any way, and some publishers act corporately in a way that encourages criticism, but the idea that journals just provide peer review is unthinking.

4. **Peter Woit**
   January 28, 2009

   anon.

   Oops… I suppose I should not write some of these things quite so fast. Fixed.

5. **Peter Woit**
   January 28, 2009

   Peter Morgan,

   Sure, the peer review process needs not just referees but editors to choose them (or decide a paper is not worth bothering them with).

   The arXiv already handles the archiving function well, and it's becoming debatable whether printing up copies of papers is a useful function.

6. **Pawl**
   January 28, 2009

   A few comments on the Fox News/LHC business, where, bizarrely, they report on an arxiv preprint concerning the possible lifetimes of micro black holes.

   I think it's a little unfair to say the large-extra-dimension proposals (which generated all the fuss by predicting micro black holes) have nothing positive to recommend them. They are attempts to solve a deep problem (the hierarchy problem), and that problem could have some really radical solution. (True, beyond that, they have a lot of negative baggage.)

   I do agree however that much of the problem comes from the fact that these proposals were discussed without anything like the appropriate caveats about how unlikely they are to be correct. It's not merely that they involve speculation, it's that they are so preliminary it's hard to say much about them. (There is no real theory yet, only some ideas and models. The ideas are so radical that they almost certainly cannot be reconciled with known physics.)

7. **Peter Woit**
   January 28, 2009

   Pawl,

   The original problem here came about because of the hype from theorists about the possibility of the LHC producing black holes, something absurdly unlikely, but you wouldn't know this from the sales job done by some theorists. Given the recent hype, I don't think it's especially bizarre that Fox News would pick up on a paper by three theorists about "the Possibility of Catastrophic Black Hole Growth in the Warped Brane-World Scenario at the LHC". I do think it's a bit bizarre that any theorists would post a paper with this title on the arXiv if they didn't want to get on Fox News.

8. **MathPhys**
   January 28, 2009

Now I'm starting to really like El Naschie. The man has guts.

9. **Shantanu**
February 2, 2009

Peter, I see there are 2 back-to-back colloquia on string theory .
Could you give us a summary if there was anything new in it?
Also anything interesting in the KITP program on string theory.

10. **Peter Woit**
February 2, 2009

Shantanu,

I'm embarrassed to admit that I was planning on attending the Gubser colloquium last week, but somehow got busy with something else that day and forgot about it. I'll probably try and go to Vafa's to see what he has to say.

So far, of the KITP talks I found the Nekrasov and Frenkel ones interesting, but haven't found time to write about them. I see Polchinski is giving a general talk about string theory today…

11. **Jason**
February 5, 2009

Anyone know what happened to John Baez's

http://golem.ph.utexas.edu/category/2008/11/the_case_of_m_s_el_naschie.html

? Did he take it down due to legal threats from El Naschie? I really want to read it. If anyone has it cached, please send it to hasten dot jason at gmail dot com. Thanks!

12. **woit**
February 5, 2009

Jason,

That's weird, I don't know what the story behind that is. The El Naschie story just gets odder and odder….

13. **Shantanu**
February 7, 2009

Peter, thanks for the info and I look forward to a description of
Vafa's talk. Also did you find anything hyped/intereresting or otherwise
in the string theory talks in the PI conference on black holes and
quantum physics?
Thanks

14. **Peter Woit**
February 7, 2009

Shantanu,

Sorry, but my interest in many quantum gravity issues is just not very great, and the black hole information loss business is something I'll happily leave to other people to debate. There are too many interesting things out there to learn about and think about, so one has to make choices, and that's one of mine…

CERN: The View From Inside

January 27, 2009
Categories: Experimental HEP News

Tommaso Dorigo has a new post up on Information control from CERN, where he discusses a Physics World interview by Matthew Chalmers of the head of communications at CERN, James Gillies.

Gillies addresses what CERN sees as a problem: information coming out first in blogs rather than from the CERN director through official press releases. One aspect of this is the release of information about experimental results, and Tommaso discusses this question on his blog. Unfortunately, I think CERN and the LHC are still quite a ways away from having any experimental results that need to be protected. For the rest of this year, the LHC will be getting a lot of attention from high energy physicists, but what they will be interested in is the question of how the machine is progressing towards the goal of colliding beams at a useful luminosity. For most of the history of the project, CERN's information policy was remarkably open: the slides from presentations made before the technical committees guiding the project were posted in locations that, while not advertised, were easy to find and did not require a password to access. Anyone with a serious interest could follow along and get first-hand technically accurate information about what was happening.

Things changed rather dramatically after the accident last September 19th. Publicly accessible logbooks were edited to remove information, and public access to the websites of the technical committees was shut off:

> **Who ordered links to photos and some presentations to be password protected after they appeared on blogs?**
>
> wanted the CERN community to receive the news from him before it was made more widely available, so access to slides was temporarily restricted. People just hadn't realized how much in the spotlight we are now.

Gillies doesn't address the issue of why these websites have now been restricted, a policy that appears to be permanent and go beyond a "temporary" restriction. According to Chalmers:

> CERN's new director general told staff on 12 January, that from now on people would hear about events first from him, not the press.

This kind of tight control of information about what is happening at the LHC seems to me to be a misguided policy. The best and most timely source of information for CERN staff about the LHC should be first-hand information from the engineers and physicists working on the project, not whatever has made its way up the chain of command and then been laundered for public consumption. Shutting off access by physicists to accurate technical information and making the DG the only source of news about what has happened at the LHC is likely to just encourage unchecked rumor.

Next week at Chamonix there will be an LHC Performance Workshop, and the slides are supposed to be publicly available here as the presenters post them over the next few days. These slides should give an accurate picture of where the project is and what a realistic proposed schedule for the rest of the year would look like. According to the Physics World interview, CERN's plan is that "a realistic schedule will be announced" after the Chamonix workshop. Of course, by then, many people will have already have a good idea about what this schedule will be, that is, if the slides are not password-protected….

Comments

1. **rumors about chamonix**
   January 28, 2009

   Well, one additional piece of news about CERN restrictive policies is that CMS is closing the outside access to their twiki page.

   Since this is going to happen on February 2nd, there is still time to dump the whole site on some disk and make a mirror. Of course, that will not allow access to future additions to the page, but still…

   On a different note, in Chamonix the plans for 2009 running (and beyond) will be laid down. There is considerable focus on whether 6 TeV c.m. would be enough to beat the Tevatron results on Higgs and other searches, given 100/pb of data or so. It seems 6 TeV are insufficient, while 10 TeV would fit the bill. However, 10 TeV will be very risky for the machine, which will not be totally safe from possible additional incidents like the one of Sept. 19th. My guess is that they will declare they're going for 10 TeV this summer, and then settle for 8-9 TeV this fall.

2. **DB**
   January 28, 2009

   I have been harbouring a suspicion for some time that the LHC management are more concerned about the long term operational viability of the LHC than they are letting on.
   There is a question as to whether the machine can fulfill its operational goals or whether is will be so prone to breakdowns that its effectiveness may be seriously compromised.
   However, I don't want to exaggerate this, it's just a minor nagging doubt for now.
   Debates as to whether the quench suppression systems really are up to the job, in which case the last incident was just a freak occurrence, are among those that you might expect to see aired in internal meetings. Management would not want the outside world to get hold of such candid discussions for obvious PR reasons and this could explain the "temporary" access restrictions which are still in place. While I don't like it, I can understand the need for internal teams to feel they can freely and candidly discuss all possibilities without the prying eyes of the media who, let's face it, can only be trusted to adopt the most sensationalist spin.

3. **Peter Woit**
   January 28, 2009

   DB,

   The only sensationalist spin about the LHC I've noticed in the media is that surrounding black holes, and that is driven by theorists. The media coverage of LHC progress, problems and the accident seems to me to be have been quite responsible, with the accurate first-hand information available from the technical committees and the links to that provided by blogs helping to ensure this. When there is trouble, the media attention is going to be uncomfortable for CERN, but they're the ones who have gone to a lot of trouble to get this media attention before the machine is operational, while they're in problem-fixing mode.

4. **Yatima**
   January 28, 2009

Groan. I can understand the urge to “control and restrict” information about the internal processes of CERN, even though the primary reason for this will be the bog-standard one that you encounter time and again in industry, public organizations and politics, namely, preventive ass-covering and the urge to not make your money sources ask too many questions that you cannot honestly answer. While there evidently will be no darker motives behind any such policy change (Dick Cheney has not being tapped for this, right?), I’m sure a lot of fringe elements will be energized and will start looking for the “story behind the story” and the coverup motives in a heartbeat. I’m sure it’s easy for everyone to list a few scare scenarios not out of place in an X-Files episode. It is doubtful that this will result in a positive message or responsible media coverage in the long run.

5. **onymous**
January 28, 2009

The only sensationalist spin about the LHC I’ve noticed in the media is that surrounding black holes, and that is driven by theorists.

Is it? My sense is that the person who has been most consistently pushing the possibility is Greg Landsberg, an experimentalist. There is a bit of theory work at one edge of the community but I think few theorists would call this a plausible possibility. Most of the work by competent people in recent years was either driven by the need to produce a safety report once the crackpots got too vocal, or by people arguing that the original estimates were too optimistic even in the implausible models where it could happen at all.

6. **Warren Platts**
February 1, 2009

One thing I’ve found conspicuous by its absence is an analysis by CERN of CERN’s culture, and what role that culture played in the explosion, er, “incident” of Sept 19. When NASA reviews what happened when a shuttle blows up, there is in addition to an analysis of the proximate, mechanical causes, there is also an analysis of how NASA culture might be involved, e.g., pressures to launch despite icicles hanging from rockets. Yet there’s be nary a word from CERN regarding its culture. The only clue that there are cultural issues came from Herr Heuer’s promise to be more cautious than his predecessor. Why would he say such a thing? It wasn’t the fault of a busbar splice after all? All this information control and spinning is not healthy–not to mention undemocratic.

7. **csrster**

Trying to stop physicists from talking about their work? Welcome to the exciting world of cat-herding!

No Chamonix For You

January 30, 2009
Categories: Experimental HEP News

In the last posting I linked to the web-site for next week's LHC Performance workshop at Chamonix, where the state of efforts to recover from last September's accident and plans for this year will be discussed. As in many previous cases, linking to an authoritative information source about what is going on at the LHC had the effect of it being quickly shut off to the public. I guess CERN really is serious about the idea that information about problems at the LHC is now only supposed to come from the DG's office.

So, from now on, I'm sorry to have to do this, but I won't be linking to any such information sources that people point me to or that I run across. Instead, I'll try to continue to post here authoritative information that comes my way, without indicating its source. Today, I'll just note that I've heard from an authoritative source about the current informed guesses for when the LHC will be able to start doing physics. The current hope is for first usable collisions at 5 TeV (per beam) in October, with two months for a physics run at that energy before winter shutdown. Peak luminosity would be a few times 10^{31}, integrated luminosity a few tens of pb^{-1}.

Update: CERN does seem to be making an effort to put out more information about the status of the LHC through their press office. Yesterday there was this update posted as "breaking news", not waiting for the next issue of the weekly bulletin. The news in the update is uniformly good, telling us about how it has been "a good week". What will be interesting to see in the future is whether less encouraging news makes it out to the public…

Update: The web-page denying access to the Chamonix slides has been changed, it now reads:

> This site is temporarily password protected during the duration of the LHC workshop but will be re-opened immediately after the workshop.

I guess that CERN still wants the news of whatever is presented at Chamonix to first come from their press office, but realizes that making available the detailed technical discussion behind this news is a good idea.

1. **onymous**
   January 30, 2009

   5 TeV c.m. energy, or 5 TeV per beam?

2. **Peter Woit**
   January 30, 2009

   5TeV/beam (I'll clarify that in the text)

   This is based upon the assumption that they don't decide that for safety's sake they need to run at a lower energy.

3. **mike**
   January 31, 2009

   I realize that October is a rough estimate but from my experience in technical project management I am guessing this means possibly spring of 2010 (figuring in winter shutdown and unknown delays) before new physics starts happening? So it looks like Fermilab is our best hope this year for the Higgs search and other new physics – is there any news on this front?

4. **Peter Woit**
   January 31, 2009

   mike,

   The main news from Fermilab is that the Tevatron is performing extremely well, significantly better than projected, with nearly 6000 pb^{-1} collected already. Even if the LHC does collect some data late this year, it won't be enough to say anything about a Standard Model Higgs. For the Higgs search, it looks to me as if the Tevatron will be the only game in town for quite a while, with a real possibility of either ruling out or finding the Higgs if it is in the expected mass range, before the LHC has a chance to weigh in.

5. **B**
   January 31, 2009

   It's important to remember that the Tevatron can only say the SM Higgs exists or doesn't exist at 3 sigma. Impossible for anything more then that.

6. **Coin**
   February 1, 2009

   So, 2 weeks in october at 5 TeV/beam followed by the winter shutdown?

   Just to be clear, wasn't this basically exactly the intended plan for last year, before the accident?

7. **Chris Oakley**
   February 1, 2009

   > 5TeV/beam (I'll clarify that in the text)
   >
   > This is based upon the assumption that they don't decide that for safety's sake they need to run at a lower energy.

   What – safety's sake in the sense that they don't want to run the machine above the threshold at which planet-swallowing black holes are created?

8. **Mikael**
   February 1, 2009

No, safety's sake in the sense not to do further damage to the machine, which would cause further delays.

9. **Peter Woit**
February 1, 2009

Coin,

Two months, not two weeks. The hope is to go as late as possible, into December, before the winter shutdown.

Yes, this is pretty much the 2008 plan, the accident has cost them most of a year to deal with

10. **SMD**
February 1, 2009

The major issue at CERN nowadays seems to be how little confidence they have in their enterprise. They are doing the same thing with information that Karl Rove et. al. did during the last presidential administration. Filtering all information is the route to spinning information and conveniently forgetting unpleasant truths. What they are doing in effectively prohibiting the dissemination of information is destroying their own credibility. GO FERMILAB!!

11. **JoAnne**
February 1, 2009

Don't count on 10 TeV center of mass this Fall – they are seriously considering 8 or even 6….

12. **Spear Mark the Second**
February 1, 2009

So little attention has been paid to the technical evolution of the LHC. On the good side is the enormous risk that was taken… CERN really has bet the farm on the LHC. Good for them! Amazing amounts of terrific engineering and applied science have been performed.

On the other side… it has been under-resourced. Hard to say that when billions $ have been spent. Still, the amount of money should be compared to the difficulty of the task. A lot of the fun of CERN has been sacrificed to try to make this a successful project… CERN used to have way more variety and a really fun scientific environment for experimental physics. Devotion to one big project kind of squeezes much of the elan out; also, the boundary between team members and outcasts who complain too much gets moved around to fit PR concerns.

Germany has been a bit lukewarm… resources into HERA and Linear Colliders… great to maintain diversity in the program, but many folks knew LHC was the main event, and was hurting.

Experimental physics is hard, really hard, much more challenging than string theory or SUSY. It will be a great success if LHC gets 14 TeV and good luminosity by 2011.

CERN is going the way of Fermilab and Cornell… dreadfully wanting to chase the great physics, but being unable to get the appropriate level of resources for a `Swiss Watch' startup. They will never give up! But what happens is delays and conversion of operating funds to finish the project. Run 2 at FNAL went through the same thing. Cornell never made a deadline that I can recall.

13. **mike**
February 1, 2009

Does anybody know when Fermilab might have definitive results on a Higgs mass? I know there is a lot of peer-review that has to be completed before the final results are published but perhaps something will leak out by the end of this year?

14. **Peter Woit**
February 1, 2009

mike,

Last summer, the Tevatron experiments released an analysis claiming that (using data from both experiments) they could exclude (at 95% confidence level) a Higgs mass in a very narrow range, essentially, exactly 170 GeV. I haven't heard anything about improvements on this, but they have a lot more data to analyze and are accumulating more all the time. With more data and improvements in the analysis, over the next few years one would expect them to be able to exclude increasingly large ranges of possible Higgs masses (or, see evidence of a Higgs). It appears quite possible that they'll be ahead of the LHC in this game until at least 2011 or so. Unclear if they'll be able to go all the way down to 114 GeV, the lower limit set by LEP.

15. **Nobody**
February 2, 2009

Dear Peter,
I think you perfectly describe the situation at CERN. I must say that I find one of the worst things of last year was the continuous exposure to "Official Press Releases", which as everybody already knew turned out to be one falser than the other. All of this without the arrogant management ever feeling the need to apologise with the Staff for the release of false and self-contradictory information. I really do hope the new DG manages to change this policy; but this will be a difficult task for him.
P.S. Your blog has been the place where one could find the most updated and complete information about CERN. Thank you.

16. **Peter Woit**
February 2, 2009

Nobody,

Thanks, I'm glad this blog has been a useful source of information. I hope that CERN decides to make as much technical discussion of the ongoing LHC project as possible publicly available. Blogs like this one can then provide the service of helping to point people to where to look for such up-to-date information.

17. **Anon**
February 2, 2009

Hi,

Did you attend the Grothendieck conference at the IHES? If so, I was wondering if you could write up a summary of what happened. I'm interested to hear what when on.

Thanks.

18. **Peter Woit**
February 3, 2009

Anon,

I went out to the IHES for parts of two days of the conference. There was a video-camera there, and I have been hoping the IHES will make available video of the talks, don't know if they have the capability or intend to. Maybe I will try and write something about the talks that I heard. This history was quite interesting, with Cartier, Deligne, Illusie, Serre and others who worked with Grothendieck during the 60s in attendance. Deligne gave a fascinating talk on motives, which is one thing I'd like to write about, but the topic is quite a challenge, and I haven't gotten up the energy yet…

19. **Anon**
February 5, 2009

Hey,

I actually found a blog that's covering the Grothendieck conference:

http://homotopical.wordpress.com/

20. **Peter Woit**
February 5, 2009

Anon,

Thanks, that's great. I'll try to find time soon to put up a posting about this, and maybe add something about motives and Deligne's talk.

21. **Chris Austin**
February 6, 2009

Returning to the topic of the LHC: if there is a new effect, such as TeV-scale gravity, which turns on very rapidly, modulo smearing by parton distributions, perhaps first collecting a lot of data at, say, 8 TeV c.m. energy, before moving up to 14 TeV, might be very helpful for trying to disentangle what is happening.

What is String Theory?

February 3, 2009
Categories: Uncategorized

Yesterday Joe Polchinski gave a lunch-time talk at the KITP on the topic of What is String Theory? No answer to the question, but he provided an outline of three topics being discussed at the current KITP workshop program that have something to do with it.

- String field theory: he wrote down the Witten open-string action and advertised that as the best candidate for a definition of string theory that could go on a t-shirt. He noted some of the problems with this, especially how to understand closed strings, which are somehow "emergent", "hidden in the measure" on string field space, which one doesn't really understand.
- The Berkovits pure spinor formalism for quantizing the superstring: if you want a consistent theory, you need supersymmetry, and Polchinski explained that the quantization of both supergravity and the superstring are ferociously complicated subjects. He hopes that the Berkovits formalism will provide a more lucid (perturbative) quantization of the superstring, one allowing a proof of finiteness at higher loops. This topic doesn't really address the "what is string theory?" question, since it is supposed to be equivalent to other ways of quantizing the superstring, and only valid perturbatively.
- AdS/CFT and integrability: here there's an answer to the "what is string theory?" question, but it's in some ways a disappointing one for the idea of a single string theory that unifies everything and goes beyond QFT. If you believe the full gauge/string duality speculative framework, there are lots of string theories, each of which is defined by fiat to be a certain QFT. If this is right, perturbative string theory is just a tool useful in the study of some strongly-coupled QFTs, and non-perturbative string theory isn't really a subject distinct from QFT. If you want to unify physics starting from thinking about the SM, at short distances you have a weakly-coupled QFT, with no role for string theory. And, in this picture, there are lots of string theories…

At the end, someone asked about the LHC and supersymmetry, Polchinski responded that string theory didn't require LHC-scale supersymmetry, but if supersymmetry was discovered at the LHC then there would be a "sociological" effect encouraging to string theorists. I also noticed recently that Polchinski has a web-page On some criticisms of string theory.

In his discussion of the pure spinor formalism, he noted that supersymmetry doesn't seem to "resonate" with mathematicians, but that pure spinors are more something they recognize. This is certainly true, with supersymmetry something frustratingly close to some standard mathematical constructions, but quite different in other ways. Pure spinors occur naturally when one tries to construct spinors geometrically. Projectively, the space of pure spinors is SO(2n)/U(n), a space which has some quite beautiful properties. In the Borel-Weil geometric construction of representations, spinors are holomorphic sections of a line bundle over this space (for details of this, see the chapter on spinors in *Loop Groups*, the book by Pressley and Segal).

For the superstring, one is interested in the case of n=5, and a certain sigma model with target space the space of pure spinors. There's a more general class of sigma models of which this is a special case, and for more about some of the interesting connections of this to other subjects, see the recent KITP talks by Nekrasov and Frenkel. The Frenkel talk is especially interesting, since it involves several other quite beautiful related ideas. He describes one motivation for studying some of these sigma models that comes from geometric Langlands. While he was at Santa Barbara, Frenkel also gave two nice survey talks about geometric Langlands, see here.

Update: Clifford Johnson explains here that not only do we not know what string theory is, but we can't even say anything useful about what it isn't, other than "it is not a theory of strings". The problem with this situation, according to him is:

> people who don't know what they're talking about, and sometimes with an axe to grind, shouting loudly (and sometimes deliberately misleadingly) about it.

Update: More thoughts from Clifford on the question of how to deal with string theory critics.

Comments

1. **Sumar Ongi**
   February 3, 2009

   > He hopes that the Berkovits formalism will provide a more lucid (perturbative) quantization of the superstring, one allowing a proof of finiteness at higher loops.

   Can one infer from this that, in Polchinski's view, there's no complete proof of finiteness yet?

2. **Peter Woit**
   February 3, 2009

   Sumar,

   He was specifically asked about this, and did not claim that a complete proof of finiteness exists.

3. **Alberto G.P.**
   February 3, 2009

   Like some banks, do you think string theory is in crisis, today? What is the opinion of the main theoretical high energy physicists?

4. **Peter Woit**
   February 3, 2009

   Alberto,

   I think the analogy with some banks is apt. One part of the U.S. financial crisis seems to be the fact that some of the largest banks are "zombie" institutions, insolvent but unwilling to acknowledge this and draw the necessary conclusions. The idea of string theory unification is also bankrupt at this point, but being propped up because it would be very inconvenient for many people to acknowledge this and they don't see any palatable alternative to soldiering on. One difference is that the banks could (and probably will) have their insolvency problem fixed by pouring in lots of government money. This won't work with string theory.

   Among "main theoretical high energy physicists" you'll find a wide spectrum of opinion about string theory, from strong defenders to those even more unhappy about its state than I am. One thing that I think is undeniable is that the spectrum of opinions has shifted in recent years toward a much more skeptical take on string theory's prospects.

5. **Coin**

February 4, 2009

Is String Field Theory still an area of active work and development? It seems when I try to look up material on string field theory I mostly find stuff from the 80s to late 90s (Witten's work in the area seems to come from this time period as well if I'm not mistaken?).

6. **chapieau**
February 4, 2009

Recently I have got the feeling that string theory is going to become a purely mathematical subject. It could be condensed in two "Theorems" to be proved:
1) Under very general assumptions every reasonable field theory can be embedded in a string theory which makes its UV (high energy) dynamics consistent.
2) Maldacena conjecture shows that both the problem of "solving" string theory and the problem of strong coupling of gauge theories are equivalently complicated. Solving one solves the other.
Waiting for some brilliant mathematician to demonstrate the theorems, phycicists are going back to (LHC) phenomenology and toward bottom-up approaches

7. **Kea**
February 4, 2009

One assumes that Clifford's *people who don't know what they are talking about* includes everybody that is not a respectable string theorist, which is to say that it includes nobody who disagrees with the basic stringy party line. This includes a rapidly increasing number of very respectable physicists from *other* areas of physics, most notably experimental. But of course, they don't really know what they're talking about because they have not really studied string theory. Heh, maybe if they did they would appreciate the necessity of forgetting about contact with experiment, and then appreciate the beauty of the mathematics, and be thankful for their now superior understanding of the fundamentals of physics. Yeah, right.

8. **Tony Smith**
February 4, 2009

Peter, you said:
"… Projectively, the space of pure spinors is SO(2n)/U(n) …
For the superstring, one is interested in the case of n=5 …",
which sort of confuses me.

As to the math (not so confusing), Reese Harvey (in his book Spinors and Calibrations) says
"… the set Cpx(n) of orthogonal complex structures on R^2n has two connected components Cpx+(n) and Cpx-(n), with
Cpx(n) = O(2n)/U(n)
Cpx+/-(n) = SO(2n)/U(n)

Harvey calls O(2n)/U(n) "the twistor space (at a point on a manifold), i.e., the twistor fiber",
and says(I am using "n" instead of Harvey's "p" here):
"… Let PURE(n) .. denote the set of all pure spinors …
consider the complex case …
PURE_C / C* = Cpx(2n) = O(2n)/U(n)
…
The square of a pure spinor represents the associated null plane in
/\R(n,n) …".

In the relevant case of n=5, it seems to me:

O(10)/U(5) which has 45 – 25 = 20 real dimensions is the twistor space,
and it has two components (for the two mirror image half-spinors of Spin(10)) that each are SO(10)/U(5) with 45-25 = 20 real dimensions.

Since PURE_C /C* = O(10)/U(5) has 45-25 = 20 real dimensions,
it has 10 complex dimensions.
Since the C* of complex scalars is 1-complex-dimensional,
PURE_C has 10+1 = 11 complex dimensions.

Since Spin(10) half-spinors are 16-dimensional,
11 of the 16 dimensions of Spin(10) half-spinors are PURE (in the real context).

That is consistent with the table in vol. 2 of the book Spinors and Spacetime, by Penrose and Rindler, that lists in table B.65 on page 453 for the even dimensional vector space n=10
the dimension d_10 of the space of pure spinors as 11
and the dimension of half-spinors as 16.

If my understanding stated above is roughly correct,
then it seems to me that the math/geometry is quite beautiful,
but
what really confuses me is how it is applied by superstring people:

Do they use the SU(5) as a GUT ?
If so, how do they deal with proton decay experimental results ?

Do they use the twistor space as generalized Penrose twistors ?
If so, how do they deal with massive fundamental particles ?

Do they just ignore concrete stuff like proton decay and particle mass,
taking the Clifford Johnson attitude "We're still working on it" so that their highly trained minds won't be corrupted by such messy detail stuff ?
(That reminds me of the HHGG where Vroomfondel said
"… our brains must be too highly trained …".)

Tony Smith

9. **Walter Mondale**
February 5, 2009

Dude, you're obsessed with string theory. Ok, we get your point. It's unprovable. But man, do you have to spend day after day, week after week, year after year, going on and on and on about this? I mean I can see a scientist being really into his research, but this is a scientist being really into "unresearch". You are just gushing about how a theory is not satisfactory. I'm not even saying you're wrong… but.. don't you ever get tired of this and think, maybe I'll go take up a new hobby like sailing or something….

10. **anon.**
February 5, 2009

'… don't you ever get tired of this and think, maybe I'll go take up a new hobby like sailing or something …'

Sailing is a good way to be alone with chicks for a few hours, but you're missing the basic string theory point. The flaw in string theory is *not* just 'it's unprovable' as you claim to grasp. The flaw is that it's not *falsifiable*. You can't prove models true in general, they are just approximations. E.g. quantum electrodynamics can't be proved, instead the theory survives experimental checks which have the capacity to falsify theories. The crisis in string theory is caused by the fact that it has been hyped as a self-consistent quantum gravity and unification theory without even any experimental support at all, never mind proof.

11. **somebody**
February 5, 2009

Alberto, look at the title of this blog, man. What do YOU think Peter thinks about the "crisis" in string theory?

Coin, in the last decade, there were two developments in string field theory that I consider "major". One was from Ashoke Sen's beautifully simple idea of tachyon condensation, which gave us the basic conceptual understanding of SFT that we have now. The second is Schnabl's solution of the closed string theory vacuum, which is more technical, but has created some powerful new tools and has made previously intractable questions within reach.

anon., Walter wasn't talking about string theory, he was talking about Peter's obsession with it. So it is not fair to say that he is "missing the basic string theory point", whatever that might be.

I have one quibble about Polchinski's talk – it seemed to focus entirely on the big-machines of formalism. Perhaps he was outlining the topics in the KITP program schedule.

Either way, he is looking for a way to answer the real question "what is string theory?", and not give the audience an exposition about "what is string theory (currently)?". This seems to have been lost on some of Peter's fans.

One interesting point I was reminded of in his talk was that there seems to be no simple way to derive 4D supergravity.

12. **Peter Woit**
February 5, 2009

Tony,

You have the geometry right. The twistors here are different than Penrose's, they're the 10d analog of what he is doing in 4d.

The SU(5) isn't the SU(5) in GUTs. This story is all about the basic question of quantizing the 10d superstring. To get GUTs or any particle physics you need to add more structure (compactification, for one thing).

13. **Walter Mondale**
February 5, 2009

Um, duh yes I know it's not disprovable either. This is given a subtle hint in the title "Not Even Wrong." Don't talk down to me, you spoon. The point is that spending years blogging and writing books about this subject is excessive. At this point in time, is there really anything else to add? Sure, there's some new conference or lecture by some renowned genius. But does it really truly add something new to the debate to point out for the 3,209th time how the latest development is still not satisfactory, because this too can't be proven or disproven via experiment? I mean he lives in NEW YORK CITY for crying out loud, there's so much to do. He could be getting laid every night. But no, instead he does this….

14. **Peter Woit**
February 5, 2009

Walter,

Odd, there's nothing in this posting about the proving or disproving string theory by experiment. You seem to be quite obsessed by this.

Also curious is how many people are concerned that my writing critical blog entries about string theory is interfering with my sex life (for instance, I recall the immortal words of Nima Arkani-Hamed as reported by Lubos "What's wrong with these people? Why don't they choose f***ing instead of writing about things that they don't like and they don't understand?"). Thanks for your concern, but rest assured, your worries about this are misplaced.

One not-so-obvious thing I should perhaps point out is that, especially after you've been doing it for a while, writing blog postings takes very little time. This one took less than a half an hour. Significantly more time was taken up by watching Polchinski's talk on-line, but it was an interesting and clear summary of the latest thinking on some quite technical issues, so definitely worth the hour or two I spent on it.

I'd be very glad if someone else would take over the job of providing a counterweight to the huge amount of hype and misleading promotion of string theory going on, which is doing continuing and serious damage to particle theory. For now it seems worthwhile to devote at least a few hours a week to this project, since the damage to my sex life is minimal. Much more serious actually is my recent fascination with reading financial news and following the ongoing economic crisis. That I've really got to stop….

15. **Syksy Rasanen**
February 5, 2009

The comic posted by Clifford is amazing. The fact that it is promoted by someone who identifies with the 'bitch-slapper' is symptomatic. Peter, nothing you write about 'string theory partisans' could possibly give a worse impression than this – this is self-parody of the highest order.

16. **yoyoq**
February 5, 2009

walter, what is worse ? :

the guy with the blog complaining about
string theory or the guy who writes into the blog complaining
about complaining about string theory

17. **Thomas R Love**
February 5, 2009

    Joseph Polchinski has an article on arXiv.org with the title "What is String Theory?"

    http://arxiv.org/abs/hep-th/9411028

    154 pages! From 1994!

18. **db**
February 5, 2009

    yoyoq> or the guy who writes into the blog complaining
    about complaining about complaining about string theory?

    Sorry.

19. **Coin**
February 5, 2009

    "Somebody", thanks for the explanation.

    I had not realized tachyon condensation was an idea from String Field Theory. Is everyone who works with tachyon condensation doing String Field Theory then, or is that just where the idea originated?

20. **Alberto G.P.**
February 5, 2009

    Peter,

    Thanks for the response!

    somebody,

    As I am a pedestrian, and my English is limited, I can only formulate very simple questions, questions that even a child would understand. As you seem a smart guy, I also have a question for you. In the last decade, what do you think has been the progress to obtain the electron mass using string theory?

    Thanks.

21. **Peter Woit**
February 5, 2009

    Coin,

    "tachyon condensation" just means that the usual perturbative vacuum state of fluctuations about zero field is unstable (there are tachyons) with a stable vacuum state given by fluctuations about some non-zero field (condensation of the tachyon). This is a general phenomenon in field theory, not specific to string field theory.

    Alberto G.P.,

    In the last decade there has been no progress towards obtaining the electron mass in string theory. There has however been a great deal of progress towards showing that you can get any electron mass you want in string theory.

22. **somebody**
February 5, 2009

    Peter, nice try. Yes, tachyon condensation exists outside of string field theory. So does gauge invariance, BRST symmetry, action functionals, … , addition, multiplication, and a zillion other things. 🙂

    "Coin": the point was that the tachyon condensation I meant was specifically the tachyon condensation that is relevant in string field theory. The one that takes you from a spacefilling D-brane to the closed string vaccum.

    Alberto, I will ignore your sarcasm and asssume it is the arrogance of the beginner. I recommend that you read my comments on this thread if you really want an answer:

    http://www.math.columbia.edu/~woit/wordpress/?p=740&cpage=1#comments

    The short answer is this: QFT doesn't predict the elctron mass either, but that hardly makes it non-preditive. I will ignore Peter's rhetoric, this has been discussed before, he has been told and knows full well whats up, and he just want to insinuate to his readers that predicting the electron mass is necessary for a theory to be predictive.

23. **Coin**
February 5, 2009

    woit: OK. Would it still be correct though to say that in order to apply tachyon condensation to String Theory, one must be using the String Field tools?

24. **Peter Woit**
February 5, 2009

    Coin,

    It's a field theoretical concept, so you need some sort of field. I don't know what it would mean in perturbative string theory.

25. **Jack Lothian**
February 5, 2009

Walter,

While I agree with many points made on Peter's site & I often enjoy reading some of the discussions, I too feel that at times the discussions become repetitive & circular. Whenever I feel like this, I tend to stay away from the site for a few weeks or a month. When I come back I can usually pick up the threads with a renewed interest.

While I understand some of the points you are making, I do not understant the anger or hostility. Peter is not forcing you come to his site. It is your free choice, so why are you angry with him? He is just doing something that he enjoys doing & the world is free to ignore it or read it.

26. **Walter Mondale**
February 6, 2009

I am not angry at him, I don't really know why you are saying that. I was annoyed at that other guy who talked down to me, but not Woit. I'm just kind of amazed at the spectacle of the blog, but I agree, if that's what he wants to do, that's what he wants to do. And he says his sex life is satisfactory, presumably from all the blog-related groupie activity. What more can one ask for?

27. **Alberto G.P.**
February 6, 2009

somebody,

Do you know if there is a solution of string theory that explains the Bhabha scattering, like QED?, Do you think I'm arrogant for asking? Maybe, 'the new science' doesn't need basic questions.

I think the problem is not with the string theory, but, with the philosophy of science.

BTW, I am not a professional physicist. I'm only a physics buff. I try to study physics as a hobby, but in a level much lower than it would be needed for studying string theory, because I'm completely unable to understand its math background. At the future, maybe, string theory will explain the other physics theories, and all the experiments, that the more conventional theories have already explained, then, I'll ask for forgiveness, even though, there were no new predictions. Meanwhile, I will come back to my Greiner's books.

Good luck.

28. **David B.**
February 6, 2009

Dear Alberto:

To the extent that string theory is compatible with gauge invariant interactions, and that the low energy effective field theory of string processes is indistinguishable from ordinary quantum field theoretical models, the Bhabha scattering is predicted with the same shape as it has in quantum electrodynamics.

The hard issue is not to say that one has quantum field theories in string theory that look sufficiently similar to what we see, but to what extent one can predict parameters that in the standard model are numbers that one measures (theoretical inputs) and for which there is no theory.

29. **Thomas R Love**
February 6, 2009

Peter,

You have mentioned this before, but it bears repeating since it echoes Polinski's title. In a 2005 article in Nature:

http://www.sns.ias.edu/~witten/papers/Unravelling.pdf

Witten wrote:

We still don't know where all these ideas are coming from — or heading to.
One day we may understand what string theory really is.

Witten doesn't know what string theory is.
Polenski asked the question, but did not answer it, so he doesn't know either.

I have observed that string theory's PR (Public Relations)
Is better than string theory's PR (Physical Review).

"Walter Mondale" wrote:

Dude, you're obsessed with string theory. Ok, we get your point. It's unprovable. But man, do you have to spend day after day, week after week, year after year, going on and on and on about this?

Walter: Peter is like the boy who said: "The Emperor has no clothes", he just has to keep saying it until the world gets the message. There are "string theorists" who treat the subject more like a religion. They have to, it is not a science.

I read Peter's book "Not Even Wrong" soon after it came out. It is a must read for all physicists. So, Walter, read the book!

30. **st**
February 6, 2009

I am baffled by the often use of analogy between string theory and religion. The two could not be more different. One is supposed to be a (correct/incorrect/not even wrong) theory about the physical world, and the other is about the supernatural, which as such, can never be proved or disproved by the scientific method.

31. **someody**
February 7, 2009

Thomas Love says : “Witten doesn’t know what string theory is. Polenski [sic] asked the question, but did not answer it, so he doesn’t know either.”

What is your point? If we understood string theory (at least at the level we understand QFT), then we would know immediately whether it was right or wrong and that would be the end of the string “controversy” nonsense. The point precisely is that string theory as it stands is incompletely understood. And no, this is not a secret known only to Witten and Polchinski.

32. **Alberto G.P.**
February 7, 2009

somebody,

After the response by David, and the response that a known string theorist gave me, I have realised that string theory is a model that can explain both QFT (Y-M theories) and general relativity in a consistent mathematical framework. Namely, we can explain all the laws of the fundamental physics/nature, although we can’t explain the fundamental parameters, using string theory. So, I have to apologise for my ignorance, for me the polemic is over.

33. **Shantanu**
February 7, 2009

somebody and other string theory enthusiasts, could you provide answers to the following questions ?

o Why hasn’t string theory solved the cosmological constant problem?

o What does string theory predict for the value of Theta_13, a quantity which is soon going to measured?

o Does string theory violate equivalence principle? (I have heard both yes
and no to this answer)

Thanks

34. **someody**
February 7, 2009

Alberto, just saying that the parameters of low energy physics are not fixed is perhaps a bit too generous a view of the current state of string theory. It is true, but the real problem is that we don’t really understand the true nature of string theory. The situation is very much like that of the proverbial blind men and the elephant. We are stuck to certain partial descriptions and specific tools, and because of this model-building is extremely hard. This is one of the reasons why “fixing all the parameters” in a useful way hasn’t happened.

35. **Peter Woit**
February 7, 2009

Alberto,

You have been misled. There’s an active campaign on to mislead people in this manner. The whole point of Polchinski’s talk is that there is no known mathematically consistent version of string theory that does what they hope (provide a unification of the SM and gravity).

Shantanu,

The answers to this are well-known:

1. the anthropic landscape “explains” the CC (and if you don’t like this, well, no one else can explain it).

2. string theory does not predict SM parameters.

3. light moduli fields will violate the equivalence principle. Like everything else, you can get whatever you want in string theory, have these or not have these…

somebody,

You are being misleading. The problem is not that you can’t “fix all the parameters”, the problem is that you can’t fix ANYTHING at all. Nothing, zero, zip nada. The excuse that “we don’t really understand the true nature of string theory” is getting very old. Everything you do learn about string theory provides more and more evidence that it can never predict anything about particle physics.

36. **someody**
February 7, 2009

Shantanu, my current view on string theory is that it is really a paradigm for building UV complete models. But if this paradigm is going to be useful, it should have a better (non-perturbative) definition, where we have the freedom to build models following ideas instead of being stuck with specific technical tools. The existence of such a definition is what made QFT useful for UV-INcomplete model building.

It is because it is a paradigm, that you can have many possibilities (“anything you want” in Peter’s pejorative description) in string theory. But note that QFT can also have anything you want, because it is also a paradigm. But because of the non-perturbative definition available in QFT, model-building was still fruitful.

One problem with not having a non-perturbative definition is that we can solve many problems (including the ones you point out) in string theory individually, but putting them all together becomes a huge challenge. This is the reason why more specific predictions at this stage are perhaps not very meaningful.

To Peter: I was talking about stabilizing (fixing) moduli in a specific vacuum. You are again confusing this with fixing fundamental constants dynamically, and accusing me of being misleading.

Peter also says: “The excuse that “we don’t really understand the true nature of string theory” is getting very old.”

The “excuse”? Should we apologize to you, Peter? 🙂

Some of these problems are truly hard, just wishing otherwise is not a particularly useful strategy for progress. Many smart people have been battling quantum gravity for 50 or so years, and it is not so unreasonable that the problem is genuinely hard. In particular, the “what is string theory?” we ask now is certainly not the same “what is sstring theory?”

37. **Peter Woit**
February 7, 2009

somebody,

Feynman said it well: "String theorists don't make predictions, they make excuses". This has nothing to do with apologizing, it has to do with being willing to admit that an idea doesn't work and move on to something else. In science this happens all the time and requires no apology. Most ideas don't work out.

The reason string theory predicts nothing, and the Standard Model is the most highly predictive physical theory known to man has nothing to do with the different statuses of their non-perturbative formulations. You can in principle write down arbitrarily complicated QFTs, and get, more or less "anything you want". If you did that, no one would take you seriously. Instead, it turns out that a quite simple gauge theory works precisely, on the nose, passing literally thousands of non-trivial experimental tests. In string theory on the other hand, all versions of the theory that are simple enough to analyze don't come even close to looking like physics. Instead, one has to invoke more and more complicated "string theory backgrounds" in order to avoid contradiction with experiment, never actually getting a calculation of anything you can compare to experiment.

"more specific predictions at this stage are perhaps not very meaningful".

You really insist on saying things in the most misleading way possible. More specific than what? Again, string theory predicts absolutely zero about particle physics. The problem is not that it is not specific enough, only giving you rough information about particle physics, it is that it gives you NO information about particle physics at all. Nothing.

38. **somebody**
February 7, 2009

Peter, I will ignore your appeals to authority and vitriolic comments. Lets stay focussed on the science.

Peter: "You can in principle write down arbitrarily complicated QFTs, and get, more or less "anything you want"…. Instead, it turns out that a quite simple gauge theory works precisely, on the nose, passing literally thousands of non-trivial experimental tests. etc."

How do you even call a QFT "simple" if you only had a bunch of rules for writing down messy scattering amplitudes? The non-abelian gauge symmetry of the non-perturbative description is what gives any sense to the statement that the theory is simple because the gauge groups are! "Simplicity" is essentially a meaningless concept when there is no non-perturbative definition (like in string theory, currently). This is one reason why it is worthwhile trying to answer the question "what is string theory?" and come up with a non-perturbative definition.

Peter: "You really insist on saying things in the most misleading way possible. More specific than what? Again, string theory predicts absolutely zero about particle physics. The problem is not that it is not specific enough, only giving you rough information about particle physics, it is that it gives you NO information about particle physics at all. Nothing. "

You are attacking a paradigm for not being a model. As a paradigm, non-abelain gauge invariance, chiral fermions, multiple generations etc. (all in the context of a theory that also includes gravity!) are all to be found in string theory. Your argument is like saying that QFT (as a paradigm) predicts nothing. But standard model, a specific QFT, is indeed predictive. So sttempts to gain model-building powers in string theory are well justified.

Last but not the least, you have a tendency to repeat claims many times hoping that this will turn them into facts. I just wanted to point out that this is not the case. 🙂

39. **Tumbledried**
February 7, 2009

Dear Peter, Somebody,

Many apologies to interject, but I would like to suggest that we suspend for the time being this increasingly vitriolic exchange and focus on some other matters instead.

Dear Somebody,

I am quite interested to hear your opinion as to whether you consider it reasonable, considering the status of string "theory" as a definite work in progress which even the world experts do not have a good intuitive feel for, as to look at other alternatives to string theory.

There are certainly many other models and theories out there that people are working on, and I assume a fair proportion of these may contain valuable insights about the nature of reality. I would be quite interested to hear from you whether it would be worth the time and energy to take a serious look at some of these, even though they are not The One True Theory that has been the focus of tens of thousands of person hours since the late 1970s.

For instance theology and pure philosophy has consumed much more of human time and effort over the centuries than string theory has for the last 30 years. Many extremely brilliant people, far more gifted than you or I, spent time on such things, debating endless metaphysical questions that were doubtless considered most profound at the time. Yet arguably we are no further than we were in such matters since the time of the ancient Greeks.

Dear Peter,

I greatly admire your tenacity in these matters. It is unfortunate, but it seems in these times that sometimes a point needs to be repeated over and over again in order for people to finally understand it.

Best Regards,
Tumbledried

40. **Peter Woit**
February 7, 2009

Thanks Tumbledried,

I confess that I'm infuriated by these arguments claiming that something that predicts nothing is the same as something that predicts just about everything we understand about fundamental physics. Once a science is taken over by people claiming that black is white since they're both kind of like grey it's pretty much all over. It's very sad to see what has happened to particle theory over the last 25 years.

41. **Luca**
February 8, 2009

I am an Italian student of Philosophy at the University of Studies of Milan. Recently I have read the book Not Even Wrong in the Italian translation and I found it very stimulating. In my university there are not many professors that study these themes and when they do it, they seem more worried to talk of old questions of early 20th century, i.e. of the paradigmatic change in physics due to the introduction of quanta. To be honest, I find more interesting the modern physics, because it seems to be in a critical phase, as the book suggests.
Reflecting on these themes, I have reached a personal opinion about the actual problem of theoretical physics. For me the problem is this: which form should a theory of everything have? There are two ways to answer this question: 1) it should be able to predict a lot of new phenomena; 2) it should be able to describe the world for what it is, without justifying it (this is the thesis I support). The problem is if a theory of everything would be scientific in accord with our normal scientific codes. I suspect not. A theory of everything does nothing but say that what it is there is because there must be or there would not be. Probably it seems a play on words, but it is not. A theory of everything, in my opinion, would not be predictive, but descriptive, and it would be a strange sort of theory in which the physical parameters have those values only because if they had not them, our universe would not exist. Hence the anthropic principle is a consequence of these assumptions. From this theoretical point of view, the most coherent string theory would not be a theory that provides us with results, but a theory that describes those results were already found. I personally regard a theory of everything as a natural language. It is only a logical connection of sentences, words and punctuations, and it cannot make predictions. However, in all circumstances (experienced before or completely new), we are able to adapt the language in order to make a detailed description of the situation, even if we have no idea why the situation is the way it is. Our linguistic code provides us with a system that can face every circumstance and also accept new terms in it without this fact implies the collapse of the whole theory (in this case, language). This is probably the form a theory of everything should have: for every new observation there is a way to accommodate the syntax of the theory without compromising the theory itself.
The problem is if this way to proceed is real science or not, and I am really dubious of it.

Kind Regards

Luca Ferrari

42. **somebody**
February 8, 2009

Tumbledried, thanks for providing the necessary distraction and saving Peter from himself. 🙂

I don't have much to say about your comments equating string theory to theology because it is in fact true that for an outsider, the difference is hard to tell. All the elaborate formalism just seems like pointless crap. To see that there is indeed direction (and a very clear one) you need a bit of expertise, I am afraid.

But, your comments regarding alterantives, I can make a few comments. I think there is a widespread misconception that there are many ignored alternatives. I think that most good string theorists would be eager to look into alternatives IF it had even *some* of the good features of a fundamental theory. But most people don't seem to realize how difficult it is to come up with even a mildly promising alternative. It is not like there are tons of alternatives out there and theorists are ignoring them. Quantum gravity is a difficult problem and despite half a century of work, there are only very few ideas which are not stillborn. The self-interest of theorists motivates them to consider new promising ideas very seriously. I don't even know one promising alternative idea out there which is not getting the attention it deserves. Another interesting fact is that almost all the ideas that seemed promising, seem to arise naturally in string theory. Supergravity, kaluza-klein theories, etc. were separate ideas initially, but they arise automatically in string theory.

43. **Shantanu**
February 8, 2009

Somebody, many people whom I know who used to work on string theory
have left string theory and switched to astrophysics, gravitational waves, LQG for precisely the same reasons Peter is talking about.

44. **Tumbledried**
February 8, 2009

Dear Peter,

You are most welcome.

Dear Somebody,

Thanks for your polite and considered response. I must admit that I was perhaps being a bit too honest with you, but you are quite correct, I am an outsider, or at least not a string theorist.

I am reassured by your response that, at least the part of the stringy community you frequent, are quite open to new ideas, providing that they are reasonably promising. This seems acceptable to me. It is of course disheartening to hear that there do not appear to be any promising alternative directions to string at the moment. Nonetheless I remain optimistic that the open problem of further unification is not impossible and some bright academic may find some different way of approaching it.

Best Regards,
Tumbledried

45. **klaus**
February 9, 2009

shantanu: people say a lot of things about why they leave a subject, partly to protect their own egos. most people I know, who left string theory, left it because the job market is brutal, and not because they got fascinated by something else. i am sure there are some people who do it because of the reasons you suggest, but the overwhelming majority that i have had first hand experience with, do not belong to that category, and leave because staying on is tough.

46. **chris**
February 10, 2009

dear somebody,

the argument of paradigm vs. model you invoke is rather interesting. however, there is one small but in my opinion rather essential point that you are missing in your comparison to early quantum field theory. you say:
"How do you even call a QFT "simple" if you only had a bunch of rules for writing down messy scattering amplitudes?"
which is partly true (because scattering amplitudes display the same sorts of symmetries just in a more hidden way) but not quite captures what early (<1970) qft looked like. keep in mind, that in qft the lagrangean was there right in the beginning. and step by step people came to grasp with how to evaluate path integrals with it. that's the story. and if you look at paradigms: there were a few. s-matrix theory, bootstrap, hadronic strings… all of them failed. advancement came about through better methods to do the path integral and that was it.

judging string theory is not up to me – future generations of experimentalists will certainly do that – but i am sceptic towards claims of paradigm shift without the paradigm fully visible. it leaves the same taste in my mouth than forward references like ‘we will show this in one of our next publications’. my gut feeling is that anounced revolutions rarely happen.

47. **Daniel de França MTd2**
February 13, 2009

This is certainly offtopic, but worth posting.

http://www.youtube.com/watch?v=MyVyDUdzvMY&feature=channel

This is a video of Levni Yilmaz talking about his private life with his father in a very creative bud sad and nostalgic way.

He is one of Yilmaz sons(that guy of the theory of gravitaion). He is a huge hit on Youtube with several million of visits, and talks about thing of daily life, no science.

48. **somebody**
February 14, 2009

Chris, I was busy and didn’t see your comment. Anyway, the point was not how history unfolded in the case of quantum field theory. The point was that the simplicity of a theory is not necessarily visible when you look at scattering amplitudes. A Lagrangian type description is where that is manifest, which we do not have yet in string theory.

Also I am using the word “paradigm” as just another word for “framework”. One of my suspicions about string theory is NOT that it is too much of a paradigm shift, but that it is probably not enough of one.

Finally, wanting a non-perturbative definition is not the advertisement for a coming revolution, it is the statement of an actual open problem.

49. **chris**
February 17, 2009

dear somebody,

thanks for your reply and clarifications. what you say sounds very reasonable to me.

Chamonix For You

February 6, 2009
Categories: Experimental HEP News

The 2009 Chamonix workshop on the commissioning of the LHC has just finished, ending with a message from the Director General, and the opening to the public of the web-site with slides from the meeting (bearing the warning "The Chamonix workshop was an open exchange of views and opinions. All the presentations made at the workshop are available here. The views expressed in individual presentations do not necessarily represent those of the CERN management.")

Here's the press release and message from Rolf Heuer:

> Many issues were tackled in Chamonix this week, and important recommendations made. Under a proposal submitted to CERN management, we will have physics data in late 2009, and there is a strong recommendation to run the LHC through the winter and on to autumn 2010 until we have substantial quantities of data for the experiments. With this change to the schedule, our goal for the LHC's first running period is an integrated luminosity of more than 200 pb-1 operating at 5 TeV per beam, sufficient for the first new physics measurements to be made. This, I believe, is the best possible scenario for the LHC and for particle physics.
>
> There were discussions in Chamonix between accelerator and detector physicists on several important issues. Agreements were reached whereby teams drawing from both communities will work together on important subjects, such as the detailed analysis of measurements made during testing of magnets on the surface.
>
> Since the incident, enormous progress has been made in developing techniques to detect any small anomaly. These will be used in order to get a complete picture of the resistance in the splices of all magnets installed in the machine. This will allow improved early warning of any additional suspicious splices during operation. The early warning systems will be in place and fully tested before restarting the LHC.
>
> Another important topic for the future was the radiation hardness of electronics installed in the service areas and the tunnel. For many years, particle detector electronics have been designed to cope with events such as loss of beam into the detectors. Until now, this has not been necessary for the accelerators, but will become so when the LHC moves to higher beam intensity and luminosity. Again, with detector and accelerator physicists working closely together, the experience gained from the detectors can be applied to the LHC itself.
>
> As the Bulletin reported on 30 January, opening up a magnet in which an anomalously high electrical resistance was measured made the reason for the anomaly immediately obvious – a splice had not been correctly made. This is one of two such splices that were identified in the five sectors tested, and as a result the magnet containing the second will also be removed from the tunnel for repair. Since resistance tests can only be conducted in cold magnets, three sectors remain to be tested: sector 3-4 where the original incident occurred and the sectors on either side. Within sector 3-4, the 53 magnets that are being replaced in the tunnel will all be tested before cool down, and the sectors either side will be cooled down early enough to intervene if necessary with no impact on the schedule. This leaves around 100 dipole magnets that we'll not be able to test until September and a correspondingly small chance that we may find further bad splices that will need to be repaired before operation.
>
> The Chamonix workshop involved a lot of work by many people. Much progress has been made, and the management now has all it needs to make an informed decision next Monday on LHC restart. I'd like to thank all those involved, and I will be writing to you again early next week to let you know our decision.

Looking at a few of the slides, it seems that the schedule for work this year has slipped, with the current plan that the machine will be cold in August, checkout in September, with powering tests in Sector 34 taking place in parallel with the checkout, which will end the third week of September. Beam commissioning will not be able to start until then, and the assumption has been that it would take two months to commission the beam and begin collisions for physics. If first collisions are not until late November, it's clear why they want to run over the winter. The main consideration evidently is cost, they will have to come up with 8 Million Euros more for more expensive power.

This assumes not all sectors are warmed up. Warming them all up to install the quench protection they would like would add another 5 weeks to the schedule.

Update: CERN has a press release today confirming the new schedule:

> The new schedule foresees first beams in the LHC at the end of September this year, with collisions following in late October. A short technical stop has also been foreseen over the Christmas period. The LHC will then run through to autumn next year, ensuring that the experiments have adequate data to carry out their first new physics analyses and have results to announce in 2010. The new schedule also permits the possible collisions of lead ions in 2010.

The decision was made to go ahead while installing additional relief valves in the four sectors that have been warmed up, leaving installation in the four remaining sectors for next year.

Update: There was a talk today at CERN by Lyn Evans on LHC status and future plans. The current plan for upgrading the LHC luminosity involves a "Phase I" in 2013 that would double the luminosity, and an upgrade of the accelerator complex that would be completed in 2017 and allow further luminosity increases.

Comments

1. **zzz**
   February 6, 2009

   With the economic recession, factories running at lower capacity, you would think electricity would be cheaper this year.

2. **Ari Heikkinen**
   February 10, 2009

   So they have no results, it's not even running and they've not even proven the machine even works and they're already talking about upgrades? I guess that's one way to secure tax money..

3. **Peter Woit**
   February 10, 2009

   Ari,

   The lead time to design and build this kind of upgrade is very long, so you need to do this in parallel if you want the upgrade to happen in the next decade. I'm sure the great majority of people's time and money is now going into getting the LHC to work, with the upgrade on the back burner and going nowhere unless the LHC project itself is successful.

4. **DB**
   February 11, 2009

   I just looked at the "Maximum Credible Incidents" and "Worst case beam incidents and protection" presentations, neither of which seemed to offer much reassurance against repeats of the September incident or possibly worse events.
   But at least the discussions are out in the open.

5. **Mikael**
   February 13, 2009

   Find here a direct link to the video of Lyn's talk:
   http://cdsweb.cern.ch/record/1160614/

6. **Steven Colyer**
   February 15, 2009

   Speaking as an engineer with 30 years of "real-world" understanding of Applied Experimental Physics and NOT asking for forgiveness regarding my skepticism, I can forsee a tremendous amount of setbacks for the LHC coming on-line before 2009, maybe 2010 and 2011 is more realistic, AND they will not like the results they get when so, when Supersymmetry and the Higgs Boson are found NOT to exist.

   I will not engage in speculation and rumor that there is a massive cover-up that they did indeed ran an experiment to conclusively prove the Higgs exists, but it failed, and this is all a massive cover-up. Conspiracy theory is not my thing; this set-back was a real one IMO. A machine as large as the LHC is going to have massive problems, this latest setback will be far from the last one, I'm afraid.

   Speaking as a lover of Science and Physics, it amazes me that Physicists have allowed Mathematicians (string Theorists) to take over their field, save for the good work by Woit, Smolin, et al., congrats gentlemen, people are listening. The analogy I like to make is you don't call a Mechanic a Wrench or a Screwdriver, those are the tools he (or she) uses.

   Time is NOT a 4th dimension of space, it is its own thing. Treating it mathematically as a 4th dimension does help though.

   I do not believe Gravity is a force either, so I do not believe in the Graviton. However treating Gravity AS a force (and therefore the theoretical graviton) does make the equations work out nicely.

   Gravity is a unification of matter and geometry. Einstein showed us the HOW of Gravity in General Relativity; you good people are working on the WHY. And in that regard, there is a heck of a lot more work being done at Waterloo's Perimeter Institute and other places than in America, which is sad. Check out "Quantum Graphity" and "Causal Dynamical Triangulations" where the most sense IMO is being done, not Strings.

   I DO believe in Quantum Mechanics as well as the Standard Model. QM may be strange but it needs to be explained better. Begin with Uncertainty, which makes all the sense in the world if you consider the Electron (and everything else) to be a "particle" in the sense that it's a bundled up wave, nothing more. Treating the Electron as a 0-dimensional "point" particle may make the equations work out nicely, but they're not real. All I ask is: Get Real.

   We and the Universe are basically 5 things: Up quarks, down quarks, gluons, photons, and electrons. Good luck figuring out how they came to be … well that's you job, isn't it? And my and the public's primary interest.

Money For Everything

February 12, 2009
Categories: Uncategorized

It now appears that the final US stimulus bill will include very large amounts of spending on scientific research. See here for a copy of the conference agreement. It has \$3 billion for the NSF, \$1.6 billion for the DOE office of science, and \$1 billion for NASA. These amounts are to be spent on top of the regular budgets (about \$6 billion for NSF, about \$1.6 billion for DOE office of science, as well as $400 million for ARPA-E, and \$17 billion for NASA). Basically, the government agencies responsible for funding math and physics research are receiving a one-time influx of money, of order half their annual budget, to be spent as quickly as possible. It will be very interesting to see what they do with it…

Update: More here.

Comments

1. **Ryan Dickherber**
   February 12, 2009

   First it was billions, then it was zero, now it is billions again. The bill has still not actually passed. Dare we be excited yet?

2. **Peter Woit**
   February 12, 2009

   Ryan,

   It wasn't ever zero, although the Senate version had much less in it for science than the House version. Whatever comes out of the House-Senate conference will be the final bill, and should pass. The document linked to and information released by Pelosi's office claims these are the numbers in the conference version, but the bill has not been completely finalized. So it remains possible that things will change, but it looks most likely now that this is what is going to pass.

3. **Yatima**
   February 12, 2009

   Yeah well, the first thing to do is transform the cash into something other than USD in order to have a safe stash when inflation decides to go hyper. Otherwise, excellent news.

4. **Alp**
   February 12, 2009

   Maybe someone should distribute this money to researchers as "bonus" before most of them leave to become quants.

5. **drunk**
   February 13, 2009

   Just because they put a budget together does not automatically mean there is money. US federal gov is already in technical bankruptcy, deep in deficit and debt. Even the interests must be borrowed. Every cent of this budget must be borrowed, or printed out of thin air. Or taxed. Are they going to tax people another $1T? Are there any more foreigners stupid enough to loan the US gov one more dollar after being screwed big time by Wall Street and see their own economies crashed by the spread of the US the financial crisis globally? So the Federal Reserve is going to print another $1T, after printing $2T last year, thus inflate the economy and reduce the worth of all USD by the same amount. This budget is a lot of smoke folks.

6. **Coin**
   February 13, 2009

   Ryan: The House has passed the conference version. The Senate votes at 5:30 eastern time.

7. **Peter Woit**
   February 13, 2009

   All,

   There are a thousand places on the internet now full of people having the same unenlightening discussions about economics. Please don't do the same thing here. If it's not specifically about math/physics, it doesn't belong here.

8. **Coin**
   February 13, 2009

   So, I am incredibly relieved to see that this funding made it back into the final bill. I wonder, though: It seems like I've been repeatedly told that between funding tricks, "continuing resolutions" and failure to correct for inflation, the budgets for these science funding agencies have been basically effectively falling for years. So we give them a 50% one time boost from their *current* budget– where does that put them in relation to the budget they really ought to have if science budgets hadn't been getting shafted lately?

   Something I find interesting, from that link it looks like the NIH gets nearly 2/3 of the additional science funding, like ten billion dollars altogether. Is this interesting or does it just reflect that the NIH has a larger grant budget to begin with?

9. **Peter Woit**
   February 13, 2009

   Coin,

   It's just not accurate to say that science funding has been falling for years. For the NSF, take a look at

   http://www.aaas.org/spp/rd/nsfauth09p.pdf

Ignore the 2009 data point, which corresponds to an increase for physics that didn't happen,

Total math + physics NSF funding has been basically flat (in constant dollars) for many years. From what I remember math has seen some increases, HEP has decreased in constant dollars. The problems of HEP are somewhat specific to the field, not indicative of the overall science-funding pattern.

The NIH is much bigger than the NSF, spending about $30 billion on medical research vs. the NSF $6 billion. This is not surprising. Voters are much more interested in figuring out how to avoid a painful death from disease than in understanding the origin of electroweak symmetry breaking.

10. **chickenbreeder**
February 14, 2009

The money distributed through the stimulus bill has to be spent within 120 days (the point being to give the economy a jolt.) This means it will not benefit people who are just about to submit a proposal to NSF. The money will likely be used to fund proposals that have already been reviewed and deemed "fundable if funds are available". If you have one of those in the hands of your NSF program manager this may indeed be a god-sent. Otherwise, it's not that useful. I believe this is also the situation with other basic research programs at NASA, DOE, etc.

11. **grant pending**
February 14, 2009

chickenbreeder, where did you see that, and how exactly does it (120 day time limit) apply to NSF?

12. **grant pending**
February 14, 2009

Okay I found one, though it's a month old, and may not be up to date.

http://www.technologyreview.com/blog/editors/22510/

13. **Steven Colyer**
February 15, 2009

How much of the $$$ do you think will be pumped into even stronger battle-ready infra-red lasers at Sandia or DARPA, not that any of us will ever know of it?

14. **mike**
February 15, 2009

So it doesn't seem to be mentioned here, but is there some consensus that the money to DOE and NSF will then stimulate QFT or mathematical physics research? Will string theory be revived from this (similar to how an infusion of steam causes bacteria to grow faster)?

15. **Peter Woit**
February 15, 2009

mike,

I don't think anyone knows yet how DOE and NSF plan to spend the money. I've heard speculation that one thing that may happen is that they'll be funding a higher proportion of grants, i.e. grants that would have not quite made the cut under the regular budget now will be funded. If this is true, all subfields will see more grants, but this shouldn't change the relative distribution of resources among different topics.

So, one guess would be that the stimulus package will mean more postdocs (which are funded by grants) in all subfields, including string theory. Tenure-track jobs may be a different story, since they are typically funded by university budgets, not grant money. I don't see any reason for the recent trend of physics departments wanting phenomenologists and cosmologists rather than string theorists and mathematical physicists to change.

16. **hungry for updates**
February 28, 2009

(bump)
News? Rumors? Anything?

17. **Peter Woit**
February 28, 2009

A more recent posting gives the FY2009 numbers that have just been decided on, and the overall FY2010 number proposed for NSF.

Basically NSF and DOE now have a lot more money to spend than usual. As far as I can tell, they still haven't decided what to do with it. The job situation is bad, so I hope they figure out how to fund some positions for young people for the next academic year.

The Landscape for Undergraduates

February 14, 2009
Categories: Multiverse Mania

I was in a local Barnes and Noble today, and noticed that there's a new, second edition out of Barton Zwiebach's A First Course in String Theory, which is the textbook for MIT's course 8.251 String Theory for Undergraduates. The new addition includes a 10 page section explaining the details of how to compute numbers of vacua in the landscape based on flux compactifications, and arguing that this provides an explanation of the value of the cosmological constant. Landscape ideology has now made it to the undergraduate level.

However, this only seems to be the case at MIT. A couple years ago I wrote about undergraduate string theory courses here, noting that there was an increasing trend to offer them, with MIT, Caltech, Stanford and Carnegie-Mellon providing examples. Recently this seems to have turned around, with Caltech, Stanford and Carnegie-Mellon not offering such a course this year. Somehow I don't thinking adding coverage of the landscape to the textbook is going to encourage physics departments to teach this material to undergraduates.

   Are there any published reviews for this book? Also how was Vafa's
   colloquium?

2. **Joseph B.**
   February 15, 2009

   Hi PW, I feel obliged to mention that at least one of those undergrad string theory courses that you mentioned 2.5 years ago was meant to be an `experiment' in whether or not such a string theory course is feasible.

   It was initiated by undergraduates who were excited by Zwiebach's book and ended up being pushed through despite the reservations of some of the hep-th faculty. Ultimately the course evolved into a de-facto string-theory-for-grad-students (i.e. a proper string course) taught out of Polchinski and the experiment as an undergrad course was generally deemed a failure. I believe the department hasn't bothered removing the course title from their catalog, even though the course has not been offered since.

   So to be fair to [at least one of] the physics departments you mentioned, it's not necessarily that the departments thought "Hey, let's teach our undergrads watered-down-strings," but rather that there was a lot of student interest and the department was willing to give it a try. In fact, the biggest proponents from the faculty were non-theorists who were working with undergrads to explore possible innovations to the undergrad curriculum.

   I just wanted to explain that the offering of such a course in the past should not [necessarily] be interpreted as representative of some deeper ideological agenda so as not to give the wrong impression of my old department… especially when it was largely an experiment initiated by naive (but enthusiastic) undergrads rather than the powers-that-be.

   February 15, 2009

   Shantanu,

   This was the first I had heard of the second edition. One review of the first edition was in the September 2005 Physics Today.

   Vafa's colloquium talk made a lot of dramatic claims, including putting up a detailed spectrum of what supersymmetric particles the LHC should see at what masses. But since it was a colloquium talk he gave few details, and nothing at all about the crucial question of how supersymmetry gets broken. It gave me a better idea of the general philosophy of what he is trying to do. They're assuming particle physics and quantum gravity are decoupled, giving up on the idea that the properties of which compactification Calabi-Yau you choose have any effect below the Planck scale. Particle physics then comes from the choice of various branes, and I guess his claim would be that the consistent possible choices of branes give some testable predictions. The lack of detail in the talk made it hard to tell to what extent this is true. I took a look at one of his papers that features the particle spectrum he showed. There seemed to be a lot of assumptions going into that plot that were not mentioned in the colloquium talk.

   Joseph B.,

   Thanks for the explanation. It has been my experience over the years that much of the enthusiasm for string theory comes from students and non-theorists whose knowledge of the subject comes from the large number of popular books, articles, TV programs, colloquium talks, etc. about string theory that hype the subject and give a misleading impression about it. Maybe someone should write a book trying to correct that and provide a more accurate description of what is really going on with the subject…

4. **Robert**
   February 15, 2009

   Thanks for informing about the second edition of this nice and usefull book.
   Yes, the landscape is mentioned, as of course it should in a book about strings, but the main change in the more than 100 additional pages seems to be contained in three new chapters about

   A look at relativistic superstrings

   String theory and particle physics

   Strong interactions and AdS/CFT

   Great that this accessible text is prevented from outdating so soon in this rapidly moving field.

5. **capitalistimperialistpig**

February 15, 2009

I'm an old physicist with no expertise in particles, gravity, or strings and I read Zwiebach I with great enthusiasm. It's development is exceptionally clear, too slow for theorists I imagine, but just right for me. There are lots of accessible (OK, easy) problems. By contrast, I found Polchinski rather impenetrable – it assumed too much that I had either forgotten or never knew. I think it's a great book for someone like me who has no designs on being a string theorist but would just like to understand some of the concepts beyond the popular level.

Its singular feature is that you don't need a sophisticated knowledge, or indeed any knowledge, of QFT – and if you don't have that you will learn a little QFT in reading it.

I'm sure its not a course for every undergrad, but it might be a worthwhile option for those who can't wait to learn QFT and GR first.

6. **woit**
February 15, 2009

CIP,

The book seemed to me a good place to start for someone trying to learn how to quantize a string (except for the part about how to get particle physics out of string theory, which is fundamentally misleading: why go on like that about an idea that doesn't work in a textbook aimed at impressionable undergraduates?).

My problem is not with the book, but with the idea that a course based on it makes any sense as part of a regular undergraduate curriculum. Seems to me that students should be encouraged to learn QFT and GR first. There's a long list of complicated speculative ideas that haven't worked out very well that don't belong in an undergraduate curriculum no matter how fond some theorists are of them or how much publicity they have gotten. By putting a subject in in the undergraduate curriculum, we implicitly say to students that this is a solid and important part of our field. There's nothing in the Zwiebach book that would make clear to a student that this is material of a completely different nature than what they are getting in the rest of of their courses.

7. **somebody**
February 15, 2009

Peter, we are talking about ambitious, smart undergraduate physicists who are eager to see whats up at the frontier. Do you seriously think that these kids don't have the cojones to see the pros and cons of string theory at the superficial level that it is discussed on this blog?

"Indoctrination of the youth" works a lot better at an even lower level. Who watches out for the far less prepared readers of your blog (or Kaku's books for that matter), who have to take your word (which I am sorry to say, is often misleading)?

8. **woit**
February 15, 2009

somebody,

Well, undergrads with adequately-sized cojones can read the many sources of string theory hype and this blog, then make up their own minds. From what I've seen they're doing that, and making a different judgment than you about who is being misleading. Women students are doing this too, same result…

9. **capitalistimperialistpig**
February 15, 2009

Peter,

I don't actually disagree, nor do I necessarily recommend it to undergrads, though come to think of it, I did recommend the course to my then undergrad son, who took it. So far as I can tell, it didn't do him any more damage than the rest of the physics curriculum – at least he didn't become a string theorist.

10. **somebody**
February 15, 2009

Peter, the point was that you started out implying that the students are being taken for a ride by this course. Now you agree with me that they are perfectly capable of making up their own minds about this.

I have no further comments if you are not going to change your mind again. 🙂

11. **woit**
February 15, 2009

somebody,

We've only agreed about the large-cojoned and female undergrads, there still are the ones with small cojones to be concerned about…

12. **Coin**
February 16, 2009

Joseph B.: Out of curiosity, would it be particularly unusual for a motivated undergrad to simply enroll in a grad-level string theory course?

(In CS at least it seems to be considered no big deal for a fourth-year undergrad to take a low-level grad course, but I don't know how things work in physics departments…)

13. **CWJ**
February 17, 2009

"Seems to me that students should be encouraged to learn QFT and GR first."

They are–at least, when I was graduate advisor in my physics department, and the current grad advisor deploys the same advice–but they don't want to hear this. Especially the ambitious but less talented ones. The smarter students are much more flexible and more willing to listen to good advice, I find.

Too Many Topics

February 15, 2009
Categories: Uncategorized

Last Friday at the KITP there was a celebration of Stanley Mandelstam's 80th birthday, with talks available here, and some messages from other physicists here. Geoffrey Chew recalls how Berkeley hired Mandelstam away from Columbia, where no one was very interested in what he was doing, in 1958. The next year the same thing happened with Steven Weinberg…

Recently I've noticed two books on a narrow topic not of general interest, but perhaps of interest to readers of this blog: histories of US math departments. They are:

- Recountings: Conversations with MIT Mathematicians, about MIT.
- Mathematics at Berkeley, about Berkeley.

Perhaps of even more esoteric interest, later this year Princeton University Press will publish Mathematicians: An outer view of the inner world, a book of photographs of mathematicians by Mariana Cook. Some of the photographs are available at her web-site here.

Via Ars Mathematica: Fulton's Algebraic Curves is available for free online. It's a good place to start if you're looking for a challenging introduction to algebraic geometry at the (quite) advanced undergraduate level.

Some wonderful expository pieces about areas of mathematics:

- Ben Webster on higher categories and knot homology.
- Vaughn Jones on operator algebras and TQFT.
- Cliff Taubes on Seiberg-Witten Floer homology, in a review of the recent book by Kronheimer and Mrowka.

The AMS Notices has an article about the current state of every mathematician's favorite tool: TeX.

Les Houches this year will have a summer school devoted to lattice gauge theory.

For the latest on the question of whether the Tevatron will manage to see the Higgs or rule it out, see excellent postings by Tommaso Dorigo here and here. The bottom line is that by the time the LHC has enough data to start saying something about the Higgs, the Tevatron experiments will have over $10fb^{-1}$ of data to analyze, which may, if improvements in their analysis work out, give them a two-thirds chance of seeing the Higgs at 2 sigma level over the entire expected mass range, or a 50/50 chance of seeing it at 3 sigma level over a large range, including a small range just above the 114Gev LEP limit. The Tevatron may remain very competitive with the LHC for some signals far longer than people have been expecting. And, at least for the next 18 months, the US stimulus legislation may make Fermilab better funded than CERN for a change…

I fear I've been remiss about not reporting on the IHES Grothendieck conference that I attended a couple days of when I was in Paris last month. Luckily, there's a new blog here with a report.

Protests and strikes in France over Sarkozy's attacks on the French scientific research system continue, see an English language report here. Some people may have misunderstood my previous mention of this. While it's not a topic I'm well-informed about, Sarkozy's argument in favor of moving to something supposedly more American, featuring a market-based, no central government regulation ideology has an obvious problem if you've been reading the newspapers.

Update: Video of the IHES Grothendieck talks is available here.

   February 16, 2009

   « Fulton's Algebraic Curves is available for free on-line.»

   It's been on-line for quite some months now.

   «It's a good place to start if you're looking for a challenging introduction to algebraic geometry at the (quite) advanced undergraduate level.»

   Is this really advanced undergraduate? Is it a good place for someone interested into Physics to learn AG from?

   It thing Griffith & Harris is probably more suited for a physicist due to it being more intuitive.

   Does anyone have suggestions of good AG introductions for physicists?

2. **Aaron Bergman**
   February 16, 2009

   I think G&H is probably the way to go. It stays away from the Zariski topology which I generally think is a distraction for physics applications.

3. **Peter Woit**
   February 16, 2009

   Manel,

   It's not really an appropriate book for physicists. You have to realize that a large part of algebraic geometry is commutative algebra, since mathematicians want to do geometry over different fields. not just over the complex numbers. Fulton does the algebraic part of the story seriously, but to follow this you need to have at a minimum a serious course in abstract algebra, which physicists normally don't.

   Physicists generally are only interested in geometry over the real and complex fields, and often general manifolds, not algebraic varieties. For them, Griffiths and Harris is good, since it approaches algebraic geometry from the point of view of complex manifolds. For something at a more undergraduate level, sticking to complex manifolds, but more along the lines of algebraic geometry, you could try Frances Kirwan's "Complex Algebraic Curves".

Another way to explain the difference in point of view is that, for one complex dimensional spaces, physicists mostly want arbitrary Riemann surfaces, but algebraic geometers are mostly interested in algebraic curves. There's a big overlap of the two subjects, but physicists rarely care about the algebraic part of it, whereas for mathematicians this is a crucial part of the subject.

   February 17, 2009

   milkshake: That is… odd. Especially given that CERN actually still has up on their website a fun but somewhat testy document talking about all the inaccuracies in the Angels and Demons book…

Mission Accomplished

February 18, 2009
Categories: This Week's Hype

A few years ago the asset value of string theory in the market-place of ideas started to take a tumble due to the increasingly obvious failure of the idea of unifying physics with a 10/11 dimensional string/M-theory. Since then a few string theorists and their supporters have decided to fight back with an effort to regain market-share by misleading the public about what has happened. Because the nature of this failure is sometimes summarized as “string theory makes no experimental predictions”, the tactic often used is to claim that “string theory DOES make predictions”, while neglecting to explain that this claim has nothing to do with string theory unification.

A favorite way to do this is to invoke recent attempts to use conjectural string/gauge dualities to provide an approximate calculational method for some strongly coupled quantum systems. There are active on-going research programs to try and see if such calculational methods are useful in the case of heavy-ion collisions and various condensed-matter systems. In the heavy-ion case, we believe we know the underlying theory (QCD), so any contact between such calculations and experiment is a test not of the theory, but of the calculational method. For the condensed matter systems, what is being tested is the combination of the strongly-coupled model and the calculational method. None of this has anything to do with testing the idea that string theory provides a fundamental unified theory.

The yearly AAAS meeting is the largest gathering where scientists present results to the press and try and draw attention to recent scientific advances. This year’s meeting was held over the past weekend and featured a program Quest for the Perfect Liquid: Connecting Heavy Ions, String Theory, and Cold Atoms. While the presentations were largely a serious attempt to explain this area of research to the public, the fact that this has nothing to do with string theory unification somehow doesn’t seem to have been mentioned, with the result one would expect. The program was reported on under the headline A first: String theory predicts an experimental result, with the story beginning:

> One of the biggest criticisms of string theory is that its predictions can’t be tested experimentally–a requirement for any solid scientific idea.
>
> That’s not true anymore.

Another report entitled A prediction from string theory? at Physics World starts off:

> Skeptics find much to complain about in string theory, but perhaps their most stinging criticism has been its inability to be falsified by experiment. A few years ago, one string theorist even told me that a particle accelerator big enough to “see” a string would be so large that its opposite ends would be causally disconnected. So this is not a problem we’ll be solving any time soon.
>
> Yet even if we’ll never see a string in the lab, it turns out that string theory does make a few predictions about how matter should behave at the quantum level…

The dramatic news that claims that string theory can’t be tested have been refuted was then spread widely by Digg, so much so that the Symmetry Magazine site featuring the story crashed. The discussion on Digg showed what got through to the public from the efforts of the scientists involved:

> Without a testable hypothesis it was only a String MODEL. Now we truly have a String Theory.
>
> Michio Kaku just had an orgasm.
>
> Brian Greene’s next book will be titled “Told You So Bitches!”

The one string theorist involved in all this was Clifford Johnson, who gives a minute-by-minute description of his participation here. It ends by invoking the phrase made famous by the last US president:

> Mission accomplished. (Hurrah!)

Update: There a better story on this at Ars Technica, which avoids the misleading “test of string theory” claim.

Update: Another story about this is Experimenting With String Theory?, where the author for some reason also missed the fact that this has nothing to do with unification, writing:

> So there you have it: finally, a potential concrete way to experiment with the predictions of string theory. But I’ll let the expert say that:
>
> “This is the first time string theory can help experiments,” Johnson said. “We haven’t proven string theory, but have found a place where string theory has been a modest guide and making testable predictions.”

Another string theorist has a long blog entry about this here, where the punch-line is:

> And it is just manifestly wrong to say that the lab tests of the predictions of AdS/QCD or AdS/CMT have nothing to do with string theory’s being the unifying theory of gravity and other forces and matter, or a theory of everything, if you wish. They have everything to do with it.

Update: Chad Orzel has sensible things to say about this here, in the context of a more general debate about the role of science journalists. In the comment section Moshe Rozali’s comment I suspect reflects the feelings of most string theorists about this:

> As for the specifics of your example, I would comment on it, but I decided to go and extract my own wisdom tooth instead. I think that would be much more fun.

Comments

1. **Stephen**
   February 18, 2009

   I know a few condensed matter theorists that are very interested in dualities, and a friend of mine is doing his thesis work technically in string theory, but in trying to work out a QCD dual (his five word summary, it’s obviously much more involved). In a sense, the ability to probe strongly coupled systems using ideas from string theory is a big step, since prior to the advent of duality, from the best of my studying, it was mostly ad hoc attempts to tackle the limit. It’s also opened up a lot of avenues of intellectual thought, and brought a lot of nice connections with mathematics.

   That said, their PR ranges from mumbles of confession that it’s probably not good for anything to downright intellectually dishonest claims to predictions that are a consequence of a formalism more than for a unified theory.

2. **A.J.**

February 18, 2009

Peter,

Clifford said explicitly that what he's doing doesn't constitute a test of string theory. First linked article, 5th & 6th paragraph. "string theory testable?" is a hook introduced by the science journalist. It's a sleazy rhetorical tactic, but that's show business for you. I don't see this is any worse than suggesting that honest research like AdS/QCD is just a PR tactic carried out on behalf of some unnamed "string theorists and their supporters."

3. **Peter Woit**
February 18, 2009

A.J.,

I in no way suggested that "AdS/QCD is just a PR tactic carried out on behalf of some unnamed "string theorists and their supporters"" and I really resent that accusation. You know very well that's not what I think and that's not what I've ever written. I've no problem with work on AdS/QCD. Some of it's very good, some of it's over-hyped, like any other scientific field. But I am critical of people who go to the press promoting this work in a way that they know full well is misleading. If you've spent twenty-five years going to the press promoting a speculative idea about string theory as a fundamental theory, when you go to them about a completely different use of string theory it's part of your job to explain that they're different things. The quote from Clifford that you mention doesn't do that.

The first story I linked to has a note from the author that explicitly thanks Clifford for helping her fix inaccuracies in the original version of the piece that she posted. If he had a problem with the whole "finally string theorists find a way to test their theory, despite what critics say" story line, he could have had that inaccuracy fixed.

Look, the many bogus stories about "tests of string theory" that have appeared in recent years are not innocent mistakes caused by journalists who, despite the best efforts of string theorists, are so stupid they can't understand what they are told, and so pig-headed that they insist on putting misleading headlines and lead paragraphs on their stories.

4. **A.J.**
February 18, 2009

Hi Peter,

Sorry for the bombast. I hope you're not too offended. I was rather annoyed by the blunt contradiction between the quotes from Clifford and your claim that string theorists weren't making it clear that use of string theory in heavy ion physics is not related to any uses string theory might have in very smale scale physics.

I think we'll have to agree to disagree about the degree to which string theorists are to blame for the misleading headlines. I should clarify my position a little though: I don't think these are innocent mistakes on the part of the journalist. I don't think the journalists are that dumb. I _do_, however, think that journalists write these sorts of headlines, knowing that they're misleading, because the hype sells the article. "Aspects of string theory useful in heavy ion physics" just isn't going to attract as many diggs.

5. **Peter Woit**
February 18, 2009

A.J.,

Sorry, my reading of the two paragraphs you point to is rather the opposite. Acknowledging that this work does not prove string theory unification isn't the point. Instead of just stating that the research under discussion has nothing to do with the string theory unification, Clifford is claiming that it does (using the logic: "we don't understand string theory, maybe comparing AdS/CFT-motivated approximations to experimental results in heavy-ion physics will help us understand string theory, and once we understand string theory, we'll see how to do string theory unification"), He's welcome to that bit of wishful thinking, but when he uses it on non-experts in the way quoted, it's not at all surprising that what they take away is the message that string theory unification is moving forward due to this first connection between string theory and experiment.

One thing about having a blog is that if something you have to say gets seriously misinterpreted, you can correct the record. We'll see if that's what Clifford chooses to do.

6. **somebody**
February 19, 2009

As a one-liner, "RHIC might test string theory" is okay I think. But it certainly comes with the caveat that it is not a test of string theory *in the context of unification*.

But your version " … the research under discussion has nothing to do with the string theory unification…", is wrong-er in the other direction. When you say that string theory is merely a "calculational method" for heavy ions, you are profoundly misrepresenting the problem. Nobody knows how to get the stringy "method" starting only with the field theory. The string theory used here is the same one that originated from attempts at unification, applied in a different context, through Maldacena's gauge-gravity duality. You are essentially saying that gauge-gravity duality is merely a computational tool.

As I have said repeatedly, you adamantly refuse to recognize the UNDERSTANDING we have gleamed through string theory, while knocking it for the lack of experiments. At RHIC, what people are trying is precisely to put this understanding to work and actually get some low energy experiments out. This is another example where thinking about the (experimentally inaccessible) Planck scale, opens up new understanding about *low energy physics* and makes previously unanticipated experimental tests a possibility. Indirectly this could give us confidence in our ideas about the Planck scale.

Finally, try not to be so negative. In your hurry to attack string theory, you seem to have lost sight of how amazing this RHIC/ALICE thing actually is. 🙂

7. **Gil Kalai**
February 19, 2009

"…any contact between such calculations and experiment is a test not of the theory, but of the calculational method."

This is not entirely true. Successful applications of ST calculations in other areas can be regarded as a (weak) support for the theory itself. The boundaries between "calculational methods" and "conceptual understanding" are often not clear cut.

8. **Peter Woit**
February 19, 2009

somebody,

I regularly report on the new understanding that progress in learning about string theory has led to. For particle theory, that new understanding is the existence of the landscape, and the inherent uselessness of string theory as a theory of unification.

I know very little about heavy ion physics, but I have to admit that I find it pretty funny to see the way string theorists now go on about how certain calculations in the subject are one of the most exciting developments in physics. Way back when (mid-eighties), I did some finite-temperature lattice QCD calculations (all this means is that you look to see what happens when one of the dimensions is smaller than the others). This supposedly was of relevance to the heavy ion experiments then being planned. I remember what most string theorists attitude at the time was about non-perturbative QCD calculations of possible relevance to heavy ions. As far as they were concerned, such a subject was about as not-exciting as could be imagined. Things have changed…..

9. **somebody**
February 19, 2009

Peter says: "I did some finite-temperature lattice QCD calculations ….. I remember what most string theorists attitude at the time was about non-perturbative QCD calculations of possible relevance to heavy ions. As far as they were concerned, such a subject was about as not-exciting as could be imagined."

Peter, I understand your frustration (we have all been there when working on unfashionable things), but I think the reason for this is scientific. The properties of heavy ions become of *conceptual/theoretical* ineterest when we are using something absolutely unprecedented (black holes) to attack the problem. Lattice approaches, while tremendously useful and important, did not require such a new theoretical perspective. The interesting message from the viewpoint of fundamental theory here is not the heavy ions themselves, but that heavy ions are telling us something about the two basic structures in physics: gauge theories and gravity.

10. **Peter Woit**
February 19, 2009

somebody,

The story about my past was about something that amuses me now, and has nothing to do with frustration, then or now. 20-some years ago I was working on doing calculations of topological invariants of lattice gauge fields and running Monte-Carlo simulations. I knew nothing about heavy-ion physics, and it wasn't a topic that interested me (there are lots of topics in science the study of which I have sufficient respect for to know I don't want to put in the time required to make a contribution to them). The fact that string theorists weren't interested either wasn't to me at all remarkable. Seeing the way some of the same people I knew then now go on about the subject now is pretty funny.

The one constant seems to be the level of hype being spouted. Back then it was hype about a grandiose, fundamental, mathematically revolutionary theory that would provide a unified theory of everything, now it's hype about an "absolutely unprecedented" crude approximation technique to predict the viscosity in a quark-gluon plasma. Perhaps you can see the humor…

11. **CWJ**
February 19, 2009

"but that heavy ions are telling us something about the two basic structures in physics: gauge theories and gravity."

That is sheer nonsense. That's like claiming studying eigenmodes in, say, bridges tells us something about quantum mechanics which also uses eigenmodes.

Duality is a tool, like eigenmode analysis, and if it proves useful in heavy ions, that gives one confidence that it may prove a useful tool in other areas. But successful application of duality to heavy ion physics does not mean that it validates, in any way, the underlying picture of string theory–only the usefulness of the tool.

If you wonder why Peter, and much of physics, is suspicious of string theory, it's exactly because of overreaching statements like this.

12. **somebody**
February 19, 2009

CWJ: "That is sheer nonsense. That's like claiming studying eigenmodes in, say, bridges tells us something about quantum mechanics which also uses eigenmodes."

Lets ignore the over-assertiveness.

About the analogy: in this case it does not work. Because if eigenmodes were difficult to access experimentally (which is the situation with string theory), it makes perfect sense to study them where we can, to see what we can learn. Eigenmodes are a really bad example in this context, because they are one of the easiest objects to do experiments with: remember that almost everything we know about physics comes from perturbation theory around the harmonic oscillator eigenmodes of systems.

Peter, no need to clarify, I wasn't implying that you were "frustrated" in any profound way.

13. **CWJ**
February 19, 2009

somebody: No, eigenmodes are a really good example, because it illustrates the confusion of mathematics with physics–which is what you were doing.

"remember that almost everything we know about physics comes from perturbation theory around the harmonic oscillator eigenmodes of systems"

Not true (although a narrow view typical of particle theorists). Perturbation theory is a very useful tool, but it's not the only tool. For example, in my field, nuclear structure, there are many people whose entire career revolves around applying group theory to everything. They couldn't do perturbation theory to save their lives, but they have productive, meaningful careers that teach us a lot about physics.

14. **somebody**
February 19, 2009

The whole reason why research is often on non-perturbative stuff is BECAUSE we understand things well when perturbation theory is valid. This is your second example where you are confusing cause and effect.

Also, asseriveness is cool, but substance is better. I have tried to be polite, but your hostility towards the (perceived) top of the foodchain is really showing.

15. **cwj**
February 19, 2009

somebody: "The whole reason why research is often on non-perturbative stuff is BECAUSE we understand things well when perturbation theory is valid. This is your second example where you are confusing cause and effect."

Umm… no.The reason research is carried out on applying group theory to physics is because nature seems to exhibit deep symmetries, which is of fundamental interest completely independently of how well perturbation theory works. This is true in particle physics, in nuclear and molecular physics, in condensed matter physics, and so on.

somebody, are you claiming to be top of the food chain?

16. **Peter Orland**
February 19, 2009

There is a point being overlooked in this discussion. AdS/CFT methods have not solved any of the hard non-perturbative problems in QCD or condensed-matter physics. These methods work with large bare coupling constants (that is, the coupling with the UV cut-off is large), where there is no universality. Qualitatively, I don't see that this activity is better or worse than lattice strong-coupling expansions. One strong-coupling method is no more universal than another.

AdS/CFT methods will probably give some more interesting results (for CFT's especially). But, in spite of early optimism, I don't think these techniques are going to be useful in studying fixed points of non-supersymmetric theories.

17. **Troy**
February 20, 2009

Peter,

I truly don't understand what your problem is (apart from the non-scientific issue of "science publishing", "public perception of science", "PR of science" and such topics, which are, clearly, not natural science. I will use the terms "science" and "natural science" as synonyms for this post.).

Yang-Mills theory was not invented to describe parts of the standard model. Does it make it bad that it is used for something completely different today than what it was invented for? Of course not. Similarly, does it make string theory bad that it is not used for what it was invented for? Of course not.
Don't worry about the Yang-Mills example, I (or you) could come up with literally hundreds of ideas and topics that found their "real" application somewhere else than was originally intended.

You might say that the original researchers on Yang-Mills (prior to the standard model applications) didn't hype their work as much as string theorists hyped their work. But this point, may it be valid or invalid, is completely a non-science point. It has to do with PR, press, journalism, etc, but it's definitely not science itself.

So please be honest and say that you don't have a science point to make, but rather you'd like to comment on PR, press, journalism and similar topics.

Best,
Troy

18. **Thomas Larsson**
February 20, 2009

What has AdS/CFT explained about asymptotically free, non-conformal gauge theories? By "explained" I mean explained in the past tense, not hopes for the future.

19. **somebody**
February 20, 2009

Peter O. says: "But, in spite of early optimism, I don't think these techniques are going to be useful in studying fixed points of non-supersymmetric theories."

Fixed points are easy because they are always conformal and conformal theories are what AdS is directly good for. The more interesting part is actually to get to a confining theory, like QCD. Also supersymmetry is already broken, because we are at finite temperature.

20. **Peter Woit**
February 20, 2009

Troy,

Actually, Yang-Mills theory was invented to describe part of the standard model (the strong interactions)…

This posting is about the problem of scientists misleading the public about certain scientific issues. If the idea of someone pointing out that this is going on bothers you, you might want to skip a lot of the postings on this blog.

21. **somebody**
February 20, 2009

cwj: "The reason research is carried out on applying group theory to physics is because nature seems to exhibit deep symmetries, which is of fundamental interest completely independently of how well perturbation theory works."

Understanding dynamics is the pre-eminent goal of physics, my friend. You are not seeing the woods for the trees.

"somebody, are you claiming to be top of the food chain?"

No, I am claiming that you are at the bottom of it. 🙂

22. **cwj**
February 20, 2009

"Understanding dynamics is the pre-eminent goal of physics, my friend."

And if dynamics has a deep group symmetry, then all the perturbation theory in the world won't help you.

Talk about your hostility, somebody. We can trade insults all you like, but I'd be happy to compare funding and citation profiles with you. I'm pretty sure I'm much higher up the food chain than you.

23. **Peter Orland**
February 20, 2009

Somebody said:

“Fixed points are easy because they are always conformal and conformal theories are what AdS is directly good for. The more interesting part is actually to get to a confining theory, like QCD. Also supersymmetry is already broken, because we are at finite temperature.”

What you are saying is incorrect. Perturbative properties of fixed points are easy, as you say. But the challenge in QCD is not finding confinement in a strongly-coupled cutoff theory. Wilson showed that thirty-five years ago.

The real problem is to show that confinement and a mass gap persist to weak bare coupling near the fixed point. This is what is needed to find the string tension and the mass gap after renormalization. This is where the AdS/CFT/QCD approaches have gone nowhere. I’ve worked on this problem a long time, and take my word for it – it is something I understand.

24. **Peter Orland**
February 20, 2009

Sorry if you could see the steam coming out my ears, somebody. I have explained (or at least tried to explain) this stuff at the end of my field theory class. That is why I reacted strongly to the implication that I don’t understand it.

25. **Troy**
February 20, 2009

Peter,

“This posting is about the problem of scientists misleading the public about certain scientific issues. If the idea of someone pointing out that this is going on bothers you, you might want to skip a lot of the postings on this blog.”

What bothers me is not that you point out anything. What bothers me is that continue to insist that this blog and book and similar polemic is part of your scientific activity. I argued, that it is not scientific activity. You apparently don’t deny this. Then, it would be best to not portrait yourself as a scientist making scientific points, but rather as a popular science writer, science journalist, etc.

Best,
Troy

26. **Peter Woit**
February 20, 2009

Troy,

This blog contains a wide mix of things, from notes on my current main research activity about interpreting BRST symmetry in terms of Dirac cohomology (more to come soon, sorry that has slowed down…) to expository comments and pointers to information about topics in math and physics that interest me, to news of various kinds, to attempts to counter efforts to mislead people about certain topics in physics. You don’t hear here about my personal life, you do hear about the areas of math and physics that my professional life is devoted to.

Popular science writers and science journalists don’t have the kind of training or professional background necessary to understand what is going on in cases like this one and to see that they are being misled. Scientists who do have such a background owe it to the public to speak up when they see this kind of thing going on. I would argue that this is part of the responsibility of a scientist, and, yes, legitimate scientific activity.

Funny, but you seem utterly unconcerned about the topic of this posting, the fact that the public is being misled about what is going on in a certain scientific research area. Instead of trying to defend what you know to be indefensible, you choose to (anonymously) write in to attack me. It continues to amaze me how much of this kind of behavior I’ve seen the past few years. The combination of having some physicists going out and actively misleading the public, and then others anonymously attacking anyone who objects to this is not exactly doing much for the public perception of this field.

27. **Peter Woit**
February 20, 2009

I’ve deleted the latest of the Peter O./somebody exchange. This kind of discussion is just not enlightening anyone about anything. Enough.

28. **Troy**
February 20, 2009

Peter,

I’m not attacking you. I’m not unconcerned about the topic of your post. I don’t know why you got that impression. I explicitly said that it doesn’t bother me that you make a point about anything.

What does bother me though is that you portrait this part of your work as science. In my opinion it is not. It is science journalism, popular science writing, etc, etc. This is not an attack on you, since science journalism and popular science writing is nothing bad. I don’t see how you can interpret this as an attack.

My point is that your observations and points about string theory and the state of particle physics are not science per se. This is because they don’t go through the same academic standard and filter as other scientific work, for example, peer review. You seem to be concerned a lot about the behavior of certain physicists. Do you seriously think that being concerned about someone’s behavior is a legitimate science project? Is it really scientific work? I don’t think so.

To illustrate my point: suppose you did nothing else at your university only wrote this blog and your book, would you be entitled to your salary? I don’t think so. This is hypothetical because I know you teach. But for the sake of argument, let’s just suppose you only wrote this blog and wrote your book. Do you seriously think you are entitled to your salary at a math and/or physics department whose mission is to further scientific knowledge through original research? I can only hope, that you also don’t think so.

Best,
Troy

29. **Peter Woit**
February 20, 2009

Troy,

You insist on completely ignoring my point that the postings here are of several different kinds, having various and different relations to “doing science”. For example, the notes on BRST are explicitly research science of the kind you insist I don’t do, so I find your (anonymous) comments an attempt to attack me by denying that I am a scientist who does science. I have no idea who you are or what your motivation for doing this is.

Some things I post here are journalism. Yes, I report news that I find interesting and not readily available elsewhere.

And to repeat myself again, I do happen to think that countering attempts by scientists to mislead other scientists and the public about scientific issues is a worthwhile scientific activity, and it’s not journalism. I’m not calling up experts, asking them what they think and reporting on this. I’m using my own training, expertise and scholarship to make scientific judgments and argue for them.

No, I don’t think Columbia University should pay my salary purely to support my writing a book and a blog. They are only one part of what I do, and the other parts (service to the department, teaching, and research) are significantly more important and central to the purposes of the university. However, I do think the book and blog are significant parts of my scholarship, and of some value to others as such. It is also part of the purpose of the university to support such activities. I’m not the only faculty member at a research university who has written a book which is not a research monograph. I’m extremely lucky and grateful to have colleagues and a university administration that is supportive of what I do.

30. **Troy**
February 20, 2009

Peter,

No, I still don’t attempt to attack you. This blog indeed has some scientific content, but in my opinion it does not qualify as genuine science research activity. You mentioned BRST, which is indeed a scientific topic, but presenting it in a blog, without peer review, without going through the usual channels of academic research, it remains the same category as science journalism and popular science writing. For example, if you would submit your work on BRST to a science journal where others would have the chance to seriously review it and it would get published, it would be a different story. But so far you did not do that. Even if you did, the publication on the blog, in my opinion, still doesn’t count as scientific research.

It seems to me you have a negative view of science journalists and that is why you want to exclude yourself from this group. I see it differently. Science journalists serve an important and relevant purpose and should be acknowledged for their effort. It’s very important that we have science journalists. Some of the science journalists were scientists themselves, some of them have a PhD. I think you are also this kind of science journalist or popular science writer. There is nothing wrong with that.

You seem to imply that a journalist is a person who has no expertise and only calls up experts, cut-n-pastes, etc. This view is pretty offending to several science journalists. Good science journalists are not like this and they can be pretty smart and as I’ve said can even have a PhD just like you.

In order to be clear, in order to not mislead the public, I think it would only be fair if you would present yourself as a science journalist or popular science writer to the public and not as an active researcher. This is because your most important views and messages (regarding string theory, etc) are not in the form of original scientific research, but rather in the form of blog posts and essays. Again, there is nothing wrong with this, this is not an attack on you, but the fact must be stated that you operate in an entirely different way than ordinary scientists who are doing active research.

Presenting yourself otherwise would be misleading to the public and a science journalist would need to come around point this out to the same public.

Best,
Troy

31. **blog reader**
February 20, 2009

Troy, please shut up. You’re just repeating yourself over and over like a cracked record. Give readers credit for being able to read various things and to intelligently draw their own conclusions.

32. **Peter Woit**
February 20, 2009

Troy,

I have a high opinion of science journalists, but I’m not one. I’ve written exactly one semi-popular book and have no interest or intention to write another. The book was intended for publication by a university press. String theorists put a stop to that and it ended up getting published by a trade publisher and getting much wider attention. The blog is aimed at other physicists and mathematicians who share my interests. What I wrote in the book and what I write on the blog is based upon training that includes a Ph.D. in particle theory from Princeton, and 25 years since then during which I’ve spent most of my waking hours thinking about and teaching mathematics and physics. There’s a huge amount of material on this blog and in the book, anyone can judge for themselves whether it is reliable and I know what I’m talking about.

I have no idea who you are, or why you are on this campaign to claim that I am not a scientist, a campaign conducted from behind the mask of anonymity. Frankly I find this extremely creepy

33. **A.E.**
February 21, 2009

This is like saying that experiments have proven the existence of Hilbert Space, because Quantum Mechanics works so well. Hilbert Space is a mathematical tool, that can be used any where including in QM, that a mathematical tool can be used to calculate something in the different context has nothing to do with the questions that mathematical tool was created to respond.

But then again, this has been a constant theme for string theorists. It was created to help with understanding Nuclear forces, failed there, then it was branded as a tool for QG, resolving divergence issues, failed there too, then it was re-branded as a theory of every thing, that unifies all other fields, spectacularly failed there. now it is being re-branded as a computational tool to calculate stuff in nuclear physics. Here is my question, how many times a formalism must fail for it to be abandoned? Isn’t 40 years enough and devotion of the best minds of physics, creating some of the most intractable body of intellectual work to-date enough ?

34. **anonymous fool**
February 21, 2009

Peter,

It’s a false argument that anonymity discredits the writer. What discredits a poster is failure to write in good faith; anonymity may or may not be a manifestation of a lack of good faith. There are perfectly reasonable motivations for writing anonymously, not least of which is that it does not seem important that it is I who am writing what I am writing – another way of putting it is that the anonymously written thing can be judged on its merits, not in terms of the perceived merits of who has written it.

35. **Peter Woit**
February 21, 2009

anonymous fool,

I'd rather not have repeated now the abstract discussion of anonymity on blogs that has taken place here and elsewhere on several occasions. People can judge for themselves what they think, in general, and in the specific. My judgment is that the kind of thing "Troy" is doing is both unprofessional and creepy.

somebody,

I've deleted your last comment because you refuse to stop attacking people as incompetents who don't understand basic facts about QFT.

36. **a**
February 21, 2009

Troy, some years ago neither scientists nor science journalists wanted to openly talk about the problems of string theory. Somebody had to do it. Peter did it.

37. **Joey Ramone**
February 21, 2009

Troy writes, "This is because your most important views and messages (regarding string theory, etc) are not in the form of original scientific research, but rather in the form of blog posts and essays."

String Theory's most important triumphs are not in the form of original scientific research which makes physical prediction and can be tested, but rather in the form of blog posts, essays, pop-sci books, and PBS miniseries.

Regarding the importance of peer-review, my favorite examples are Bruno being burned at the stake, Galileo being placed under house-arrest, Socrates being sentenced to death, and Boltzman being called a crackpot. He ultimately committed suicide before he ever knew of the vast triumph of his ideas. On his tombstone is s=klogw.

Thank goodness that Troy is of a far more civil era, where the tacit perseuction of those who speak and write about the truth regarding string theory is limited to anonymous blog posts, and the rejection of books reporting on reality by univeristy presses.

This blog is continually reviewed by thousands of peers. Its words might not fund some antiquated journal's cartel, where universities are forced to pay tens of thousands for papers–indeipherable papers that are all too often judged and juried by a nepotistic, self-serving system; and are generally published two years after the fact.

This blog contains philosophy. It contains sociology. It contains science and math. It contains entertainment and journalism. And it is making a far greater contribution to the realm of science than those who are all too happy to run with the disingenous stringster hype/headlines so as to sell copies of their magazines and run up their "diggs."

This blog is important *because* it is coming from a genuine, unique perspective. It takes more courage to honestly criticize the system than it does to conform to it, but those who do oft make a greater and more enduring contribution.

38. **Peter Woit**
February 21, 2009

Thanks Joey,

It's a great honor to be so appreciated by one of my musical heroes, even if it is from beyond the grave….

39. **Thompson**
February 21, 2009

Has anybody seen the new data from the Fermi (formerly Glast) satellite indicating a frequency dependent speed of light? This effect has also been seen previously by the MAGIC telescope, and could be the first experimental probe of string theory (more generally, quantum gravity).

40. **rhofmann**
February 21, 2009

Joey and Peter, let me express it this way. An attack strategy such as issued by Troy clearly expresses the fact that there is nothing constructive both, scientifically and sociologically, to be expected from his camp. It is a sad example of screaming helplessness. As a real physicist I am grateful to you, Peter, for all the informed and uncompromising postings of your blog and for the valuable service your book has done to support physical truth. High regards and thank you!

41. **aliaspg**
February 21, 2009

Troy wrote "What does bother me though is that you portrait this part of your work as science."

I may be wrong, but I do get the impression that this statement is linked to a very narrow view of what science is.

A discussion about the question whether a certain theory X has fulfilled its promises and expectations is an intrinsic part of scientific activity – if it is done by people who know what they are talking about, i.e. scientists.

The internet (blogs etc.) has made these discussions much more public, but doesn't change the fact that they are an intrinsic part of scientific activity.

42. **woit**
February 21, 2009

Thompson,

The paper you mention

http://www.sciencemag.org/cgi/rapidpdf/1169101v1.pdf

does not claim to have shown a frequency dependent speed of light, for that they need data from bursters at different distances. What they do do is give a limit on the scale of such an effect: it has to be at an energy level larger than 1/10 the Planck mass.

If such an effect does really show up, that would be exciting, but not an "experimental probe of string theory". Problem is, string theory is consistent with pretty much any scale. For an old posting about MAGIC and yes, yet another "finally a test of string theory is found" media story, see here:

http://www.math.columbia.edu/~woit/wordpress/?p=591

43. **Will**
February 21, 2009

I completely agree with Troy. At some stage, Peter should recognize that he is not exactly an active scientist but an active science journalist whose views are somewhat unobjective. The notes in BRST is of some value, but that doesnt qualify you to claim that you have done work on topics like quantum gravity and so on. If you have done so, you should put in preprint or publish it out. I dont think in this case you will have an excuse to say, the string theory community did not allow you to publish your work. As we all know, that you have done anything of value as far as scientific publication in a long time. I seriously think that you should

44. **Will**
February 21, 2009

….(remainder of the above post)

I seriously think that Peter should not be excessively opposed to anything that is of value that comes out from ideas like ADS CMT and so on. I am really concerned about the negative impact on scientific research by these attacks. If there is something objective that you have to say, please publish. Dont try to sway public opinion and do damage to the spirit of scientific research.

45. **Joey Ramone**
February 21, 2009

Hello Will,

You write, "I completely agree with Troy. At some stage, Peter should recognize that he is not exactly an active scientist but an active science journalist whose views are somewhat unobjective. "

Again, one could easily say, "(Insert Name of String Theorist Here) should recognize that he/she is not exactly an active scientist but an active science journalist/science-fiction writer whose views are somewhat unobjective."

But Peter actually often defends Ed Witten's genius, as well as the valuable mathematical contributions that the original String Theorists made, and the funny thing is he does it far better than most of the younger string theorists, who sometimes seem to forget their lines.

I sympathize with Peter, because as a founding member of the Ramones, I can say we did it not for titles and tenure, but for truth, beauty, and art.

Wikipedia reports: http://en.wikipedia.org/wiki/The_Ramones

"The Ramones were a major influence on the punk rock movement both in the United States and Great Britain, though they achieved only minor commercial success. . . In 2002, the Ramones were voted the second greatest rock and roll band ever in Spin, trailing only The Beatles.[9] On March 18, 2002, the Ramones—including the three founders and drummers Marky and Tommy Ramone—were inducted into the Rock and Roll Hall of Fame."

Now just as American Idol has replaced authentic rock, modern string theory has replaced authentic physics. We rocked out from the soul, and Peter writes from the soul. He has a sense of humor and is fun to read–my favorite part of NEW is the part where he is at Princeton and he sees Ed Witten up ahead in-between Jadwin and Fine. Witten goes up some stairs, and when Peter goes upstairs, Ed Witten is suddenly gone. Perhaps Witten really does have superpowers, or is other-worldly, Peter reasons.

Woit speaks for an entire generation of physicists who were oft muscled out of academia because they took the hard path–because when the choice came–to support questionable obfuscation and peer-review groupthink for a salary, title, tenure, and benefits, or to call it as they saw it, they chose the nobler route. And the Lubos Motls of the world–the end result of the Orwellianification of physics– were unleashed on them.

And that's why I'm supporting Peter from beyond the grave, because I know how it feels, and I wouldn't have had it any other way.

At the end of the day, it is not the Rock'n'Roll Hall of Fame, nor the honors in Spin and Rolling Stone that give us honor–but it my band–the Ramones–who give honor, meaning, and street-cred to them.

At the end of the day, it are not all the millions of refereed, peer-reviewed papers on String Theory that give honor to Princeton, Harvard, and Columbia, but it are bold intellectuals such as Peter by whom the academy is exalted, furthered, and remembered.

Now Troy and Will–I forgive you, as you remind me of all the jocks in high school who laughed at us; but I can't speak for Johnny and Dee Dee, who might not be so kind.

Will–you write, "I am really concerned about the negative impact on scientific research by these attacks. If there is something objective that you have to say, please publish. Dont try to sway public opinion and do damage to the spirit of scientific research."

Peter publishes far more than the vast majority of physicists. His output is truly phenomenal on this blog, and again, it is peer reviewed to a far greater extent than the vast majority of string theory papers–even anonymous snarkers without advanced degrees in physics are allowed to review and comment on the blog posts. It is also read far more than string theory papers, and it is having a far more positive influence on science than all those papers, and that–that is what bothers you most. Peter uses words and math in the pursuit of truth, so naturally, time is on his side, as it was on ours–again, Wikpedia writes:

"The Ramones made little commercial impact, reaching only number 111 on the Billboard album chart. The two associated singles, "Blitzkrieg Bop" and "I Wanna Be Your Boyfriend", failed to chart at all. At the band's first major gig outside of New York, a June date in Youngstown, Ohio, approximately ten people showed up."

String Theory has generated hundreds of millions and is revered by thousands of fanboys at Digg, and American Idol has also generated hundreds of millions of dollars and is revered by many of the same fanboys, but there is some sort of a mystical "super symmetry" in this world, wherein it are those misfit bands who play to ten people in Youngstown, Ohio–who play with heart, soul, and meaning–who end up defining and era and revolutionizing the world of music–not the winners of American Idol.

Peter running this rock'roll blog through modern peer-review would be akin to my band–the Ramones–audtioning before Simon Cowell and the American Idol judges.

It ain't ever goin' to happen–neither in this world nor the next–not even in your landscape's favorite multiverse.

46. **Peter Woit**
February 21, 2009

Well, there certainly appears to be a range of opinions on the Peter Woit issue.

"Will",

I guess it's clear what some string theorists have decided is the right tactic to deal the Peter Woit problem: try to convince people he doesn't know what he's talking about since he's merely a journalist. I don't think this is going to work for you.

You miss the whole point of the posting, which is not in any way critical of AdS/CMT research. What I'm criticizing is the highly misleading way it is being promoted. If you actually care about the reputation of this field, you might want to stop worrying about me, and see what you can do to stop people from going to the press with absurd claims about it. This kind of thing may work with some of the public, but it makes you a laughing-stock among your colleagues, and may have something to do with why no one wants to hire string theorists at the tenure-track level anymore.

47. **Will**
February 21, 2009

Hi Peter,

There are always going to be people in any fields and subfields who will exagerrate things they do.I dont see that this as a major issue. Also, I dont think this is a problem that is unique to string theory community. I tend to think that string theorist tend to do this lesser than most other discipline.

It is clear that ADS/CFT has helped us understand different physical phenomena in different energy scales. It has given us valuable too to understand phenomenas that were thought to have no relations what so ever. Now, ADS CFT was borne out of string theory. I dont know if you just despise the word "string theory". You have been around physicists enough years to understand that we are more or less an opportunist and we tend to work in whatever we can put our hands into.

In my opinion the term string theorist is too narrow.As you know, only a small fraction of people work in the fundamental theory. Most tend to work in other aspects where they think they can make progress.

48. **Will**
February 21, 2009

continued….

If some person decides to do a press release about whatever they do, this doesnt reflect the position of the whole community. You should know better than that. String theory is not an organization with a governing board which gives decree for certain press releases. Now, for you to suggest that the whole of string theory community is just working as some giant corporation is just silly.Now your critique of string theory tends to be always social. May be you should try to study the new developments rather than nit pick and focus on buzz words. It would be better than commenting on a cartoon picture in string theory, press releases or Polchinski's colloquim talk.

49. **Peter Woit**
February 22, 2009

Will,

Again, this was not a post criticizing AdS/CFT research but was about a specific egregious example of misleading hype. The huge area known as "string theory" has been heavily damaged by the amount of overselling and hype that has gone on for 25 years now, with a serious loss of credibility. You might want to think about what can be done about that, and whether reacting to new even more egregious hype by complaining that someone is criticizing it is a fruitful thing to do.

Believe it or not, I do spend significant effort trying to learn about what is going on in many parts of string theory, especially the more matematical end, but also others. I wish there was more interesting to report from this effort, but this seems to be a very quiet time for the subject.

50. **N. Nakanishi**
February 22, 2009

I believe that the aim of this blog is to discuss scientific topics and to communicate various opinions, but not to criticize particular person's activity. I think that the action of Troy and Will is unfair because they criticize not Peter Woit's opinion but his personal activity, keeping their names anonymous. The natural guess based on their anonymousness is that they are totally non-scientists.

51. **H-I-G-G-S**
February 22, 2009

Peter,

You said "Actually, Yang-Mills theory was invented to describe part of the standard model (the strong interactions)"

Not true. Go back and read the original paper. YM theory was invented to reconcile isospin invariance (which had new experimental results supporting it) with the concept of local fields. They give the impression that they think global rather than local isospin invariance is inconsistent with local fields. In any case, they decide to see what they can deduce if isospin invariance is made local. I don't believe the claim that they were trying to describe the strong interactions is supported by any statements in their paper.

52. **Peter Woit**
February 22, 2009

H-I-G-G-S,

Actually I have read the paper, and seriously studied the history of that era. I'm well aware that what they were gauging was isotopic spin, but it really is true that what they were hoping to get was a theory of the strong interactions. There's nothing in the paper about the weak interactions, the introduction is all about the strong interactions (nucleons, mesons, no leptons), then they state:

"We then propose that all physical processes (not involving the electromagnetic field) be invariant under an isotopic gauge transformation…"

It was only several years later, after V-A, that people like Schwinger and his student Glashow started working on the idea of using Yang-Mills theory to get a theory of the weak interactions.

If you don't believe me, maybe you'll believe David Gross, who writes in http://psroc.phys.ntu.edu.tw/cjp/v30/955.pdf

"The application of Yang-Mills theory to the strong interactions-the original motivation for the theory- was even trickier"

53. **Peter Woit**
February 22, 2009

One more, in case you also think Gross doesn't know what he's talking about:

See Weinberg's

http://arxiv.org/abs/hep-ph/0401010

"Yang and Mills [9] in 1954 constructed a gauge theory based not on the simple one-dimensional group U(1) of electrodynamics, but on a three-dimensional group, the group SU(2) of isotopic spin conservation, in the hope that this would become a theory of the strong interactions."

February 22, 2009

Peter,

""""I have a high opinion of science journalists, but I'm not one.""""

Okay, let's break this down more. Now that we agree that being called a science journalist is not an insult, hopefully you will stop thinking that I'm attacking you. I'm not.

""""The blog is aimed at other physicists and mathematicians who share my interests. What I wrote in the book and what I write on the blog is based upon training that includes a Ph.D. in particle theory from Princeton, and 25 years since then during which I've spent most of my waking hours thinking about and teaching mathematics and physics.""""

This is all true. But this doesn't mean that your current activity is not closer to science journalism than to original scientific research.

""""There's a huge amount of material on this blog and in the book, anyone can judge for themselves whether it is reliable and I know what I'm talking about.""""

All true again. I don't say you don't know what you are talking about either. I did not say that and I never implied it. All I'm saying is that writing a blog and popular science book, even with the strong credentials you have, does not constitute scientific activity, in my opinion. To be clear, there is nothing wrong with this, this is not an attack, not a creepy ad hominem, etc, nothing like that, it's a simple observation that doesn't contain anything insulting.

""""I have no idea who you are, or why you are on this campaign to claim that I am not a scientist, a campaign conducted from behind the mask of anonymity. Frankly I find this extremely creepy""""

Let's not get into the discussion of posting anonymously, this will only sidetrack the discussion.

I did not say you are not a scientist. I certainly start getting the feeling that you are a slightly bit paranoid. Again, I did not say you are not a scientist. What I said is that your most recent activity, writing a blog and a popular science book, does not constitute original scientific research activity.

Example: Terence Tao is a scientist. He writes a blog. His blog does not constitute original scientific research, based on which one could label him a scientist. We think about him as a scientist for other reasons, for example his papers, theorems, etc, etc, all the usual stuff. But he is not spending 100% of his time on original science research, he does other stuff too. He does popular science too, popular science writing, science journalism, etc. His blog is an example of his popular science activities. I bet he wouldn't be offended if somebody would point it out that his blog writing activity is popular science writing. In fact he knows this.

Just as John Baez knows that his This Week's Find is popular science writing, aimed at scientists, but something that does not meet the strict requirements of rigorous science. But he would not be offended by this. In fact, that's exactly the reason he does what he does. He wants a free form of exchange of ideas without the burden of rigorous academic channels and there is nothing wrong with that. In fact, it's pretty good that he is doing what he is doing. He is also a scientist and large part of his time is spent on original scientific research. His blog writing activity is something else though.

So back to you. Your blog and book writing activity is the same. It's popular science writing or science journalism. You have a PhD. You graduated from a good school, you wrote a couple of papers. So you are a scientist. But in the last 5-10 years, you did not carry on your scientific research, instead you are writing this blog and writing a book and publish drafts of some scientific ideas as blog postings. There is nothing wrong with this. But Terrence Tao and John Baez does this type of popular writing and original research on top of that. You apparently dropped original research and stick with popular writing. That's a difference between you and Terrence Tao or John Baez.

I simply don't understand why it's so hard for you to admit this. It's not a stigma. It doesn't make the value of your writings any smaller. Nobody will think less of you. But if you continue to go against the facts I outlined above maybe we don't agree as to what constitutes original science research and what constitutes popular science writing.

I think I made my definitions clear (Terrence Tao's blog or This Week's Find are both popular science writings, aimed at scientists, for example). If you disagree, please let me know what you think is original scientific research and what is popular science writing.

Best,
Troy

55. **Peter Woit**
February 22, 2009

Troy,

I've already answered you repeatedly. I'm no Terry Tao, but I currently spend many hours a week working on original scientific research in the narrowest possible sense (my work on BRST and Dirac Cohomology), and I have been doing this my entire adult life. Some of this has appeared on the blog, more will in the near future, as well as ultimately in more conventional forms. If you want to describe me as a scientific researcher who has a problem with not writing things up for publication out of a combination of laziness and not being willing to publish things that he's not happy with, that would be fine.

This is a posting about a rather egregious example of string theory hype. Instead of discussing that, you're on an obsessive and off-topic campaign to convince the world that I'm not a scientific researcher but a journalist. I don't know anything about who you are, or why you are trying to do this. It really is creepy though.

56. **Sung Lee**

February 22, 2009

Troy,

Your tactics is so transparent. What you are trying to implicate is that Peter is not a scientist but a scientific journalist, therefore his criticisms about string hypes are less credible.

I presume a lot of regular readers of this blog are professional physicists or mathematicians. I myself is a mathematician. Even without your pointless effort, I believe people can use their own judgment to see whether Peter's argument is credible or not. If you have a problem with his criticisms, you just need to point out what the problem is with your own rationales. If you are a string theorist, I would personally like to hear about your expert counter argument on Peter's criticisms. While I agree mostly with Peter's criticisms about string hypes, I believe it is still too early to dismiss string theory itself. I personally am interested in string theory and am trying to understand it along with standard QFT.

If you really have something to say to counter argue with his criticisms, please do. Otherwise, quit it.

Best,
Sung Lee

57. **anon.**
February 23, 2009

The H-I-G-G-S and Troy arguments are of the philosophy:

'When in hole, keep digging.'

No matter how many failures there are, no matter how many false claims are exposed, no matter how much spin and hype is proved vacuous, there is no apology. Far from it…

58. **Eugene Stefanovich**
February 23, 2009

Re: Troy vs. Peter

The naked Emperor is funny, but the naked Emperor throwing insults is truly hilarious.

59. **Joey Ramone**
February 23, 2009

Many people accused my band the Ramones of not being a real band because we did not put out top-40 hits like Boy George in the 80's.

I recall getting a snail-mail fan letter from Troy. Back then we did not have email and blogs, so people had to pay for stamps and envelopes when they sent anonymous words belittling us. I saved "Troy's" letter. Here it is:

"Joey–So back to you. Your band and record-making activity is the same. It's alternative rock or punk rock. You learned some chords. You got yourself a decent guitar, you wrote a couple of songs. So you are a musician. But in the last 5-10 years, you did not carry on your higher musical duties as did Billy Idol and Tears for Fears, instead you are performing for a dozen fans in Toledo Ohio and ignoring the corporate music scene. There is nothing wrong with this. But Adam Ant and Madonna also perform in Toledo and compose corporate top-40 music on top of that. You apparently dropped corporate top-40 music and stick with punk/alternative. That's a difference between you and Adam Ant and Madonna."

Without Troy's insights, I doubt we'd ever been inducted into the Rock'n'Roll Hall of Fame.

60. **Will**
February 23, 2009

I think everyone is misinterpreting Troy's point. I think Troy's claim is that Peter does not have credentials like Shelly Glashow to counter string theory. This does not mean that Peter is not entitled to his opinion. I think Peter has done a good job in pointing out websites, lectures etc in both math and string theory.

61. **Will**
February 23, 2009

My last thought is that I hope Peter would show the details in the flaws about the new development in arguments in string theory as opposed to touching on tangential point. Anyways, there I rest my case and I will not say more in this post.

62. **Peter Woit**
February 23, 2009

Will,

I don't think anyone is misinterpreting Troy's attack on my credentials. Anyone who wants to judge arguments about string theory based purely on the credentials of who is making them should ignore me and listen just to Nobel prize winners and senior faculty at places like Harvard and Princeton. On the other hand, if you want to make your own judgment about this scientific controversy, you might want to read what I have to say, what string theorists have to say, and make up your own mind. One thing you may notice is that often, in cases like this posting, string theorists don't bother to try and defend the indefensible hype coming from their colleagues that I am pointing out, and instead try and attack my credentials. This tactic hasn't worked out for them so far, but they keep at it…

63. **Joey Ramone**
February 23, 2009

I remember when Troy and Will used to follow us around after concerts, yelling at us from behind masks–"You are no Depeche Mode! You are no Duran Duran! You are no Dexy's Midnight Runners!"

Boy, did that creep the band out.

It turns out they were fans of Tears for Fears, but attacking our credentials never did get Tears for Fears into the Rock'n'Roll Hall of Fame.

And attacking Peter probably won't save string theory.

64. **Aaron Bergman**
February 23, 2009

Are you bashing Dexy's Midnight Runners? Because if you are, I'm not sure I can stand for that. I mean, they have the toora and the loora. You can't beat that shit.

65. **Will**
February 23, 2009

Peter,

Well, I almost feel compelled to make one more argument. If you see nobel lauretes like Weinberg, Thooft, Nambu, Gross, Gell Mann and others in particle physics tradition we know for a fact that they tend to support string theory.

In fact a number of them have worked in the fields and there is no denying this. These are not conspiracy theories. Now, obviously like with any discipline, there are skeptics within particle physics community but their criticism are more constructive and not outright negative.

Other criticism come from subdisciplines of physics. For instance people like Philip Anderson have opposed even building particle colliders: his battles with Weinberg about this issue and the congress hearings are well documented. As good as people like Anderson or other condensed matter physicist are, their skepticism is only good to understand their taste.

If one looks at physicist who have thought deeply about the problems in quantum gravity, it would be misleading to claim that most distinguished physicist are against string theory. In fact the evidence suggests quite the contrary.

66. **Peter Woit**
February 23, 2009

Will,

Deciding a scientific question by counting up how many Nobel prize winners are on each side of the question is one way to do it, another is to actually learn about the subject and make up your own mind. By the way, you don't seem to mention Veltman, Wilczek, Glashow,, and 't Hooft doesn't seem to me to be much of a fan of string theory unification. I have no idea what Kobayashi and Maskawa think.

In recent years I've had the honor of discussing the issue with many eminent physicists, including a sizable number of Nobelists. They each have their own take on the situation, I think it's a mistake to simplify any of their views to "for" or "against". One thing to keep in mind is that there isn't any real disagreement about the fact that string theory has not worked as a unified theory. Some remain optimistic that this will change, others are very skeptical.

To get back to the topic of this posting, the misleading story about string theory and experiment. There I don't see any disagreement. I can't think of any physics Nobelist who would want to defend the "string theory finally makes contact with experiment" headlines as not being misleading.

67. **Joey Ramone**
February 23, 2009

Yes–like the String Theorists of your era, Dexy's Midnight Runners had all the funding in the early eighties. They had all the lighting, intricate stagesets, professional choreography, fx, makeup & hair, complex story, and cool costumes:
http://www.youtube.com/watch?v=RXLHUThBib8

All we had were our leather jackets and a single camera which didn't move, and we didn't even dance:
http://www.youtube.com/watch?v=wMD7Ezp3gWc
The only time I ever met Weinberg, T'hooft, Nambu, Gross, and Gell Mann was during the filming of this video. You can see them around 1:00-1:10.

When one juxtaposes these two videos it is quite surprising that we–the Ramones–were the ones who ended up in the Rock'n'Roll hall of fame–not DMR. I would have never guessed, as you know how those "hall of fame" things go. Twenty years from now, when people watch an Elegant Universe, they will probably be surprised that nobody won a Nobel for String Theory.

68. **Aaron Bergman**
February 24, 2009

You can talk about the Rock and Roll hall of fame all you want, but you never had a fiddle in your band. Never had and never will.

69. **H-I-G-G-S**
February 24, 2009

Peter,

Perhaps Yang and Mills were hoping to develop a theory of the strong interactions. Perhaps not. Where is the evidence that they were? You don't cite any statements from their actual paper. You don't direct me to any historical documents where they were interviewed about their thoughts. If you did I would be happy to have a look and I might be convinced that this was indeed their motivation. Instead you argue by appeal to a higher authority, in this case Gross and Weinberg. Of course when they argue about the importance of string theory you do not agree with them, but when they support a point you like they are suddenly experts who cannot be disputed. Gross was 13 years old when the Yang-Mills paper was published. Why do you think he should know what they were thinking?

PH

70. **Peter Orland**
February 24, 2009

H-I-G-G-S,

I once read the Yang-Mills paper when I was much younger (though I was probably older than thirteen. Maybe I was twenty. Or seventy. I can't recall). They were trying to describe vector mesons, which were regarded as fundamental mediators of the nuclear force (along with the pion). Sakuri and other people were thinking of the Yang-Mills particle as rho mesons.

The mass was inserted by hand, since they didn't know about Y-O-U at that time.

As far as I know, the first people to try to apply the idea to the weak force were Schwinger and Glashow (his student).

71. **Pawl**
February 24, 2009

Re: Will's comments on unification and particle physics

There is a premise here — which seems to be unquestioned by many superstringers — that the problem of quantizing gravity is enough like a particle physics problem that it will be solved by a particle-physics-type approach. True, the electromagnetic, strong and weak interactions were all described by quantum field theory, but we may need something of a different (and arguably deeper) character to tackle gravity — which affects causal relations in a way the other forces do not.

From this point of view, one should be especially cautious about particle physicists who endorse some particular quantum gravity program, because there is the question of whether they are so conditioned by successes in their own field they may not appreciate the very real possibility that it may be necessary to move beyond it.

It might be interesting to consider how string theory is viewed by relativists. While there certainly are some relativists who do string theory, it seems to me that on the whole relativists have at best a wait-and-see attitude towards string theory.

(I agree with Peter that citing what other people think is really a distant second to having an informed opinion of one's own. I am trying to make the point that to have an informed opinion it would be a mistake to rely only on expertise in particle physics.)

72. **Will**
February 24, 2009

Pawl,
I was answering Peter's point that senior faculty at Harvard and Princeton were overwhelmingly against string theory.

I was pointing out names just to show that, in fact the balance of people with serious credential tips towards string theory and others who are skeptical make constructive arguments as oppose to whining about what a new scientists magazine thinks about string theory because a string theorist did not do a "good job" in a press conference. Again, any one string theorist is not representative of the entire field and these are mind numbing arguments.

Pawl, I however agree with you that everyone should make an informed decision and forum such as this almost inevitably engage people in discussion which has less to do with science but press releases, who said what and so on. I have said repeatedly, that
scientific debates are won in black boards as opposed to sociological comments in blogs or press releases.

Hence, I am urging people to make more scientific arguments as opposed to just playing the game which now seems old and not at all constructive.

73. **woit**
February 24, 2009

Will,

I never claimed that "senior faculty at Harvard and Princeton were overwhelmingly against string theory", something which is very much not true. I just wrote that if all you care about is credentials, they're the people you should be listening to, not that they as a group agree with me about string theory or anything else.

74. **Peter Woit**
February 24, 2009

H-I-G-G-S,

Wow. The refusal of some particle theorists to admit it when they're wrong about something is nothing short of spectacular.

Actually I did cite a relevant statement in the paper. My claim that Yang and Mills were thinking about the strong interactions is based upon my knowledge of the history of the period, not on the quotes from Gross and Weinberg. I quoted them because they are very serious scholars, with a deeper knowledge of the history than my own, since they are personally closer to it.

This whole topic seems worth a blog posting…

75. **Pawl**
February 24, 2009

Will,

You'll notice that my arguments are either directly scientific or go to the question of whether the authorities others cite are likely to have considered all pertinent scientific issues.

If you do want to encourage rational argumentation, I suggest you write courteously, avoiding terms like "whine."

76. **Mitch Miller**
February 24, 2009

Peter wrote:
"This whole topic seems worth a blog posting"

I know you probably don't take requests but some posts about the historical development of particle theory topics and how people reacted to things when they were first presented would be very interesting (i think) to alot of your readers and is something that is not found in detail very easily online. So if you were leaning in that direction I think it could make for some good posts.

77. **Sebastian Thaler**
February 24, 2009

Hi Peter,

I thought you'd get a kick out of this job posting for a "short-term science research assistant" that recently appeared on Mediabistro.com. Whoever posted the job lumps string theory in with meditation, clairvoyance, and psychokinesis:

http://www.mediabistro.com/joblistings/jobview.asp?joid=87703&page=1

78. **TCO**
March 1, 2009

pop culture has already moved on and decided that string theory is unphysical and untested. you won the meme war. don't let some Motl dead enders dissuad you. Even if the job holding onto professors don't agree…the public has already written of string theory. It's stock price is in the crapper. Trading on the pink sheets now. Even just regular physicists think so.

79. **Troy**
March 1, 2009

Peter,

TCO and Joey Ramone illustrate my point very well. They both talk about popular culture. It might be the case that the standing of string theory in pop culture is declining but just as it did not matter one bit what the standing of string theory is in pop culture when this standing was high, it does not matter one bit now when this standing is low. This is simply because pop culture and science are two different things and, for me at least, science is infinitely more important when discussing the merits of a scientific field.

There is nothing wrong with pop culture. In fact, I like it a lot. But it has nothing to do with science.

And in the last years you have contributed a lot to pop culture but exactly zero to science. As soon as you decide to contribute to science again I'd be more than happy to change my opinion.

You, in fact, promised almost a year ago that you will write up your ideas on BRST in the form of a paper by the summer of 2008:

http://www.math.columbia.edu/~woit/wordpress/?p=673&cpage=1#comment-36514

At that time you still recognized that writing this blog is less important than science itself. You wrote "I probably should be spending less time on the blog…." and it seemed you wanted to dedicate more time to science. This seemed encouraging but now there is still no paper, not even an arxiv posting and you even seem to have changed your mind and you started to think that blogging is part of your scientific activity.

What happened? What made you change your mind? Why don't you say today that "I should be spending less time on blogging and more on writing science research articles."?

Given your super paranoid reactions, let me reiterate:

1. I'm not attacking you.
2. I'm not saying you are not a scientist
3. I'm not questioning your credentials (in fact, I wrote that your credentials are strong)
4. I'm not bringing in personal/character/etc issues into the discussion
5. I'm not posting anonymously because I'm "hiding"
6. I'm not a string theorist (in fact, I have never written a paper on string theory)
7. I'm writing anonymously because I believe it's possible to discuss the merit of my posting on merely the posting itself, regardless of who the author is

Best,
Troy

80. **Peter Woit**
March 2, 2009

Troy,
Your obsesssion about this topic really is creepy. Latest news about the BRST project is that I spent yesterday working on rearranging the paper, based on some better understanding of what is going on that the last couple months of work has led to, this week hope to get more written.

81. **Troy**
March 2, 2009

Peter,

I'm eagerly waiting for the arxiv preprint, since this is a very interesting topic!

Best,
Troy

On History

February 24, 2009
Categories: Uncategorized

When learning about various ideas in mathematics and physics, I'm always fascinated by the history of these ideas and eagerly read whatever I can find on the subject. Partly this is because my understanding of ideas is often enlightened by finding out where they came from, especially what problems they were invented to solve. It's also true that the history of these fields is a huge and remarkable story, in many ways far more intricate, subtle and surprising than any novel ever written, and can be appreciated as such. It's quite possible that I've spent more time on this than is healthy, since there are good reasons for the fact that many scientists wait until late in their career to develop serious historical interests. Time spent studying history is not time spent developing new ideas.

One peculiar aspect of the present state of particle theory is that our current best fundamental physical theory, the Standard Model, is getting so old that fewer and fewer active physicists have any first-hand knowledge of its history. To a large degree, this history spans just about exactly a quarter-century, from renormalized QED in 1948 to asymptotic freedom in 1973. Before 1948 all we had were first-order calculations in QED, by 1973 the full Standard Model was in place. Physicists who finished a Ph.D in 1973 are now in their early 60s and soon will be getting to retirement age. First-hand understanding of where the Standard Model came from is now not part of the background of particle physicists in the most active stage of their careers.

One reason I started thinking about this is a recent exchange in the comment section of the last posting, sparked by my referring parenthetically to the fact that Yang and Mills had developed Yang-Mills theory (in 1954) in the context of trying to describe the strong interactions. The SU(2) gauge theory they wrote down didn't work for this purpose, since what was needed was an SU(3) theory of quark colors, something that had to await at least the discovery of quarks. The SU(2) gauge theory of isotopic spin they were considering ultimately did find a role in the electroweak part of the Standard model, but this idea got started only after the symmetry properties of the weak interactions became clear later in the 1950s. Schwinger and his student Glashow were among the first to work on this idea, with the correct theory not appearing until 1967 after the role of the Higgs mechanism was understood.

Anonymous commenter "H-I-G-G-S" reacted to my allusion to this history as follows:

> You said "Actually, Yang-Mills theory was invented to describe part of the standard model (the strong interactions)"
>
> Not true. Go back and read the original paper.

Well, I have read the original paper, as well as a lot of secondary literature about it. The paper begins with a discussion of the symmetry properties of the strong interactions of nucleons and pions, which was the main topic of the day in 1954, due to the large number of strongly interacting states being discovered at accelerators. Nothing about the weak interactions, which was a different topic, with the symmetry properties of such interactions not understood until a few years later.

I devoted a few minutes to Googling "Yang-Mills" and "history", and turned up quotes from David Gross and Steven Weinberg explicitly stating that the strong interactions were the motivation for Yang and Mills and posted comments with those. It seems though that "H-I-G-G-S" is not satisfied with this, recently responding:

> Perhaps Yang and Mills were hoping to develop a theory of the strong interactions. Perhaps not. Where is the evidence that they were? You don't cite any statements from their actual paper. You don't direct me to any historical documents where they were interviewed about their thoughts. If you did I would be happy to have a look and I might be convinced that this was indeed their motivation. Instead you argue by appeal to a higher authority, in this case Gross and Weinberg. Of course when they argue about the importance of string theory you do not agree with them, but when they support a point you like they are suddenly experts who cannot be disputed. Gross was 13 years old when the Yang-Mills paper was published. Why do you think he should know what they were thinking?

I had actually cited a relevant statement from the paper, but I'm not sure what if anything could possibly satisfy "H-I-G-G-S". Perhaps there is a published interview where Yang makes the kind of explicit, unambiguous statement about his motivations that "H-I-G-G-S" requires and maybe someone with enough interest can dig this up. Since "H-I-G-G-S" insists on anonymity, all I know is that he or she is from a major metropolitan area home to major universities, and appears to be a particle theorist who has been around for a while, although not long enough to know much history. Despite this, he/she has rather definite ideas about what this history is, coupled with a steadfast skepticism about any information which might indicate these ideas don't correspond to historical reality.

I don't know to what extent the case of "H-I-G-G-S" reflects the general understanding of the historical roots of the Standard Model among active theorists working on trying to extend it. Much effort on this blog has been devoted to trying to puncture the historical narrative that has solidified over the last 25 years about the supposed march forward of such speculative ideas such as extra dimensions, supersymmetry and string theory. Perhaps it would also be a good idea to worry about misconceptions concerning the history of successful parts of the subject, as well as the unwillingness of many particle theorists to give up such misconceptions.

Update: Here are some suggestions for reading about the history of the Standard Model, ordered very roughly from more popular to more technical:

- *The Hunting of the Quark*, Michael Riordan
- *The Second Creation*, Robert Crease and Charles Mann
- *Inward Bound*, Abraham Pais
- *50 Years of Yang-Mills Theory*, edited by 't Hooft
- *Pions to Quarks: History of Particle Physics in the 1950s*, edited by Brown, Dresden and Hoddeson
- *The Rise of the Standard Model: Particle Physics in the 1960s and 1970s*, edited by Hoddeson, Brown, Riordan and Dresden
- *History of Original Ideas and Basic Discoveries in Particle Physics*, edited by Newman and Ypsilantis

For the early history of gauge theory, there is

- *The Dawning of Gauge Theory*, Lochlainn O'Raifertaigh

Comments

1. **Thomas R Love**
   February 24, 2009

   This is a great time to be studying history. Besides google, there is scholar.google.com which links to papers that reference the paper you searched for, as does Phys. Rev. And most major journals are online. I can find more articles in one hour online than I used to find in a week at the library.

   I've been studying history to see where things went wrong. The introduction of quarks met with the same criticism as strings do today. The discussion of EPR through the ages is fascinating.

   Some of the most fascinating papers have no citing articles.

Yes, I am in my 60's, 63 to be precise and without the interruption of the Vietnam tour, I would have had my PhD in 1973. But then I would have been part of the establishment I am now criticizing. I am not a fan of the standard model, I am bothered by the idea that there are conserved quantities which are not defined for all particles and not conserved in all interactions (isospin, strangeness…)
and it is exciting that people long ago had the same reservations.

One of my cousins has a PhD in history and she says "Nothing changes faster that the past" both because scholars keep digging up new material but also because there are some who keep rewriting the past.

2. **anon.**
   February 24, 2009

   The widespread ignorance of the history of the ideas of particle physics is disgusting. The first application of Yang-Mills SU(2) to attempt to deal with weak interactions was by Schwinger and Glashow in 1956, see Glashow's Nobel Prize lecture here:

   'Schwinger, as early as 1956, believed that the weak and electromagnetic interactions should be combined into a gauge theory. The charged massive vector intermediary and the massless photon were to be the gauge mesons. As his student, I accepted his faith. … We used the original SU(2) gauge interaction of Yang and Mills. Things had to be arranged so that the charged current, but not the neutral (electromagnetic) current, would violate parity and strangeness. Such a theory is technically possible to construct, but it is both ugly and experimentally false [H. Georgi and S. L. Glashow, *Physical Review Letters,* 28, 1494 (1972)]. We know now that neutral currents do exist and that the electroweak gauge group must be larger than SU(2).

   'Another electroweak synthesis without neutral currents was put forward by Salam and Ward in 1959. Again, they failed to see how to incorporate the experimental fact of parity violation. Incidentally, in a continuation of their work in 1961, they suggested a gauge theory of strong, weak and electromagnetic interactions based on the local symmetry group SU(2) x SU(2) [A. Salam and J. Ward, *Nuovo Cimento,* 19, 165 (1961)]. This was a remarkable portent of the SU(3) x SU(2) x U(1) model which is accepted today.

   'We come to my own work done in Copenhagen in 1960, and done independently by Salam and Ward. We finally saw that a gauge group larger than SU(2) was necessary to describe the electroweak interactions. Salam and Ward were motivated by the compelling beauty of gauge theory. I thought I saw a way to a renormalizable scheme. I was led to SU(2) x U(1) by analogy with the appropriate isospin-hypercharge group which characterizes strong interactions. In this model there were two electrically neutral intermediaries: the massless photon and a massive neutral vector meson which I called B but which is now known as Z. The weak mixing angle determined to what linear combination of SU(2) x U(1) generators B would correspond. The precise form of the predicted neutral-current interaction has been verified by recent experimental data. …'

   February 24, 2009

   Peter, this H-I-G-G-S fellow is a typical internet troll, I wouldn't waste time on him. Though he did allow you to make a point I suppose…

   Thomas R Love, I'm not sure I understand your reservations about the standard model. Isospin and strangeness are approximately conserved quantities (that is, they are not conserved, but they almost are). And surely they are defined for all particles? The strangeness is the number of strange quarks minus anti strange quarks, for example. Or am I mixed up?

4. **Peter Woit**
   February 24, 2009

   big vlad/Thomas Love,

   Please stick to the topic of history. Again this is not a forum for people to explain their favorite unconventional ideas to the world.

5. **Michael**
   February 24, 2009

   Peter,

   Wasn't Gross' remarks made at a celebration of Yang's 70th birthday — was he present?

6. **Peter Woit**
   February 24, 2009

   Michael,

   Yes, that's true. Almost certainly Yang was there.

7. **Pawl**
   February 24, 2009

   I agree that there's a great deal of interest attached to sorting this out.

   I have a general impression (perhaps someone can correct me about this) that in the mid-50's there was less theoretical urgency felt in moving beyond the four-Fermi theory of weak interactions than in trying to develop the theory of strong interactions. The reason was that the non-renormalizability of the theory was not widely perceived as a fundamental failing (only later did that general sentiment develop), and, given the weakness of the force, the f-F treatment seemed a good start. On the other hand, the strong force was — well, strong, and so worries about finding a consistent way of doing perturbations were much more timely.

8. **Peter Woit**
   February 24, 2009

   Pawl,

   I think what's most relevant is that in the early 1950s there was a huge amount of experimental data coming in about the strong interactions, with all sorts of new particle states being discovered, and hardly any theory at all to account for them. Because of this, just about all theorists those days were focused on the strong interactions. There was much less data concerning weak interactions, and the four-fermi theory accounted for what was known, with the question of higher loop calculations in that case a purely academic one.

   Yang and Mills didn't need to explain in their paper that they were thinking about the strong interactions, that would have been obvious to everyone. If they were thinking at all about the weak interactions, they would have mentioned that explicitly.

9. **Pawl**
February 24, 2009

Peter,

Thanks. I think we're saying almost the same thing.

10. **Shantanu**
February 24, 2009

Peter and others , I agree history of physics is a fascinating subject.
In cosmology, history of cosmic inflation is also very interesting
and quite differnent form what appears in textbooks with very important papers by Kazanas, Starobinsky and Sato (and probably others) before
Guth's paper.

11. **publius**
February 24, 2009

On the question of wether or not is healthy to devote time to study history of physics, i believe that history itself (a "one loop" reflexion:) shows that really deep thinkers like Galileo, Newton, Maxwell or Einstein were quite interested an well informed on that respect. Probably the usefulness of that kind of knowledege depends on what yo do: if you are a problem solver working on a given predetermined conceptual background (a "local thinker", a man of detail)it is probably OK not to know anything about history, but if you are a big picture "strategic" thinker, you better be aware of your discipline history.
At any rate, any self respecting phys grad student should have some exposure to phys history, at least as an antidote to the dreadful possibility of being some sort of phys "energyzer bunny" stuffed with batteries and set to go in the place and direction of choice of his PhD advisor, as many wannabe string theorists in this days.

12. **McPint**
February 24, 2009

I think Abraham Pais's Inward Bound has something to say on this. In the discussion on page 585 of the introduction of Yang-Mills theory the discussion over the next few pages is exclusively phrased with respect to nucleons and to vector mesons as the exchange particles. This surely gives the context for the discussion above.

Perhaps also reference 172 in that chapter also has something interesting to say – this reference is "C.N. Yang, Selected Papers 1945-1980, p 19, Freeman, San Francisco 1983" where the page reference describes Yangs recollections of a seminar he gave in Princeton where Pauli was very critical and Pais was also present.

This would perhaps give the definitive answer?

13. **Sumar Ongi**
February 24, 2009

> Yangs recollections of a seminar he gave in Princeton where Pauli was very critical and Pais was also present.

that story is so well-known, yet so funny… Pauli was asking Yang about the mass of the intermediate vector mesons (now gluons), probably knowing that they were massless and therefore a killer for the theory (there are no massless hadrons…). Yang responded he wasn't sure of the answer. Apparently, Pauli was so insistent and hostile with his questions that Yang just sat down at the front row and stopped talking! Then Oppenheimer encouraged him to continue delivering his talk, which he did.

14. **Indrajeet**
February 24, 2009

Hi,
Can anybody suggest me a good book on history of particle physics?…..Other than Pais' "Inward Bound"

15. **D R Lunsford**
February 24, 2009

Pauli did it first, before Yang-Mills, in some letters to Pais, "Meson Nucleon Interaction and Differential Geometry" (written "to see what it looks like", in three days in July. See O'Raifeartaigh, "Dawning of Gauge Theory". Like Gauss, he did not publish.

-drl

16. **sz**
February 25, 2009

Peter,

I have a copy of "Selected Papers by C.N.Yang, 1942-1980", in which Yang made extensive comments on every paper there, mainly with historical interests. The comments on the Yang-Mills are on p19…Maybe this gentleman H-I-G-G-S can go to the library to find it out.

17. **chris**
February 25, 2009

http://universe-review.ca/R15-21-YangPauli.htm

18. **Rajagopal**
February 25, 2009

@Indrajeet: I found 'Second Creation' by Robert Crease and Charles Mann to be a very interesting history of particle physics etc. Covers the period from early 20th century to early eighties (only) – very little, if not nothing, about string theory IIRC. Maybe others (physicists in particular) can comment on how good an account of history it is.

Rajagopal

19. **Cormac O Raifeartaigh**
February 25, 2009

Hi Peter, interesting post.
In the book 'It Must be Beautiful' (Granta Books), Christine Sutton has a lovely chapter on Yang-Mills theory, outlining the development of the theory, its initial failure and its modern use in particle physics.
There is also a nice reference to Lochlainn's book on the history of gauge theory!

20. **DB**
February 25, 2009

Chris Quigg deals with this issue in his "Gauge Theory of the Strong, Weak and Electromagnetic Interactions", p.55. where he cites the original 1954 paper by Yang and Mills.:

I'l paraphrase his remarks a bit:
"A free nucleon Lagrangian, written in terms of the composite fermion fields for the proton and neutron, has an invariance under global isospin rotation, and the isospin current is conserved. Thus one has complete freedom in naming the proton and the neutron (in the absence of electromagnetism), but only at a single point in space-time. Once freely chosen, the convention must be respected everywhere throughout space-time.
This single restriction may seem, as it did to Yang-Mills, at odds with the idea of a local field theory. Furthermore, we have seen that electromagnetism possesses a local gauge invariance, and that by imposing a local symmetry on a free-particle Lagrangian it is possible to construct a correct theory of electrodynamics. In analogy with electromagnetism we are led to ask whether we can require that the freedom to name the two states of the nucleon be available independently as every space-time point. Can we, in other words, turn the global SU(2) invariance of the free field theory into a mathematically consistent local SU(2) invariance"

He then goes on, following Yang-Mills, to construct the non-Abelian Yang-Mills Lagrangian for the nucleon, pointing out the standard defect, namely that as a consequence of local gauge invariance, the Yang-Mills quanta are massless vector bosons and of infinite range and therefore cannot serve as a successful phenomenological description of the strong nuclear force which involves the exchange of massive particles.

So of course, as you pointed out, Yang-Mills were trying to develop a phenomenological description of strong interactions, specifically a SU(2)-isospin gauge theory, but hit a brick wall once the quanta their theory produced were massless vector bosons.

Lochlainn O'Raifeartaigh (Cormac's father) in his beautiful monograph "Group Structures of Gauge Theories" also refers to the 1954 paper (p.79)

"It is now generally accepted that Weyl's gauge principle can be used to describe the strong and weak interactions and well as the EM ones by generalizing U(1) to other compact Lie groups. The first extension of the principle, to the isospin SU(2) group, was made by Yang and Mills (1954)"

21. **Christine**
February 25, 2009

Moriyasu's book "An Elementary Primer for Gauge Theory" is the shortest path to learn the subject that I know of and it nicely outlines the history involved.

> In 1954, C. N. Yang and R. Mills took the bold step of proposing that the strong nuclear interaction be described by a field theory like electromagnetism which is exactly gauge invariant. They postulated that the local gauge group was the SU(2) isotopic-spin group.
>
> (…)
>
> On the tenth anniversary of the Yang-Mills theory, there was still no successful gauge theory of the nuclear forces. A significant breakthrough had been achieved, as we saw in chapter VII, by finally solving the problem of the zero gauge field mass through spontaneous symmetry breaking. And the weak interaction, not the strong force, appeared to be the best candidate for a gauge theory. Yet the insurmountable difficulty of the "non-renormalizable" infinities still plagued both the weak interaction and quantum field theory. Nevertheless, the final step toward a successful gauge theory was taken almost simultaneously by Steven Weinberg at MIT and Abdus Salam at Imperial College, London. They boldly ignored the problem of the "non-renormalizable" infinities and instead proposed a far more ambitious unified gauge theory of the electromagnetic and weak interactions.
>
> The idea of unifying the weak and electromagnetic interactions into a single gauge theory did not originate with Weinberg and Salam. It had been suggested much earlier by Schwinger and Glashow. As we noted in chapter VI, Glashow and Schwinger had also pointed out that the leptons should carry weak isotopic spin like the mesons and baryons involved in the weak decays. Thus much of the detective work had already been done in untangling the weak interactions and laying the logical foundation for a gauge theory. However, the essential ingredient missing in all of these earlier theoretical attempts was an understanding of the origin of the gauge field masses. Weinberg and Salam were the first to realize that the Higgs mechanism could supply the last piece of the puzzle for a unified gauge theory.

22. **Indrajeet**
February 25, 2009

Rajagopal,
Thanks a lot. I will have a look at it.

23. **Peter Woit**
February 25, 2009

I've added to the posting a list of books that I've found most useful for learning some of the history of the standard model.

24. **Tony Smith**
February 25, 2009

Peter, would you consider adding to your list of books

Constructing Quarks: A Sociological History of Particle Physics
by Andrew Pickering (Chicago 1984)

Tony Smith

Yang-Mills is sometimes called Yang-Mills-Shaw theory on this side of the pond:

http://www.hull.ac.uk/php/masrs/reminiscences.html#Anchor-3.4-55015

26. **H-I-G-G-S**
February 25, 2009

Peter and minions,

I may not have been clear, or perhaps you are deliberately misunderstanding me. In either case it might be good if I amplify my remarks. I'm quite aware that isospin is a symmetry of the strong interactions and that Yang and Mills were discussing strongly interacting particles like the neutron, proton, and pion. They were obviously trying to make isospin a local symmetry in the context of the strong interactions. So I'm sure they viewed what they were doing as related to the strong interactions. If that's all you mean by saying that "Yang-Mills was invented to describe the strong interactions" then I have no quibble with you. But your statement, and the statement in many of the quotes in the comments sound quite a bit stronger. It makes it sound like they were trying to develop a full theory of the strong interactions based on gauging isospin. While this has a certain historical resonance to it since Yang-Mills theory ended up being the basis for QCD, I suspect it overstates the case. For example, at the time the strong interactions were known at large distances to be mediated by pion exchange. Yang and Mills make no attempt to describe the pion or its affects in their theory. They don't try to describe the neutron or the proton. What they do is to gauge isospin and then speculate that the apparently massless isovector spin one particle they find might acquire mass by some mechanism. So it seems they were trying to describe features of the strong interactions, and perhaps new particles resulting from the strong interactions, but I still see no evidence that they had any reason to think they were developing a full theory of the strong interactions.

What undoubtedly gave their theory a strong boost was the discovery 7 years later of a massive spin one isovector partice, the rho meson, just as predicted except for the awkward question of its mass. This, along with the work of Sakurai around 1960 gave Yang-Mills theory a strong boost, but even then it was used to describe features of the strong interactions such as Vector Meson Dominance and not as a comprehensive attempt to describe the full spectrum and structure of the strong interactions.

In general I suspect that history is often more complicated than the "just so" kind of descriptions that Christine quoted which make it sound like Yang and Mills almost had QCD except for using SU(2) instead of SU(3).

27. **Peter Woit**
February 25, 2009

H-I-G-G-S,

The historical record of the context of the Yang-Mills paper is unambiguous: they were hoping to get a theory of the strong interactions with a gauge theory of isospin, which they showed would imply that interactions were due to exchange of isospin 1 vector mesons. This idea doesn't work, which they clearly realized since they didn't pursue it after the original paper.

Your comments here about this being "not true", telling me to go read the paper, that you "don't believe the claim that they were trying to describe the strong interactions", that maybe they were not trying to develop a theory of strong interactions, and that Gross might not know what he was talking about since he was only 13 in 1954 are just completely ridiculous. All you are doing is providing an amusing example of how some particle theorists don't know the history of their field, are quick to accuse others of not knowing what they are talking about, and completely incapable of admitting it when they make a mistake.

No one claims anywhere that Yang and Mills "almost had QCD", you're trying to justify your own absurd comments by putting sillier ones in other people's mouths.

28. **Christine**
February 26, 2009

H-I-G-G-S wrote:

In general I suspect that history is often more complicated than the "just so" kind of descriptions that Christine quoted which make it sound like Yang and Mills almost had QCD except for using SU(2) instead of SU(3).

No. I just included some excerpts that I thought being relevant for the discussion, but evidently one should read the book to have the complete outline that Moriyasu offers. In any case, I hope the following excerpts will complement my previous ones:

> Although the Yang-Mills theory failed in its original purpose, it established the foundation for modern gauge theory. The SU(2) isotopic-spin gauge transformation could not be regarded as a mere phase change; it required an entirely new interpretation of gauge invariance. Yang and Mills showed for the first time that local gauge symmetry was a powerful fundamental principle that could provide new insight into the newly discovered 'internal' quantum numbers like isotopic spin. In the Yang-Mills theory, isotopic spin was not just a label for the charge states of particles, but it was crucially involved in determining the fundamental form of the interaction.
>
> (…)
>
> In retrospect, it is clear that both the original theory of Weyl and the Yang-Mills theory failed because they were too early for a gauge theory at their respective times. When Yang and Mills proposed their revolutionary idea for an SU(2) gauge theory of the strong interaction, an adequate understanding of the essential properties of the nuclear forces was still lacking. The final successful rediscovery of gauge theory had to wait nearly ten more years for several crucial experimental and theoretical developments to provide the necessary clues.

From my previous quotes and the present ones, I see in no place any claims that you suggest. I agree that Moriyasu's book is a very concise and elementary treatment of gauge theory but I fail to see where he got history unbalanced. Since I just included excerpts, reading the book is advisable. In any case, Peter has included a nice list of references on the matter.

Thanks,

Christine

29. **Christine**
February 26, 2009

I still see no evidence that they had any reason to think they were developing a full theory of the strong interactions.

Cao in his "Conceptual Developments of 20th Century Field Theories" puts the matter under two main motivations (pages 273-274):

> The Yang-Mills theory emerged entirely within the framework of the quantum field programme, and was motivated by two considerations. **First**, more and more new particles were discovered after the Second War, and various possible couplings among those elementary particles were being proposed. Thus Yang and Mills felt it necessary to have some principle to choose a unique form out of the many possibilities being considered. The principle suggested by Yang and Mills is based on the concept of gauge invariance, and is thus called the gauge principle. **Second**, in choosing a proper gauge symmetry, Yang and Mills were driven by curiosity to find the consequences of assuming a law of conservation of isospin, which was thought to be the strong interaction analogue of electric charge.

Since I am not certain whether this conciliates Peter and H-I-G-G-H's points of view, I let the matter with you.

30. **Peter Woit**
February 26, 2009

Lubos weighs in supporting H-I-G-G-S against Gross and Weinberg here

http://motls.blogspot.com/2009/02/history-of-yang-mills-theory-and.html

According to him, the desire of Yang and Mills to come up with a theory of the strong force had nothing to do with their gauging isospin. He does draw some historical lessons, noting correctly that a theory developed for one purpose may turn out not to work for that, but find use elsewhere. For instance, a theory once thought to be a spaceship capable of giving a TOE may turn out to be a toaster capable of approximately describing the viscosity of a quark-gluon plasma….

31. **Peter Woit**
February 26, 2009

Tony,

The list I put up is certainly not exhaustive, and "Constructing Quarks" is also a good history of subject. There are quite a few others, but I'll leave that list as a personal one of the things I most enjoyed or found useful.

32. **H-I-G-G-S**
February 26, 2009

Peter,

Your statement "The historical record of the context of the Yang-Mills paper is unambiguous:" is certainly true, but it is also not what we are talking about. I agree that the context is clear, but the motivation and thoughts of Yang and Mills, which is the topic under discussion, are not.

The historical record is rarely unambiguous on any topic, and you have yet to cite a single iota of primary material, by which I mean statements in the original paper or interviews with Yang and Mills or their colleagues near the time they were doing the work. I'm just as well acquainted with the secondary material as you are, but its not much help in trying to figure out what Yang and Mills were actually thinking at the time.

33. **Peter Woit**
February 26, 2009

H-I-G-G-S,

This is just ridiculous. Yang, like almost every other major theorist of the day, at that time was trying to find a theory of the strong interactions. The paper explicitly mentions this context, and every knowledgeable person who discusses it describes it as an effort to come up with a strong interaction theory, except you.

You completely ignored the what I quoted from the paper itself:

"We then propose that all physical processes (not involving the electromagnetic field) be invariant under an isotopic gauge transformation…"

What physical processes do you think he's talking about? If it's not the strong interactions, it's gravity or the weak interactions. If you're claiming that Yang had the idea of getting a weak interaction theory by gauging the right SU(2) a couple years before Schwinger, that's a dramatic new advance in the history of the subject. Except I don't think anyone will believe it except you.

At the end of the paper, they discuss experimental limits on the mass of the vector boson in their theory. They explicitly say it should decay into pions with a lifetime less than 10^-20 seconds. This is a strongly interacting particle.

34. **D R Lunsford**
February 26, 2009

It's always astonished me how ignorant people are of physics history, how quick to make pronouncements when it's patently obvious that they have never bothered to even learn what the papers were, much less read them. This is hardly new – it was true when I was in school 25 years ago.

Of course everything you say about Yang-Mills and their motivation – which had to be enormously strong in the face of Pauli's criticism (he himself had tried the idea a year or so earlier but did not publish it) – is entirely correct.

-drl

35. **Thomas**
February 26, 2009

Yang makes a few remarks concerning his motivation in his "Selected Papers (with commentary)" book. He says that as more and more hadrons were discovered there was clearly a need to find a general principle that would constrain the possible interactions, and he was looking at local isospin gauge invariance for this purpose. He also remarks that Pauli's unpublished note was called "Meson-Nucleon Interaction and Differential Geometry".

This idea is not totally wrong, by the way (if the Higgs mechanism is added). If the rho meson is a gauge particle, then the rho-pi-pi, rho-N-N, etc couplings are related. These relations are experimentally satisfied to a reasonably good (20%, or so) accuracy (for reasons that are not understood very well).

36. **Sumar Ongi**
February 26, 2009

> This idea is not totally wrong, by the way (if the Higgs mechanism is added).

The idea of gauging isospin and making the rho triplet massive by means of the Higgs mechanism was, I think, what Weinberg had in mind before realizing that it could be applied more successfully to leptons.

In any case, isospin symmetry cannot be spontaneously broken in QCD (like chiral symmetry is), according to a theorem by Vafa and Witten.

37. **H-I-G-G-S**

February 26, 2009

Thomas,

The reason for those relations is starting to be understood as a consequence of string dual models of QCD where isospin is in fact a gauge symmetry in the higher-dimensional dual theory.

38. **Shantanu**
February 27, 2009

Peters and others , see these talks at PI which does touch upon some historical aspects.
http://pirsa.org/09020027/
http://pirsa.org/09010009

39. **a quantum diaries surivivor**
February 27, 2009

Hi Peter,

I think the way we study even scientific matters in Italy is different from the way these are studied elsewhere. Maybe this is a hindrance, maybe it is an advantage – but I feel cultured by having studied the Standard Model not as it is now, but how it was developed – and I was 7 years old when the theory was sealed.

During my studies, by no means deeper than those of most of my italian colleagues, I for instance took great pleasure in understanding in deep detail what drove the choice of V-A over S-T, for instance, and the historical developments of the mid fifties.

As for Yang-Mills theory: I have never had any doubt that their aim was understanding strong interactions. I thank Professor Antonio Bassetto for teaching me a thing or two in his powerful course of Quantum Field Theory.

Cheers,
T.

40. **Ghame**
February 27, 2009

H-I-G-S-S, that's interesting. Is SU(6) symmetry also a gauge symmetry in the dual model?

41. **H-I-G-G-S**
March 1, 2009

Ghame,

Which SU(6) do you mean? The SU(6) of six flavors (u,d,s,c,b,t) or the non-relativistic SU(6) mixing rotations and isospin?

42. **Ghame**
March 2, 2009

H-I-G-G-S, I meant the nonrelativistic SU(6). The reason why I asked is that the octet meson-octet baryon-decuplet baryon couplings obey SU(6) with pretty good accuracy. So, if the pretty badly broken isospin relation between rho-pi-pi and rho-N-N couplings comes from a gauge symmetry, why not the SU(6) relation for decuplet couplings? Sure, SU(6) is not an internal symmetry so it seems unreasonable for it to be a gauge symmetry but,t what do I know about dual models?

HEP Budget News

February 24, 2009
Categories: Uncategorized

These are dramatic times for news about the US HEP budget, with the FY2009, FY 2010 budgets and stimulus package all coming together at the same time. The final stimulus package was very favorable for DOE and NSF, providing an extra $1.6 billion for DOE science and $3 billion for NSF.

Today there's a draft FY2009 budget out of Congress, news about it here from Adrian Cho at Science magazine. HEP at DOE was down in FY2008, at $721 million (after a $32 million supplemental appropriation). For FY2009, which is half over, the draft budget has $796 million. There should be stimulus package funding on top of that. A proposed FY2010 HEP budget is being presented to OMB this week, and the President's FY2010 budget proposal to Congress should be released in April. In the same draft, NSF research will get an overall increase of $362 million to a total of $5.18 billion (see here).

Today HEPAP is meeting in Washington, with presentations starting to appear online here. There are no decisions yet about what the supplemental funds will be used for, but according to the slides the guiding principles are to accelerate ongoing construction projects and update labs, increase operations and support of experiments at user facilities like Fermilab, and fund "selected research programs", minimizing commitments in out-years. A program to support graduate students and early career scientists is under discussion.

More from HEPAP and more details about the FY2009 budget should be available soon.

Update: An outline of the FY2010 budget proposal from the President is now available. The proposed NSF budget is $7.045 billion, an 8.5% increase from the recent FY2009 omnibus legislation. The $3 billion from the stimulus package is on top of this. No detailed numbers, but priorities listed include "substantial increases for NSF's prestigious Graduate research Fellowship and Faculty Early Career Development programs." and increased "support for promising, but exploratory and high-risk research proposals that could fundamentally alter our understanding of nature, revolutionize fields of science, and lead to radically new technologies." Sounds kind of like FQXI….

   Hi,
   This might be irrelevant here. But the list of speakers for Strings 2009 is out on its website.

Yang-Mills and Wikipedia

February 26, 2009
Categories: Uncategorized

I was recently looking up references about the history of Yang-Mills theory in order to write about it here, and one thing I ran into was the Wikipedia entry for Yang-Mills theory . It has three sections, the first two of which are standard material, but I was surprised to notice that the last section is completely unconventional, promoting the ideas of Marco Frasca and referencing two of his papers. It was written by an anonymous "Pra1998", who I'm guessing is Frasca himself.

I've never tried to edit Wikipedia entries before, but I thought it would be a good idea to remove this material, which is not the sort of thing that belongs there. My edit was immediately reversed. I tried again, justifying this in the discussion section, but the material is still there. At this point, I give up, lacking time to deal with this and any understanding of what mechanisms are available in Wikipedia to deal with such a situation.

Over the last few years I've been finding myself consulting Wikipedia entries more and more, especially ones on mathematics. The quality of the mathematics entries is often shockingly high. In the past if one ran into mention of some mathematical concept one didn't know about, tracking down a readable account of it was often insanely difficult. Now, one can often just look it up in Wikipedia and find a well-written, concise explanation of just the sort needed. It's a wonderful and incredibly valuable resource, and I'm mystified about how such a high quality is achieved and maintained. I hope the same mechanism, whatever it is, can work for the Yang-Mills entry.

Comments

1. **Marco Frasca**
   February 26, 2009

   Dear Peter,

   I have not appreciated your behavior. What is present in that section is a classical solution of Yang-Mills equations that is also present in the Smilga's book

   http://www.amazon.com/Lectures-Quantum-Chromodynamics-V-Smilga/dp/9810243316/ref=sr_1_1?ie=UTF8&s=books&qid=1235660829&sr=8-1

   These are solutions with all equal components. Also the title of the section gives immediately hints of the content. You can remove, as I have already said, all the references about my work and the section still gives useful information that you arbitrarily removed without any clear judgement.

   This is unacceptable and relies on your authority. No good for someone criticizing this kind of behaviors.

   Marco

2. **Peter Woit**
   February 26, 2009

   Marco,

   I see you don't deny being the author of this material. I've no interest in wasting time arguing with you about your ideas, here or anywhere else. I'll just point out that it's incredibly inappropriate for you to try and insert them into a Wikipedia entry in this way. Please do not do this.

3. **Marco Frasca**
   February 26, 2009

   Dear Peter,

   My regret now is for Wikipedia. Vandals intervention is just begun.

   Marco

4. **Turing E.**
   February 26, 2009

   Peter,

   First off, you are an expert in the field. As such, that in itself gives you some weight when it comes to editing articles in the field. Check out http://en.wikipedia.org/wiki/Wikipedia:EXPERT for more information. Be sure to put your credentials on your user page and you can even link to the Wikipedia article about you!

5. **Oakland Peters**
   February 26, 2009

   Peter,

   You are absolutely correct about the quality of the mathematics articles on wikipedia. Their quality has increased steadily over the last five years or so. At this point, it would not be a stretch to say that wikipedia is the most readable guide to mathematics on the web — at least up to the level of graduate level applied mathematics (past that point the articles tend to resume the standard level of mathematical incomprehensibility).

   However, the physics articles of wikipedia have not shown the same level of growth. This sort of disagreement has been frequent, and reoccurring.

   Why is this? Does the physics community lack general agreement on what should and should not be considered established knowledge?

6. **none**
   February 26, 2009

   In my experience, it is hopeless to try to argue with people like Frasca who don't speak English but who think they do. They just get more and more angry and incoherent.

   Wikipedia is very much overrated for just the reason you found: there is a tremendous amount of partisan wrong information on it that knowledgeable people are too busy to correct.

7. **Torus**
February 26, 2009

Somebody also vandalized The Dispersive Wiki page for Yang-Mills with this nonsense.

8. **Marco Frasca**
February 26, 2009

Just a question. Why do you consider an authority a person with just 15 publications in 26 years?

http://www-spires.fnal.gov/spires/find/hep/www?rawcmd=find+a+woit%2C+p&FORMAT=WWW&SEQUENCE=

Marco

9. **Peter Woit**
February 26, 2009

Marco,

The problem is that your idea of vandalism and other people's is very different. Most people consider what you are doing to these online encyclopedia entries, trying to stuff them with your ideas and references to your papers, to be vandalism.

Oakland,

Actually I've found even the most advanced mathematical material to be often quite good. Some of this is very specialized and inherently requires a lot of background to appreciate, but the authors do a very good job with it.

One reason for the difference may be that high-level mathematics tends to repel non-experts, whereas certain areas of high-level fundamental physics attract a large number of people who want to flood any high-quality information source with their own ideas. It's not going to be very rewarding to put work into this kind of expository writing if it's going to be vandalized by people trying to promote themselves.

10. **anon.**
February 26, 2009

I don't see why he would feel the need to spam Wikipedia with his ideas. His papers get plenty of citations from some guy who is *also* named (and this is a crazy coincidence!) Marco Frasca.

11. **A.J.**
February 26, 2009

Marco,

Please don't try to change the subject to Peter's credentials. That's a loser's tactic.

You need to make the case that the material you inserted belongs in the main article on Yang-Mills theory. I don't think this is possible. The main Yang-Mills article is supposed to be a broad overview of the most important parts of the subject. It's not an appropriate place for this sort of specialized material.

12. **D R Lunsford**
February 26, 2009

You might as well forget it with physics – there are too many people – students I suspect – with agendas. I tried with the Dirac equation and while at first the presentation was said to be clear, I found that it was almost immediately vandalized – someone who knew neither German nor Grassmann kept changing "Lineale Ausdehnungslehre" (correct) to "Lineare.." (incorrect) – it became comical to see how quickly the change back to the correct form would be reversed – so I just gave up. I suspect there are far fewer people in math who are willing to blunder ahead with no understanding. WP tends to be very good also with history and popular culture. Forget physics for the most part.

-drl

13. **Ryan Dickherber**
February 26, 2009

Maybe you can't correct the Wikipedia article, but this post is a fine substitute. Anyone who delves even slightly deeper than the Wikipedia article will come across it and realize the Wikipedia article is not the end of the story.

14. **Joe S**
February 26, 2009

Ah, a chance to be moderately on topic!

I suspect this kind of controversy is why my daughter's first year university professor warned his students not to cite authoritatively anything in wikipedia in their research.

15. **db**
February 26, 2009

I'm not qualified to argue the merits of the particular work, but wikipedia does have a no original research policy:

http://en.wikipedia.org/wiki/Wikipedia:No_original_research

My reading of it is that you don't get to post your own work, and you shouldn't get around the restraint by citing your own work.

A bit of a shame, as I have a wonderful theory about….

16. **Coin**
February 26, 2009

Dunno if this helps, but in the past when I have run into a situation where someone is deadset on keeping something incorrect in a wikipedia article, I have found that the quickest and most effective thing to do (since edit reversal wars are simply unwinnable) is visit #wikipedia on irc.freenode.net and ask for help. Wikipedia does have a layer of editors and people who understand how to navigate wikipedia's arcane conflict resolution mechanisms who seem to be legitimately interested in keeping the site clean, the problem is getting their attention…

Of course if you have a highly trafficked science blog, that probably is a good way of calling attention to problems too…

17. **Chris W.**
February 26, 2009

Well, at least the disputed section ("Integrable solutions of classical Yang-Mills equations and QFT") has been helpfully annotated. 🙂

Marco: Out of simple courtesy it seems to me that you should back off on this and present this material on your blog. Using a Wikipedia article on a major topic to present a non-standard or relatively esoteric sub-topic strikes me as a disservice to the readers of Wikipedia, and a fairly obvious attempt to freeload off of whatever claim to authority and reliability Wikipedia has managed to earn. (Of course, some may be confusing notoriety with authority and reliability.)

18. **Yatima**
February 26, 2009

Gentlemen,

Is there really a point in getting into debates about the contents of "Wikipedia" also known as "Jimbo Wales' Big Bag of Trivia Online?". I'm sure there are better venues for research or publication (maybe scholarpedia?). I do not deny that there are interesting nuggets to be found in there, however, for an (I'm afraid) realistic take on Wikipedia by "yoof" culture one need just google "wikipedia + scribblings on a truck stop bathroom wall" (readers who can't stand 'shock jock' talk should beware of clicking on the first link which is displayed).

19. **Headbomb,**
February 26, 2009

Hello, after you pointed out the problems at Yang-Mills theory, I reviewed the contributions of Pra1998, and there is another one that contains publications from Frasca (Perturbation theory, found here
http://en.wikipedia.org/wiki/Perturbation_theory). If you people could comment on these additions, it would be much appreciated:

On the Perturbation theory article

here

and

here.

Thanks to all who helped pointing out the problems in the Yang-Mills theory article. I also would like to invite you all to join the Physics WikiProject:
http://en.wikipedia.org/wiki/Wikipedia:WikiProject_Physics

20. **ll**
February 26, 2009

that's why math is my favourite subject in high school: it's fair, u can't cheat easily in front of truth and greatest mind of human beings.

21. **ML**
February 27, 2009

It is surprising for me as a young mathematician the love for Wikipedia by grown ones.

Of course Wikipedia is a great source when coming to a first approach to something that one does not know or haven heard about (specially for the youngest or for people who are far away from the neuralgic points in math research).
But nothing more than that!

The articles there have no referee, and anyone can write them trying to sell his own ideas. This is a global community and for me is ok. Why is it ok for me? Just because it is just a first approach. Then one can go to the arxiv or to mathscinet and look for a nice paper and take the effort to learn. It is a long process but we are being paid for it.

I just think that Wikipedia is the effort of many trying to help others, or even selling themselves (it does not matter), but just a tool. Like a good or not so good (depending on the people) conversation on maths.

I just hope that in the future the people will NOT end up citing wikipedia in their papers as a source!

22. **davetweed**
February 27, 2009

ML mentioned "Then one can go to the arxiv or to mathscinet and look for a nice paper and take the effort to learn. It is a long process but we are being paid for it." I entirely agree that it takes long effort to learn something in detail, but it's worth remembering that not everyone who uses even relatively abstract mathematics is being paid for it (and even if their employer accepts spending time figuring out what's already in the literature that's applicable, we may only be being paid to "learn enough to produce results from it" rather than truly understand it). I think that people tend to forget that wikipedia is an attempt to make a sort-of encyclopedia, and the same conventions ought to apply. Would you cite a printed encyclopedia article? I would only if the material was so well-known that the only reason for including a citation was to keep reviewers happy. Otherwise, there's going to be more focussed sources that are more suited to the task in hand.

23. **Engineer**
February 27, 2009

Scholarpedia actually promises to address some of the peer-review issues that wikipedia has. Unfortunately it does not have the following or diversity of articles that wikipedia has. I think that if a true scholar is concerned about the bias in the wikipedia articles, than a better way to alleviate their frustration is to volunteer to write and maintain an article on scholarpedia, especially if they have the credentials. There are some additional rules about how one gets elected/selected to be a curator, so I don't know how hard it would be to actually gain the power to control an article, but if people are interested it might be worth checking out.

http://www.scholarpedia.org/

24. **Don**
February 27, 2009

Gentleman,
I can't understand what is the real point about this post… Is there any mathematical/physical problem with those classical-YM solutions?
I am sorry, but all this argument here doesn't seems to be based just on scientific grounds…
Cheers
Don,

25. **tomate**
February 27, 2009

Italian wikipedia has the same problems:

http://it.wikipedia.org/wiki/Teoria_quantistica_di_Yang-Mills

A personal thought. I think scientific articles in wikipedia are both too technical and not enough. I mean: from a generalistic encyclopedia I would expect the articles to be accessible to laymen, at least in the first few sentences. From a specialistic encyclopedia I would expect rigour and carefulness. It seems to me that there is a sort of clash among opposite forces in Wikipedia that mediates these two positions with the result that articles are neither simple nor correct, and in the interstice anything can insert. Moreover, they almost never are fluent: different sections of an article are decorrelated one from another, there often is not a coherent development.

(Of course, it's not an easy task to simplify sentences like

Yang-Mills theory is a gauge theory of quantum field theory based on the SU(N) group.

but we have scientists who do a great job popularizing stuff.)

26. **Peter Woit**
February 27, 2009

Don,

See the discussion about this question in the talk section of the Wikipedia article. Independent of the issue of the merits of the material involved, I don't think it's hard to see that it's a very bad idea to allow people to add sections to Wikipedia entries about the most central concepts in physics promoting their own ideas and referencing their own papers.

27. **Don**
February 27, 2009

Peter, you have a point.
However, I just want to emphasize mine:
it seems me that since one can not prove that Dr. Frasca was the person that introduced the "heretical section" in Wikipedia, one should not cruficy a person that, in principle, is "Not even wrong" =)
Cheers,
Don.

28. **woit**
February 27, 2009

Someone is submitting anonymous comments here defending Frasca and attacking me, coming from the same IP address as Frasca's first comment here. They have been deleted.

29. **Peter Woit**
February 27, 2009

I'm shutting off comments on this section, and will delete any comments on this blog re: Frasca, since I don't want to waste any more of my time dealing with him, and he is flooding this blog with anonymous comments. If you want to debate his Wikipedia entry, do it using Wikipedia's discussion feature.

Worth Reading

February 28, 2009
Categories: Uncategorized

Lots of wonderful blog postings about math and physics out there worth reading, with a small sample including these:

- Jester on SUSY and the Higgs.
- Dmitry Podolsky has some very useful guests posts on various topics, including chirality on the lattice (here and here), and 3d-gravity.
- Rigorous Trivialities has lots of nice expository postings about algebraic geometry, with the latest by Columbia's own Matt DeLand on the K-theory of coherent sheaves.

From CERN, here's a report from JoAnne Hewett about the summary session discussing the Chamonix workshop on the state of the LHC and plans for getting it up and running. The current schedule, which is tight, has collisions starting in November of this year, and running for nearly a year until late 2010. To accumulate an amount of data that would allow some significant new results (about $50pb^{-1}$) should take six months or so, until mid-2010. The hope is to get to 2-300 pb^{-1} later in 2010 before shutting down. This would not allow the LHC to do better than the Tevatron on the Higgs. For that, we'll probably have to wait for data from the 2011 run. By the time this data is in, the Tevatron should have about $10fb^{-1}$ to analyze, and may already have seen evidence of the Higgs.

Also at CERN, there has recently been a conference on the topic From the LHC to a future collider. Lots of interesting talks about future possiblities, including the ILC, CLIC, colliding LHC protons with electrons, as well as the possibility of a muon collider.

More and more areas of mathematics have a blog, here's one for motivic homotopy.

Bert Schroer has updated two of his long articles that discuss both the sociology and conceptual framework of quantum string theory: String theory deconstructed, is dedicated to Philip Anderson and has a new section about history of the subject in Germany, and String theory and the crisis of particle physics, which is dedicated to Juergen Ehlers.

I hadn't realized that Physics World has a blog. Among the latest entries are two reports (here and here) about Lenny Susskind's recent talk to 700 people in Bristol about Darwin and the Cosmic Landscape. Susskind is still at it selling string theory and the multiverse to the public, no matter how unconvinced his colleagues may be:

> Just as there is a vast landscape of biological designs, our best theories of physics imply an equally vast landscape of universe designs. String theory provides an analogue of DNA for the universe and modern cosmology makes use of a principle of mutation that creates a tremendously large multiverse.

It seems that

> The central tenet of Susskind's talk was that string theorists should look to Darwin because he "set the standard for what an explanation should be like".

Funny, I always thought it was physics itself which set such a standard for the biological sciences, but I guess the idea now is to give up on that and have them be the gold standard.

While many theoretical physicists in their later years try and go for the Einstein look, according to one of the Physics World bloggers, Susskind is doing a good job of looking like Darwin.

Comments

1. **anon.**
   February 28, 2009

   The argument Susskind makes for the large size of the multiverse being a benefit to physics is basically the very small positive value of the cosmological constant. You need a large multiverse to accommodate the possibility of such a small positive value arising by accident. String theory predicts 10^500 vacuum states, so it is (allegedly) inconceivable that it doesn't contain states with suitably small positive cosmological constants. This is similar to evolution, where a vast number of DNA mutations occur, but we only get to see those which survive. The other universes in the multiverse were either unsuitable for the evolution of human observers, or else they are indeed populated by people in the same condition as ourselves, pondering on the string landscape!

   But the clever thing about evolution is that it makes falsifiable predictions. E.g. if conditions change, the individuals best able to adapt are those to survive and reproduce, so a new strain emerges which is adapted to the new conditions. If you use a new disinfectant inefficiently on bacteria, the survivors will be those which are more resistant, so you evolve a new hardy strain.

   > Funny, I always thought it was physics itself which set such a standard for the biological sciences, but I guess the idea now is to give up on that and have them be the gold standard.

   It might not be the most quantitative science, but biology does make checkable predictions, and is built upon experiments and observations, not speculation. If string theory was really analogous to evolution theory, there wouldn't be any problem.

2. **Shantanu**
   February 28, 2009

   Peter , did you find anything interesting in Maldacena's talk at
   KITP in the string theory conference?

3. **Marion Delgado**
   February 28, 2009

   This brings to my mind the question of what you thought/think of Lee Smolin's possibly evolving universes theory. For instance, selection of possible universes for having black holes?

4. **Peter Woit**
   February 28, 2009

   Shantanu,
   I haven't followed closely the topic of Maldacena's talk, CFT methods applied to LHC collider physics.

Marion,
I was never a big fan of Smolin's CNS version of the multiverse, which involved some analog of "natural selection" and was supposed to be predictive, unlike the string theory landscape. From what I remember Susskind was a critic of CNS, I'm surprised to see him invoking Darwin and natural selection. As far as I know, the string theory multiverse has an anthropic selection aspect, but no notion of Darwinian evolution.

5. **Hartford Wheeler Dealer**
   March 1, 2009

   Having recently completed Not Even Wrong, beneath the heading "Worth Reading" is perhaps not an unfitting place to post? It is a fairly rare occurrence that the author of a book is so accessible to his or her audience. Please allow the following comments.

   A central contention is that string theory has an increasingly dubious place within the realm of science. I have deliberately chosen not be buy Lee Smolin's Trouble With Physics despite knowing its reputation of more bibulously imparting similar content for the less knowledgeable learner. Only about 1/3 of the earlier book is absorbable to me though.

   Some things perhaps can be done better. Despite any impression that a scientist tends not highly prioritize floridity in their expression, your comparison (analogy/simile?) criticizing the 'Beauty' of string theory takes the form of a cliché at first. Also, an example involving postmodern humanities departments probably has multiple motivations behind it; though none of them are obvious? There may not have been ground to reference Lyotard?

   My hardcover copy, published by Basic Books, has a yellow spine and black cover. The image under the title is not explained? Maybe the small circular object represents some type of compactified multidimensional space?

   The overall lucubration is exciting. A response saying "I hope you are right" would not seem appropriate. Nevertheless, the implications have the potential to be incredibly important! Its impacts must be being felt.

6. **Robert**
   March 11, 2009

   Susskind doesn't look like Darwin, but he and Alain Connes look alarmingly similar. Has anyone ever seen them in the same room?

Living With Infinities

March 3, 2009
Categories: Uncategorized

Steven Weinberg has a new preprint out entitled Living with Infinities, which is the written version of a recent talk given in memory of Gunnar Källén. Källén was a Swedish mathematical physicist, who died in a plane accident in 1968 at the age of 42. For more about him, see this by Ray Streater.

Weinberg begins by recalling his first first trip to the Bohr Institute in 1954, where he met Källén, who suggested a research problem involving an exactly solvable QFT model invented by TD Lee. The solvability of this model made it possible to use it for investigating renormalization outside of perturbation theory. Källén and Pauli showed that the model was non-unitary, Weinberg showed that it had states with complex energies.

In his talk, Weinberg describes Källén's work during the 1950s investigating the question of how QED gets renormalized, outside the context of perturbation theory. Källén found an argument showing that at least one of the renormalization constants must be infinite but Weinberg notes that Källén never claimed the argument was rigorous, and concludes: "As far as I know, this issue has never been settled." He goes on to give the now conventional Wilsonian description of the non-perturbative situation and the possibility that no non-trivial continuum limit exists. This question is now considered somewhat academic, since it is assumed that QED gets unified with other interactions and ultimately with gravity at energies below those at which the behavior of the coupling becomes problematic.

Weinberg states in his abstract that he will present his personal view on how the problem of infinities may ultimately be resolved. Here's what he has to say about this:

> My own view is that all of the successful field theories of which we are so proud — electrodynamics, the electroweak theory, quantum chromodynamics, and even General Relativity — are in truth effective field theories, only with a much larger characteristic energy, something like the Planck energy….
>
> None of the renormalizable versions of these theories really describes nature at very high energy, where the non-renormalizable terms in the theory are not suppressed. From this point of view, the fact that General Relativity is not renormalizable in the Dyson sense is no more (or less) of a fundamental problem than the fact that non-renormalizable terms are present along with the usual renormalizable terms of the Standard Model. All of these theories lose their predictive power at a sufficiently high energy. The challenge for the future is to find the final underlying theory, to which the effective field theories of the standard model and General Relativity are low-energy approximations.
> It is possible and perhaps likely that the ingredients of the underlying theory are not the quark and lepton and gauge boson fields of the Standard Model, but something quite different, such as a string theory. After all, as it has turned out, the ingredients of our modern theory of strong interactions are not the nucleon and pion fields of Källén's time, but quark and gluon fields, with an effective field theory of nucleon and pion fields useful only as a low-energy approximation.
> But there is another possibility. The underlying theory may be an ordinary quantum field theory, including fields for gravitation and the ingredients of the Standard Model…

He then goes on to describe the "asymptotic safety" scenario where the renormalized couplings approach a non-trivial fixed point as the energy cut-off is taken to infinity, a fixed point which presumably cannot be studied in perturbation theory, writing:

> Other techniques such as dimensional continuation, 1/N expansions, and lattice quantization have provided increasing evidence that gravitation may be part of an asymptotically safe theory.

and referring to papers by Reuter/Saueressig, Percacci, and Litim (Percacci has a web-page about asymptotic safety here). He ends with the conclusion that, since string theory might not have any role in a fundamental theory, with only QFT needed to understand quantum gravity:

> So it is just possible that we may be closer to the final underlying theory than is usually thought.

In these days of string landscape ideology, this possibility is an important one to keep in mind.

Comments

1. **Shantanu**
   March 4, 2009

   Peter you mentioned
   "This question is now considered somewhat academic, since it is assumed that QED gets unified with other interactions and ultimately with gravity at energies below those at which the behavior of the coupling becomes problematic."
   Does this unification solve the problem?
   Also a related question (re QED). Are you worried about issues such as the
   Landau pole?
   thanks

2. **Peter Woit**
   March 4, 2009

   Shantanu,

   The problem that Weinberg explains is the Landau pole problem, and I agree with his description of it.

   Conventional guts don't solve the problem, because they require a Higgs sector, and this is not asymptotically free, so has the same problem as QED.

3. **Peter Orland**
   March 4, 2009

   Shantanu,

   Yes, unification solves the problem for QED. The Landau pole of QED occurs at a higher energy than the unification scale. Unfortunately the standard model still has a problem at high energies, because of the HIggs and the U(1) sector.

   Peter: I think K\"{a}ll\'{e}n would have called himself a theoretical physicist, not a mathematical physicist. In his day, the latter referred to people who used rigorous methods to prove things about physics. There was much interaction between the two subfields, but there was a clear distinction.

4. **Sulfer Surfer**
March 4, 2009

It is remarkable that Weinberg is also the one who did much to bring the anthropic principle into physics. One of the things that has made him a great scientist, time and again, is that he seeks to understand the universe without preconditions on what form the answer will take.

5. **N. Nakanishi**
March 4, 2009

Peter: Your description concerning the Lee model is not precise. The original Lee model, in which the V particle is of positive norm,
is unitary if cutoff factor is introduced. What Kallen and Pauli investigated is the indefinite-metric Lee model, in which the bare V particle is of negative norm. In this model, there are three cases for the physical V particles: one or two real eigenvalue(s), one of which is of negative norm, one double real eigenvalue, which is Heisenberg's dipole ghost, and two mutually complex-conjugate eigenvalues. For details, see my review article, Prog. Theor. Phys Suppl. 51 (1972), Sec.12.

6. **Chris Oakley**
March 5, 2009

SW seems to have a knack of capturing the mood of the moment – lauding String Theory when everyone (except Peter, of course) was working on it and then supporting the sceptics when PW's & Smolin's books came out. But being a trendsetter himself, his measurements of the state of the art have a habit of forcing the system into a quantum state, and no doubt now that he is saying that people should be going back to QFT basics, a large number of researchers will now do just that. It is high time.

7. **Peter Woit**
March 5, 2009

Nakanishi,

Many thanks for the added information about the Lee model, it's not something I knew about before this, quite interesting to hear more about it.

Peter,

Actually I think Kallen is an interesting case on the borderlines of classification. He wrote a well-known rather phenomenological book about particle physics in the mid-sixties which I learned a lot from as a student. The bulk of his work was investigation of fundamental issues in QFT, although not at a mathematician's standard of rigor. Later on I think he worked on more mathematical issues concerning analytic behavior of amplitudes, some published in mathematical physics journals. So, I think both conventional particle theorists and mathematical physicists can claim him as one of their own.

8. **Peter Woit**
March 5, 2009

Chris,

I'd love to count Weinberg as an enthusiast for my book and arguments about string theory, but I'm afraid the evidence doesn't really support that. After a few years working on string theory himself, he did vote with his feet and move into cosmology, something that probably encouraged that trend, which is ongoing. But it's my impression that his attitude for many years has been one more of agnosticism on the string theory/QFT question, that work on both is justified, with string theory remaining as much a possible TOE as any other idea on the subject. As far as I can tell, pointing out that string theory unification has failed as an idea about finding a TOE is not on his agenda.

9. **dir**
March 5, 2009

the landau pole problem has two aspects, i think. one is that whether is it really there? the pole apears from perturbative calculation, but the pole itself is in non-perturbative region. lattice peole said that the landau pole can exist. the other is that even if it exists (almost for sure), does this imply the theory is meaningless? maybe not. it can be an evidence of some phase transition which has to be described by a totally new theory.

10. **Chris Oakley**
March 5, 2009

Peter,

Didn't Weinberg say that "the sceptics are right" when yours and Smolin's book came out 2 1/2 years ago?

As for Kallen, IMHO he did much more than average in trying to make QFT rigorous. He did not succeed, of course – but then no-one else has either.

11. **Peter Woit**
March 5, 2009

Chris,

That doesn't correspond to anything I remember, but I've mercifully forgotten some details of the "string wars".

12. **dan**
March 5, 2009

The Nova program on string theory, hosted by Kaku and Greene, Weinberg was interviewed and asked and answered with a qualified endorsement of string theory.

13. **anon.**
March 5, 2009

Weinberg 2.5 years ago mentioned that there are critics of string theory who perhaps are motivated because they want some of the money string theory is getting. He then added 'perhaps they are right' to want funding for alternatives. He didn't say string critics are right in dismissing string theory, and he still supports string theory.

See 15 July 2008 interview of Weinberg by Dawkins at http://www.youtube.com/watch?v=kNpiX8XQhJM where Weinberg states at 9 mins 12 seconds:

'It's been a little disappointing that it hasn't led to any specific breakthrough in understanding what we already know, but it's still the best game in town.'

14. **Chris W.**
March 6, 2009

Off-topic: Ilya Piatetski-Shapiro, died Feb. 21 in Tel Aviv (*New York Times*).

15. **mike**
March 8, 2009

Peter,

Has there been any success in resolving perturbative issues with the two-dimensional models and conformal QFTs?

16. **Peter Woit**
March 8, 2009

mike,

There are lots of 2d models you can solve exactly, and infinities are much easier to deal with (no coupling constant renormalization), so there isn't the same kind of problem as in 4d.

17. **Thomas R Love**
March 10, 2009

Peter, Thanks for the info on Gunnar Kallen. After reading some more about his work, I finally ordered two of his books, QED and Elementary particles.

Latest on the Higgs

March 10, 2009
Categories: Experimental HEP News

The news media are full of stories about the observation at the Tevatron of “single top” production, at a rate consistent with that expected from the Standard Model. There are talks at Fermilab going on about this today, and the papers are here and here. For an expository account, you can’t possibly do better than this one from Tommaso Dorigo.

While these results represent an experimental *tour de force*, they just confirm what is expected based on the standard model. Much more exciting would be if the Tevatron experiments can tell us something new about the Higgs and the Standard Model, and it looks like that may be coming this Friday afternoon, when a joint talk by the two experiments entitled “Higgs Results from CDF and D0” is scheduled at Fermilab. The two experiments have each collected about 5 fb^{-1} and started announcing limits on the Higgs based on analysis of up to 4 fb^{-1}, but this is not quite enough for either experiment to be able to on its own exclude at 95% confidence level the Higgs at any particular mass. For this, one needs to combine the data from the two experiments. This was done last year, with results announced last August based on 3 fb^{-1} per experiment of data. This analysis allowed exclusion of the Higgs at 95% confidence level only in an extremely narrow range, basically just at exactly 170 GeV.

I’m guessing that what will be announced on Friday is exclusion of a Higgs over a much larger mass range. For a preview of this, see page 24 of the slides of a recent talk, where a graph shows what things would look like if you took twice CDF’s data set. This would come very close to excluding a range from 160-165 GeV, and perhaps within reach of excluding a region as large as 155-175 GeV, if not now, with only a moderate amount of more data and effort. It will be very interesting to see what they have…

For more evidence that this is what we’ll be hearing, Newsweek reports that:

> This week scientists at Fermilab in Batavia, Illinois, will announce new data that not only narrows the gap between them and the coveted God Particle, but also suggests that the LHC may not be particularly well placed to make the discovery at all. The finding is a public-relations blow to the LHC and tarnishes Europe’s newly burnished image as a leader in Big Science….
>
> The Higgs, the new Fermilab data show, does not exist for a portion of the upper range, putting it in the Tevatron’s cross hairs and suggesting that the LHC may be more peripheral to the search than previously thought. “We’ve made their jobs a little bit harder,” says Fermilab physicist Dmitry Denisov, “because we’ve excluded the region they’re good at.”

As the Tevatron shows that it can exclude the Higgs in the higher end of the expected mass region, where the LHC has a huge advantage, that means that either there is no Higgs (and presumably something else more interesting to find), or it exists in the lower part of the expected mass range (above the LEP limit of 114 GeV), where it is hard to find, but the Tevatron is not at such a disadvantage to the LHC. In any case, even if things work out as currently planned, the LHC will not start accumulating the kind of luminosity needed to compete with the Tevatron in this game until their 2011 run. It now appears highly likely that the Tevatron will be running at least through FY 2011 and possibly longer(for more about this, see here).

Comments

   March 10, 2009

   The physics is quite interesting, but politically the spin is completely stupid. If the Fermilab public-relations machine cannot see the short-sightedness of a “the LHC is a big waste of money” message, then we will shortly be doomed to repeat the harsh lessons of the SSC.

2. **Cormac O Raifeartaigh**
   March 10, 2009

   Well said Xerxes. That passage in Newsweek could have been put a lot more diplomatically.

   Speaking of science and the media, is there any chance you could all stop talking about “single top” quark production? This sounds awfully close to single quark production, guaranteed to confuse the rest of us…

3. **Stan**
   March 10, 2009

   Frankly, I just wish people would stop calling the Higgs the “God Particle.” It’s ridiculous and only serves to confuse people. Lederman is a smart guy and a great speaker, but his whimsical name for the Higgs is far to appealing to newspaper writers who want to allude to the “science vs. religion” fights in a strictly scientific story.

   (The last thing we need if the Higgs is discovered is a bunch of smug editorials laughing at physicists who “think they found God.”)

   I also wonder how much of the Fermilab vs. CERN friendly professional rivalry is getting misinterpreted and magnified by the popular media into something more like a race or conflict. Even if CDF and D0 actually find the Higgs, it will be at such low significance you’ll want the LHC experiments to confirm it and check its properties. Still, Fermilab wants to show what their machine can do, and so is pushing it to the limit in the few years left to run. Conflict is exciting, and so I’m not surprised the media is pushing that angle.

4. **a quantum diaries surivivor**
   March 10, 2009

   Hi Peter,

   thank you very much for the appreciation of my account of the single top discovery.

   As for the Higgs, although I sometimes let go myself with optimism about CDF, I think that one should be a bit cautious about the over-optimistic interpretations of the Tevatron claims, for one reason.

   Take the single top discovery plots and for one moment imagine that we jump four years ahead in the future and what we’re looking at is a Higgs signal instead than single top: would you claim that such excess is an observation ? Yes, five sigmas are still five sigmas, but those global combined-multi-likelihood distributions contain just too many ingredients to be conclusive, if they claim to be the discovery of something that might not be there. Only because single top cannot possibly NOT be there, those plots can be really believed, in my humble opinion.

Mind you, I am not saying there is anything wrong in either the CDF or the DZERO analyses (although in my blog I explain why the DZERO result is slightly less convincing than the CDF one). All I mean to say is that the Tevatron will never be able to show a conclusive signal for the Higgs, because the Signal to noise ratio is really too small: only by combining many channels, and cooking up powerful complicated discriminants, can the Tevatron experiments obtain results on the Higgs.

The LHC advantage is there: eventually, they will have enough statistics to show a signal that has all the characteristics needed to convince everybody.

To stress the point: somebody in CDF in 1993 had seen the first evidence for top pair production by using a likelihood discriminant. Now, those were quite different times, and likelihoods were still looked at with suspicion. But back then the top quark was still not compelling, it had already been claimed falsely once, and most people were really, really sceptical with a signal shown only on a not easily interpreted variable: until a counting experiment showed a signal, no publication was allowed.

Cheers,
T.

5. **Shantanu**
March 10, 2009

I looked at the agenda pointed to my Peter. The
antimatter gravity experiment looks cool.
Hope it gets funded.

6. **Nobody**
March 11, 2009

To the first two posts: you are absolutely right; but certainly statements like "In one year, we will be competitive. After that, we will swamp them." (Lyn Evans at the AAAS meeting, middle of February) do not help to mantain the relationship on a pure scientific level

7. **Peter Woit**
March 11, 2009

Thanks Tommaso!

You make a very good point. My main reaction to seeing the details you explained of the single top result was something like "Wow, those plots are not exactly obviously convincing of anything…", and presumably any Tevatron Higgs "observation" will be of a similar nature.

But, if the Higgs really is down at 115 GeV, is it really true that the LHC will be able to see it in a really convincing way? How much luminosity will this take?

About the public relations aspects of this: I don't see any problem at all with a well-publicized Tevatron/LHC competition, trash-talking and all. Given that it's often the same people on both sides of this, I can't believe it will generate any serious bad blood among the physicists involved. It might generate some real public interest and appreciation for the subject, more so than the uncomplicated "wondrous new machine finds obscure particle" story that has been pre-sold already, and doesn't draw the public in that much. It's also true that the way the LHC story was going, Fermilab and US HEP in general were in danger of being left for dead as road-kill, something which is not exactly healthy for the subject.

8. **Coin**
March 11, 2009

The finding is a public-relations blow to the LHC and tarnishes Europe's newly burnished image as a leader in Big Science

Although I don't really see anything wrong with the idea of a friendly LHC/Tevatron rivalry, this specifically seems like a weird interpretation for Newsweek to take. From anything I've ever been able to tell there seem to be an incredible number of Europeans working at Fermilab and an incredible number of Americans working at CERN.

9. **John Baez**
March 12, 2009

If the Higgs is found, what can we do to keep the public interested in particle physics? How can we possibly top the "God particle"?

Here's my suggestion: say that "sparticle" stands for SATAN PARTICLE!

10. **PV**
March 30, 2009

Europe lost many good scientific minds during World War II so CERN was developed to bring those minds back and establish Europe as a center of scientific power. Big Science is never really about science. NASA is another example of Big Science but its roots are in the Cold War. If you want real science, it begins with good conceptual physics. If we had any real conceptual idea of what the Higgs is we would know how likely it is of finding it before the experiment.

11. **J.J. van der Bij**
April 3, 2009

There has to be a Higgs field, but not necessarily a particle.
The Higgs field may have been seen at LEP (Phy. Lett. B638, 234 (2006)).
In this case neither the LHC or the Tevatron can see the Higgs.

Particle Fever

March 12, 2009
Categories: Uncategorized

LHC media fever continues this year, with at least three books out or on the way:

The Quantum Frontier: The Large Hadron Collider by Fermilab experimentalist Don Lincoln.

Collider: The Search for the Worlds Smallest Particles by Paul Halpern.

and

The Large Hadron Collider by Lyn Evans, who knows a thing or two about the subject.

There's also a documentary entitled Particle Fever being made about the LHC, produced by theorist David Kaplan, who "has discovered some of the most recognizable extensions to the standard model of elementary particles." The film web-site has bios for five physicists who will feature prominently in the film: three theorists well-known for their work on large extra-dimensional models, one experimentalist from CMS, and one from ATLAS. The ATLAS experimentalist is described as "a leader in the search for extra dimensions." I can't find anything about the Higgs on the web-site, maybe they've already given up on that and left it to the Tevatron…

The descriptions of the theorists include "responsible for some of the wildest theories about the nature of gravity, cosmology and fundamental particles", "a leader in the fields of supersymmetry, extra dimensions and new forces… has become a controversial figure by questioning experimentalists' traditional methods of analyzing the data" and "the most likely to win a Nobel Prize after the LHC data is interpreted." The experimentalist description is rather more modest ("has been involved in detector R&D and construction, software development and physics data analysis"), nothing about any possible Nobel prizes. If you had to choose whether to be a theorist or an experimentalist, the choice looks easy.

   March 12, 2009

   You forgot to mention "is considered the greatest theoretical particle physicist of his generation." How do you say chutzpah in Farsi?

2. **woit**
   March 12, 2009

   H-I-G-G-S,

   I think the percentage of physicists who consider Nima "the greatest theoretical particle physicist of his generation" is at least a couple of orders of magnitude larger than the percentage who think it likely that extra dimensions will be seen at the LHC. I won't speculate on the absolute magnitudes of these two numbers…

Twistor Fever

March 12, 2009
Categories: Uncategorized

It's becoming clear what the hot new topic in particle theory is these days: the use of twistor space methods to try and understand scattering amplitudes in Yang-Mills and gravity theories, especially the maximally supersymmetric versions. This evening on the arXiv there are two closely related papers on the topic: Scattering Amplitudes and BCFW Recursion in Twistor Space by Lionel Mason and David Skinner, and The S-Matrix in Twistor Space, by Arkani-Hamed and collaborators (there's also a third, much more distantly related paper, this one). The Arkani-Hamed et al. paper gives an extensive discussion of motivation for this work in the introduction: the structure of scattering amplitudes for these theories is remarkably simple in twistor space, leading to the question of whether one can formulate the full theory directly in twistor space somehow, giving a different sort of holographic dual than the AdS/CFT one.

A very influential version of this idea goes back to Witten's 2003 paper Perturbative Gauge Theory as a String Theory in Twistor Space, where the dual theory investigated was a topological string theory. This most recent work doesn't appear to use topological string theory, although Arkani-Hamed et al. are rather cagey on the topic of what sort of twistor space theory is at issue. They promise a forthcoming paper entitled "Holography and the S-matrix", with:

> a completely different picture for computing scattering amplitudes at tree level than given by the BCFW formalism, that we strongly suspect is connected with a maximally holographic description of tree amplitudes that makes all the symmetries of the theory manifest but completely obscures space-time locality.

The history of using twistor-space to study gauge theory goes back a very long ways. Penrose started using twistor techniques to study gravity back in the mid-sixties, and after the 1975 discovery of self-dual solutions to the YM equations (instantons), it became apparent that twistor-space techniques could be used to solve them, turning the problem of solving these non-linear equations into a problem in algebraic geometry, that of constructing certain holomorphic vector bundles. Atiyah was among the mathematicians who got interested in this, and his beautiful 1979 lecture notes *Geometry of Yang-Mills Fields* remain a wonderful introduction to the mathematical side of the subject. While still a post-doc, Witten worked in this area, coming up in 1978 with an interpretation of the full YM equations using supersymmetry. Work on this topic was what brought Atiyah and other mathematicians into contact with physicists, including Witten, beginning a quite remarkable period of very successful interaction between the two camps.

Twistors were among the things I started thinking about at the end of my graduate school days in the mid-eighties, for a completely different reason, one that has nothing to do with the current interest in the subject. I was interested in the problem of how to put spinors on a lattice, and the twistor geometry story gives a beautiful way of thinking geometrically about spinors. This idea never really got anywhere, although I did notice some relations between the geometry of the standard model gauge groups and representations that I wrote about back in 1987 and still find quite remarkable. It will be interesting to see what new ideas emerge from this latest wave of interest in thinking about quantum field theory in twistor-space.

   Twistors are in the air… Earlier today, for no particular reason I dug up the lectures by Cachazo and Svrcek on their work with Witten. Great timing!

2. **Bee**
   March 13, 2009

   You would make a good trendscout. The last months I've heard a 'twistor' here or there and was wondering if that takes off. Well, it seems like it does.

3. **Higher Life**
   March 13, 2009

   All this perturbative field theory fashion is so retro. When will people go back to really cool stuff like the landscape or warped extra dimensions?

4. **Peper Pan**
   March 13, 2009

   You should mention Freddy Cachazo, not just "Arkani-Hamed and collaborators ". The main contribution is due to both Freddy and Nima, plus Freddy is the expert of this specific area. 🙂

5. **Peter Woit**
   March 13, 2009

   Peper,

   You're right, the way I wrote this is not fair, but either writing all the names or picking and choosing who to label things by are both also problematic. Now I see why this field is full of acronyms. Instead of "Arkani-Hamed et al." I'll write "ACCK"….

6. **Artful Codger**
   March 14, 2009

   My experience suggests that when a paper contains exclamation marks which do not refer to the factorial, this is a sure sign that something is being hyped. I seem to recall that this principle worked very well, for instance, in the case of the now completely dead and forgotten "PP wave" craze. This too shall pass.

7. **piscator**
   March 14, 2009

   re:artful codger, i think the presence of NAH on the author list is also often a good sign that something is being hyped ….

8. **Adam Helfer**
   March 14, 2009

   Peter,

   The twistor-Yang-Mills correspondence grew out of a gravitational version by Penrose (the "nonlinear graviton"); it was Richard Ward who worked out the electromagnetic and Yang-Mills analogs — and I think Ward may have been stimulated to take up the Yang-Mills case by discussions with others. At any rate, Ward deserves mention here.

9. **Peter Woit**
   March 14, 2009

   Adam,

   Thanks. I wasn't trying to give a detailed history here or even mention all the crucial people involved (because there were quite a few of them, including several physicists).

10. **twisting the night away**
    March 17, 2009

    I've always thought that the history of twistor methods as applied in physics contains a valuable lesson for string theory, albeit on a smaller scale.

    Twistors started as an attempt to formulate a nature. Not a bit of it, but the whole thing. This didn't quite work in the form conceived, although it obviously had an inherent beauty. This led to ever increasing mathematical sophistication, with only brief touches with physics. Sounds familiar?

    Of course, as recent developments appear to show: twistors remain a very clever idea that now might find it's right place in physics. In my opinion, strings is something similar in nature.

11. **Peter Woit**
    March 17, 2009

    twisting,

    Actually, in some ways the history may be the opposite. Twistors were initially a tool in general relativity, with some hope for using them to quantize gravity. There was little if any interest in the idea of getting particle physics or a TOE out of them. They did have an impact on particle theory, but purely as a technical tool for constructing instanton solutions, which could then be used in semi-classical approximate calculations in Yang-Mills theory.

    In the recent work, they also a appear as a technical tool, better variables for scattering amplitudes. But I still think there's a chance that twistors are much more than a technical tool, but instead a fundamental insight into how geometry and physics are connected. Maybe someone will make some progress on the question of how to reformulate QFT in these variables in an interesting way, and twistors will move from being a technical tool to a fundamental idea behind a TOE.

12. **Adam Helfer**
    March 17, 2009

    Here is a link to an article by Penrose on the origins of twistor theory. You'll see that the motivations were diverse, including both insights from g.r. and hopes of integrating quantum theory.

    Twistor diagrams were an early part of this, growing in part out of spin-networks. The diagrams can be viewed as attempts to define scattering amplitudes for massless fields of pure helicity; associated with this was an attempt to develop a theory of massive particles with such massless constituents. (See e.g. Hughston's *Twistors and Particles*.) That attempt didn't gain much traction, partly because the twistor diagrams were so hard to evaluate that that limited the degree to which the theory could be developed.

    It has been challenging, but not impossible, to adapt twistors to g.r. The most full-bore approach is via CR structures (Penrose again, with notable contributions by LeBrun, Sparling and Mason), which associate to a Cauchy surface (or more generally an acausal hypersurface) a CR twistor space. The mathematics is very interesting, but so far I am not aware of any contributions to physics from this.

    Another approach in g.r. is to define twistors on spacelike two-surfaces of interest as a first step towards defining energy-momentum and angular momentum quasilocally (Penrose again). I've recently built on these ideas to give a treatment of angular momentum at null infinity.

13. **Joe Hucks**
    March 17, 2009

    In case it might be useful, I did about a third of my dissertation on a chiral twistor formulation of the closed bosonic string in 3+1 dimensions:

    http://adsabs.harvard.edu/abs/1994PhDT…….128H

    (In Chapter 3, the application of twistor variables to the study of massless spinless particles is reviewed and discussed, and is generalized to give a chiral twistor formalism with first-order Lagrangian for the closed bosonic string in four space-time dimensions.)

14. **twisting the night away**
    March 18, 2009

    Joe,

    there were even earlier papers by Shaw on applications of twistors in string theory that I know of (sorry can't open your thesis 🙁). Now only generalise these to AdS_5xS_5 🙂 On that note, Berkovits's pure spinors are very close cousins of 10D twistors.

    Peter,

    I would agree that the scale is completely different (at least two order of magnitude in numbers of people involved for one). However, as measured in usefullness in physics there is a parallel I think: if string theory does not connect to the real world, it will devolve into mathematics in a similar way. Just classify the world's living, working twistor theorists today: most of the Penrose group went and worked on other things than physics. Of course, you and I would come down on different sides on whether strings is a good idea in the first place 🙂

15. **Academic Career Links**
    March 20, 2009

    For those interested: there is a fairly recent mini-survey on twistors by Penrose himself.

16. **twisting the night away**
March 23, 2009

Choice quotation from Penrose about recent twistor developments from the article mentioned by Academic Career Links:

"My reaction to these developments, however, is to feel rather like someone on safari in Africa, observing through binoculars a herd of water-buffaloes rampaging around at a safe distance away, when suddenly I realize that they have changed direction and are now heading straight towards me!"

🙂

New Higgs Mass Limits

March 13, 2009
Categories: Experimental HEP News

The new combined CDF/D0 Higgs mass limits are out, there's a paper here. At a confidence level of 95%, a standard model Higgs is excluded for a mass range between 160 and 170 GeV. At a confidence level of 90%, the range excluded is 157-181 GeV. Precision electroweak measurements already constrain the Higgs mass to lie below 185 GeV (at 95% confidence level).

Taken all together, it now looks likely that, if there is a standard model Higgs, its mass is in the region 114-157 GeV. With the data they have analyzed so far, the Tevatron experiments are only able to say that the cross-section for producing a SM Higgs over this mass region cannot be more than 2-3 times the SM value. They still have more data in hand to analyze, and the machine continues to run well. It will likely stay in operation at least a couple more years, possibly doubling the number of collisions already collected. The paper promises:

> The sensitivity of our combined search is expected to grow substantially in the near future with the additional luminosity already recorded at the Tevatron and not yet analyzed, and with additional improvements of our analysis techniques which will be propagated in the current and future analyses.

Now, we just need to hope that they don't find the SM Higgs in this remaining region, which would make things really interesting…

Comments

1. **Shantanu**
   March 13, 2009

   Peter, doesn't this rule out (or severely constrain) MSSM? If I remember right, MSSM has a some upper bound on Higgs boson mass in the region already excluded, but maybe others should clarify.

2. **Peter Woit**
   March 13, 2009

   Shantanu,

   I don't think this says much of anything about the MSSM. There the SM-like Higgs is supposed to be light, you have to tune things to get it above the LEP limit.

3. **Anon**
   March 13, 2009

   Unrelated, but the talks at the IHES conference on Grothendieck are available online at:

   http://video.google.com/videosearch?q=grothendieck&hl=en&emb=0&aq=-1&oq=#q=grothendieck&hl=en&emb=0&aq=-1&oq=&start=10

4. **Peter Woit**
   March 13, 2009

   Thanks!

   A somewhat better link for these might be

   http://www.dailymotion.com/visited/Ihes_science/1

5. **Nameless**
   March 13, 2009

   According to the Fermilab press release, they expect to triple the integrated luminosity by the end of 2010, bringing it up to 10 fb^-1 per experiment.

   If it's not there, CDF/D0 should be able to rule it out at 95% CL before LHC has a chance to say anything definitive. If it's there and it's sufficiently heavy (say, 150 GeV), they might be able to claim evidence of Higgs at 3 sigma. However, 10 fb^-1 would be insufficient to claim discovery at 5 sigma, whatever the mass.

6. **chris**
   March 16, 2009

   "Precision electroweak measurements already constrain the Higgs mass to lie below 185 GeV"

   you forgot a very essential 'standard model' here. in SM extensions, there is no problem obtaining Higgs mass as large as 600GeV

7. **Arun**
   March 17, 2009

   Happy 5th birthday!

8. **diver**
   March 18, 2009

   I remember Alain Connes has a paper in which he also predicts the mass of Higgs. Does anyone know what was his prediction? and whether it is still within the viable range?

9. **Peter Woit**
   March 18, 2009

   diver,

Connes's prediction was for about 170 GeV, which is in the ruled out range. This was even true last summer, and Connes acknowledges this, see

http://noncommutativegeometry.blogspot.com/2008/08/irony.html

Old Enough for Kindergarten

March 17, 2009
Categories: Uncategorized

Today is the fifth anniversary of the start of this blog, something that has caused me to go back and take a look at some of the early postings, and meditate a bit on what has happened during the past five years.

The first posting was content-free, just an experiment to see if the software worked. The inspiration for starting the blog included the examples of Jacques Distler's Musings, which had been around for a while, and Sean Carroll's Preposterous Universe, which he had just started. At the time I had finished writing the book *Not Even Wrong*, and was in the process of getting it published. The initial idea behind the blog was that it would be a place to comment on and share information with others about topics in math and physics that interested me, including following the on-going story of string theory, which plays a crucial role in the intersection of the two subjects.

A few days later, the first substantive posting was a discussion of a talk by David Gross at CUNY on *The Coming Revolutions in Fundamental Physics*. Gross had been giving similar talks for several years (you can see a version from 2001 here), and continues to do so to this day (in a few weeks, he'll be at UC Davis, see here). I don't see anything I'd want to change in my posting from five years ago, and find this in itself somewhat remarkable. One thing that I'm sure has changed in the more recent versions of the talk is that they don't include the prediction that 2007-8 will see a headline in the New York Times about the discovery of supersymmetry at the LHC. One feature of many theorist's talks in recent years has been consistently overly optimistic predictions about when results from the LHC will arrive.

The next posting was an attempt to balance the previous one with something positive and uncontroversial, a discussion of the importance of understanding electroweak symmetry breaking, along with speculation that this might end up having something to do with our still imperfect understanding of chiral gauge symmetry at a non-perturbative level. I found the reaction to this posting truly bizarre, and it gave an inkling of some of the strange chapters to come in what some started to refer to as the "string wars". Over the years I'd heard from some people that quite a few string theory enthusiasts were convinced that the only possible explanation for skepticism was the ignorance of skeptics. String theory is certainly a remarkably complex and difficult subject, and many skeptics will freely admit to not understanding the subject well, but my own personal experience talking to string theorists was that they were well-aware that there were good reasons for skepticism. Over the years, even many experts who had worked on the subject had come to the conclusion that string theory unification was not as promising as initially hoped, and had moved on to work on different things.

A few months later, Harvard's recently promoted faculty member Lubos Motl started up his blog, The Reference Frame, which kicked the pathological nature of the discussion of string theory up to a whole new level. By the way, it seems that the main character of one of the most popular shows on US television is based on Lubos, and there's a campaign to get an Emmy for the actor portraying this character. You really couldn't make stuff like this up.

Five years later, some things have definitely changed. String theory remains a very powerful political force in the theoretical physics community, but the very public debate over the problems of the subject has taken a huge toll. Perhaps the most accurate indicator of how an academic field is doing in the marketplace of ideas is how many universities are investing in tenure-track appointments in the field. At least in the US, the situation here for string theory is dire. I may be missing someone, but taking a look at the latest information about particle theory tenure-track positions in the US available here, I don't see any string theorist even making it to the short lists. At least in the US these days, if you want a permanent position in particle theory, you need to be doing something in phenomenology or cosmology. From what I hear, a common situation in physics departments is that the argument for string theory that "let's wait for the LHC results for vindication" has been taken to heart, with departments figuring that now is not the time to hire in string theory, deciding instead to wait a few years and see if it collapses completely or gets revived by whatever comes out of the LHC.

One sad aspect of all this is that it includes a generalized backlash against the use of sophisticated mathematical ideas in particle theory. Many physicists have drawn the conclusion from the failure of string theory that the problem was too much mathematics, rather than a wrong idea (even string theorists are moving away from mathematics: unlike many years, I see no mathematicians listed as speaking at Strings 2009). Maybe LHC results will point the way forward, but if not, and progress instead requires a deeper mathematical understanding of quantum field theory, the only place for people to get hired working on this will be mathematics, not physics departments, and this is a less than ideal situation for many reasons.

The devolution of string theory unification into pseudo-scientific argumentation about the multiverse is another cause for physics departments to shy away from the subject. This has also been deadly for the public perception of the subject. For this week's example, see a story in the Boston Globe which compares the scientific status of string theory with that of alchemy:

> And at the cutting edge of modern physics, string theory purports to offer a complete but possibly unprovable explanation of the universe based on 11 dimensions and imperceptibly tiny strings.
>
> Alchemists wouldn't recognize the mathematics behind the theory. But in its grandeur, in its claim to total authority, in its unprovability, they would surely recognize its spirit.

Searching the NSF physics awards database for the strings "multiverse" or "anthropic" turns up nothing, and I suspect that even the proponents of this research are well aware that their colleagues want nothing to do with it. For funding they may have to turn to other sources, including the Templeton Foundation, which recently financed a meeting at a resort in the Cayman Islands which brought together people from the world of business and philanthropy with an array of physicists, including the multiverse crowd. A report on the meeting, with some slides of presentations, is available here.

A somewhat related piece of news is that yesterday the Templeton Foundation announced that Bernard d'Espagnat is the latest winner of its $1.4 million Templeton Prize. d'Espagnat has a long career of serious work on the philosophy and interpretation of quantum mechanics, but what makes him eligible for the prize is having indulged in a certain amount of obscurantism concerning quantum mechanics, coupled with an indulgent attitude towards religion:

> Classical physics developed by Isaac Newton believes it can describe the world through laws of nature that it knows or will discover. But quantum physics shows that tiny particles defy this logic and can act in indeterminate ways.
>
> D'Espagnat says this points toward a reality beyond the reach of empirical science. The human intuitions in art, music and spirituality can bring us closer to this ultimate reality, but it is so mysterious we cannot know or even imagine it.
>
> "Mystery is not something negative that has to be eliminated," he said. "On the contrary, it is one of the constitutive elements of being."
> …
> "I believe we ultimately come from a superior entity to which awe and respect is due and which we shouldn't try to approach by trying to conceptualize too much," he said. "It's more a question of feeling."

I'm looking forward to seeing what happens over the next five years. Surely we'll finally start seeing results from the LHC and maybe they'll re-invigorate particle physics. The wide variety of work on mathematics inspired by quantum field theory may also lead to progress of one sort or another. As ever, obscurantism and pseudo-science will find proponents, but I don't think they'll make much headway in the scientific community, even with funding from the wealthy. Undoubtedly things will happen that I can't possibly imagine at this point. I hope that they're positive things for mathematics and physics, or, at least, entertaining.

Comments

1. **Shantanu**
March 17, 2009

Peter what will happen if LHC sees nothing, not even a Higgs?
Will that reinvigorate particle physics? Also you haven't mentioned
anything about neutrino physics in this post or in most other blog posts.
Do you think neutrino physics tells us nothing about particle physics?
Non-0 neutrino mass has been the
most (only) new discovery in particle physics in the last 10 years
and that has invigorated particle physics much more, I think.

Or do you think neutrino physics does not tell us much about electroweak symmetry breaking and other stuff?

2. **Peter Woit**
March 17, 2009

Shantanu,

If the LHC just sees a SM Higgs, that won't reinvigorate particle physics at all. The best-case scenario is no Higgs, which means there is something else behind electroweak symmetry breaking, and the LHC should be able to go searching for this something else, whatever it is.

Non-zero neutrino masses are a clue about what lies beyond the standard model, but unfortunately just a clue, one we don't know how to interpret. Unless there's some unexpected new result from neutrino experiments, I fear this will remain the case.

Maybe the best non-LHC bet for something dramatic would be from the experiments looking for dark matter. But I think these remain a long shot.

3. **Bee**
March 17, 2009

Happy bloggiversary 🙂

4. **Shantanu**
March 17, 2009

Thanks, Peter. BTW is non-zero neutrino mass evidence for physics beyond standard model? I thought so, but Tomasso and others pointed out to
me at that non-0 neutrino mass can be accomodated in the standard model (which was news to me).
Do you agree with Tomasso and others?

5. **Peter Woit**
March 17, 2009

Shantanu,

You can just treat neutrinos the same as other leptons, giving them mass by introducing right-handed neutrino fields and Yukawa couplings to the Higgs. This isn't really a significant extension of the minimal, no neutrino mass standard model, and people often mean this when they say "standard model" now. If you do this, there's no reason for neutrino masses to be so much smaller than other masses, but then again, you have no idea why any of the Yukawa's have the values they do.

Due to the fact that a right-handed neutrino field transforms trivially under SU(3)xSU(2)xU(1), there are other interesting possibilities for how to get a mass term, ones where the smallness of the mass would be natural, and these involve introducing new physics. It's in this sense that non-zero mass is a "clue".

I looked around for a minute and found this nice explanation of the neutrino mass situation:

http://library.lanl.gov/cgi-bin/getfile?25-04.pdf

March 17, 2009

congrats on 5 great years!

7. **Simplicio**
March 17, 2009

Alchemy isn't provable? I don't think that's really fair to alchemy. It was provable, and its practitioners ran experiments of a sort, it just happened to eventually be proven wrong.

String theory, on the other hand, is not even….well you get the idea.

Happy bloggoversery.

8. **Roger Schlafly**
March 17, 2009

So what were alchemists proved wrong about? That gold and lead were made of the same fundamental particles? It is true that they never turned lead into gold, but they weren't necessarily wrong to try.

9. **Low Math, Meekly Interacting**
March 17, 2009

Happy fifth!

10. **Aaron Bergman**

March 17, 2009

Neutrino masses can be accommodated in the standard model without the addition of extra fields. The point is that the mass arises from a higher dimension operator and is thus suppressed by the inverse of a cutoff scale at which you expect new physics. Since that scale's a bit less than the Planck scale, there's good reason to expect it isn't the standard model all the way up to quantum gravity.

11. **D R Lunsford**
March 17, 2009

I have thoroughly enjoyed the blog over the years. I hope in five years we can talk about really new things.

I think some of the backlash against the culture of mathematics, as it exists inside physics, is justified. People are not taught to think physically and so cook up all sorts of preposterous ideas. Physics is not blameless for endorsing wishful thinking all too often. I am amazed that it required so many years for a coherent voice about the matter (you) to emerge. Anyway it is good that you had the courage to do all this.

-drl

12. **capitalistimperialistpig**
March 17, 2009

Peter,

Has anyone besides Lubos really suggested that Sheldon Cooper (the string theorist on *The Big Bang Theory*) is based on Lubos? I consider myself pretty well acquainted with both characters and I don't see the resemblance – except that they are both well off the mass shell.

13. **capitalistimperialistpig**
March 17, 2009

But,

Happy Blogoversary!

14. **Tumbledried**
March 18, 2009

March 18, 2009

Happy 5, Peter!

16. **says:**
March 18, 2009

So this blog is Old Enough for Kindergarten.

What is string theory is Old Enough for?

17. **Engineer**
March 18, 2009

Congratulations on 5 years. It is rare that a professional can keep a popular public blog without it (sadly) undermining their career. Regarding string theory, my opinion is that it does show that there is a way to unify quantum mechanics and general relativity, however, at first glance the whole idea of little strings being the answer is childish in its simplicity. It was probably a mistake for physicists to call it string theory.

I would argue that outside your dislike of string theory, you do share the same sort of contempt for the misuse of physics that your infamous rival Lubos has. I hate to say this, but there is a small circle of blogs that offer some of the most intellectually stimulating entertainment that one could ask for, and Not Even Wrong is a well established member.

However, I will also happily say this, my own education stopped prematurely due to my own career and obligations, and if it weren't for Not Even Wrong, The Reference Frame, Back Reaction and Cosmic Variance, and a few other blogs, I doubt my recent progress in self-education in physics would have been remotely successful or even possible.

Looking forward to your 10th anniversary!

18. **Peter Woit**
March 18, 2009

Thanks CIP,

I've only watched the show a few times, and the first episode I saw had Sheldon going on about the superiority of string theory to LQG, and how stupid LQG supporters were. At the time, my first thought was "Wow, somebody at this show has been reading The Reference Frame…"

19. **theoreticalminimum**
March 18, 2009

Thanks for sharing so much during those past 5 years Peter. Through your blog, you have made it possible for people like me to have a better appreciation of contemporary and historical ideas in physics and mathematics research. We wish you all the mental stamina to keep it going for a few more years.

20. **Steve Esser**
March 18, 2009

I'm not informed enough to comment often, so this seems like a good opportunity to say thanks for an interesting and informative blog (I enjoyed your book as well).

Best regards,
– Steve Esser

21. **John**
March 18, 2009

Ther are some string theory-educated people on the faculty short-list : Harold Steinecker, David Shih, Sebastian Franco

22. **mathematician**
March 18, 2009

Peter Woit, thanks for the blog. It's one of the better ones on the Internet.

I miss Lubos. I used to run into him at his old job and listened in on some of his QFT lectures. It's too bad he left the USA (and possibly academia). The wit and humor overbalance the arrogant craziness, I.M.O.

re: alchemy, it's just chemistry done in secret. Alchemy would have become modern chemistry and physics had there been open publication.

23. **Johan**
March 18, 2009

Thanks for this excellent blog. I am a mathematician with a casual interest in physics.

I am glad to have your critical perspective on string theory as a contrast to the frequently over-enthuiastic treatment in the media.

24. **Jacob DeGoede**
March 18, 2009

Hi Peter,
Thank you for your blog wich is a source of inspiration to me.

Jacob DeGoede

I cannot but join the cheering crowd for these brilliant, exhilarating, instructive, constructive five years. Keep it going strong, Peter!

Cheers,
T.

26. **AM**
March 18, 2009

I came across your blog quite by accident a few years back and have been a visitor on and off ever since. Cheers Peter on a very nice blog.

27. **Dmitry**
March 19, 2009

Dear Peter,

Being a blogger-beginner, I do appreciate how hard it is to keep coming up with a new stuff for months (many persons report writer's blog after a couple of weeks 🙂). You kept coming up with new stuff for years – you ARE a marathon runner.

Cheers and congratulations,
Dmitry.

28. **Shantanu**
March 19, 2009

Peter, thanks for the link on neutrino mass. Btw what do you (and others)think
about strong CP problem in QCD. I haven't seen much posts on this.
Or is this a solved problem? Would you classify this as a holy grail of physics?
Is the axion the only accepted solution? do you think there is any connection between strong CP problem and problem of electroweak symmetry breaking?

29. **Peter Woit**
March 19, 2009

Many thanks to all for the nice birthday greetings…

Shantanu,

If I had to pick a holy grail, it's the mechanism of electroweak symmetry breaking, including understanding where fermion masses come from. The strong CP problem is more of a hint than a holy grail, like the small size of neutrino masses. Maybe it's a hint about axions, but adding new fields just to solve this particular problem isn't very convincing. It's also possible that somehow, once we understand the origin of fermion masses, the problem will go away. If the bare mass of the lightest quark is zero, there is no strong CP problem. This doesn't seem to be true, but maybe it's also a hint…

30. **Daniel**
March 19, 2009

5 years of anti-scientific ranting? Enough already. Try finding a job you can be productive in.

31. **Academic Career Links**
March 19, 2009

Thanks for all the interesting posts & greetings!

32. **a**
March 20, 2009

hi Peter, I remember that 10 years ago the situation in theoretical physics was discouraging: we had a big problem, but nobody wanted to openly talk about it, keeping working on the usual topics. It is impressive to see how much the situation improved now.

Probably your blog played a key role, and without this new powerful tool that you managed in a great way, all criticisms would have been ignored.

33. **Syksy Rasanen**
March 20, 2009

Happy birthday, Not Even Wrong! Thanks for your informative and useful blog. (You know, in some countries, children are already at school at the age of five.)

34. **Joey Ramone**
March 20, 2009

Happy Birthday Peter's Blog!

Yes–I remember when we tried to get $1.4 million for our art, but the foundations supporting science, physics, and philosophy turned us down. Good to see they are now supporting, "art, music and spirituality can bring us closer to this ultimate reality, but it is so mysterious we cannot know or even imagine it."

Yes–it is so mysterious we cannot know nor imgaine it, which is why I gave up on physics and wrote "I wanna be sedated."
http://www.youtube.com/watch?v=wMD7Ezp3gWc

We're applying to Templeton to get a second camera for our next video, a mobile tripod, and more postdocs than shown in this shoot.

35. **Marcus**
March 20, 2009

"hi Peter, I remember that 10 years ago the situation in theoretical physics was discouraging: we had a big problem, but nobody wanted to openly talk about it, keeping working on the usual topics. It is impressive to see how much the situation improved now.

Probably your blog played a key role, and without this new powerful tool that you managed in a great way, all criticisms would have been ignored."

Could you be specific? What are some objective indications that the situation has improved?

Can you name any prominent theoretical physicists whose research direction has changed for the better, by your standards? Or any other concrete signs of improvement?

I don't doubt you are right, a. By my criteria there has been an big improvement. What I want is to understand your criteria.

36. **Russ**
March 20, 2009

I hope I'm not too late to wish your blog a happy birthday! I'm a relatively new reader of your blog and an amateur maths-physics follower. I didn't realize the stakes against string theory until I started reading 'Not Even Wrong' . I really do hope mathematicians and physicists make some progress in TOEs and all before I'm too old to care 😉 ! Meanwhile, I will keep reading, wondering, and learning from your blog. Thanks!

Russ Van Rooy

37. **Joey Ramone**
March 20, 2009

Hello Marcus,

One of the invaluable services Peter has performed has been to provide a moderate, well-reasoned, honest voice. It is not easy sifting through the volumes of hype of our era and then summarizing it all in concise words, while enduring anonymous attacks from well-funded apponents and their hired fanboys. We had the same problem with Dexie's Midnight Runners and Bon Jovi in the early eighties but we ended up in the Rock'n'Roll Hall of Fame. Just as the univeristy presses were told not to publish Peter's book, the major labels were told to steer clear of our rock'n'roll. But truly, it is the music that makes the label, not the label that makes the music. And by rejecting Peter's book while embracing strings/convulted/obfuscatory math, the university presses took themselves down a notch, just like AIG/Merrill/Fannae Mae. This is sad, because math is a great and powerful entity; and now people are losing trust in it, just as people are losing trust in music because of American Idol and the Jonas Brothers.

The good news is that Peter is spearheading a renaissance in the university, where cleared of the string theory (antitheory) administrators, the schools will again be able to focus on more exalted maths and further real physics:
http://www.youtube.com/watch?v=BL4od3xzthM

Towards the end you can see the LHC creating black holes in a brillaint explosion where it neither proves nor disproves string theory, which is beside the point, as far before that we see proof that Phenomenologists (in black leather jackets) Sing and Dance Better Than String Theorists.
http://blogs.discovermagazine.com/cosmicvariance/2005/07/21/do-phenomenologists-sing-and-dance-%20%20%20%20better-than-string-theorists/

Over the past five years Peter's blog has shown that science can also be pursued in the spirit of truth-seeking, in addition to driving traffic to websites to sell ad space. Rock-rock-rock-rock-rock-and-roll-high-school!

38. **Thomas Dent**
March 20, 2009

> "One feature of many theorist's talks in recent years has been consistently overly optimistic predictions about when results from the LHC will arrive."

In what universe could this be a meaningful or fair criticism? Is Gross is at fault for failing to anticipate – by some type of clairvoyance, I suppose – that the LHC schedule would slip by several years? Back in 2001, I seem to remember the plan was that operation would start in 2005/6 and data start flowing in 2006/7. Why would one not take this at face value?

Just what attitude should Gross and other theorists have taken to avoid these cheap shots with five years' hindsight? 'LHC will probably be late and break down, so there's no point trying to plan how we're going to deal with the data'?

Someone who never goes on the record about what the state of the field might be in 5 years' time will never be wrong – but such a person also deserves no voice in allocating scientific resources. Many big experiments have to be scientifically motivated and planned 15 years in advance. In context, the quoted remark is more than myopic.

And who could ever have predicted that mathematical physics would suffer from a prolonged publicity campaign against a field where large numbers of the most talented mathematical physicists work?

39. **Peter Woit**
March 20, 2009

Thomas,

In my original 2004 posting, I pointed out that Gross's prediction of a 2007 announcement of discovery of supersymmetry was unrealistic, given the schedule in place then, even ignoring the fact that schedules on projects of this kind almost always slip. The criticism of his prediction as unrealistic was a rather minor one, but I continue to think it was valid. More generally, I think particle theory as a whole has suffered for a long time from too much wishful thinking about how the LHC is any day now going to solve all problems.

The current bad reputation of string theory comes not from my blogging, but from the combination of the way it was (and continues to be) overhyped, together with its complete failure as an idea about unification, and the unwillingess of its proponents to admit publicly what has happened. Sure, it was possible to predict that this would cause serious damage to the willingness of other physicists and society in general to support particle theory, especially in its more abstract forms. The hope that this could be stopped before it did a lot of damage was one motivation for why, back in 2001, I started pointing out the problem.

40. **Chris Oakley**
March 20, 2009

Hi Joey,

We have had all sorts of people contributing to this blog: not just high-energy physicists, but engineers, philosophers, science writers, and all the possible shades of loons. Despite this, they have all had one thing in common: they have all been alive. With your posting, though, the blog can claim something unique – a contribution from a dead person. I look forward to more insightful comments from you, and hope that you can persuade some of your fellow dead people to contribute also. Personally, it would be the insights of Paul Dirac and Ernst Stueckelberg that I would most value. So if you could have a word …

41. **Simon Cowell**
March 20, 2009

Joey Ramone, that was indulgent nonsense.

42. **Joey Ramone**
March 20, 2009

Thanks Simon. Congrats on American Idol and all the educational shows it has helped inspire:
http://www.math.columbia.edu/~woit/wordpress/?p=1520
http://www.math.columbia.edu/~woit/wordpress/?p=1237

Chris–it is a little known fact that Dirac was our ;lead science advisor on this video for rock 'n' roll high school:
http://www.youtube.com/watch?v=EiDvKqRjYn0&feature=related

Not content to merely have the leading science/hollywood experts of our day and age advise our artistic creation, we hopped on Michio Kaku's time machine and went back in time to ask Dirac questions. You can see the results about five seconds before the end.

We knew we could do better than those who brought you Dr. Manhattan in The Watchmen–who owes his blue glow to quantum black hole creation in an LHC experiment designed to probe higher dimensions, test string theory, and prove the existence of parallel universes.

It has been a lot of fun hanging out with Einstein, Feynman, and Bohr. None of us can stop laughing. Please do keep it up everyone! Never in the history of mankind has such supreme satire been conducted for so long with such straight faces. Ha!

43. **Revlin**
March 20, 2009

I'm happy to have discovered your blog a few weeks back and I hope it continues for at least another 5 years. I know you're one of those complex math types so the content is reflective of that, but I'm more turned on by the introspective articles like this one. I like that you brought up the trend of private groups funding "far out" research, because I think this is an area where academia has really fallen behind. Organization like Templeton and the Singularity university are going to leave university sponsored research in the dust, not just in the ideas that they validate, but in the way those ideas are actually applied to the broader society.

I have some gripes about your characterizations:
"d'Espagnat has a long career of serious work on the philosophy and interpretation of quantum mechanics, but what makes him eligible for the prize is having indulged in a certain amount of obscurantism concerning quantum mechanics, coupled with an indulgent attitude towards religion"

First off, the quote you provided mentions nothing specifically concerning religion, but does however address "art, music and spirituality." I don't see where you're coming from when you label these memes "obscurantism" considering their prominence and scope in the course of human development. I'll realize this is a somewhat specifically targeted blog, but surely you are aware that the topics you cover here (bosons, fermions, twistors, etc.) are exponentially more obscure to most people on this planet than music and art. And why is that?

Is there a connection between the waning interest in academic research, the growing enthusiasm for private research, and the widening gap between "mainstream", scientific theory and the various ontological theories that the public has locked on to? Why is occultism growing in variety, scope and sheer numbers of believers, concurrent with "real" scientists' efforts to explain everything through empirical means? In my mind it's a failure of the educational system to bridge the divide between scientific data about reality and public perception of reality. Can science explain my experience of the world?

I think the groups that attempt to answer these questions will become increasingly relevant to the common person as the years roll on, regardless of the legitimacy of their answers. If scientists cannot explain the implications of their research to the life of the individual, someone else will, and they will be believed, crack-pot of not.

44. **Revlin**

March 20, 2009

"…crack-pot or not."

Also, I wish there was some way to edit a submitted comment. Thanks for your reference to the Cayman Islands conference. The site you linked to has some really interesting blog topics:

45. **Cormac O Raifeartaigh**
March 20, 2009

Happy birthday Peter, well done and long may you keep it up. I myself have already started to repeat myself, two weeks shy of my 1st birthday!

Re "D'Espagnat says this points toward a reality beyond the reach of empirical science", I'm surprised. This looks like a fairly clear misunderstanding of HUP – as you know, it is not an uncertainty in our knowledge of position/momentum, but an inbuilt fuzziness in the quantities themselves…some philosopher!

46. **Eugene Stefanovich**
March 20, 2009

Peter,

almost five years ago I asked myself: "Is there a single person in the world who is independent and courageous enough to stand up against the string theory hype?" I started to Google word combinations like "string theory", "wrong", etc. The first thing I found was your blog. I have been reading it non-stop since then. Congratulations!

47. **stj**
March 21, 2009

Hi Peter,

happy birthday for this very informative blog.

Concerning d'Espagnat being awarded by the Templeton prize, it is of no surprise since, you might not know, he is member of "Université Interdisciplinaire de Paris" (UIP) [1]. On their website, the presentation of UIP is as follows: "The mission of the Interdisciplinary University of Paris (UIP) is to disseminate and bring into contact different visions of the world based on the study of contemporary scientific paradigms, mainly in the area of astrophysics, quantum physics, the theory of evolution, the neuro sciences and the philosophies of the spirit." In fact, UIP is the French equivalent of the Templeton Foundation (and they have partnerships). The veiled-reality concept from d'Espagnat was largely used by UIP members (including d'Espagnat but especially Jean Staune, the perpetual General Secretary of IUP) to advocate reconciliation between science and religion [3]. See also the article in Science [4].

48. **Peter Woit**
March 21, 2009

Revlin,

I don't think obscurantism and pseudo-science are an increasing problem among the general public. There have always been many sources of this, and they don't seem to be doing any better than in the past. The coverage of science in the media and the understanding and respect the public has for science seem to me as healthy as ever. The problem I do see is an increasingly large number of respectable scientists engaging in this kind of thing, and that's very dangerous. If you don't have real progress to promote, it's tempting to start hyping things which are not scientific progress, and too many people have been doing that.

49. **Revlin**
March 21, 2009

"the understanding and respect the public has for science seem to me as healthy as ever. "

Ah, but what is "science" in the public mind? What you call "obscurantism and pseudo-science" is what many others commonly infer as being based on "science." In a certain loose way it is based on science, but would you say it *is* science or in any way *validated* by science?
You are voicing my exact point when you say, "The problem I do see is an increasingly large number of respectable scientists engaging in this kind of thing, and that's very dangerous." This trend is going to continue in the upward direction and the division between what these guys profess and what you would call "real" science will become more and more blurry. Remember your entry on *What the Bleep*? Remember your frustration at having been in a minority group of critics of the scientific legitimacy of this films statements (relative to the millions who said, "Hmm, that was really interesting?"–how many people recommended the film to you?) That is evidence of the wide gulf between your circle of colleagues and *everyone else*.
I also don't see how you can say the general public is well informed about anything, especially through observation of states of media coverage, which are so disparate from real public perception. Try going to the mall and asking a random sampling of people what they think about the federal reserve central banking system. The breadth and consistency of ignorance about most worldly info is unbelievable, even when that info is overtly related to everyone's day-to-day existence.

50. **Peter Woit**
March 21, 2009

Revlin,

Maybe I'm an incurable optimist, but my take on "the general public" seems to be different than that of a lot of my Ivy League classmates. What I've seen over the years of talking to people is that, sure, they're often ill-informed about science, economics, whatever (although they'll often surprise you with how much they know). At the same time, they often are well-aware that they don't know much about these subjects, have a lot of respect for them, as well as common sense about them.

But, in the end, I'm in some ways an elitist. I just don't think it's very important if the general public is well-informed about, say, elementary particle physics. It's important that they have a general idea what the subject is about, and an openness to the idea that it's worth studying, even if they don't want to do so themselves. The serious problem worth worrying about is the quality of the thinking on a subject by its experts. If experts in particle theory are devoting their time to studying Boltzmann Brains, that's a big problem, far worse than whatever misconceptions the general public may have.

Similarly, the general public may not understand how the Federal Reserve works, but it's not clear that that's important. What is important is what happens with the people who do understand how it works, e.g. those who run it. We're in the middle of a world-historical disaster caused by the experts who run large financial institutions, including those most expert at the technicalities of how they work. That the average person does not understand these technicalities is both not surprising and mostly irrelevant.

51. **Revlin**
March 21, 2009

"We're in the middle of a world-historical disaster caused by the experts who run large financial institutions, including those most expert at the technicalities of how they work."

Experts who made, are making, and (if the trend continues) will continue to make a lot of money. The disaster is not a result of the experts failing in their understanding and capability to manipulate market systems. Perversely, the failure is a result of their *success* in diverting as much capital from the general public (including their own share-holders) to their pockets as possible. They are so good at this that they're *still doing it*, and being highly compensated for doing it well. So, what's the problem? The Big Picture.
"Experts" who have no interest and no incentive to consider the Big Picture will act with no heed or care for the needs of others. I see this happening in engineering consistently. If global change is the supposed big issue of our times, why is so much money being poured into developing tech for telecoms, popular entertainment, and non-renewable resource harvesting and so little going towards alternative resource management? Lack of incentive. Lack of public insight. Why is *Watchmen* backed by a $120 million budget while public universities across the country are struggling to keep their doors open?
The public gives a damn about inane, big-budget action movies. They do not give a damn about particle physics. You don't think this is a problem?

52. **D R Lunsford**
March 22, 2009

More should be written on the relation of the failure of fundamental science to that of financial practice, which I am calling "the hyperverdant castastrophe" because so many ex-physicists and mathematicians ("quants") were involved. Of main interest is the role of the appropriate press in both cases, both internally (journals and whitepapers) and externally (OMNI and the Wall St. Journal).

Collider Smackdowns

March 21, 2009
Categories: Uncategorized

If you're interested in particle physics and not regularly reading Tommaso Dorigo's blog, you should be. His latest posting reports on incendiary claims by Michael Dittmar of the CMS collaboration that recent Tevatron Higgs mass limits are wrong and not to be believed. According to Dittmar, the Tevatron is basically useless for looking for a SM Higgs, with only the future LHC experiments ever having a chance to see anything or produce real limits. You can look at the slides and the blog posting and make up your own mind. From what I can tell, Dittmar doesn't make a strong enough case to show that the Tevatron results are wrong. It remains true of course that the statistical significance of the limits being set ("95% confidence level"), is right at the edge of what is normally taken as capable of seriously ruling something out.

In the latest New York Review of Books, Freeman Dyson, in context of a review of Frank Wilczek's The Lightness of Being, engages in his own smackdown of particle physics at colliders. Here's what Dyson has to say about the LHC, and colliders in general:

> Wilczek's expectation, that the advent of the LHC will bring a Golden Age of particle physics, is widely shared among physicists and widely propagated in the press and television. The public is led to believe that the LHC is the only road to glory. This belief is dangerous because it promises too much. If it should happen that the LHC fails, the public may decide that particle physics is no longer worth supporting. The public needs to hear some bad news and some good news. The bad news is that the LHC may fail. The good news is that if the LHC fails, there are other ways to explore the world of particles and arrive at a Golden Age. The failure of the LHC would be a serious setback, but it would not be the end of particle physics.
>
> There are two reasons to be skeptical about the importance of the LHC, one technical and one historical. The technical weakness of the LHC arises from the nature of the collisions that it studies. These are collisions of protons with protons, and they have the unfortunate habit of being messy. Two protons colliding at the energy of the LHC behave rather like two sandbags, splitting open and strewing sand in all directions. A typical proton–proton collision in the LHC will produce a large spray of secondary particles, and the collisions are occurring at a rate of millions per second. The machine must automatically discard the vast majority of the collisions, so that the small minority that might be scientifically important can be precisely recorded and analyzed. The criteria for discarding events must be written into the software program that controls the handling of information. The software program tells the detectors which collisions to ignore. There is a serious danger that the LHC can discover only things that the programmers of the software expected. The most important discoveries may be things that nobody expected. The most important discoveries may be missed.

He goes on to somehow count Nobel prizes for experimental results in particle physics, with the conclusion:

> The results of my survey are then as follows: four discoveries on the energy frontier, four on the rarity frontier, eight on the accuracy frontier. Only a quarter of the discoveries were made on the energy frontier, while half of them were made on the accuracy frontier. For making important discoveries, high accuracy was more useful than high energy. The historical record contradicts the prevailing view that the LHC is the indispensable tool for new discoveries because it has the highest energy.

His argument that proton collider physics is problematic because of the huge backgrounds and difficulty of designing triggers just states the reasons why these are complicated and difficult experiments. Despite the difficulties, they have produced a huge number of new physics results. He doesn't give the details of how he is counting and categorizing Nobel Prize winning results, so that part of his argument is hard to evaluate.

In opposition to colliders, Dyson wants to make the case for passive detectors, with his main example Raymond Davis's discovery that the neutrino flux from the sun is 1/3 what it should be. I don't really see though why he sets up such experiments in opposition to high energy accelerator experiments. Right now many of them actually are accelerator experiments (for example MiniBoone), with an accelerator being used to produce a beam of neutrinos sent to the passive detector. Dyson's point that if one is very smart and lucky one may get indirect evidence about physics at high energy scales from passive detectors looking at cosmic rays is valid enough, but there is no shortage of people trying to do this, and it is every bit as problematic as working with colliders. There are inherent reasons that such experiments can't directly investigate the highest energies or shortest distance scales the way a collider experiment can. It's extremely hard to come up with a plausible scenario in which cosmic ray experiments will give you any information about the big remaining mystery of particle physics, electroweak symmetry breaking.

While I agree with Dyson that the huge sales job to the public about a new golden age of physics coming out of the LHC is a mistake. I don't see any reason to believe that if it fails cosmic ray experiments are going to get us to a golden age. If and when particle physics reaches a final energy frontier, with higher energies forever inaccessible to direct experiment, hopes for a golden age are going to rest on theory, not experiment, and recent experience with such hopes isn't very promising.

Update: This Sunday the New York Times will have a profile of Dyson, see here.

Comments

1. **TSM**
   March 21, 2009

   Very naive newbee question by why did the LHC designers decide to go with a proton/proton system versus proton/anti-proton? Wasn't the SSC suppose to be proton/anti-proton?

2. **TSM**
   March 21, 2009

   For got my last part: are anti-proton/proton experiments less noisy with regards to background?

3. **Shantanu**
   March 21, 2009

   Peter, proton decay is one example of a non-accelerator particle physics
   experiment which probes physics at very high energies. Or you are no longer sanguine about proton decay being discovered?
   Also any comments on Raphael Bousso's colloquium at PI?

4. **Peter Woit**
   March 21, 2009

   TSM,

   I believe the SSC was also a proton-proton machine. The problem with antiprotons is that it's hard to accumulate them and get an intense enough beam, limiting the luminosity one can achieve. As one goes to higher energies, the cross-sections one is interested in fall off, and you need higher luminosity. Maybe someone more expert than I can address the issue of relative backgrounds.

Shantanu,

I think the most likely end result of proton decay experiments will just be that protons don't decay at any rate one can ever hope to observe. If so, these experiments won't tell you anything about high energies, other than that baryon number stays conserved. If proton decay is observed, that would be extremely interesting, and would give the sort of thing Dyson is hoping for.

As far as I can tell, Bousso's talk is just more of the same. I don't see any hope for getting real science out of that.

5. **Bee**
March 22, 2009

Sounds like what he is actually saying is: hey folks, even if the LHC fails, be prepared to spend more billions on a lepton collider.

6. **anon**
March 22, 2009

Hi Peter

You said:
"It remains true of course that the statistical significance of the limits being set ("95% confidence level"), is right at the edge of what is normally taken as capable of seriously ruling something out."

As far as I was aware it is only in the social or medical sciences that 95% or two sigma is considered even worth mentioning, in astronomy its usually 3 sigma and in particle physics five sigma. Many in astronomy think it should be five sigma as well. I think two sigma should never be taken as more than the slightest of a hint that something could be ruled out.

7. **AOJ**
March 22, 2009

In comparing the potential of cosmic ray experiments to collider experiments, you should remember cost scale. Auger, the biggest and most ambitious cosmic ray experiment had a price tag between $100 and $200 million. If you threw LHC-sized funding at a building a single, amazing cosmic ray detector, you would get immediate breakthroughs in multiple areas of astrophysics and quite likely particle physics as well. The center-of-momentum energy for collisions of the highest energy cosmic rays is ~100 TeV. We certainly won't be probing that scale in collider experiments any time in the foreseeable future.

8. **Peter Woit**
March 22, 2009

AOJ,

Yes, but the luminosity of cosmic ray experiments is way too small at TeV and above center of mass energy scales to be useful, and building a 50xAuger that cost as much as the LHC wouldn't change that. You would learn more about astrophysics, but I don't believe you'd learn anything about TeV-scale particle physics phenomena like electroweak symmetry breaking. For a 120 Gev Higgs, how big a cosmic ray experiment would you have to build to see evidence of it?

9. **David B.**
March 22, 2009

TSM

Antiprotons are expensive to produce and maintain. At very high energies the collisions are dominated by gluons rather than quarks, so most of the events will be from glue collisions that do not distinguish protons from antiprotons.

For some types of searches, it is better to have a proton anti-proton setup, if the physics depends heavily on having quark-antiquark collisions at high energies.

If you are looking for colored particles or the Standard model Higgs, proton-proton will do just as good a job as proton anti-proton.

10. **Chris Oakley**
March 22, 2009

I am not quite sure what Dyson is getting at vis a vis choice of particles as at TeVs one tends to produce a godawful mess regardless of whether the beams are p/p, e+/e- or whatever.

11. **The Real Deal**
March 22, 2009

I don't know if Dyson is smart or dumb.

First the dumb part:
Sitting on his high armchair in comfort, he criticizes the LHC in hindsight, even before it's operational. The LHC costs some $4B to build, another $1B to run experiments, a dozen years to design and built, by thousands of physicists and engineers. The most sophisticated of intellectual efforts contributed by people who actually sweat it out instead of setting pretty in armchairs. Vast amount of public money, reputation, national dreams poured into it. It had better work. It had better produce. No further hyping necessary. The scale of the effort is 'hype' enough. Dyson should simply shut up and stop looking dumb.

Now the smart part:
If Dyson is so smart educating us all the reasons why the LHC should not be built, why don't he propose his superior design to replace it? Try getting $10B to build it. And let other do the criticizing in their armchairs.

12. **Observer**
March 22, 2009

…It had better work. It had better produce…
But what if not. We all have seen the main problems in the first run of the LHC are due to basically Quenching and heating, both of this problems relatively "basic" despite

all the intelectual effort behind them.

13. **Zathras**
March 23, 2009

The Real Deal,

Dyson has been criticizing p-p colliders for about 20 years now. I myself went to a talk of his in 1991 where he criticized the SSC for being as such. He is not coming late to this, and he has proposed alternative designs (a lepton collider). He just hasn't been able to convince enough scientists of what he perceives as the superiority of lepton colliders.

14. **milkshake**
March 23, 2009

Dyson is mildly non-conformist – he also likes to write against the global warming agenda orthodoxy. I bet he finds the neatly- designed passive detector experiments far more marvelous than accelerator physics.

15. **a quantum diaries surivivor**
March 23, 2009

Hi Peter,

I feel obliged!

I would like to stress, to answer anon's comment 6 above, that HEP physicists do not use 95% CL limits as a claim of anything. However, I agree that unfortunately the importance of such results gets unduly overestimated. So much so that the occasional Dittmar can feel compelled to refute them and waste his reputation in meaningless talks.

Cheers,
T.

16. **John K**
March 23, 2009

TSM
re : PBar (Antiproton) -P vs, PP

Advantages of PP (vs. PBarP)
–much easier to get intense P beam than PBar beam, so can get to much higher luminosity (interaction rate) –perhaps a factor of
hundreds or even thousands
–does not need the Pbar production system (which, in the case of the Fermilab PbarP collider, involves a very complicated system of production target, collector (lithium lens), cooling ring, accumulator, etc.
–LHC at 7+7 TeV will have a much higher production crosssection of new physics, especially above 200 GeV–and can reach masses not available in the 1+1 TeV Tevatron

Disadvantage of PP (vs. PBarP)
–PBarP need only one ring of magnets (PBar and P goes in opposite direction in the same ring)
–in low masses (such as 100-200 GeV, where the Higgs is expected to be), Signal to background is somewhat better
than PP

17. **Chris Oakley**
March 24, 2009

John K,

Another advantage of the p-p_bar system is surely that the resonances are likely to be more interesting, having zero charge and baryon number. Did they not use that (in an e+e- system) to investigate the J/Ψ? Would this still be relevant at much higher energies?

18. **Coin**
March 24, 2009

The machine must automatically discard the vast majority of the collisions, so that the small minority that might be scientifically important can be precisely recorded and analyzed. The criteria for discarding events must be written into the software program that controls the handling of information. The software program tells the detectors which collisions to ignore. There is a serious danger that the LHC can discover only things that the programmers of the software expected… The most important discoveries may be missed.

I don't think this is a very compelling argument. As Peter points out this is certainly a challenge for the LHC operators, but it's hardly a reason to cast aspersions on the LHC's results.

First off, the dangers of selectively discarding data sound entirely possible to mitigate. Even knowing very little about particle accelerators but knowing something about software I can think of basic ways to test for such a problem, like running tests with different triggers. Meanwhile [I actually got a chance to ask one of the USLHC bloggers about this exact problem once] and part of her response was:

> We can study these efficiency and biases using a very detailed Monte Carlo simulation of the trigger and detector. And we validate this simulation with the actual data using well-measured physics channels such as W, Z decays and QCD processes. As most SUSY models predict very energetic and multiple jets of particles, the trigger is expected to be very efficient and non-biased. But these are statements that we have to confirm before we can hope to publish.

I take this last sentence to mean that part of the published data for the LHC will be their evidence that their trigger scheme is not biasing or eliminating signal from the data. If Freeman Dyson thinks that evidence is inadequate, he can write a paper presenting his argument and it will be a big deal and everyone will read it because he is Freeman Dyson.

Second off, it kind of seems like this would be one of the easiest things about the LHC to upgrade. As far as I know the only reason for the automatic discarding of data is that storing and processing all that data is impractical. But what is practical in data storage changes all the time. If this is shown to be legitimately a problem it seems like it would be much easier to just slap in some fancy new hard drives than it would be to, say, increase the LHC's luminosity.

19. **Coin**
March 24, 2009

Sounds like what he is actually saying is: hey folks, even if the LHC fails, be prepared to spend more billions on a lepton collider.

Are there currently any plans to start building any lepton colliders at any point?

20. **Peter Woit**
March 24, 2009

Coin,

I don't disagree with Dyson that the necessity of using triggers is a serious problem for colliders, but there really isn't any choice, and it's up to the experimenters to do the best they can within the constraints imposed by the necessity of the triggers.

The nature of the problem is not that you won't be able to trust the results coming out of these experiments. If they look for an sparticle with certain properties, the trigger will be designed with this in mind, and the limits they quote or evidence they find should be trustworthy. The problem is with new physics that is not expected, that it might get missed because no one is looking for it. Dyson's point is that in something like a proton-decay experiment, you look at every event and make sure you understand it. New physics will be quickly identified, no matter what it is. In a collider experiment, one can imagine that there might be new physics that no one has thought of, with an experimental signature that gets thrown out by the triggers. I don't have much of a feel myself for what the likelihood of this might be, but I imagine it's a worry that keeps some of the experimentalists up nights when they design triggers.

There are two major on-going projects to design a lepton collider (ILC and CLIC). The current situation though is that no decision to build such a thing is likely until several years from now, after results from the LHC are in. Knowing what if any new physics is in the accessible energy range is crucial for the design of such a machine.

21. **Coin**
March 24, 2009

Ah, I hadn't realized the ILC was a lepton collider.

22. **srp**
March 24, 2009

Dyson has written eloquently in the past about what he sees as the "ecological" error of putting too high a percentage of a field's resources into a single project. That's one reason why he opposed the SSC, criticized the USSR's giant optical telescope, etc. Read his brilliant essay in From Eros to Gaia on the subject (I can't remember the exact essay title–it had something to with first, second, and third worlds).

23. **Thomas D**
March 30, 2009

Perhaps Dyson hasn't noticed that many theorists have been busy trying to think of classes of theories that 'standard' triggers and cuts miss, and have been working with the experimentalists to ensure that as little as possible gets away.

Also that experimentalists have been developing 'model-independent' search techniques that look for excesses over background regardless of whether they fit a favourite model or not.

I wouldn't expect anything different from someone who has been retired from research in particle physics for a long time. Dyson is extremely old and clever and respected but(/and) has no reason to keep up with recent developments.

The idea of trying to use cosmic rays to do electroweak scale particle physics is utterly impractical, because you would need literally square miles, if not cubic miles, of tracking detectors high in the atmosphere to see any interesting interaction. Auger is great by any cosmic ray detector standards but it just measures the overall parameters of a huge cloud of hadrons and photons.

I understand that p-pbar collisions were disfavoured for LHC as they would produce significantly more hard q-qbar events which from the point of view of new physics are almost entirely background.

24. **Andrei**
April 16, 2009

Don't you get the feeling that the Dittmars at CERN are getting scared? Until now they had this sort of monopoly on the Higgs boson as they thought that the Tevatron would never say anything meaningful on the matter. Not that the Tevatron has tresults, CERN is getting ants in the pants. Especially since the LHC is as far from running as it was 2 or 3 years ago.

I think running deadlines should be set by the funding governments not some scientists and contractors interested in prolonging their jobs. In other words: operate by x date or lose it.

The Nature of Truth

March 24, 2009
Categories: Multiverse Mania

Seed Magazine has a video and transcript up of a discussion between cosmologist Paul Steinhardt and philosopher of science Peter Galison advertised as *The physicist and the historian discuss the nature of truth as theoretical models of the universe become increasingly difficult to test*.

Steinhardt is no fan of the anthropic landscape and makes a general attack on the idea of eternal inflation, explaining why he prefers his cyclic model:

> The original idea — the way it's often talked about in literature and textbooks, even the way we talk to students — is that inflation makes everything in the universe the same. What we've learned is that inflation actually divides the universe up into little sectors that are all different from one another. Some regions of space would be habitable like ours, but others would be inhabitable; still others would be habitable but would not have the same physical laws or the same distributions of matter that we see here…
>
> Because you have an infinite number of everything, you have no rigorous mathematical or statistical way of computing a probability — it's not even a sensible question to ask. So people are in the process of trying to regulate this infinity. For example, they try to invent a rule for deciding probability that makes what we see likely. But there's no way of deciding why that rule instead of some other one. They simply keep trying until they've found the answer they wanted. Some people are going down that path and are prepared to declare victory if they find something they think works.
>
> Others take a different path. They accept the infinity of infinities and the fact that they can't find any measure for deciding whether our circumstance is more probable or not. They'll be satisfied with the fact that at least some patches look like what we see, and will declare victory on that basis.
>
> Personally, I don't find either of these approaches acceptable, which is why I have developed an alternative picture in which the big bang is not the beginning. A big bang repeats at regular intervals of a trillion years or so, and the evolution of the universe is cyclic.

The two then get into a philosophy and history of science discussion, starting with Steinhardt's:

> We've been talking about an example in which you have a complex energy landscape and an infinite number of possibilities for the universe. But we have no real explanation as to why things are the way they are, because it could have been different.
>
> So it has no power. And without real explanatory power, it's not interesting to me. But I'd be interested to hear how this has played out in the history of science.

and Galison's response:

> We have that sort of split right now among the string theorists. One side says, "Look, what's really scientific is to say there's this infinite or very huge number of craters to be imagined in some landscape, each of which carries different physical particles and different physical laws and so on. And we happen to live in one of them."
>
> But the other says, "You've given up! You've given up the historical project of science. We went into string theory because we wanted to produce a theory that had one parameter, or very few movable parts. And now instead of a glider you've got a helicopter with 10,000 little pieces that have to move exactly the same way. If the slightest thing goes off, it falls to the ground in a heap of burning aluminum."
>
> It's really an interesting moment in that way.

Steinhardt describes the current situation as follows:

> I think it's historic. There's a certain community that feels, "This is an 'aha' moment. Science has to change. We have to accept that science has limits. There's only a certain amount that we'll be able to predict. Beyond that we're going to accept that we live in some special corner of space in which seemingly universal laws — including Newton's law of gravity — are just local environmental laws that aren't really characteristic of the whole."
>
> Other groups say, "Hold it, this is failure. We either find ways of fixing the problems in those theories, or we scrap them and replace them with something else."

The source of the problem here is not actually eternal inflation, but string theory. It is the fact that one needs to postulate a huge landscape in string theory in order to have something complicated and intractable enough to evade conflict with experiment that is the problem. Once one has this, and populates it with eternal inflation, then one has a pseudo-scientific framework with no explanatory or predictive power. Galison notices that string theorists are dividing up into those who follow this path, and those unhappy with it, but it is only Steinhardt who makes the obvious point that what's going on here is just garden-variety scientific failure. The failure though is not attributable to the general idea of inflation, but rather to the string theory-based assumption that fundamental physical theory involves a hopelessly complicated set of possibilities for low-energy physics.

Comments

1. **srp**
   March 24, 2009

   Straight up now:

   1) One could argue that it's too soon to give up looking for "simple" theories that a) unify all of high-energy physics and that b) deduce most of the empirical parameters from just a few, but that string theory isn't the answer to this problem. (This is my understanding of the Woit position.)

   2) One could argue that someday string theory will become that simpler elegant theory and that it is by far the leading candidate to achieve unification and parameter reduction. (This is my toned-down understanding of the Motl position.)

   3) One could argue that no fruitful approach to unification and parameter reduction has been found after a lot of effort and that there are reasons to think that the task is impossible (e.g. a small cosmological constant that is hard to derive from first principles). Then trying to develop a theory of why the parameters are what they are is like trying to develop a first-principles theory of why the earth has its specific circumference or why Britney Spears is blond–a misguided exercise in futility. (This is my understanding of the Susskind position.)

   4) One could propose some theory of one's own that allegedly solves the problem but has been ignored by everybody for various political and sociological reasons. (This is my understanding of the position of some of the commenters on this blog.)

Other than existential or philosophical commitments, is there any rational basis for choosing amongst 1) – 4)? Because what I mostly see is a lot of foreign tourist syndrome–people repeating their assertions LOUDER and S-L-O-W-E-R in the hopes that their interlocutors will understand the invincible correctness of their view.

2. **Peter Woit**
   March 24, 2009

   srp,

   Personally, I don't think this has anything to do with existential or philosophical commitments, rather with the fact that 2) is wishful thinking, 3) is pseudo-science, and 4) are generally being ignored for good scientific reasons. But that's just me….

3. **srp**
   March 25, 2009

   I guess I think that objections to 3) ARE purely philosophical or existential (having to do with the definition of science). Further, they rest on a very particular view of science that is really most relevant in physics and chemistry–that science doesn't study the particular histories of things but seeks only general laws that apply in all times and places.

   I personally find this ideal rather congenial but there is no way to make it a necessary condition for work to be scientific. Otherwise structural geologists who explain how a particular mountain came to be would not be scientists. Not to mention the issue of evolutionary histories in biology.

   In my opinion, the ideal of ahistorical and universal explanations in physics was really placed in danger by two related phenomena: The end of steady-state cosmology and the interpenetration of cosmology and physics. When I was growing up, I just assumed that the universe was eternal and had always existed; talk of "in the beginning" or "the beginning of time" seemed to me nonsensical, poetical, or mythological. In such an eternal universe, we don't explain "where things came from"–the universe has no history and just IS. In such an environment, it wouldn't be possible to explain why the particles have the masses they do (or any other empirical parameter) by appealing to historical accident.

   Then came the Big Bang theory, which necessarily opened the door to the possibility of such developmental accidents. "The symmetry just happened to break this way" and similar arguments become ways of saying that "stuff happens" when an explosion happens and creates the universe.

   The impact of the new cosmology on physics was delayed a bit because at first the flow of ideas was mostly from physics to cosmology. But as the Big Bang and its attendant ideas (e.g. inflation) took hold of the imagination, and as physicists started speculating about high-energy regimes beyond the range of their accelerators, they started to use ideas from cosmology to make sense of the physics. I'm not sure this intimate embrace is healthy for either field (I worry that each assures itself that the other has the answers to its deepest problems rather than solving them directly), but it was probably inevitable.

   Now that physicists turn to cosmology to think about things like ultra-high energy regimes where forces are unified, and given that cosmology is historical given the Big Bang, the door is open for thinking that lots of facts about the universe–particle masses, forec strenghts, etc.–are accidents not derivable from first principles or models with fewer parameters. It almost seems natural, even if you don't believe in multiple universes.

   After all, we turn to historical accident to explain the strength of the Earth's magnetic field, the size of the Sun, and so on. Yet no one argues that the people studying these things are unscientific because they don't deduce these facts from basic symmetry principles. So I think that the general discomfort with these ideas is philosophical and existential.

4. **Aleksandar Mikovic**
   March 25, 2009

   I liked the description of philosophies behind the various proposals for the Theory of Everything given by Srp, and it is good that people are aware of various approaches. Note that even the usual scientific method is based on the beleif that our world can be described in a certain way. However, formulating a TOE is not just another scientific theory, because the domain is the whole Universe and everything in it, and this clearly is not the usual situation. A good analogy is when somebody tries to apply the usual quantum mechanics to the whole universe, and consequently encounters problems of how to define the measurement (no outside observers), how to define probabilities etc. Every scientist has a dream that the Universe can be described by a set of equations which can fit on a t-shirt, but our Universe may not be of this kind. But even if our universe is not described by a simple mathematical structure, I don´t think that would be the end of science. This situation would require a more general way of thinking then the usual scientific way.

5. **thought**
   March 25, 2009

   I think some people need to realize the difference between everything that can exist, and everything that does exist.

6. **Rick Ryals**
   March 25, 2009

   It is a historically recorded fact that scientists ignore certain types of theories for political and sociological reasons, and you can bet your last buck that there will be no complete theory of quantum gravity, and no ToE, as long as this remains the case:

   http://dorigo.wordpress.com/2008/06/23/

7. **Zathras**
   March 25, 2009

   I also like srp's description of the various options. Peter, could you explain further why you would contend #3 is pseduoscience?

8. **Peter Woit**
   March 25, 2009

   Zathras,

   I think I've already done this ad nauseam on this blog. There's nothing wrong with the idea that some things are just an accident of history and you can't compute them. But if you want to do promote a theory and claim that it is science, it has to have some predictive power. If your theory is nothing but an elaborate excuse for not being able to predict things, then it isn't science. If you look into what is going on with the string theory landscape, that's what you find.

9. **Zathras**
   March 25, 2009

Peter, I agree with your stand on Susskind's view on string theory here. This, however, is not what #3 says (although it is part of what Susskind says; there is a discrepancy here). Susskind has two points; one negative (described in #3) and one positive (effectively demolished by you). My question was what do you think of the negative theory described in #3, and why is it pseudoscience?

10. **Joey Ramone**
March 25, 2009

String theory is pseudoscience.

It will be around for a decade or so yet, mostly promoted by physicists in their 70s, some of their past postdocs yet writing grant proposals, and journalists who will slowly realize that it no longer sells magazines like it used to, as it just isn't "cool" anymore, due to the old men hyping it. Brian Greene wore a cool black leather jacket much like mine in an Elegant Universe, and the DVD sold very well, but he probably won't be inducted in the Rock'n'Roll Hall of Fame. He might yet win a Nobel, but in literature or maybe even economics, for mining higher dimensions for millions.

11. **Peter Woit**
March 25, 2009

Zathras,

It seems to me that I'm just repeating myself, but again, the point is that a theory has to have some conventional predictive power about something or else it's not science. If you can't even in principle test it and find out if it's wrong, it's not science. The theory that the fundamental constants were chosen on a whim by the Jolly Green Giant has a great deal of explanatory power but predicts nothing.

It's bad enough to promote pseudo-scientific explanations, worse to do so as a bald-faced attempt to evade the consequences of failure.

12. **Zathras**
March 25, 2009

Peter,

I understand what you're saying. The underlying assumption you are using, however, is that a predictive theory to find these constant (a) exists and (b) can be found. This kind of assumption does not seem to me to be scientifically based, since no such theory of everything has been found.

The inherent problem in the debate is that science self-selects those people who believe the assumption above. If someone did not believe it, they probably would not go into, or stay in, science. I know this from personal experience. I left graduate school at Caltech for mainly these reasons. I lost my faith that such theories could be found, and so I left science.

Again, I am not defending Susskind's defense of string theory. It is not defensible. The lack of an ability to find a testable theory does not allow one to ironically spin out elaborate B.S. and call it science. The negative theory stands on its own. It can be falsified by the finding of such a theory. Since this has not occurred, and I doubt it ever will, the negative theory is what I will place my stake in.

13. **thought**
March 25, 2009

I don't see what people like in srp's classification of possibilities into cases 1)-4). The cases are not mutually exclusive and don't even come remotely close to covering the possibilities.

On the other hand they have the interesting recursive characteristic that srp's classification itself clearly falls into case 4).

14. **Peter Woit**
March 25, 2009

Zathras,

I honestly have no idea which if any of the parameters in the SM can be computed from first principles, and which are historical accidents. I'm not making any assumptions about that at all. I do believe though that the SM is not a final theory and we can do better. That's a working assumption based on history, looking at the problems of the SM, and having some very general ideas about what a better theory might look like that I think are worth pursuing. People who think the SM can be improved upon and who want to try should work on this, those who think it's hopeless should do something else, just not invoke the failure of one idea as proof of hopelessness.

15. **anon.**
March 25, 2009

'The underlying assumption you are using, however, is that a predictive theory … (a) exists and (b) can be found. This kind of assumption does not seem to me to be scientifically based, since no such theory of everything has been found.' – Zathras

You only know what exists and what can be found once you've found them. Scientific research is exploration, and no explorer ever knows in advance for certain what will or can be found. You try to find things. If you stop science because you are uncertain whether you will make progress, you're finished straight off.

I don't think that Woit is implicitly assuming that a theory of everything that makes falsifiable predictions exists and can be found; merely that science is about searching for such things.

If you find a road turns out a dead end, you should admit failure, and try to find a new pathway. You can't know what you are going to find in advance. That's the point of science. Religion is about believing claims that can't make falsifiable predictions.

Scientists should pursue ideas they find interesting, but they shouldn't believe in their validity until they have solid evidence.

Some guy essentially discovered X-rays (causing fluorescence outside a cathode ray vacuum tube) before Roentgen, but he didn't bother to publish (or feared censorship?) because it seemed to contradict the reigning theory of solid impenetrable atoms! That's what you get from believing unproved orthodoxy.

16. **Peter Shor**
March 25, 2009

My opinion (which probably shouldn't count for too much): It's clear that the Standard Model isn't the final theory because it doesn't account for gravity. Previously, any time we've unified two existing theories, this has increased our predictive power – think of Maxwell's equations, special relativity, general relativity, the SM. It would be very disappointing if that didn't happen with the unification of the SM with gravity.

17. **milkshake**
March 25, 2009

There is just not enough to go on. If they cannot propose any signature of the multiverse spawning business then they should say so (and try to do something about the problem).

Not too long ago geologists used to argue whether the continents are moving and whether meteorites produce craters. These things are hard to watch in action but the indirect evidence got pretty good eventually.

18. **neo**
March 25, 2009

The issue is no doubt philosophical–that is why it is not science. As a committed Copernican, I recognize that I live in a privileged environment (the inhabitable zone of a star), and I have no problem with the Anthropic principle as an explanation. So what is wrong with the landscape? the difference is that I know that the (much greater) nonhabitable zone exists–I can observe it. Those who invoke the landscape assert non-habitable universes that we cannot observe, nor have any hope to observe. That is why it is not science. The question is whether Steinhardt's cyclic universe theory is any different.

19. **Artful Codger**
March 25, 2009

[a] Inflation is well-supported observationally
[b] Many models of Inflation are eternal
[c] It is therefore perfectly "scientific" [in the sense that it flows from a theory with observational support] to believe in the existence of large numbers of other ["Coleman-De Luccia"] universes.
[d] Standard QFT makes the *observed* value of the cosmological constant seem utterly bizarre [See Polchinski's 2006 article on the arxiv].
[e] I conclude that the anthropic explanation of this particular number is very plausible.

What I find strange is this: detractors of the anthropic explanation of the CC never seem to be able to propose an alternative. Dear Peter: would I be correct in assuming that you believe that one day somebody will come up with a physical theory that allows one to *compute* the value of the CC from mathematics? This means that *mathematics* is "designed" to allow our existence. This is far more bizarre than the anthropic explanation.

I have sympathy for your points about the role of string theory here, *though* as you can see above, string theory really doesn't have much to do with it at all! What I mean is: if *anyone else* had invoked the anthropic principle, say the LQG people, then certainly the macho string types would have started testiculating about the flabby philosophizing of their opponents. But one should not allow these sociological phenomena, striking though they may be, to obscure the fact that the anthropic explanation of the facts is actually the *least* weird alternative.

20. **Peter Woit**
March 25, 2009

Artful Codger,

No, I have no idea whether the CC is the kind of thing computable from first principles. Maybe the anthropic explanation of its size is correct, who knows? But if you want to claim scientific evidence of an eternal inflation scenario producing a multiverse with a distribution of CCs that allows such an anthropic explanation, you have to come up with a conventional scientific prediction. If this is science, there has to be some way, at least in principle, to put it to a convincing experimental test. Tell me some measurement that someone will someday be able to go out and make that your theory gives a distinctive prediction for. If you can't do this, what you are doing is just making up untestable speculative scenarios, with no way to ever find out which corresponds to reality. That's not science, it's pseudo-science.

And, like any pseudo-science, it's harmless as long as it's ignored by most of the scientific community, which so far seems to be the case (do you have any idea how idiotic most physicists think this kind of thing is?). It's not harmless if it becomes a dominant ideology, used to prop up a failed research program.

21. **Artful Codger**
March 25, 2009

"And, like any pseudo-science, it's harmless as long as it's ignored by most of the scientific community, which so far seems to be the case (do you have any idea how idiotic most physicists think this kind of thing is?)."

Sure, "most physicists" think, or pretend to think, that this kind of work is idiotic. That means nothing. Phil Anderson seems to think that *all* fundamental physics research is idiotic, and I guess that most condensed matter physicists agree. So what? If we allow physics research to be directed by the inferiority complexes of the collective, then we really are doomed. By the way, these same physicists whose help you are enlisting might apply the same words to the kind of research *you* favor. In fact, I'm pretty certain they would.

Calling something idiotic is not terribly scientific. Coleman certainly was no idiot. The fact that our best theory of the early universe [Inflation] leads to unpleasant consequences is not something we should ignore.

Experience suggests that suspending judgement on such matters is not a productive way to go. It's better to identify the most plausible explanation of the facts, and then push it until it works or something better comes along.

22. **srp**
March 26, 2009

Kepler attempted at one point to explain the structure of the solar system by mapping it to nested Platonic solids. Thus the sizes of the various planetary orbits would be a consequence of fundamental mathematics.

Today we think that is crazy, not just because the particular geometric model is unmotivated but because the entire category of explanation is believed to be impossible and misguided. There IS no fundamental, ahistorical explanation for the sizes of the particular planetary orbits in the solar system and nobody sensible wastes his time trying to find one.

We understood this for centuries not because we had data about other stars' planets (we didn't) but from general principles about Newtonian theory and what it could or could not do. The assertion that there is no way to derive specific planetary orbits from first principles is not pseudo-science at all, even if it generates no empirical predictions.

So, since we don't need to rely at all on string theory or multiverse ideas to do it, it can't be pseudo-science to tell people to stop looking for ahistorical explanations of things that are, on theoretical examination, very unlikely to be derivable from first principles. It may be bad advice, in that a clever or lucky person might actually stumble upon some deeper structure, but the argument against such a quest can be made using evidence. That evidence is the nature of existing theory and the nature of the phenomenon in question. It may even be possible to prove that a given class of theories cannot deduce the phenomenon.

I agree that "explaining" an accidental fact by reference to unobservable other universes doesn't add much to our understanding of anything. The urge to do so, I believe, stems from the psychological conflict between physics's deep ambition to explain everything with ahistorical laws and the advent of Big Bang cosmology which gives the universe an unavoidable history. The multiverse and evolutionary universe ideas are halfway houses between historical (accidental) and ahistorical (lawful) explanations– we can imagine a structure or process that makes local accidents part of a broader lawful scheme, which makes some people feel better even if it has no additional scientific payoff.

23. **anon.**
March 26, 2009

'Today we think that [Kepler's nested solids solar system] is crazy, not just because the particular geometric model is unmotivated but because the entire category of explanation is believed to be impossible and misguided. There IS no fundamental, ahistorical explanation for the sizes of the particular planetary orbits in the solar system and nobody sensible wastes his time trying to find one.' – srp

The Titius-Bode law was formulated to predict planetary radii in the solar system and lots of people tried to make sense of it theoretically. Theories of the solar system have been formulated which attempt to model the planets condensing out of a contracting, rotating cloud of gas, and one thing such models try to predict is that empirical law.

Kepler tried all kinds of data-fitting explanations before formulating the three laws of planetary motion, which served Newton so well. I don't think that we need to be biased 'believe' that any approach is impossible and misguided: either it works and is useful, or it doesn't. The whole solar system idea of Aristarchus (250 BC) with the earth rotating daily and orbiting the sun was believed by the mainstream to be impossible and misguided for 17 centuries. Thus there is no science in being prejudiced and disbelieving ideas without evidence, any more than in believing string theory without evidence. What you believe or disbelieve is not relevant for science, which isn't about beliefs.

24. **theoreticalminimum**
March 26, 2009

I just stumbled upon this by accident. The list of participants, and the mention of "God" are somewhat intriguing.

March 30, 2009

If Steinhardt's 'cyclic' model – whatever its exact guise is nowadays – were scrutinized with the same rigour as he spends on inflation (or eternal inflation or landscape/eternal inflation) he would never have proposed it in the first place.

It relies on a mathematically unsound concept of infinite past time to a much greater extent than eternal inflation does. (What is the number of our current cycle?) Steinhardt likes to claim there is an 'attractor' behaviour from one cycle to the next – but attractors only attract in one direction: either the behaviour diverges in the past or the future. A past- and future-infinite number of cycles, of which we inhabit a specific one, is not only mathematically problematic, it is dynamically unrealizable.

The scalar potential necessary for the 'cyclic' model to work is even more complicated and absurdly fine-tuned than most inflation or dark energy models. I don't know of any paper where it is written down algebraically. Steinhardt likes to criticize inflation models based on the form of their scalar potentials, but if you never write down your own model in closed form this criticism can be evaded…

And to get a hot Big Bang and restart the cycle one needs a process that (unlike inflation) cannot even be modelled meaningfully in field theory. They call it 'brane collision' and like to send the field value off to infinity while it is occurring, hoping that it will somehow spring back for a fresh new day.

If one compares string theory/ eternal inflation/ landscape ideas to a certain US car manufacturer, Steinhardt's logic seems to be 'GM cars are disappointing and unreliable, therefore I prefer to travel by camel'.

Latest Langlands

March 24, 2009
Categories: Langlands

The site at UBC collecting the work of Robert Langlands is now no longer being maintained. There's a new site now at the IAS. It includes some interesting recent short articles of various kinds that I hadn't seen before, including a short autobiographical memoir, an expository piece written for *Pour La Science*, and another piece which includes extensive speculative remarks about his current thinking on the topic of the "Langlands Program".

The expository piece includes remarks about the remarkable centrality of representation theory both in number theory and quantum theory:

> La leçon que nous voulons tirer de ce dicton, "il se trouve derrière tout nombre quantique une representation d'un groupe", c'est que tomber en mathématiques ou en physique sur les représentations d'un groupe, c'est souvent tomber sur une veine d'or à laquelle il faut tenir corps et âme.

("The lesson we would like to draw from this motto 'behind every quantum number is a group representation', is that when one comes upon group representations in mathematics or physics, one has often come upon a vein of gold, which one must pursue body and soul.")

On the geometric Langlands front, earlier this month the Clay Mathematics Institute organized a series of talks at RIMS in Kyoto by Bezrukavnikov, Gaitsgory and Nakajima about various aspects of the subject. Unfortunately notes from the lectures don't seem to be available anywhere that I have looked.

Last week the KITP in Santa Barbara hosted a mini-conference on Dualities in Physics and Mathematics, with some of the talks devoted to topics relating geometric Langlands and quantum field theory.

   At the UCSB conference, there were also a number of really good talks on wall-crossing formulae in math and physics which are well worth checking out.

The Expanding Universe (of Cosmology Centers)

March 26, 2009
Categories: Uncategorized

The past couple months I've seen announcements of the founding of two new cosmology centers at US universities, and I realized that there has been quite a lot of this going on over the past few years here in the US. Going back 5 years or so, I count at least a dozen:

Texas Cosmology Center, Austin (March 2009)

Center for Particle Cosmology at the University of Pennsylvania (January 2009)

Bruce and Astrid McWilliams Center for Cosmology, Carnegie Mellon (May 2008)

Astrophysics and Cosmology Center, Los Alamos (January 2008)

Berkeley Center for Cosmological Physics (December 2007)

Center for Cosmology and Astroparticle Physics, Ohio State (October 2007)

Beyond Center, Arizona State (September 2006)

Moore Center for Theoretical Cosmology and Physics, Caltech (April 2006)

Center for Cosmology at UC Irvine (June 2005)

Kavli Institute for Cosmological Physics, Chicago (March 2004)

Kavli Institute for Particle Astrophysics and Cosmology, SLAC (October 2003)

Center for Education and Research in Cosmology and Astrophysics, Case Western (October 2003)

The job market being what it is, if you're a string theorist you better be an incredible genius (and lucky) to find employment. On the other hand, if you're a cosmologist, well, it doesn't look that hard…

Update: A commenter points to one more:

Institute for Gravitation and the Cosmos, Penn State (August 2007)

This one replaced a previous "Institute for Gravitational Physics and Geometry", part of a trend in physics: cosmology hot, geometry not.

Comments

   March 26, 2009

   Has anybody heard of a Finnish professor Kari Enqvist? He seems to be a true string believer and famous in the circles or at least they say so on this page (see the link, sorry it's in Finnish). The string theory research is funded by Academy of Finland, so live long string theory con artism. ;-(

   http://www.aka.fi/fi/A/Tiedeyhteiskunnassa/Huippuyksikot_/2008—2013/Teoreettisen-fysiikan-tutkimuksen-suomalainen-huippuyksikko/

3. **chickenbreeder**
   March 26, 2009

   I don't believe there are that many jobs available for cosmologists, either. The phenomenon (of growth in numbers of cosmology centers) simply reflects the trend that U.S. universities are now run by career administrators and buraeucrats. I am positive physicists in those universities didn't initiate the establishment of cosmo centers. Administrators and bureaucrats, on the other hand, have nothing else to do so they constantly reorganize their universities as a way to pretend to be relevant. Since they don't have any professional skill all they rely on is perceived fades and buzz. So, if X University has a cosmology center we want one, too. Cosmology is actually a small thing if you count how many schools and centers of "sustainability" have been created in the last 5 years. I bet it numbers at 100s, even though no one knows what sustainability really means.

4. **AcademicLurker**
   March 26, 2009

   What chickenbreeder said.

   At my own university, there seems to be constant pressure to move toward a center based organizational model and away from a traditional department based one.

   One of the reasons, I suspect, is that the faculty have less and the administration more power in such an arrangement.

5. **anon**
   March 26, 2009

   The grass always looks greener on the other side!

6. **Shantanu**

March 26, 2009

Peter you missed some more 🙂
Institute for Gravitation and Cosmos Penn State (2007)
Tufts Institute for Cosmology (this one has been in existence for almost 20 years)
I am sure there are many more

7. **Peter Woit**
March 26, 2009

Thanks Shantanu,

I did miss Penn State, will add it. Pre-2003, there are a small number of others I didn't try and list, including Tufts, NYU, and Columbia's ISCAP.

chickenbreeder,

These centers are typically not just re-shufflings of existing positions, but involve new money and positions. Notice that a bunch of them have someone's name on them, and it's not the name of a physicist… That's one source of the new money, another is "seed money" from universities. A typical way these centers get funded is by the university agreeing to put up some number of millions of dollars to hire a few people and get the thing going, with the idea that after a while it will be successful enough to attract grants that will fund it for the future. From the university's point of view, putting money into such a center is an investment (or a bet…) that they hope will in later years pay off in new outside funding for the university. I don't believe the impetus behind these things is just from administrators.

8. **Shantanu**
March 26, 2009

There is also another center at
Georgia Tech (although not called a "cosmology") which opened last Fall, with emphasis on gravitational waves and particle astrophysics (which for all practical purposes can considered
be cosmology)

9. **Peter Woit**
March 26, 2009

Thanks Shantanu, but that one seems somewhat different. In this day and age, going on about high energy particles and labelling what one does "relativistic astrophysics" seems very retro.

10. **Chris W.**
March 26, 2009

Are they all getting funding from the Templeton Foundation? 🙂

11. **The Real Deal**
March 27, 2009

Not to be outdone, Perimeter not only expanding its cosmology program but erecting a brand new 55,000 sq ft building soon. One needs appropriately fancy facility to accommodate none other than Stephen Hawking. Who else can claim Hawking on staff? The writings on the wall – strings is out, cosmology is in. And money trumps everything.

12. **Cormac O Raifeartaigh**
March 27, 2009

Re "a bunch of them have someone's name on them, and it's not the name of a physicist…"
I'm glad you said that, I was getting worried at all these important names in cosmology that I've never even heard of!

More seriously, there is a point that has not been mentioned – cosmology has truly come of age in the last decades and the convergence of cosmology and particle physics is a relatively late development (when I was a student, cosmology was still an 'out-there' branch of physics). IN this regard, cosmology institutes might be a good thing for particle physics, if the atter is done there – it'sprobably easier to convince uninformed skeptics to fund institutes that study the 'universe' as opposed to the 'atom' – while maintaining particle research!

13. **Shantanu**
March 27, 2009

Peter, in this age particle astrophysics is really intertwined with cosmology
and neutrino/gamma ray telescopes can tell you about nature of dark matter.
With grav. waves also, a whole lot of cosmology can be done. A few other similar centers whose names are not "cosmology" (in recent years) which have come up are
Center for Particle Astrophysics (Fermilab) (and many of its members are
involved in cosmology). Also MIT's center for space research was renamed to
Kavli Institute of astrophysics and space research with main emphasis on
determining nature of dark matter and energy.

14. **Mike**
March 28, 2009

Has anybody actually detected gravity waves yet? The last I heard LIGO was still looking and not seeing the waves from GRBs.

15. **Thomas D**
March 30, 2009

At current sensitivity LIGO expects to see signals from things like –

SN1987a – ie any SN at comparable distance;
Neutron star and black hole binary mergers up to some number of (M)pc;
GRBs above some threshold on energy release over distance.

The fact that no signals arrived is not really a surprise as the number of such events per year in our vicinity is not large. We may be lucky tomorrow with another supernova. But basically the detector is performing as expected.

Future experimental sensitivity is expected to be one (soon) or two (not soon) orders of magnitude better. Since detectability goes with 1/distance, the expected number of events goes up roughly with the inverse cube of the sensitivity. Just wait a few years.

Anything Goes

March 26, 2009
Categories: Multiverse Mania

Yesterday at the KITP Wati Taylor gave a talk entitled [Freedom and Constraints in the Landscape of Intersecting/Magnetized Branes](). During the talk he explained in detail the problem of lack of predictivity caused by the landscape. As far as anyone knows, to the extent you can calculate anything, you can get whatever you want: "Anything Goes", and string theory is useless for ever predicting anything. He was looking at some particular classes of vacua, chosen for their computational tractability, and hoping to find some constraints among the quantities one can compute. There's no known reason to expect this, but one can compute anyway and hope. The end result was the expected one: you can get whatever you want. Here are some quotes from the talk:

> So, We're really in a very challenging situation where we don't really know how to define the theory, we don't know what the set of solutions are, and even if we did we would have a very hard time making a sensible statement about what that means for predictions…
>
> Every piece of data we have so far I would say is consistent with the notion that everything is pretty much uniformly and randomly distributed in the landscape.

There was extensive discussion of the predictivity problems and overwhelming evidence string theory can't ever predict anything below the Planck scale (this wasn't discussed, but I don't see how it predicts much above the Planck scale either). For some reason there was no drawing of the obvious conclusion that one should just give up on the idea and try something else.

5. **Nameless**
   March 27, 2009

   Did we move away from 10^500 string theories to infinite number?

   If we did not, the problem is not that string theory is useless for ever predicting anything, it's that the structure is too big and complex. But it should still be theoretically possible to answer the question whether there is at least one in 10^500 that has the right particle content and predicts low-energy constants in agreement with observations. Maybe not at this stage (we need 500*ln(10) = 1150 bits of information), but eventualy. We have 19 constants just in SM, some, such as electron mass, are known to 10 digits. Neutrino oscillation means that we get at least 7 there (three masses, four MNS parameters). If LHC finds supersymmetry, the number of parameters will blow up. Sooner or later we will get to the point where the number of string theory false vacua within the boundaries of observed constants is either 1 or 0. And that will be the definitive test. In the mean time it's a valid avenue of research to analyse the landscape.

   Does anyone have a reference to an article that initially computed the 10^500 number?

6. **Bee**
   March 27, 2009

   Odd. This doesn't quite seem to agree with what Dienes and Lenneck have found. See arXiv:[0804.4718]() or PIRSA:[08120000]().

8. **Masochistic Troll Feeder**
   March 27, 2009

   Who cares whether string theory can ever predict anything below the Planck scale? It's supposed to be quantum gravity, so the real test is what it predicts ABOVE the Planck scale!

   Do you throw out the Standard Model because it does not predict biology? If we ever discover life on other planets, it will likely have very different biology from our own. All these possible different biologies will of course be consistent with the Standard Model, just like many different low energy field theories are consistent with string theory, but the Standard Model does not select out a unique possible biology, just like string theory does not select out a unique low energy physics!

9. **Peter Woit**
March 27, 2009

Bee,

What Dienes is doing is a bit different. He's counting vacua and hoping for correlations. Taylor explicitly says he doesn't think counting is relevant: if you don't know the details of what cosmological process is producing our universe, you don't know what the right probability measure on vacua will be, no reason to believe it's the simple counting measure.

Nameless,

I don't have a specific reference at hand, but look up Michael Douglas's papers on the landscape and either he's the first to come up with this number, or he refers to the paper that did. People (e.g. Denef) have come up with constructions of vacua that produce much larger numbers of vacua than 10^500, effectively the number you would have to examine is infinite.

Hi Cormac,

I'll be in Edinburgh April 21-23 (for the conference in honor of Atiyah), then the 24th will stop for the day in Dublin on the way back to NY. I'm hoping to extend that and stay for another day or so. Once I've got definite plans I'll contact you and maybe we can get together.

March 28, 2009

Yes–I have been talking with Feyman about how ridiculous the string theory folly is getting. You know how Feyman once said that science is like creating in a straight jacket. And just the other dya he said string theory is like taking the jacket off, saying and doing anything in the landscape, calling it science, and then putting the straight jacket on your critics.

Remember that one band which tried to get famous by just removing all the frets, putting their fingers anywhere on the guitar neck, and proclaiming it to be music? I don't remember them either. And I'm pretty sure they weren't state funded nor tenured either.

12. **Aaron Bergman**
March 28, 2009

Dissing fretless guitars now? You're still bitter about that whole Fleetwood Mac thing, aren't you?

13. **Joey Ramone**
March 29, 2009

We were all for innovation, rebellion, and rock'n'roll, but even we had our rules honoring the mathematical vibrations of strings. It just wouldn't be fun walking out there on stage with strings vibrating in an infinite array of possibilities, all over the landscape, and then shouting at the press, "THIS IS BEAUTIFUL, ELEGANT MUSIC!" Sure, some of the press would write wahatever we said just so they could join us on the bus later, but would we really want them there? I mean they don't even trust their own ears so how can we trust them? Would you want them on your bus around your groupies?

Peter wrote, "For some reason there was no drawing of the obvious conclusion that one should just give up on the idea and try something else," and my good friened Einstein stated, "Insanity: doing the same thing over and over again and expecting different results." Maybe Feynman was more right about those straight jackets than he even knew.

14. **Aaron Bergman**
March 29, 2009

Well, you shouldn't stop thinking about tomorrow. It'll soon be here.

15. **Joey Ramone**
March 30, 2009

Yes–tomorrow will be better day as string tehory fades away.

I have also had the opportunity to converse with a lot of other classical economists–folks like Adam Smith and Ludwig von Mises. They see a lot of parallels between the snarky math of String Theory and Wall Street. Smith and von Mises dealt in ideals, ideas, integrity and *words* that meant things. String Theorists and Quants deal in math that never quite proves their fundamental postualte taht they are smarter than us, but rather which proves the exact opposite. They have given math a bad name and this makes me angry. Good Pythagoreas comes up with the theory of harmonies on vibrating strings and then they corrupt and convolute it all into a discordant landscape, while bankrupting a nation and currency with their silly little equations which have absolutely no predictive power, robbing them of math's higher beauty, which is married to the power of prediction. Riding on Einstein's, Smith's, et als. coattails, the modern snarkyalarks levelethey pay d physics and finance. Newton stood upon the shoulders of giants to see further, and they stood upon the shoulders of giants to cut the giants' heads off. And now we're supposed to buy their "Elegant Universe" DVDs and bail them out, while they pay Lubos to call us names.

Speaking of Lubos, not only did he inspire that character on The Big Bang (perhaps String Theory's greatest lasting contribution), but back in the eighties we were able to hop on Michio Kaku's time machine and travel to 2012 and then back again with Lubos so that he could play the cop at 50 seconds in this 80's video for Rock'n'Roll High School:
http://www.youtube.com/watch?v=c5vh0QHUA1w

16. **Mikael**
March 30, 2009

Hi Peter,
about predictivity of string theory:
Imagine we had one million string vacua, whose low energy physics content look exactly like the standard model. (We can discuss later how realistic this is.) Now, we could say, that predictivity is totally lost, when we want to go to high energy physics. On the other hand, let's compare the status of string theory in this situation with quantum field theory. In quantum field energy there is simply no way at all to go to high energy physics. QFTs are even understood today as the low energy effective theories of some unknown high energy theory. So computational issues aside we can use one of our one million string vacua and it is just as good as the standard modell. One could argue that it is even better because it is a theory of gravity as well and you can calculate general features of gravity like the black hole entropy.
Questions:
1. Is there an error in this line of thought? Is the error that in the assumed standard model string vacuum you just had to many parameters to fit?
2. Do you think my assumption is realistic to have string vacua, which look exactly like the standard model in the low energy range?

17. **Peter Woit**
March 30, 2009

Mikael,

One problem with this sort of argument is that it's just not true that string theories with a choice of one of these vacua gives you a consistent theory at any energies. You don't even in principle know what the theory is outside of perturbation theory, so you don't know that you have a consistent unified theory at arbitrarily high energies. Even if you did, the freedom of choices presumably would allow you to get all sorts of different physics at very high energies.

The Standard Model is a gauge theory with one of the simplest possible choices of groups and representations, and it is this simplicity that makes it highly predictive and gives an extensive array of very strong tests that it has passed. In "string vacua" constructions, simple choices don't look like the real world, so people have to make constructions more and more complicated in order to evade making a prediction that can be compared to existing data.

There's all the difference in the world between these two situations, and going to high energy changes nothing. String theory is no more predictive there than at low energies. The only difference is that at high enough energies you can make sure your predictions can't be checked.

18. **Mikael**
March 30, 2009

Peter,
let's forget about high energies. Let's just compare string theory and QFT in energy regions explored by today's colliders. Is it conceivable that we arrive at a situation, where we can say, string theory did not keep its promise but it is not worse than QFT?

19. **Peter Woit**
March 30, 2009

Mikael,

Again, at collider energies, quantum gauge theory is a huge success. You pick one of the simplest ones, it predicts all sorts of things, they all come out true on the nose. In string theory instead, you get no predictions, because you have to make your model more and more complicated in order to evade getting a wrong answer. The difference between these is the difference between dramatic success and dramatic failure.

20. **Shantanu**
March 30, 2009

Peter (and other QG enthusiasts), what do you people think of
a href="http://arxiv.org/abs/0806.0665″>this
Hogan has given talks on this which are available
at here?
This paper however as been refuted
here
Have you seen any papers by string theorists claiming this as a prediction
of string theory?

21. **Peter Woit**
March 31, 2009

Shantanu,

I haven't seen this claimed as a "prediction" of string theory. For one thing, just being "holographic" doesn't mean you're doing string theory. Personally, I find it hard to believe that you can get any serious prediction just by invoking "holography", which is a very general concept. Because of that and my general lack of interest in quantum gravity, I haven't looked into exactly what Hogan is doing.

22. **Durendal**
April 4, 2009

Right, this is just like how classical mechanics is totally worthless to predict anything, because a lagrangian can be anything I want it to. A lagrangian can be any function at all! How can we expect to ever find a lagrangian that describes reality when they can be anything we want!

23. **Herodotus**
April 6, 2009

Not quite. Not only, once the Lagrangian is chosen, the predictions of the classical mechanics are known, but the useful Lagrangians are simple. If one had to use a completely different Lagrangian to predict the fall of an apple compared to the behaviour of the Moon, or even the fall of different apples, then we would have a "stringy" classical mechanics.

24. **Shantanu**
April 8, 2009

Peter, from listening to one of his talks, the kind of holography is a

prediction of Bank/Susskind et al's Matrix theory models .
(see the audio of his talk at
here
Anyhow do u know of any string theorists who are citing this tentative result from GEO-600 as an "evidence" for string theory?

25. **Peter Woit**
April 8, 2009

Shantanu,

I haven't seen any string theorists claiming this.

In any case, this can't be claimed as a prediction of such matrix models, since they haven't been made to work at all in realistic cases (four large dimensions).

Origin of the World

April 1, 2009
Categories: Multiverse Mania

Arizona State University's new Origins Initiative is starting off this year with some mind-expanding programs, including an Origins Symposium that will start tomorrow. The number and quality of speakers who will be making the trip to Tempe is remarkably high. The event will be webcast, so the rest of the world can get the inside dope by following along here.

Cosmology will be the main topic on the first full day of the Symposium, with Science Friday broadcasting live at 11am a panel discussion on "Physicists and the Origin of the Universe". The afternoon program will be in three parts, with the last part about new observational methods. The first two deal more with the chronic heady topics and pipe dreams of theorists ("How Far Back Can We Go?" and "Is our Universe Unique, and how can we find out"), and will have a break for tea and brownies, finishing up at 4:20 with Glashow (whose title is the blunt "Is Particle Physics Over?") and Vilenkin ("Mediocrity as a principle").

I hear that refreshments will be provided by Tempe's own ChebaHut and there will be an exhibit featuring work of local artists. Arizona is putting on quite a show, with a major effort to attract cutting-edge researchers in physics to the state, including the recent announcement of proposed new legislation.

Update: The final paragraph above was inspired by the posting date, and is pure fantasy. In addition, I have no idea whether brownies will be served during the break tomorrow, or what might or might not be in them. I do look forward to seeing what the various speakers will have to say, and am sure they will be addressing the multiverse/pre-big-bang topic without the aid of any mind-altering substances, difficult as that may be to believe.

   April 2, 2009

   If we can get Paul Davies' time machine working on time, the Ramones will be headlinig the big bash at the Origins Initiative!

   We have a new song :

   Rock-rock-rock-rock'n'roll cosmology center!

   "Rock N Roll Cosmology Center"

   Well I don't care about string theory
   Rock, rock, rock'n'roll high school
   'Cause that's not where I wanna be
   Rock, rock, rock'n'roll high school
   I just wanna have some multiverse kicks
   I just wanna get some multiverse chicks
   Rock, rock, rock, rock, rock'n'roll high school

Well the girls out there knock me out, you know
Rock, rock, rock'n'roll landscape
Cruisin' around in my time machine GTO
Rock, rock, rock'n'roll high school
I hate all predictions and old principles
Don't wanna be taught to be no fool
Rock, rock, rock, rock, rock'n'roll high school

Fun fun rock'n'roll cosmology center
Fun fun rock'n'roll cosmology center
Fun fun rock'n'roll cosmology center
Fun fun, oh baby

The album is called "A Cosmology Center in every Multiverse."

Hope to see you at the conference!

Towards the end of the video, the LHC is turned on and it
1) proves string theory
2) finds seven multiverses
3) locates 17 higher dimensions
4) proves the anthropic principle
5) creates baby black holes which become bouncing universes
6) explodes before any of this can be recorded

9. **John Hungaton**
April 9, 2009

In one of the discussions in the Origin conference on Monday, it was suggested that Sundrum's model "must be right", as it "got him tenure". This sort of reasoning is almost unbelievable…

On the other hand, Brian Greene made it clear that one should talk about "string conjecture", not "string theory". He was not giving the impression to be completely sure that the whole endeavor is on the right track. Now, if Greene does not believe in it, who does?

John

10. **woit**
April 9, 2009

John,

I'm pretty sure the comment about Sundrum was a joke. On the other hand, in an environment where no one is coming up with models that make contact with experiment, maybe a model is "successful" if it gets one tenure.

From what I've seen, Brian has always been careful to claim that string theory is a conjecture, and it's not appropriate to "believe" in it. I think he and most string theorists desperately want to find some sort of prediction of the theory that would allow it to be tested, and are very frustrated that that has not turned out to be possible so far. To what extent he and others in their heart of hearts are getting to the point of doubting that the whole idea is on the right track is an interesting question I don't know the answer to.

Various News

April 6, 2009
Categories: Experimental HEP News, Multiverse Mania, Uncategorized

The CERN Bulletin has been providing weekly updates about the progress of LHC repairs, with the latest one here. One thing they don't seem to have mentioned is that it looks like the schedule has recently slipped by nearly a month. The schedule approved in early February had checkout of the machine in week 38 (week of Sept. 14) and first beam week 39 (week of Sept. 21). The latest draft of the schedule (see page 42 of this presentation) has checkout in week 42 and beam in week 43. So, it looks like the latest plan calls for injection of a beam around October 19th, collisions sometime in November.

I today heard an odd rumor about a problem this past weekend with the on-going repairs in sector 34, but there may be nothing to it, so I'll try to stick to only mongering confirmed rumors.

The blogging world continues to expand with new institutional initiatives to set up blogs. There's a new version of Quantum Diaries out, along the same lines as a similar site set up back in 2005. That's the one that Tommaso Dorigo survived, along with some other physicists who have kept blogging, including Gordon Watts and Peter Steinberg. Unlike the 2005 incarnation, this version seems to be restricted to experimentalists, no theorists allowed. It also uses the same address as the old site, which unfortunately seems to no longer be accessible. Whether it is possible or desirable to set up a mechanism to ensure the availability in the future of blog content is an interesting question.

The AMS has set up a blog for mathematics graduate students, which so far mostly consists of professional advice.

One piece of news that might be interesting to some of these graduate students is that the NSF has just announced a plan to use some of the stimulus money to provide 30 two-year postdocs aimed at students on the job market this spring who have not yet found employment. The money is being funneled through the various institutes supported by the NSF, with the idea that the jobs will generally be hosted at other institutions, which will provide a mentor and possibly teaching opportunities. The deadline to apply for these jobs is very soon (April 10), there's more here, here, here and here.

One unusual thing about these postdocs (compared to usual NSF postdocs) is that it appears they are available to anyone who is getting their degree from a US university, not just US citizens or green-card holders. It also seems to be possible to hold the postdoc outside the US, at some MSRI-affiliated institutions such as the University of Toronto. Adding up the cost of the 30 postdocs comes to maybe $3 million or so, leaving open the question on everyone's mind in academia: what about the other %99.9 percent of the $3 billion in NSF stimulus money? Where's that going to go?

I always wondered who the Pupin building housing the physics department here at Columbia was named after. Here's the scoop.

The Origins symposium at ASU is finishing up today. It was webcast, but if you missed it archived video is starting to appear here. The Science Friday segment featured Michael Turner responding to Steven Weinberg's claim that some anthropic argument is just common-sense with the remark that "some of us chafe at using anthropic and commonsense in the same sentence". I haven't yet seen the full multiverse discussion from later last Friday, but presumably that will be available soon.

Update: One more. Today at CERN they're celebrating Carlo Rubbia's 75th birthday. Webcast going on right now, slides here.

Update: Hamish Johnston at Physics World asked CERN spokesman James Gillies about the delay in the draft schedule:

> He also said that CERN is now looking for ways to make up the extra time identified by Bailey and he said that the repair team are confident of having the LHC running towards the end of September as planned.

Update: Yet one more: New Scientist has an interview of Witten by Matthew Chalmers here.

   April 7, 2009

   Hi Peter,

   the rumor about a problem in LHC sector 34 has some truth, in so far as there is a magnetic which will take longer to repair than originally planned. However, I have it on good authority that sector 34 is not on the critical path, so this problem magnet will not delay the LHC schedule further. (I was personally very worried about further delays, so I asked someone in a meeting for details, which he delivered.)

   regards,
   Michael

4. **Thomas R Love**
   April 7, 2009

   Columbia has a site about Pupin:

   http://www.columbia.edu/cu/physics/about/main/one/michaelpupin.html

I read his book:
The New Reformation: From Physical to Spiritual Realities – Michael Pupin –
many years ago. He refers to scientists as prophets.

5. **Thomas R Love**
April 7, 2009

According to the Mathematics Genealogy Project:

http://genealogy.math.ndsu.nodak.edu/id.php?id=72169&fChrono=1

Pupin had a graduate student by the name of Robert Millikan.

6. **Nigel Cook**
April 7, 2009

Pupin independently rediscovered and patented Heaviside's original 1875 discovery that long telegraph cables could be made suitable for distortionless speech (long distance telephones) by increasing the inductance (e.g., putting inductance coils at intervals – merely amplifying the signal just amplifies the distortion, because the inductance effect is frequency dependent). Heaviside didn't have funds to apply for a patent. Pupin's patent in the USA made $1 million.

Heaviside in England, despite formulating Maxwell's equations in vector calculus, was simply ignored by Sir William Preece, head of the Post Office Telecommunications. Preece instead used public money to fund his own incorrect theory that the long-distance telephone voice distortion was due to the cable design, and tried for years to overcome distortion with better cables, setting back the introduction of long-distance phones in England by 20 years. Heaviside became increasingly rude towards Preece:

'If you have got anything new … you need not expect anything but hindrance from the old practitioner even though he sat at the feet of Faraday. Beetles could do that … . But when the new views have become fashionably current, he may find it worth his while to adopt them, though, perhaps in a somewhat sneaking manner, not unmixed with bluster, and make believe he knew all about it when he was a little boy!' – Oliver Heaviside, 10 March 1893.

Preece had just stated in his 1893 IEE Presidential address: 'I took the opportunity to formulate the theoretical views of electricity that I had acquired at the feet of Faraday.'

7. **Peter Woit**
April 7, 2009

Thanks Michael,

From looking at the schedule, I had assumed that fixing sector 34 was on the critical path. If that's not true, do you know what it is that now is considered the most likely source of delays?

That sounds like a different rumor about a sector 34 problem, one better founded than what I heard…

8. **KevinS**
April 7, 2009

from the link…

While studying electrical engineering at Columbia, Pupin became interested in Maxwell's equations. After graduation in 1983, he went to Cambridge, England in order to work under James Clerk Maxwell in 1883 (looks like time travel was possible then). Alas, when he arrived at Cambridge, he found out Maxwell died four years earlier in 1979. This was the reality of trans-Atlantic communication at that time. There has been some improvement since then. (though, it would seem, not in editing)

damn…1979…I could've tried for a signed edition from Maxwell.

9. **Andrei**
April 8, 2009

There is no way the LHC will run this year. Last time it took 6 months or more to cool each sector. To have beam in September, Cern would have to start to cool them now. Sector 34 is still under repairs so the cooling of this sector will realistically be sometime in july or August. You might be better off covering the new batch of results expected from the Tevatron in August. The most optimistic expect a Higgs 3 sigma anouncement. After all if the LHC was running the source of excitement would come from its results not from the simple fact that it is running. And having a low power beam cannot be called "running" in any case. Some of you might have to face a brutal truth: the LHC is a bit of a failure.

10. **Peter Woit**
April 8, 2009

Andrei,

If you look at the draft schedule, they certainly have a detailed plan for the cooldown, and a lot of experience from last year in how long it takes. My guess would be that, if nothing else goes wrong, in October they'll be able to circulate a beam, colliding beams in November. They may be able to take some data late this year, but it will be at very low luminosity. It's also true that even during 2010 the luminosity will be rather low, and energy only 5 TeV per beam. For many things (especially the Higgs), it won't be until 2011 that they start getting useful data.

This doesn't mean at all that the LHC is in any way a failure, it just means that it is taking longer to get running than the official estimates originally indicated. This isn't surprising in the least for a project of this complexity. In the long run, how long it takes to get the thing working is not important, what is important is whether it works. Even if it takes 10 years to get the thing working at design luminosity, if it then makes important discoveries, it will be a huge success.

Official schedules are almost always overly optimistic, naturally reflecting estimates based on assuming that nothing significant goes wrong. Something almost always does go wrong, but, with some time and effort, whatever it is gets fixed. The huge media attention on the LHC may be more of an education for the public about how major scientific projects get done than some people intended.

11. **Sumar Ongi**
April 10, 2009

> Update: Yet one more: New Scientist has an interview of Witten by Matthew Chalmers here.

Well, *interview of Witten* turns out to be a wild overstatement. The article contains a couple of unremarkable sentences said by Witten, surrounded by several tens of lines of mostly meaningless chit-chat by the author, who doesn't seem to be a specially gifted writer. I think a more correct description is *a little bit of trivia about Witten*.

12. **Peter Woit**
    April 10, 2009

    In defense of Chalmers, I know a large number of science writers who have tried unsuccessfully to get a comment out of Witten about the "String Wars". He's the first one I know of to have any success at all with that…

13. **Shantanu**
    April 10, 2009

    Peter, I agree with Andrei. If LHC keeps getting delayed, it will be hard to attract grad. students (and postdocs) towards it as they need data for their thesis and no one likes their Phds to get extended and that is not a good sign.
    These grad students would gravitate towards particle astrophysics, neutrino physics or cosmology instead of LHC.

14. **Shantanu**
    April 10, 2009

    Peter, while looking at CERN site found these acadameic training lectures on "String theory for pedestrians"
    here
    Have you seen it? any comments?

First Principles

April 10, 2009
Categories: Book Reviews

I learned recently from Sabine Hossenfelder's blog that there's a new book out by Howard Burton, entitled [First Principles: The Crazy Business of Doing Serious Science] (she has some comments on the book [here]). It's a fascinating and entertaining book. I couldn't put it down this morning, so took a very long breakfast during which I finished reading it.

Burton got a Ph.D. in theoretical physics at the University of Waterloo, which led him (like most Ph.D.'s in theoretical physics) to need to find some sort of employment doing something else. He was saved from getting wealthy in the financial industry by Mike Lazaridis of RIM, who was on a list of people that Burton wrote to asking if they had any job openings. It turned out that Lazaridis was starting to think about the idea of funding a theoretical physics institute, and decided that Burton was just the person to hire to look into the idea.

One of the most interesting parts of the book is Burton's description of the process he went through of talking to a large number of theorists around the world to get their ideas about the state of theoretical physics, and about what sort of well-funded new institute would be viable and make sense. An interesting problem to have, and one that he got a lot of good advice about from many people.

One of the main motivating ideas behind the founding of Perimeter was to support work on foundational issues that normally don't get funded because they are considered "too hard" to make progress on. The other was to encourage openness and communication between groups that normally don't talk to each other. Burton was quite struck by the situation with superstring theory (this was back in the late 1990s, long before the recent "string wars"):

> …what did shock me was my growing awareness that the field was rife with dissention and sociological barriers. Superstring theorists, for example, did not interact in any meaningful way with people pursuing other approaches to the problem, and vice versa. Worse still, the groups were downright hostile to one another, lobbing ad hominem and defamatory attacks across one another's bows, condemning mountains of work with a dismissive (and often ignorant) wave of the the hand while trumping up the claims of their own theories well beyond any defensible level… they were simply refusing to engage with one another, separating off into rival sects like high school gangs…
>
> My first, albeit indirect, encounter with superstring theory was a perfect case in point. As a PhD student, I spent a good deal of time talking with Nemanja Kaloper… Actually Nemanja did most of the talking, particularly once he discovered that I had gone over to "the dark side" by opting to spend time learning various non-superstring approaches to quantum gravity instead of his beloved superstring theory. For Nemanja, this was nothing more than a time-wasting combination of obstinacy and simple-mindedness: superstring theory simply was quantum gravity; trying to learn quantum gravity without string theory made about as much sense as writing music without notes…
>
> The more I kept my eyes open the more I realized that Nemanja's behaviour was hardly unusual: indeed such counterproductive squabbling and rampant dogmatism existed on all sides of the issue, making it hard to see how any genuine progress in any direction might be attained in the near future…
>
> The Olympian heights of pure reason, when examined in more detail, turned out to be reducible to a furiously contested form of highly esoteric tribal warfare.

The story of how Perimeter grew out of these ideas and came into being is a fascinating one, and Burton tells it with a sense of humor in a very entertaining way. He became executive director of the institute, all the while lacking the usual sort of credentials as an eminent researcher that would be expected for such a position. The book ends with a short epilogue discussing the fact that he was forced out of this position in June 2007:

> The official reason given for my departure was that contract negotiations broke down, but I think it's fair to say that such a justification hinges on a particularly loose interpretation of the world "negotiations".

He speculates that the reason for this was the book he was writing:

> So what on earth happened?
>
> What happened, so far as I can determine, is the book you hold in your very hands. Bizarre as it may seem, it appears that a major preoccupation of the institute's board of directors for the first six months of 2007 was what to do about this pernicious book, followed closely, presumably, by how to get rid of its author who had the brazen temerity to once again bring the dark story forward publicly.

I know nothing about what really happened, but if Burton is right that the book played such a role, that's extremely odd. The book makes a wonderful case for Perimeter and what it has been doing, portraying it (accurately I think) as a big success. It does so in a way far more effective than the kind of PR materials such institutions usually hire professionals to produce.

Perimeter does seem to have become quite a success, playing an increasingly large role in the theoretical physics community. It now has a new director (cosmologist Neil Turok), plans to expand, and nine prominent members of the theoretical physics establishment have recently signed on as "Distinguished Research Chairs". If anything, one might worry that the institution is in danger of too much conventional success, merging with the establishment that it was set up to provide somewhat of a challenge to. Their advertisements for new faculty specify that they are looking for people in "Cosmology and Quantum Information". I don't know much about the quantum information business, where they seem to be leaders, but these days the idea of a well-funded institute for cosmology isn't exactly revolutionary (see [here]).

I'm curious to see what happens with Perimeter now that it's entering adulthood, and glad to have read Burton's book which does a great job of telling the story of its birth and infancy.

Update: Lubos has a [posting] about this, although it's clear he hasn't read the book. According to him Burton "managed to write a public text that exposes pretty much all the business (and personal) secrets of the Perimeter Institute. He wants to earn money by publishing this sensitive stuff."

If you buy the book hoping to find out the "business (and personal) secrets" of PI, I think you're going to be very disappointed.

   April 10, 2009

   Thank you for shedding light on these beginnings. This is much better than a hazy, rose-colored "creation myth" growing up as penumbra to an organization.

2. **Bee**

April 10, 2009

Odd indeed, isn't it? The only part of the book that is critical about PI is for all I can tell that epilogue.

Howard's assessment about groups that don't talk to each other etc sounds very familiar doesn't it? I think it's good it is being said by somebody who has not been personally involved with either of these research topics. It would be interesting to know whether similar problems exist in other fields of science.

From what I have seen in the last years, PI is just simply an excellent place (I don't get paid for saying that, it's true). They have some growing pains though that I am afraid will persist for some while. It won't be easy for Neil.

3. **Matt Leifer**
April 10, 2009

Having recently made hires in quantum gravity and quantum foundations, I wouldn't worry too much about PI losing its unconventional edge. They usually just focus on a couple of subject areas for hiring each year because they don't have the resources to conduct a comprehensive search in all subject areas all of the time. They have recently lost Michael Nielsen in quantum information, meaning that quantum information and cosmology are currently the smallest groups, consisting of one researcher each.

4. **Chris W.**
April 10, 2009

Where is Nielsen going (or where has he gone)?

5. **Kea**
April 10, 2009

If you look at the PI website it says "Cosmology" OR "Quantum Information". I would be much more impressed if the conjunction had in fact been used.

6. **Matt Leifer**
April 10, 2009

Chris W.,

As far as I am aware Nielsen has not taken another job, but has decided to focus on writing at the moment. See his blog http://michaelnielsen.org for more news.

7. **anon.**
April 10, 2009

I can't say I know Nemanja well, but I don't see how any reasonable person could think he's dogmatic.

8. **Chris W.**
April 10, 2009

It does so in a way far more effective than the kind of PR materials such institutions usually hire professionals to produce.

There seems to be an inescapable dynamic at work in organizations, such that when they become prominent they become susceptible to a banal and paralyzing risk aversion—a stealthy form of risk-taking in itself.

From Helen Keller, as quoted by former NASA program manager Donna Shirley:

> "Security is mostly a superstition. It does not exist in nature nor do the children of men as a whole experience it. Avoiding danger is no safer in the long run than outright exposure. Life is either a daring adventure or nothing."

9. **Joey Ramone**
April 12, 2009

Boy oh boy does Lubos go on and on and on.

If it weren't for String Theory's ruse, which Lubos served for a short bit, would we even know who he is? He is definitely a case study of something–I'm not sure what yet–but something.

He reminds me of all those eighties bands that grabbed onto the passing fads of hairspray and makeup.

Then Kurt Cobain came along in his thriftstore sweaters, power chords, and simple production values and restored rock back to its proper roots, just as Woit has been retruning physics and philosophy to its natural, cordial roots. With Cobain and Woit, again one could see the humanity of the endeavor exalted over the corproate-state's machine, reminding us of the reasons we love physics, philosophy, and rock'n'roll music; as the truth sets us free.

I hang out with Cobain now and then, and while he has never heard of Lubos' blog, he sometimes plays the bongos with Feynman.

Here's Dee Dee Ramone covering Curt Cobain's Negative Creep, as sometimes we mentors become students, as our studnets become mentors: http://www.youtube.com/watch?v=MAabjXoiJhk

I wish that the String Theorists/antitheorists knew this–there is a time for everyone to step down and salute the new. But perhaps humility is harder for those yet waiting to succeed.

10. **mike**
April 12, 2009

"which led him (like most Ph.D.'s in theoretical physics) to need to find some sort of employment doing something else."

— Is it really that bad in theoretical physics? Gives new meaning to the term "is the end in sight for theoretical physics?".

11. **Peter Woit**
April 13, 2009

mike,

Yes, the job situation of theoretical physics PhDs is bad, and has been bad for a long time. There's nothing really new about this though, it has been the situation since about 1970…

12. **Jack Lothian**
April 13, 2009

True Peter, I left Physics in the early 70s because there were no jobs. Universities, junior colleges, etc were seeing massive drops in enrolment in the hard sciences, the aero & space sector was in a slump & we were between electronic innovation periods. It was a waste land for physics in particular & hard science in general. I remember when a recruiter showed up at our university & gave a presentation, it appeared every graduate student in physics attended and we were all looking for that job that did not seem to exist. When I left, I had the choice of a junior college or a long post-doc journey with no definite job at the end or a career change. Because I worked in Statistical Mechanics & most educated persons do not really know what that means, I got hired as an expert in statistics and eventually became a survey consultant. Physics was always my first love though & if I thought I had a real shot at doing it, I would have. My career change though did turn out to be a good second option.

Sadly my experience is that science & math get lip service but little real support in our education system & culture. Most middle class families that I know want their children to get good marks in math & science in order to get into medicine, law or business schools. Science is a poor second choice & hard to do as well, so most students and parents see it as a dead end for a bright kid. Almost anything else is preferable.

13. **Paul Frampton**
April 13, 2009

My knowledge of Burton and PI stems from two visits: one day in 2004 then four months in 2005. That seminar was (I suspect) the last in Waterloo's post office. I learned theoretical physics at PI. Howard had a PhD in physics, was not an active researcher, yet deserves credit for making almost everyone happy. I met Mike Lazaridis whose idea and resources underly PI. A little bird said he wanted editorial control of Howard's book which I look forward to reading having ordered it from Canada. Turok is co-inventor with Steinhardt of cyclic cosmology a big idea.

Strings Strike Back

April 14, 2009
Categories: This Week's Hype

The February AAAS press event (discussed here) designed to get out the word that the critics are wrong and string theory is making predictions about physics that are getting tested has finally made it to Slashdot, via an article in Science News by Tom Siegfried.

Siegfried has been making his living selling string theory hype since at least the mid-nineties when he wrote quite a few articles for the *Dallas Morning News* with titles like "Physicists sing praises of magical mystery theory". In 2000 he published The Bit and the Pendulum: From Quantum Computing to M-theory, which somehow manages to put together quantum computing, consciousness, and string/M-theory. His next book, in 2002, was Strange Matters: Undiscovered Ideas at the Frontiers of Space and Time, 300 pages of solid hype for problematic speculative ideas, with branes and superstrings playing a leading role. More recently, he has been at work hyping cosmic superstrings in the pages of *Science* magazine (see here) and trashing me and my book for claiming that string theory doesn't make predictions (see here).

Most of the Science News article actually gives a reasonably sensible description of the story of attempts to use string duals and holography to study strongly coupled systems in 3 and 4 dimensions. But in the concluding paragraphs this story is shanghaied into service in the string wars, in a section entitled "Strings strike back" which begins:

> In recent years it has become popular to criticize string theory as out of touch with reality. Popular books have been written by scientists, some prominent and others not so prominent, arguing that string theory makes no predictions that experiment can test, that its fundamental objects can't be observed, that physicists have wasted their time on an enterprise that isn't even scientific to begin with.
>
> Such arguments leave an impression of utter unfamiliarity with the history of science. In times past, the same kinds of aspersions were cast against quarks, neutrinos, even the very existence of atoms. Superstrings are in good company.

You see, some critics of string theory are such ignorant idiots that they question the existence of superstrings even though any student of history knows that they are no more problematic than quarks, neutrinos and atoms. And experiments at RHIC show that string theory does make predictions, ones that have been successfully tested by experiment….

Update: I just read through some of the comments by Slashdot readers. The level of hostility towards string theory and string theory hype is remarkable.

Update: Commenter Hendrik points to a new piece from New Scientist where they have helpfully gathered together in one place all the outrageous string theory hype that has appeared in their pages in recent years.

Comments

1. **Tom**
   April 14, 2009

   Hi Peter, if you generalized the last sentence down to "The level of hostility is remarkable.", it could be used to accurately describe the comments for ANY Slashdot story.

2. **Peter Woit**
   April 14, 2009

   Tom,

   Good point. The level of hostility and ignorance in Slashdot comments is often remarkable. What struck me here is how one-sided things are in this case. At least among the nerd population that reads and comments on Slashdot, string theory has a big PR problem….

3. **Aaron Bergman**
   April 14, 2009

   I would say that slashdot commenters being against something is generally a sign that it's on the right track.

4. **Anon**
   April 14, 2009

   I do not take sides in the "string wars" but I don't really like his following statement.

   "Such arguments leave an impression of utter unfamiliarity with the history of science. In times past, the same kinds of aspersions were cast against quarks, neutrinos, even the very existence of atoms. Superstrings are in good company."

   It smacks of confirmation bias. What about all the other theories that were correctly rejected?

5. **csrster**
   April 15, 2009

   Anon: yes, it's the old "they said Einstein was mad" argument. They also said my uncle Morty was mad – but he actually was mad.

6. **Dennis Towne**
   April 15, 2009

   Yes, the level of hostility toward string theory is rather high among technical minded people and skeptics; I myself have shown the light to a number of technical and less-than-technical people.

   The critical, deciding factor for most of these people is in fact that disconnect from reality, from experiment. It's one thing to have the standard model, which has predicted many things to ridiculous accuracy for decades; it's another to have an idea which has clearly predicted very little, if anything.

   We might not be physicists, but we're not stupid. We know how to glean the most likely truth from the things we see, and we know where to place credibility:

   1) The standard model is questioned, in that 'corner case' effects, near the edge of our testing regime, are not explained or predicted accurately. The vast bulk of data supports it. The few detractors of the standard model can only point to corner case failures. This would be considered 'highly credible'.

2) String theory, in general, predicts at best only ‘corner case’ effects, which are near or beyond the edge of our testing regime. The few strong detractors of string theory make legitimate points regarding its foundation, not its details; the vast bulk of string theory moderates agree with the detractors, but simply maintain that regardless, string theory appears the best path. This would be considered ‘less than highly credible’.

As a software engineer, the string theory process so far reeks to me of software overdesign; by trying to reach too far, they have doomed the project. Incremental, small, and beautiful changes are the norm in software. Perhaps this is why Lisi’s work attracted such attention.

7. **Chris Oakley**
April 15, 2009

> Incremental, small, and beautiful changes are the norm in software. Perhaps this is why Lisi’s work attracted such attention.

I disagree. The reason that Lisi’s work attracted so much attention is that Lee Smolin said it was awesome, and he has a lot of influence. It is very far from being minimal and, like string theory, any beauty evaporates once one tries to apply it to the real world (although in neither case has this been successful). The point in its favour is that it is less arcane that ST.

8. **Joey Ramone**
April 15, 2009

I remember when Siegfried tried to get on the Ramones tourbus for some inside scoops.

While the String Theory machine evolved (in an anthropic manner) to support and promote sycophantic, soulless, sellout, scienceless hypesters, we wanted to keep our rock’n’roll pure and clean. It spoke for itself. Hypesters could only damage our cred. We didn’t need to create careers for non-scientist hypesters who actually do a vast disservice to science while personally profiting by hyping antitheories which sap all the funding that ought be going to true scientists–to all the postdocs and grad students and young professors struggling out there.

The only time I met Sigfreid was when he hopped on Michio Kaku’s time machine to sneak on the set for the music video for “I Wanna Be Sedated.”

He’s dressed like a scientist/doctor (in a white coat) around 1:02 in the video and he’s bothering us. I almost called cut as it was creepy.

http://www.youtube.com/watch?v=8FxaJKm9sdI

Sometimes people would do anything just to touch us, and then there are those who would do anything just to touch a string theorist, or be liked by one. We generally kept them off our tour busses and out of our videos.

9. **ohwilleke**
April 15, 2009

Compared to commentary on newspaper and political blog sites, the commentary at slashdot is downright calm and rational. If the same story were posted at the Denver Post, you would surely see complaints in the comments about how science is a conspiracy of liberal immigrants, and is based upon the non-biblical belief that pi is equal to something other than three. The really clever ones might complain that the numeral system used represents a false pro-Islamic bias. The main flaw of both sides of that debate is a lack of evidence or sourcing which isn’t necessarily customary in Internet comments as opposed to academic writing.

Apart from Tom Siegfried, who isn’t the world’s best public face for string theory, string theorists have done a pretty poor job of popularization and P.R. in the past half a dozen years or so, despite being the dominant school of thought in academic theoretical fundamental physics. Given that almost all fundamental physics research is ultimately funded with taxpayer dollars one way or another, this is a very bad choice to be making by default. Quantum gravity advocates, in contrast, have done a decent job in that time frame of bridging the gap between expressing ideas in academic journals, and popularizing the gist of what is important about those articles to the educated lay public. The version of the story that can be told in half a dozen Science News sized articles matters a great deal to popular understanding, something that few physicists since Feynman have realy understood well — most people will never read the book length version, even if it is readable. Not enough people are writing stories that briefly summarize the most important half a dozen or so key experimental data points that make someone say “string theory, not something else” and most importantly experimental data that is suggestive of a resolution of the string theory v. LQG debate.

There are also serious semantic issues going on in both Siegfried’s article and the larger discussion. It is very hard to tell how narrowly or broadly string theory is being used as a term. What components of the theory are definition (>4 multi-dimensionality, perhaps), and what are not (e.g., ironically, strings themselves as opposed to mathematially similar fine structures, and both LQG and string theory both involve what could be called strings although no one familiar with the discussion would ever describe LQG as a subset of string theory). In other words, it is not always easy to distinguish which parts of the theory are “moving parts” and which are a common core — something that is complicated by the fact that versions since rejected remain out there like ill considered blog posts, for all and sundry to see and recirculate without realizing that they are out of date. When one refers to superstrings, does one mean a supersymmetric theory, or simply that these strings being the ultimate cause of everything are especially cool. “String theory” has become the “cloud computing” of theoretical physics.

One of the more insightful of the slashdot comments notes that there is not just one string theory, but instead many variations on the theme. As a result, new evidence sometimes merely sorts the stack of available sub-theories without ruling any overall approach out.

10. **Joey Ramone**
April 15, 2009

Yes ohwilleke, but should it really be all about PR?

You write, “Apart from Tom Siegfried, who isn’t the world’s best public face for string theory, string theorists have done a pretty poor job of popularization and P.R. in the past half a dozen years or so, despite being the dominant school of thought in academic theoretical fundamental physics. Given that almost all fundamental physics research is ultimately funded with taxpayer dollars one way or another, this is a very bad choice to be making by default. Quantum gravity advocates, in contrast, have done a decent job in that time frame of bridging the gap between expressing ideas in academic journals, and popularizing the gist of what is important about those articles to the educated lay public. ”

Instead of PR shouldn’t physicists concentrate on physics?

It seems that equations such as F=ma and E=mc^2 have a way of generating PR on their own.

We never used a PR firm–we just rocked out. And long after the Jonas Brothers and Britney Spears and Quantum Gravity PR specialists are forgotten, we will be remembered.

It is funny how physicists are seeking to imitate pop stars as opposed to physicists who advanced physics such as Feynman, Fermi, Dirac, Einstein, Bohr, and Boltzman, who would have been embarrassed to devote their precious time to pondering PR strategies for untsetable antitheories.

Life is short and if one pursues empty PR, one ends up with empty PR, which becomes more and more embarrassing for certain “physicists” as they age, causing them to engage in bizarre behavior, hyping nontheories to the press in most creative manners.

I would advise everyone to rock out for truth, and so would Feynman.

11. **Hendrik**
April 16, 2009

String theory strikes back on a new front: check the article in NewScientist and in particular the Witten interview. Seems he hasn’t read your book yet.

12. **luny**
April 16, 2009

Aside from everything else, what exactly is the prediction that string theory made about RHIC?
That viscosity over entropy density (eta/s) is 1/4 pi?

Well, this is not anymore a prediction (see, for example,
http://arxiv.org/abs/0812.2521): eta/s in theories with string duals can go to lower values to 1/4pi, perhaps all the way to 0 (or quantum mechanics could prevent this. But this was known way before string theory
(see,eg Phys.Rev.D31:53-62,1985).

That eta/s is “low” in a strongly coupled theory? Well, thats a pretty obvious point that transcends string theory.
It is cute that AdS/CFT reproduces many phenomena also observed in hydrodynamics, but there is NO AdS/CFT result that can be sensibly compared with data and used to make a prediction. NONE. Not one. If anyone disagrees, please give an example.

AdS/CFT is,currently, a very interesting conceptual exercise. Perhaps tomorrow someone WILL extract predictions relevant to heavy ion collisions out of it. But it hasnt happened yet. And to claim it has is dishonest Public Relations.

13. **Peter Woit**
April 16, 2009

For those who can’t get enough, and want to follow yet another battle in the string wars (inspired by the Witten interview Hendrik mentions), see this posting at Cosmic Variance.

http://blogs.discovermagazine.com/cosmicvariance/2009/04/09/string-wars-the-aftermath/

14. **Mitsis**
April 16, 2009

Peter,

I do not understand your position on “string duals” fully.
Is it not true that the string theory of AdS CFT is really the same as the string theory one would use for unification?
Certainly the compactification is very different (the boundary of AdS instead of our flat space etc.) but the kinematics etc. and the whole formalism is the same – no ?

So if AdS CFT turns out to work correctly it would be a good argument for string theory. Is this not true?

15. **Peter Woit**
April 16, 2009

Mitsis,

The string theory side of AdS/CFT gives you gravity in 5 dimensional AdS space, not four dimensional space. For this and many other reasons you can’t use it for unification. The 4d physics of the theory is supposed to be N=4 SYM (no gravity), this may be a useful approximation to QCD, but it’s not a unified theory.

If you believe in much much more general conjectures about gauge duals of string theories in different “string vacua”, then you could imagine that there are gauge theory duals of the kind of string theory used in unification. These would be 3d gauge theories, and looking for them is an active field of research. As far as I can tell though, if it is successful, all you will get is a different parametrization of the “Landscape”, an infinite number of complicated qfts, corresponding to the infinite number of complicated “string vacua”.

16. **Andrei**
April 16, 2009

String theory does not have a PR problem. On the contrary most of the media gobbles up any crazy thing someone like Witten cares to say. I think the problem with strings is that it is not new as some people misleadingly say. It’s been around for about 40 years. And in all this time it has proven itself to be nothing more then mental pollution. Besides there are much more interesting and much newer aproaches to quantum gravity based on superconductivity. I think it is time string theory was filed in the round file (garbage can) and other approaches given a chance.

17. **Dennis Towne**
April 16, 2009

Chris Oakley,

When I talk about Lisi’s work, yes it’s less arcane, but the real hook can be found in his TED talk about it. It sounds plausible, it seems reasonable, and what little he predicts (the missing particles) make sense. But most importantly, his presentation -looks- cool, with nice symmetric/geometric visuals that people immediately understand.

That it has some gaps and handwaving in the middle is irrelevant; it has everything it needs to sell well to the techie crowd. Only a solid “this doesn’t match reality, even though it looks cool” is likely to change that.

18. **Thomas Larsson**
April 16, 2009

“So if AdS CFT turns out to work correctly it would be a good argument for string theory. Is this not true?”

But does it work correctly? In a recent discussion here, I became aware of the paper arXiv:0806.0110v2. Therein, the following statements are proven:

1. AdS/CFT makes a prediction for some quantities c'/c and k'/k, eqn (5).

2. This prediction is compared to the exactly known values for the 3D O(n) model at n = infinity, eqns (28) and (30).

3. The values disagree. Perhaps not by so much, but they are not exactly right.

This may be expressed by saying that the d-dimensional O(n) model does not have a gravitational dual (an euphemism for "AdS/CFT screwed up"?), at least not in some neighborhood of n = infinity, d = 3, and hence not for generic n and d. There might be exceptional cases where a gravitational dual exist, e.g. the line d = 2, but generically it seems disproven by the above result. In particular, I find it unlikely that the 3D Ising, XY and Heisenberg models (n = 1, 2, 3) can be treated with AdS/CFT.

19. **DB**
April 16, 2009

I note that Witten expects any useful new insights in String Theory to come from a younger generation. Well at least he's realistic, unlike his wife. Theoretical physicists over the age of 45 rarely make significant fundamental contributions. Even the smartest are burnt out by then.

20. **Aaron Bergman**
April 16, 2009

this doesn't match reality, even though it looks cool

How about "it doesn't look cool when you look closely at it and it's not even a quantum theory"?

21. **Joey Ramone**
April 16, 2009

Trying to defend classic, epic physics at Discover's Cosmic Variance blog would be like trying to promote the Ramones at a Jonas Brothers concert. I wonder if the same parent company owns both the Jonas Bros. and Discover as well as Disney and Miley Cyrus?

22. **Joey Ramone**
April 16, 2009

DB writes, "I note that Witten expects any useful new insights in String Theory to come from a younger generation. Well at least he's realistic, unlike his wife. Theoretical physicists over the age of 45 rarely make significant fundamental contributions. Even the smartest are burnt out by then."

Well, no doubt that Witten's a genius, but what useful "old" insights into String Theory came from the older generation, as far testable physics goes?

Kudos to Witten for advancing mathematics, but it's kindof like Milli Vanilli saying that they expect any useful new insights into lip-syncing to come from the younger generation.

23. **Chris W.**
April 16, 2009

Joey, you can go back to being dead now, thank you.

24. **Marion Delgado**
April 17, 2009

What do the leading actual string theorists say when someone asks them if Tom Siegried's very strong claims are correct?

25. **Sumar Ongi**
April 17, 2009

Although not directly related to the topic of this post, there's been a recent development in the field of SM extensions that, I think, shouldn't go unnoticed.

In the family of models known as Little Higgs Models, the naturalness problem is solved by making the Higgs be a pseudo-Goldstone boson of a certain global symmetry group that is spontaneously broken above the electroweak scale, where a sector of the model becomes strongly coupled. In fact, the Higgs boson is the lightest of those pseudo-Goldstone bosons, and is especially and naturally light due to the particular implementation of spontaneous symmetry breaking adopted in these models, the so-called "collective" symmetry breaking.

The Higgs boson does not get quadratically divergent corrections to its mass because it is a pseudo-Goldstone, and it also remains light with respect to the global symmetry breaking scale (unlike the other pseudo Goldstones in the model) due to the collective symmetry breaking.

A very recent preprint shows that this collective breaking mechanism is unstable under renormalization. Thus, unless the top quark couplings are fine tuned in an unnatural way, the Higgs boson does receive quadratically divergent corrections. To quote the authors of the preprint "This defeats the purpose of introducing the model in the first place." The preprint goes on to show that this problem is generic, therefore affecting all Little Higgs models.

All in all, it seems that Little Higgs models have been ruled out (so to speak).

26. **Sumar Ongi**
April 17, 2009

Well, as expected, the link came out wrong. It should be,
http : //arxiv.org/abs/0904.1622

Quantum tunnelling of a new, third kind could finally put string theory to the test

April 20, 2009
Categories: This Week's Hype

The whole "finally, a way is found to test string theory" business is starting to become a complete joke. See the latest such nonsense:

Quantum tunnelling of a new, third kind could finally put string theory to the test

which is based on this preprint.

Note: I'll be traveling this week, first to Edinburgh, where a celebration of Sir Michael Atiyah's 80th birthday is going on, then stopping in Dublin on the way back to New York.

Update: As usual, Slashdot can be relied upon to promote the latest "predictions from string theory" hype.

Comments

1. **Felipe**
   April 20, 2009

   Dublin? Is there a talk planned?
   Are you going to be around Trinity College by any chance?
   Cheers.

2. **Peter Woit**
   April 20, 2009

   Felipe,

   No, the trip to Dublin is really just my vacation. I will be around Trinity meeting someone there Friday, might be at tea that afternoon…

3. **David G.**
   April 20, 2009

   Hi! Just bookmarked your blog. I picked up the book yesterday. Mainly looking for more info (I liked your posts and the links, along with the sidebar links). Esp. interested in book reviews and recommendations for my library and reading.

   Have a great trip to Eire! – David in Houston

4. **bz**
   April 21, 2009

   It's not quite fair to criticize this paper as a joke in testing string theory. In the preprint, the only time the word "string" comes out is in page 2:

   "tunneling of the 3rd kind can serve as a tool to search for physics beyond
   the standard model in the form of light minicharged particles. The latter arise naturally
   and consistently1 in many extensions of the standard model based on field and string
   theory"

5. **Marion Delgado**
   April 21, 2009

   bz: the paper is definitely not a joke, the hype might be.

   The remnant question is: Does this "third kind of tunneling" exist and would it bolster string theories?

   First, we KNOW from experience that no matter what, any result won't be taken as weakening, let alone falsifying, string/etc. theory. Partly because there's such a large variety of possible string theories.

   Second, we DON'T know whether discovering this conjectured tunneling would help bolster string theory generally, because it's unclear from the article to what extent string theories uniquely posit that.

6. **Coin**
   April 21, 2009

   So do I understand this "third way" tunneling paper correctly that they're not proposing a new effect, they're just deriving a previously unnoticed emergent behavior of old effects?

   I don't think I quite understand their remark on page 2 which bz quotes– how exactly is it that this effect could allow us to more easily detect previously undiscovered particles, as they claim?

7. **Engineer**
   April 22, 2009

   The author of the referenced paper also has another one about checking for anomalies in the coulomb field.
   The author does state that both field theories and string theory allow for mini-charged particles.

   I am for any tests that give null results, however I have to agree with Peter that there are a lot of recent discussions about angels on the head of a pin, including some over at Cosmic Variance.

Atiyah-Singer String Index Theorem

April 21, 2009
Categories: This Week's Hype

Just made it to Edinburgh for the Atiyah conference. It seems that someone at a local newspaper really wants to get my goat. See the story headlined [World's Great Minds Gather to Celebrate Atiyah's Birthday].

Update: Will try and write more about the conference soon. At least one string theorist [argues] for the new name for the index theorem, on the grounds that it is used in string theory. When I get back to Columbia I think I'll tell my Calculus students about the Taylor string series….

Comments

   April 21, 2009

   I'd not be too worried if I were you, the Herald hasn't much of a reputation for Science reporting.

   If you're at the public lecture at the RSE this evening drop by the Particle Physics for Scottish Schools display exhibits- I'll be demonstrating some basic particle physics to the public and I'd love to hear your take on our work! I'm very keen to strip the hype from HEP and show the public that it can be fascinating without the need for media sensationalism.

2. **Chris Oakley**
   April 21, 2009

   On the subject of goats, did you know that last March – for the first time – there was an [Oxford vs. Cambridge Goat Race], on the same day as the Boat Race?

3. **alex**
   April 21, 2009

   Sorry, I'm probably a bit slow today (maybe every day), but what do you object to in the article? They've added the word string to the Atiyah-Singer Index Theorem, but that's hardly disastrous. Or was it something else?

4. **Peter Woit**
   April 21, 2009

   alex,

   The Atiyah-Singer index theorem is one of the central results of 20th century mathematics, and probably my favorite theorem in mathematics. It has nothing to do with string theory. Clearly the theorem was renamed to annoy me. It's a plot I tell you.

   Experimentalist,

   Will try and stop by, but I may not get there in time….

5. **Dan**
   April 21, 2009

   Is alex being sarcastic? The troubling part is not the shoddy journalism but the natural question: "Where on earth would the journalist even get the idea that this is the name of the theorem?" The most likely answer is that the mistake was caused by too much string theory hype.

6. **Mitch Miller**
   April 21, 2009

   Calling it the Atiyah-Singer String index theorem is pretty crazy. Atiyah obviously has spent alot of time thinking about string theory (much of that thinking was very fruitful for math and physics/ST) but the index theorem is not part of that group.

7. **Cormac O Raifeartaigh**
   April 21, 2009

   A Freudian slip? my guess is that the journalist first wrote 'The Atiyah String Index Theorem', then corrected the omission of Singer without understanding his mistake!

8. **Bored Busybody**
   April 21, 2009

   The Herald's online editors have been notified of the gaffe. It will be interesting to see if they respond.

9. **Experimentalist**
   April 21, 2009

   Thanks for dropping by, Peter. Enjoy the rest of your time in Edinburgh!

10. **M**
    April 22, 2009

    About string jokes, there is today a new string paper in the string hep-th arXiv (0904.3101) with a string abstract where they claim a string prediction for the amount of string CP violation. Reading the paper, one can see that the string Harvard authors just assume a qualitative string texture for the string Yukawa matrices of the string quarks and of the string leptons to estimate the string Jarlskog invariant.

11. **alex**
    April 23, 2009

Dan

I wasn't being sarcastic, I think the article is quite good. In a short space it does a reasonable job of explaining who Atiyah, Singer, Witten and Higgs are and what they've done. It says that the LHC will be used to look for the Higgs boson. It doesn't say that the LHC will be used to look for evidence of string theory.
The mistake with the theorem's name is not a big deal, I imagine Cormac's guess is not far from the truth. To all but a vanishingly small fraction of humanity "Atiyah-Singer index theorem", "Atiyah-Singer string index theorem", "Atiyah-Singer string theorem index", "Atiyah string singer theorem" etc are all equivalent complicated sounding gobbeldy gook.
Peter's conspiracy theory amused me, but the harrumphing from others about "shoddy journalism" and a "gaffe" doesn't seem to be intended as humour. I think it is likely to convince any journalist reading it that you lot are going to flick peanuts whatever they do.

12. **Peter Woit**
April 23, 2009

alex,

The printed version of the article has a sidebar with the headline "How huge is this piece of string?" which repeats the name "Atiyah-Singer String Index Theorem" and describes its significance for math and physics as huge. This wasn't a typo, it was a misunderstanding based upon being subjected to some of the standard hype about string theory, mathematics and physics. I don't blame the author of the piece, the problem is the hypsters who are happy to spread this sort of misinformation.

13. **Thomas R Love**
April 23, 2009

Googling 'Atiyah-Singer String Index Theorem' yields only one site other than NEW (or references to NEW):

http://www.gabbr.com/blogs/2009/4/26979/Michael-Atiyah:-80th-birthday/

There is nothing on scholar.google.com

So this nonsense is not widespread.

14. **Benni**
April 23, 2009

By the way Peter, what do you think about the journal "progress of physics"?
http://www3.interscience.wiley.com/journal/109802073/issue

These days, that journal publishes almost only string phenomenology (but sometimes also articles of witten).

In the early view section
http://www3.interscience.wiley.com/journal/109802073/issue

there is now an article about String theory and the LHC by the journal Editor D. Lüst:
http://www3.interscience.wiley.com/journal/122304902/abstract

What do you think of it?

15. **Eric Habegger**
April 23, 2009

"It seems that someone at a local newspaper really wants to get my goat. "

Didn't know you had a goat. It seems very odd for a Columbia professor to have a goat. It must be a very attractive goat. What's his/her name? Is this some new fashion among the east coast professional elites to acquire goats?

16. **csrster**
April 24, 2009

"It seems that someone at a local newspaper really wants to get my goat. "

Don't worry Peter, I'm sure you're also getting their goat by referring to them as a local newspaper when they consider themselves a national newspaper. The best way to annoy them is to refer to them by their old name, The Glasgow Herald.

17. **Chris Oakley**
April 24, 2009

> Is this some new fashion among the east coast professional elites to acquire goats?

The latest round of grant cuts have put many academics in the New York area below the poverty line, and without the chickens, pigs and goats they keep they would probably not survive.

18. **Jeff Moreland**
April 24, 2009

I hope you don't tie your goat up with string.

19. **Coin**
April 24, 2009

I always assumed it would be difficult enough just to keep a dog in Manhattan.

20. **Eric Habegger**
April 24, 2009

The Scotch are big connosoires of goats from way back. A word to the wise: its generally not a good idea to bring your best goats to Scotland. They are known for trying to get it.

21. **Jack Lothian**
April 26, 2009

    Eric, my grandmother was very scottish & proud of it & one of her favourite phases to her grandchildren was “you are not scotch you fool, you drink scotch, you are a Scot”. Reading your remark, I could hear her again, accent & all.

22. **Chris Oakley**
April 27, 2009

    OK – since we are all in a pedantic frame of mind let me point out that the Scottish – or at least the ones that live in Scotland – never, ever drink “Scotch” although they do drink rather a lot of “Whisky”.

23. **Low Math, Meekly Interacting**
April 27, 2009

    No true Scotchman?

Atiyah80

April 27, 2009
Categories: Uncategorized

Last week I was in Edinburgh for a few days and managed to attend the last two days of the conference in honor of Sir Michael Atiyah's 80th birthday. Atiyah is now retired, but he was one of the dominant figures in mathematics during the second half of the twentieth century, as well as perhaps the person most responsible for bringing together mathematicians and physicists around issues of common interest in geometry and physics. His interactions with Witten played an important role in several major developments, including the whole idea of "topological quantum field theory". One major part of my mathematical education was spending quite a lot of time for a few years reading through Atiyah's collected papers. He is at all times a very lucid writer, with his expository writings quite marvelous and uniformly worth reading.

The biggest news at the conference was the announcement by Mike Hopkins of his solution (with Mike Hill and Doug Ravenel) of most of an old problem in topology that goes back to the sixties, known as the Kervaire invariant problem. Hopkins in his talk labeled the new theorem a "Doomsday Theorem", because it nearly finishes off the subject it deals with, by ruling out the existence of a certain class of possible interesting topological invariants in all the remaining open cases except one. I wasn't looking forward to trying to explain this here on the blog, since what is involved are issues in stable homotopy far beyond my expertise, so I was pleased to find this morning that others have beat me to it with explanations. The slides from his talk are here, John Baez has a posting here (including a comment from Hopkins here), and the news was spread to the ALGTOP mailing list here.

Another report of impressive progress on a problem was Simon Donaldson's talk on the problem of showing that a Fano manifold has a Kahler-Einstein metric if and only if it is stable. This is one of the big open problems in complex geometry, and Donaldson discussed the appropriate notion of stability and outlined a strategy for getting a proof. He is not claiming a proof, with significant work still to be done, but experts seem to believe that the goal is now within sight and the next few years will see a resolution of this problem.

Unfortunately I arrived too late at the conference to hear Witten's talk, the slides of which are available here. He is continuing his work of the past few years on Geometric Langlands. Dijkgraaf gave a nice talk reviewing a wide range of topics connected in one way or another with topological strings. Perhaps his slides will soon become available, but the topics covered were similar to those of his talks at UCSB last spring (see here). Vafa gave a rather clear explanation of his program to try and get particle physics out of local F-theory models. I'm not convinced this does more than reinterpret GUT extensions of the standard model using quite complicated constructions, but you can see for yourself here. He didn't talk about the crucial question of whether this approach makes distinctive predictions about supersymmetry breaking testable at the LHC.

One evening was devoted to a public program about the Higgs particle, with a panel discussion featuring Higgs himself. It was not clear to me how much got through to the public about the electroweak symmetry breaking issue and what we hope to learn at the LHC. As always, some of the public wanted to know about what string theory has to do with this question. Unfortunately they were not given the simple, accurate and easy to understand answer "nothing at all."

Update: The web-site for the conference is here, and conference organizer Andrew Ranicki has set up another web-site here for various materials associated with the conference.

Update: Videos of the talks at Atiyah80 are now available at the web-site linked to above.

   April 28, 2009

   Hi Peter,

   Very good post! Very useful too!

   Can you suggest the most important / relevant papers to read from his collected works?

   Regards.

2. **David Edwards**
   April 28, 2009

   In the spring of 1972 I was a post-doc at IAS. One day Mrs. Atiyah dropped by my house. I enthused about how deep and broad Michael's work was. Then, getting reflective, I said "But he hasn't done any mathematical physics". She immediately piped up "He will, he will!"

3. **former mathematician**
   April 28, 2009

   Hopkins's talk is already referenced in the Wikipedia article on the Kervaire invariant. I'm impressed!

4. **woit**
   April 28, 2009

   John,

   Here are some suggestions, taken from among the expository pieces. Most of the non-expository research articles are also quite readable, and include many classics. As an example, his paper with Bott on Yang-Mills in 2d is chock-full of remarkable ideas and results.

   Algebraic topology and elliptic operators (Comm. Pure. Appl Math XX (1967))

   Topology of elliptic operators (Proc. Symp. Pure. Math 16)

   The index of elliptic operators (1973 AMS Colloquium Lectures)

   Algebraic Topology of operators in Hilbert Space (LNM 103)

Classical Groups and classical differential operators on manifolds. (CIME Varenna 1975)

Geometry of Yang-Mills Fields (Pisa 1979)

The moment map in symplectic geometry (Durham Symposium 1984)

Anomalies and index theory (Lecture notes in physics 208)

Topological aspects of anomalies (Symposium on Anomalies, Geometry, Topology, 1984)

New invariants of 3 and 4 dimensional manifolds (Weyl symposium 1988)

The Geometry and Physics of Knots, CUP 1990.

5. **Successful Researcher**
April 28, 2009

Thanks for the post and the reading suggestions in the comments!

6. **John**
April 29, 2009

Thanks Peter!

Reading Atiyah is certainly no time spent unproductive! He's written seminal works on a whole eclectic body of math and physics topics.
Admittedly, I also take a more-than-passing interest in what he has researched upon and written on over the years, along with E. Witten (my interest/s lie in tandem to such (gargantuan! and needless-to-say awe-inspiring) figures).

Please do provide more such posts. Recommended readings are even more welcome.

Regards.

(PS: Slightly off-topic, but if you have a Facebook account I would like to add you to my friends list.)

7. **Daniel de França MTd2**
April 29, 2009

So, witten has been working on the Langlands program for 32 years. Nice to know that.

8. **Stevem**
April 29, 2009

Peter, was the conference held at the James Clerk Maxwell building on the Kings Buildings campus or somewhere else? Just curious.

9. **Felipe Zaldivar**
April 29, 2009

May I point out the recently published monograph: "Stable Homotopy around the Arf-Kervaire Invariant" by V. Snaith (Birkhauser Verlag, 2009) where we can find some history and background on the (non)-existence of framed manifolds of Arf-Kervaire invariant 1 in 2^n-2 dimensions, with the known exceptions?

Math goes quite fast, sometimes, as Mike Hopkins' breakthrough shows!

10. **Peter Woit**
April 29, 2009

Stevem,

The conference was held in a new building, the "Informatics Forum".

11. **Peter Woit**
April 29, 2009

Thanks Felipe,

For an interesting survey of the state of the Kervaire invariant problem before last week, see the introductory chapter of the Snaith book, which is available courtesy of Springer here

http://www.springerlink.com/content/t75067/front-matter.pdf

12. **Andrew Ranicki**
April 30, 2009

I am now maintaining an Atiyah80 home page http://www.maths.ed.ac.uk/~aar/atiyah80.htm
concerning the conference itself (including photos, cake, gift, wine label etc.) and subsequent mathematical developments.

13. **Peter Woit**
April 30, 2009

Andrew,

Thanks, I'll add that link to the main body of the posting. And thanks for all your work organizing the wonderful conference!

14. **Successful Researcher: How to Become One**
June 1, 2009

For those interested: Witten has recently posted a preprint based on his Atiyah 80 talk.

The Strangest Man

April 29, 2009
Categories: Book Reviews

When I was in Edinburgh I picked up a copy of Graham Farmelo's new biography of Dirac. It's entitled The Strangest Man: The Hidden Life of Paul Dirac, Quantum Genius, and is not yet available in the US. I read the book on the plane trip back to New York and very much enjoyed it. While I've read a large number of treatments of the history and personalities involved in the birth of quantum mechanics, this one is definitely the best in terms of detail and insight into the remarkable character of Paul Dirac. I gather that Farmelo had access to many of Dirac's personal papers, and he uses these well to provide a sensitive, in-depth portrait of a man who often is reduced to a bit of a caricature.

The book is less of a scientific biography than the other book about Dirac I know of, Helge Kragh's 1990 Dirac, A Scientific Biography, and emphasizes more the development of Dirac's personality and the story of his relations with others, especially with his father, his mother, and his wife (who was Wigner's sister). I learned quite a lot about Dirac that I'd never known before, including for instance the story of his work on the atomic bomb project during WWII.

Dirac is responsible for several of the great breakthroughs in 20th century physics. At the age of 23, while still a graduate student, he took Heisenberg's ideas and found the fundamental insight into what it means to "quantize" a classical mechanical system: functions on phase space become operators, with the Poisson bracket becoming the commutator. This remains at the basis of our understanding of quantum mechanics, and Dirac's textbook on the subject remains a rigorously clear explanation of the fundamental ideas of quantum theory. Two years later he found the correct relativistic generalization of the Schrodinger equation, the Dirac equation, which to this day is at the basis of our modern understanding of particle physics. This equation also turns out to play a fundamental role in mathematics, linking analysis, geometry and topology through the Atiyah-Singer index theorem. Around the same time, Dirac was one of the people responsible for developing quantum field theory and quantum electrodynamics, as well as coming up with an understanding of the role of magnetic monopoles in electromagnetism.

The period of Dirac's most impressive work was relatively short, ending around 1933. By 1937, the year he married, Farmelo reports Bohr's reaction to reading Dirac's latest paper (on the "large numbers hypothesis"):

> Look what happens to people when they get married

Farmelo discusses a bit the question of why Dirac never later achieved the same sort of success after the dramatic initial period of his career. There may be a variety of reasons: the open problems got a lot more difficult, marriage and celebrity changed the way he lived and work, the war intervened, etc. For the rest of his career, Dirac took the attitude that there was something fundamentally wrong with QFT, and this may be why he stopped making fundamental contributions to it. He believed that a different sort of dynamics was needed, one that would get rid of the problems of infinities. He never was happy with renormalization, either in the form used to do calculations in QED after the war, or the more sophisticated modern point of view of Wilson and the renormalization group.

Unfortunately, some of the later parts of Farmelo's book are marred by an attempt to enlist Dirac in the cause of string theory. This starts with the claim that Dirac's work on "strings" during the fifties should be seen as a precursor of present-day string theory. These "strings" occur in the context of QED and magnetic monopoles, where they are unphysical artifacts of a choice of gauge, and have very little to do with the modern-day interest in physical strings as a basis for a unified theory.

Farmelo sees string theory as a resolution of the problem of infinities that Dirac would have approved of:

> What would surely have impressed Dirac is that modern string theory has none of the infinities he abhorred.

I don't see any reason at all to believe that Dirac would have been impressed with the idea of resolving the problems of QFT that bothered him by replacing it with a 10-dimensional theory that, despite the endless hype, has its own consistency problems (its perturbation expansion diverges, just like that of QFTs, and, unlike QFT, a 4d non-perturbative theory remains unknown). String theory was around for at least a dozen years before Dirac's death, I'm sure he had heard about it, and there is no evidence he took any interest in the idea. Farmelo reports the reaction Pierre Ramond got from Dirac in 1983 when he tried to sell him on the idea of replacing 4d QFT with a higher-dimensional theory:

> So he asked Dirac directly whether it would be a good idea to explore high-dimensional field theories, like the ones he had presented in his lecture. Ramond braced himself for a long pause, but Dirac shot back with an emphatic 'No!' and stared anxiously into the distance

The book ends with long discussion of Dirac and string theory that I think is seriously misguided, but it does include a mention of the fact that many physicists are unconvinced by the idea of string theory unification. Veltman is quoted, and the last footnote in the book refers the reader to *Not Even Wrong*.

Dirac is famous among physicists for his views on the importance of the criterion of mathematical beauty in fundamental physical law, once writing:

> if one is working from the point of view of getting beauty in one's equation, and if one has really sound insights, one is on a sure line of progress.

Farmelo believes that Dirac "would have revelled in the mathematical beauty" of string theory, but this is based on an uncritical acceptance of the hype surrounding the question of the "beauty" of string theory. "String theory" is a huge subject, and one can point to some mathematically beautiful discoveries associated with it, but the attempts to use it to unify physics have led not to anything at all beautiful, but instead to the landscape and its monstrously complex and ugly constructions of "string vacua" that are supposed to give the Standard Model at low energies.

I very much share Dirac's belief that fundamental physics laws and mathematical beauty go hand in hand, seeing this as a lesson one learns both from history and from any sustained study of mathematics and physics and how the subjects are intertwined. As it become harder and harder to get experimental data relevant to the questions we want to answer, the guiding principle of pursuing mathematical beauty becomes more important. It's quite unfortunate that this kind of pursuit is becoming discredited by string theory, with its claims of seeing "mathematical beauty" when what is really there is mathematical ugliness and scientific failure.

Ignoring the last few pages, Farmelo's book is quite wonderful, by far the best thing written about Dirac as a person and scientist, and it's likely to remain so for quite a while. Definitely a recommended read for anyone interested in the history of the subject, or some insight into the personality of one of the greatest physicists of all time.

Comments

1. **Shantanu**
   April 29, 2009

   Peter, thanks for pointing to this. Also in this post, you forgot to
   mention Dirac's contributions to GR. There is a good exposition on that
   in here
   Does this book discuss Dirac's contributions to GR?

2. **Peter Woit**
   April 29, 2009

   Shantanu,

   Yes, the book does discuss a bit his contributions to GR. What I wrote is by no means intended as a comprehensive list. Dirac did significant work on many topics, but I think the general notion of quantization and the Dirac equation are the two that are both of greatest importance, and cases where the insight is purely his, no one else was doing the same thing around the same time.

3. **Chris Oakley**
   April 29, 2009

   I have to applaud Farmelo for having the courage to point out that Dirac was weird and probably mildly autistic – people normally just try to make excuses for his odd behaviour.

   I have only skimmed the book so far (tho' it is near the top of my reading list) and am disappointed to read here that the author has tried to enlist Dirac in the String Theory Roll of Honour. I do not blame him for that in itself (I am just as guilty as any in claiming "support" by the great man): it is just that I did not expect that Farmelo, as an adjunct physics professor not obviously attached to any String program, would have a horse in that particular race.

4. **Eugene Stefanovich**
   April 29, 2009

   I must disagree that Dirac slowed down after 1933. For me, his most precious (and, unfortunately, underappreciated) work is P. A. M. Dirac, "Forms of relativistic dynamics", Rev. Mod. Phys. 21 (1949), 392.

5. **Jules Moulin**
   April 29, 2009

   A strange story about Dirac's equation is told by Thomas Racey, who with Battey-Pratt deduced the Dirac equation from a slightly expanded version of Dirac's belt trick: see E.P.Battey-Pratt; T.J.Racey, Geometric model for fundamental particles, International Journal of Theoretical Physics, 19:437-475, 1980. They deduced all the details of Dirac's equation from a few simple topological ideas. They then sent a copy of the paper to Dirac, but unfortunately, Dirac never answered.

   Racey then turned to other research topics. Only a few scattered people are trying to revive interest in the approach.

   Jules

6. **Thomas R Love**
   April 29, 2009

   I thought some of Dirac's best work was his 1951 Letter to Nature:"Is there and Ether" and his idea that the velocities of the ether provide potentials. Thanks Jules, I've thought for a long time that "Geometric Models" one of the most important papers that never developed a following.

   Dirac presented his last talk at the 2nd New Orleans Conference on Quantum theory and Gravitation in 1983. I went up to him carrying his book on General Relativity and asked for an autograph. He refused saying "I don't do that".

7. **MathPhys**
   April 29, 2009

   Many scientists and artists are probably slightly autistic.

8. **Francois Vanderseypen**
   April 29, 2009

   Made me laugh: '…string theory as a resolution of the problem of infinities that Dirac would have approved of…'. I don't have the right to claim the opposite but it's fun to see how these days anything and everything is used to defend string theory. Like many, I reckon he would have liked the mathematical integrity/beauty of string theory but that doesn't make it a physical theory.
   Soon there will be a book about Boltzmann who anticipated string theory, a book about Wolfram's NKS which proves the statistical advantages of the landscape…?
   I love you blog, keep writing, you're my hero.

9. **cynic**
   April 29, 2009

   'As it become harder and harder to get experimental data relevant to the questions we want to answer, the guiding principle of pursuing mathematical beauty becomes more important. It's quite unfortunate that this kind of pursuit is becoming discredited by string theory, with its claims of seeing "mathematical beauty" when what is really there is mathematical ugliness and scientific failure.'

   In 1930 he wrote:

   'The only object of theoretical physics is to calculate results that can be compared with experiment.'

   – Dirac, *The Principles of Quantum Mechanics,* 1930, page 7.

   But he changed slightly in his later years and on 7 May 1963 Dirac actually told Thomas Kuhn during an interview:

   'It is more important to have beauty in one's equations, than to have them fit experiment.'

   – Dirac, 'The Evolution of the Physicist's Picture of Nature', Scientific American, May 1963, 208, 47

   Other guys stuck to their guns:

   '… nature has a simplicity and therefore a great beauty.'

   – Richard P. Feynman (*The Character of Physical law,* p. 173)

‘The beauty in the laws of physics is the fantastic simplicity that they have … What is the ultimate mathematical machinery behind it all? That’s surely the most beautiful of all.’

– John A. Wheeler (quoted by Paul Buckley and F. David Peat, *Glimpsing Reality,* 1971, p. 60)

‘If nature leads us to mathematical forms of great simplicity and beauty … we cannot help thinking they are true, that they reveal a genuine feature of nature.’

– Werner Heisenberg (page 2 here)

‘A theory is the more impressive the greater the simplicity of its premises is. The more different kinds of things it relates, and the more extended is its area of applicability.’

– Albert Einstein (in Paul Arthur Schilpp’s *Albert Einstein: Autobiographical Notes*, p. 31)

‘My work always tried to unite the true with the beautiful; but when I had to choose one or the other, I usually chose the beautiful.’

– Hermann Weyl (page 2 here)

10. **Lowell Brown**
April 29, 2009

I once asked Dirac how he invented the Dirac Equation. He said:

I found that a times sigma sub x plus b times sigma sub y plus c times sigma sub z — quantity squared — was a squared plus b squared plus c squared, and I marveled at the beauty of this result.

11. **Thomas Larsson**
April 30, 2009

The circle is the most beautiful geometrical shape. Hence planets must move in circles, or in circles around circles.

A misguided concept of beauty held progress back for 1500 years. Something to ponder when arguing for beauty.

12. **Chris Oakley**
April 30, 2009

Lowell,

This version of WordPress seems to allow you to write that in HTML, or the generalisation:

σiσj=δij+iεijkσk

I feel a piece about “the square root of the Klein-Gordon equation” coming on. But don’t worry – I’ll put it on my web site and not here.

13. **publius**
April 30, 2009

While it seems clear that Dirac was not seduced by the idea of extra dimensions, as shown by his answer to Ramond, and it also seems to be no evidence of interest from him on string theory during his last years, he was certainly one of the firt researchers (if no the first) to consider fundamental relativistic extended objects in physics, introducing a relativistic brane, motivated partly by the hope to get rid of just those troubling infinities in particle theory. I believe the reference is
Proc. R. Soc. London A 268(1962)57
This reference is quite more pertinent than Dirac’s string to make a connection between Dirac and string theory (which possibly Dirac himself would have rejected…) It would be surprising if the author of the book does not mention it.

14. **Chris Oakley**
April 30, 2009

Forget that – it did the _… in the preview, but not in the final result.

15. **Peter Woit**
April 30, 2009

publius,

Farmelo does mention the 1962 paper in this context. In it Dirac was trying to interpret the electron as a charged conducting surface, with the muon an excited state. The connection to current ideas about branes seems rather slim….

16. **none**
April 30, 2009

The Dirac-Born-Infeld action, a nonlinear modification of the Maxwell action, shows up in string theory as part of the effective action for a D-brane.

17. **Carl**
May 1, 2009

Thomas,

the smarter physicists used “beauty” in physics to mean “simplicity” (see the citations above) which is the real thing to achieve. Beauty is maybe misguided, simplicity is not. Over the years, the description of physics has become simpler and simpler. Maybe also more beautiful, but most of all, simpler.

18. **dir**
May 1, 2009

mentioning infinities in qft, i once read a small book by yukawa who also tried to use extended objects to replace point-particles. maybe this trend had an influence to japanese theoretical physicists, including nambu?

19. **davetweed**
May 1, 2009

With regards to Chris Oakley's comments, it is rather strange that people insist on ascribing medical conditions to people where they cannot possibly know enough details to make a meaningful medical diagnosis, rejecting the idea that many people can be weird without some having some medical condition to explain it. (Autism is a relatively precise medical diagnosis, and someone not acting with the general societal level of gregariousness and following of social conventions doesn't automatically imply they have some degree of autism.)

Note that I'm not arguing either that Dirac would or wouldn't have been diagnosed as autistic by a specialist had he been examined by one, but rather about the cavalier "well those anecdotes sound vaguely like they fit with autism, so he must have been mildly autistic" approach.

20. **D R Lunsford**
May 1, 2009

I have to disagree as well that Dirac was spent in the 30s. "Forms.." as mentioned is an extremely important work. His book on GR remains the most concise exposition imaginable. His attempts to rid classical EM of inconsistencies were heroically motivated and fascinating to follow. The LNH remains an extraordinary idea. He was the first person to rigorously explore anti-deSitter space (early 60s) ("A Remarkable Representation of the 3+2 deSitter Group"). Very late in life he was working on infinite dimensional representations of the Lorentz group. Like Beethoven, he knew only one direction, forward.

I agree that connecting the "Dirac string" as it came to be called with string theory, is analogous to connecting General Relativity with General DeGaulle.

-drl

21. **D R Lunsford**
May 1, 2009

T R Love,

This work behind this article in Nature was no doubt his "New Classical Theory of Electrons" which appeared in the Royal Society Proceedings in three papers – early 50s. Basically he posited an equation of state such that the current was proportional to the potential,

J = -k A

so one has a sort of superconducting vacuum in the London sense. It's an extremely interesting series if only as a demonstration of how to think physically, and how intractable is the problem of the electric charge.

-drl

22. **Thomas Larsson**
May 1, 2009

Carl,

A circle is simpler than an ellipse. Thus Ptolemy was right. And since we remember him after 2000 years, I bet he was really smart, too 🙂

The problem with simplicity or beauty is that it lies in the eyes of the beholder. Beauty is an important motivation and inspiration, but eventually it must be up to experiments to decide whether Nature agrees with your subjective notion of beauty. E.g., it really doesn't matter how fearful a symmetry that SUSY might be; if the Tevatron finds no light Higgs and the LHC finds no sparticles, SUSY is dead nontheless.

One of my favorite models is the CFT with c = 1/2, which describes the 2D Ising model at criticality. It consists of three fields, belonging to three separate Virasoro representations (with h = 0, 1/16 and 1/2). This model is thus not unified in the sense that all fields belong to the same multiplet of the relevant symmetry, but it is unified in the weaker sense that the representations are connected by fusion rules. If this is the way that things will work out in Nature (and it does for the 2D Ising model), then the idea of GUTS (putting everything in the same multiplet) may be fundamentally misguided. And so may SUSY, since fusion rules of a purely bosonic symmetry can connect both bosonic and fermionic fields.

23. **Greg Sivco**
May 1, 2009

Dirac was the way he was because of an extremely strict father. Read the Wiki entry and it explains that precisely. I look forward to reading the book, P.A.M. Dirac is one of our all-time favorites. The list of his accomplishments (right hand side, Wiki again) is so amazingly large. Is there anyone who did more? I often debate with myself if either he or Max Born loved Mathematics more. Shrug, I'll never know, but they're up there amongst the Early Titans of 20th Century Physics.

Thank you, Peter for your excellent review, we have been looking forward to this book for a long time, and I will most assuredly skip the last "string section" on purpose. That New Scientist article is depressing enough … I see no reason to add to the masochism. 🙂

24. **Carl**
May 3, 2009

Thomas,

beauty might lie in the eye of the beholder, simplicity does not.
The inverse square law is simpler than epicircles.

A single QED Feynman diagram is simpler than Maxwell's equations.

The issue now is how to continue this…

Carl

25. **Georges Melki**
September 20, 2009

I would like to add to the list of quotes by Cynic regarding the importance Dirac assigned to the "beauty" of a physical theory. My quote is taken from a very good book :"

Paul Dirac-The Man and his Work", Peter Goddard,Ed.(Cambridge UP), page 89:
"In 1977, he explained his attitude in a particularly vivid way when describing his affinity with Erwin Schrœdinger(with whom he shared the Nobel Prize:
…Schrœdinger and I both had a very strong appreciation of mathematical beauty, and this appreciation of mathematical beauty dominated all our work.It was a sort of act of faith with us that any equations which describe fundamental laws of Nature must have great mathematical beauty in them. It was like a religion with us. It was a very profitable religion to hold, and can be considered the basis of all our success.
It has to be admitted that in most hands and at some times in the development of science this approach can be dangerous."
I believe this to be as clear and concise as possible…
On the other hand Peter, I prefer your review of the book to that of the New York Times!

The Only Game in Town

May 1, 2009
Categories: Multiverse Mania, This Week's Hype

This week's New Scientist has an article promoting the string theory multiverse, starting off with positive comments from Brian Greene, and continuing with a claim that the majority of physicists now embrace the idea:

> Greene's transformation is emblematic of a profound change among the majority of physicists. Until recently, many were reluctant to accept this idea of the "multiverse", or were even belligerent towards it. However, recent progress in both cosmology and string theory is bringing about a major shift in thinking. Gone is the grudging acceptance or outright loathing of the multiverse. Instead, physicists are starting to look at ways of working with it, and maybe even trying to prove its existence.

In his promotional book on the subject, Susskind is able to come up with exactly one bit of information that the string theory multiverse hypothesis provides, a prediction of the sign of the spatial curvature of the universe (others don't think that even this bit is there, see this by Steve Hsu). The New Scientist article ends:

> …says Susskind. "If it turns out to be positively curved, we'd be very confused. That would be a setback for these ideas, no question about it."
>
> Until any such setback the smart money will remain with the multiverse and string theory. "It has the best chance of anything we know to be right," Weinberg says of string theory. "There's an old joke about a gambler playing a game of poker," he adds. "His friend says, 'Don't you know this game is crooked, and you are bound to lose?' The gambler says, 'Yes, but what can I do, it's the only game in town.' We don't know if we are bound to lose, but even if we suspect we may, it is the only game in town."

The arguments for string theory have evolved over the years, with the "it's the only game in town" one being made starting fairly early on. Weinberg seems to be willing to go for a new variant of this, that not only is it the only game in town, but it's probably crooked (i.e. can't possibly work, is obvious pseudo-science…), and this doesn't matter, one should continue anyway.

It has become increasingly clear to me in recent years that there is a large cohort of people who have so much invested in string theory that they will never, ever give up on the idea of string theory unification, no matter how clear it becomes that the game is crooked and not legitimate science. They will be active and with us for a long time, but the idea that there has been "recent progress in both cosmology and string theory … bringing about a major shift in thinking", causing the majority of physicists to sign on to this is nonsense. Quite the opposite is true, with the increasingly obvious problems with string theory causing non-string theorists to shun the subject and avoid hiring anyone who works on it.

The New Scientist article is also available here, and if you want more recent multiverse promotional material, there's this. Finally, a panel discussion on this was held at the Origins symposium at ASU recently, and is now available on-line.

Update: The torrent of string theory hype seems to continue unabated, with claims that the Planck satellite will tell us something about string theory (see here):

> The results could also offer insights into the much vaunted string theory – science's big hope for a unified theory of everything. The idea involves a complex 11-dimensional universe, with seven 'hidden' dimensions on top of the four observable dimensions of space and time.
>
> Professor Efstathiou said: "The potential for fundamental new discoveries that will change our understanding of physics is very important and that is what I'm really hoping for with Planck.
>
> "We might find signatures of pre-Big Bang physics. We might find evidence of cosmic defects – superstrings in the sky.
>
> "Unravelling the physical information may tell us something about the warped geometry of the hidden dimensions."

Comments

1. **Lucy in the Sky**
   May 1, 2009

   Oh my God… You are really a sick puppy. Vitriolic, unfounded and really pathetic banter. Do us (= scientists) a favor and offer us when rejecting (whatever you do not like and that's your perfect right) a valid – or at least interesting – alternative. This blog is really becoming the prime example of the emperor with(out) his clothes. PLEASE: publish a scientific paper and BUILD instead of destroying…

2. **DB**
   May 1, 2009

   Examine the psychology of these people who are doggedly promoting string theory. They are desperate. The vast majority are over 45, the age beyond which it is extremely rare for a mathematical physicist to make significant contributions. They have devoted most of their professional careers to string theory. They need a new generation to continue the quest or they will have wasted their research lives.
   Egotism, the refusal to face the consequences of their folly, and the terrifying realization that they will never be more than footnotes to science unless the next generation can make the breakthroughs building on their work is what drives them on. Worse, the failure of the past thirty years risks being held up as a model of how not to do theoretical physics. So they have to succeed.
   The fact that they are sucking young talent into the same futile exercise is of no concern to them.
   It's clearly a form of fanaticism. Almost religious in nature.
   Weinberg is only lukewarm, his place in history is secure.

3. **Peter Woit**
   May 1, 2009

   LSD,

   Sometimes I do think of giving up on trying to do anything about the endless hype and pseudo-science going on under the banner of "string theory", mainly because it seems hopeless and there is no way to have an effect on it.

   Then, I hear from people like you that I've managed to really upset, who seem to feel that I have great destructive powers, and I get the strength to go on. Thanks.

4. **Jo**
   May 1, 2009

   "Sometimes I do think of giving up on trying to do anything about the endless hype…."

   Peter, One thing you could do is encourage people to actively seek alternatives (or help find one yourself).

5. **Peter Woit**
   May 1, 2009

   Jo,

   I do work on alternatives myself, spending far more time on that kind of work than on the blog. The whole point of the hype campaign is to convince people that they should not seek alternatives, that string theory is the "only game in town".

   That Weinberg is admitting that the game is probably crooked and unwinnable seems newsworthy, and pointing people to that news seems like a good way to encourage them to look for alternatives.

6. **Lucy in the Sky**
   May 1, 2009

   "I do work on alternatives myself, spending far more time on that kind of work than on the blog. " I am impressed by this 15+ years of time&efforts and the results which emerged from it… http://www.slac.stanford.edu/spires/find/hep/www?rawcmd=find+find+a+p.+woit .

7. **Peter Woit**
   May 1, 2009

   Thanks again LSD. Responding to criticism with anonymous personal attacks does a good job of convincing people that proponents of this particular game have neither a scientific case nor the guts to stand up publicly for it. Your destructive power is far greater than mine….

8. **Successful Researcher**
   May 1, 2009

   Is there an interview or something where Weinberg is more verbal on the string theory and landscape? In the NS article he is just quoted to say "We just can't make a list of 10^500 things. That's more than the number of atoms in the observable universe.", and I fail to read much of an attitude out of this…

9. **Peter Woit**
   May 1, 2009

   Just remembered that "Lucy" had been here before, leading to a similar exchange. He or she really doesn't like it when I say critical things about multiverse research.

   http://www.math.columbia.edu/~woit/wordpress/?p=717

10. **Peter Woit**
    May 1, 2009

    SR,

    For Weinberg's views on the multiverse, probably best to read this

    http://arxiv.org/abs/hep-th/0511037

    Recall that he's generally the one credited with pointing out that the size of the cosmological constant could be understood by an anthropic argument. I suspect that, like Gross and many others, to some degree he recognizes how problematic the whole string landscape subject is, but one naturally tends to think more highly of one's children than is reasonable…

11. **Eric Habegger**
    May 1, 2009

    Regarding the endless hype of string theory, it seems to me that much unwarranted help is being enlisted by periodicals such as New Scientist. I subscribed to it for about a year but realized quickly that my interest in physics was not being at all well served by it. I had to actually get my credit card replaced to end their tireless automatic resubscription.

    It seems to me a good plan to hit string theory where it hurts is to stop subscriptions to pseudoscience periodicals such as New Scientist. That may hit string theory harder than large amounts of well reasoned arguments against it.

12. **Peter Woit**
    May 1, 2009

    Eric,

    I don't think the problem is New Scientist. They're generally reporting reasonably accurately what physicists, often prominent ones, say to them.

13. **coolstar**
    May 1, 2009

    Very timely post Peter as I just NOW read on the Bad Astronomy blog how the Planck mission will test string theories of cosmology.

14. **Peter Woit**
    May 1, 2009

    coolstar,

    Looking at that blog, it seems to me that Phil Plait avoids making the claims about string theory that you state. Perhaps Planck will see evidence for gravitational waves in the CMB, that would tell us something new about the Big Bang, and that's what he's excited about. Wouldn't tell us whether strings have anything to do with anything though….

15. **Observer**
May 1, 2009

Keep up the good work Peter, thanks for let us know why string theory does not work. It is apalling how some called "(= scientists)" can't see the objective of your blog

16. **David G**
May 1, 2009

Thanks Peter. It's spotlighting the hype which makes an interested non-scientist like myself want to delve deeper into the alternative material, which this post does very well.

17. **Shantanu**
May 1, 2009

Peter ,see this nice talk by Krauss on inflating , string theory etc.
he points out how one can/may never test inflation with CMB experiments.
http://www.stsci.edu/institute/itsd/information/streaming/archive/STScIScienceColloquiaSpring2009/

18. **Pawl**
May 1, 2009

Lucy, Jo,

Your criticism of Peter's publication record rather than his arguments only shows how little you have to offer in support of the "multiverse." (It's also not a self-consistent position, as you don't offer your own publication records to be examined.)

The argument you make, which seems to be popular among string theorists, is that one should "build, not destroy." This is not science. Poor ideas should be criticized. Proponents of ideas should be frank about their limitations — and not encourage hype, whcih was the whole point of Peter's post. Some ideas are so poor that it is really better to give up on them and work on something else.

In fact, what Peter reported seems to go well beyond hype and into a level of serious misrepresentation — New Scientist suggesting, presumably on the basis of their interviewees' comments, that most physicists accept the multiverse.

It's hard to see Peter's points there as objectionable at all.

19. **Mark Stuckey**
May 2, 2009

Peter,
I am glad you're doing this work and I believe it's valuable. I've heard fm more than one researcher who believed stupor string theory was draining talent and thwarting progress in physics, e.g., "Is string theory a futile exercise as physics, as I believe it to be? … The sad thing is that, … other avenues are not being explored by the bright, imaginative young people, and that alternative career paths are blocked." P.W. Anderson, NY Times, 4 Jan 05. So, I believe it's important that someone takes the time to communicate flaws in SST.

As for your own attempt at an alternative to SST unification, what are you working on? I see you had pubs in lattice gauge theory, are you working on a discrete method now? Maybe this isn't the place to discuss it based on the warning that "this is not a place for people to promote their favorite ideas about fundamental physics." If so, please email me your answer. Thanks.

20. **Peter Woit**
May 2, 2009

Mark,

No, I haven't worked on lattice gauge theory in a long time, and I don't have any particular ideas about discretization as helping with fundamental issues.

Recently I've been working on a variant of the BRST approach to handling gauge symmetry, using something mathematicians are calling "Dirac Cohomology". Still sorting out some things about this that confuse me. Now that classes are almost over, I hope to devote the summer break to finishing something I'm writing on the subject.

21. **coolstar**
May 2, 2009

Peter: perhaps you're correct about Bad Astronomy, Planck, and string theory but on a second and third reading, and on following the links, I'll still have to disagree. I've obviously been wrong before, but less than average about that particular blog. And of course, what you've said about gravitational waves and Planck is correct (I certainly didn't mean to imply that Planck wasn't a worthwhile mission).

22. **Joey Ramone**
May 4, 2009

Who is the greater musician–he who wins American Idol and sells a million records or he who plays from the heart, come hell or high water, whether there are three people in the audience or 30,000?

Who is the greater physicist–he who publishes millions of indecipherable, fundaemnatlly-erroneous and intenionally- misleading papers in meaningless, groupthink journals, or he who speaks the simple, honest truth regarding physics and physical reality?

Truly, many "scientific" journals have been hijacked by the same financial "geniuses" who brought us the decline of the economy, giving a bad name to mathematicians, physicists, and economists.

23. **hmm...**
May 4, 2009

`Joey Ramone', you seem to be having trouble maintaining a consistent character.

24. **Andrei**
May 5, 2009

One can only hope that the new minds are steering clear of string theory. In the beggining the string people were all confident (read arogant) about how their theory will explain everything. Now they are desperately clinging at straws. Looking for any kind of confirmation even marginal ones. This is a good sign. String theory is on its death bed. The question is how long will it linger before someone gives it the final dose of painkiller. The idea that Planck will confirm some aspects of string theory is absolutely pathetic. The final nail in the string's coffin must come from alternative theories. Otherwise all those tenured types with their lives vested in it will continue to push it forward. And their task is not hard because by definition string theory is impossible to disprove. So I agree that this blog should also describe and discuss alternate theories.

25. **Joey Ramone**
May 5, 2009

Hmmmm writes, "`Joey Ramone', you seem to be having trouble maintaining a consistent character."

Hey Hmmm–you try fathering/furthering/defininining the American punk rock/alt.-rock movement, never selling out, getting inducted into the Rock'n'Roll Hall of Fame, and then taking up physics in the afterlife.

It are all the string theorists who have trouble maintaining a consistent character, as they have displaced and suppressed their own characters and curiosities to serve the greater goals of the group–never has physics, like rock'n'roll, been furthered by corporate-state groupthink. The String Theorists are always waiting for their marching orders from their antitheory, physicsless elders, who command them to show their loyalty by anonymously attacking Peter Woit's blog, which makes for good entertainment. Imagine if Einstein or the Ramones had had to take dictation from seventy-year-olds going on and on about the Anthropic Principle and Multiverses–the very opposite of physics–when there were in their twenties!

Imagine if Lenny Susskind or Michio Kaku were in charge of writing the Ramones' lyrics! Brian Greene wouldn't be so bad–he wears cool black leather jackets in his music video for The Elegant Universe. If he grew his hair out he could definitely audition to be a roadie.

26. **Thomas R Love**
May 5, 2009

The best thing NEW did was to steer new graduate students away from string theory into other fields where they might actually do some real physics.

Peter, are you going to write a sequel?

27. **Peter Woit**
May 5, 2009

Thomas,

No plans for a sequel. For one thing, little has changed since 2002, when most of the book was written. There would have to be something new to write about for me to get interested in thinking about a sequel. Maybe if LHC results change things dramatically.

Someday I would like to write a technical book on representation theory, QM and QFT, but that project is also a long ways off right now.

28. **Tim**
May 6, 2009

Hello Peter,
sorry, my comment is obviously a little bit off topic: String theorists tend to claim that "string theory contains all of general relativity". As far as I understand this, this statement reduces to "string theory contains massless spin-2-particles". It seems to me that the impression that this implies all of general relativity contains can be traced back to the Lectures on gravitation by Feynman who showed that one can indeed derive the field equations from this fact. But is general relativity not much more than just the field equations? Can a spacetime containing a black hole even be generated by gravitons? This seems to be one of the key arguments of the LQG-people, but has this question even been asked by some string theorists?
On the other hand do the field equations of general relativity enforce consistency of the energy-stress-tensor and the spacetime geometry, meaning the energy-stress-tensor generates spacetime curvature which back reacts on matter = energy etc. To postulate some spacetime and putting some strings in it that may or may not generate gravitons seems to completly ignore this point.
I would be very grateful to any link or hint to further discussions of these points,
with kind regards,
Tim (interested layman)
P.S.: Could it be that string theory is mostly popular in the US has to do with the fact that Feynman did not publish his lectures, but that they were passed around from hand to hand?

29. **Peter Woit**
May 6, 2009

Tim,

I don't think the availability of Feynman's lectures had anything to do with it, the argument was well known and I believe repeated in many sources. The sociology of particle theory in the US has always been more trendy than in other countries, with a big emphasis on hiring people working on the "cutting edge". Actually, at the moment, I think this trendiness is cutting against string theory in the US, as the perception has grown that string theory is dormant, with cosmology and phenomenology the "cutting edge". String theory seems to me to be doing better in other countries, where there is more willingness to hire people in field perceived as "prestigious", even if not currently very successful.

String theorists certainly do worry about the question you ask, and there have been extensive debates over the issue of "background dependence" in string theory here and elsewhere. I don't want to get those started again, unless some commenters willing and able to provide a well-informed, balanced discussion free of hype and wishful thinking magically appear.

Perhaps the main reason I have little interest in arguing these issues is that if you can't use the criterion of solid mathematical consistency or that of agreement with experiment, you can't ever be shown to be wrong, So you may be doomed to a future of arguing over who has the "best" not truly consistent quantum gravity theory that can't be tested, with no objective way to decide. I'll leave this to others.

30. **Aaron Bergman**
May 6, 2009

In addition to containing gravitons, it is possible to demonstrate that string perturbation theory makes sense precisely when the background spacetime satisfies Einstein's field equation. The gravitons are the perturbations around the background.

31. **Michael T.**
May 6, 2009

Thanks Peter for the link to the Origins Conference at ASU. I did find Sheldon Glashow's comments most interesting. What I got from it was that the cancellation of the Texas collider created a 17 year pause in experimental physics. With no real data to construct new theories it seems that the imaginations of some very bright people over the years got a bit carried away which eventually led to untestable notions like string "theory". If the devil truly does find work for idle hands then with a nod to Occam it is the most simple and most human explanation of why ST has garnered so much attention.

32. **Paul James**
May 7, 2009

The claim of "only game in town" may be exaggerated. String theory uses, as Witten says, 4 ideas: supersymmetry, higher dimensions, duality, and stringiness. If one leaves out the first two or three, which have little counterpart in experiment, another game in town pops up: to produce a unified model based on stringiness alone, but in three spatial dimensions.

I would be ready to take a long bet that this game has better chances than any one that uses 11 spatial dimensions.

33. **Tim**
May 7, 2009

Hi Peter,
thanks for your answer, I was kompletly unaware that the thing with the gravitons is common sense,
I looked at severel sources and found no reference I could follow, e.g. wikipedia or several
books on string theory. Mr. Kaku in his two books on string and M-theory e.g. does not mention
the origin of his starting point at all (I mean the axioms that any quantum theory of gravity
needs to live in Minkowskian spacetime and contain massless spin two particles aka gravitons).

Of cource since I am not affiliated with any physics department I am a little out of the loop 🙂

It is completly understandable that you do not like to repeat any extensive discussions that
obviously did take place, but one wonders if it would be possible to give a little overview over
the conclusions if there were any, or over the arguments of both sides (or a link to that), for someone who was not involved.
All I did came up with is that "background independence" for string theory seems to mean that one can choose
any spacetime one likes to start with, while the LQG idea is that a spacetime is a classical state
and a quantum state should be a wave function living on some space where each "point" is a
classical spacetime that is a valid solution of general relativity.

If this post happens to fuel any hostility on your blog please accept my apologies.

34. **christina philosina**
May 8, 2009

Hello Peter,
In fairness to Steven Weinberg, I believe you completely misinterpreted his little joke about the poker game, and more importantly, his attitude towards string theory. If one reads the New Scientist article, the correct interpretation becomes obvious. It's not, as you say, that he admits string theory is 'crooked and you are bound to lose' and that means he thinks string theory 'can't possibly, work, is obvious pseudoscience'. Rather, he feels that physicists can't win in the sense that it may well be that the fundamental values of nature cannot ever be predicted by theory because they are randomly determined in each universe of the multiverse. THAT is regarded by physicists as a 'crooked' game because for at least a century they operated on the assumption that a 'fair' universe would be one whose values had to be what they were, and it was the job of physicists to create a theory that predicted those values. It pains and sometimes infuriates them to think that that glorious undertaking may be doomed to failure. And think about it Peter—why on earth would Steven Weinberg embrace a theory he considered obvious pseudoscience?

Christina P

35. **>2**
May 9, 2009

christina philosina, are you saying that Steven Weinberg doesn't recognize a false dichotomy for what it is? I find this hard to believe.

36. **christina philosina**
May 9, 2009

>2, your comment mystifies me.
What is the 'false dichotomy'? There's a real dichotomy: 1)We live in the only universe there is, whose mathematical values for the forces and constituents of nature MAY all be derivable from first principles or 2)we live in one of many (or an infinite number) of universes, whose fundamental values are randomly affixed.
Until the strong version of the anthropic principle (implying the existence of a 'fine-tuning' God) led atheistic physicists to propose a multiverse as a rebuttal in the 1970's, no one ever considered the notion of other universes. The only issue was: could all quantitative aspects of the (one and only) universe be deduced? Physicists fervently hoped so, since only then could their theories have a sense of 'completeness'. Steven Weinberg certainly shared this craving, but now he is reluctantly accepting the notion that a number of lines of argument (string theory's 10^500 solutions is just one) suggest the unfortunate truth may very well be that we live in a multiverse. If so, any Theory of Everything will have to have deeply irritating arbitrary elements, determinable only by experiment. 'The only game in town' would then be 'crooked.'

37. **>2**
May 9, 2009

christina philosina you forgot 3), 4), 5), …

38. **christina philosina**
May 9, 2009

>2:
What third (or fourth—or fifth!!) option do you have in mind that is scientifically or philosophically relevant to this discussion? Or do you always just reflexively reject

any Either/Or as too simplistic? While I admire the almost poetic brevity of your comment, there IS such a thing as being TOO succinct.
And I notice that Peter has been more than succinct, he's been utterly silent in the face of my having pointed out his error in interpreting Steven Weinberg's poker game joke as indicating that Weinberg believes that string theory is pseudoscience. Hmmm.

39. **Pawl**
May 9, 2009

Christina,

Having read the NS article myself, it seems to me that Peter has a direct reading of it and you have rather an interpretation based on what you think Weinberg must have meant. (Your interpretation could well be right; the article might have misrepresented Weinberg's meaning by juxtaposing two quotes.)

I think bringing in religious issues can only obscure the matter — if it's hard enough to agree on objective issues, the discussion will become impossibly fragmented if you add a religious element.

It is of course possible in principle that certain things about the universe are not knowable. (Science recognized this in one precise sense when it found that the results of quantum measurements could only be predicted probabilistically.) But the aim of science is to say as much as possible, and so giving up on making predictions in an area is the very last thing a scientist should do — and it should not be done without a very strong argument for the failure of predictability *even in principle* for the situations considered.

The "mutliverse" ideas motivated by strings suffer from a basic misjudgment. They are predicated on the notion that string ideas are so convincing that it is preferable to consider a major retreat from the goals of science rather than to call strings into question.

This from a "theory" which is not at all a theory in the strict sense, and which has no phenomonological successes. (String-inspired mathematical tricks — which do appear to be useful — cannot count as much evidence for strings as a theory of nature.)

40. **Peter Woit**
May 9, 2009

christina,

The reason for Peter's silence is a bit different than you think. For the last 24 hours he has been having a life: taking advantage of the break in the weather to go on a long bike ride, going out to dinner with friends, sleeping in and having a lazy morning, and doing laundry. He just got into the office, where the main item on the agenda is to make up Monday's final exam for his class. Tonight will be taken up with going to see Star Trek with some friends, Sunday devoted to a day-long celebration of mother's day and to meeting up with Tommaso Dorigo.

So, there's a short window of opportunity here to respond to your comment. Of course I understand that part of what Weinberg was doing was making the standard argument for the anthropic multiverse ("maybe we can't calculate things we hoped to, they're just environmental"), and couching this as "the universe has put us in a crooked game". But unfortunately, that's not all he was saying. He explicitly identified "the only game in town" as string theory, and is making the very popular argument for string theory that, even though it predicts nothing, it should not be abandoned as a failure. The idea seems to be that, since it provides a framework that explains why it can predict nothing, we should believe in it since we don't know how to do better. Personally I think this is pseudo-science. I don't think Weinberg thinks of this as pseudo-science, probably because he still has some hope that string theory will somehow lead to a legitimate scientific prediction of some kind. Some people like him still think this, lots of others, including me, think this is just wishful thinking.

While writing this, I saw the comment from Pawl come in, which I agree with.

41. **christina philosina**
May 9, 2009

Peter, all I said was "Hmmm"!!!
And I do admit to having a soft spot for a roguish yet gallant Highwayman-like character defying the authorities in pursuit of, not Bess, the landlord's daughter, but, far nobler, True Science! (Remember The Highwayman, from Junior High? "Then look for me by moonlight, Watch for me by moonlight, I'll come to thee by moonlight, though Hell should bar the way!" And isn't it amazing how swiftly String Theory has become the dare-not-challenge Establishment, and how thoroughly dissenting views like yours have taken on the stigma of heresy?)

However, one should not let admirable zeal lead you to mischaracterize someone's comments so that it converts (in this case) Steven Weinberg from a reluctant supporter of string theory into someone seriously impugning it. Let's review, for the record, what you said about Weinberg in your original post:

"The arguments for string theory have evolved over the years, with the "it's the only game in town" one being made starting fairly early on. Weinberg seems to be willing to go for a new variant of this, that not only is it the only game in town, but it's probably crooked (i.e. can't possibly work, is obvious pseudo-science…), and this doesn't matter, one should continue anyway."

You now acknowledge, in your last post, that Weinberg doesn't actually think it's pseudo-science; I think I gave a far more plausible interpretation of his joke in my previous posts. As for whether string theory has been prematurely crowned 'the only game in town' is a separate issue–you have advanced powerful arguments in support of the notion that the Physics Establishment has shown reckless haste in its embrace of it, a haste that I think would have propelled Thomas Kuhn, were he still alive, into a possible revision of his belief that theories were always accepted only long AFTER the evidence in support of them justified acceptance.

Pawl,
You fault me for introducing religion into this discussion. Religion subtly lurks at the heart of the acceptance of string theory!! Or more precisely, the antithesis of religion —the fierce materialism of most physicists. It is delightfully ironic that the very thing that makes string theory scientifically unpalatable—the prospect that the 10^500 solutions are irreducible—makes it philosophically irresistible (if you're an atheist). Atheism, the intelligent and informed person realizes, is now untenable without a multiverse—the strong version of the anthropic principle demolished traditional atheism (one universe, without a God being necessary to explain our presence). Incidentally, one reason for the quick embrace of inflation theory was its mechanism for the spawning of other universes. Of course, string theory with 10^500 solutions doesn't prove there IS a multiverse, it simply is consistent with one. Dark energy, as a cosmological constant, WOULD be evidence. And of course, a multiverse would not DISPROVE the existence of God, only make him unnecessary as an explanation for the existence of intelligent life in our universe. Then one would have to decide if one wants to use Occam's Razor on God.

42. **Pawl**
May 9, 2009

Christina,

You seem to have a number of premises (about what atheism or theism is and how they bear on science) which you think the rest of us share. They are certainly far enough from my understanding that I can only guess at what you have in mind.

You seem to have in mind that having a scientific perspective must mean thinking the world is so far from being god's special creation that a multiverse is an appealing idea. I don't know any scientist who holds that view (although perhaps there are some). Virtually all scientists (and the "virtually" is there only to do multiverse proponents the courtesy of not dismissing them, for the purposes of this discussion, as scientists), including atheists, do believe in a world of natural laws and order.

You seem to want to turn this into a theistic/atheistic debate. I decline to do so.

Brane Science

May 2, 2009
Categories: This Week's Hype

There's a nice article in Nature News about the solution to the Kervaire invariant problem mentioned here. It's an excellent and accurate description of the result and its significance, except for the last paragraph, on "Brane science", where the author can't resist following the convention of appending some nonsensical hype about string theory:

> Because the new approach involves looking at topological problems of a manifold from the perspective of a space that has one more dimension, it is analogous to the use of one-dimensional strings as the basis of zero-dimensional (point-like) fundamental particles. Similarly, it has become popular for cosmologists to study the behaviour of space-time from the perspective of higher-dimensional 'branes' that interact with one another. This is why studying the Kervaire invariant problem might offer useful mathematical techniques to fundamental physics.

Update: This news is now featured on the AMS web-site, together with the misleading hype about strings and branes:

> Ball explains "although it looks at face value to be extremely abstruse, the mathematics involved in the solution might be relevant to quantum theory and string theory, not to mention brane theory, which has been invoked to explore some issues in Big Bang cosmology."

Comments

1. **newcomer to QFT**
   May 3, 2009

   For a framed 4k+2 manifold Kervaire defined a refined intersection pairing (on middle dimensional homology). However the refinement is non-trivial only if the exist certain elements in the stable homotopy groups of spheres that are represented by elements in Ext groups. Hill-Hopkins-Ravenel show these elements don't exist for 4k + 2 != 2,6,14,30,62, or 126.

   The case 4k + 2 = 6 is very relevant to string theory. See for example
   Hopkin's ICM address: math.AT/0212397

   Loosely speaking, the existence of certain quadratic refinements is essential for string/M-theory to avoid potential anomalies.

   Of course the new results are about k >> 1, so its not clear what the implications for physics will be.

   There's much to learn about tmf and index of Dirac operators on loop space and the new results are very exciting.

   Claiming that the hopeful wish:

   "studying the Kervaire invariant problem might offer useful mathematical techniques to fundamental physics."

   is "nonsensical hype" seems flippant at best.

2. **Peter Woit**
   May 3, 2009

   newcomer to QFT,

   That an old result about a topological invariant of 6d manifolds has some application to string/M-theory is not surprising, but the new Hopkins et. al result is about non-existence of similar topological invariants of manifolds with dimension 254 and higher. There simply is zero reason to believe that this has anything to do with string theory. The one possible connection to physics that Hopkins mentioned is not about string theory, but a speculative idea about a possible 4d QFT.

   It is also just absurd to describe this kind of mathematical work as being based on the idea "analogous to the use of one-dimensional strings as the basis of zero-dimensional (point-like) fundamental particles". This is not just nonsensical hype, but actively misleading.

3. **Austin**
   May 3, 2009

   Some elementary explanations by John Baez why this problem is string theory:

   http://golem.ph.utexas.edu/category/2009/04/kervaire_invariant_one_problem.html

4. **HarryD**
   May 3, 2009

   Hi,

   I just found that your book "Not Even Wrong" was recently translated into Korean. Since it is not easy to translate 'not even wrong' into Korean, the title of the book is "The truth of the superstring theory" (in Korean). Congratulations.

5. **Peter Woit**
   May 4, 2009

   Austin,

   You're misreading Baez's posting, and presumably the same misreading is what led to the Nature News article.

   Baez explains that there are important relationships between level 2 cohomology theories (elliptic cohomology, tmf) and 2d QFT. This goes back to work by Witten, where he investigated index theory on the loop space of a manifold. Index theory on the manifold itself can be understood in terms of supersymmetric quantum mechanics, going to the loop space means one's path integral is now an integral over world-sheets, so a 2d QFT (which is different than string theory, but maintaining that distinction seems to be a lost cause…).

The new work of Hopkins et. al involves a level 4 cohomology theory, which (speculatively) might have something to do with some sort of quantum field theory on 4d manifolds. Baez refers to such a theory as involving “3-branes”, just because for any n-dim QFT, one can call its n-1 dim boundary conditions “n-1 branes”.

So, what Baez was explaining was a speculative connection between this mathematics and 4d QFT. 4d QFT is not string theory.

If you want to make the argument that any QFT in any dimension d has dimension d-1 boundary conditions and people have called these “branes”, and “branes” also occur in work on string theory, so any QFT is really string theory, I suppose you can do that. But it’s extremely misleading….

6. **Jr**
   May 5, 2009

   Well, they are not exactly hyping string theory. Rather Nature is hyping the result by claiming a connection to string theory.

7. **H-I-G-G-S**
   May 5, 2009

   Typical blog post.

   You are at a meeting where they are discussing blah blah blah or there is an article about blah blah blah. Various smart and accomplished people have done the following interesting thing which is being discussed. Unfortunately these smart and accomplished people are under the delusion that their work has some connection to string theory. Whereas I, PW know that is impossible because nothing interesting or useful can possibly be connected to string theory.

   At some point I would think most of your readers would draw the obvious conclusion.

8. **Peter Woit**
   May 5, 2009

   Jr,

   The hype does go in both directions. There’s some of both here, with the author claiming that “the new approach” of Hopkins et. al. is somehow based on the idea of replacing points by strings (which is simply untrue).

   H-I-G-G-S,

   Do you know anything at all about the mathematics involved here and what its connections to 2d QFT and to string theory are? If you’d like to discuss this, please go ahead, it’s an interesting subject. If you don’t, you might think for a minute about whether using anonymous blog comments to attack people who do know something about this is a good idea or not. I don’t know who you are, but if you don’t have the excuse of being a high school student, I find your behavior on this blog both shameful and unprofessional.

LHC On Schedule

May 7, 2009
Categories: Experimental HEP News

A couple weeks ago I linked [here](#) to a draft LHC schedule that had about 3 weeks slippage from the previous schedule, which has beam commissioning starting again on September 21 (week 39). This was due to delays in getting the new quench protection system in place, which meant that powering tests could not start until later than planned. The latest news is that a way has been found to get some of the powering tests done earlier, and then get the bulk of the tests done in 11 rather than 14 weeks by adding shifts and working on sectors in parallel. The latest schedule thus is able to stick to the September 21 start date.

The working assumption remains that it will take a month or so from that date to get colliding beams and the possibility of starting to get some data. The plan now is to run through the normal winter shutdown period for about a year until the late fall of 2010, hoping to collect 100-500 $pb^{\wedge -1}$ at 10 TeV center of mass energy. This week in Berkeley there's a workshop on Physics Opportunities with Early LHC Data. At the projected luminosities there's not much hope of competing with the Tevatron on the search for the Higgs, but the LHC would be able to push up current Tevatron limits on masses of some superpartners (gluinos).

There are also recent postings about prospects for the LHC from Tommaso Dorigo, and John Conway at Cosmic Variance.

At the KITP in Santa Barbara, there had been plans to have a program on The First Year of the LHC, starting in May of next year. The delay in LHC startup has caused that program to be pushed back, with a new startup date of June 6, 2011.

The latest CERN Bulletin has news and video of the recent transport of the final replacement magnet for the damaged sector 34. All the necessary refurbished magnets are now in the tunnel, and work on the interconnections is on-going.

In other CERN news, I hear that the Austrian government has decided, for budgetary reasons, to withdraw from membership in CERN by the end of 2011. This decision still needs to be ratified by the parliament, so perhaps there is some hope of getting it over-turned.

Update: Maybe not all is well. I hear that new problems have turned up with some of the busbar connections. It turns out that in some cases the way the superconductor was soldered in some interconnections melted the solder connecting superconductor and copper. This could be a problem during a quench. Investigation of the problem is ongoing, and it will take a couple weeks before data is in, analyzed and conclusions can be drawn.

Comments

1. **Andrei**
   May 7, 2009

   Ah so the pressure beggins to gather. Well CERn'd better start running soon and show some spectacular results (as opposed to just hype). Last year the Brittish were cutting down money for this kind of research. Only recently Stephen Chu announced his estimate for the ILC to be about 25 billion. In contrast to Barrish's estimate of about 6 bil. I don't think Chu really believes the large figure. It is more of a veiled message. These big projects need an infusion of legitimacy soon or they in for a rude awakening. Perpetual delays and cute computer simulations just will not cut it anymore.

   As to the LHC schedule I wouldn't get too excited. The first year of data will be inconclusive or more measurements of what nature is not. Then at the end of 2010 after a year of "operation," (I.m sure CERN will say it was a great success just like they did last year despite the fact that the machine blew up in their face) the LHC will stop for a year to install some additional hardware. So in reality we are looking at a de facto additional delay of at least 2 years before some legitimate results will issue from CERN.

2. **Andrei**
   May 8, 2009

   Well here is an update on this. Altough the official reason was budgetary reasons, the Austrian government has actually in creased science funding and (quote):

   The government will use its contribution to CERN — roughly €17 million per year, or 2% of the laboratory's budget — to make up some of that shortfall and to begin participation in other international collaborations in physics, sociology and biotechnology. Among the projects that may benefit are the European Biobanking and Biomolecular Research Resources Infrastructure project, the European X-ray Free Electron Laser near Hamburg, Germany, and the Facility for Antiproton and Ion Research in Darmstadt, Germany.

   here uis a link to that article: http://www.nature.com/news/2009/090508/full/news.2009.459.html.

   A final decision to withdraw is expected in the fall. CERN would better make the LHC run in the fall. According to the above article they are now affraid that other nations will follow suit.

   Well what did they expect? So far, in contrast to the promise to elucidate the secrets of the universe, CERn has been sinking money in one embarrasing failure after another. But that should have been foreseen by European governments because the LHC was sold in France as a job creation tool and not a scientific experiment. I wonder how long the other goverments will tolerate a perpetually delayed project intended to keep French workers in weine and croissants.

   Sorry for not proofing my comments. I am rather tired.

Witten Away From the Energy Frontier

May 7, 2009
Categories: Uncategorized

Edward Witten has been visiting CERN this past academic year, and it seems that besides continuing to work on things related to geometric Langlands (see his recent talk at Atiyah80), he also has been returning to his roots as a phenomenologist, and taking a wide interest in a range of phenomenological questions being discussed at CERN.

Next week CERN will be hosting a workshop on New Opportunities in the Physics Landscape at CERN, to discuss experiments at CERN over the next 5-10 years that are NOT directly related to the LHC. Witten will open the workshop with a talk on *Perspectives in the Physics Landscape away from the Energy Frontier*, and his slides are already available. He comments on a variety of topics, including CMB measurements relevant to inflation, neutrino masses and mixings, proton decay, CP violation and axions, and dark matter candidates. All in all, it's a quite comprehensive survey of how possible non-LHC results might address beyond Standard Model physics questions, mostly from the point of view of the now conventional speculative framework of Supersymmetry/GUTs/String theory.

Comments

1. **Haelfix**
   May 7, 2009

   Witten did some beautiful work in phenomenology, including a bunch of obscure but still highly relevant gems like his work on neutrino physics.

2. **M**
   May 8, 2009

   I wonder what is the opinion by Witten about using a novel non-scaling FFAG or a SC-linac feeding a system of accumulator and compressor rings to limiting the duration of pulses below a few msec in a 50 Hz proton driver?

3. **Greg**
   May 9, 2009

   The most saddening aspect of Witten's slides are that he is excited about the many possible theoretical options. (See the slide before last, for example). One day we will have the final theory, and we will know that all options except one are wrong. So how can one be excited about the existence of many options? It just means that unconsciously, one has given up on distinguishing the true from the false, one has given up on finding the correct option.

   Witten was my hero in the 1990s, when in an interview he stated that he decided to dedicate his life to finding unification. Now he is excited about many options. In short, he has given up. That is incredibly sad!

   It is sad that in order to remain friends with colleagues, we all feel forced to cite all their toy models, as weird as they may be, without saying that they are wrong. Worse, we do not use these mistakes to narrow our search, but we use them to widen it. That is a disservice we do to students – and to ourselves.

   We will never find the toe if we do not "cut the crap". Anybody has the right to publish on any topic, but we need to make use of all these mistakes to proceed. We (the community of physicists) are not doing that, at present.

   Another person, who liked to cut the crap has given up doing so: Motl. We can all notice that he cuts the crap only in topics far from his own field. In string theory, he rarely does so. Thus he will not advance to the toe, even if it is inside string theory! (remember his post many years ago were he speculated the direction to go? He did not follow it up himself, nor did he ever correct the aim.) All these are examples were people prefer to stay friends than to search for the true theory.

   Peter, you cut the crap, and we all admire you for this. Let us go on – life is too short. We now need to clarify the mistakes done in the past and provide guidance, for ourselves and others, into the right direction for the search.

   Woul it be possible to open up a new speculative tag on your blog, called something like "lesson of the week" (partner of "hype of the week") in which you/we all clarify (1) which ideas have to be dropped from the search for the toe, and (2) which ideas have to be retained?

   Nobody is doing this in public in the whole world; who else but you can do it?

4. **anon**
   May 9, 2009

   Who are you? You're supposed to teach Edward Witten, 339 papers and 87,000+ cites old, what is the right path to take and what's wrong? Hilarious!!! Just that he said other options are exciting doesn't mean the options are right..

5. **Francis**
   May 9, 2009

   If I read the post, Greg is not telling Witten what to do, he is writing only about his own sadness. Greg's point and reason for sadness is that Witten has given up searching for the toe.

6. **anon**
   May 9, 2009

   oh really? as I read it, the word 'sadness' seems to enrobe his firm conviction that Witten has given up on unification and instead is promoting other people's ideas to stay in their good books, which I think is plain accusal of a great scientist.

7. **Francis**
   May 9, 2009

   No, it is much worse, Greg is saying that all physicists, including himself and "anon", are too kind to false ideas in order to remain friends, and that this is the reason that the toe has not been found.

8. **BigG**

May 9, 2009

You people should be careful about using the term TOE. First of all the name is misleading as it would not be a theory of everything. Second, even as physicists intend it, there is no certainty it is possible or even an existent. If a point was reached that was labeled TOE, there is no way of being certain that's it. A further objection is that a TOE would be something that is not subject to further investigation, implying something that exists independent of anything else. This concept is highly problamatic. Physics lost its way when it decided philosophy had nothing to offer.

The biggest problem with physics today is those attempting to push the edge of theoretical physics are still stuck in the mindset that made the standard model so successful. This kind of thinking would not have been beneficial in the early 20th century and is holding back progress today.

Its a difference between technicians and thinkers.

9. **Peter Woit**
May 9, 2009

Greg,

The whole problem with beyond the SM physics is that no one has any really compelling ideas. Witten gives a good survey of some of what is out there, but that doesn't mean that he's claiming they are convincing. Like everybody, he's hoping for some unexpected experimental result that will show the way….

10. **anon**
May 9, 2009

It would be better if you speak for yourself Mr. Greg, rather than for the whole physics community as such and Witten in particular, I think Woit's point explains it better..

11. **anon2**
May 12, 2009

I think its important to contrast these two statements…

"Who are you? You're supposed to teach Edward Witten, 339 papers and 87,000+ cites old, what is the right path to take and what's wrong? Hilarious!!!"

vs.

"Science is the believe in the ignorance of the experts"
-Feynman

12. **Paul**
May 18, 2009

But is there any physics beyond the standard model? (I'm counting neutrino masses as part of the standard model.) This is not sure at all. Some argue that no argument for the existence of physics beyond the standard model is really watertight. A likely situation is that the LHC find one Higgs and that is it, and none of Witten's experiments finds anything. We would not be smarter than we are now.

Then Greg's proposal for a "cut the crap" approach might be useful. In fact, if higher dimensions and supersymmetry are dropped because they are "crap", then there are only extremely few options left. But nobody seems to want to explore them.

13. **FNesti**
May 29, 2009

I agree that Witten's slides were quite disappointing.

Lack of new ideas or hints.. (ok, this is hard for everybody, but I was expecting something more.) All theories on equal footing – those with predictions and those with none. Superficial analyses..
And more importantly: the lack of insight, of taste, of understanding of the relations among things, of hyerarchy among problems..

It was something like a student's talk, just a list of possibilities – as if one studied phenomenology just the night before.

So the sad point to me is to realize that, after having provided outstanding contributions to Physics, one can go so far to loose the contact with the real problems. That is to me, the main lesson – be careful not to loose too much contact with physics. Then, no doubt Witten will be back on topic very soon if he wants.

14. **Peter Woit**
May 29, 2009

FNesti,

I don't think Witten's problem is having lost "contact with physics". He's very much in contact with the activities of phenomenologists (and always has been), and his talk reflects the conventional wisdom of the field. To expect some insights into phenomenology from him that are dramatically deeper than those of other experts is unreasonable.

One could perhaps make a stronger argument that he (and many other theorists) are too much in "contact with physics" now, that until something new comes out of experiment, time is better spent doing what they are best at, trying to get a better understanding the formal underpinnings of the subject. But, I agree with other commenters that offering Witten advice about how he should be choosing to spend his time is rather silly…

15. **FNesti**
May 30, 2009

Hi Peter,

well, I do was expecting something more – some concrete points:

Neutrino masses – is it really a surprise the "largness" of the neutrino mixings? (to me this is a naive and misleading observation..) should this be mentioned in a talk?

GUT – in reality there is no prediction of the GUT scale, beyond say 10^14. There are models where proton decay can be suppressed and you can lower the scale .. there are models where the additional mattter content before GUT pushes the scale up to MPL. What one can say is just that the idea is not ruled out by unobservation of proton decay, a fairly weak statement (sad for older generations, not for the new ones). Also SUSY is really a non-theory, when you look at the few complete real models you find big uncertainties from soft terms.. or any sort of fragments in the desert so no real connection with the weinberg angle.. no real connection between GUT and neutrino masses. I would have hoped to see some of this noticed.

p-decay – again – there is no prediction from real GUT models – e.g. it is not true that dim.5 operators are challenged by the SK limit.. they are too model dependent (btw dim5 does not give p->e+pi !) and thus there is no need to invoke extra dimensions or Split-SUSY or string models, where – again – there is no prediction.

DM – we all know there are many candidates, but a solid evidence is already there (DAMA – incompatible with the WIMP picture – waiting to be confirmed whether it is really DM). Similarly for other excesses like ATIC… Would have been nice to have those new evidences put in perspective.

So in any topic I look I am not satisfied.. what can I say.

Yes, probably I am also not satisfied with the “conventional wisdom”…

Whatever Works

May 7, 2009
Categories: Uncategorized

The latest Woody Allen film, *Whatever Works*, was shown recently at the Tribeca Film Festival. I missed it there, but it looks like I'll have to see it when it comes out in theaters later this year. It features the conventional Woody Allen theme of a gorgeous young woman falling in love with a misanthropic Manhattanite old enough to be her grandfather. But this time, the Woody Allen character is a string theorist. Here's part of the plot summary:

> A former Columbia Professor and self-proclaimed genius who came close to winning a Nobel Prize for Quantum Mechanics, Boris fancies himself the only one who fully comprehends the meaningless of all human aspirations, and the pitch-black chaos of the universe….
>
> Boris once had a picture-perfect life. A world-renowned physicist teaching String Theory at Columbia, he was married to Jessica (Carolyn McCormick), a brilliant and beautiful, rich woman, and lived in an opulent uptown apartment. But Boris's good fortune didn't alleviate his perpetual feelings of despair, and one night, in the midst of an argument with Jessica, he leapt out the window. To his great disappointment, he landed on a canopy and survived. Afterwards, he divorced Jessica and moved downtown.
>
> One night, Boris is about to enter his apartment when he is approached by a young runaway, Melody St. Ann Celestine (Evan Rachel Wood), who begs to be let into his apartment….

Comments

1. **Some guy with a laptop**
   May 7, 2009

   Dear Professor Woit,

   do you happen to know that Woody Allen is a huge believer in String Theory? But seriously, it is true.

2. **BigG**
   May 8, 2009

   Woody Allen is not qualified to come to a decision on string theory. Who cares what someone like him thinks about string theory. For the layperson, the only position they can reasonably take is that string theory is highly problematic and if they must should tend towards not accepting it.

3. **Russ Van Rooy**
   May 8, 2009

   Well, that is so Woody! America's best known, crotchety existentialist would live in a universe embedded in the backdrop of a 10 to the 500th power vacua embracing landscape – how else could it be? Woody is the crankiest of cranks and anything that can make his outlook even more depressing is what works.

4. **Chris Oakley**
   May 8, 2009

   Au contraire, Allen's *Slepton production from gauged orbifold flux tube brane compactifications in 198+465 dimensions in the early universe* is widely recognised as the most significant contribution to String Theory since Feynman realised his shoelaces were undone before being called in to interview at Princeton in 1937.

   In my humble one, though, the best thing that Woody Allen ever did – and even funnier – was this, purporting to be the memoirs of Hitler's barber:

   The Schmeed Memoirs

5. **Timothy P. Keller**
   May 8, 2009

   Good Morning,

   Prof. Woit is much too modest.

   Never mind what Woody thinks of
   string theory, the truly interesting
   question is : what real life personage
   is 'Boris' modeled on ? The answer
   is : Prof. Woit! himself !

   Of course, as is well known, mathematicians
   have a debonair charm, which gives them
   the edge over physicists in matters of the
   heart – More particulary, that 'mad poet'
   ambience of the typical algebraist, is just
   madly attractive to the Melodys of the world.
   (I did my dissertation on quadratic forms over
   fields … umm,hmm, …)

   So good to see popular culture finally
   coming to the realization of what we've
   know all along.

   All the best, Tim

6. **Peter Woit**

May 8, 2009

Thanks Tim, but I'm having difficulty finding any points of contact between Boris and myself:

No Nobel Prize prospects
No teaching of string theory
No ex-marriage to rich woman
No opulent apartment
No suicide attempts
No perpetual feelings of despair
No current marriage to gorgeous young woman young enough to be my granddaughter.

Wait a minute though, reading the full piece again, there is something about "irritating his still-loyal friends with his never-ending tirades about the worthlessness of absolutely everything." Maybe Woody reads this blog sometimes….

7. **Chris Oakley**
   May 8, 2009

   > irritating his still-loyal friends with his never-ending tirades about the worthlessness of absolutely everything

   Yeah … though I am prepared to substitute "entertaining" for "irritating"

8. **warp speed!**
   May 8, 2009

   hi Peter. Ignoring your idiotic rants against string theory and its lack of testability, some serious but modest string theorists silently developed for mankind a practical application of M theory:

   http://www.sciencedaily.com/releases/2009/05/090507175838.htm

9. **Peter Woit**
   May 8, 2009

   Thanks warp speed!

   You've inspired another quick blog posting…

10. **BiggerG**
    May 9, 2009

    BigG: `Woody Allen is not qualified to come to a decision on string theory. Who cares what someone like him thinks about string theory.'

    He is about as qualified as Peter Woit is. They have authored the same number of string theory papers. And Woody still has a somewhat bigger audience…

11. **Peter Woit**
    May 9, 2009

    I'm guessing BiggerG is the same person as the one responsible for the "Peter Woit: crackpot or not?" thread over at Tommaso Dorigo's blog:

    http://www.scientificblogging.com/quantum_diaries_survivor/blog/lesser_jetflying_clown_rubbia

    I encourage all people who want to discuss this endlessly fascinating topic to do so over there and help out Tommaso's traffic numbers. Attack Woody as a pedophile here, me as a crackpot there…

12. **Kea2**
    May 9, 2009

    I am shocked that anyone would question Woody Allen's knowledge of physics. Here is what he wrote in The New Yorker, July 29, 2003.
    "I am greatly relieved that the universe is finally explainable. I was beginning to think it was me. As it turns out, physics, like a grating relative has all the answers. The big bang, black holes, and the primordial soup turn up every Tuesday in the Science section of the Times, and as a result my grasp of general relativity and quantum mechanics now equals Einstein's — Einstein Moomjy, that is, the rug seller. How could I have not known that there are little things the size of "Planck's length" in the universe, which are a millionth of a billionth of a billionth of a billionth of a centimetre? …."

13. **Mitch Miller**
    May 15, 2009

    From the trailers it looks like Larry David is going to play the lead role. You can see the trailer on Hulu.

Star Trek Warp Speed?

May 8, 2009
Categories: This Week's Hype

To continue with the string theory/movie theme, a commenter just wrote in to tell about some new ideas for using M-theory to create a warp-drive. These are contained in some papers from the past year or two by string theorists Richard Obousy and Gerald Cleaver (see here, here and here). Today, as a tie-in to the release of the new Star Trek movie, Baylor University issued a press release with the title 'Star Trek' Warp Speed? Two Baylor Physicists Have a New Idea That Could Make it Happen, which states:

> String theory suggests the universe is made up of multiple dimensions. Height, width and length are three dimensions, and time is the fourth dimension. Scientists believe that there are a total of 10 dimensions, with six other dimensions that we can not yet identify. A new theory, called M-theory, takes string theory one step farther and states that the "strings" actually vibrate in an 11-dimensional space. It is this 11th dimension that the Baylor researchers believe could help propel a ship faster than the speed of light.

Interesting to know that there's a "new" theory called "M-theory". Maybe it will replace the old one that has been around for 14 years or so. In any case, while the Woody Allen film is not out, the new Star Trek is, and when I go see it tomorrow night, the fact that it is based on solid science will be reassuring.

Update: Sadly, no explanation in the Star Trek movie of how M-theory was used in the design of the warp drives. However, according to EETimes, a Star Trek warp drive is already in the works.

Comments

1. **Chris Oakley**
   May 8, 2009

   If you go to it for the science you may be disappointed [how weird that that should be the case for a Star Trek movie]. My favourite in this regard was the young Spock saying that he "estimated that he had a 4.6% [or whatever it was] probability of succeeding" in his mission. See Feynman's "What do you care what other people think?" for insightful comments on assigning probabilities to the unquantifiable/imponderable. You will also be introduced to "red matter" which looks like tomato ketchup, but is altogether more scary as it turns stars and planets into Black Holes. I can't remember whether it had the same effect on hot dogs, but to play it safe, if the movie theatre dispenses ketchup from large, glass spheres then *don't order one*.

   Nonetheless, the movie is a fine piece of drama and some of the visuals are breathtaking. Well worth the admission price!

2. **Coin**
   May 8, 2009

   Isn't the 11th dimension in M-Theory just the dilaton field?

   So they're saying they can create the effect of an Alcubierre drive by manipulating the dilaton field?

   …Does that even mean anything?

3. **BigG**
   May 8, 2009

   This is truly an embarassing time for physics. These crap popular articles read like something you'd find in a post-modern studies journal. First of all, you shouldn't speak about inflation like it is fact. Secondly, the use of terms like "tearing the fabric of space" and "shrinking space-time" are meaningless in this context. Regardless if they have a meaning among professionals, when popular articles use such terms its is simply to give people who know nothing something to do at cocktail parties. Its about promoting your program to the public than truth. There are very few true great thinkers anymore. In a time when physics needs seers it is being dominated by craftspeople.

4. **milkshake**
   May 8, 2009

   Coin: Isn't the 11th dimension in M-Theory just the dilaton field?
   Cleaver: [pause] These go to eleven.

5. **LMAO**
   May 8, 2009

   From the article

   "The Baylor physicists estimate that the amount of energy needed to influence the extra dimensions is equivalent to the entire mass of Jupiter being converted into energy.

   "That is an enormous amount of energy," Cleaver said. "We are still a very long ways off before we could create something to harness that type of energy." "

   I am now convinced that at least some string theorists shouldn't be allowed to speak in public.

6. **Janne**
   May 8, 2009

   That red matter sure is mysterious, but I guess Angels & Demons next week will straighten things out for the layman.

7. **Andrei**
   May 8, 2009

   Red matter? I guess it is a spin on "red mercury." Remember that super destructive substance the Russians had invented? Which was another red herring. I wonder why in Hollywood psychologys all evil things or villains are either red or green. The green has been explained by some comentators as resulting from a perceived association of the color green with gas swamp, which is suposedly green (I've never been to a swamp). The Romulans had green ships so did the Borg. And remember Star Trek Nemesis. That was an ovwerload of green. But what's with the red? Is it because of the Romans with their capes or the Soviets or perhaps the Nazis. Or because the evil tea sucking British troops had red uniforms back in revolutionary times? For once I'd like to see a b;ue or say orange villain or ship.

8. **Ralph**
May 9, 2009

Cool, does this mean that implementing a working warp drive is a test of string theory, and that if we can't send people to Alpha Centauri and beyond by next year, then the string people will shut-up and let the LHC work out what reality is like instead?

9. **Chris Oakley**
May 9, 2009

Some script that was cut from the final version:

NERO

You b*****d, Spock! You could have saved my planet! If you had arrived twenty minutes earlier, you could have created a black hole with your Red Matter which would have swallowed up the supernova!

SPOCK

Let me get this straight – you seriously think that a few drops of tomato ketchup could have prevented a star from exploding. Am I right or am I right?

NERO

That is correct, pointy-eared freak!

SPOCK

What are you? A Trekkie fan? Believer in String Theory? I suppose that you think Elvis is still alive, having been abducted by anal-probe-inserting aliens?

NERO

Indeed! He is our prisoner! And will be until we find out who killed JFK!

10. **Bubos**
May 9, 2009

Shame on Chris Oakley who should have the brains to know that Star Trek is backed by, and actually starred in, by Stephen Hawking. So it's factual as Hawking radiation.

(Hawking wouldn't have got any Nobel Prize if it was just a stringy type speculation nobody could check, unmeasurably submerged in the intense gamma ray background radiation spectrum of space!!)

11. **Chris Oakley**
May 10, 2009

Hi Bubos,

1. Stephen Hawking appearing in Star Trek to me signifies that he needs the money/publicity, not that he endorses the "physics".

2. Even if he did, I would not care that much. I am afraid that the clip is misleading you in claiming that he ranks with Einstein and Newton as he is not even close. Those who claim to the contrary I think you will find are publicists for his book, not physicists.

12. **Thomas Larsson**
May 11, 2009

"Hawking **wouldn't have got** any Nobel Prize" ???

Maybe it is because I am a non-native English speaker that I have problems parsing this sentence, but it seems to me that you believe that Hawking has got a Nobel.

13. **db**
May 11, 2009

@Thomas Larsson

I am a native english speaker, and can't parse it either. It looks like the output of a physics oriented dada engine to me.

14. **Larry**
May 12, 2009

Peter,

You will be happy to find that you and Lee Smolin have a new soul mate:

Oswaldo Zapata:

On Facts in Superstring Theory. A Case Study: The AdS/CFT Correspondence

http://arxiv.org/abs/0905.1439

Congratulations, the anti-string horde is growing with more and more fine warriors! I'd be interested to know and I suppose other readers as well, what you think.

Larry

15. **Austin**
May 12, 2009

Dear Larry, the historical essay you mentioned is actually – decently – pro-string theory.

There is a whole blog by the same author dedicated to these ideas. I assure you that neither Peter Woit nor Lee Smolin can be found among the 20 authors of the popular and semipopular books about string theory that the author discusses.

http://spinningthesuperweb.blogspot.com/

16. **Tim**
May 12, 2009

Dear Larry, Austin,

after skimming the essay I got the impression that the author does not
make a clear statement if he is pro or con the way the Maldacena conjecture
“evolved” from a conjecture to a “fact even mentioned in undergraduate courses”.
His point is that this process did not follow what was common sense
in Mathematics/Physics in the 20th century (mathematical theorems need proof,
physical theorems need experimental verification, to be accepted by the scientific community).
Is this impression correct? Or does the author propose that
human kind just developed a brand new way to establish scientific truth? 🙂

P.S.: I think we can forget about this Star Treck thing as public relations gone wild.

17. **Peter Woit**
May 12, 2009

Austin,

Actually Zapata quotes my book at least a couple times in the first essay. He wrote recently to tell me about his project, and I pointed out to him that one of the quotes was out of context and misleading. I started writing a blog posting about this, will finish it soon. Yes he’s “pro-string theory”, but he does seem to agree with me that hype, propaganda, and public relations are an important part of string theory. But, for him I guess, that’s a good thing…

18. **Tim**
May 12, 2009

Hello Peter,

I understand that Zapata got his Ph.D. for working on a topic in string theory, so I am not surprised that he is a supporter – but I am quite surprised that he does not seem to have a problem that “hype, propagande” etc. are important parts of string theory. How come? As I said before from his first essay his personal viewpoint did not become clear to me.

19. **PhilG**
May 15, 2009

The FQXi have launched an essay contest on “What’s Ultimately Possible in Physics?” This could take speculation and hype to a whole new level.

http://fqxi.org/community/essay

Spinning the Superweb

May 12, 2009
Categories: Uncategorized

Oswaldo Zapata is a young string theorist who recently got his Ph.D. in the subject in Rome. He recently wrote to me to tell me about some essays on the history of superstring theory that he has written, which he is starting to put up on a web-site he calls [Spinning the Superweb](). I'll be interested to follow the rest of the essays. He has also posted the first of these on the [arXiv]().

Zapata's history is largely concerned with the question of how string theory has achieved acceptance in certain circles despite its failure to satisfy the conventional criteria normally demanded of a successful scientific theory. Reading him, you might initially get the idea he is a string theory skeptic unhappy with what has happened:

> From the previous examples we have learnt some important things about the development of string theory. Firstly, as research progresses in a given topic, an explicit reference to the unsolved problem tends to disappear from the literature. For instance, we saw how the quantization of gravity is considered by string theorists to be an accomplished task that does not deserve further study, or even a mention. Secondly, while research advances, the initial problem changes in such a way that it becomes increasingly difficult to unravel the convoluted relationship connecting the final problem to the original one. This was illustrated by our second example concerning string theory and the unification of the forces. Originally the idea was to extract the standard model from superstring theory, an investigation encouraged during the second half of the eighties by the promising results obtained from the heterotic string. Then, by the mid-nineties, the goal was to determine the unique vacuum of the mother of all the theories, the M-Theory. And, more recently, the focus was on the right "environment" of the anthropic solution. Things have changed, but the fundamental query remains unsolved: how do we get the standard model from string theory? With these examples we have learnt something else: this occurs while an "outward" discourse (from the "inside" to the "outside" of the professional community) proclaims that the theory has solved such problems. Indeed, in this movement disadvantages have been transmuted into virtues…
>
> At first, a hypothesis is made, explaining openly its significance as well as its difficulties. At this stage no one is sure of the real value of the conjecture, however, it is interesting enough to drive a significant part of the physics community to devote itself to its development. Step by step "evidence" accumulates and after a while the string theory fact emerges. String theorists have created in this way their own nature: a supersymmetric world, a big bang with all the fundamental forces combined, a multi-dimensional universe, and so forth.

Zapata appears to be claiming there is such a thing as a "string theory fact", which is somehow different than the usual scientific notion of "fact", one that requires experimental confirmation.

Among the other unusual aspects of the string theory story that Zapata recognizes is one that has often struck me. This is a subject so complicated that very few people actually understand what is going on, including many of the people working on it. As a result, overhyped claims in the popular media play a big role, with few people able to evaluate them properly:

> In fact, string theory is so complex that experts are neither able to understand entirely the main developments nor to follow its rapid growth. In general, practitioners feel confident only in a specific subfield. People working on the AdS/CFT correspondence or twistor theory, for example, do not comprehend the whole area, even though they can be extremely competent when tackling the particular problems of the subfield. Because of this, paradoxically, those that have provided the evidence in support of superstrings do not fully grasp it. Many do not understand the AdS/CFT correspondence completely but they believe in it; it is a matter of fact. A fact in string theory is a shared belief that something is unquestionably true. What I will try to show here is that string theorists often base their beliefs on what they have seen proclaimed everywhere. This ubiquitous discourse includes technical seminars and articles, which I will call the in-in discourse, as well as popular speeches and books, the out-in discourse. Furthermore, I will try to convince the reader that string theorists start to internalize the rules of the game long before they become experts; by means of a discourse that embraces the whole society. I will dub this the out-out discourse when the information comes from non-experts, and the in-out discourse when it comes from professional physicists.

Zapata goes on to give a truly remarkable description of the sociology and psychology of how people get into string theory. Remember, this is coming from a young string theorist:

> The discussion above suggests that many string theorists have begun their careers with a biased view of the subject. How they conceive the theory during their formative years depends crucially on previous contact with materials intended for the general public and, later on, on the systematic training given by senior members of the community. We have seen how these two stages in the education of future string theorists coincide at one point: they present new subjects as confirmations of the most fundamental claims of the theory. The theory has succeeded in: quantizing gravity and unifying all the fundamental forces of nature. In addition, it explains the thermodynamics of black holes and has also demonstrated a precise gravity/particle physics correspondence. This is what is taught. Even though young string theorists can feel sometimes uncomfortable with the weakness of some arguments, the challenge usually exceeds their skills. Moreover, in such a competitive field there is no time to digress by asking fundamental questions. When finally the young researcher becomes a full member, with many more resources at hand to tackle fundamental issues, it turns out that they are probably working on a specific topic with its own problems. And, not surprisingly, all these investigations assume the validity of the basic claims of the theory. The once controversial claims are no more questioned; they have been internalized as matters of fact. Eventually, the young researcher becomes an accomplished theoretician; it is now their turn to protect the theory and contribute fervently to the in-out discourse. This final step consolidates further the scientific fact and, very importantly, guarantees the reproduction of well-trained newcomers. This long and tortuous process of internalizing the rules of the game is sociological, but unavoidably also psychological. As I said above, a fact in string theory is a deep and sincere belief, and nobody can dispute certain issues without at the same time denying their own self.

With belief in string theory based on this sort of psychology, it's not surprising that defending it from skeptics can't be done with the usual sort of scientific discourse, but requires propagandistic techniques:

> What I've described in this section is an alternative strategy of validation that string theorists have persistently employed in order to preserve what they consider a worthwhile field of research. The purpose of this is to protect the theory from attacks from defenders of contending models; attacks due in part to theoretical and experimental shortcomings. It is not an exaggeration to say that string theory uses propaganda, more or less as Galileo did in his times: ''He uses psychological tricks in addition to whatever intellectual reasons he has to offer. These tricks are very successful: they lead him to victory.''

Describing a New York Times article on the Maldacena conjecture, he writes:

> This article, and many others of the same sort, reinforce, willingly or not, the social belief that superstring theory is ''on the right track.'' In this case, the circle of believers is expanded thanks to the participation of non expert actors: science writers and interested readers. This sympathetic environment, which will be illustrated further in the next essays, has been vital for the development of the theory. It must be mentioned that this out-out discourse does not originate independently from professional string theorists. In general, it simply reproduces the in-out discourse of the experts. I do not mean to suggest that string theory popularizers are scientifically illiterate, I just want to highlight that the substance of what they say reflects the opinion and enthusiasm of string theory specialists. In such an abstract area, things could not be any other way. As a consequence of this discourse, a favourable disposition regarding superstrings has permeated into the public domain. The lay public's attitude functions as a support for the internal discourse. What is more, the layman's view of superstrings is sometimes internalized by experts on the theory and then works as a reconfirmation of the old belief. To put it differently: the out-out discourse is not only oriented to popular audiences but towards experts as well; the out-out discourse is also an out-in discourse. Consequently, "non-pure" conceptions penetrate and modify the theoretical development of the

field. I will call this the in-out-in process. Notice that unlike the in-out-•••-in process explained above, the in-out-in process only concerns the movement of ideas (of course, persons are also involved here, but not in the sociological sense meant before). In this way, with contributions from the in and the out, the creeping belief in the accomplishments of superstring theory is gradually confirmed…

> The effects of these kinds of comments on the theory are two-fold. On one side they create a favourable background for the theory to develop, on the other they send a clear message to string theorists that they are doing right, that nature is really as they think it is. I must confess that this hypothesis is hard to prove. However this is what the next essays try to do. Before moving on to these more detailed discussions, I would like to observe something that a string theorist would be unlike to deny: when a newspaper says that colleagues at Harvard are dancing "La Maldacena," they feel more confident about their own results. Something similar occurred when David Gross was honoured with the Nobel Prize for physics in 2004. My experience was that the general mood among string theorists was very optimistic. They felt that this award was somehow recognition of their own efforts in string theory. Evidence in support of this claim is varied: from technical seminars to public speeches, and from published articles to forwarded emails.

All in all, Zapata does an excellent job of explaing why string theory has been the subject of such a long-term relentless campaign of hype and propaganda, one that continues to this day.

In his essay, he concentrates on the story of AdS/CFT, the one place that string theory has had some real success. As part of this, he engages in some propaganda himself, quoting me out of context in a misleading way. When I wrote in my book about string theory as a "failed project", I was referring to its failure as an idea about unification, not describing AdS/CFT as a failure.

All in all, Zapata's essay is something quite remarkable: a view from the inside of what things look like to someone who is both a true believer, as well as a clear-eyed observer of how string theory has gotten to where it is today. I suspect though that his history is already starting to be out-of-date, with the same phenomena that he describes looking very different to the rest of the world. Most physicists have begun to lose patience with the hype and propaganda surrounding string theory, and want nothing to do with a supposedly scientific subject full of true believers acting on a new and non-standard concept of what is a scientific fact and what isn't.

Comments

1. **Spiny Norman**
   May 12, 2009

   "I will call this the in-out-in process. Notice that unlike the in-out-•••-in process explained above, the in-out-in process only concerns the movement of ideas (of course, persons are also involved here, but not in the sociological sense meant before)."

   You do realize, Peter, that this is a crude (but funny) joke?

2. **Peter Woit**
   May 12, 2009

   Norman,

   The thought has occurred to me that the whole thing is a rather fantastic joke of some kind. But I can't figure out what kind…

3. **Leonard Ornstein**
   May 12, 2009

   Peter:

   Oswaldo doesn't seem to accept the distinction between belief in a mathematical conjecture, which may ultimately be 'provable' as a theorem, 'merely' through consistent application of 'axiomatics', and assurance of completeness; and 'belief in' a scientific conjecture (model), which requires some degree of empirical inductive support to warrant any 'degree of belief', and can never be 'completely' verified.

4. **Sandro**
   May 12, 2009

   I think I've got to agree with Leonard Ornstein. He makes actually a good point in distinguishing the two kind of "beliefs": indeed, in my opinion, mathematical beliefs like that homological Mirror Symmetry must be there for pairs of mirror Calabi-Yau n-folds are well worth pursuing, and of course knowing what has been done by String theorists can be quite useful. This is my mathematician's view of the subject, though…

5. **Peter Woit**
   May 12, 2009

   Sandro and Leonard,

   The big problem with the Zapata essay is that he doesn't distinguish between two completely different things:

   1. The AdS/CFT conjecture, which is an essentially mathematical conjecture about a relationship between two different mathematical structures, and for which there is quite a lot of evidence, with many people working on gathering more evidence and making the conjecture more precise.

   2. String theory as a 10/11d unified theory of particle physics and gravity. For this, not only is there no positive evidence, there is now a lot of evidence that this can't work.

   Case 1. is a rather conventional story about how "belief" in a mathematical conjecture becomes stronger as it passes various tests, you understand it better and make it more precise. It is case 2. that is highly problematic, where you have lots of people "believing" in an idea about the fundamentals of physical reality. Zapata gives a good explanation of how hype, propaganda, PR, and hiding behind extreme complexity have led to this much more problematic sort of "belief". I'm still having trouble believing myself that he has a positive view of this second situation.

6. **Peter Shor**
   May 12, 2009

   I just realized: part of the problem of string theory may be that the sociology of physics departments does not let people work on purely mathematical things like AdS/CFT without some claim that they are connected to the laws of physics.

7. **Coin**

May 12, 2009

So… reading Zapata's Arxiv essay (which only seems to contain the first of Peter's blockquotes– what are the other quotes from?) something that seems to me important is that he doesn't seem to be *judging*, particularly, anything he's writing about– taken by itself the paper seems to mostly just be describing a sociological process, a process where a conjecture becomes a fact just because everyone's given up on trying to prove it.

Ornstein/Sandro/Woit above raise some objections having to do with the idea that in some contexts (say mathematics vs physics) this process or something like it might be *appropriate* more so than others, and Zapata doesn't really acknowledge this distinction? But it seems like the question of whether and when this process is appropriate is separate from the question this *particular* essay seems intended to address, which is more just whether the process is happening at all. I think this can be an interesting and valuable question by itself– is String Theory progressing with time on its central questions, or just gradually shrugging them off?

This said the main question I'd ask about Zapata's paper is whether the process he describes is unique to String Theory. It's certainly not hard to come up with examples in mathematics where a very large body of work springs up around a conjecture which is proven either much later or not ever at all. Even in physics I seem to hear a lot about incidents where questions about the mathematical validity of some quantum physics procedure or other (renormalization and "integrating over the singularity" in path integrals come to mind) just got kind of dropped over time without ever really being addressed. I have a strong suspicion if you tried to take the analysis Zapata performs on string theory, of catching unsolved problems in the act of being "disappeared", and applied this to a number of other sciences in their early stages, they would not come across very differently.

(Of course, even if the kind of behavior Zapata describes is widespread within math and/or science, this wouldn't necessarily reflect well on string theory anyway– that is, I'm not trying to suggest string theory gets an "everybody does it" pass. It seems like string theory's unique status, that of simultaneously being widely assumed to be central in science yet performing relatively poorly in terms of contact with experiment, means we might reasonably demand higher expectations of string theory than we might some other young sciences. For example it might be that, I don't know, the theory of motives is on just as shaky theoretical grounds as AdS/CFT due to an analagous failure to prove the underlying conjectures; but motives do not get the sort of central, "only game in town" treatment in mathematics that strings get in physics, and are in fact kind of obscure. Or it might be that the early historical stages of QFT brushed over some critical questions of consistency and finiteness, in a way similar to what string-theory based quantum gravity studies have done; but in QFT the reason why this was forgiven is that QFT was actually producing practical numerical results, in a way which I don't think string theory QG can.)

8. **John Baez**
May 12, 2009

Peter Shor wrote:

> I just realized: part of the problem of string theory may be that the sociology of physics departments does not let people work on purely mathematical things like AdS/CFT without some claim that they are connected to the laws of physics.

Yes. The mere fact that a mathematical structure is beautiful and interesting is typically not enough for physicists; it's supposed to be related to the real world. At first glance this sounds entirely sensible, but it has a bad side-effect: even when physicists are studying a mathematical structure with no clear relation to the real world, they feel psychological pressure to act like they're studying the real world – or even to *believe* that they are. This creates misleading rhetoric – or even self-deception.

It's not just a problem in string theory; it's also true in loop quantum gravity.

This is one reason I've quit going to quantum gravity conferences and started focusing on pure mathematics. If it's "merely mathematics", the need for certain kinds of rhetoric is eliminated.

9. **BigG**
May 13, 2009

This choice of term "real world" needs to be done away with. What does real mean? What does world mean? Is math not real? Not part of the world?

10. **Tim**
May 13, 2009

@Coin: I totally agree that Zapata does very carefully avoid any judgment, maybe in order to not offend anyone – seems to be done extremely clever, at least to me.

11. **Sandro**
May 13, 2009

"[…]even when physicists are studying a mathematical structure with no clear relation to the real world, they feel psychological pressure to act like they're studying the real world – or even to believe that they are."

This is exactly the problem.

"This is one reason I've quit going to quantum gravity conferences and started focusing on pure mathematics. If it's "merely mathematics", the need for certain kinds of rhetoric is eliminated."

And this is exactly the solution.

12. **Peter Shor**
May 13, 2009

Sandro says (quoting John Baez)

"'This is one reason I've quit going to quantum gravity conferences and started focusing on pure mathematics. If it's "merely mathematics", the need for certain kinds of rhetoric is eliminated.'"

"And this is exactly the solution."

This is, unfortunately, not the solution for many string theorists. Mathematicians have a similar, although different, problem: to claim you're really doing mathematics, and be accepted by most mathematicians, there has to be some pretense of mathematical rigor. Physicists don't require mathematical rigor; historically, the connection to the real physical world has presumably been a good substitute for this. While some string theorists would fit fine in mathematics departments (and some already are), I would guess that most could not.

For a non-string theory example, Michel Talagrand has recently proven some of the claims of the physicists using the replica method using mathematically rigorous techniques. This work is acclaimed among mathematicians, but physicists are completely unimpressed.

13. **Chris W.**
May 13, 2009

Following up on Peter Shor's latest comment, there is an obvious parallel to the above in the relationship between the work of physicists and engineers. That is, a nagging and possibly fundamental issue of understanding for a physicist might be—in fact, typically will be—of little or no interest to engineers. In some cases this applies to entire subfields.

More to the point, the kinds of shifts of attention and effort that Zapata describes can be regarded as shifts of *problem formulation*, in the hope of finding a better avenue for understanding and technical progress. I've mentioned it before in comments on this blog, but it's worth repeating an observation of Shiing-Shen Chern. In a volume published during the Einstein Centennial (1979) there is a reminiscence by Chern about Einstein, partly based on discussions Chern had with him when he was at IAS (1943-1948). Chern observed that problems generally (always?) come to a mathematician in a reasonably well-stated form, whereas a substantial part of the task of a theoretical physicist is to arrive at a good problem formulation before attempting to apply any refined technique or method of attack. This is especially true at the frontiers. (I and others would argue that metaphysical ideas often play an essential role in arriving at these problem formulations.)

Of course, the central issue and recurring theme on this blog has been whether this process of redefining the problem—in physics and science generally—should be allowed to extend so far as to undercut the very possibility of refutation by observation of the proposed solutions.

14. **Chris W.**
May 13, 2009

PS: I'm pretty sure the book I have in mind is *Some Strangeness in the Proportion: Centennial Symposium to Celebrate the Achievements of Albert Einstein*, edited by Harry Woolf (Addison-Wesley, 1981). It's listed on Amazon.

15. **Sandro**
May 13, 2009

@Peter Shor,

sorry about the misunderstanding: I wasn't referring to a common string theorist, but to "physicists (who) are studying a mathematical structure with no clear relation to the real world". In most cases these people have the necessary rigor to be called mathematicians (unless you define a mathematician to be someone that can't read physics papers), and there's just a psycological barrier, as John says. I agree with you that many sting theorists would struggle in a maths department.

16. **Peter Shor**
May 13, 2009

Hi Sandro,

Sorry to have misunderstood you. I agree that most of the quantum information theorists (for example) in physics departments are working with sufficient mathematical rigor to be accepted by mathematicians.

On the other hand, the replica method in statistical mechanics is completely non-rigorous, and it has led to some amazing mathematical results which I don't think could have been found if the theorems hadn't been discovered first by the replica method, and then proved rigorously by mathematicians. Some of the physicists using it are studying statistical mechanics systems which have nothing to do with actual physics, but which arise in computer science, and I don't think they've suffered any adverse consequences. Of course, the replica method is also very useful for systems which arise in the real physical world, so there's no need to justify the whole field.

17. **Sandro**
May 14, 2009

Hi Peter Shor,

I completely agree with you. The situation I've in mind is that of a physicist who realizes at certain point that he's actually a working mathematician, with prevalent interests being on the maths, and decides to go for pure maths. Of course, his background in physics will allow him to realize that some results in physics, like those implied by the replica model in statistical mechanics you mention, can have an impact also on mathematics, or at least constitute results which are worth investigating from a mathematical point of view. In an ideal world, such a person should not have any problem fitting in a good mathematics department, but I'm not sure if this is always the case…

18. **davetweed**
May 14, 2009

I think the discussion between Sandro and Peter Shor slightly misses the point. Isn't the problem not that people who want to switch from physics to mathematics can't, but that it's very difficult for a physicist to say "I think this mathematical structure may be useful in modeling some physics, but I can't demonstrate this yet. I want to keep studying this IN THE HOPE IT WILL LEAD TO PHYSICS rather than purely for its own sake (ie, mathematically), but it's not successful physics yet". It's a version of the problem in many disciplines that there's arguably a bit too much short-term-ism you can't really get the time to "build up some conceptual tools for discipline X (that aren't yet convincing)" within the X department itself.

19. **H-I-G-G-S**
May 14, 2009

This supposed history of AdS/CFT omits one of the three foundational papers on the subject (hint: the paper appeared about a week before the Witten paper he discusses at length). He also seems ignorant of many of the ideas and results that led up to Maldecena's conjecture. A clear-eyed observer? Looks to me more like one eye only partially open.

20. **Joao Leao**
May 14, 2009

Peter,Leonard,Sandro, etc..

I am afraid you are splitting hairs you don't have! A conjecture, in either math or physics, may be more or less *plausible* as it is supported by more or less plausible arguments. But it is not *a fact* until it meets the standard of a mathematical proof or a modicum of empirical data in its favor. What Oswaldo points out is that this is no longer the case as far as the Maldacena correspondence is concerned and even your reaction to his observation supports him! Since BMN asserted it as such the AdS/CFT correspondence is an *undisputed fact* and no one holds any doubts about it, including yourselves! This in spite of the fact that there is no mathematical proof of it or any real world experimental results to support it. No one in his right mind would even spend time trying to find a proof or, more crucially, the likely limits of its applicability. Funny that BMN are still kind of cautious about it obtaining in the non-supersymmetric gauge theory case but who doubts that today after all the great heavy-ion collision "duality predictions"? 3,000 papers could not be wrong, could they?

It seems to me that OZM is hardly making a joke but instead an insightful and judicious analysis about something he has directly witnessed: the production of "string theoretical facts" by a mix of social pressure, dogmatism, popular hype, PR, and tabloid level journalism. I think what he is saying deserves better attention than you seem willing to give it.

21. **David B.**
May 14, 2009

Dear Joao:

Few of the experts believe the correspondence is a fact in the mathematical sense of having a proof. If you want a real explanation of why a great part of the field has moved on, read the post I made on my blog. Calling something a fact has more than one meaning.

There are also plenty of people trying to find a proof of it, all of them rather respectable physicists.

22. **Joao Leao**
May 15, 2009

Dear David,

Thank you for your kind response and for pointing me to your blog entry. I read the very interesting exchanges and marveled at your clever "bayesian belief argument". Unfortunately I have the same qualms with it that other people well expressed on your blog. But I do not think that you have to believe a conjecture to be true to do relevant work on it. Think of the Artin and Langlands conjectures or, more gloriously, of the Riemann Hypothesis. And, mind you, I fully recognize that there is considerable heuristic support for some form of a gauge/gravity duality. I only object to this compulsion to state as established fact something that you know it is not quite yet so! In this I have to concur with Oswaldo and point to this as a form of bad faith that has regrettably become the norm in and around the string community.

I am glad to know that there are people still hunting for the proof, though. If it is not asking too much maybe you can point us out one or two, no? Thanks in advance.

23. **David B.**
May 15, 2009

Hi Joao:

For recent work, there is a huge community that is using the hypothesis of integrability to try to bootstrap the AdS/CFT correspondence for the maximally supersymmetric case. Some of the main proponents and characters are Beisert, Dorey, Kazakov, Minahan, Staudacher, Tseytlin, Zarembo (but there are many more). The discussion is rather technical at this point, but the aim has always been to prove in a rigorous way various key aspects of the AdS/CFT correspondence.

For other setups, Gopakumar et al. have been studying how to rewrite Feynman diagrams in four dimensions so that the AdS geometry becomes more manifest.

Maldacena and collaborators have found a huge number of the pieces of the AdS/CFT dictionary.

Berkovits and Vafa have a different starting point from string actions.

I am also aware of various puzzles that have been raised by Giddings regarding locality on sub-AdS scales, and Polchinski has been studying various problems related to understanding black holes and the problem of information loss (even if at the level of toy models). One of the key missing links that people really want to get their hands on is deducing the flat space S-matrix of string theory from SYM (recovering the Veneziano amplitude of flat space).

My own work in the last few years has been on starting from field theory and trying to deduce everything else.

Don't be deceived by outward appearances: people in the field are very aware that this is a conjecture. People take it to be true in the same spirit as the Riemann hypothesis, and as such there are a lot of applications that spring forward from the equality of two apparently different formalisms.

A lot of the work assumes it is correct to make deductions about situations where there are no other computations one can do. Because in some situations one really does not know what quantum gravity is, many papers assume that the definition of quantum gravity in AdS spaces is exactly via a QFT in fewer dimensions. This would sound as a tautology, but there is still the burden of showing that the semiclassical intuitions about quantum gravity are indeed correct in the appropriate limits.

No matter how one looks at it, if one really wants something close to a proof (real understanding of what's going on), one has to solve problems at strong coupling in one way or another. This is just extremely hard in general, but the community of people looking into this issues is huge. Although sometimes it is hard to tell what is going on from the way that the papers are worded if you are not working on the field itself.

24. **Joao Leao**
May 16, 2009

Hi David,

Thanks so much for the references. You provide a very detailed guidebook. I will withhold judgement until I can read through some of the work you point out. I am aware this is hard work and that it can no longer be considered as part of sting theory apologetics since it aims to set a general context for strong coupling regimes in general. Still I maintain that that is precisely why one needs to be extra careful in separate facts from fictions of convenience.

Thanks again for indulging me,
-Joao

25. **Amir**
May 22, 2009

Hi Peter
I was wondering where you got the quotes that you've put on your blog here. I'm going through the arXiv paper and can't find any reference to for example this sentence:

"Even though young string theorists can feel sometimes uncomfortable with the weakness of some arguments, the challenge usually exceeds their skills. Moreover, in such a competitive field there is no time to digress by asking fundamental questions."

The above quote is also nowhere to be found on the author's blog.

Best, Amir

26. **Peter Woit**
May 22, 2009

Amir,

The quoted material is in the fourth paragraph from the bottom of this page of the author's blog

http://spinningthesuperweb.blogspot.com/2008/05/1-on-facts-in-superstring-theory-iii.html

New York Events

May 12, 2009
Categories: Uncategorized

I'm afraid that most of you have already missed one event here in New York involving someone who blogs about high energy physics. This was Tommaso Dorigo's visit this Sunday to New York for a few hours. Luckily for you, he blogs about it, with pictures, here. I'm quite pleased to have finally gotten a chance to meet him in person. My mother feels the same way.

There is something else though here in New York, next Monday, that you still haven't missed. I'll be talking and answering questions at an event organized by the Center for Inquiry, which will take place at the Brooklyn Society for Ethical Culture in Park Slope. More information about the event is available here.

Comments

   Not that I know of…

Austria May Leave CERN

May 12, 2009
Categories: Experimental HEP News

I mentioned this here when I first heard about it, but by now more information is available. Last Thursday the Austrian government announced their intention to withdraw from membership in CERN, effective late 2010. This decision still needs to be approved by the parliament. An official statement from CERN is available here, news stories here and here, blog postings many places including here.

The cost to Austria of CERN participation is not extremely large (less than 20 million Euro/year, roughly similar to the cost of running the math department here at Columbia), and this decision came as a surprise to the physicists in Austria who will be most affected by it. Unfortunately, joint efforts like CERN that produce fundamental scientific knowledge with no direct applicability suffer from an inherent structural problem. After leaving CERN, Austria will still benefit from knowledge produced there, even if they are no longer paying for membership. In times of budgetary problems, a government could rationally decide to cut-back on its contribution to organizations that it believes will manage to go on without its help. The problem here is not so much the loss of Austria's contribution, which is a budgetary problem CERN can find some way to deal with, but the danger that other members of the European community may decide to follow suit. If a lot of other European governments make the same calculation as Austria, CERN could not survive.

A letter signed by representatives from all the particle physics groups in the UK is going to the Austrian government, asking for reconsideration of this decision, and presumably similar efforts will come from the rest of the CERN member states. The Austrian Institute for High Energy Physics has set up a web-site dealing with the issue here, and an on-line petition here.

If the decision is not overturned, CERN will be in a very uncomfortable position with respect to collaboration with Austrian physicists. While cutting off contacts goes against all traditions of the field, continuing them would encourage other states to follow Austria's example.

Update: It looks like the decision has been overturned, and Austria will stay in CERN. There's a news story in German here.

Comments

1. **karl**
   May 12, 2009

   Hi Peter, are you sure about the 20 Mios for the Math Department?
   b.t.w. the actual CERN Membership is somewhat less for Austria, rather around 16 Mios. it adds up to 20 if they also close the Institute for High Energy Physics HEPHY. But I wonder if you should be sympathetic to the plan: just as you want to shoot down string theory there are scientists who want to shoot down experimental high energy physics. I guess in the US you do have experience with people like that.

2. **Peter Woit**
   May 12, 2009

   karl,

   That was an order of magnitude estimate. I checked into this a bit, and if you add all costs up, maybe 10 million dollars would be closer. So, I edited the post a bit to reflect this.

   I understand that HEP has always had a problem that it's an expensive business, and other scientists sometimes believe that if the budget for HEP were to be cut, there would be more for them.

3. **J.F. Moore**
   May 12, 2009

   The Tragedy of the (unreguated) Commons manifested as usual.

   Peter, regarding HEP we can only hope that the likely budget increases to all science in the next few years will remove that kind of pressure. Most sensible scientists know already that total science funding is not a conserved quantity, and further that coupling within and between departments is weak at best (e.g. zeroing out ILC would not lead to a commensurate increase in cancer research).

4. **DB**
   May 13, 2009

   It's ironic. Just six months ago, Fermilab and the Tevatron was being written off, and the consensus was that it would be converted into a user facility in 2010. Since then we've seen substantial new funding from the new administration which seems to indicate a genuine HEP future for Fermilab beyond 2010, the serious problems at CERN and their subsequent mishandling by the PR department, the latest CDF/D0 limits on where the Higgs is likely to be found (if indeed it exists) which place it in energy ranges not so favourable for the LHC.

   Now come the Austrians and a new set of (as yet unconfirmed) rumours indicating that there are additional problems with some magnets and that the new CERN schedule may have to be further delayed.

   While I don't welcome any of these difficulties for CERN, one side-effect is a revitalisation the sense of competition and rivalry between US and European groups which has always been an important and healthy feature of HEP research.

   There is now a possibility, and it is by no means as remote as once thought, that the Tevatron will discover the Higgs before the LHC.

5. **Andrei**
   May 13, 2009

   I agree with DB here. The best science happens when there is healthy competition. I.e. pressure to perform. I realize most of the scientists there who are not really in it for the science but more for the cushy jobs are absolutely apoplectic about the new pressures. But in my view the pressure on CERN from a revitalized Tevatron and the threat of withdrawal are welcome and overdue. The only reason CERN got away with so many program failures was their perceived monopoly on physics. This is manifested everywhere where physicists take this high horse attitude: support the LHC or you do not understand this and that and the other. This pressure is a blowback that tells the high horse people either you are in the game and produce physics or let somebody else do it. LET THERE BE PRESSURE. PLANCK SCALE PRESSURE OF

POSSIBLE.

6. **jpd**
   May 13, 2009

   yes, einstein made his great breakthrough competeing with all those other patent agents

7. **karl**
   May 13, 2009

   Dear Andrei,
   I have spent several years at CERN, believe me, everybody there would
   be happy with feeling the scientific pressure of rival program to the LHC in the US! to blame the lack of this pressure and not to mention the continuing budget cuts CERN had to face over the last decade for some of the technological problems is an original ansatz.

8. **Peter Woit**
   May 13, 2009

   Andrei and respondents,

   Enough. I've deleted the last few comments here since they transmit no information, just anonymous hostility and abuse. Please stick to the topic at hand.

9. **Cormac O Raifeartaigh**
   May 13, 2009

   Hi Peter, re
   "After leaving CERN, Austria will still benefit from knowledge produced there, even if they are no longer paying for membership."

   This argument against joining CERN has been employed by government mandarins in Ireland for decades now. The result has been twofold: the decimation of research in experimental particle physics (an area that Ireland had a proud tradition in, from Walton to O Ceallaigh etc) and a feeling among european scientific partners that we are not pulling our weight…

10. **art**
    May 13, 2009

    re:jpd

    "yes, einstein made his great breakthrough competeing with all those other patent agents"

    it is relevant to point out that Einstein was in race to the finish with Hilbert to find field equations for general relativity.

11. **Pedro**
    May 13, 2009

    «it is relevant to point out that Einstein was in race to the finish with Hilbert to find field equations for general relativity.»

    And lost.

12. **neo**
    May 13, 2009

    This is not tragedy of the commons (the over use of a depletable resource) but the free rider problem (refusal to pay for a public good that benefits all). Sorry to be picky.

13. **Marion Delgado**
    May 14, 2009

    I was going to say what neo said.

    I can add one thing – free riders are a subset of the prisoner's dilemma.

    And prisoner's dilemmas are solved by either an outside coordinator or by negotiation over a series of transactions.

    The 2nd case is what Peter Woit is discussing.

14. **srp**
    May 14, 2009

    If it discovers the Higgs, CERN should claim a process patent on using the particle to create mass and then force Austria to pay up big if it still wants to have inertia.

15. **http://sos.teilchen.at/**
    May 15, 2009

    thx for putting up the link for the petition!

    I'm a physics student at the university of vienna and I have to say it's all just politics.
    They decided to leave CERN without asking anyone who would even know what a taylor series is…

16. **wolfgang**
    May 18, 2009

    It was just announced that Austria will *not* leave CERN and remain a member.
    Science minister Hahn could not convince the (larger) part of the coalition government, including the chancellor, of his plan.

17. **Peter Woit**
    May 18, 2009

Thanks Wolfgang,

Good news. I’ll add an update to the posting about this.

Feynman Diagrams and Beyond

May 16, 2009
Categories: Uncategorized

The Spring 2009 IAS newsletter is out, available online here. It includes the news that the IAS is stealing yet another physics faculty member from Harvard, with Matias Zaldarriaga moving there in the fall.

The cover story of the newsletter is called *Feynman Diagrams and Beyond*, and it starts with some history, emphasizing the role of the IAS's Freeman Dyson. It goes on to describe recent work on the structure of gauge theory scattering amplitudes going on at the IAS, emphasizing recent work by IAS professor Arkani-Hamed and collaborators that uses twistor space techniques, as well as Maldacena's work using AdS/CFT to relate such calculations to string theory. Arkani-Hamed (see related posting here) says he's trying to find a direct formulation of the theory (not just the scattering amplitudes) in twistor space:

> We have a lot of clues now, and I think there is a path towards a complete theory that will rewrite physics in a language that won't have space-time in it but will explain these patterns.

and explains the relation to AdS/CFT as:

> The AdS/CFT correspondence already tells us how to formulate physics in this way for negatively curved space-times; we are trying to figure out if there is some analog of that picture for describing scattering amplitudes in flat space. Since a sufficiently small portion of any space-time is flat, figuring out how to talk about the physics of flat space holographically will likely represent a real step forward in theoretical physics.

One IAS member who is also working in this area is Emil Bjerrum-Bohr, a great-grandson of Niels Bohr, and the newsletter has an article about him and the various members of the Bohr family who have been at the IAS at one point or another.

For one more piece of news related to Feynman diagrams, Zvi Bern et al. have a new paper out where they explicitly construct the four-loop four-particle amplitude, for N=8 supergravity, and show that it is ultraviolet finite in both 4 and 5d. This provides yet one more piece of evidence for the ultraviolet finiteness of N=8 supergravity. Remember all those claims made for string theory that it is the only way to tame the short-distance fluctuations of a quantum theory of gravity?

Update: One of the authors of the four-loop paper wrote to me with some comments about it, which he gave me permission to post here:

> I just wanted to point out what I see as two of the interesting things with this calculation:
>
> 1) Honest four-loop QFT calculations in (massless) gauge and gravity theories are now possible, if not exactly trivial. This isn't just "big fancy computers." Sure, computers help with the book-keeping of the calculation, but no computer in the world could have accomplished this by naively marching through Feynman diagrams (just look at the size of the expression of 3-graviton Feynman rule in your favorite gauge, and do vertex counting on the number of distinct graph topologies). Rather, this is due to advances in understanding how to manipulate lower-loop and tree-level scattering amplitudes to get (complete) higher-loop scattering amplitudes.
>
> To understand how powerful this is, consider the following: the construction of the four-loop four-point N=4 super-Yang-Mills amplitude required (as input) nothing more complicated than the Parke-Taylor expressions for MHV three-, four-, and five-gluon scattering amplitudes in four dimensions — not even requiring the (very nice) recursion relations for higher point trees mentioned in the IAS piece above. (Verification, of course, required more 🙂). If you've seen the Parke-Taylor expressions you'll know how simple they are! The construction and verification of the four-loop N=8 supergravity amplitude requires only knowing the four-loop four-point N=4 super-Yang-Mills amplitude.
>
> Even had we not gotten the nice result regarding the tame UV behavior, getting to the point where these types of calculations are doable is I think important in its own right, and possibly even more important in the long-run. I should probably point out that these types of approaches can and are being generalized to more physical theories, like the exciting high-multiplicity one-loop QCD work going on.
>
> 2) Maybe there's a perturbatively finite (point-like) QFT of gravity in 4D. This is exciting as it suggests that QFT could be a more powerful framework for describing the universe than people have been giving it credit for recently. We do believe that, if it is perturbatively finite, it will be so due to some previously unrecognized symmetry or dynamical mechanism that once understood should greatly improve our understanding of gravity. There does seem to be some connection with the very good scaling behavior of tree-level pure-graviton amplitudes in theories related to Einstein-Hilbert gravity.
>
> That being said, we really don't have anything to say about its non-perturbative behavior. Really. Nothing at all. It absolutely could require non-perturbative completeness from string theory. It could already be non-perturbatively complete in a way that's best described by a string theory in certain regimes (emergent string theory if you like). Maybe it only works with higher-dimensional invisi-pink elephants. I really don't know; it's not what we're after right now. I certainly encourage people to consider working on non-perturbative N=8 questions if they're curious!
>
> Not to be overly contrarian, but I wouldn't characterize any of this as a blow against string theory, and I don't think most string theorists see it as such. String theorists have, on the whole, been very supportive of this line of research (even if it might mean a small technical modification of certain sentences in the introduction of certain texts 🙂). Besides one of our collaborators (Radu) also being a practicing string-theorist, we've met with a lot of support from all sorts of people who appreciate calculation, and are honestly curious about the results. Besides, there have been very strong string-theorists actively working on understanding this from the string-side. In terms of community support, i.e. not just good individuals here and there, Zvi's been invited to talk at Strings '09, Lance talked at '08, and I think Zvi talked at '07 if I remember correctly.
>
> I, of course, can't help but flinch a little when people glibly say string theory is the only way to talk about gravity (which is manifestly wrong, e.g. the CFT side of the AdS/CFT *duality*). Most thoughtful string-theorists I've met who say something similar, however, are using it as a shorthand for a much more long-winded statement which is accurate. Namely they're compressing a statement regarding the level of understanding we've gained about gravity and gauge theories and non-perturbative solutions through string-theoretic analysis, which we haven't from anywhere else. As we can see by my comment here, there are perils to giving in to long-windiness, so I tend to refrain from giving them too hard a time about it. There is trouble of course when similar statements are mindlessly parroted by the thoughtless, but the thoughtless tend to generate grief generically in any case.

Comments

1. **bla**

May 20, 2009

no comments? this N=8 SUSY being finite idea looks interesting, I’d appreciate more info on this. Is it really a blow to string theory?

2. **Peter Woit**
   May 20, 2009

   bla,

   Evidence for the finiteness of N=8 supergravity has been around for a few years now, I first wrote about it here:

   http://www.math.columbia.edu/~woit/wordpress/?p=268

   One reaction to this possibility from string theorists is to argue that N=8 supergravity has problems non-perturbatively. Another is to basically just ignore all evidence that there are QFTs with sensible perturbative expansions and keep on repeating the argument that “string theory is the only known way” to get a finite theory of quantum gravity.

Why Colliders Have Two Detectors

May 20, 2009
Categories: Experimental HEP News

Last year the D0 collaboration at the Tevatron published a claim of first observation of an Ω_b particle (a baryon containing one bottom and two strange quarks), with a significance of 5.4 sigma and a mass of 6165 +/- 16.4 MeV. This mass was somewhat higher than expected from lattice gauge theory calculations.

Yesterday the CDF collaboration published a claim of observation of the same particle, with a significance of 5.5 sigma and a mass of 6054.4 +/- 6.9 MeV.

So, both agree that the particle is there at better than 5 sigma significance, but D0 says (at better than 6 sigma) that CDF has the mass wrong, and CDF says (at lots and lots of sigma..) that D0 has the mass wrong. They can't both be right…

For a detailed discussion, see here, here and here.

Comments

1. **ObsessiveMathsFreak**
   May 20, 2009

   5.4 sigma is pretty accurate (~0.999999 probability of data being within this many standard deviations of the mean if my statistics is still correct).

   But how many of these experiments do they have to run in order to find a particle again?

2. **Dmitry**
   May 20, 2009

   Hi,

   I am from CDF, so I am biased.
   But: D0 result cannot be right for two reasons:
   1) they observe relative production rate of Omega_b/Xi_b to be almost 1 (0.8). Normally you expect a penalty of about 1/10 in production rate for additional s-quark. A picture which quite consistent across many experiments for different species (Xi_b/Lambda_b), (Xi_c/Lambda_c), (Omega_c/Xi_c).
   2) The mass they measure for Omega_b is way off of Xi_b (expect difference to be ~0.2GeV) which is again is observed in other systems (B_s vs B, Xi_b vs Lambda_b, Omega_c vs Xi_c, Xi_c vs Lambda_c)

   There is third, reason – theoretically these states are studied very well and there is no really a wriggle room for the Omega_b mass. It is pretty firm 6.05 +/- 0.01 GeV. If observed mass is significantly different it means tons to Heavy flavor physics. This means that HQET does not work for baryons – a statement which is a very bold statement since HQET has been a very precise tool in describing property of heavy flavors so far!

   (1) and (2) make D0 observation a very extraordinary claim and therefore require extraordinary scrutiny.

   CDF has just provided this scrutiny by performing a simple cut based analysis on a sampe which is almost 4 times bigger than one used by D0. Nothing in the claimed region and a nice peak in the anticipated region with good precision matching theory expectations.

3. **Dmitry**
   May 20, 2009

   Also: people should not get fooled too much by > 5*sigma claims. There have been way too many cases so far of > 5sigma claims that dissolved or failed to be reproduced. Independent confirmation is the only way to really establish am effect.

4. **zanzibar**
   May 20, 2009

   Dmitry says:

   "(1) and (2) make D0 observation a very extraordinary claim and therefore require extraordinary scrutiny. "

   What is the effect of *not* subjecting all measurements to the same "extraordinary scrutiny". A bias towards orthodoxy?

5. **a quantum diaries surivivor**
   May 20, 2009

   Hi all,

   first of all many thanks to Peter, who is always very generous with links to my site. At least I can say I bought him a beer already… I hope I will have a chance to buy him a dinner another time, although he'll probably try to fight for the check.

   Second, Dimitry is right, but there are more reasons, experimental ones, to say that the DZERO result is unfortunately wrong this time.

   1) First of all, the DZERO significance is computed by taking the probability of the -2 log (L_s+b/L_b) variation between the likelihood of a fit with signal and background to a likelihood with background only. Their signal has variable amplitude AND mass in the fit, so the s+b fit has TWO degrees of freedom more than the background-only one, but they compute the significance as if the delta log L distributed as a chisquared with ONE degree of freedom. Their true significance is 5.05 sigma, not 5.4 as mentioned in the paper.

   2) second, the systematic part of the mass uncertainty in the CDF mass measurement is below one MeV, the one of the DZERO mass measurement is more than tenfold. This means that if one of the two experiments got the mass wrong, it must be DZERO, since the statistical uncertainty is well-measured in both cases, and the two measurements are totally inconsistent. To be clear, if you had to inflate the systematics of one of the two experiments with a k-factor as the PDG does when they get their averages, you would have to inflate DZERO's with a K=5, or CDF's with a K=60. Your pick.

3) third, CDF analyzed three times more data. If the rate measured by DZERO were right, CDF would have seen more than thirty events of signal in its dataset, in a sample which counts 35 (where CDF measures 12 of signal). This is utterly unlikely. If, instead, the CDF rate is right, then DZERO would have seen only five or six events in their data due to Omega_b production. They saw more, and that is not a too unlikely fluctuation.

4) then theory agrees with CDF, disagrees wildly with DZERO both in rate and in mass. This of course can only be taken in consideration after all the rest.

Best,
T.

6. **Dmitry**
May 20, 2009

Hi Tomasso,

I am not in argument with you, just my observations:

1) 5.05*sigma vs 5.4*sigma is really a nitpicking.

2) you assume that both experiments see the same particle and ask yourself who could be wrong on its mass CDF or D0. But given > 6.5 sigma discrepancy between CDF and D0 we can be sure they see *different* particles. So the question on who got Omega_b mass wrong is kind of irrelevant.

3) Rate is the killer argument. that put a big question over the D0 measurement. Huge rate and extraordinarily high mass put a big question on their result.

CDF of course looked for Omega_b all along even back in fall of 2007 (with 2.2 fb) . There was empty space in D0 mass range and something promising at 6.05 which was decided to be left alone until we had more data and therefore significant signal.

The real interpretation of CDF result:
– discovery of Omega_b
– ruling out of structure @ 6.110 GeV previously reported by D0

Given discrepancy with expected mass D0 must have called their work not a "First Direct Discovery for Omega_b" but "Evidence for a new particle in Omega, J/psi mass spectrum".

They justified that what they see is Omega_b by taking a broad sample of theoretical works going back 20 years. Where you may indeed find someone who thought that its mass could be 6.120. But since then the predictions have narrowed down significantly to 6.05 +/- 0.01 (based on input from measured states like Lambda_b, Sigma_b, Xi_b). Having assumed that this is expected particle they automatically overestimated the significance of the signal.

7. **Dmitry**
May 20, 2009

– ruling out of structure @ 6.165 GeV previously reported by D0

I put wrong mass there….

8. **Dmitry**
May 20, 2009

and last post: The cool thing about CDF analysis is that the Omega hyperon (for Omega_b search) was actually tracked in silicon allowing for precise Omega_b vertex determinations and cutting down on combinatorial background. This is relatively sophisticated technique that provides high purity sample of Omega combined with pretty simple cut based analysis later on gave CDF enormous confidence in this result.

9. **a quantum diaries survivor**
May 23, 2009

dmitry, 5.05 differs from 5.4 by a factor seven in probbility! nit-picking? maybe, but enough to fire the PRL reviewers, if you ask me!
cheers,
T.

10. **Dmitry**
May 23, 2009

It is nitpicking cuz it does not do anything to prove that the result is wrong. Maximum and errata could be issues – "oops, this is 5.05 not 5.4 sorry, but still > 5., so we are cool".

My point is that D0 Results is Not Even Wrong (what a proper board we are discussing this stuff!), so poking small holes in it is waste of time.

The production rate and mass value measured by D0 are so outrageous, as to should they be true we should be throwing Standard Model away!!! This is what is implied by D0! This is like all of a sudden someone tells you that 2+2 is not 4 anymore but 5 (not even 4.000000001), this is how badly it is violated. I am surprised than none pointed this out. As soon as I learned that they got almost the same strength signal as Xi_b in the same size sample I told our B-group conveners – be cool, this is rubbish and stopped paying attention.

One cannot call Omega_b something that does not look like Omega_b.
As soon as you remove that condition, and estimate probability of getting 17 events above background in any random place in wide mass range you will go below 5 sigma immediately.

In this view, I recommend you to peruse D0 Xi_b observation, which I still don't quite believe (so shell-shocked I was when I learned that we got scooped in 2007 – myself and Pat were authors of CDF analysis) .
Note, their Xi_b/Lambda_b production rate is 2 times larger than ours (granted with errors big enough as not to cause a stir). Fluctuation?
Does D0 thrive by fluctuations? B_s mixing infamous "first ever double sided limit"? First singe top 3 sigma evidence? Xi_b was lucky fluctuation (at the "right mass") and Omega_b was unlucky one. Payback time 🙂

11. **a quantum diaries surivivor**
May 25, 2009

Hi Dmitri,

I take it that you did not read my last post on the matter, which shows conclusively what you are arguing, from a statistical standpoint.

I however insist: the error in the D0 PRL had to be spotted by PRL reviewers. They get poor grades for that.

Cheers,
T.

12. **Dmitry**
May 25, 2009

Tomasso,

Lets be simple. D0 has signal S = 17.8 on top of background B=1.75*6. =10.5 (looking by eye at their plot).

converting probability of no signal to give signal into Gaussian significance is roughly the same as calculating:

significance = S / sqrt(B) = 17.8/sqrt(10.5) = 5.5 sigma

So I, personally, do not really doubt their figure for significance. Or rather I do not put *too much emphasis* on it. You probably know statistics better. IMO ratio of likelihoods is not a probability to get signal from background by background fluctuation even if you recast this ratio to look like chi2 difference.

But *I do not want to argue this*. Read my post. You're right, they should have put 5.05 sigma in paper. Whatever.

I shoot in different direction – mass is off from theory by at least 4.4 sigma (even inflating theory error by at least 1.5). So according to this the probability that what D0 was seeing Omega_B is
Erf(4.4/sqrt(2))=1.1e-5. This is low. Given that, and very high relative production cross-section (w.r.t to Xib) I would (If I was on D0 editorial board) have required more data to be analyzed, just to be sure. A valid demand, given that by 2008 D0 has twice more data compared to the sample they used to publish their Omega_b observation. May be they would have found it in the same place where CDF found it, then!

Cheers,
Dmitry

Various and Sundry

HEPAP is meeting in Washington today, talks starting to become available here. Things are very different now than in past years, with huge budget increases for all areas of HEP at the NSF and DOE.

FQXI has awarded quite a few mini-grants, the list is here. They also have a new essay contest, on the topic What is possible and impossible in physics?

Some worthwhile expository mathematics pieces:

Motives—Grothendieck's Dream
The Theory of Witt Vectors

At least one mathematician is a viscount and has a coat of arms.

Witten has a new paper on the arxiv entitled Geometric Langlands From Six Dimensions, an expository account of a rather special 6d superconformal theory and how its existence implies SL(2,Z) symmetry of N=4 SYM, and thus duality in geometric Langlands theory. He remarks that there isn't a widely used name for this theory, calling it the "six-dimensional (0,2) model of type G".

This week there's a workshop on Topological Field Theories going on at Northwestern, with David Ben-Zvi lecturing on *Topological Field Theory, Loop Spaces and Representation Theory*. I hope he'll soon follow his standard practice of putting notes up on his web-site.

Tomorrow I'll head up to Cambridge for the weekend, to visit my brother and his family and to attend the Perspectives in Mathematics and Physics conference being held in honor of Is Singer's 85th birthday.

Update: Notes from the Northwestern workshop are available here (from Evan Jenkins) and here (from Alex Hoffnung).

Update: David Ben-Zvi has posted notes from his talk and some others at the Northwestern workshop here.

Comments

1. **Evan Jenkins**
   May 21, 2009

   I've been putting up handwritten notes for the Northwestern TFT workshop here. Should my handwriting prove unbearable, Alex Hoffnung has been typing notes, which are available (albeit currently without drawings of pairs of pants and the like) here. Someone has also been recording audio, but I'm not sure how good the quality is or when it will be made available.

2. **Peter Woit**
   May 22, 2009

   Thanks Evan, that's great.

3. **H-I-G-G-S**
   May 22, 2009

   To maintain your reputation for being fair and balanced you might want to add the following to your description of the (0,2) theory.

   "Until relatively recently, it was believed that four was the maximum dimension for nontrivial (nonlinear or non-Gaussian) quantum field theory. One of the surprising developments coming from string theory is that nontrivial quantum field theories exist up to (at least) six dimensions. "

4. **Cplus+**
   May 23, 2009

   J. Freese in a rather technical article on predictive promiscuity in deductive applications has named "vampirical hypotheses" those which can not be killed by mere evidence.

   The phenomenon extends beyond string theory.

5. **Alex Hoffnung**
   May 24, 2009

   Regarding notes from the TFT workshop, several people are working on some version of notes/reports from the Lurie and Ben-Zvi lectures in a more expository form than they currently exist (also with pictures). I hope to have these up soon.

6. **Hendrik**
   May 25, 2009

   You may interested in the thesis of Patrick Costello (here) which just appeared on the ArXiv regarding the mathematical aspects of quantum BRST. Its focus is on the functional analytic aspects of current quantum BRST-methods, in particular the Kugo-Ojima approach (although there is also some analysis of the Hamiltonian approach).

7. **Peter Woit**
   May 26, 2009

   Thanks Hendrik

   That's very interesting. There clearly are a lot of remaining mysteries in the BRST story…

8. **David G.**

May 31, 2009

Dr. Abhay Ashtekar's 60th birthday conference 'Abheyfest 2009' is next weekend. Anyone attending?

Latest on the LHC

May 28, 2009
Categories: Experimental HEP News

The Resonaances blog has a report from Planck 2009 on a talk about the status of the LHC. The slides of the talk explain the problems with training quenches that have necessitated initially running the machine at 5 TeV per beam instead of the 7 TeV design energy. They also explain the analysis of what caused the accident last September: bad soldering of the interconnections between copper bus-bars connecting the magnets.

There has been an ongoing campaign to check the quality of the interconnections by careful measurements of the resistance, with slide 44 noting:

- Ongoing race to identify and repair faulty joints.
- Unfortunately poor quality joints are localized in many places – likely to slow down progress with the machine re-commissioning.

It remains unclear exactly how many joints will have to be opened up and repaired, and what impact that will have on the re-commissioning schedule. While this remains to be decided, the latest draft schedule I've seen has about 1-2 weeks of slippage from the current official schedule, with powering tests on all sectors not finished until the first week of October, whereas the official schedule now envisages first circulating beam the week of September 21. The Planck 2009 talk just says "Beam commissioning scheduled to resume in September or October 2009".

For some misinformation about the LHC schedule, see here.

   May 28, 2009

   "It remains unclear exactly how my joints will have to be opened up and repaired"

   Get well soon!

2. **woit**
   May 28, 2009

   Thanks roland, my joints are now fine and the posting is fixed…

3. **ANdrei**
   May 29, 2009

   So what is the difference between "beam commisioning" and "circulating beam.?

4. **Peter Woit**
   May 29, 2009

   Andrei,

   My understanding of the terminology is that beam commissioning starts when they first try and circulate a low energy (450 GeV?) beam around the ring. They got this far last year. From there, one has to get stable circulating beams in both directions at high energy (4-5 TeV), get them to collide, and get the luminosity in each beam up to a usable level. This is scheduled to take a month or so.

Singer Birthday Conference

May 28, 2009
Categories: Uncategorized

Last weekend I was up in Cambridge attending the conference in honor of Is Singer's 85th birthday. Singer has had a very long and distinguished career in mathematics, much of it at MIT, where he arrived as one of the first Moore instructors back in 1950. Besides a wide range of purely mathematical contributions, Singer was responsible for bringing together mathematicians (including Atiyah) and physicists starting back in 1976, at first around questions related to instantons. He has run a joint physics and mathematics seminar for about a quarter century, at Berkeley while he was there, then back at MIT. Unfortunately, this past year will have been the last year of the seminar, partly due to Singer's imminent retirement, partly due to a shift in the interests of Boston area physicists towards phenomenology and away from mathematics.

Jim Simons, an old friend and student of Singer's, played an important role at the conference, as master of ceremonies at the dinner, and as a financial backer. Back in 1975 it was his lectures to physicists at Stony Brook that got Yang and ultimately Singer interested in the question of the relation of gauge theory to geometry.

While in Cambridge, I picked up a copy of a new book, Recountings, which has interviews with many MIT mathematicians (including Singer), and does a good job of portraying the history of the MIT math department over the past 50 years or so.

Of the conference talks I managed to get to, probably the best was that of Mike Hopkins, who gave a blackboard talk about the Kervaire invariant problem. This one was a lot more accessible than his talk last month at the Atiyah80 conference, where he unveiled his dramatic new results with Hill and Ravenel (more about this story here). In the MIT talk, Hopkins concentrated on explaining the background and significance of the problem, as well as giving some of the philosophy of the proof, which uses what he describes as a "designer" cohomology theory.

Some quick notes on a few of the other talks that I made it to:

- Atiyah described some of the history of how Singer got him interested in physics, then went on to promote a very speculative idea about a non-local version of the Dirac equation.
- I can't say that I really understood Polyakov's talk, but it was along the lines of this.
- Cumrum Vafa talked about his local F-theory models and attempts to understand the hierarchy of particle masses this way.
- Michael Douglas gave a rather odd blackboard talk: no equations, no math, just pretty much straight promotional material about the philosophy of the landscape.
- Richard Kadison mostly reminisced about working with Singer, leading into a description of what is known as the Kadison-Singer problem.
- Greg Moore talked about work with Dan Freed and Jacques Distler. You can see their versions of the talk here and here.
- Wati Taylor gave another landscape talk, similar to the one discussed here.
- Orlando Alvarez gave a talk about work with Paul Windey, based on this paper.

Comments

1. **Barry Cunningham**
   May 28, 2009

   I just finished Recountings a few weeks ago and really enjoyed it. I attended MIT from 1966-1971 as an undergraduate. I was fascinated to get some insight into what was really going on then and learn some more about some professors I knew (or briefly met), both those directly interviewed (Hartley Rogers, Ken Hoffman, Harvey Greenspan, and Arthur Mattuck) and those they mentioned (e.g., Frank Peterson, George Whitehead, Harvey Friedman, Gerald Sachs, Dave Benney, Dirk Struik).
   I know! Just another old guy reminiscing.

2. **Thomas R Love**
   May 29, 2009

   Sorry to hear that the Physics-Mathematics seminars will end with Singer's retirement. I attended 4 quarters of the seminar when it was a Berkeley and it sparked my research on geometry and physics. I left when he started with supersymmetry.

3. **Walter Mondale**
   May 29, 2009

   It would appear that you are a "math groupie".

4. **Thomas**
   May 30, 2009

   Exist texts of Atiyah's and Hopkin's talks?

5. **Peter Woit**
   May 30, 2009

   Thomas,

   The talks were being recorded on video, I don't know if and when this will be publicly available.

6. **Andrew Ranicki**
   May 31, 2009

   Videos of the talks at Atiyah80 are now available from http://www.maths.ed.ac.uk/~aar/atiyah80.htm

7. **Peter Woit**
   May 31, 2009

   Thanks Andrew,

   I'll add a link to the posting about that conference.

Role Reversal

May 29, 2009
Categories: Multiverse Mania, This Week's Hype

It used to be that *New Scientist* had somewhat of a reputation for publishing misleading articles about speculative physics, and *Science News* was a more stodgy but reliable publication that stuck to serious physics. Recently there has been a role reversal. *New Scientist* is running a long, relatively sensible article about the use of AdS/CFT methods in condensed matter physics, entitled [What string theory is really good for]. It avoids the usual “String theory finally makes predictions!” hype that some string theorists have been trying to promote. *Science News* on the other hand, is now being run by Tom Siegfried, who is quite a fan of string theory hype, the more speculative the better. Last month was [Strings Fight Back] at *Science News*, this week it’s multiverse madness, with a cover story on [Infinity], which promotes the latest multiverse/Boltzmann Brain pseudo-science. Towards the end of the article, David Gross is allowed a few words as skeptic, arguing that we don’t understand string theory, so can’t be sure it leads to this mess: maybe some missing insight will get string theorists out of it. Siegfried responds with the thought that the “missing insight is merely realizing the need to master the inconveniences of infinity to resolve the cosmic conundrums.”

Update: The New Scientist article makes it to [Slashdot] where, as usual, it gets transformed into nonsense:

> His theory states that the known universe is only a 2D construct in anti-de-Sitter space, projected into 3 dimensions.

Comments

1. **Russ**
   May 29, 2009

   This guy Tom Siegfried apparently actually has some amount of training in chemistry and physics. You wouldn’t know it, through, from such statements as “Such calculations encounter a major impediment, though: To test whether the universe is the way it is because it’s a good place for men and women to be born and die, scientists must learn how to cope with infinity.”, and of course the gem from the end of the article that Peter quoted above.

   Man, I hate science journalists.

2. **woit**
   May 29, 2009

   Russ,

   I think it’s important to remember that journalists like Siegfried don’t just make this stuff up. The multiverse/Boltzmann Brain business, together with the idea that it is achieving some fundamental breakthrough in physics by thinking about infinity was fed to him by reputable physicists.

No Landscape and No Math in Rome

May 29, 2009
Categories: Uncategorized

Strings 2009 is about three weeks away, and it will bring 450 or so string theorists to Rome. The topics of the talks at the Strings 200x conferences give a good idea of what the hot topics in the field are, and this year's talk titles are now available. What's big this year are scattering amplitudes, as well as the usual AdS5/CFT4 topics, supplemented by the more recently popular AdS4/CFT3. As far as phenomenology goes, the hot topic is definitely local F-theory models, with three separate talks on the subject.

One topic that is not hot is anything mathematical, with no research talks by mathematicians or Witten, and little about mathematically significant topics such as mirror symmetry. What also seems to no longer be hot is either string cosmology or the landscape. No cosmology, multiverse or Boltzmann Brains are to be found among the research talks, although Brian Greene will give a public lecture about the issue of possible multiple universes.

Comments

1. **gues**
   May 30, 2009

   So what about Horava gravity theory? TBC ? when confirmed?

2. **David Ben-Zvi**
   May 30, 2009

   Hi Peter – Three talks that stand out to me as mathematically significant are those by Gaiotto, Nekrasov and Ooguri (not to say others aren't, these are closer to things I've been exposed to..). The math of N=2 d=4 gauge theories continues to be very inspiring, with new relations to representation theory, algebraic geometry, Hall algebras, Donaldson-Thomas invariants etc emerging recently, and these three speakers are very much in the forefront of the subject and influencing many mathematicians from what I can tell.

3. **MathPhys**
   May 31, 2009

   I thought the talks by Antoniadis and Narain on their work on topological amplitures would be primarily of mathematical interest as well.

4. **Peter Woit**
   May 31, 2009

   Hi David and MathPhys,

   I was of course exaggerating the point with both "No Landscape" and "No Math". Just as some of the talks surely contain material of use to landscapeologists, the ones you mention will contain material of real interest to mathematicans. But, still, just as none of the talks are primarily about the concerns of landscapeologists, I don't see any of the talks as having primarily mathematical interest, and suspect that relatively few mathematicians will be able to get something out of them. Looking through the 400+ long participant list I only saw a couple people I recognize as working in math departments.

   In any case, I tend to believe in the existence of a large area of overlap between math and physics, making putting things in one or the other category often impossible. My perception though is that, while string theorists have in some past periods been interested in reaching out to and interacting with mathematicians, that is less true recently.

   David's comment about the mathematical significance of recent work on N=2 d=4 gauge theories is a good case in point. I'm sure he's right, but also suspect that he's one of a very small number of mathematicians able to appreciate these connections. I hope he'll continue to do a great job of explaining this to me and others.

5. **no**

   wow, No Chinese either.

Interview With Simons and Yang

June 1, 2009
Categories: Uncategorized

Steve Miller pointed me to a fascinating interview with Jim Simons and C. N. Yang, available on YouTube here.

Simons tells the story of how he got kicked out of his job at the IDA in 1968 over his opposition to the Vietnam War, and ended up at Stony Brook as chair of the math department there. He and Yang collaborated on raising money to support anti-war efforts.

They describe how Yang went to Simons to try and find out about fiber bundles and what they might have to do with gauge theory. Simons started by referring Yang to Steenrod's *The Topology of Fibre Bundles,* which Yang couldn't make any sense of (Simons admits he never made it all the way through the book himself). This did in the end lead Simons and Yang to some real understanding of how vector potentials in gauge theory and connections on bundles were the same thing, with monopoles examples of topologically non-trivial bundles. Simons lectured at Stony Brook in 1975 on this, and a paper later that year by Wu and Yang included what became known as the "Wu-Yang dictionary" relating terminology in gauge theory and geometry. Singer learned about this soon thereafter when he visited Stony Brook, and went on to spread the news to Oxford, MIT and elsewhere.

Simons also describes what is going on with plans for the new Simons Center for Geometry and Physics, including some of the thinking that led him to decide to support this. The official ground-breaking ceremony for the new building there was held last week, you can follow construction progress here.

Comments

1. **Rene Meyer**
   June 11, 2009

   Well, it might have been different in 1968, but certain recent comments by C.N. Yang on what a great achievement of "Chinese science" the mainland chinese development of the atomic bomb actually was let me doubt that Mr. Yang always was a genuine pacifist…

2. **Peter Woit**
   June 11, 2009

   Rene Meyer,

   I have no idea what statement of Yang you allude to, or what his opinions are about nuclear weapons, either US or Chinese. What was discussed in the interview was not pacifism, but opposition to the Vietnam war in the late 1960s. Simons explicitly says that he is not a pacifist, would have supported the involvement of the US in WWII. I assumed the same of Yang, but don't know anything about his views on this, or on politics in general.

3. **Rene Meyer**
   June 11, 2009

   The comments of Yang are to be found here in English language:

   http://english1.people.com.cn/english/200004/12/eng20000412_38790.html

   I have to say that I read an even stronger statement in chinese language somewhere at some news portal, but I cant find this statement right now. Now since the People newspaper is the official mouthpiece of the CCP, I can not guarantee that the atomic bomb was not added to the there-presented list due to a suggestion of the editor or who-knows whom, just to show the necessary amount of patriotism. The chinese are generally very proud of being a nuclear power. However, if he really thinks himself that developing weapons of mass destruction is a great achievement of science and technology, in my mind his moral integrity as a scientist has to be questioned. After all, it would probably have been better if nobody had invented those things. But maybe it was just a mis-represented statement of an old man, who knows.

4. **Peter Woit**
   June 11, 2009

   It seems to me that Yang was just noting that development of nuclear weapons requires some significant scientific and technical expertise, while making no comment about the morality of such weapons. He could be dedicated to the abolition of nuclear weapons or support their development, I don't see anything he had to say addressing this.

   Again, I don't know what his political views are, and get the impression that, whatever they are, he tends to keep them to himself. The Vietnam War story surprised me a bit, but then the late 60s were an unusual time. The issue of the war was tearing the US apart, and it would have been difficult to not take a position on it.

   The interview is indeed fascinating. Thanks for the link, Peter.

The Music of the Superstrings

June 1, 2009
Categories: Uncategorized

String theorist Oswaldo Zapata continues (see here for an earlier posting about this) his remarkable series of essays about string theory and how it came to dominate research in theoretical high energy physics. The latest one, entitled The Music of the Superstrings is about the metaphorical use of classical music to promote superstring theory, and it concludes:

> Metaphors are powerful rhetorical tools. But, at the same time, they are much more than that. Indeed, when used astutely, that is, when anchored in deep shared meanings and aspirations, they can create an enthusiastic army of supporters to the discourse displayed. This has been one of the strongest weapons of string theorists in the battle for the control of future research in high energy theoretical physics.

Zapata examines how and why string theorists have chosen to advertise string theory to the public by claiming a deep connection to music, especially to classical music. He recalls the many ways this analogy has been promoted by many different string theorists, from Brian Greene, who has made it a prominent part of his popular explanations of the theory, to Edward Witten, who told an interviewer in 1988:

> In the case of a violin string, the different harmonics correspond to different sounds. In the case of superstring, the different harmonics correspond to different elementary particles.

I've always found this kind of thing grating, for a reason that Zapata doesn't address. Statements like Witten's give people the impression that the known fundamental particles of nature somehow correspond to the harmonics produced by vibration of a string. This is rather misleading, since all known particles correspond to the lowest energy state of the string. The quantum states corresponding to "harmonics" of a string are all supposed to be at unobservably high energy. The way the theory is sold to the public, via the musical metaphor that electrons and muons are different "harmonics" of a string vibrating at different frequencies makes it seem that such particles can be matched to the characteristic behavior of the harmonics of a string-like mechanical system, which is simply not true.

Zapata also now has a Reactions page, where he has posted links to commentary about his essays, as well as some comments from Bert Schroer in a recent preprint.

Comments

1. **Matt Leifer**
   June 1, 2009

   Personally, I've always found comparisons to classical music rather pretentious and off-putting. If you want to get me interested in a subject then you would be much better off comparing it to punk rock 🙂

   paging Mr. Ramone….Mr. Joey Ramone

3. **piscator**
   June 1, 2009

   >This is rather misleading, since all known particles correspond
   > tothe lowest energy state of the string. The quantum states
   >corresponding to "harmonics" of a string are all supposed to be
   >at unobservably high energy.

   um, in string theory gravitons and gauge bosons are harmonics of the string. the ground state with no oscillators is tachyonic.

   piscator

4. **woit**
   June 1, 2009

   piscator,

   Yes, I know. My point is that the way this is advertised to the public is misleading: the different notes coming from the different harmonics of a vibrating string in a stringed instrument do correspond in a quantized theory to different sets of states. But those different states are not the known different particles.

   Put differently, string theorists go on about an analogy with the musical notes in Bach string concertos, failing to mention that, as far as their strings are concerned, there's only one note.

   You can argue that this is justifiable poetic license, but, as Zapata explains, it is license taken in the cause of creating "one of the strongest weapons of string theorists in the battle for the control of future research in high energy theoretical physics."

5. **Tom Whicker**
   June 1, 2009

   Yes, grating is the word for it!

   The vibrating string metaphor really falls apart if you consider the internal forces involved in a real vibrating string. Do quantum strings have an internal structure that gives them a characteristic bulk modulus? If so, then the string is certainly not
   a fundamental particle. And in the quantum world, what provides the needed connections to each end of the string so that it may be tensioned? I seem to recall that Randall spoke of strings being anchored at one end to a brane….but if that is so, then how
   do strings move freely as particles?

   One thing that made Greene's "Elegant Universe" so hard to watch was the repeated use of bad metaphor. For instance, ants walking on the surface of a long piece of wire says nothing of substance regarding "compactification of dimensions".

How about a full issue of the blog dedicated to bad (and good, if they exsit) string metaphors?

6. **Hendrik**
June 1, 2009

In response, some classical composers have taken up strings (in the physics sense), e.g. here. Maybe it has to do with all the hype about beauty.
NewScientist is back onto strings too.

7. **Bert Schroer**
June 2, 2009

The metaphor to a musical string is actually correct, but in a very queer unintended sense. But the string is not in spacetime, it rather "sits" in the little Hilbert space "above" one point i.e. at the place which normally is reserved for the spin indices. And in some contorted way a small number of string theorists (Martinec,…) know that, but by the time they made this observation the metaphor of "those little wiggling strings" was already so powerful within the community that they called it an "invisible string" of which only one point is visible thus deriding decades of year of foundational research on quantum theory, including the work of Bohr and Heisenberg (who are left to rotate in their graves).
String theory can of course not be corrected by correcting the terminology and calling those objects what they really represent namely the first illustration of infinite component fields or wave functions (which Fronsdal, Barut, Kleinert,..in the 60 looked for in vain). One really needs the incorrect metaphor and not the real thing in order to make sense of those Feynman-like tube pictures which leeds into one of these abominable "catch 22" problems.
Question: do you think that there ever will be a description of those tube rules in terms of operators in a Hilbert space? This is what every object in QT admits, in the entire quantum theory there has been no exception to this rule.

8. **robert**
June 2, 2009

Witten's off piste lingusitic abilities are well known; I've never heard mention made of his musicianship. Is he an accomplished performer or avid listener, by any chance?

9. **Giotis**
June 2, 2009

Peter, my feeling is that you are exaggerating on this one. They just wanted to convey the basic idea to the public. Such pictorial representations are often used by scientists. I don't think that their intention was to mislead anyone and I don't see how an intuitive image intended for the public, could possibly influence the trends in theoretical physics.

10. **Peter Woit**
June 2, 2009

Giotis,

The problem is that it doesn't actually convey the basic idea to the public very well, but gives them a wrong idea about what is going on. While I think this is misleading, I don't think that's the intention.

As for whether I'm exaggerating: the fact is that I thought about writing something on the topic in my book about the problems with the musical metaphor, decided it wasn't important enough to write more than a sentence about. Note that this posting is about Zapata's essay, he's the one arguing that this kind of misleading metaphor has influenced trends in theoretical physics.

11. **Giotis**
June 3, 2009

I see. I misinterpreted then.

12. **Bert Schroer**
June 4, 2009

Giotis and Peter
You both came very close to what what is the core of the string problem. It is often said that a pointlike free quantum field is a collection of oscillators. This is a somewhat perilous characterization because no student who knows the QM of the oscillator would be able to reconstruct a free field from this indication. The most important aspect of the quantum field is its causal localization in one spacetime point; if it is a free field one most add the information that it obeys a specific equation of motion. From these (or similar formulated) data one can uniquely construct a free field.
The vibrating oscillators are then the Fouriercomponents of the pointlike field, but it is physically clearer to make the linear decomposition into creation/annihilation operators a(p), a(p)*. In every state, in particular in the vacuum state, there are fluctuations of these oscillators. Most aspects of these oscillators are unphysical, but certain fluctuations have physical consequences. For example the fact that the sum (integral) of all the vacuum fluctuations diverges is not of direct physical relevance, it is equivalent to the fact that the field A(x) is not an operator but a more singular object namely an "operator-vaued distribution" with excellent mathematical credentials.
As far as localization in the material sense is concerned, the field A(x) is localized in one point and there is no trace of the wiggling from the oscillators, the Wiggling comes when you look at expectations of products A(x_1)…A(x_n) in states (the most important state being the vacuum).
Behind these remarks there are two very different concepts of localization namely the Born localization of QM (in the relativistic setting the Born-Newton-Wigner localization) which comes with wave functions and the causal localization which in the above example is the point x i.e. independent of any state in which the local observable is studied. Nobody in his right mind would say that the oscillator wiggling in states has anything to do with the localization of an observable. The causal localization concept has a completely intrinsic meaning, there is a new mathematical theory which allows to liberate this meaning from the contingency of what field-coordinatization one is using: modular localisation.
What are Nambu-Goto strings or their supersymmetric counterparts? They turn out to be infinite component pointlike wave functions/fields. String theorists know that they only use a different name they call them (those who looked at the localization aspect) "invisible strings" or "strings of which only one point is visible". Why? because at the time they realized this the string mataphor was already so strong that they coud not resist the suck which they themselves created. What helped this incorrect metaphor was the fact that the classical Lagrangian is indeed that of a string. But all the work of Bohr Heisenberg … was done to liberate QT from false analogs to classical physics.
Where did all the oscillator degrees of freedom go which correspond to the classical string? They went into the rich infinite components i.e. they are in the inner space which metaphorically one likes to picture "above" the localization point (see my previous remark). There is nothing, I repeat, there is absolutely nothing which resembles a wiggling string in spacetime.

13. **Joe Dimaggio**
June 4, 2009

"This is rather misleading, since all known particles correspond to the lowest energy state of the string."

In other words… the string-music analogy falls flat.

You have to love my triple entendre 🙂

14. **Bert Schroer**
June 4, 2009

Peter, Giotis and Joe,
The analogy to a an acoustic string would be a legitimate metaphor (metaphors are never correspondences but at best analogies) if strings would really be what string theorist claim they are, namely stringlike extended objects (as opposed to the pointlike fields of QFT).
But they are not, and some string theorists (Martinec, Dimock,…) have seen this by explicit calculations. Since at the time of these calculations they were already committed to strings (the community influence which Zapata describes so vividly) they called it an "invisible string" or "a string of which one sees only the c.m." They should have used the name "infinite component wave function" or (in second quantization infinite component pointlike fields). These objects were searched for before by Fronsdal, Barut, Kleinert…but without success because they were using group theoretical methods. When you permit quantum mechanics of infinitely many oscillators you can do it but only in d=26 resp. 10
Now if the result of ST would have been a string in spacetime than the analogy would be tolerable at least in order to reveal some flavour of that theory to the public. But the crucial point is that it isn't and to use the musical analogy with an infinite component field (with all the higher frequencies having gone into the inner ("little" biut now infinitely large) Hilbert space namely that which goes with the indexing of the components is a very misleading metaphor.
Or in Peter's words, if you apply the analogy to the infinite component pointlike fields (called string) than you must also allow it for a few component i.e. standard QFT, but you should not do this in either case.
I would expect a blogger telling me that names are hollow words, so what string theorists discovered (by a tube analogy to Feynman graphs) is a finite interaction between infinite component wave functions. This is their great discovery, something which one cannot do with a finite component field.
My answer would be: show me an operator realization. Every prescription in QT permits a formulation in terms of operators in Hilbert space other wise it has nothing to do with QT. Witten looked for such a description over many years and did not find any. Anybody in the blogger community who believes that such a thing exists?
The relation between the above strings and the way how to implement interactions in terms of pictures is hopeless, a genuine "catch 22" situation if you know Joseph Heller's novel.

15. **A.J.**
June 4, 2009

Dr. Schroer,

It's not quite true that the strings are always point-like objects in spacetime. They can wrap cycles, and this is essential for mirror symmetry.

16. **Bert Schroer**
June 4, 2009

A.J.
Ihave to disappoint you, all of them are really infinite component wave functions or fields. Real strings also exist in QFT but they are very very different. You can call the objects of ST "invisible strings" or "strings of which only the c.m. point is visisible" (look up the computations of Martinec or Dimock if you find my computation to sketchy or suspect), but that is just a metaphoric circumscription id infinite conponent pointlike objects.
I expected your reaction which is typical, because how can a young man (assuming that you did not live through pre 1980 particle physics) look through an extremely plausible metaphor which was solidified over 5 decades not only by its proselytizes of ST as Gross and Witten, but also by the silence of all the others including several Nobel laureates.
How can a young man believe in what somebody like me, a nothing, says about string localization? You probably will not even find it worthwhile and look up the references by string theoreticians where they showed that the (graded) commutator is that of a pointlike field (which is the definition of pointlike localization) which they then unfortunately expressed in the described way. But physics is a democratic science and I have no doubt that at latest at the great ST and TOE crash which has to happen because there is simply no progress without it, you will remember me.
I am just trying to back up Zapata's cutting insider report in how facts are created in a community (the only place where this is possible) by massaging conjectures. I am using my 40 years experience as a research scientist in an era where at the end only the truth counts independent of who said it, but where the formation of gigantic communities (as compared to individual researchers up to the 80s) may delay this for a very long time.
A.J. do you seriously believe that I would write such things in public if I would not have clarified this issue with all my colleagues who do understand QFT on a profound level? Please do me a favor and look up any reference about localization in ST (take the two above) and come back if you find anything else than invisible strings or strings which come with only one point and let me know. For a twitter session where you just day things without backing them up by a proof or at least an argument, time is too valuable. If you want to know how real strings look like, this can be explained and the result is that they have nothing to do with ST.

17. **A.J.**
June 4, 2009

Dr. Schroer,

Please explain how a string wrapping the circle once is a localized entity. The notion of center of mass is a bit meaningless when the spacetime lacks an affine structure.

18. **Sulfur Surfer**
June 5, 2009

Prof. Schroer's technical claims about string theory are so manifestly ridiculous as to provide no motivation to read the tomes that he claims are necessary to understanding QFT (and there are many hundreds, perhaps thousands, of theorists using QFT correctly and productively without the formalisms that Schroer claims are necessary). Indeed, AJ has provided two counterexamples, and the long strings that appear along excited Regge trajectories are another: these behave in every physical respect like string-like objects.

19. **Bert Schroer**
June 5, 2009

Dear A.J.
The metaphor of the invisible wrapped string (with only one point is visible) is not mine but the phrasing of those string theorist theorist who really computed the spacetime extension of the string and found just a point. I am not using such misleading metaphors because the english language offerers a word for what it really is: an infinite-component pointlike field or better wave function.
This blog discussion is impeded by the weight of almost 50 years of metaphors because when you hear the word "string" you think automatically in terms of those little wiggling closed or open things, don't you? What I am asking you is to delete this in your memory and find our for yourself. The only reason I mentioned those computations done by string theorists because you trust them more them me. But the result of the computation is the same, the only difference is that they phrase the result in that (misleading) metaphor whereas I present the result without using metaphors.

By the way to see the uncorrectable metaphoric Maldacena AdS-CFT conjecture cannot be dealt with in terms of a simple calculation, one needs more demanding structural tools: but since it does not come music (besides that of its string theory parents) one would have to open a separate section.
Of course all these aberrations would not exist if the sociological conditions for particle physics would be similar to what they were at its best times namely by individual researchers as Pauli, Schwinger, Kallen, Lehmann, Weinberg,..and not by globalized communities with a guru at their leader.

20. **Bert Schroer**
June 5, 2009

When I came back to my office just now and looked at this blog, I realized that my last contribution intersected with sulfur's. It so happened that in anticipation of my contribution and against his will he gave me a helping hand by confirming that particle physics these days is a matter of guru-directed communities who measure the validity of ideas in terms of community size and/or viewing rates.
I expect however that possible further contributions of this Asperger Neird will be less useful and it would be a good idea if he can be kept out of this series blog in which every statement should be proven or documented following the example set by Oswaldo Zapata (who showed that string theory and objectivity do not necessarily have to be contradictory).

21. **Giotis**
June 5, 2009

Personally I don't quite understand where the problem is. The EOM of the string is a wave equation. The solution to the EOM is expressed in terms of Fourier series. Upon quantization the commutation relations of the Fourier modes are those of the harmonic oscillator creation and annihilation operators. We have an infinite number of creation operators and by acting on the ground state (of the string i.e. no oscillations) they create the infinite set of basis states that span the infinite dimensional Hilbert space. Each quantum state of the string is described by a wavefunction (that satisfies the Schrodinger equation) and can be thought as a one particle state. Thus there should be the corresponding quantum field in space-time (the realm of String Field theory).

But that doesn't change the fact that the string is *really* the fundamental one dimensional object that sweeps a worldsheet in spacetime or wraps around a circle. Likewise in QFT the fundamental object is the field and its Quantum states can be interpreted as particles. Anyway I'm a little confused by these assertions.

22. **Bert Schroer**
June 5, 2009

Sure Giotis, a string of ST like a pointlike field with infinitely many component i.e. an infinite component field in the sense of the book on QFT by Bogoliubov, Oksak, Todorov,… But those degrees of freedom which reside in the e.g. Nambu-Goto Lagrangian are not the oscillator degrees of freedom which you see if you look at the creation/annihilation operators of a finite component free field. Those oscillator degrees of freedom which are in that classical N-G string rather go into the inner Hilbert space i.e. they create the infinite internal dimension which has nothing to do with the creation/annihilation operators of fields. The reason why those people who tried infinite component fields before string theory did not get anywhere is because they did not use vector-valued quantum mechanical variables to built up this infinite dimensional Hilbert space, but they tried it with noncompact group theory. It is very tragic that the dual model people did not realize that the Veneziano solution for a dual amplitude led precisely to those infinite component pointlike objects (the infinitly many poles whose residua are formed according to Gamma function properties), we would have been much better of.
I agree with you that words are all hollow, but this ceases if words generate series misunderstandings. This is the case here. The oscillators of quantum fields nobody would call strings, they are pointlike localized and that they contain oscillators you only see through taking their expectation values in states (e.g. vacuum fluctuations), e.i. these fluctuations are their spacetime mark. With other words the oscillation (fluctuations) comes in through states, there is nothing oscillating in the observable pointlike localized field A(x), i.e. the a and a* do not start to fluctuate by themselves.
The role of the oscillators which are characteristic for string theory is very different since they create an inner Hilbert space (which accounts for all those infinitely many spin components) and to speak about fluctuation is physically completely meaningless, their role is just to catalog the particle tower.
There are two remarks which one could add here
1) there are genuine stringlike objects; e.g. the electricall charged fields in their sharpest-localized form. They are very different from ST.
2) dismissing strings/infinite component field as hollow words has its end when you come to the way in which string theorists introduce interaction via tube recipes for those infinite component string wave functions.
3) The incorrect picture of ST can be traced back to the idea of source and target space (world sheet). You cannot embed a chiral conformal current with 26 internal vector indices into a 26 dimensiomal spacetime, when you do this the chiral degrees of freedom go into the internal space, i.e. the resulting 26 dimensional object is an infinite component pointlike field in 26 dimensions. This is where the tragic journey into metaphor-land begun.

But I think I answered your question and I do not want unsolicited enter related subjects.
Resume: the strings you mean when you make this comparison with oscillators (and vacuum fluctuation) in quantum fields are perfectly compatible with the true nature of what ST call strings and which they should have called infinite component fields, but they are not compatible with those metaphoric pictures of ST as an object which has an intrinsic (state independent) extension in form of a string.

LHC: status and commissioning plans

June 1, 2009
Categories: Experimental HEP News

The LHC's Mike Lamont has just posted a preprint here based on a recent Moriond talk describing the current status of the LHC commissioning. Here is his discussion of the on-going campaign to identify bad splices and figure out what to do about them. From it, I gather that the big unanswered question is what to do about possible bad splices in sectors that have been cooled down, since warming up the sectors would significantly delay the scheduled startup.

> One additional danger that has recently surfaced is a bad electrical contact between the copper of the busbar and the U-profile of the splice insert on at least one side of the joint. Combined with a bad contact between the cable and the copper this leaves the splice without an alternate route for the current in the case of a busbar quench – in a good splice the current can flow in the copper removing the danger of excessive resistive heating in the quenched superconductor. A good contact between the Rutherford cable joint is assumed (i.e. less that 2 nano-ohm).
>
> Such situation can be detected by measurements at warm using low current and a nanovoltmeter across short segments of the machine. Under such circumstances the current flows in the copper and the resistance of a good joint is around 12 micro-ohm. Extensive measurements of the four warm sectors (May 2009) have revealed 16 segments with excess resistance of over 30 micro-ohm. The relevant interconnects have been opened. Individual splice measurements have revealed resistances of 30 – 50 micro-ohms. All such splices have been re-done and re-measured.
>
> Warm quadrupole measurements started in May 2009. Measurements at at 80 K in sector 23 are also ongoing at this time. The measurements at 80 K are more difficult and show a lot more signal variation – the resistivity of copper falls by a factor of 7.5 at this temperature. The question of what to do if suspect splices are found at this stage of re-commissioning is to be addressed.

Multiverse News

June 1, 2009
Categories: Multiverse Mania

Some items from around the multiverse:

- Srednicki and Hartle have a new preprint on hep-th about Science in a Very Large Universe. Like many other multiverse papers, it doesn't really have any equations in it, so it's a bit hard to figure out what their argument is. Maybe readers can figure it out from the conclusion:

> It is no surprise that information about us is required to make predictions for our observations. Our data suggest that we are located some 13.7Gyr from a Big Bang. To make a reliable prediction from that information, we have to assume that it describes our physical situation. If the universe is rife with delusion, we must assume that we are atypical in order to have predictive and testable scientific theories. Indeed, it is only by making such assumptions that we are able to do science in a very large universe. We imagine that even Copernicus would have agreed that it was necessary to assume that Ptolemy was not deluded in his observations of the planets.

The authors thank about a dozen or so other theorists for their help with this.

- World Science Festival 2008 here in New York was a huge success, and I suspect that the 2009 version starting June 10 will be too, which is great. Of the many events, one where I might have a difference of opinion with some of the panelists will be a session on Infinite Worlds: A Journey through Parallel Universes, sponsored by the Templeton Foundation.
- Seed magazine had a story a couple months ago about the theological implications of the multiverse.
- Astrophysicist Jeffrey Zweerink has a book out called Who's Afraid of the Multiverse?
- Over at FQXI there's a recent blog entry discussing the question of whether God might be "unsure as to whether He is really just a brain floating in a vat?"
- Somehow I missed this one last year. Wheaton College held a research symposium on String Theory and the Multiverse: Philosophical and Theological Implications.

Update: For a more skeptical and philosophical take on the multiverse, there's The Unique Universe, a piece by Lee Smolin that just came out in the latest Physics World.

Update: The proceedings of the Wheaton College conference on string theory, the Multiverse and theology are available here. They include audio recordings of the discussions, and inform us that string theory

> implies that physical reality is far vaster and possesses greater grandeur than ever imagined.

Comments

   The universe IS rife with delusion … that it is one of a multiverse.

2. **Shantanu**
   June 2, 2009

   Peter are u planning to attend the 2009 Amaldi meeting ?
   2 weeks from now

3. **Peter Woit**
   June 2, 2009

   Thanks Shantanu, I didn't know about that. I'll be around those days, may try and catch some of the talks.

4. **Arun**
   June 2, 2009

   Re: Lee Smolin *As we attempt to realize those principles, we seek a notion of law that cannot be applied to an imagined universe within a multiverse, and which cannot be imagined to hang around timelessly waiting for a universe to begin that it can then govern. Given that the universe only happens once, we must try to imagine a new kind of law that applies only that one time. Such a law need not — and should not — have any sense in which it exists outside of time. Nor could it be conceived of as apart from the universe it describes.*

   Our universe began with low entropy – it applies to this universe, not imagined universes within a multiverse; it is not hanging around waiting for a universe to begin, it comes into being with the Big Bang. It cannot be conceived of as being apart from the universe it describes. Talk me down.

5. **GR**
   June 2, 2009

   Good lord. I may just be a beginning graduate student, but my bullshit detector reads off-scale high when I try to parse that. My best guess is that it means "in order to do science, our observations have to match up with reality"?

   Who knew Aristotle was the first string theorist. It's sad that theoretical physics is rife with third rate philosophy hacks trying to come to grips with solipism.

6. **Coin**
   June 2, 2009

   Why is the brain always in a vat? Is this really the most efficient and safe way to house a trapped brain? It seems like a neutrally buoyant brain floating in fluid might still tend to drift and hit the side of the vat, or something. And would a brain suspended in nutrient fluid actually even successfully be able to intake the fluid? In the human body the "nutrient fluid" has to keep continuously flowing via external force and if it ever goes stagnant we call this a stroke. Right? Why not just keep the arteries connected to the brain and pump fluid through those?

7. **Chris W.**
   June 2, 2009

GR: I can guess, but would you mind being more specific about what triggered your bullshit detector?

8. **GR**
June 2, 2009

Chris:
Well, to be fair, when I first wrote that I'd only read the excerpt. I've read the whole thing now and my opinion hasn't really changed. Of course, I may just lack the sophistication needed to understand the paper, but it reads like an exercise in metaphysics, not physics.

In any case, the sentence "To make a reliable prediction from that information, we have to assume that it describes our physical situation." is what made me skeptical. I think they're questioning the idea that the laws of physics are the same everywhere in the universe. Fine, but what really is the point? There's not much use in doing cosmology if they aren't.

Again, from my perspective as a beginning graduate student, all of this wild speculation about multiverses just sounds like the string theory crowd making excuses for why their theory doesn't come up with predictions…

9. **Chris W.**
June 2, 2009

Okay, so you were talking about the excerpt from Lee Smolin's article in Arun's comment (6/2, 10:42 am), and have since read the entire article.

I get the impression that you're fairly new to this discussion. Lee Smolin is not a string theorist, although he has done some work in the field. The whole point of his article is explain why certain assumptions implicit in our conventional understanding of quantum theory lead us to a multiverse in the context of quantum gravity and cosmology. He is trying to find a way past those assumptions, precisely because the idea of a multiverse severely undercuts or eliminates the possibility of making testable predictions.

Is his article an exercise in metaphysics? Absolutely! In this context metaphysics is unavoidable. Modern physics inherited some key metaphysical ideas from the ancient world, most notably atomism, and found ways to give them empirical depth and substance, ie, to build testable theories around them. I think the same process must be repeated now, although the required ideas will almost certainly have a much more recent origin, and may have to be invented anew.

Smolin is not questioning the importance of the universality of the laws of physics across space-time. What he is emphasizing is the potentially disastrous effects of separating the fundamental laws from *effective* laws in such a way that only specific effective laws can be tested, but are also assumed to be highly contingent on how the observable universe is situated in a hypothetical multiverse. The result is that a failure of any effective theory simply results in selecting another effective theory from a vast ensemble allowed by the fundamental theory. Potentially, then, the latter therefore can never be tested; it devolves into a generator of effective theories, with unlimited latitude for accommodating actual observations.

Of course string theory (not to mention particle physics and cosmology), considered as a formal discipline, is a vast subject, and one can bury oneself in mastery of parts of it while ignoring these issues. Smolin and others are trying to resist this attitude. Mathematical formalism can be just as metaphysical in its relationship to nature as ideas expressed in prose, even if its logical structure is tighter and its definitions are more precisely stated.

10. **GR**
June 2, 2009

That quote was from the first bullet point in Peter's post, not Smolin's article, which I haven't had time to read.

11. **Dude**
June 3, 2009

Peter, can you please consider using a widget in the sidebar that shows the titles of your posts for your archives? The same thing for your categories would also be nice.

In the past, I used a widget called Wp-dTree. The wordpress.org page is here: [Wp-dTree 3.5](). One of the tabs near the top shows some screeshots.

Here's a blog that's using Wp-dTree: [here]().

You have posts that I may want to refer to in approximately 14.34 years, when I've achieved greatness of some sort, probably via American Idol, or Britain's Got Talent, singing as fat woman. Or occasionally, I might like to surf through old posts of yours in a non-linear manner.

I could link to your posts now to separate them from the myriad of posts on your blog, but this could be a waste of my time, considering there's a possibility I'll move to Sudan, or never move to Britain, and lose my chance of competing on American Idol or Britain's Got Talent as a fat woman, and never achieve the greatness I desire, and therefore never have any real use for your posts.

12. **chris**
June 3, 2009

Chris W,

i am not aware of even one single instance in modern physics where pondering about metaphysical questions resulted in progress of any sort. all examples that i am aware of show that progress is usually reached through detailed understanding of experimental data. metaphysics is usually produced in the aftermath of a breakthrough to digest what was learned or put it in some sort of perspective. this is very natural, but i seriously question its usefulness for any sort of scientific progress.

13. **A.**
June 3, 2009

The discussion above reminds me of the following exchange I overheard in the department, the other day:

Senior string theorist: "The definition of "science" has nothing to with modern physics."

Postdoc physicist: "I'd say that modern physics has nothing to do with science."

Senior string theorist: *looks like he has just been slapped*.

Sigh. Seriously.

14. **Peter Woit**

June 3, 2009

Dude,

Thanks for the suggestion. I've implemented it for the archives, where it looks quite useful.

15. **Dude**
June 3, 2009

Peter, thank you very much. That's the main thing I wanted, but here are two more requests/suggestions, although you may not care about implementing them.

#1: Please increase the width of the sidebar as wide as can (but to where it still looks good). Wp-dTree truncates the post titles based on the width of the sidebar. This isn't of ultimate importance since the complete title is shown if the mouse cursor is hovered over a truncated post title, but it would make viewing titles faster.

#2: Include the sidebar in every view. For example, the sidebar is shown if I enter using your main blog URL, but if I click on a post, the sidebar isn't shown. If I was surfing lots of old posts, I wouldn't have to go back to your main page each time.

Suggestion #2 would also be good for those who aren't familiar with you, and who enter a page through a search engine. If the sidebar is there, a person may see something that interests them.

To do the above, you'd have to edit the CSS, and I can't tell you how to do that. The last time I did it, it took me a long time to figure out how to mess with CSS.

Thanks again.

16. **Peter Woit**
June 3, 2009

Dude,

I don't think I'll change anything more right now, have been trying to keep the changes from the default theme to a minimum, which makes upgrading the version easier.

17. **Mitch Miller**
June 3, 2009

A's comment sort of reminds me of George W. Bush's comment on the free market.

"I've abandoned scientific principles to save the scientific system."

18. **GR**
June 3, 2009

Chris W:

Now that I've read Smolin's article, I don't have a problem with it. Mainly because it offers a concrete prediction: the universe maximises the production of black holes. I'll be damned if I can ferret out any sort of prediction from Srednicki and Hartle.

If string and multiverse theorists want to play the metaphysics game, they're more than free to. But they shouldn't call it physics. This whole probability game reminds me of that Feynman quote about the license plate…

19. **Chris W.**
June 3, 2009

— from 'Chris': "i am not aware of even one single instance in modern physics where pondering about metaphysical questions resulted in progress of any sort."

1) Since the 18th century, metaphysical considerations have remained in the background, and even in their intellectual biographies most scientists downplay or omit any mention of their influence. At most, they might acknowledge having studied philosophical writings in which metaphysical presuppositions are discussed. In addition, there is the question of what assumptions one considers to be metaphysical. I doubt that most working scientists spend much time thinking about the demarcation. They're more concerned with distinguishing between ideas that might prove fruitful for the formulation (!!) and solution of scientific problems. In practice, "metaphysical" is often considered a synonym for "useless" or "sterile". Indeed, most metaphysics, like much thinking in many areas, is of dubious value. ("Ninety percent of everything is crap. ")

2) The metaphysical ideas that have most important to modern science (not just physics) so far have ancient roots, and are so embedded in our cultural and intellectual heritage that are rarely consciously considered, except by philosophers and historians.

3) Avoidance of metaphysical assumptions, interpreted as an uncompromising operationalism, was very much part of the philosophical background of quantum mechanics. Einstein's stated motivations for the development of special relativity provided considerable impetus for this, along with the influence of the Vienna Circle. (Einstein later repudiated this attitude.) This is deeply embedded in modern scientific culture, so that metaphysical assumptions, when employed, are rarely acknowledged or even recognized as such.

4) Re your remark: "all examples that i am aware of show that progress is usually reached through detailed understanding of experimental data." The question becomes, how is that understanding achieved? Perhaps it is considered to be in poor taste to discuss it publicly, but when the necessary ideas don't exist, somebody has to wrestle with the obstacles to understanding, including the possible role of an unquestioned metaphysical framework, or the lack of such a framework. Of course, as soon as empirically testable assertions can be made, they take center stage, and most researchers *not directly involved in developing the key ideas* take little interest in their background.

I hope these observations serve to indicate why consideration of metaphysical presuppositions is so routinely avoided, even when it could be illuminating, and even essential, both in formulating and in appreciating important scientific ideas.

20. **Observer**
June 3, 2009

…"The definition of "science" has nothing to with modern physics."
Are string theorists slipping their discipline into religious faith…? Now that sounds amazing .

21. **John Duffield**
June 3, 2009

Ouch. Is that what passes for HEP these days? The Srednicki/Hartle paper read like a spoof. It falls over in the first paragraph when it claims that “there is a quantum probability for these data to exist in any spacetime volume”. No, there isn’t. There is no evidence whatsoever for any kind of xerographic multiple copies of me sitting at this desk. There is no evidence whatsoever for an infinite number of Boltzmann brains magically popping into existence. These speculations do not serve as the basis for a typical/atypical computation or experiment dressed up with Bayesian respectability. This isn’t science. There are no testable predictions. These guys are riding the many-Worlds misinterpretation of quantum physics and they surely don’t even understand that the fine structure constant alpha $\alpha = e^2/2\varepsilon0hc$ is a running constant or why. So when they say “It is only the combination of fundamental theory and an assumed xerographic distribution that is predictive and testable by observation” it’s just castles in the air.

22. **anon.**
June 3, 2009

they surely don’t even understand that the fine structure constant alpha $\alpha = e^2/2\varepsilon0hc$ is a running constant or why

It’s not as if one of them wrote a textbook on quantum field theory, after all! Oh, wait.

23. **Titanium Dragon**
June 3, 2009

Your extract has the scent of nonsense clinging to it, but it actually does make sense. It is an incredibly complicated restatement of a very basic principle. It could be summarized more simply as follows:

In an infinitely large universe, any set of physically possible events will occur somewhere. Therefore, it is possible that all of our conclusions are the result of coincidence, so we can only be as confident in our data as probability allows.

Or, in other words, it is possible (if vanishingly unlikely) that our observations of physical phenomena are coincidental. Of course, this is a worthless statement, as we all already knew this fact; its basic science that we are never absolutely certain of anything.

It is also worth noting that this is not, in fact, limited to an infinite universe, as it can be true in even a finite universe, so the whole multiverse part is completely extraneous to this statement. We could simply say:

We can only be as confident in our data as chance allows us to be.

And be done with it.

24. **Titanium Dragon**
June 3, 2009

Incidentally, the linked-to article strikes me as pretty vapid itself, I’m afraid. Of course, so does the entire timelessness argument. He claims that we evoked chess into existence, as opposed to it always existing in some timeless state. Both strike me as completely meaningless, unscientific ideas. Indeed, both are equally falsifiable; we cannot confirm the existence of something until we do so by definition, so we cannot check if it was there “beforehand”; ergo both are meaningless.

Really, the argument strikes me as a very metaphysical one which doesn’t make unique predictions about the universe. What in that article is really worth considering? That we cannot know the initial conditions of the universe? Isn’t that something which is generally suspected because of the massive amount of energy involved, as well as our inability to observe the universe as a whole and the fact that our laws of physics break down before we go back all the way to the big bang?

25. **jpd**
June 4, 2009

i think i agree with you ,but quick question

re: “In an infinitely large universe, any set of physically possible events will occur somewhere”

if the probability of a physically possible event is infinitely small, couldn’t it be ruled out in a (not sufficiently) infinitely large universe?

in other words: a boltzmann brain is ridiculous.

26. **Shantanu**
June 4, 2009

Peter you found anything interesting at
“New Prospects for Solving the Cosmological Constant Problem”
conference at PI?
It has a wide spectrum of talks from anthropic principle to LHC etc.

27. **Peter Woit**
June 4, 2009

Shantanu,

I have the same problem with explanations of the CC that I have with quantum gravity in general. The only way that I can see that any purported explanation would be convincing would be if it also implied other non-trivial facts about observable physics. I haven’t seen anything like this, either from the anthropic people or from other attempted CC explanations.

28. **alex**
June 5, 2009

re: “In an infinitely large universe, any set of physically possible events will occur somewhere”,

or as Hartle and Srednicki put it,

“in the universes considered in contemporary cosmology the following often hold:

1. The probability is near unity that our data D0 exist somewhere.

2. The probability is near unity that our data D0 is exactly replicated elsewhere many times."

The reasoning behind this claim isn't specified but it seems to be that given an infinite number of tries every possible outcome will occur. But his is not so. Even in an unbounded universe you have a countable number of planets, brains, desks or whatever else you include in "our data D0". If the number of allowed states D0 is not countable, which would seem to be the case, then it is impossible for all of them to actually happen and the chance of there being another me sitting at an identical desk looking at an identical night sky somewhere out there beyond the observable universe is not close to unity, it is zero. At least if you consider D0 being "exactly replicated" as they state. There are some loopholes. You might think of a multiverse with uncountably many universes within it. Or better, you might consider states similar to but not exactly the same as D0. Maybe you'd want to consider the probability of states where the expectation values of all possible measurements are within epsilon of those for the state D0, and see if you can keep the probability of there being one at unity whilst epsilon tends to zero. Though you might then worry about chaotic systems and the amplification of arbitrarily small differences in initial conditions. I guess you might also consider that you are talking about some sort of reduced density matrix for each candidate subsystem and the implications of that. But they don't.

29. **GR**
June 5, 2009

Peter,

Have you seen the latest rehash of the string-theory-in-CM on slashdot?

30. **Peter Woit**
June 5, 2009

GR,

Hadn't seen that. It's the New Scientist article I wrote about here a while ago, which wasn't bad, although Slashdot as usual manages to do a good job of garbling it with nonsense like:

"His theory states that the known universe is only a 2D construct in anti-de-Sitter space, projected into 3 dimensions."

31. **Claver**
June 8, 2009

re: "In an infinitely large universe, any set of physically possible events will occur somewhere"

In the real and measurable universe only certain events happen. That is, doesn't such a universe exhibit a bias? Such a bias permitting and excluding events.

If the universe exhibits such a bias today, why shouldn't an observer some where afar off not see the same bias? And, why should that bias change?

I mean is the universe 'compelled' to pick different events tommorrow? Implying that the universe 'remembers' which events happened yesterday? (Which gives rise to an interesting observation: information from the past influences events of today.)

Put in another way, if in an infinite amount of spacetime EVERY set of physically possible event will occur, then surely every event can be repeated, within the same infinite universe. In which case the probability of an event occurring in an infinite universe can be more than 1 because
'who can measure how many times, in an infinite universe, a particular event is repeated?'Is there an observer? If not, then saying …

"In an infinitely large universe, any set of physically possible events will occur somewhere"

is saying something that cannot be physically proven. It is an unobservable and unmeasureable statement?

i.e if ANY set of physically possible events WILL occur then there is a probability that ALL will occur.

I thought that in physics (real and measurable) the notion of an infinitely large universe was purely a mathematical construct? A consequence of the inherent mathematical difficulty – in expressing ongoing repetitive structures – carried over into physics from mathematics.

Or is this just being naive?

32. **Dr Lewney**
June 9, 2009

Hi Peter,

Did you happen to have a look at the last page of the June issue of Physics World containing Lee's excellent article? (I'm afraid it wasn't picked for online publication.)

Cheers

Mark

33. **Peter Woit**
June 9, 2009

Hi Mark,

I'm afraid I haven't seen a physical copy of the June issue of Physics World yet. What's on the last page?

34. **Dr Lewney**
June 10, 2009

It's a light-hearted article on my Schools Lecture Tour which mentions this very blog! Send me a private email and I can reply with the PDF.

Cheers

Mark

35. **Matthew Putman**
June 14, 2009

i am wondering if you had a chance to get to any of the World Science Festival this year? And if you do have any issues, i am curious about them. I thought that this year the events were rather brave in presenting opposing theories. I say brave, because there is a danger when presenting ground breaking and interesting science to a group most interested in the artistic interpretations of it. They might tend to misunderstand scientific discourse, relating it to differences in religion. In Religion the wrong party goes to hell. In science, they jump on board the proven theory and try to improve it. This is why scientific debate is always positive, and why religious debate always a waste of time.

36. **Peter Woit**
June 15, 2009

Matthew,

I was out of town for most of the World Science Festival this year, so just saw some reports in the newspaper, which indicated that, like last year it was a great success. The high level of public interest in this kind of thing is pretty amazing.

String Universality

June 7, 2009
Categories: Multiverse Mania

There's a new paper out on the arXiv this evening, advertising a new concept called "string universality". The authors argue that in six dimensions, by use of appropriate compactifications, any consistent 6d supergravity theory has a string theory realization. They go on to conjecture that the same might be true in four dimensions. As for the implications of "string universality", they write:

> If it is correct, or even close to correct, that string universality holds in six dimensions, then in this case we seem in some sense to be in the worst possible situation vis a vis low-energy predictions. If every possible consistent theory can be identified from low-energy considerations, and all of these theories can be realized in string theory, then string theory would seem to have no predictive power for low-energy physics…

Not being able to predict anything sounds bad for string theory. But wait, they go on to explain why not only is this not a deadly problem, it's actually a "strength of the theory". You see, there's "symmetry and elegance" to a principle that is consistent with absolutely everything and constrains nothing. Some worrywarts might have problems with such a principle since it can't be tested, but, just because something can't be tested doesn't mean it's not right, no?

> This may seem like a very awkward situation for string theory. It should be emphasized, however, that there is no reason a priori why a theory of quantum gravity relevant at the Planck scale of 10^{19} GeV should make any prediction for physics at the scale of 1 TeV, 16 orders of magnitude below the quantum gravity scale. String theory is valuable as a framework for describing quantum gravity. If in fact, string theory can be used to provide a UV completion of essentially any low-energy theory whose coupling to quantum gravity does not violate some basic principle like unitary via anomalies, this can be seen as a strength of the theory. There is a certain symmetry and elegance about the notion of a quantum gravity theory which provides for the production of essentially all possible low-energy behaviors in some regime of the theory or region of the metaverse.
>
> If indeed, string theory can give rise to such a wide range of low-energy behavior that predictions at the TeV scale cannot be made precisely, it may bother some scientists that this makes the theory difficult to test. But, on the other hand, this does not make the theory any less likely to be correct. It just makes it more difficult to verify.

Comments

1. **fh**
   June 8, 2009

   I actually think this would be great, this is a good place for String theory, not as a unique theory that gives immidiately testable predictions but as a generic framework like QFT.

   Just as in QFT you specify gauge groups and representations to obtain a theory, in ST you specify a geometry/compactification.

   It's not a theory of everything but a theory of every theory.

2. **MathPhys**
   June 8, 2009

   I think it's a beautiful idea: Strings form a completion of effective, low-energy field theories, and (hopefully) offer the correct way to make the loop diagrams finite order by order.

3. **Engulf and Devour**
   June 8, 2009

   Why stop there? String Theory should not be satisfied until it has subsumed all of the *in*consistent theories as well.

4. **Peter Woit**
   June 8, 2009

   MathPhys,

   But that's not the idea the authors are claiming is beautiful. Their new idea "string universality", for which they claim "symmetry and elegance", is that of a "theory which provides for the production of essentially all possible low-energy behaviors in some regime of the theory or region of the metaverse."

   In the past, a physical theory was considered to be "symmetric and elegant" if it explained a large number of observable phenomena with a small number of constructions. What is new here is the discovery that you can get "symmetry and elegance" at the opposite extreme: a theory which explains no observable phenomena using extremely complicated constructions. They couple this with a very powerful new principle of how to do science: just because a theory can't ever be tested doesn't make it any less likely to be correct. This principle has wide possible applications, promising to bring back together science and religion, healing the terrible split which occurred with Galileo.

5. **Peter Shor**
   June 8, 2009

   If this in fact can be proven (or at least shown to the satisfaction of the string theorists), this would be a significant advance; it would also put a stop to the incessant "test of string theory" press releases.

6. **Chris W.**
   June 8, 2009

   They couple this with a very powerful new principle of how to do science: just because a theory can't ever be tested doesn't make it any less likely to be correct.

   Yeah. I'll bet that the IDers will be all over this, not to mention the astrologers and diehard believers in psychic phenomena. Talk about riding coattails…

   > …… But, on the other hand, this does not make the theory any less likely to be correct. It just makes it more difficult to **verify**.

Notice (yet again) the way the author skates right by the essential emptiness of "verification" without testability. This is precisely what galvanized Karl Popper as a young man, as he observed the depressing contrast between Freudian psychology and Marxism on the one hand, and what he saw happening at the same time in theoretical physics, where people actually seemed to care about checking for the possibility that their ideas might be wrong, ie, might imply assertions that contradict observations and results of experiments. More precisely, they cared enough to *formulate* ideas that were logically capable of contradicting observations and results of experiments.

Richard Feynman died in February of 1988, but even then he smelled a large rat.

7. **A.J.**
June 8, 2009

If this in fact can be proven (or at least shown to the satisfaction of the string theorists), this would be a significant advance….

Not to mention a great piece of mathematics.

8. **Peter Woit**
June 8, 2009

Peter Shor,

There's no more claim here than anywhere else to be able to show "string universality" in 4d. What is remarkable in this paper is the claim that "string universality" would not be a reason to give up on string unification, but instead would be evidence of "strength", and a "symmetric and elegant" scientific picture of the world, with the fact that it could never be checked not a problem. Most string theorists I talk to claim the argument for string theory unification these days is "we still don't understand string theory", that when we do, maybe it will somehow work out. They acknowledge that if, once string theory is completely understood, it has nothing to say about particle physics, then the game is over, you can't claim string unification as successful science.

I don't think there's any prospect of press releases about "tests of string theory" stopping. Even now, these pretty much all just ignore what is known about string theory.

One other peculiar thing in this paper is the wording of the implication of "string universality" as "predictions at the TeV scale cannot be made precisely". The problem being discussed is whether ANY predictions, no matter how crude, can be made, not the question of precise predictions. It's unclear to me why the authors use this language that doesn't correspond to what they are talking about.

9. **M**
June 8, 2009

why the 6d case is even worse than the 4d case? Naively I would guess that to get 4d one needs to compactify more extra dimensions so there is more arbitrariness about how to choose the extra dimensions: one M-theory in 11d, 5 string theories in 10d, …, 10^500 not-even-wrong theories in 4d.

10. **Peter Orland**
June 8, 2009

fh just repeated the far too common retort on this blog…

"just as in QFT you specify gauge groups and representations to obtain a theory, in ST you specify a geometry/compactification."

NO! There is the SUBJECT "Field Theory" about the properties of different field theories. This is not the standard model, which is a, single, not family of, not class of, not generic, not a googol of, but ONE field theory. That's the theory.

11. **Leonard Ornstein**
June 8, 2009

It seems that the distinction between possibly beautiful math, which doesn't require empirical confirmability; ultimately, only 'logical proof' – and science, which requires empirical testability, no matter how beautiful a model (or 'theory') – is still not appreciated by many of the posters above!

12. **Benni**
June 8, 2009

Well, i do not think that it is important for a theory of quantum gravity, to make predictions at the TeV scale. Someone who is interested in predictions at the TeV scale should work on ordinary phenomemology, and not on any quantum gravity.

The aim of theories of quantum gravity are just to give possible models that describe a possible quantum version of gravity, and mayme come up with additional fields.

Research on quantum gravity is mostly purely foundational research that deals more with mathematical consistency and mathematical innovations than phenomenology.

13. **Peter Woit**
June 8, 2009

Benni,

I don't disagree with you that string theory has nothing to say about particle physics (other than as a possible calculational tool in QCD). However, many of the people who work on the subject seem to think otherwise and disagree with you.

14. **Nige Cook**
June 8, 2009

'What is new here is the discovery that you can get "symmetry and elegance" at the opposite extreme: a theory which explains no observable phenomena using extremely complicated constructions. They couple this with a very powerful new principle of how to do science: just because a theory can't ever be tested doesn't make it any less likely to be correct. This principle has wide possible applications, promising to bring back together science and religion, healing the terrible split which occurred with Galileo.'

This humorous sarcasm is just not funny anymore, just sad.

15. **Marcus**
June 8, 2009

Nigel, your sadness surprised me, so I had to react. That passage made me laugh out loud. "healing the terrible split which occurred with Galileo" is perfect!

The tone is controlled for maximum effect. On occasion Peter gets it just right. Perhaps if we can laugh at the way this branch of physics is going, things are not so bad. I have the impression that you are sad because you are pessimistic about the decline of empiricism in theoretical particle physics. The decline in standards.

But other branches of science are quite healthy and that includes other types of physics (does it not? You may know better than I about that.) So be of good cheer. If I may venture a prediction, things will all turn out fine.

16. **Thomas Larsson**
June 9, 2009

This humorous sarcasm is just not funny anymore, just sad.

Not even fun.

17. **Chris W.**
June 9, 2009

Benni said: *Well, I do not think that it is important for a theory of quantum gravity, to make predictions at the TeV scale. Someone who is interested in predictions at the TeV scale should work on ordinary phenomemology, and not on any quantum gravity.*

Consider a rephrasing of this for an earlier era:

Well, I do not think that it is important for a theory of relativity that is consistent with Maxwell's electrodynamics, to make predictions at relative velocities small compared to the speed of light. Someone who is interested in predictions at these velocities should work with ordinary Newtonian kinematics and dynamics, and not with [Lorentz-invariant] relativity.*

I trust that the problematic nature of the second formulation is apparent. 🙂

———————
(* of necessity, an alternative to Galilean relativity)

18. **A.J.**
June 9, 2009

Well, I do not think that it is important for a theory of relativity that is consistent with Maxwell's electrodynamics, to make predictions at relative velocities small compared to the speed of light. Someone who is interested in predictions at these velocities should work with ordinary Newtonian kinematics and dynamics, and not with [Lorentz-invariant] relativity.*

Most models of quantum gravity — including the string theories Benni was talking about — predict that the effects of quantum gravitational phenomena at the TeV scale are negligible, just as relativity predicts minimal deviation from Newtonian mechanics.

If you want easy access to TeV scale phenomenology, quantum gravity isn't likely to help much, for the same reason that QCD doesn't do much for people studying solid state physics.

19. **Daniel de França MTd2**
June 9, 2009

Nigel Cook, if you look for research into Graphene in arxiv, you will see SciFi materializing in front of you.

20. **Coin**
June 10, 2009

NO! There is the SUBJECT "Field Theory" about the properties of different field theories. This is not the standard model, which is a, single, not family of, not class of, not generic, not a googol of, but ONE field theory. That's the theory.

Okay, so here's what I don't get.

Let's say the 4D string universality conjecture above turns out to be true, and every 4D SUSY particle theory has a compactified string theory equivalent. Let's say that we ignore the infinite landscape of theories this opens up, and pick a *single* one of these compactifications– let's say we arbitrarily pick a compactification that precisely corresponds to the MSSM.

It does seem basically impossible to go from this point to any new predictions about low-energy particle theory– our MSSM-string model will only give us the same predictions that the MSSM would if we were using field theory tools, by definition.

But, there is one difference, which is that our MSSM-string model will incorporate supergravity. Our MSSM-string model will necessarily include a graviton; and it's understood to be impossible to calculate anything concerning gravitons with field theory, whereas string theorists claim that under their formulation it *is* possible.

This means our MSSM-string model will allow us to do supergravity calculations in a setting where all the MSSM particles exist: we will have the ability to do all the low-energy things we could in field theory, since as 4D universality would tell us we can convert any field theory into a string compactification, and we will have new abilities at the SUGRA scale. Is this not useful?

21. **anon.**
June 10, 2009

Our MSSM-string model will necessarily include a graviton; and it's understood to be impossible to calculate anything concerning gravitons with field theory, whereas string theorists claim that under their formulation it is possible.

Nonsense. It's perfectly possible to calculate things involving gravity in field theory — that's what GR, or SUGRA, *is*. The difficulty sets in only (a) near the Planck scale or (b) in subtle situations like the correlations that encode information in Hawking radiation. We also know that super-Planckian scattering doesn't do much except make black holes, so there's some sense in which the only regime where quantum gravity could be probed is right in the vicinity of, but not much above, the Planck scale. (This is a little cavalier.)

22. **Peter Woit**

June 10, 2009

Coin,

The standard argument that string theory is “better” because it provides a consistent “ultraviolet completion” of a QFT has several problems with it:

1. It’s not true. Recall that we don’t know what non-perturbative string theory is, and we do know that perturbative string theory is not fully consistent. What is being sold as the new piece that will provide consistency is not a known theory, but an unknown one that is just conjectured to exist.

2. Such a supposed completion is not unique, you probably can come up with 10^500 of them. Not only do you get no predictions at 1 TeV, you get no predictions at any scale, since you’ve always got lots of possibilities.

3. Claiming that adding a complex superstructure that can’t be tested somehow is an improvement is just bad science.

What I really don’t understand about some string theorists these days is why they just can’t face up to standard scientific practice: if you pursue conjecture X and find that it is basically empty and can’t be tested, you admit failure and move on. You don’t start writing about “X universality”, promoting X as a great scientific success, an improvement over other ideas.

June 10, 2009

I enjoy lurking here and thought I’d venture a question:

Peter Woit says:
June 8, 2009 at 7:53 am

…a “theory which provides for the production of essentially all possible low-energy behaviors in some regime of the theory or region of the metaverse.”

I looked up “metaverse,” and found no physics references to this term, only references to a “cyberpunk fiction virtual world,” that is presumably emulated in Second Life, and such applications. Yet, the authors of the paper in question seem to be using it in a physical sense. Can anyone clarify? Are “metaverse” and “multiverse” being used interchangeably by some physicists?

24. **Peter Woit**
June 10, 2009

hrt,

In the usage of people interested in this, “metaverse” just seems to be a less popular variant of “multiverse”. I don’t know why these authors decided to use it.

25. **Markk**
June 11, 2009

Off the topic of this post but perhaps related. Have these papers
been causing any kind of stir around the theoretical physics community? They seem to be new or perhaps renewed approaches to unification with interesting fallout like inflation. Looking at these with limited understanding it seems like there are some promising approaches to larger scale theories. Hat tip to Ars Technica for their article. To this layman’s eye this seems vaguely related to things like the double relativity and such that have been around.

Nature Physics, 2009, DOI: 10.1038/nphys1298
PRL, 2009, DOI:10.1103/PhysRevLett.102.161301

PRL, 2009, DOI: 10.1103/PhysRevLett.102.221301

26. **Peter Woit**
June 11, 2009

Markk,

Yes, lots of people have started writing papers about this kind of quantum gravity model. Presumably it will soon get sorted out whether there’s a serious inconsistency in the idea. But even if it’s consistent, this looks to me like just one more untestable quantum gravity theory. It explains nothing about observable particle physics. For more discussion of it, best to find a blog run by someone with more interest in quantum gravity than me.

Latest From the LHC

June 9, 2009
Categories: Experimental HEP News

Last week was the annual Fermilab User's Meeting, for all sorts of interesting talks see here. These included a talk by Sergio Bertolucci giving recent news about the LHC status. This week CERN is hosting a CERN-Fermilab Hadron Collider Physics summer school, talks here, including one from Jorg Wenninger about the LHC status.

The main concern now involves bad soldering of some of the 1700 or so bus-bar inter-connections between magnets. One of these seems to have been at the origin of the accident last September. For the sectors (four of them) that are warm, such bad joints can be identified relatively easily, by their higher-than-normal resistance, and repaired. Unfortunately, for the four sectors that are now cold, identifying such bad splices is much more difficult. Warming up these sectors and cooling them back down is a time-consuming process that could significantly push back the LHC schedule.

Late last week the decision was made to start warming up sector 45. Measurements at 80K had identified 3 cases of anomalously high resistance. The plan is to warm up the sector, take measurements which can be compared to the measurements made when the sector was cool, and fix splices as necessary. For this particular sector, things can be rearranged so that warming it up and cooling it back down will not seriously impact the schedule.

For the other three cold sectors though, the situation remains unclear. They're gathering more data and analyzing it, trying to understand better what is going on, as well as analyzing the question of whether it's possible to go ahead and find ways to run the machine safely, even given the possible existence of somewhat iffy interconnections.

The latest version of the schedule, from mid-last week, has powering tests ending in mid-October. So, as long as it does not turn out to be necessary to warm up more sectors, late October is the time-frame for trying again to circulate a beam and begin beam commissioning.

Update: There's a video of Wenninger's talk last week available here, where he gave some more details in the question session afterwards. Sector 45 will be warm and ready for measurements next Monday (June 22). If the results show good correlation with what was measured at 80K, at the end of the month the temperature of the three remaining sectors will be stabilized at 80K and measurements will be made on those.

About the current schedule for when to try and circulate a beam, he says "I know that officially it's still September but I have problems to sell that…" with a better guess of sometime in October (assuming the three sectors at issue don't need to be warmed up). He also remarks that it will be a while (2012?) if ever before the machine operates at 7 TeV. 5 TeV is the likely energy at the beginning, with a possibility of going up to 6 TeV.

Comments

1. **DB**
   June 10, 2009

   Isn't is surprising that such a straightforward test, i.e., the test for anomalously high resistance wasn't part of the quality control procedure during the initial construction phase?
   Makes you wonder.
   I'm also surprised that it has taken so long to identify this issue. Had it been flagged earlier there would have been plenty of time to warm up the sectors, test and fix.
   Perhaps there is something I'm missing.

2. **Yatima**
   June 10, 2009

   >Perhaps there is something I'm missing.

   You are probably underestimating the vagaries of real-world engineering. Especially for "once-off" projects of high complexity, things are left out, checks are not made, problems are not considered due to failure of imaginations, paperwork is lost and of course short-cuts are made due to budget and time constraints. Moreover, a lot of the stuff being designed is bleeding edge, so you cannot just expect production-run quality in any case.

3. **Steve Myers**
   June 10, 2009

   How are these connections soldered? I am familiar with control & construction work from 5 VDC to 13000 VAC & know a good electrical tech can tell an "iffy" joint by just looking. Of course, a resistance test proves it.

4. **Vladko**
   June 10, 2009

   I'm wondering if they could use some kind of isolated thermal suits to go inside the cooled down areas and do the repairs. If people can repair the Hubble space telescope in orbit I would hope this to be a simpler operation.

5. **Peter Woit**
   June 10, 2009

   Vladko,

   My understanding is that the problem is that there is not yet a reliable way of figuring out which of the cooled-down interconnection might be problematic and need repairs.

6. **ObsessiveMathsFreak**
   June 10, 2009

   You'd think there would be a better way to do things by now. The idea of having to shut down the entire LHC for weeks to deal with even a slight error resembles a programming project in which the most minute change requires a complete recomplication. If the LHC fails again it's going to look very bad for the entire project.

   Whats with the cool down times anyway? How long are the times at other accelerators like the Tevatron?

7. **Tom Whicker**

June 10, 2009

These are not your ordinary solder joints! The interconnects are layered with alloys of platinum if I recall correctly. Modelling behavior as it is cooled may be a difficult problem.

As an aside, these are anxious times for any project that depends on quantities of PGMs. Take a look at the five year
chart for platinum:
http://www.kitco.com/charts/liveplatinum.html

8. **Yatima**
June 11, 2009

>>The idea of having to shut down the entire LHC for weeks to deal with even a slight error resembles a programming project in which the most minute change requires a complete recomplication.

You meant to say “recompliation” I suppose (note that recompilations indeed took significant time a few decades hence, when I first hit the keyboards, but today are measured in minutes, which is nice as we then get “continuous recompilation” and the attendant quality improvements – but that’s another story).

Your comparison is wrong of course – I would say you could compare the innocent-sounding “solder joint fixing” with opening up, reviewing and redesigning a sizeable part of a software architecture for an embedded system which in this case is partly live. Any prospect of doing that will put cause sweat to appear on any project manager’s brow.

9. **Yatima**
June 11, 2009

Ouch, I misspelled “recompilation”, too. I blame my lousy keyboard and the infuriatingly tiny blog text area!

10. **Tom Whicker**
June 11, 2009

I cannot now locate the info on PGM metal use in the LHC, other than the use of Platinum for the temperature sensors. Sorry for the mis-information.

But there are plenty of exotic alloys throughout the machine. In the interconnection assemblies alone there are some quarter million components!

The number of connections is given at 123,00: http://cerncourier.com/cws/article/cern/29012

11. **Steve Myers**
June 12, 2009

A note from February CERN COURIER: Meanwhile, work continues apace on the repairs at the LHC. At the end of January, a dipole from sector 1-2, which had been identified as having an internal splice resistance of 100 nΩ, was opened up after removal from the tunnel and was found to have little solder on the splice joint. It is likely that a similar small resistance was at the root of the incident in sector 3-4. The LHC teams can now detect a single defective splice in situ when a sector is cold and they have identified another dipole showing a similar defect in sector 6-7. This sector will be warmed up and the magnet removed. Each sector has more than 2500 splices, but the resistance tests can only be conducted on cold magnets. Three sectors remain to be tested: sector 3-4, where the incident occurred, and the adjoining sectors, 2-3 and 4-5.
Looks like standard splicing. And, yes, platinum & platinum alloy used in high temp thermocouples.

12. **Sorinis**
June 18, 2009

So no operations this year after all. I’m willing to wager that the other sectors will need to be warmed up. So all these articles talking about how the LHC will valiantly run through the winter are now moot. I see from the article that Peter is not convinced that the LHC will ever run at 7 tev. This project is deeply disapointing both qulitatively and quantitatively.

13. **Peter Woit**
June 18, 2009

Sorinis,

It still seems possible they will not have to warm up the other sectors, looks like we’ll find out within the next couple weeks.

From what I’ve read, getting all the magnets to reliably work at high
enough fields to do 7 TeV may never be possible, but maybe something like 6.5 TeV is, and the difference of .5 TeV is not of big significance.

I suspect that the LHC will ultimately be a significant scientific success, although it may be a public relations failure. Promoting the thing as possibly discovering extra dimensions, and making a big public fuss over it while it is still being tested and debugged (something that always takes longer than expected…) seems to me to have been a mistake.

14. **Tomatonator**
June 18, 2009

I know this may not help, but it took over two decades for the 200-inch Hale Telescope on Mount Palomar to be completed, and it turned out to be a pretty useful instrument for astronomy.

And then there is the Hubble….

15. **Sorinis**
June 18, 2009

Peter,

Would you at least agree that the design seems unsound. If you must spend months warming and cooling every time there is a bad wire you are looking at years of stoppages for every little flaw immaginable . . . like a bad wire. God forbid you get something major like the explosion that was not an explosion last year. If this were an airplane, many people would be dead by now.

16. **Sorinis**
June 18, 2009

With regards to my latest comment above. I know because it has been pointed out that even wires at the LHC are special and made up of gold and platinum and angel dust. But I cannot imagine a smaller increment of tecnology than a wire. Except perhaps a bolt. But I bet even bolts there are fashioned by the elves from precious metals.

17. **Peter Woit**
June 18, 2009

Sorinis,

It's not at all clear that the design is unsound. So far the fact that it takes time to warm up and cool down sectors has not been the main thing delaying them (rather it has been things like bad magnet support design, bad PIMS, bad splices). Their problems have been pretty much the kind of thing you would expect when you first try and run an extremely complicated piece of equipment that has never operated before.

It's not an airplane, it's a tricky piece of scientific apparatus, and its problems have put no one in physical danger. When the thing is running, people are kept far away, and it should be able to explode perfectly safely, if that's what happens.

String Universality Reloaded

June 12, 2009
Categories: Multiverse Mania

I still haven't figured out yet what the arXiv's trackback policy is, since trackbacks to my blog entries sometimes appear there, sometimes not. One example in the "not" category is my recent posting about the Kumar-Taylor paper on "String Universality", which now has trackbacks to postings by Jacques Distler (recently seen here) and Dmitry Podolsky. The ways of the arXiv remain mysterious, but I can't help recalling that my original problems with them seemed to have to do with powerful people who did not like having their multiverse pseudo-science disrespected. Even without the trackback, I'm wondering if the authors of the paper somehow heard about my comments and felt they needed to be addressed, since a new version of the paper has just appeared.

The most extensive changes are to the section on "predictivity" discussed in my posting. Here's some of the added text:

> It may be that string universality holds for four-dimensional theories with supersymmetry, but that supersymmetry breaking mechanisms lead to a constrained subset of non-supersymmetric low-energy theories in 4D.
>
> It is possible that the dynamics of string cosmology may define a natural measure on the space of string solutions, which would favor some solutions over others. Currently, however, we lack a mathematically complete or background-independent formulation of string theory. It is likely that significant progress in this direction will be needed to understand the cosmological measure on the string landscape. In this brief discussion, we describe the situation for predictivity in the absence of such a breakthrough.

Some other changes:

> This may seem like a very awkward situation for string theory.

has been replaced by

> If we were living in six dimensions, then this would seem like a very awkward situation for string theory.

and the assurance that string theory would explain anything seen at the LHC has been toned down a bit, with

> any new and unexpected phenomena found in experiments at higher energies should be realizable in the string theory context

replaced by

> any new and unexpected phenomena found in experiments at higher energies may be realizable in the string theory context

Comments

1. **Sakura-chan**
   June 14, 2009

   100% off topic, but when you search for "terence tao" on google, the two related search suggestions at the bottom are grigori perelman and not even wrong.

2. **Tom Whicker**
   June 14, 2009

   The comments from Clifford Johnson and Jacques Distler are defensive; at times almost desperate. The level of denial
   is palpable.

   Even though string theory is now more than 30 years old, Clifford claims that it cannot be questioned because it is still in naiscent form and must be protected from prying eyes:

   "The point, Peter, is that we don't know whether it is right or wrong either, nor what the outcome of the entire program of research will be, ultimately. But we're not (or at least, that large percentage of the field I know and trust) are not presuming the answer at the outset, like you are. That's why it is called research. We don't know.

   But next he turns 180 degrees and lambasts critics of string theory, saying they do not speak with enough detailed
   equations and scientific rigour:

   "So, Peter, come out from behind that silly figleaf and tell us: How is the actual scientific argument for your claims coming along then? Have you written a paper yet? Constructed a demonstration the community can discuss? Is anyone going to see it soon?
   Try to do some science, Peter. Please try. Back up your claims with science and not obfuscation if you want them to be taken seriously. Until then, you're wasting everyone's time."

   All the while Clifford proudly proclaims that he is just too busy to read either book from Woit or Smolin.

   The taunting, sneering tone from Johnson and Distler is something I haven't heard since teenage locker-room days.
   If this is what the world of academic physics has come to; I'm so glad I left that world some time ago!

3. **George Dorn**
   June 15, 2009

   I am also flabbergasted at the tone used by what would appear to be grown up people on various blogs devoted to what would appear to be science and scientific arguments. If nothing else going back and reading all this stuff has provided hilarious entertainment. I have always been a little sceptic when historic accounts of scientific breakthroughs presented the community as conservative and childishly clinging to old ideas but I must admit that it all seems so much more plausible in the light of all these exchanges.

4. **Peter Woit**
   June 15, 2009

   Tom Whicker,

One of the most surprising things to me about the "String Wars" has been the strange behavior of the few well-known string theory bloggers. Besides the Distler/Johnson business, there's always Lubos, whose activities (see next posting) seem to embody Hunter Thompson's slogan "When the going gets weird, the weird turn pro."

5. **Arnaud**
   June 15, 2009

   Is String Theory really 30 years old? That would mean papers before 1980?

   A.

6. **Peter Woit**
   June 15, 2009

   Arnaud,

   Work on string theory as a theory of the strong interactions started in 1970, as a unified theory including gravity 1974. It was only in 1984 that it became incredibly popular, once Witten started working on it. We're about to hit the 25th anniversary of that event…

7. **nbutsomebody**
   June 16, 2009

   Lubos is a lunatic, and right now he is somehow out of scientific community. His views may well be dismissed as paranoia. However I am shocked to see how comparatively well respected guys like Clifford Johnson etc behave towards criticism. It is really a shame to string theory community, a big shame.

8. **GR**
   June 17, 2009

   Ostensibly string theorists are funded by NSF-type grants, and apparently have been for the past 20 years… is there no one at the institutions that's asked for tangible results? Or is the problem that almost everyone in HEP theory these days is doing string theory?

   As a grad-school-bound student, I can safely say that the diatribes by people like Lubos and Johnson are a big turn off for theory in general and HEP in particular. I (naively and optimistcally) want to do science and discover something new and cool, not bicker endlessly about what the "right" way to do physic is. I don't want to immerse myself in what (again, from an outsider's perspective) looks like groupthink and wagon-circling.

   And I know most undergraduates feel the same way about string theory. We're not dumb, we read PT and blogs. In the end, string theorists might have doomed themselves through this nasty and childish behavior.

   Also, as a side note, what's with the proliferation of extra dimensions? What's the historical justification for this avenue of research? Has anyone ever been able to show something about 4D from all this n-dimensional balderdash?

9. **nbutsomebody**
   June 17, 2009

   "Has anyone ever been able to show something about 4D from all this n-dimensional balderdash?"

   No, not in anything related to unification and standard model.

   However there is something called holography. Which may help us to aspects of gauge theory like QCD.

10. **anon**
    June 17, 2009

    "We're not dumb, we read PT and blogs."

    You contradict yourself.

11. **Rhys**
    June 17, 2009

    "However I am shocked to see how comparatively well respected guys like Clifford Johnson etc behave towards criticism. It is really a shame to string theory community, a big shame."

    So because I'm studying string theory I should feel shame at the actions of others engaging in the same pursuit? That's absurd, but it is not unusual to see this attitude endorsed, implicitly or explicitly, in various blogs (posts and comments).

    But to comment in dot points on the actual subject matter of the post:
    – As Peter admitted, the paper has no bearing on models of 4D physics.
    – The paper seems only to deal with the low energy theory ('massless' fields, roughly speaking). Stringy signatures will always appear at the compactification or string scale.
    – Nothing seems to have been proved.
    – It would be worth working on string theory, as a theory of quantum gravity/geometry, even if it could produce all low-energy effective theories.
    – I agree that if the swampland is empty, low-energy model building from string theory is somewhat pointless.

12. **nbutsomebody**
    June 17, 2009

    Rhys,
    I agree to your physics points. However you said
    "The paper seems only to deal with the low energy theory ('massless' fields, roughly speaking). Stringy signatures will always appear at the compactification or string scale."
    This is not strictly true. It depends on the particular theory.

    "So because I'm studying string theory I should feel shame at the actions of others engaging in the same pursuit? That's absurd, but it is not unusual to see this attitude endorsed, implicitly or explicitly, in various blogs (posts and comments)."

If you are just “studying” string theory, you may not have to bother about them. However, if you are a “string theorist”, you may have to share a little responsibility. There is nothing absurd about it, your credulity and scientific standard is indeed judged (at least in part) by looking at the scientific community you belong to. Look these guys are not some nuts who are doing fringe science. They are the main stream guys. People read their papers, they arrange conferences, they have money to heir postdocs/visitors/students. They appear in front of press, they act as refree and the list goes on and on. Like it or not they are the spoke person for the community, hence if you belong to the community they speak for you too :(. Only way to get rid of this uncomfortable situation, I believe, is a overt opposition to their erratic behavior.

13. **Peter Woit**
June 17, 2009

Rhys,

What I find remarkable here are not the arguments over remaining hopes that string theory somehow can say something about particle physics, but the notion that “string universality” is somehow a positive thing, rather than a simple expression of failure. When an idea doesn’t work, you’re supposed to give up on it, not promote it as some new kind of science.

14. **anon.**
June 18, 2009

‘When an idea doesn’t work, you’re supposed to give up on it, not promote it as some new kind of science.’

As people keep pointing out, dogmatic belief systems with no evidence from start to finish like religions, don’t operate like rational science. When they fail to a achieve something, the failure is interpreted as a proof of decisive knowledge that it is impossible for anybody ever to achieve that thing.

E.g., if string theory can’t predict everything, then that’s not the failure of string theory. It’s proof that nature is simply not predictable. Don’t you see that, you fucking moron?

15. **Mitch Miller**
June 18, 2009

Peter,

I apologize in advance as this is pretty far off topic, but I have a question on the slides that you posted on the other thread. On slide 30 you say that violations of WW scatering at the LHC could actually be good for string theory, I don’t see how that is possible. The standard model is already falsified because of gravity, what is not known is the energy scale at which naive GR+SM stops being valid. If violations are found, it seems like string theory would be dead since AFAIK string theory can’t handle Lorentz breaking at this (possibly any?) scale or unitarity/analyticity breaking.

I think I agree with the spirit of what you are saying, this is sort of lame as a test of ST since it is such a long shot to begin with but I’m not sure if I am missing something else. And feel free to ignore/delete if too off topic. Thanks.

16. **Peter Woit**
June 18, 2009

Mitch,

The only point I was trying to make was that the claim made in that case about a test of string theory was actually about a test of basic QFT axioms. There was an argument on various blogs about this way back when, but it still seems to me that a Lorentz-breaking string theory ground state is possible. Unlike QFT, you don’t have a non-perturbative definition, or agreed upon axioms.

As a matter of sociology, I am quite convinced that if the LHC sees something that violates QFT axioms, this will be touted as evidence for string theory…

17. **Mitch Miller**
June 18, 2009

Thanks, that clears it up. It will be very interesting to see how people react if something crazy actually does happen at the LHC.

La Tête dans les Étoiles

June 15, 2009
Categories: Uncategorized

This past weekend the city of Villeneuve-sur-Yonne organized a science festival entitled La tête dans les étoiles; les pieds sur terre! It featured Lubos Motl speaking on "Physics at the Planck Scale", and the Bogdanoff brothers on "The Beginning of Time".

Comments

1. **Arnaud**
   June 15, 2009

   Well, I'm not sure if you posted that in jest, Peter?

   I am slightly ashamed at a town in my country of origin putting on such a mish-mash, looking at the program, Lubos is mixed with a farmer's market and wild bird conservation society. I think rather than hear the Bodganov I'd prefer to join the "cheese workshop"! Then again, Villeneuve sur Yvonne is hardly a hotbed of scientific debate…
   I think you previous comment about weird and weirder hits the mark.

   What you won't know is that the infamous Brothers used to present a science and SiFi kids show on French TV in the 80s, which I used to love, as well as I (probably) a good portion of the Gallic physicists currently using your site. I suppose that's one of these embarassing childhood stories they tell at weddings.

   How on Earth did you find out about this anyway? too much time on your hands, mate.

   A.

2. **Peter Woit**
   June 15, 2009

   Arnaud,

   I've been following the activities of the Brothers for quite a few years ago, and quite a few people have told me of their fond memories of the TV series.

3. **theoreticalminimum**
   June 15, 2009

   It's funny Lubos still hasn't stopped being a Harvard professor. Makes me smile. Thankfully the kids were already half asleep by the time he and the crackpot brothers gave their talks, and obviously Hubert Reeves would have made the biggest impression (although I am intrigued how he could have got involved..).

4. **Chris Oakley**
   June 15, 2009

   > … wild bird conservation society

   Maybe they are the ones who invited Lubos.

5. **John Baez**
   June 16, 2009

   Is this their only performance, or have they teamed up to form a kind of traveling circus? Does anyone know? I'm in Paris for two months — it might be fun to see them if they come to town.

6. **MathPhys**
   June 16, 2009

   Are the B Brothers heavy users of plastic surgery? or is it the Elephant Man syndrome?

7. **Peter Woit**
   June 16, 2009

   Hi John,

   I don't know about any more appearances, but the new Bogdanov book
   "Au Commencement du Temps" is coming out tomorrow.

   And on Saturday at 3:20pm, the France 3 channel is having a program about the Bogdanovs, with them interviewed in their Paris "gothico-medieval" home.

8. **Fabien Besnard**
   June 16, 2009

   Arnaud, that's Villeneuve-sur-Yonne… Villeneuve-sur-Yvonne probably hosts other kinds of shows…

9. **observer**
   June 16, 2009

   Never more appropriate the saying " …This is a place for everything and every thing will fit in its place". weird at best.

10. **Cormac O Raifeartaigh**
    June 17, 2009

That was I call a neutral post. Magnificent restraint…

11. **YBM**
June 21, 2009

Would you believe this, Peter (I guess you did): again, there is a lot of "quotes" of you in their book.

What's hilarious is that they now present themselve as mainstream string theorists, quoting t'Hooft and Witten at every page.

12. **Peter Woit**
June 21, 2009

Thanks YBM, I'll have to at some point get a copy and find out what I have to say about the Bogdanovs. If it's anything positive about their research, it doesn't correspond to my actual views.

I see from the publicity for their book that

"ils enseignent la physique primordiale à l'université Megatrend de sciences appliquées de Belgrade."

so I guess they're no longer in Riga (where I'll be visiting in a couple weeks) at the "Mathematical Center of Riemannian Cosmology"

http://phys-maths.edu.lv/

Funny, but the web-site of Megatrend University

http://www.megatrend.edu.rs/vest_strana.php?v=806&language=1

seems to think that they're professors at Bourgogne University…

13. **YBM**
June 21, 2009

I doubt that they are actually teaching there, anyway they are registred there, but, as you noticed, it's a plain lie to present themselve as professors from Bourgogne Univ.

Megatrend is not a real university, it's a private school of economics with a bit of engineering. By chance it happens that its director is the translator of the serbian edition of "Avant le Big Bang".

Same dirty old tricks as usual. These days in France, the Bogdanov are playing a lot with policital influence (they are members and have responsabilities in the presidential party, they get a new TV show on the main public channel by direct order from the french presidency, etc.)

As disgusting as ever…

Summer Programming

June 18, 2009
Categories: Uncategorized

As far as academics are concerned, summer has started, which means that there are lots and lots of conferences going on. The past couple weeks we've had two here in the Columbia math department, one in algebraic geometry, and another covering various related topics in hyperbolic geometry and knot theory.

Next week 450 or so physicists will gather for the big annual string theory conference, and a couple weeks ago there were more than 400 participants at the big annual SUSY conference, SUSY 2009. For more on this, see reports from Jester and Sabine. Jester's take on the conference included:

> Over 400 participants, not counting squatters. 42 plenary speakers, most of whom witnessed the glorious days when supersymmetry was conceived. Seven parallel parallel sessions to cover every aspect of supersymmetry that has not yet been covered thoroughly enough. Royal coffee break menu fully adequate to the royal conference fee. And so on and on since 16 years and into the future.
>
> Meanwhile, there is no single hint from experiment that supersymmetry is realized in nature… but that should not upset anyone. As my fellow blogger skillfully put it, supersymmetry is the "shining beacon", the "raison d'etre" and for this reason "the conundrum is how it will be discovered, not if". That's why every year we come together to enjoy old familiar faces and old familiar talks. The point is, while waiting for the inevitable, to maintain that kind of spirit that David Lodge praised in his books.

At Santa Cruz this week, there was a conference in honor of the 60th birthdays of Tom Banks and Willy Fischler, blogging from David Berenstein.

At Penn there's a summer school on Geometry of Quantum Fields and Strings, blogging at Rigorous Trivialities.

On the multiverse front, Thibault Damour has a survey article about constancy of physical constants, where he makes the reasonable argument that checking such constancy is one of our few ways of getting insight into the origin of these parameters of physical theory. Sometimes you see the claim made that string theory predicts time-dependence of constants (since they are moduli parameters), other times the claim is made that string theory does make one prediction, that such constants won't change (due to energetics of the landscape). Damour summarizes this as

> However, there is no firm prediction for the observable level of EP violation. Actually, the current majority view about the "moduli stabilization" issue in String Theory is to assume that, in each string vacuum, the coupling constants are fixed by an energy-minimizing mechanism which is generically expected to forbid any long-range violation of the EP. This, however, makes EP tests quite important: indeed, they represent crucial tests of a widespread key assumption of string-theory model building. This exemplifies how EP tests are intimately connected with some of the basic aspects of modern attempts at unifying gravity with particle physics. Some phenomenological models (inspired by string-theory structures, or attempting to understand the cosmological-constant issue) give examples where the observable EP violations would (without fine-tuning parameters) be just below the currently tested level.

The "string universality" principle discussed here recently is related to Leibniz's "Principle of Plenitude":

> all logically possible "things" (be they objects, beings or, even, worlds) have a tendency to (and therefore must, if one does not want contingency – be it God's whim – to reign) exist.

So, experimental measurements are important not because they can tell us whether string theory is right or wrong, but because they can tell us which kind of string theory is right….

The latest Seminaire Bourbaki was last week, here's a summary of the talks. Edward Frenkel has posted his survey of Gauge theory and Langlands duality on the arXiv.

Earlier this week I learned from my colleagues one obscure piece of mathematical culture that I had been unaware of. Physicists have the famous story of how Alpher and Gamow brought in Bethe as co-author to improve the author list, but it turns out that mathematicians have a somewhat different story of this kind. At lunch one eminent algebraic geometer started snickering when someone (using standard terminology) brought up the well-known ring associated to an algebraic variety due to David Cox. At this, it was pointed out that Cox was co-author of a famous paper with Steven Zucker, and the story goes that this came about because Cox had decided once he heard of Zucker that a Cox-Zucker paper just was asking to be written. A supposedly authoritative source on the internet claims:

> Cox and Zucker were admitted as grad students to Princeton in precisely the hope that they would someday collaborate. This kind of forethought is why Princeton is Princeton.

For a related mention of this, see the Journal of Improbable Research.

Comments

June 19, 2009

My english is not good enough to understand why "Cox-Zucker" is funny, can somebody please explain?

9. **!!**
June 20, 2009

> funny, can somebody please explain?

If you read it backwards you'll notice an allusion to an old Yiddish joke first quoted in English by Shakespeare.

10. **Peter Woit**
June 20, 2009

?,

Here's a hint: everyone who tried to explain this explicitly here had their comment intercepted by the automatic spam detector.

Beyond that, I'm not convinced that your English is really that bad…

11. **Henry Tucker**
June 22, 2009

Felipe, where can one find scans of those Princeton entering mathematics graduate student group photos? I've seen them around the web and have been curious.

12. **Felipe Zaldivar**
June 22, 2009

Hi Henry!

I found that one picture when looking for something else at the "Hopf Archive", a site created by Clarence Wilkerson with news and an album of photographs of fellow algebraic topologists, but I don't think that there are more of those "entering class photos" in that site: http://hopf.math.purdue.edu/

News from CERN, Witten Interview

June 18, 2009
Categories: Experimental HEP News

The new CERN Bulletin is available, and it contains a link to a recent video interview of Witten, who has been visiting CERN during the past year.

Some other things in this issue:

- Bill Gates recently visited the LHC, bringing his son Rory. Gates announced:

> I just bought the rights to the Feynman 'Messenger Lectures' that he gave in Cornell in the 1960s. The BBC filmed Feynman giving what I think are the best physics lectures I have ever seen. So we are going to make these lectures free for anyone to watch.

- There's news about the LHC restart here and here, including the warming up of sector 4-5 discussed in postings here recently. Here's what Director General Heuer has to say:

> The bottom line is that we remain on course to restart the LHC safely this year, albeit at reduced energy.
>
> A tremendous amount of work has been done to fully understand the splices in the LHC's superconducting cable, one of which was the root cause of the incident last September that brought the LHC to a standstill. We've learned a great deal. It's mostly good news but there's also plenty of food for thought. The good news is that all the measurements done so far indicate that we will be ready by September or October to run the LHC safely at around 4-5 TeV per beam. If new evidence appears in the meantime to suggest otherwise, we'll modify the energy for this year's run accordingly. The food for thought is that the same tests tell us that before we can run safely above 5 TeV, more work is needed, and this will be carried out in a shutdown starting in Autumn 2010.
>
> Many of you will have heard, or seen on the LHC web pages, that we're warming up sector 4-5. This sector can be warmed and re-cooled within the time remaining before we inject the first beam of 2009 into the LHC, and doing so will give us increased confidence that we fully understand the splices. We're warming up this sector because we have developed a new non-invasive technique for investigating the splices. The sector has been measured at a temperature of 80K, indicating a suspect splice or splices. By warming the sector, the results of the test can be checked at room temperature, thereby validating the procedure at 80K. If the 80K measurements are validated, any suspect splices in this sector will be repaired.

From this, it sounds like the current plan is to not wam up the cold sectors, but reach a decision on what the highest energy they can safely run at in case of a quench, given their understanding of remaining problems with bad splices. This might mean running below the planned 5 TeV/beam.

- On July 1 CERN will be providing training for its employees on how to deal with the press.
- On July 2 there will be a talk by Steve Myers on the LHC status

Update: While the CERN DG indicates readiness of the LHC for start-up in "September or October", the most up-to-date schedule (which somehow came into my possession this morning…) shows powering tests in sectors 4-5 and 8-1 going through the end of October, so machine checkout and first beam not until the beginning of November.

Update: There's now a press release. According to this, they are now planning to start up at some energy in the range 4-5 TeV, currently 2-3 weeks behind schedule (so start-up second half of October).

Comments

1. **chris**
   June 19, 2009

   very interesting

   the marketing speak they adopted (good news vs. food for thought) and also the ever so slightly decreasing beam energy (4TeV now – what will it end up being?) and slipping schedule (first beam end of december as it seems).

   maybe it was not such a good idea celebrating September 10 2008 so publicly. or is Holger Nielsen right after all?

2. **Sorinis**
   June 19, 2009

   Chris

   It might end up beeing the same energy as the Tevatron. Wouldn't that be funny? It is also interesting that Peter has seen the latest schedule but Heuer somehow has not. Makes you wonder about the lax attitude at CERN. I think you are right. CERN has a long history of declaring success before even operating. We've gone from discovering all the secrets of the universe including extra dimensions to a really humiliating media spin about a freefloating schedule and ever decreasing energies.

   They may have lectures on dealing with the press but you can't put a positive spin on this.

3. **Cplus+**
   June 21, 2009

   le Déluge commence.

   From Luca Trevisan:

   "Two days ago, the Chancellor announced that because of the cuts expected as a consequence of the state-wide budget crisis, UC Berkeley needs to cut about $100 millions. Next year, we should expect a complete freeze on hiring, layoffs of administrative staff, strong cuts to student aid, increased tuition, and salary cuts of 8%. For 2010-2011, rumors are that the sun will go dark, it will rain blood from the sky, and then the locusts will come and eat us alive. Unfortunately, 2011-2012 will be much worse…"

   If the markets resume their decline during the next two years, nearly all the University Endowment funds, which to date have been only badly damaged, will be unable to contribute to cover operating expenses and the non-public universities will experience the same or posssibly worse.

4. **Thomas R Love**

I was happy to hear that Gates will make Feynman's Lectures available. Our library has them on film but the film is in very bad shape. It will be a pleasure to watch them again but without having to change the film reels!

Manufacturing universes in a fractal multiverse

June 21, 2009
Categories: Multiverse Mania

I gather that the World Science Festival here in New York a week or so ago was a great success, although I was out of town for most of it. The one part of the program I was dubious about (Infinite Worlds) seems to have come off even more one-sided than planned, since David Gross couldn't be there.

There's a report on this at Ars Technica from someone who was sitting near Cameron Diaz while watching the program. Philosopher of science Nick Bostrom did point out the obvious, that for the multiverse to be science it has to predict something. Someone seems to have convinced the author of the piece that there actually is such a prediction:

> Early in our Universe's history (before the mulitiverse's inflation pulled things apart), it was possible that the Universe bumped into a neighboring one. If that's the case, there should be remnants of that event buried in the cosmic microwave background. Less than a month from now, the ESA's Planck mission should arrive at the L2 Lagrange point with instruments sensitive enough to pick up this signal.

So, I guess in a couple years from now, we'll know if there is a multiverse or not…

For another report, see here.

Sean Carroll reports here on some other parts of the festival, including the panel on Time Since Einstein, where he explained to the audience that "the fact that an a splattered egg cannot turn back into a pristine unbroken egg is the best evidence we have that we live in a multiverse."

Comments

1. **milkshake**
   June 21, 2009

   regrettably, Dr. Carroll cannot take back the splattered egg remark because it would collapse our multiverse

2. **ManyMe**
   June 22, 2009

   I think the nonsense of Sean Carroll is the best proof for the multiverse.

   If there is only one universe, it would be very unlikely that it contains physicists who make such statements.
   It is much more likely that there is a large number of universes with silly physicists trying to explain eggs and such – and we just happen to be the one with Sean Carroll in it …

3. **bjm**
   June 22, 2009

   It seems to me that whenever nature is able to do something, it does it more than once.

4. **Tim**
   June 22, 2009

   Is there a reference to a paper to back up Sean Carroll's claim?

5. **Peter Woit**
   June 22, 2009

   Tim,

   There's a paper with a student from 2004, extensive promotion of the idea in Scientific American and elsewhere, and he's writing a book on the subject. There are some links here:

   http://www.math.columbia.edu/~woit/wordpress/?p=689

6. **Tim**
   June 22, 2009

   Hello Peter,
   thanx for the link, unfortunatly I did not really understand the paper by Collins/Chen, but I think I understand now a little better the motivation of Lubos Motl to write in one and the same sentence about a paper "I don't understand it, but I am absolutly shure it's crap" as he does time and again in his blog…

7. **Tomatonator**
   June 22, 2009

   I am amazed at how catty scientists can get regarding each other and their work.

   I guess you are all human, too.

8. **Peter Woit**
   June 22, 2009

   Tim,

   I think I understand the paper, but just don't see how it adds up to a scientific explanation of anything. I see that Sean has a website up for the book

   http://preposterousuniverse.com/eternitytohere/

including a copy of the book prologue

http://preposterousuniverse.com/eternitytohere/prologue.html

where he quotes the reaction of one physicist to a talk of his about this, a reaction which I'd guess is pretty common.

The main problem I see here, with much of the multiverse stuff, including Sean's, is that extremely speculative ideas that most physicists don't think deserve to be called science are being heavily promoted to the public, often in a misleading way. There was always a bit of this problem with string theory, but this is far worse.

9. **Arun**
   June 22, 2009

   …"the fact that an a splattered egg cannot turn back into a pristine unbroken egg is the best evidence we have that we live in a multiverse."

   Since the microscopic laws of physics are (effectively) time-symmetric, all that I come up with is that there are far fewer initial conditions where splattered eggs unsplatter than where splattered eggs remain splattered. This is a fact independent of cosmology. Whole pristine eggs do not arise from a process of unsplattering, other methods are far more probable.

   I need to broaden the question – "explain a universe in which eggs and observers like myself can arise", before there is a mystery. It remains a mystery. But it is an even deeper philosophical mystery as to how postulating an infinite number of other universes so that the asymmetry in initial conditions can somehow be erased*** constitutes an explanation.

   *** The fact that there are far fewer initial states that lead to splattered eggs unsplattering than initial states where splattered eggs remain splattered is simply a matter of counting and so remains true in each universe in the multiverse.

Templeton Foundation Strategy and Planning

June 22, 2009
Categories: Multiverse Mania

Most physicists are rather dubious about whether "multiverse" research is deserving of any support since it's not clear that it is even science. Because of this, such research has been finding financial support in recent years not from conventional sources like the NSF, but from the Templeton Foundation, a very wealthy organization devoted to the goal of bringing together science and religion. Some examples of this funding include the World Science Festival program mentioned in the last posting, and the Foundational Questions Institute, which provides grants, many of them for multiverse research.

I'd always wondered if there was some kind of organized effort by Templeton to push this kind of research, and and got a partial answer to this question recently when I took a look at some of their web-pages. Last year they organized two days of conferences at the Royal Society in London, associated with their choice of cosmologist and Catholic priest Michael Heller for their 2008 Templeton Prize of a million pounds. The preparatory readings page of the second day's conference provides a link to a document entitled Towards the Establishment of the Philosophy of Cosmology at Oxford. There's also a link to "Password Protected Papers" on the topic of Toward a New Philosophy of Cosmology, but these papers aren't really password protected since the password ("multiverse") as well as the user name ("universe") are given right next to the link.

If you follow this link, you are taken to the web-site for "A Strategy and Planning Workshop of the John Templeton Foundation", held in May 2007 at the Royal Society. The purpose of this workshop is described as:

> To bring cosmologists and philosophers together to review the 'state of the field' of the philosophy of cosmology and to explore the most effective ways of developing and enriching the philosophy of cosmology. How might the John Templeton Foundation contribute to field development?

and here are some other extracts from that page:

> The John Templeton Foundation would like to help develop this field. We are considering the creation of substantial research support opportunities in the philosophy of cosmology. In addition, our expectation is that there is some need for infrastructure, and the Foundation would be interested in helping to support development of a suitable context for a flourishing field….
>
> …the afternoon session, a discussion of strategy for field development. The Foundation is serious about providing resources if we can find a strategically-effective plan to make a difference.

This afternoon session was described in the program as follows:

> *Goal*: Finally, we explore what is needed to develop the field of philosophy of cosmology in a dramatic way over the next decade. Our initial thought is that the field needs some infrastructure development as well as basic research support. Because this work must bring together such disparate fields, it is not easy working through basic university structures. It may be that beyond core research projects, we need to support the creation of major long-term initiatives or centers, and help establish training for a new kind of scholar as well as faculty positions and perhaps other elements of infrastructure such as book series or a journal to take two common elements of the scholarly enterprise. Also needed, perhaps, are ways of making it more visible to the public in ways that improve on current popular presentations.

The afternoon talks were by Priyamvada Natarajan, a Yale astrophysicist described as "currently a member of the advisory panel for the Dialogue on Science, Ethics, and Religion of the American Association for the Advancement of Science (AAAS) and has an abiding intellectual interest in understanding issues in spirituality and science", and 2004 Templeton Prize winner George Ellis who is described as "co-author of *On the Moral Nature of the Universe: Theology, Cosmology, and Ethics"* and "editor of the *Far Future Universe: Eschatology from a Cosmic Perspective*." The respondent was the Reverend Keith Ward, described as "his main work is a four-volume comparative theology from OUP", and "His most recent book, published in 2006, is *Pascal's Fire – religious understanding and scientific faith*." The evening program was devoted to a celebration of Bernard Carr and the book based on three Templeton-funded conferences that he edited, Universe or Multiverse?

In a whitepaper prepared for the strategy session, Carr argues not just for the anthropic principle, but for the necessity of a "new science":

> In one sense the current debate today about the scientific status of M-theory and the multiverse proposal is nothing new. We've seen that progress on the outer and inner fronts has always been controversial, so perhaps history is just repeating itself. However, there is another sense in which the current situation is very special. This is because today — for the first time — the boundaries at the largest and smallest scales have connected. They are unified through quantum gravity and so the two science/philosophy frontiers have merged.
>
> One might argue that this merging represents the completion of the scientific process. This is why the symbol of cosmic uroborus is so powerful: it represents both the evolution of our knowledge of the universe and the triumph of physics in producing a unified view of the world. Have we therefore reached the endpoint of science just as the macroscopic and microscopic frontiers merge? I doubt it. Personally I believe this merely represents a transformation in the perceived nature of science.

He then explains why Templeton money is needed:

> Whether one redefines science to include exotic new ideas is not just a semantic issue. It also has practical implications because research in topics deemed to be "unscientific" is unlikely to be funded through the usual channels. For example, even in my own field, I have sometimes found that I cannot obtain a grant for a research project because some funding council has changed the definition of what constitutes "astronomy". There will always be research areas (especially cosmological ones) which straddle the border between science or philosophy and this is why JTF's initiative to support such areas is so important. It can promote or nurture ideas which have not yet been accepted into the world of legitimate science.

Carr is a past president of the Society for Psychical Research, and in its proceedings recently published a paper entitled *Can Psychical Research Bridge the Gulf Between Matter and Mind?*. In the white paper he advocates the idea that Consciousness is somehow part of this new science:

> Another feature of the new paradigm – and here I am definitely venturing beyond the boundaries of current science – is likely to be mind. One feature of the Universe which is noticeably absent in the current paradigm of physics is consciousness….
>
> …even the mention of the C word was taboo until recently. On the other hand, one might be sceptical of physicists' claim to be close to a "Theory of Everything", when such a conspicuous aspect of the world is neglected.
>
> Certainly physics in its classical form cannot incorporate consciousness….
>
> But what has this to do with cosmology? At first sight, developments in cosmology and particle physics might appear to have diminished the status of mind. The more we understand the Universe, from the vast expanses of the cosmos to the tiny world of particle physics, the more irrelevant humans (and hence minds) seem to become. Curiously, however, in recent decades cosmology has brought about a reversal in this trend, suggesting that mind may be a fundamental rather than incidental feature of the Universe. I'm referring here primarily to the Anthropic Principle…

He ends with some comments on theology, beginning with:

> Of course, most scientists are even more uncomfortable straying into the domain of theology than philosophy, so the G word (God) is usually regarded as even more taboo than the C word. However, since science seems to be coming to terms with the A and C words, perhaps the same will happen with the G word. Maybe there is a gradual process of desensitization in which the A, C and G words become successively accepted!

The whitepaper by Ellis deals with the crucial question of whether untestable speculation is science:

> There is also a reverse flow, whereby the development of the philosophy of cosmology – pushing the philosophy of science to its limits – may well have useful influences in wider realms of philosophy. Indeed it must be so, as cosmology helps us understand the nature of being human by clarifying the overall physical context through which we come to have our existence. So a useful part of the whole enterprise may be to try to develop that link: the different ways in which our understanding of the universe helps shape our views of humanity, and the ways that the philosophy of cosmology may help shape the philosophy of science. This may be particularly useful in terms of those aspects of physics which also face problems of testability for fundamental reasons, and so where some physicists are proposing to lessen the degree of rigour usually demanded in a scientific proof, decrying usual scientific criteria of testability as they do so (string theory comes to mind).

The whitepaper of Simon Saunders is an earlier version of the proposal for a new Oxford program available on the 2008 conference site. It proposes a new masters level 2 year course in philosophy of cosmology, with Templeton funding 2 3-year postdocs, a 5-year research fellow, a visiting scholars program, buy out time for those teaching in or administering the program, and funding for fellowships for graduate students. He also proposes to spend about 20,000 pounds a year on an outreach program to promote "philosophy of cosmology" in schools.

I haven't seen any evidence that this planning and strategy session led to anything. For one thing, there does not seem to yet be a "Philosophy of Cosmology" program at Oxford, although perhaps Templeton will at some point fund such a thing. But, this session does give a good idea of where some people would like to take theoretical physics, and indicates Templeton's interest in the idea of heavily funding ventures to promote such a "new science".

On a somewhat related note, see today's PZ Myers posting entitled [The name "Templeton Foundation" needs to become a mark of failure](#).

Comments

1. **Matt Leifer**
   June 22, 2009

   Hmm. I do actually think that developing the philosophy of cosmology is a good idea, but not if support for the multiverse is taken as a foregone conclusion. We need people who are willing to engage in a thorough criticism of these ideas as well.

2. **Tony Smith**
   June 22, 2009

   Peter, about Templeton and FQXi and the multiverse,
   you mention "… the Templeton Foundation … funding … the Foundational Questions Institute [FQXi] …"
   and
   the FQXi web site (including blog entries by Anthony Aguirre, who appears to be an official FQXi spokesman regarding the essay contest) says in part:
   "… FQXi Essay Contest …
   The theme for this Essay Contest is:
   "What is Ultimately Possible in Physics?" …
   the challenge will be to maintain high relevance by focusing on *ultimate* possibility …
   the focus of these essays should be
   more about physics and what is ultimately possible *in physics*
   rather than what is ultimately possible *using physics*, i.e.
   technologically attainable in some way
   …
   an essay that is centrally about how a multiverse limits physics ultimate predictive power — or doesn't — would feel … relevant
   …
   Entries will be accepted from May 15, 2009 to October 2, 2009
   …
   This forum category will contain discussions of essays submitted to FQXi's 2009 essay contest. Please check back in early June to join the discussion! … There are no topics yet in this category. [as of Monday 22 June 2009 around 5:30 PM EDT] …".

   It seems interesting that even well after early June has come and gone,
   and well over a month after the essay contest opened on 15 May 2009,
   and even though FQXi's spokesman explicitly approved the topic
   " … about how a multiverse limits physics ultimate predictive power — or doesn't …"

   there are NO essays on that (or any other, for that matter) topic on the FQXi Forum web page where they are supposed to appear for discussion.

   Does that mean that few essays have been submitted
   or
   does that mean that FQXi is having difficulty screening/refereeing submitted essays to ensure that they "… explore the most effective ways of developing and enriching the philosophy of cosmology …"
   and "… to promote such a "new science" …"
   ???

   Tony Smith

3. **Peter Woit**
   June 22, 2009

   Tony,

   I have no idea how FQXI is dealing with their essay contest, you have to take that up with them, not here.

4. **Eric Habegger**
June 22, 2009

Even though the multiverse idea seems intrinsically silly I actually don't think the idea of developing a philosophical structure that accompanies some of our newer knowledge is a bad idea at all. For instance, I think people should understand that the multiverse idea is an essentially amoral concept. That is, it projects that anything that has a probability of occuring "does" occur, even if not in our universe. Supposedly it occurs with a statistical rate that coinsides with the initial probability.

But the whole idea gives one, if one chose to, the ability to rationalize doing bad things because someone will commit that abomination somewhere. So it gives the excuse that you can do anything you want if it will give you an advantage. I think besides being a really stupid idea the multiverse is an essentially destructive philosophical stance. I think everyone should understand that.

I am much more comfortable with one universe, one event occuring out of the initial probability of events, and a world which can be better or worse for that event happening. It gives all of us a responsibility for living a life that will provide a better world in the future.

5. **Peter Woit**
June 22, 2009

Matt,

If people want to discuss the "philosophy of cosmology", that's fine, but they should do it as philosphers, according to the intellectual standards of philosophy. The problem is that there are quite a few physicists, some motivated by a need to find some way to avoid admitting that string unification has failed, who want to engage in something that is not science, claiming it to be a "new kind of science". Unfortunately, the Templeton organization seems interested in funding and encouraging this (or maybe not, maybe the "planning and strategy" workshop convinced them that this would be a mistake…).

Eric,

An excellent example of something which is not science and has no place in a science department.

6. **David H. Miller**
June 22, 2009

Peter, you said:
>If people want to discuss the "philosophy of cosmology", that's fine, but they should do it as philosophers, according to the intellectual standards of philosophy.

Putting all flippancy aside (a bit difficult in this area!), are there really any "intellectual standards of philosophy" generally accepted among academic philosophers?

Can the pomo folks, any lingering existentialists, the growing group who hark back to the ancient Greeks, the old "analytic philosophers" of the twentieth century, and the few philosophers who have some literacy in science really agree on any intellectual standards at all?

Don't get me wrong – I respect and like personally some individual philosophers. For example, I am friendly with Colin McGinn, even though Colin is more pessimistic than I about solving the problem of consciousness. Colin tries to seriously learn about science before he comments on it, he separates his own speculations from established science, he adheres to standard norms of reason and evidence. He's a good guy, even if you disagree with him.

But I am doubtful if he is the norm among contemporary philosophers.

Of course, I suppose this goes back to your ongoing central theme, Peter: science has outstripped other intellectual disciplines by adhering to one central rule – our speculations have to be checked by experiment.

Take that away, and chaos looms.

Dave Miller in Sacramento

June 23, 2009

So, why do religious people like Templeton believe in a multiverse? Where does the Bible talk about it?

8. **cos**
June 23, 2009

Maybe they just view it as solidarity among faith-based ideologies.

9. **Tim Solton**
June 23, 2009

Anybody who has ever tried to write down a definition of the term `universe' will see that his definition does not allow him to define the word `multiverse'.

It is a bit like first saying `everything' and then saying `even more everything'.

I find it appalling that a person with high school degree is not ashamed to use such words. But, "ex falso quodlibet". Maybe that is the real motto of the Templeton Foundation?

Tim

10. **asdfasf**

"Philosophy of science is about as useful to scientists as ornithology is to birds."

11. **Tim vB**
June 23, 2009

Hello,
actually there is already a very nice work addressing the program of the Templeton Foundation, see "The Physics of Christianity" by Frank J. Tipler. He has a nice proof of

the existence of god using cosmology and some concepts from QM/QFT, it basically goes like this:
The universe will collapse (big crunch), all intelligent live forms will unite in the process to form one entity, called the omega point. The heating universe will then fuel the ability of the omega point to process information, so it's intelligence will diverge to infinity. Now imagine that your brain could process information twice as fast as it does now, that would mean you would have twice as many thoughts per second than you have now. Tipler's hypothesis is, that you would experience a second therefore as twice as long as you do now. For the omega point this means that, while the (proper) physical time of the existence of the omega-point is finite, it's consciously experienced time will be infinite since it's information processing ability will diverge. Note that the concept of "time as experienced by a consciousness" does not correspond to any concept of time as an observable in conventional physics, so we really are expanding physics as a science in one of the direction the Templeton program would like to.
Now, what does the omega point do with his abilities? It will of course emulate everything that ever existed before in the universe, including you and me (our original selves are probably long dead and gone by then).
Since QM says that identical systems cannot be distinguished, an emulation of you cannot be distinguished from you, so it is really you. So you and me will be resurrected by the omega point, and be judged by it (why that necessarily happens escapes me at the moment, but hey, I read the book some 15 years back).
So here we arrive at god and judgment day by scientific reasoning.
Tipler doesn't use any stringy concepts, so you could probably throw in some stringy buzzwords and resell the theory to Templeton, if you would like to get funding from them (I won't, so here you go).
Maybe, if you choose the buzzwords carefully enough, you could even post it in hep on the xArchive without too many people dying from a laugh attack.
Have fun,
Tim

12. **chris**
June 23, 2009

Tim, 'multiverse' is a very respected concept for decades – among science fiction and fantasy writers.

look. at e.g:
http://en.wikipedia.org/wiki/Eternal_Champion
http://en.wikipedia.org/wiki/Plane_(Magic:_The_Gathering)#Dominia
http://en.wikipedia.org/wiki/Chronicles_of_Amber#The_Amber_Multiverse
http://en.wikipedia.org/wiki/The_Chronicles_of_Narnia#The_Narnian_universe

i am always surprised about the nonchalancy with which respected scientists have recently started pushing this 'scientific' term that for decades was so firmly rooted in the area between fiction and obscurity. they could have at least cooked up another word to avoid the obvious connotations.

13. **Tim vB**
June 23, 2009

Hi Chris,
the core of the problem seems to be that there can't be any interaction between different universes in the multiverse as Sean Carroll repeatedly pointed out, so his theory does not set the stage for an interesting scifi or fantasy story, as the central part of that would be some kind of interaction between the different worlds.
Actually I remember some scifi stories where humans encounter aliens that experience a "reversed arrow of time", so one should probably check that no copyright is violated if one alters the whole story in this direction.
Nonetheless I think there have been quite a few interesting interactions between science and science fiction, e.g. the novels of Jules Verne may well have inspired scientists and engineers alike, but he openly admitted that he was writing novels, not research papers 🙂
Kind regards,
Tim

14. **Yatima**
June 23, 2009

"Now imagine that your brain could process information twice as fast as it does now, that would mean you would have twice as many thoughts per second than you have now."

Cool, I will be able to watch twice as many Battlestar Galactica DVDs in the same amount of time!

Seriously though, even if your "mind" is sped up by a factor x – and it makes sense to assume that the perceived world would consequently speed up by 1/x – you are limited at least by the speed of light and the uncertainty relationships. As any fule know, except those misguided souls looking for ways to circumvent the "Turing Barrier" or other such B.S., there should be a maximum number of bits processable in this universe:

http://www.scottaaronson.com/democritus/lec20.html

15. **Matt Leifer**
June 23, 2009

I think it would be fun if someone were to submit an article about why multiverse theories cannot be confirmed by physics to the FQXi essay competition. I am fairly sure that it would be taken seriously because FQXi does have a large degree of independence from Templeton (disclosure – I have accepted money from FQXi in the past and am a member). There are a number of anti-multiverse people involved with FQXi, so it is not completely crazy to think that such an essay might win something.

Peter,

"If people want to discuss the "philosophy of cosmology", that's fine, but they should do it as philosphers, according to the intellectual standards of philosophy."

I agree with this 100%. What I am saying is that people who are rigorously trained in philosophy really SHOULD study these issues in order to find out whether the pseudo-philosophy promoted by some contemporary physicists really stands up to scrutiny, or at least to give them a hard time about it.

Part of the problem with this is that the most common route into philosophy of physics involves doing a physics undergraduate degree followed by a philosophy masters and Ph.D. This is why you will find vastly more philosophers studying the foundations of nonrelativistic quantum theory than any truly "modern" physics, e.g. quantum field theory, general relativity, cosmology, strings, etc. That's not to say that there are no philosophers studying these topics, just that there are fewer of them than there ought to be. They also tend to be people with two Ph.Ds.

Personally, as someone who is sometimes active in the foundations of quantum theory community, I have to say that the input of philosophers is tremendously useful. They play a key role in moderating the fantastical claims that physicists sometimes make and they are good checking whether arguments hold water. I'd cite Tim Maudlin's work on Bell's theorem and the Oxford group's work on probability in the Everett interpretation as prime examples of good philosophical work (even if I don't agree with all of their conclusions). It would be very useful to have this sort of quality of philosophical work in cosmology and other areas of "modern" physics.

Therefore, I do partly agree with Templeton that there needs to be a special grad program for people who want to do philosophy of cosmology, which teaches them the conceptual underpinnings of modern physics in a rigorous way whilst at the same time covering the standard philosophy material. However the program should definitely not be one-sided or designed to produce multiverse yes-men.

David,

"Putting all flippancy aside (a bit difficult in this area!), are there really any "intellectual standards of philosophy" generally accepted among academic philosophers?"

Yes. Pomo types tend to steer clear of topics like philosophy of physics. Although it is true that these people often misappropriate terminology from modern physics without understanding it, they are usually not explicitly analyzing physics when they do so. In fact, since science does not occupy a central position in their worldview, they are much less likely to study it seriously than people trained in analytic philosophy. Therefore, the vast vast majority of philosophers of physics are in the western analytic tradition and their style of argument meshes quite well with that of theoretical physics.

As for standards, perhaps you should read an issue of Stud. Hist. Phil. Mod. Phys. and see what you think. Sure, you'll probably find a few meaningless papers, but not more than in an average issue of Phys. Rev. Lett. and there are bound to be a few gems in there too. Another method of checking would be to attend a conference on the foundations of quantum theory and make a note of the number of crackpot talks given by physicists vs. the number given by philosophers.

16. **Tim**
June 23, 2009

Hello Yatima,
well, unfortunatly BSG ended with season 4, so there is not so much to gain here…
the interesting point here is, that Tiplers theories allow critique based on physical arguments,
some of these he even addresses in his books (including yours on an upper bound of information
contained in a finite volume of spacetime, see Bekenstein, resp. an upper bound on bits that could be processed in a collapsing
universe). I would not know how to formulate citique in any comparable way on the multiverse theories.
However, the supposed infinity of information processed means that everything that
is physically possible will be emulated by the omega point, according to Tipler,
so that's a little analogy to the multiverse ideas.
Regards,
Tim

17. **Syksy Rasanen**
June 23, 2009

Peter,

George Ellis is not a proponent of the multiverse, quite the contrary. See for example

http://arxiv.org/abs/astro-ph/0602280

and

http://arxiv.org/abs/0811.3529

18. **Bee**

19. **Peter Woit**
June 23, 2009

Syksy,

I didn't mean to imply that Ellis was a multiverse proponent. Thanks for clarifying that.

20. **Mitch Miller**
June 23, 2009

Do multiverse supporters think it is a coincidence that the multiverse was put forth as a serious idea at a time when experiments can't help narrow down the phase space? It seems like it was obvious from the start that the standard model would only be 1 particular solution out of a large family of possible solutions but I don't think anybody started talking about the mulitverse at that point since people were content to do experiments and fix all free parameters of the standard model.

If the multiverse is some deep insight about nature, it is quite fourtunate that we can't do the relevant experiments!! If we could, we would probably be content to describe our string theory vacuum and just throw away all the other solutions.

21. **Peter Woit**
June 23, 2009

Matt,

I do think philosophers could make a major contribution here, by critically examining the issues surrounding multiverse research. Unfortunately I don't see much of that happening, and to the extent it does, multiverse proponents like Susskind take the attitude that scientists should ignore philosophy of science when it challenges what they are doing.

In any case, this doesn't appear to be what interests Templeton. Their motivation seems to be to increase multiverse "research" and blur the issue of what is science and what isn't.

I hope someone does submit the kind of article you suggest to the FQXI competition, and I'm sure they would take it seriously. There is something very weird though about having to explain to scientists the most basic fact about what science is. The reaction I've seen so far from multiverse proponents makes me rather pessimistic that rational argument has anything to do with the issue at this point. Some people just inherently like doing speculative pseudo-science, and some string theorists are going to grasp at any straw that allows them to avoid admitting failure.

22. **Lee Smolin**
June 23, 2009

I have no objection to Oxford or anyone instituting a program in philosophy of cosmology, but what the documents you quote seem to miss is that throughout the history of philosophy a number of the most influential philosophers have been driven by cosmological concerns. So it would not be good to isolate "philosophy of cosmology" from philosophy itself.

An example of a cosmological concern is how a law of nature is to be formulated, understood, or tested if it is to be claimed to apply to the whole universe, and not just a portion of it. Certainly Leibniz in his Monadology was thinking about these issues, and his principles of sufficient reason and the identity of the indiscernibles only make sense in a cosmological context. What was at stake in the relational/absolute debate between Leibniz and Newton's followers were different approaches to cosmological issues. Mach's principle is cosmological as is Einstein's understanding of general relativity he formulated in response to it. And C S Pierce's arguments for evolutionary explanations for laws were in response to cosmological concerns.

Coming closer to our time, Everett, deWitt and Wheeler's claims for the MWI were explicitly cosmological, and much of the literature by philosophers on the MWI by Sanders and colleagues reflects them. And the debates about the nature of time, among philosophers as well as physicists are also cosmological. Roberto Unger, with whom I have been working recently, is an example of a philosopher with cosmological concerns. And a number of philosophers have written on the anthropic principle, multiverse issues, and the subtleties of reasoning about probabilities and possibilities, much of it strongly critical of naïve ideas of physicists.
To my mind the debates on these issues among physicists could only be improved by the inclusion of good philosophers who have critical and thought out views on these issues. I personally have learned an enormous amount from listening to philosophers who have been kind enough to critique things I've written. At the first two meetings that the Templeton Foundation sponsored on the AP, at Cambridge and Stanford, philosophers were conspicuously missing, despite proposals by some of us that they be included. The reason given was that philosophers would not be able to follow the technical issues, but my sense is the opposite, contemporary philosophers of physics are mostly well educated in physics. The effect was rather to protect some physicists from the blistering attacks a good philosopher might give to their proposals, unaware as they seem to be how naïve they sound to someone educated in the history of philosophy and science. My sense is that the best thing the Templeton Foundation could do now is support venues where the physicists who have been proposing multiverse and anthropic ideas have to listen to criticisms of these views by good philosophers.
More generally, while I would never say that every physicist needs an education in philosophy, I would certainly recommend that any physicist who wants to publically speculate on issues that have a long history in philosophy, and who wants to actually contribute to progress, would be well advised to know that history before wasting everyone's time with naïve views that don't stand up to basic criticisms.

23. **Tomatonator**
June 23, 2009

It should be obvious why the Templeton Foundation supports the multiuniverse concept: Heaven and Hell and all those other afterlife places of the JudeoChristian tradition can now be considered real places that just happen to be alternate universes.

Like the creationists, slap a little science on your ideology to make it look legit – ironically to the very groups that otherwise disdain and do not understand science.

The worst part is that, just as UFO fringe elements tarnish the serious study and search for alien life, these guys will do the same to multiverse studies.

Lee, I do like seeing your acceptance and appreciation of branches of learning outside physics. We need to get back to having well-rounded teachers and students who know more than just one field.

24. **Brian**
June 23, 2009

Tim Solton,

The term "atom" originally referred to an indivisible piece of matter. It's just that we ultimately learned that the things we'd gotten used to calling called atoms actually weren't atomic, and it wasn't worth changing the terminology. By extension, it's not unreasonable to refer to an element of a multiverse as a "universe." If multiverses are something you want to talk about, of course.

Brian

25. **Dave Miller**
June 23, 2009

Matt wrote to me:
>As for standards, perhaps you should read an issue of Stud. Hist. Phil. Mod. Phys. and see what you think. Sure, you'll probably find a few meaningless papers, but not more than in an average issue of Phys. Rev. Lett….

Hmmmm. Even when I was a doctoral student thirty years ago, there was an awful lot of nonsense making its way into PRL! Damning with faint praise?

Seriously, I tried to make clear that I was not condemning all philosophers: I explicitly mentioned McGinn as a good guy, and, yes, I have seen a number of intelligent philosophers writing on QM — as you imply, often writing more intelligently than many physicists write.

I was just addressing Peter's point about "intellectual standards of philosophy." Even if we restrict ourselves to philosophy of science alone, we have to face up to the fact that Feyerabend was one of the best known philosophers of science in the previous generation.

And even Karl Popper, who did make some good points, was ludicrously uninformed when it came to his writings on quantum mechanics.

Yes, there are some bright and thoughtful — I'd go so far as to say some who are brilliant – philosophers writing in the philosophy of science today. On the other hand, I am still skeptical that there are decent, generally-accepted, "intellectual standards of philosophy" that prevail within the profession of philosophy as a whole. A profession that honors Feyerabend, Popper, Foucault et al., even though it also includes truly informed folks such as McGinn, Jeff Barrett, Mike Redhead, John Searle, etc., has a problem with standards.

I'm making a narrow sociological point about a lack of serious standards that prevail throughout the profession of philosophy taken as a whole.

Now, if you want to argue that physicists also now have a similar lack of standards (maybe worse when they write on the philosophy of quantum mechanics!), well….

Dave

26. **milkshake**
June 23, 2009

the style is not postmodern – is a rather traditional New Age doppel (lightly hopped with Aquinas to compliment the sponsors)

27. **cormac**
June 24, 2009

I had a look at Saunder' paper, thanks for the link. Actually, reading down through the syllabus, the breakdown of topics looks very interesting – looks like a decent introduction to philosophy for any physicist. I didn't see any evidence of foregone conclusions, wouldn't mind doing this course myself!

28. **Steve Esser**
June 24, 2009

Lee Smolin spoke to something I noticed: Templeton funds some science and alot of theology, but skips over non-theistic philosophy for some reason. I hope they do reconsider this.

29. **concerned cynic**
June 30, 2009

Lee Smolin wrote:

"At the first two meetings that the Templeton Foundation sponsored on the AP, at Cambridge and Stanford, philosophers were conspicuously missing, despite proposals by some of us that they be included. The reason given was that philosophers would not be able to follow the technical issues, but my sense is the opposite, contemporary philosophers of physics are mostly well educated in physics. The effect was rather to protect some physicists from the blistering attacks a good philosopher might give to their proposals, unaware as they seem to be how naïve they sound to someone educated in the history of philosophy and science."

I cannot believe that the absence of philosophers was at the insistence of Templeton people. The physicists must have been the ones to insist on this. Lee, if your cynical conjecture as to the motivations of the physicists who organised those conferences is correct, that is breathtakingly damning and further evidence that you and Woit have put your fingers on a real and grave problem in the temple of theoretical physics.

Disclosure: I admit to being a stuffy Popperian in my views on how to do science. I also believe that doing physics is like ballroom dancing, you need a partner. And theorists have to dance with experimentalists; nothing happens worth noticing until the two pair off.

The activities of the Templeton Foundation do not bother me as much as they do Peter. As a private entity, they should be free to pursue their ends as they see fit. Acknowledging Templeton Foundation support should not be dismissed as the Mark of Cain. Here's hoping that other foundations emerge that support other viewpoints on theoretical physics. Let us not forget the good people who created Lee's employer, the Perimeter Institute.

If Oxford were to start a program in the philosophy of cosmology, that would be fine by me, as long as Joe Silk were invited to be part of it. And I think that Oxford should hire students, and students of students, of Sciama's to help staff it.

The apparent "fine-tuning" of the facts and laws of physics as summarized, e.g., in Paul Davies's recent Goldilocks book, deserves to be included in Smolin's list of fundamental open questions in physics. In particular, hypothesizing a vast multiverse is not a satisfactory explanation. I do not think we are anywhere near a satisfactory naturalist explanation of the universe and the laws of physics. We are like Dorothy in the Emerald City, not knowing that there is a man behind the curtain.

The Man behind the Curtain could be taken to be a God-like entity, but I do not take that as evidence confirming the monotheism we have inherited from the Middle East. If the Universe was willed into existence by a Creator, who fine tuned the laws of physics to make intelligent life possible, we cannot conclude that the Creator values each of us as individuals. It would not justify religious ceremonies or customs, would not make an eternal soul and an afterlife more or less likely. It does not help us know more about how we should conduct our lives. It does not even assure us that God is unique. God may have left clues in the laws of nature, but that tells us nothing about the veracity of the scriptures of historical religions. It is evident that actual religions contain a huge element of human imagination.

The universe began, a finite proper time ago, in a state of extreme simplicity / symmetry. As it expanded, a fantastic cascade of broken symmetries has resulted in the very complex reality we observe. The universe has gradually unpacked itself. In my view, the creation myth with which the Bible begins is consistent with these facts — this may be nothing more than a coincidence. Regardless, Templeton funded scholars should feel free to explore this further.

30. **Chris W.**
June 30, 2009

From Lee Smolin:

Gina Says

June 23, 2009
Categories: Uncategorized

At the height of the string wars a couple years ago, one of the participants was a mysterious anonymous commenter going under the name "Gina". Earlier this year Gil Kalai wrote to me to reveal that he was the person behind "Gina", and that he had put together a book based on these blog discussions, to be entitled "'Gina Says,' Adventures in the Blogosphere String War". He has now put the first part of manuscript up on his blog, the posting is here.

Back in January he sent me a copy of what he had written, I haven't checked to see what changes might be in the version available now. Instead of writing something about this here now, I think I'll just include part of my e-mail to him back in January, which gave my reaction to the project then:

> Hi Gil/Gina…
>
> Thanks for sending me the draft of the book. I read through it quickly, amused to relive again some battles of the string wars. When people ask me if I'll write another book, often I've answered that I was considering just cutting and pasting together a lot of things from my blog, other blogs, and my e-mail, all of which told a rather amazing and often amusing tale. Funny to see that you've done something a bit like this yourself. During this period I also remember often telling people that I felt like I was living in a comic novel.
>
> Actually, I've no intention of publishing anything about the "String Wars", although happy if other people want to. I'm rather glad that they have died down, and I'm trying to devote my time instead to a research project I'm quite excited about (the BRST stuff I've started writing about on the blog).
>
> Some comments about issues you raise, and some added context for some of these stories:
>
> In my book, I tried to avoid saying much at all personally critical about string theorists and their behavior, the sort of thing that Lee Smolin did more of. I generally agree with what Lee wrote, but, in the past my personal contacts with string theorists were mostly with quite reasonable people that I didn't think it appropriate to criticize in this way. After my experiences in the "string wars" though, I ended up feeling that Lee actually didn't go far enough; that, individually and as a community, there are very real behavioral and ethical problems in how all too many string theorists do business. My impression is that the "string wars" brought a lot of this out into the open, and have damaged the perception of string theory among physicists and the wider community, more so than anything Lee wrote. Like Lee, what I was hoping our books would lead to would be a serious discussion of the issues involved. There was some of this, but all too much name-calling and bad behavior.
>
> Some context about Clifford Johnson: independently of each other, both Lee and I wrote to him when our books were in draft form, asking if he would be willing to take a look at them, and let us know if there was anything we had wrong. He just ignored my e-mail, and I gather Lee got a similar response. He appears to be a rather nice guy, and I found this response kind of odd, it was one reason for my mistaken guess that he was the Cambridge referee. I still find his behavior exceedingly strange: how can you write long blog entries denouncing books you refuse to read? He seems to have an ability to refuse to acknowledge the existence of inconvenient realities that goes beyond anything I've seen before.
>
> …
>
> In your fantasy of the future, you mention my book being translated into Czech. Funny, a publishing company there did buy the rights a year or so ago, and I think they will be bringing it out. Sometimes reality and fantasy are indistinguishable in this story…

Update: There's a posting about this over at Physics World.

Comments

1. **Tim vB**
   June 23, 2009

   Hello Peter,
   now that was hilarious, but I wonder why the "string wars" have cooled down? Is everybody exhausted from going in circles?
   Regards,
   Tim

2. **karl**
   June 23, 2009

   Hi Peter,

   Why don't you declare victory? Time seems ripe. Note that the annual string conference is going on this week in Rome, but this year it has basically zero impact on the blogosphere or elsewhere in the internet.
   Lubos says almost nothing and even you ignore the event totally. Nobody seems to be live-blogging, no videos or audios of the talks, not even pdf's. Looks as if strings do not rise emotions anymore. Hmm, bad prospects for a new book on the "string wars" ?

3. **Peter Woit**
   June 23, 2009

   Tim vB and karl,

   I think exhaustion has a lot to do with it. At this point the arguments on both sides have been made repeatedly and extensively, and no one seems to now have any new arguments to make. I'm not about to write another book on the subject.

   The problems of string theory have gotten a fair amount of attention, and there is a much more skeptical attitude about the subject now, among all parties except for string theory's hard-core fans. Some string theorists seem to be hoping that since attention has died down, maybe they can go back to issuing some hype for the subject. So, the blog still has a role to play…

   Unfortunately I don't think my point of view on this has been victorious, since the problems of string theory have caused a backlash among physics departments against mathematical and formal studies, not only of string theory, but of QFT also, which is a shame.

It is odd that there’s nothing on the internet yet about Strings 2009. No video, no slides, no blogging. Some years ago Jacques would live-blog the conference, this year his only blog entry so far has been about finding someone to go to dinner with. Presumably at some point he’ll write something about the talks.

4. **Aaron Bergman**
June 23, 2009

This seems to be a copyright violation waiting to happen.

5. **AcademicLurker**
June 23, 2009

“During this period I also remember often telling people that I felt like I was living in a comic novel.”

Peter,

On another blog we were discussing comic novels set in academia and noticed that the famous academic satires like David Lodge’s Small World (and many others) focus almost exclusively on the humanities, with science largely ignored.

Perhaps you could write a novel to complement Not Even Wrong. There’s definitely an unfilled niche:)

6. **Peter Woit**
June 23, 2009

AcademicLurker,

There’s definitely an excellent comic novel in this story, and the idea of writing such a thing in 21st century epistolary form (i.e. as blog comments and e-mail) did appeal to me. One reason I didn’t pursue that idea was that I’m pretty sure that I don’t have the skill to put together a really good piece of fiction in any form, the other was that reality as usual seems to me more strange and fascinating than fiction. What novelist could possibly come up with Lubos Motl?

Still, maybe I should have done my own version of Gil’s cut and paste job, there’s some wonderful material. In any case, it’s all still out there for anyone who wants to try….

7. **Thomas R Love**
June 23, 2009

Thanks for another interesting link, Peter. I read the book and had quite a few laughs, but then I went to Gil’s web site and read his list of publications. Nothing on string theory, so I have to wonder what his motivation is. Gil posted as Gina here. Did he ever write anything here under his own name?

8. **Peter Woit**
June 23, 2009

Thomas,

Gil did post some comments under his own name “Gil Kalai”. He’s not a string theorist, and I think makes pretty clear his motivation, which was basically an interest in trying to understand the lively controversy.

The “Gina” comments were always frustrating to deal with. For one thing, the anonymity is always frustrating, partly because not knowing what someone’s background is, it’s hard to know at what level to try and interact with them. How much do you need to explain? Not knowing who you are dealing with makes this a more difficult and time-consuming process.

As recounted in the book, I ultimately decided to put an end to Gina’s comments. They sometimes raised interesting points and were worthwhile, but towards the end more often were attempts to enter into technical debates, without any expertise in the issues. This led to lots of confusing misconceptions being thrown around, encouraging other not very expert commenters to add theirs, and generally led to me being put in the position of allowing a lot of uncorrected misinformation here, or having to put in a lot of time to straighten it out. I was trying to encourage what at that time was sometimes a serious discussion of the issues between people fairly expert in them, and felt that Gina’s comments were interfering with that.

9. **tomate**
June 23, 2009

It is quite odd to hear from overseas the string war is cooling down, and that time is ripe to declare some form of victory. Here in Italy, at the periphery of the empire (not only from a scientific point of view) such a discussion is yet to come, and problably will never come. It is amazing to see how much scientific discussion goes on the internet in the US and in other more civilized european countries; we are almost illiterate in comparison, so no wonder that Strings 2009 is held in Italy, and that it has no resonance on the web.

10. **Peter Woit**
June 23, 2009

tomate,

I think there’s nearly unanimous agreement that the string war has cooled down, unfortunately not so unanimous about which side won…

It does seem pretty 20th century that nearly halfway through Strings 2009 not a single blog posting has yet come from any of the 450 people attending (or are they all on Twitter now…?). But I don’t think you can blame that on the Italians. There are physicists there from the very center of the Empire (Austin, Texas) who for some reason don’t seem to be blogging.

11. **David**
June 24, 2009

Ever occur to anyone that measuring blog interest is not actually a measure of scientific impact or in fact anything at all.
Hhhm, perhaps we should use other criteria.

12. **themanwithaplan**
June 24, 2009

Having read some of it, I have to say that it leaves one with a distaste for what Kallai has done. By selecting which blog entries to show and which to omit, he could have tried to give a narrative to his writeup. But the way he has written it now, it is very sleazy: after showing snippets of blog responses, "Gina" then tells us what she thinks about it…. sometimes sneering at the blog posts, sometimes indicating how idiotic the writer of the post must be.

The role of kallai should have been the one of a silent commentator, above all the comical aspects of this whole story, whose simply organizing and showing us what happened. But gil is not satisified with that, he lacks any sense of decent restraint. He simply cannot resist jumping into the story, and rolling in the mud himself.

Peter, you should have not given space to such idiocracy by gracing it with a blog post. From what you wrote above on your idea of such a project, I got a different impression, one closer to what I just said. Gil is just using this whole story to get *his* last word on everything in there.

13. **Peter Woit**
June 24, 2009

themanwithaplan,

I don't know if my version of this would have been more objective than Kalai's, but I do think it would have been a lot funnier….

14. **Tim vB**
June 25, 2009

As entertainig as all of this is: please keep in mind that there are people out there, and will be, for years to come, who are primarily interested in the arguments that were exchanged.
If anyone thinks right now "well, just go to your local string guru and then to your local QFT of whatever non-string-guru": Extrapolating and abstracting my experience boils down to this: Go to professor X at the physics faculty of university y in city z and ask about string theory. You will get a sermon living up to the late Ajatolla Chomeini, be it pro or contra string theory, but a sermon it will be.
How is one supposed to make any sense of this?
To give a complete account of the string wars, you would probably have to team up a string theorist, a non-string-physicist, a philosopher fond of epistemology, a sociologist and some talented writers from Hollywood.

15. **Hendrik**
June 26, 2009

I ran into "Gina" in a hot debate on Cosmic Variance some years ago. I found that "she" dissipated the debate by asking for instruction at an elementary level. She was often a distraction from the main scientific issues under discussion. Later on "she" actually emailed me when the debate ran out of puff, asking me to post more basic explanations. Overall, I think she added substantially to the noise level of the debate.

16. **D R Lunsford**
June 26, 2009

Peter – you say the arguments have exhausted you, and I totally understand – but the social behavior of string theorists is the real problem and not the details of the (non) theory, which any reasonable person can see to be bad science in general and awful physics – it's the terrible effect on careers and science itself generated by this entrenched majority that needs to be exposed, attacked, and put to an end. The real problem to explore, is how this all came about and how it persists.

-drl

17. **Chris Oakley**
June 28, 2009

Hendrik,

Ah … who could forget that one? 530 comments over 2 months and practically the entire Fundamental Physics blogosphere, and then some, chiming in.

I did not object to "Gina"'s contributions, though. But as a general principle I do not think that people should be allowed to post anonymously, especially when they are being contentious.

I like the final comment (#530) – more than 6 months after the original posting, which was my old pal William Shaw realising that I had taken his name in vain in mentioning his work on 4D Superstrings.

18. **Gil Kalai**
June 29, 2009

This is a nice reference to my book, Peter. Thanks. The issue of anonymous posting (and allowing various cyber or collective or even computerized entities) is interesting. I remember that a year ago or so we briefly discussed it here.

The marathon 530 comments long thread over the cosmic variance that Hendrik and Chris referred to was indeed unusual and interesting. Close to the end (from 446 or 445 to around 490) There was an interesting long discussion on renormalization which featured different attitudes and different personalities that perhaps could only come together on blogs. There were also several interesting subthreads on other matters.

19. **Peter Woit**
June 29, 2009

Hi Gil,

I did take a look recently at that marathon comment thread. Probably it is the best single location for people to get an idea of the discussion going on during that period. Unfortunately the rest of it is spread around quite a few other different blogs and postings. You gather together some of it, a useful project I might get to someday would be to put together a page of links.

20. **Tim vB**
June 30, 2009

Hello Gil, Peter,
some random thoughts about this monster thread:
– This is the first time I think I got a good idea of the kind of discussions at that time, I did not find anything comparable on my own.
– This thread should probably have been split into one for the experts, and one for posting elementary questions at textbook level (Gil, the questions about renormalization

seem to be quite off topic to me).
– It would seem that everybody has to learn how to communicate using a blog. Personal insults, sublte irony etc. will easily be misunderstood by at least some of the participants, spawning responses that could kill the whole thread.
The posts that basically repeat former postings strike me as particularly odd, this may make sense in a personal conversation, if you get the impression that you have not been heard, but in a blog everyone can just scroll to the top of the page…
– Personally I would be most interested in an excerpt of the arguments of both sides, since I fear I have neither the time nor the energy to read all the postings (let alone understand everything).

21. **Aristarchus**
July 6, 2009

Peter, would you like to comment on the following quote from
the post here:

http://motls.blogspot.com/2009/07/against-philosophy-2009.html

"Unfortunately, the world's crackpots – including some of their leaders such as Peter Woit and Lee Smolin – can never understand that their philosophical preconceptions trying to dictate a priori what science should look like may be wrong and are wrong.

"Physics cannot respect Smolin's opinions that it shouldn't be based on deep and accurate mathematics; it ignores his desire for the laws to respect his own version of the background independence; Nature cannot respect Woit's or anti-quantum zealots' opinion that physics must avoid all concepts that are too hard for their small brains to visualize them or to improve their everyday life; science disagrees with Woit's dumb illusions that correct physical theories are obliged to guarantee that physicists must always have sufficient resources to test these theories (or even cheaply or soon). Nature has no such obligations. Even if these people managed to write one correct sentence – which is as likely as in the case of the proverbial monkey writers – the method how they arrived to such a sentence is scientifically flawed."

22. **Tim vB**
July 7, 2009

Hello Aristarchus,
Hopefully Peter will have time to answer you himself soon, but: Is it really necessary
to comment on this quote? I always liked the attitude "let everybody publish and
let everybode else make up her/his mind about it".
During the last few years I got the impression that this attitude is a luxury
that people working in hep cannot afford, at least not all the time.
In the case of Lubos Motl I think we can.
The only remarkable point in this quote seems to be "science disagrees with Woit's dumb illusions that correct physical theories are obliged to guarantee that physicists must always have sufficient resources to test these theories".
This seems to be a relapse to pre-Aristotelian concepts about what science is and what it is not (no need to discuss that it is also quite impolite, right?).

23. **Aristarchus**
July 7, 2009

Tim, I was not trying to be rude. I want to hear the other side of the story and I wanted to quote what was said EXACTLY without editing so no one can accuse bias.

24. **Peter Woit**
July 7, 2009

Still traveling, back at work on Thursday. Tonight I've got decent internet access and some free time for the first time on this trip.

Aristarchus,

Lubos is pretty much nuts on the topic of string theory and this is so obvious that it's usually not worth the time to respond to his endless rants. As for this one:

1. I firmly believe that at a fundamental level physics is based on deep mathematics, not on things that humans are readily able to visualize. The problem with string theory is not that it uses too sophisticated mathematics, it's that it is a wrong idea about unification, and no amount of mathematical technology can fix this.

2. The problem with string theory is not that it can't be tested today, but that it is inherently untestable, no matter how high an energy accelerator we ever figure out how to build. There's nothing wrong with working on ideas you don't know how to experimentally test, but you have to have some plausible explanation about how, if your research program works out, someday your ideas can be tested. In the case of string theory, in 1984 there was such a proposal, but what has been learned about the theory since then has shown that it doesn't work, leading instead to landscape pseudoscience. In short, the problem with the project of getting string theory to the point of being testable is that by any measure of progress, the derivative is the wrong sign. 25 years of research has just made the whole thing more and more implausible the more we learn.

25. **Anonymous**
July 7, 2009

"but that it is inherently untestable,"

Can you explain? What if there is a way?

26. **chris**
July 8, 2009

"but that it is inherently untestable,"

Can you explain? What if there is a way?

well, nobody can show any way up to now. as Peter said, 25 years ago it looked more or less like there would be some predictive power but now this hope is dwindling by the year as the landscape is explored and no preferred point seems to be found.

27. **Aristarchus**
July 8, 2009

Is it true what I once read, that in order to ever have a chance to detect a string, we would need to build a particle accelerator the diameter of the Milky Way galaxy?

When I see how much trouble they are having with the LHC….

28. **Peter Woit**
July 9, 2009

Aristarchus,

A particle accelerator the diameter of the Milky Way could not test string theory. The problem is not one of technology…

Strings 2009 Out of Juice?

June 23, 2009
Categories: Strings 2XXX

I had a suspicion that Strings 2009 wasn't going to be scientifically very active, since not much has been going on in that field recently, but I still found it surprising how little news from the conference was making its way out to the internet. The conference is nearly half over, no evidence of any activity has appeared on the conference web-site, and until now I couldn't find anything at all on the internet discussing what is going on there.

However, something did just turn up. Over at the Bad Astronomy and Universe Today Forum, under the topic heading "Off-Topic Babbling", there have been two communications from Terry Giblin. In the first, written on Sunday, Terry writes that he's on the road to Rome for the conference, and since it looks like he'll be late, he'd like someone from the stage or audience to call him on Skype so he can ask the opening speaker (David Gross) a "strings question on quantum tunneling and singularities."

That doesn't seem to have worked out. In his latest communication, he says that he finally did make it to Rome, where he reports:

> It would appear that I have not missed much over the past two days, yesterday the internet at the conference was only working slowly.
>
> Today they had a power outage, so the conference was cancelled.
>
> I hope I have more success tomorrow or the coming week.
>
> Its amazing to think you can change the outcome of a conference, without being physically present………

Update: A twitter from Marco Baumgartl has made it out to the internet, bringing more confirmation of problems:

> I'd loved to give you live updates from the Strings 2009 conference, but they have severe wifi problems there, can't connect

Update: An anonymous correspondent attending the conference reports that disorganization is a problem, and that there have been no major announcements. David Gross's talk listed 8 fundamental problems for string theory and gave the string community a grade of A-F for progress on each problem (this sounds familiar, I vaguely recall him giving such a report card at some other talk a few years ago, I wonder if the grades have changed…)

The atmosphere was much like in other recent years: some disillusionment in the air, but people continuing to work along similar lines. The talks were described as sketchy and mostly incomprehensible to much of the audience, with many of the younger string theorists rather bitter about the lack of much of an attempt on the part of the speakers to give clear explanations and put their work in any sort of context (the audience of 450 has widely varying backgrounds, this is not a specialist conference).

Update: Well, the conference is over now, but still no slides of talks, or any blogging from anyone there, other than Jacques Distler's attempt to find someone to go to dinner with a week ago. Reports I've gotten from the conference describe Vafa's talk as "Good, in fact too good to be true", and claim that Arkani-Hamed showed up two hours late for his talk, then went over time by 20 minutes.

Update: Still nothing on the conference web-site about the talks, or on blogs. Physics World does have a report from Edwin Cartlidge, who noted that the scientific talks were appropriately held at the University of St. Thomas Aquinas, named after the great Scholastic philosopher. He also reports on the public talks held yesterday. Witten appears to have decided the best thing to do was to not talk about string theory, but instead talk about particle physics, the LHC, dark matter and supersymmetry. He left string theory to Brian Greene, who somehow convinced Cartlidge that what this is all about is "that 10500 is somewhat bigger than 10120, and that's a measure of how much we don't understand dark energy."

> Greene pointed out that string theory requires an extra 6 (or 7) dimensions of space in addition to the three that we are aware of. Helpfully, these dimensions are so small that we can't see them, but unhelpfully there are rather a lot of ways of curling these extra dimensions up – some 10500 different ways as it turns out. And we would have to study all 10500 if we want to find out whether or not string theory describes the real world.
>
> For Greene, all is not lost, however. He pointed out that 10500 is somewhat bigger than 10120, and that's a measure of how much we don't understand dark energy. In a nutshell he argued that if we happen to live in one of the few of the 10500 universes where conditions are just right for us to exist then there's a damn good chance that we could have such an apparently statistically unlikely dark energy. For Greene, this suggests we might be on the right lines with string theory. Others may be less convinced.

Update: The exponent problem has been fixed.

Comments

1. **M**
   June 23, 2009

   Any word on the food? People do not go to conferences for free wi-fi really.

2. **tomate**
   June 24, 2009

   Still sure you can't blame our medieval gap? I think this might be symbolic of the status of research and university here.
   At least the food will be just fine.

3. **Per**
   June 24, 2009

   My girlfriend is Italian she told me before it started – the organization is so gonna break down. Guess that's what happened. It's hard not to like Italians, but their skills in organizing and planning sometimes lacks a bit behind 🙂

4. **Tim vB**
   June 24, 2009

   Hello Peter,
   "I had a suspicion that Strings 2009 wasn't going to be scientifically very active, since not much has been going on in that field recently…"

Asking with honest interest, since I do not follow the field intensely: This statement is based on what observation(s)?
Regards,
Tim
P.S.: A little note on my background to provide some context to my question: I graduated in theoretical physics from the University of Heidelberg and stumbled upon your book and Lee's while trying to decide what to do next, in order to get a second resp. n'th opinion on string theory. Almost everything I know of the subject itself comes from Barton Zwiebach's book – I know it is addressed at toddlers, but one has to start somewhere.

5. **H-I-G-G-S**
June 24, 2009

Good to see that you have such reliable sources. In one his postings Mr. Giblin says "This equation also implies that an electron and a photon cannot, exist together." He seems to be a crank. Wifi problems, yes. Conference cancelled, I doubt it.

6. **Peter Woit**
June 24, 2009

H-I-G-G-S,

We Report. You Decide…

Tim vB,

I've been following the field quite closely for 25 years, and don't think it's a very controversial statement that the last few years haven't seen any major developments. The planned titles of the talks are online, and from that there doesn't appear to be anything dramatically new, although one can't really know without having access to the talks themselves.

7. **Bee**
June 26, 2009

Totally off-topic: On mouseover the "latest comment" feed in the sidebar says "Last comment was 39 years, 6 months ago…"

8. **woit**
June 26, 2009

Hi Bee,

That bug has been around for a while, you've encouraged me to try and fix it. Right now it looks like it is fixed for all but this posting, maybe my adding this comment will do the trick….

9. **Peter Woit**
June 26, 2009

Fix seems to have improved matters, but not completely fixed the problem. I think I'll not spend more time on this now though…

10. **brief aside**
June 27, 2009

Peter,

I have been reading your lecture notes on Hamiltonian Mechanics and Symplectic Geometry, which I found on your site. In particular, 'Quantum Field Theory for Mathematicians: Hamiltonian Mechanics and Symplectic Geometry'

On page 7 I came across the equations z = p + iwq and… z(t) = Cexp(iwt). I would be thrilled if you could please tell me where I can get more material on these equations. Do you have indepth lectures on this? If you have any free material could you please direct me to it. Thanks.

11. **brief aside**
June 27, 2009

I mean those equations in particular. Thanks.

12. **Peter Woit**
June 27, 2009

brief aside,

The equations you mention are just the standard trick of expressing a pair of canonical variables in terms of a complex variable. This is in almost every quantum mechanics book, when you solve the harmonic oscillator by writing annihilation and creation operators (a and a^*) in terms of position and momentum operators. For some long expository related pieces by John Baez, see

http://math.ucr.edu/home/baez/photon/intro.htm

and, at a higher level

http://math.ucr.edu/home/baez/harmonic.html

I hope this helps. I'm sorry, but I don't have the time or energy now to devote this blog to basic expository questions like this. Some day in the distant future I would like to write up some much more detailed lecture notes on QM and representation theory, but that project is a ways off…

13. **Tim vB**
June 28, 2009

Hello Peter,
the article by Edwin Cartlidge seems to be a joke along the line "you all know that no one can possibly make any sense of what these nerds say".
This is unfair to Brian Greene and to string theory (not that I am a fan of one or the other).

Meanwhile Lubos has blogged about the conference, so if there were anything dramatically new we would know by now,
therefore confirming your expectations.
He talks about applications of string theory in many body problems,
with experts telling us that "string theory computes things that we
acutally see in experiments", any opinion on this claim?
Regards,
Tim

P.S.: Almost every journalist misunderstands 10^500 as 10500, disregarding the hat
(humans tend to ignore signs they do not understand 🙂
Maybe we should all switch to "10 to the power of 500", at least when
writing an email to a non-specialist.

14. **Simplicio**
June 28, 2009

17985 is an exact measure of the amount by which I don't understand where 10120 comes from.

15. **Peter Woit**
June 28, 2009

Tim vB,

It's quite true that sometimes in this business you can't tell what's a joke and what isn't. That isn't a good thing….

Applications of AdS/CFT duality to studying strongly coupled models that may have something to do with heavy-ion physics and condensed-matter physics has become a large and active subject. I confess to not having a lot of interest in it, since it says nothing about particle theory and nothing mathematically interesting. From what I have seen, some of this may definitely be useful, but there also appears to be a lot of hype going on. I was interested to see that Lubos describes some of this negatively as "an industrial activity", which "has become a routine".

Lubos's blogging about the conference talks seems to be based purely on the titles of the talks. When and if the talks are on-line, perhaps he'll have some more substantive comments.

16. **observer**
June 28, 2009

I am currently half-watching a program on the Science channel about Hawking's endorsment of string theory and how it's the best candidate for TOF. The program calls the development of string theory a "break through" discovery that unites gravity and QCD. There is no evidence presented but I am not sure the listening public cares. Will it matter if Strings 2009 collapses but the spoon-fed public absorbs it as the current theory of everything? The violin and banjo sounds demonstrating the theory are a nice touch (even if its truly a horrible analog).

17. **Michael Thaddeus**
June 28, 2009

For what it's worth, Lubos has some discussion of the Strings 2009 talks on his blog… but I preferred his pronouncement about Michael Jackson: "His pale skin could have been caused by a skin disorder."

18. **Tom O'Bulls**
June 29, 2009

Lubos M has a simple rule in deciding who he likes, viz. he just has to ask how similar they are to himself. Hence his worship of intensely insecure and obnoxious historical figures like Pauli and Feynman. The fact that he liked Michael Jackson is therefore deeply revealing.

19. **nbutsomebody**
June 29, 2009

String 2009 is really out of juice. At least string theorists are not at all talking about it. Not only in blogosphere but also in real life. May be it is time people stop a yearly Strings meeting and go for a longer cycle like 2-4 years.

20. **Anonymous**
July 1, 2009

It was interesting to hear Horava's talk on his new approach to quantum gravity. The idea is unrelated, and most likely incompatible with string theory. It left many of us (including apparently Ed Witten) unconvinced, but I think it is nice that string theorists are willing to devote time to considering such radical departures.

Peter, I have not seen you mention this development, which strikes me as an interesting new turn in the string theory debate. Perhaps it is does not interest to you because Horava's approach does not have much to say about electroweak symmetry breaking. Do you have any thoughts on this?

21. **Peter Woit**
July 1, 2009

Anonymous,

I have the same problem with the Horava proposal as with all quantum gravity proposals that say nothing at all about unification and particle physics: I don't see how you can ever know if they are right. Like lots of ideas though, it might be worth studying since you might learn something useful. This particular idea doesn't involve anything particularly mathematically interesting, so it's not something I'd personally want to pursue.

The sociological story is a bit interesting. Even though this has nothing to do with string theory, and would kill the main argument for string theory, it still is getting a respectful hearing from string theorists, who write papers on it, and invite the speaker to Strings XXXX. If Horava was not a fairly prominent string theorist, I doubt this idea would be getting as much attention. And Lubos would not be polite….

22. **Chris W.**
July 1, 2009

As a PS on Peter's comment, a number of prominent condensed matter theorists (eg, Volovik, Laughlin) have developed broadly similar ideas over the past decade. Volovik has recently commented on Horava's proposal.

23. **Chris W.**
July 1, 2009

Also see this review by Volovik:

Emergent physics: Fermi point scenario
(arxiv:0801.0724)

24. **Anonymous**
July 1, 2009

I do not think there is any convincing evidence that particle physics at accessible energy scales has much to do with quantum gravity. At one time some people hoped that string theory could have some explanatory power in this regard, but not so much anymore. So I do not think it is quite fair to judge a theory of quantum gravity according to its particle physics implications, anymore than it is fair to judge QED based on it's implications for geophysics.

On the mathematical side, Horava mentioned a connection between the RG flow in his theory and the famous Ricci flow. I am not knowledgeable in these matters and am not sure how seriously to take his analogy. Do you have any thoughts on this?

25. **Peter Woit**
July 1, 2009

Anonymous,

The problem with your geophysics/QED analogy is that geophysicists deal with experimentally accessible quantities. If your quantum gravity is not going to say anything about physics except at completely inaccessible scales, there is a very real issue of how to pursue the subject as a science.

I don't know about Horava's case. In the case of 2d non-linear sigma models, the relation between the Ricci flow and the renormalization group flow is well-known.

26. **Chris W.**
July 1, 2009

Speaking of problematic analogies, Leonard Susskind has a new article in *Physics World*:

Darwin's legacy

I think you can guess where it ends up.

27. **Tim vB**
July 2, 2009

Hm, I think I do not want to diskuss if if the idea of the multiverse etc. meets any established standards of science,
but I think it clearly does not meet established standards of science fiction (it is just not interesting enough).
Maybe we should sharpen the title of the blog to something like "not even entertaining" or "not even funny".

28. **nbutsomebody**
July 6, 2009

Slides of the talks are available now. Talks look pretty boring and most speakers are randomly selected without any real reason.

29. **jmars**
July 8, 2009

nbutsomebody,

who precisely do you have in mind?

Peter,

can you give an assessment of Vafa's proposal? It really seems to give a lot of very detailed predictions; since you are the leading critic of string theory unification, this F-theory business (which I assume you are following with great attention) is probably worth a whole blogpost. Don't take it as a criticism, but the actual research of the leading string theorists about the particle physics phenomenology should probably be much more relevant for the readers of your blog than a press-release from a university in a remote Dutch province… 🙂 On the other hand, it'd be good to have an unbiased and detailed account of the work of Heckman and Vafa from an outsider's point of view.

30. **Peter Woit**
July 8, 2009

jmars,

I wrote about this here

http://www.math.columbia.edu/~woit/wordpress/?p=697

when it was first getting started, more than a year ago, and recently quoted opinions I heard reported second-hand from Strings 2009: "Too good to be true".

You can certainly pick some string-inspired model, make lots of choices so that you get something that doesn't obviously disagree with experiment, and then try to show that with your choices things are constrained enough to make predictions and test the idea. That's what the people working on this are doing. What I've seen of it looks to me highly implausible, but they see it differently and are making a very hard sell of the idea. My impression is that many people share my skepticism (one other blog that has covered this is Resonaances, with a similar point of view).

In any case, this is a story that can't go on forever. The true believers here claim they can make predictions that will be tested reasonably soon. Let them make their predictions and see what the LHC says. But note that this is in no sense a “test of string theory”: this is just one of many possible string theory scenarios, if it fails it won’t show string theory to be wrong.

Some very recent work (arXiv:0906.4672) claims to show that the versions of this idea studied so far don’t actually work, that you need to make even more non-minimal choices to get things to work. It may be that the scenario being studied intensively now will turn out to be inconsistent, and people will lose interest after some more iterations of adding complexity to the story to evade contradiction.

31. **Terry Giblin**
    August 9, 2009

    who was the opening speaker at Strings 2009?

    Kind Regards

    Terry Giblin

Conferences

June 29, 2009
Categories: Uncategorized

In a couple days I'll be leaving for a week-long trip to Riga and St. Petersburg. I'll be in St. Petersburg from July 5-8, and will give a talk on BRST and Dirac Cohomology at a conference there. I'm finishing up a draft of a paper on the subject now, will try and write about it here after I get back from the conference.

The Strings 2009 information blackout continues. Still no talks or blogging on-line, although a new twit has made it out, summarizing the conference:

> more effort being put into contact w experiment•hope for LHC•fundamental issues need more attention•much optimism

although that could have functioned as a summary of pretty much every Strings XXXX conference held during the past 20 years.

Even if no information about the Strings 2009 talks ever gets out, many of the same speakers are speaking at uncountably many other strings conferences scheduled before and after the big one, conferences that are likely to have web-sites that make the talks available. Here are some of them:

Florence

Warsaw

Saclay

Porto

Lisbon

Benasque

Frascati

Potsdam

Wroclaw (Robert Helling will be blogging)

Comments

1. **Robert**
   June 29, 2009

   Please move my name one line down, I am in Poland, not in Potsdam.

   So far, I have not heard much worth reporting.

2. **Tim vB**
   June 29, 2009

   What is "string phenomenology"? Had a look at some of the slides of the talks in Warsaw, there seem to be
   a) talks about string theory,
   b) talks about (IMHO) totally different topics (like the Navier-Stokes equation and turbulence, see Y. Oz – "Gravity and the Shape of Turbulence") that the author tries to connect to string theory in a rather ad hoc way.

3. **Peter Woit**
   June 29, 2009

   Thanks Robert, fixed.

4. **anon.**
   June 29, 2009

   Do you speak any Russian? Just wondering how you will chat at the bars in St Petersburg? (I'd like to visit Russia myself, but am apprehensive about the language.)

5. **Peter Woit**
   June 29, 2009

   No Russian. I fear that any extensive conversations with the locals will be restricted to those who speak English (or French I guess…).

6. **Ilya**
   June 29, 2009

   Hi Peter, I've been following your blog for some time and I should say that I rather share your attitude to the string theory hype.

I'm a physics undergrad at Cambridge but now on vacation back home in St Petersburg so it'd be great to meet you here. What date is your talk?

7. **Peter Woit**
   June 29, 2009

   Hi Ilya,

   I'll be at the conference definitely all day next Monday, my talk is scheduled for 15:40. Come by and find me there….

8. **The Vlad**
   June 30, 2009

   "No Russian. I fear that any extensive conversations with the locals will be restricted to those who speak English (or French I guess…)."

   Speaking from personal experience, don't hold your breath waiting for a local to speak English there. It took me a lot of sign language to get where I wanted to go, most of the time.

9. **Chris Oakley**
   June 30, 2009

   Hi Vlad,

   Your native language being what – Romanian?

10. **Chris W.**
    June 30, 2009

    Somewhat off-topic: Oswaldo Zapata has posted his 3rd essay, "Superstrings, The Most Beautiful of All Existing Theories?"

    See the post here.

11. **Coin**
    June 30, 2009

    I'm sure you will find it entirely unhelpful to know that your trip to Russia more or less precisely coincides with Barack Obama's.

12. **The Vlad**
    July 1, 2009

    @Chris Oakley

    LOL…Aussie actually mate 🙂

13. **the h bar**
    July 9, 2009

    I just noticed that they have uploaded most of the Strings 2009 talks to the official site. It was about time:

    http://strings2009.roma2.infn.it/cgi-bin/roma_program.pl.cgi

14. **Marcus**
    July 9, 2009

    @the h bar,
    All I can find using the link you gave are the PDF files for the slides. I don't find any video. Does anyone have a link to a video of David Gross' talk?

15. **A.**
    July 10, 2009

    Lightcone 2009 is currently going on in Sao Jose dos Campos, Brazil. Organisation: amusing.

    Participants: old boys network.

    Talks: the postdocs are putting in a lot of work and delivering nice talks. The old crowd are mostly putting up "walls of text" and things are a little rambling.

    Hot topics: "lightfront holography", which relates lightfront hamiltonian mechanics to AdS/CFT giving AdS/QCD.

LHC Status

July 1, 2009
Categories: Uncategorized

If you want to keep up with the latest news on the LHC status, tomorrow at 3pm Geneva time there will be a webcast of a talk by Steve Myers. The abstract reads:

> The status of the LHC will be presented. This will include the repair of sector 34, the ongoing consolidation work in the other sectors, and the progress with the new Quench Protection System. The results of recent resistance measurements of the copper stabilizers will be presented.
> The plans for powering the LHC and the tunnel access restrictions will also be discussed. Finally the planning for the start-up and the programme for future operational consolidation work will be detailed.

One crucial piece of news will be what was learned from the resistance measurements in the sector that was just warmed up, and whether warming up of the other sectors will be required.

I'll miss this since I'll be on a plane.

Comments

1. **Sorinis**
   July 1, 2009

   Let's prepare for major dissapointments and hope for the best.
   Could it be that they are going to operate ahead of schedule? (I can even write that with a straight face.)

2. **Greg Sivco**
   July 4, 2009

   Major disappointments? You mean other than 2007 was to be start-up and 2010 is now presented as the soonest?

   How does 2020 grab you, realistically? I'm willing to take bets on the over/under as to when the LHC really takes off. I'm betting on 2020 personally, so we'll set the over/under at 2018. Because my God gentlemen, if something as simple as WELDS are off, what the heck else is wrong that we (and they) don't about yet?

   The defection/return of Austria is a bit telling IMO. Do they know something we don't, but have too much class to admit publicly? Too many cooks, maybe? I don't know, I'm just speculating, just like bootstrapping String Theorists.

   I am not criticizing LHC management. Nor am I being a pessimist or skeptic, just being Realistic. As a Mechanical Engineer, I assure you there is always this ONE guy who shows up at work in projects of this complicatedness (rather than complexity), and his name is Murphy. You may have heard of him, he has a Law ascribed to him.

   The Pauli Effect. It rules, alas.

   But the other particle accelerators were eventually developed, so don't lose hope. The LHC's day will come, sooner or later. Probably later, which is bad news for those putting all their particle physics eggs in the one basket that is the LHC.

   OK, so what do we spend our time on in the meantime, anyone?

   QCD? That would be my call. Quarks and Gluons are after alll …. 99.9 something percent of all there is (not called Dark Matter and Dark Energy by Mass/Energy), right? Much work to be on there I think. Who are the top people working on QCD?

   And what about LQG and CDT? What's new there?

3. **Sorinis**
   July 4, 2009

   I think Frank Wilczec is the best source in OCD. LQG sounds like phrenology to me. Also I think the CERN management were abysmal. I'm thinking robert Aymar. This is project failing because of quality control issues and not "complicatedness." And that is just not acceptable. Perhaps this idea of intenational cooperation in science is not the best way. If there was competion between nations you would see much bettrer and spectacular developments. At thus point even seeing a development (even if not a spectacular one) would be something.

4. **Greg Sivco**
   July 4, 2009

   Ah, thank you Sorinis, much appreciated. "Frank Wilczek, who along with David Gross and H. David Politzer, was awarded the Nobel Prize in Physics in 2004 for their discovery of asymptotic freedom in the theory of the strong interaction."

   Awesome, because Asymptotic Freedom is awesome. Mind blowing in fact, but there must be a reason. In the meantime, there is much David Mermin-ish "Shut up and calculate" work to be done, and if anyone is looking for someone to help in that regard, I am available.

   I assumed early management of the LHC would be abysmal, but I also assumed they would learn from their mistakes. I think they are (or am I just WISHing they are?). IMO it's not a CERN thing, just a human thing. I am open minded enough to be proven wrong, pls advise.

   As far as "International Co-operation" goes, it seems to be working well enough for the ISS. Granted it will be slower than America with Mercury/Gemini/Apollo and the Soviet Union with their programs in the 60's (less bosses, … less BS), but still …

   I understand LQG is speculation. The difference between the advocates of LQG and Strings is that the LQG guys admit that, and the String guys don't, they promote their stuff as "fact."

   Bull. I am SO grateful Peter wrote his book. What an eye-opener. I am especially happy that Ed Witten, who along with Schwartz and Green was responsible for the first Superstring revolution and singlehandedly for the second one, seems to be backing off from Strings, if not completely.

Much diplomacy will be involved. These things have to be handled del-l-l-icately, so said the Wicked Witch of the West. 😉

5. **jks**
   July 4, 2009

   122 slides from the talk are available from the second link in Peter's post. Interesting reading. Among other things, there is a new quench protection system being deployed along side the existing one. Maximum machine energy versus spice integrity seems to be an ongoing concern, but with much new data and understanding.

6. **Sorinis**
   July 4, 2009

   Am I wrong or did Myers basically say that there is no schedule any more? It is all up in the air?

7. **pessimist**
   July 5, 2009

   Greg,

   I am with you – from one engineer to another (I am electrical), I can testify to you that Mr. Murphy is always on the job, waiting for somebody to ignore him. In my business we call it de-murphizing the project – that means planning and checking to excruciating detail which reduces the probability of a Murphy event. Design teams are always doing reviews on each other and the project lead is making everybody do feasibility tests as a part of their design. Based on the report so far, I have a feeling Mr. Murphy has free run of the LHC! As painful as it sounds, the only way to solve the problem once a project has been hosed is to carefully pull each weed out one at a time without messing up the rest of it. It's at least 4 years from turn-on time before all of the bugs are removed.

8. **Sheepdip**
   July 6, 2009

   Off topic for this thread but I thought you'd want to see this new claim:

   http://esciencenews.com/articles/2009/07/06/physical.reality.string.theory.demonstrated

9. **Coin**
   July 6, 2009

   Sheepdip: Trying to respond in short because Peter seems to dislike taking threads too far offtopic, but: One thing I'll note is that the grandiose and wildly inaccurate claim of the headline– "Physical reality of string theory demonstrated"– does not appear to be a claim anyone with Leiden University has made. It was added by ScienceDaily (where I think this article originated?). In fact, it wasn't even a claim made in the ScienceDaily article itself– the claim appears only in the headline, and is in no way supported by anything in the article itself (which is much more conservative in its phrasing). A consistent problem in science journalism is that someone will write a decent article and then an editor will tack on an "exciting" but wildly inaccurate headline which changes the tenor or content of the piece itself. (Actually this is a frequent problem in many other kinds of journalism as well, especially in politics– most people writing in traditional journalism have no control over their own headlines.) If you ignore the headline and just look at what Leiden University team actually *did* you'll find it doesn't have anything to do with "demonstrating the physical reality of strings" (although what they *did* do sounds actually pretty awesome and like a legitimately positive development for AdS/CFT as a research program).

10. **Anonymous**
    July 7, 2009

    Here's a better article on it:
    http://www.physorg.com/news166097923.html

11. **Marcus**
    July 7, 2009

    Here is the actual journal article:
    http://lanl.arxiv.org/abs/0904.1993
    It does seem that we've been hyped again by irresponsible pop-sci journalism. It's not evidence of string "physical reality" at all. Just another application of the AdS/CFT mathematical tool applied to something else besides fundamental particle physics.

This Week’s Hype

July 7, 2009
Categories: This Week's Hype

A Leiden University press release headlined [Physical Reality of String Theory Demonstrated] is being picked up and used to generate news stories in the media.

It starts off:

> String theory has come under fire in recent years. Promises have been made that have not been lived up to. Leiden theoretical physicists have now for the first time used string theory to describe a physical phenomenon.

which follows the usual dishonest and misleading template for attempts to deal with string theory’s failure as a unified theory. The idea is to put out a press release announcing that string theory has finally lived up to its promise and shown its critics to be wrong, because of evidence it may work as an approximation method for some strongly coupled condensed matter or nuclear physics model. The fact that this has nothing to do with string theory’s continuing utter failure as a fundamental theory is carefully not mentioned, ensuring that non-expert readers of the press release will be misled.

A common excuse for this is that it is being done by journalists, with the scientists involved having no responsibility for the misleading material. In a news media story, conceivably this could be the case, but a university press release is something different. University researchers have both the right and the responsibility to ask for the retraction of a university press release that mis-characterizes their work. When they don’t do this, they make themselves responsible for actively misleading the public about this subject.

Comments

1. **Marcus**
   July 7, 2009

   A poster at Physicsforums with pseudonym “Civilized” has taken issue with this post:
   http://physicsforums.com/showthread.php?p=2263776#post2263776
   ==quote==
   On his blog Woit says:

   [The idea is to put out a press release announcing that string theory has finally lived up to its promise and shown its critics to be wrong, because of evidence it may work as an approximation method for some strongly coupled condensed matter or nuclear physics model.]

   I guess he doesn’t know that the AdS/CFT duality is an exact correspondence, not an “approximation method.” String theory consist of equations that describe relativistic quantized strings, and AdS/CFT allows us to test these equations. The only remaining question is whether quantized relativistic strings exist in nature on the scale of the Planck length, and AdS/CFT will continue to be silent on this subject, but the fact remains that the AdS/CFT duality can be and is actively being used to test the exact equations of string theory.
   ==endquote==

   Several things about this puzzled me, one being why wouldn’t the person come here and comment directly? The PF thread had no link to this particular post (although string hype and bad journalism was being discussed.) So it seems like here is a better place to post fulminations against this N.E.W. post and aspersions against the author. It also seemed like a straw man ploy, you didn’t say that AdS/CFT was approximate but he pretends you did and makes a show of correcting your “mistake”. Anyway here it is if you care to reply.

2. **chris**
   July 8, 2009

   Dear Peter Woit,

   the researchers often have no control over the headline of the press release of their own institute – i know this from bitter experience. and once it got snapped up by some of the larger media outlets it is a very very steep uphill battle to get anything revoked. basically, they won’t do it on the grounds that nobody understands it anyways and retraction is always a statement of sloppy work on the part of the media.

   of course you are right that they should do all they can to stop it anyways, but probably the only way of finding out whether they did is asking them directly.

3. **ManyMe**
   July 8, 2009

   I am working on a new theory of everything based on the Ising model. It already predicts gravity and I am sure it will contain the standard model and it will also describe supersymmetry and all kinds of new particles.

   So far there is no evidence whatsoever for my new theory, but
   it turns out that the Ising model is very useful in cond. mat. physics, in particular to understand phase transitions of ferromagnets.

   I take this as evidence that I am on the right track with my theory of everything.

4. **anon.**
   July 8, 2009

   “may work as an approximation method for some strongly coupled condensed matter or nuclear physics model.” – Woit

   “AdS/CFT duality is an exact correspondence, not an “approximation method.”” – Civilized

   Civilized fails to understand that you can use an exact correspondence between conformal field theory and anti-de Sitter as an approximation method to systems that don’t exactly correspond to either. Duh.

5. **ManyMe**
   July 8, 2009

I forgot to mention that I will put out a press release about it soon.

6. **John F. McGowan**
July 8, 2009

Is this that remarkable?

As I understand, the string theories started out as models of nuclear resonances, mesons, and so forth in the 1960's. There were and are many empirical observations of nuclear resonance behaviors and properties that can be explained by modeling the nuclear resonances as vibrating strings of some sort of subatomic nuclear matter.

It is my impression that Veneziano's original string formula was a model for nuclear scattering data.

The Lund Monte Carlo which at least used to be heavily used in experimental particle physics to model hadron jets and so forth is based on a string model of the mesons.

The modern interpretation is that QCD somehow yields a tube or string of flux that connects the quark and anti-quark in a meson. There used to, at least, be numerous theoretical attempts to show that QCD produced string-like behavior either through an exact analytical solution to QCD or some type of approximation.

While there is little (no?) empirical evidence to support superstrings as a unified field theory, there has been evidence of string-like behavior in strong nuclear forces for forty to fifty years.

It does not seem surprising that mathematics that had its roots in modeling strong nuclear interactions might be successfully applicable to nuclear physics.

7. **Peter Woit**
July 8, 2009

chris,

The problem isn't just the headline, it's the entire lead paragraph and context in which the story is put. I haven't heard of any cases where researchers have tried to get string theory hype about their work retracted and failed. One case I know of where a researcher complained about this, the story was retracted and rewritten, for more, see

http://blogs.discovermagazine.com/cosmicvariance/2006/02/27/any-publicity-is-good-publicity/

If the researchers involved in this case are unhappy about the misrepresentation of their work, there are many ways that they can make that known. I haven't heard anything…

8. **karl**
July 9, 2009

@ John:

Yes, string theory was originally intended as a theory of strong nuclear interactions. And now it is back to describe precisely this: QCD in the strongly coupled regime. So is this remarkable?

Well, YES!
and the story behind all this is truly revolutionary. Note that there was at least one revolution involved in that story that lead to several Nobel prizes: non-abelian gauge theories. How they first killed strings and now resurrect them, making a sidestep into the fifth dimension is amazing. It took 40 years or so to develop all this (and a community of several hundreds of scientists). It is a complicated story and it is still being written and probably we will not know for another 40 years if it is "wrong". Is it worth being told? Definitely!

Many non-string theorists think it is (jan zanen is a condensed matter physisicst). b.t.w. just now, something like the creme de la creme of condensed matter physics is gatherning right now at kitp santa barbara to learn string theory (and to teach condensed matter theory to string theorists).

Don't get fooled: science is a tough job. As a scientist you can do a valuable job even if you don't yet know if your theory is right or wrong!
After all, the only rule of science is "anything goes"!

9. **Chris Oakley**
July 9, 2009

Karl,

I am under the impression that fundamental physics nowadays is dominated by hippies and comments like yours do nothing to assuage this belief.

Anything goes – really? What about if it does not fit known experimental facts? Or even makes no predictions at all? What about if it is mathematically inconsistent?

And why should researchers in a relatively healthy branch of physics wish to co-opt ideas from a failed research program in another?

10. **David B.**
July 9, 2009

Hi Chris:

High TC superconductivity has not been solved theoretically. There is agreement that it requires a strongly coupled system, for which very few theoretical techniques actually work.

The AdS/CFT setup provides new ways to understand strongly coupled systems that serve as toy models for real world physics. The AdS/CFT ideas are not a 'failed research program' as you describe it.

Toy models usually provide insight that is unavailable otherwise. That is why Condensed matter theorists are learning this stuff, and this is why string theorists are learning condensed matter physics.

11. **karl**
July 9, 2009

Dear Chris,

yes really “anything goes” (P. Feyerabend)!

and if our theory does not fit any experimental facts, why do you care?
evolution will take care of us, or at least of our theories 😉

(although I admit that last point is more Popperian than Feyerabend)

12. **Chris W.**
July 9, 2009

So, the string theory community (or a portion thereof) has become a collection of applied *mathematicians*, currently assisting condensed matter *physicists*.

Nice to have that cleared up…..

13. **Coin**
July 9, 2009

Ugh, so I made a post in the previous thread which now looks pretty stupid. In that thread someone posted a reprint of this press release; looking around I was able to find the same article printed more or less verbatim on several other websites including sciencedaily, but wasn't able to find the actual original Leiden University press release they were actually copying. Trying to be charitable, I made a post attempting to pin this on an overenthusiastic journalist somewhere who then got picked up by some other sites. But no, the whole thing was copied verbatim from the Leiden University release Peter linked. Which just… I don't even know. There really is no excuse for something like this coming out of a university PR department– I realize university PR departments aren't great but I feel like this article crosses a couple of lines.

What's really fascinating me at this point is the thing that tripped me up in the last post– that this press release got more or less literally copy-and-pasted and posted as a story on so many internet news sites with no indication of authorship more clear than, say, (as sciencedaily put it) “Adapted from materials provided by Leiden University”, or “Source: Leiden University”, or other tags written such as might lead the naive or foolish (i.e. me) to assume that the story had been written *using* Leiden as a source, not that Leiden had simply outright written the article. More interesting yet is that so many of these sites, including a couple that one might think of as at least attempting respectability, printed this article seemingly without even having read it– not only accepting its premises as accurate without stopping to question them, but in most cases not even bothering to *proofread* it. Is this sort of thing happening more often than I thought?

14. **Peter Woit**
July 9, 2009

Coin,

Traditionally what a lot of media outlets really do is just take press releases and wire service reports, and print them without much editing. The main function of the editor/reporter is just to sort through the mountain of such things and identify the ones of interest to their readers. These days the web is full of sites that do little but reproduce press releases and stories from elsewhere. This Leiden press release is now on dozens of sites.

By now I've seen a lot of press releases like this, and it's pretty clear how they get generated:

1. Press office at university has someone whose job it is to find stories like this to write. Publications like Science/Nature/PRL encourage such press releases, so press office person gets notified that someone at their university has a new result tha might be worth a press release.

2. A story about how your university's researchers have found a possible new approximation method for dealing with certain condensed matter models doesn't sound very sexy. Press officer notices the “string theory” angle, knows that “string theory” is sexy, as well as controversial because it has been criticized as not predicting anything about nature.

3. They talk to researchers, planning to put together a story about how “university X researchers have solved the great problem in the sexy subject of string theory, how to use it to predict something”.

4. Researchers play dumb. They're not the ones who wrote the headline…

15. **Roger**
July 9, 2009

I think you're being a little unfair Peter.

There are many things researchers should do but, for various reasons, don't – this is one of them. If it helps them raise their profile inside the university then this type of stuff may still be for the good even if a distorted message comes out. Furthermore, arguing with a PR department to make sure they get it right takes time and energy and is frequently a fruitless task.

Also, your comments would carry more weight if you took the time to publish and disseminate (inside and outside the community) your own original research instead of just criticising other researchers who do publish.

16. **Arun**
July 9, 2009

Roger, what you're saying seems to me to be analogous to “don't criticize credit default swaps, go and create your own”.

17. **Peter Woit**
July 9, 2009

Roger,

The misleading message of the title and lead paragraph of this press release is not some random distortion introduced by an ignorant journalist that busy researchers don't have the time and energy to get fixed. Some string theorists have decided that the way to deal with criticism of string theory's failure as an idea about unification is not to answer it honestly, but to engage in a campaign to mislead the public about the topic. I'll keep pointing this out as long as people keep doing this.

I've just got back from a trip disseminating my own original research, I'll write more about this here soon.

18. **Shantanu**
July 9, 2009

Peter any thing interesting from PLANCK 2009, TAUP 2009 or AMALDI 8 comferences?

19. **Tim vB**
July 10, 2009

Hello karl,

"yes really "anything goes" (P. Feyerabend)!"
Surely you were joking, right? However, what Feyerabend said in "against method" was that you cannot decide if some activity is science by judging the methods that are used. "against method" should be understood as "against the enforcement of certain methods as the only ones that may be used by scientists". Feyerabend would say that astrology and astronomy do not differ much in the methods used, but in the results that are obtained (useful or not useful). So, if you get your best ideas by throwing chalk at the blackboard, you do that. But don't claim that the dots you get are useful results, Feyerabend would not agree 🙂

"evolution will take care of us, or at least of our theories (although I admit that last point is more Popperian than Feyerabend)"
Thomas Kuhn is your friend here, Popper was always rather idealistic and supposed that a theory dies by falsification, not by loosing all fans due to a plane crash or something like that.
BTW, I do not want to wait that long! Please? Let's hope string theorists find a different way than dying in dealing with their research program.

20. **Roger**
July 10, 2009

Arun, I'm saying nothing of the sort .

Publishing and disseminating work directly exposes a scientist to the machinations of university PR departments. Opinions backed up by direct experience are often more solid than those given by people without direct experience of the processes they're criticising.

Peter – I can't comment on this individual case. However, in my experience, university PR departments jealously guard their right to determine "the message". I've been involved in a few cases where it just wasn't worth the effort to try to correct their misconceptions.

21. **nbutsomebody**
July 25, 2009

After all this hype it seems that the paper (arXiv:0904.1993) was indeed wrong as confirmed in arXiv:0907.2694.

22. **Thomas Larsson**
July 27, 2009

FWIW, there is a new paper on the arxiv 0907.4238 that references NEW (ref 82).

23. **concerned cynic**
August 20, 2009

University PR departments have a mission: to get what researchers do be known and talked about, and to increase the likelihood of success of future grant applications by researchers employed by the university. The preceding somewhat pedantic sentence deliberately omits "telling the truth about what researchers are doing." That's the job of the researchers themselves, via what they upload to arXiv and eventually publish.

I learned what I say here when I was first intereviewed by a journalist employed by university PR, in 1986. It quickly dawned on me that the person across the desk had been carefully briefed to promote an agenda. Roger above is indeed right: "university PR departments jealously guard their right to determine 'the message'."

A Montreal category theorist told me a few years ago that the Canadian equivalent of the NSF will no longer award grants to category theorists. String theorists, fearing a similar fate, have enlisted university PR departments in their defence. All's fair when faced with the prospects of having one's department closed (yes, simply because physics is not a popular major), of having one's PhD program shut down. or of having to teach undergrad service courses. To tell, in effet, a natural scientist "You will not be awarded another grant unless you make substantial changes to your research agenda" is akin to banishing him/her to Coventry.

Those who don't like Smolin's book patronize it by saying that Smolin does sociology. Those who don't like Woit's book may have similar opinions. But the problem of string theory is as much economic as sociological: the dearth of tenure track positions in theoretical physics. Publishing a lot of papers does not assure one of a job; you need to find a department that also likes your work. And we tend to like work that supports our pet agendas. This puts too much power in the hands of the tenured conformists.

Various and Sundry

July 10, 2009
Categories: Experimental HEP News, Multiverse Mania, Uncategorized

For the latest on the status of the LHC, see the July 2 talk of Steve Myers mentioned here earlier, and a July 8 talk (slides, video) that has some more recent news. The question of what to do about bad splices is still up in the air. The current plan is to make measurements at 80K during the next few weeks on the three sectors that have not been warmed up, then present options during the second week of August to the DG and the experiments. The decision to be made will be about how long to delay the start-up to fix more splices. If more splices get fixed, the machine can safely be run at higher energy. The optimistic scenario now seems to be that it will be possible to run at some energy in the range of 4-5 TeV/beam, without introducing further delays in the current draft schedule (the latest schedule has the machine ready to start circulating beams around the end of October). Gordon Watts has more detail in a recent post, including one of the relevant plots showing the energy vs splice resistance trade-off.

Two items on the multiverse front:

- Lenny Susskind gives new depth and meaning to the word “chutzpah” with an article in Physics World on Darwin’s Legacy. It seems that Darwin’s legacy for physics is the field of string theory anthropic landscape pseudo-science. Luckily, I don’t think creationists normally read Physics World.
- Sean Carroll’s book “From Eternity to Here” is now scheduled to appear next January. It has a Facebook page and a mission statement:

> You can turn an egg into an omelet, but not an omelet into an egg. This is good evidence that we live in a multiverse. Any questions?

String theorist Oswaldo Zapata has posted the third part of his essay on the history of superstring theory, dealing with the question of the “beauty” of string theory. Basically he argues that it was only in 1999, after it started to become clear that string theory unification wasn’t working out, that a publicity campaign about the “beauty of string theory” got started:

> During the late eighties and early nineties, and motivated by the relative success of the heterotic superstrings, string theorists were submerged in intricate and endless computations trying to recover the standard model using a ‘‘top-bottom’’ approach. At that time no one was talking publicly about a beautiful construct. In fact, the theory was in an ugly impasse and mathematical consistency was the only remote trace of beauty…
>
> In this section we have seen that, in contrast to what is currently claimed, string theory was not always considered to be a beautiful theory. The public recognition of the beauty of the theory is recent, dating from around 1999, and it was due mainly to the convergence of two factors: a favourable context, “internal” and “external,” and an acute sense of opportunism.

From the Publisher’s Weekly review of Graham Farmelo’s life of Dirac:

> In 1955, Dirac came up with a primitive version of string theory, which today is the rock star branch of physics.

The opera Hypermusic Prologue: A Projective Opera in seven Planes, libretto by Lisa Randall, had its first performance last month in Paris. It will be presented again in Barcelona in November.

FQXI seems to like to have conferences for their members at scenic volcanic locations in the mid-Atlantic. This year it’s the Azores, here’s their schedule, talks to appear here, blogging here (Sabine Hossenfelder) and here.

Strings 2009 finally got around to putting slides from most of the talks online here. The one talk that seemed to have something new wasn’t about strings, it was Arkani-Hamed’s talk on Holography in Flat Space: Algebraic Geometry and the S-matrix, based on work to appear with Cachazo, Cheung and Kaplan. It’s based on studying the structure of amplitudes in twistor space, and the talk includes many exclamation points, and the claim that “SOME POWERFUL MATHEMATICAL STRUCTURE IS AT WORK!”. More specifically:

> Very natural and beautiful mathematical structure – intersection theory and Schubert Calculus – seems to lie at the heart of tree and loop gluon scattering amps!

From the slides it does appear that there’s some nice mathematics at work here, I look forward to seeing the paper.

   July 10, 2009

   Citing the last paragraph of the article by Lenonard Susskind:
   “Whether string theory with its huge landscape, and eternal inflation with its reproducing pockets of space, will prove to be correct is for the future to decide. What is true is that as of the present time, they provide the only natural explanation of the universe that lives up to the standard set by Darwin.”
   Currently I am greatly enyoing his book “An Introduction to Black Holes, Information And The String Theory Revolution”.
   How can a capable physicist and author like him write an article like that? This is completly beyond me.
   A key of evolution is the survival of the fittest, with the definition of “the fittest” being constantly in danger to become a tautology (“Well, the fittest were the ones that survived, what else?”).
   Did Leonard Susskind give somewhere a definition of what being the fittest universe of the multiverse means (boy, I hope it is the one we live in!) and how a process of selection would work?
   At least he admits that string theory has still to prove itself.

2. **Daniel de França MTd2**
   July 10, 2009

   Peter,

   In your opinion, do you think Nima, Cachazo and others are trying to find a non-string quantum gravity, but that uses susy just as a scattering symmetry rule?

3. **ManyMe**
   July 10, 2009

   you cannot turn an omelet into an egg, but you can turn stupidity into a book.
   This is good evidence that we live in a multiverse, because stupidity is infinite and a single universe could not contain all of it.

4. **Peter Woit**
July 10, 2009

Daniel,

My understanding is that one motivation is to get some sort of analog of AdS/CFT for flat space (rather than anti-deSitter), but, unlike AdS/CFT, this is supposed to a weak-weak duality, so it's something very different. The CFT side I guess is N=4 SYM, or maybe N=8 supergravity, but I have no idea what they are expecting on the "AdS" side, other than that it would involve twistor space.

5. **Count Iblis**
July 11, 2009

If all the technical problems with the LHC are fixed in time, Murphy's law suggests that a swine flu outbreak may cause further delays.

6. **Jim Clarage**
July 11, 2009

"You can turn an egg into an omelet, but not an omelet into an egg…" ergo proof of multiverse.

Bah.

Maybe you or I can't turn an egg into an omelet, but the universe does this all the time. Or are we to presume eggs came preformed as initial conditions of the big bang? Farmers and chicken coops do this reaction millions of times each day. I'm not being flippant, but pointing out the obvious observation which wrinkles this entire argument. Higher order biological laws create low entropy eggs from initial states with much higher entropy than the proverbial omelet, viz., disordered solutions of amino acids and H2O.

7. **Jim Clarage**
July 11, 2009

Time's arrow edit. I meant:

Maybe you or I can't turn omelets into eggs, but the universe does this all the time…

8. **Pawl**
July 11, 2009

Jim,

I'm not endorsing the multiverse, but the argument about the second law depending on low entropy in the early Universe is a good one and almost by definition as valid as the second law is.

Chickens do produce eggs daily, but with a significant expenditure of energy. Where does the energy come from? Plants, which derive their energy from the Sun, a star. That the Universe is populated with stars (and is not a much more random structure) is a result of the near-uniformity of matter in the early Universe **together with** the fact that the gravitational field was of such a special type as to allow that near-uniformity. If a more "random" gravitational field had been there, the form of the Universe would be entirely different (no stars and no chickens, probably).

The near-uniformity of the matter does contribute some entropy, but it is the extreme specialty of the gravitational field which makes the early Universe a low-entropy state (compared to a "random" Universe).

9. **Greg Sivco**
July 12, 2009

Even Lubos Motl disagrees with Susskind re Anthropic/Darwinism if you check out his website.

Is the situation still as Peter wrote in his book re String Theorists that there are 2 camps: Anthropic (Susskind, Polchinski) and Not-Anthropic (Gross, Witten)?

"How can a capable physicist and author like him write an article like that? This is completely beyond me." … Tim vB

Might I suggest==> "Cognitive Dissonance?" That's a psychology term about why the human brain finds it difficult to accept things when evidence is shown that a fast-held belief is wrong. Happens all the time and has no correlation to IQ. Synonyms include "lying to oneself" or "Rationalization."

Peter's book explains the Anthropic in String Theory beautifully: in a nutshell, it's a desperate measure to explain the non-predictive and unfalsifiable String Theory. Essentially, it's desperation.

10. **Tim vB**
July 13, 2009

Hello Greg,
I know about cognitive dissonance: In the EU every package that contains cigarettes or cigars must by law have a big label saying something like "smoking can kill you" or "smoking can cause cancer" etc.
I once asked a heavy smoker what his opinion of this was, he answered "of what?".
He had not noticed…(the labels are big, you cannot miss that by chance).

11. **Greg Sivco**
July 14, 2009

Tim, that's a nice analogy but I was thinking of Leonard Susskind and String Theory, because as far as I can tell the "String Theory War" is either over or coming to a close, and ST isn't the winner. Motl, Susskind et. al. will obviously disagree. If the Anthropic Landscape doesn't spell D-E-S-P-A-R-A-T-I-O-N, what does?

There's an outside chance (think: Quantum Tunneling) that Witten will bring his incredible intellect back to falsifiable and predictive Physics, indeed I think I see signs (but do not know …. I'm speculating), but I don't think Susskind ever will. He was there at the beginning, and he strikes me as a very stubborn man. Which isn't a bad thing all the time, actually. His is also an incredible intellect.

Nor do I think String Theory should completely go away. I just don't think it will be falsifiable or predictive until 2200, 2300, or even 2400. Can I hear a 2500? Shrug, who knows?

Leonard Susskind will speak at the Holographic Cosmology Conference that will run from tomorrow through the 18th at The Perimeter Institute. I hope Peter or someone links to his talk.

12. **Shantanu**
July 14, 2009

Peter, have you seen this
paper ?
It is an example of a string theorist venturing into LQG.

13. **Greg Sivco**
July 14, 2009

Thank you for that link, Shantanu, good stuff. I especially liked this line in the abstract:

"This suggest [sic] the possibility of a relation between Loop Quantum Gravity and supersymmetric string theory, where the Barbero-Immirzi parameter and field of the former play the role of the supersymmetric axion in the latter."

Well, what can we say? Lee Smolin, former author of string theory papers and ever the diplomat, mentions in TTWP that LQG and St need not be combative, but co-operative i.e. complementary, the point being (if I read Lee correctly) that the difference between (some but not all) Strings and LQG is one of scale, with LQG (and Quantum Graphity and CDT especially) operating at the smaller scale.

But good luck trying to get String Theorists (the hardcore ones) to agree with that! Their field has gone from something very specific, namely: trying to explain quarks and the Strong force until Quantum Chromodynamics kicked them to the curb, to getting more and more general until we arrive at the present with Anthropic Landscape, in which case everything is possible and we may as well embrace Many Worlds. Which I will not, nor do I think most reasonable people will.

14. **Peter Woit**
July 14, 2009

Please, remember this is not a general physics discussion board, and the owner has a rather limited degree of interest in quantum gravity.

15. **Greg Sivco**
July 14, 2009

Thank you, Peter, my interest in QG is primarily as a hobby. It's fascinating, yet not as important as those branches of Mathematics and Physics that push knowledge a bit farther than where we are. It would be nice if we have a 1925-1929 situation where the curtains of ignorance are vastly pushed back, and years such as those may well be in hand, but who knows?

I love your weblog, so much so I couldn't find time to read your book until a month ago, and of course I am juiced as a rookie reader.

And what can I say about your book; it's awesome, and pleasantly surprising, as your road to this stuff we're talking about is the same as mine, from Astronomy to Physics to Mathematics.

Best of luck to you by the way on your exploration of BRST Dirac Cohomology. Sounds enticing.

Specifically, I have completed a 10-month general overview of current Physics/Mathematical physics, and find it is now the time to choose a specialty, with QG forever a hobby that I will spend time on, time willing. I have narrowed it down to the following fields. your opinion, please:

– Math: Representation theory of 4D space-time gauge symmetries and diffeomorphism group representation theory as related in the last two paragraphs of your book. How has that developed since publication. Where is the most current work needed?

– Physics: The Quantum Hall Effect. Low temperature sure, but incredible how the quantum world can be made manifest in the macroscopic. I'll work on this one by myself, what a puzzle.

16. **Peter Woit**
July 14, 2009

Greg,

The paper on Dirac cohomology is intended to be a toy model for the interesting case of 4d. You study representations by studying an invariant, their Dirac cohomology. To do this in 4d requires new ideas: everything is parametrized there by the space of background connections and metrics and you need to figure out what to do about that. Right now I'm thinking about the easier case of 2d…

I think we're still quite a ways away from even knowing what the right way to think about such representations is, so this is a difficult subject for someone to study. It's too wide open right now, and the relevant mathematics is not even clear. That quantum Hall effect looks like a much more straightforward problem…

17. **M. Wang**
July 14, 2009

The most relevant application of Darwin's theory on high-energy physics is the evolution of the physicists landscape. Here, natural selection works through paper publications, and the fittest are those who can keep publishing the most, however meaningless these papers may be. Susskind and his cohorts are successful survivors of this process. Although I admit this result is not pretty, but hey, that's part of Darwinism.

18. **observer**
July 14, 2009

…..Wait a minute; with the DNA you can identify a person from a million, with ST (and branes), still you cannot do anything concrete just hope for some right arrangement to be correct. Sorry but lame analogy.

BRST and Dirac Cohomology

July 11, 2009
Categories: BRST

For the last couple years I've been working on the idea of using what mathematicians call "Dirac Cohomology" to replace the standard BRST formalism for handling gauge symmetries. So far this is just in a toy model: gauge theory in 0+1 dimensions, with a finite dimensional Hilbert space. Over the last few months I've finally got this to the point where I think I understand completely how this should work, at least for this toy model. I talked about this last week in St. Petersburg, and have a preliminary version of a paper on the subject, which is available here. Next weekend I'm leaving for a trip to Shanghai and Hong Kong (the plan is to be in Shanghai for the July 22 total solar eclipse, which will be visible there). After I get back at the beginning of August I'll work on the paper a bit more, hoping to have a final version done by the beginning of September, when the academic year starts.

The paper uses quite a lot of mathematical technology, so I fear most people will find it hard to read. This fall I hope to get back to finishing the Notes on BRST I was writing up, the idea behind those was to give a more expository account of this subject. That project got bogged down when I realized there was something I was still confused about, and after getting unconfused it seemed like a good idea to get the basic ideas down on paper, since the expository project might take a while to complete.

First of all, what this is and what it isn't. It's a toy quantum mechanical model, with gauge symmetry treated using some new ideas from representation theory which are related to BRST, but different. It's not a QFT, and not a treatment of gauge symmetry in the physical case of four space-time dimensions. I've been thinking about how to extend this to higher dimensions, but this requires some new ideas. Next on the agenda is to try and get something that works in 1+1 dimensions, where one can exploit a lot that is known about affine lie algebras and coset models. There also appear to be interesting possible connections to geometric Langlands in that case.

Given a quantum system with G-symmetry, the BRST method allows one to gauge a subgroup H, picking out the H-invariant subspace of the original Hilbert space using Lie algebra cohomology methods. The proposal here is to do something different, picking out a subgroup H of symmetries one wants to keep, and gauging the rest. In the special case where Lie G/Lie H is the sum of a Lie subalgebra and its conjugate, the method proposed here reduces to the standard BRST method, but it is more general.

An algebraic version of the Dirac operator plays a role here somewhat like that of the BRST operator in the standard formalism. One difference is that the square of this operator is not zero. However, it is in the center of the algebra of operators acting on the Hilbert space, so its action on operators squares to zero. This sort of thing has been studied a bit before in the physics literature, in the context of supersymmetric quantum mechanics models, but I do believe that the interpretation here as a method for handling gauge symmetry is new.

One thing I want to add to the paper is some comments about the relation to the physical Dirac operator. The point of view on the Dirac operator explained here that comes out of representation theory seems to me perhaps the most intriguing part of this story. Remarkably, this Dirac operator is in some sense a quantization of the Chern-Simons form. The full story of how to use this in higher dimensions remains obscure to me, but there is some hope it will bring together the physical Dirac operator, something like BRST, and something like supersymmetry in a new way.

Comments

1. **Austin**
   July 11, 2009

   Peter, what are the testable predictions of the generalized physically unphysically topological Woit-Dirac-Kostant-BRST-supersymmetry non-nilpotent cohomology-non-cohomology and how can one falsify it, aside from pure mathematical proofs that it cannot work?

2. **Peter Woit**
   July 11, 2009

   "Austin"

   The problem with string theory is not that it doesn't now make testable predictions, but that 25 years of intensive effort have shown that it inherently can't.

   Whether ideas related to Dirac Cohomology will ever lead to progress on doing better than the Standard Model, I don't know. I think it's reasonable to hope that they might lead to a better understanding of the Standard Model and its relation to fundamental mathematics. This seems to me worth working on and I'll keep doing that. If 25 years from now this hasn't led anywhere, but there are institutes of Dirac Cohomology and thousands of physicists working in the field, I'll be the first to criticize this.

   Quantum gauge theories remain a largely unexplored rich mathematical territory. Exploring this may lead to new physics, or it may lead to new mathematics. What I'm writing about is just one idea about how to make progress on this. We'll see if it gets anywhere.

   And, with that, from now on I'll delete any more stupid anonymous comments to this posting. If you want to discuss the ideas I'm writing about here, I'm happy to do so. If you want to engage in juvenile argumentation, you'll have to do it under your own name here, or find another posting.

3. **Per**
   July 11, 2009

   Congratz

   You must be a bit nervous now tho. All those string theory people has critized you over and over again for not publishing anything. Now it comes, so I am sure they'll all jump on it.

   Best of lucks.

   // phd student.

4. **Christine**
   July 11, 2009

   Peter,

   Sounds interesting, but it will make a somewhat hard reading for me. I understand that it is just a toy model for the moment, but I missed the main motivation for it. Do you envision any methodological advantages over BRST or perhaps a possible connection to the Langlands programme?

Best,
Christine

5. **Tumbledried**
July 11, 2009

Per,

In my opinion, there in nothing wrong with pursuing a speculative line of enquiry – that is what research is supposed to be all about. "Search", and "search again" ie Re-search. Results are never guaranteed. In fact the chance of a particular line of reasoning being successful, in absence of some very good heuristic/intuitive/formal/physical reason, is very, very small.

And even if there are grounds to believe something to be true, that does not ensure success. String theory is an example of this. There originally were relatively good grounds and motivation to pursue it as a topic – 30 to 40 years ago. But it is pure foolishness in an area **where results are not guaranteed** to put all resources into one particular topic.

The whole scientific community benefits if a variety of ideas/approaches are posed to attack fundamental questions. Contrariwise, the whole community suffers if all avenues of attack save a few – which furthermore have yet to be vindicated (if ever!) – are stifled.

So the burden of proof is not on Peter in this case, since I do not think he is advocating/demanding that everybody drop everything and work on BRST.

tumbled

6. **Peter Woit**
July 11, 2009

Per,

Thanks, but I'm not worried about that. The problem with working on something rather abstract and far from what other people are used to is that it's likely to be ignored. If string theorists decide to learn about Dirac cohomology in order to criticize what I'm doing with it, so much the better…

Christine,

The BRST treatment of gauge symmetry has various problems, especially non-perturbatively. Maybe Dirac cohomology avoids these, too soon to tell. It also may be useful in a non-perturbative formulation of chiral gauge theory, something which doesn't really exist at the moment. Another possible application would be to make sense of the vague idea that spinor fields are the analogs of ghost fields for local translation symmetry. All of this is rather speculative at the moment.

One approach to geometric Langlands uses BRST, perhaps Dirac cohomology gives something of mathematical interest there, including a closer connection between geometric Langlands and 2d gauge theory. Again, all speculation at the moment…

7. **Michael Zeiler**
July 12, 2009

Off topic, but you mentioned that you'll be in Shanghai for the total solar eclipse on July 22.

I just posted some eclipse maps with lines of equal duration for totality and local circumstances at

http://www.eclipse-chasers.com/tse2009maps.php

The map for Shanghai is TSE2009_China_120E_123E.pdf. If you need to dodge clouds and drive east, then you also want TSE2009_China_117E_120E.pdf

For a larger view, try Regional_TSE2009_CentralChina.pdf and Regional_TSE2009_EastChinaSea.pdf

Clear skies!

8. **Peter Woit**
July 12, 2009

Thanks Michael,

The plan so far is to watch the eclipse from downtown Shanghai, we'll see if that works out…

9. **a quantum diaries surivivor**
July 12, 2009

Another eclipse! I am extremely envious! I still have to see one… I seem to be on the opposite side of the world when one occurs. Have fun!

T.

10. **Tipster Dude**
July 13, 2009

Peter, if you add this WordPress shortcode in the HTML of a page, [archives], it will list links to all your posts on one page, which would be around 750 links.

WordPress shortcodes.

So you could create a page such as "Archives", and then create a link to that page in one of your link categories, if inclined.

Formalizing theory from a heavy mathematician's perspective ==> magical mystery tour for all but a few select physicists. Serves them right.

11. **Thomas Larsson**
July 20, 2009

I cannot say that I understand what you are writing. However, it seems to me that you make the same crucial assumption in Dirac cohomology as in BRST: that the relevant algebra has representations. This becomes problematic if you want to study current groups in multi-dimensions. Classically, there are no problems; the representations typically act on fields over spacetime, i.e. on sections of some bundles. However, after quantization you run into various infinities, which can not be removed by normal ordering. This problem seems independent of whether you consider Dirac or BRST cohomology.

One can construct representations acting on quantum fermions parametrized by a classical background gauge field. This idea, which you seem to favor, has been put forward by Jouko Mickelsson. Alas, I think it is a bad idea, at least if you want to study fundamental physics. It may work within a limited scope, but fundamentally everything must be quantized. The introduction of a classical gauge field is therefore manifestly unphysical.

The reason why Jouko considered this type of representations is a no-go theorem by Pickrell. IMO, the moral of this theorem is that no interesting representations of current groups can be constructed within the framework of QFT, but one must consider a more general framework instead. Since I know that you don't want me to mention my own work, let me link to an old paper by Rao and Moody, where they construct vertex representations of current algebras. The thing to note is that these representations do not depend on some background gauge potentional, so Pickrell's no-go theorem is evaded. However, the Rao-Moody representations can not arise in QFT.

12. **Jonathan**
August 5, 2009

Were you in Shanghai for the eclipse? I made it West to Wuhan and saw a few fleeting glimpses, a few km South West had perfect skies, but such is life. Third eclipse, third cloudy eclipse – I'll get my corona yet!

13. **Peter Woit**
August 5, 2009

Hi Jonathan,

Yes, I was in Shanghai, which was cloudy, except for a few short glimpses of the partial phases (one just after totality). I can't complain too much though: this was the fifth eclipse I've tried to see, the previous four had clear skies.

14. **Peter Woit**
August 5, 2009

Thomas,

I agree that the background gauge field needs to be quantized. But it appears to me that what you naturally are getting is not a representation, but a family of representations parametrized by the background field. Perhaps this can be quantized by a path integral sort of construction, basically integrating over the background fields.

Interestingly, in geometric Langlands, Frenkel argues that you should think of the group as acting not on a representation, but on a category of representations.

15. **Thomas Larsson**
August 7, 2009

Peter,

I strongly disagree, and much prefer the Rao-Moody class of representations. They cannot arise in QFT (their extension is proportional to the second Casimir rather than to the third), but we know that QFT must break down anyway since it is incompatible with gravity. The extra ingredient that must be added is the observer's trajectory in (n-1)-dimensional space. This is secretely encoded in the n-1 null roots, defined in R-M's Definition (3.3).

Given that every experiment involves an observer, and none fundamentally involves classical fields, I believe that representations are more physical if they depend on the former rather than on the latter. But then again, my opinion might be colored by the fact that I have invested 15 years of my non-career into this class of representations.

Latest From the LHC

July 15, 2009
Categories: Experimental HEP News

Here's an announcement from the CERN DG Rolf Heuer sent out to CERN employees today:

> The foreseen shutdown work on the LHC is proceeding well, including the powering tests with the new quench protection system. However, during the past week vacuum leaks have been found in two "cold" sectors of the LHC. The leaks were found in sectors 8-1 and 2-3 while they were being prepared for the electrical tests on the copper stabilizers at around 80 K. In both cases the leak is at one end of the sector, where the electrical feedbox, DFBA, joins Q7, the final magnet in the sector.
>
> Unfortunately, the repair necessitates a partial warm-up of both sectors. This involves the end sub-sector being warmed to room temperature, while the adjacent sub-sector "floats" in temperature and the remainder of the sector is kept at 80 K. As the leak is from the helium circuit to the insulating vacuum, the repair work will have no impact on the vacuum in the beam pipe. However the intervention will have an impact on the schedule for the restart. It is now foreseen that the LHC will be closed up and ready for beam injection by mid-November.

This is an extra two week or so slip with respect to the latest draft schedule I'd seen. In addition, the question of how to deal with defective splices remains open. Efforts now are directed towards determining what the maximum safe energy is, assuming that the cold sectors are not warmed up, with the plan to have an answer to this question by the second week of August. Part of this effort involves study of possible changes in the parameters that determine how quenches are detected and dealt with, in order to optimize the maximum safe energy.

Update: The latest CERN Bulletin is out, with more about this.

Comments

1. **ObsessiveMathsFreak**
   July 16, 2009

   I'm beginning to think that the LHC will never run as advertised. It's too big, has too many single points of failure, takes far too long to repair. It's like a giant software project, where a single tiny bug can crash the system, but that takes six weeks to recompile from source, even if only the slightest change needs to be made.

   I don't think these issues are teething troubles. The design of the LHC was probably too optimistic about the potential for errors. There has been a years delay already, and the machine hasn't even done anything yet.

   Is it reasonable to say at this point that this device will at some point be in continuous operation for, say, five years? How many potential gremlins will have to lie dormant for that long? Hundreds? Thousands? More than a million? Has there ever been a single project in human history that has run so smoothly for so long?

   Admittedly, I'm being very pessimistic. I'm sure that these issues have been discussed, and indeed have been surmounted in other colliders. But the LHC is over 4 times larger than the next largest particle accelerator. By my offhanded reckoning, with the same instruments, wouldn't that mean that it is only likely to run for a quarter the length without failure. Have our instruments become four times more reliable in the meantime?

   The cooldown time is not so big a problem as the fact that almost every component in the machine is a single point of failure. I honestly don't think that humans can reliably operate such delicate devices on such a large scale.

2. **Peter Orland**
   July 16, 2009

   OMF,

   I don't think we should be so pessimistic. Yes, it is a complicated project, hence many unanticipated delays, screw-ups, etc. The people who built this machine are smart and dedicated, however, and the set-backs don't imply it will never work.

3. **Charles**
   July 16, 2009

   Obviously the previous poster decided that his own personal paranoia is important to the rest of the readers here, and also to the running of the LHC.

   Amyway, since some of the sectors to be warmed up because of the leaks can then also be checked for bad splices, the reliability of the whole machine should increase considerably.

   Charles

4. **Greg Sivco**
   July 16, 2009

   Whoa, man, " the fact that almost every component in the machine is a single point of failure."? That's a bit much, but I do hear you that there is an outside chance (very small, I hope) that the damned thing will never start up.

   The fact straight up though regarding that is: we don't know. Experimental Physics, Applied Ahysics, and Engineering are extremely well-defined fields. I say let's give the Euros in those fields a break, and hope, rather reasonably hope, they slay their dragons and get the sucker up and running, later if not sooner. We really don't want the machine to go the way of the SSC, right?

   In the meantime … there much work to be done. We have a sweet opening between the death (or dimishment) of String Theory, and the LLC producing particles that raise more questions that answer.

   Peter is working on BRST Cohomology. Good for you, Peter. Go for the gold.

5. **Peter Woit**
   July 16, 2009

OMF,

I think it’s way too early to start worrying. In a huge, complicated project like this, you’re going to run into all sorts of problems. So far, they’re all things that are readily fixable, it just takes time (except maybe the magnets not getting to 7 TeV, it’s possible the machine will end up being a 6-6.5 TeV machine). Getting the LHC up and running, and working reliably at design luminosity may very well end up taking a few more years. The publicity campaign that encouraged people to think the machine was going to be working and producing (safe) black holes any day now may have been a mistake. Realistically, this is a process that takes a lot of patience.

6. **Sorinis**
   July 16, 2009

   We all apreciate optimism. But this project is as dead as a can of spam. Notice too that the latest delay (in a long series to come) is getting leaked now after Heuer announced that his new budget was aproved. Yes it is huge and complicated. But it is years over schedule, it will not run at design energy for the foreseeable future . . . and there is no credible start date at any energy. You can define failure more acurately.

7. **Loco**
   July 16, 2009

   Sorinis and greg, you’re so pessimistic it’s hard not to take it as personal paranoia. As PW himself stated (and you don’t think PW is especially naive don’t you?) you’re going to run into all sorts of problems when you build a new collider. “So far, they’re all things that are readily fixable, it just takes time.”

   An extra 5 years before full luminosity at 7 Tev is unlikely but would not be so surprising (remember the now glorious Tevatron?), and it doesn’t matter. You’re talking about a 40 years project. Who cares if it takes 45?

   Anyway don’t worry, don’t change anything in your attitude. That explains a lot about why the LHC is not in the USA and why the SSC went the way it did.

8. **Shantanu**
   July 16, 2009

   Loco, the basic point made by Sorinis and Greg is correct. If LHC is delayed,then people will start losing interest (esp. grad. students/postdocs) and will gravitate towards particle astrophysics/cosmology/gravitational waves. In fact AFAIK the top cited experimental HEP paper is not aparticle physics experiment, but WMAP. In fact in the last 8 months or so most hep-ph papers seem to be PAMELA rather than TEVATRON or LHC
   (of course this is anecdotal and I have not done a count).

9. **Sorinis**
   July 17, 2009

   I think the tevatron is due to announce some higgs results towards the end of august. Peter, are you covering htat?

10. **Mikael**
    July 17, 2009

    OMF,

    your analysis is very superficial.

    A vacuum leak is a trivial problem which has been overcome during the last cool down. Remember, the machine was already completely ready once proving you wrong.

    The bad splices are annoying because completely fixing them would require a complete warm up of the machine. They just don’t want to do it now just because they want the machine be running now so everything can be tested including the detectors.

    Once the bade splices are fixed, they are just fixed and do not interfere with anything.

    There may be a couple of other problems ahead, but their number is surely finite.

11. **Loco**
    July 17, 2009

    Shantanu, I’d say you have a generous way of extracting “the basic point” made by some folks here.

12. **Nobody**
    July 17, 2009

    Sorry Mikael,
    we all saw one week after what it was ready for. And please do not talk of bad luck; in the past they had a similar accident on a test bench, but it looks like the potential consequence of it on the final machine was totally neglected.

13. **Peter Woit**
    July 17, 2009

    Sorinis,

    If the Tevatron has new results on the Higgs this summer, I’m sure I’ll post about them when they come out. If someone at CDF or D0 has preliminary results now they’d like to share, feel free to e-mail me…

14. **Greg Bishop**
    July 17, 2009

    Shantanu, who cares if some marginal hangers on are discouraged that experimental physics is hard? That’s a good thing. It leaves more money for those that actually care.

    Certainly the string guys typing arbitrary ‘science free’ formulas (IMHO) into computers could use some company on World of Warcraft. That’s (probably) the more useful activity they perform for society, after all the Orcs aren’t going to defeat themselves.

15. **Shantanu**

July 17, 2009

Greg, one counter-example to your point is "Gravity Probe B" which was launched after almost 40 years. Are you really looking forward to their results?
Also if an experiment keeps getting delayed
it risks not getting funded (rather than the opposite way) (another example been the DUMAND experiment

16. **student**
July 18, 2009

Shantanu,

As a student on ATLAS who is waiting for data to come in to complete a thesis analysis, I think you have a point. However, to assume that the delays of the LHC are driving students and post-docs to different fields is a bit of a stretch in my opinion. Some American students have switched to Tevatron experiments recently (as they're nearing the end of their degree and simply can't wait any longer for data to come in, and unlike they're European counterparts, aren't allowed to graduate on a Monte Carlo analysis), but I've yet to hear of a single person moving entirely away from collider experiments, simply because they're discouraged by the delays.

17. **Shantanu**
July 18, 2009

student, if such delays continue then obviously you will see more people
migrating away from collider/accelerator physics. as I mentioned WMAP
papers have more HEP citations than any particle physics experiment.

18. **Pessimist**
July 20, 2009

The migration to astrophysics seems unlikely by students already in the pipeline; however, we might have seen an exodus to the Tevatron had the real extent of the damage been made public earlier. Recall that the "He leak" was to be fixed, and LHC ready for beam in "early spring". Now we see a steady dribble of two week schedule slippages.
To compound the misery, the detectors have been closed and are going through periods of 24 hour shifts to be ready for beam in summer ….fall … winter …..
We all know this is a difficult undertaking, but the management of information is starting to have a real effect on the participants lives.

19. **Sorinis**
July 21, 2009

Yes Peter, I'll email you what I've got when I have it. But only if you stop erasing my rants about the LHC. 🙂 That is the deal with Satan. I had such high hopes for it and the europeans just ruined everything.

20. **Coin**
July 22, 2009

> people will start losing interest (esp. grad. students/postdocs) and will gravitate towards particle astrophysics/cosmology/gravitational waves

Do grad students and postdocs really have the ability to so completely shift their research focus within the timeframe that the final burst of LHC delays has covered (1-3 years)?

…and if some people did shift their focus as you describe… would that even be a bad thing? There's some really important stuff happening in astrophysics and cosmology.

21. **Hal**
July 28, 2009

Don't forget the paper that argues that the LHC will never be operated (at close to full luminosity) due to a time travel cancellation effect from the future.

http://www.fqxi.org/community/forum/topic/230

Every time I read about new delays and new problems I wonder if the idea might just be crazy enough.

22. **nigel**
August 5, 2009

Are you unable to log on from China due to internet filtering? Hope you start blogging again soon.

23. **Peter Woit**
August 5, 2009

nigel,

I did have internet access periodically in China, no posting just because I was on vacation… Internet filtering did keep me from following Lubos's blog.

Weinberg at CERN

July 17, 2009
Categories: Uncategorized

Steven Weinberg was visiting CERN recently and gave a talk entitled The Quantum Theory of Fields: Effective or Fundamental? He discussed the ups and downs of the "market price" of quantum field theory, showing a decline since a peak in 1984, followed by a conjectured increase in the future. He also described the history of his work that led to the modern point of view on the role of QFT as an effective theory.

He ended with comments on the "asymptotic safety" approach to quantum gravity, noting that it is quite possible that string theory is not needed, that the world can just be described at a fundamental level by quantum field theory (and thus his conjecture that QFT may come back into fashion as a fundamental theory):

> I don't want to discourage string theorists, but there's just the possibility that maybe that isn't the way the world is, that the world is much more like we've always known, that is, the Standard Model and General Relativity.

Update: Weinberg has a new paper on the arXiv, covering much the same material as this talk.

Comments

1. **Charles**
   July 17, 2009

   The talk is somewhat confused. If the world is really described by the standard model plus general relativity, why do we need to discuss asymptotic safety at all? This is not made clear by Weinberg.

2. **Peter Woit**
   July 17, 2009

   Charles,

   This is all about the renormalizability problem of gravity. The asymptotic safety idea allows you to make sense of GR as a quantum theory, despite the renormalizability problem. It's a matter of some controversy whether this actually works and does what one would like.

   My own interpretation of what Weinberg is saying (which he might not agree with…) is something like: "unifying the SM and quantum gravity via string theory may very well be the way to go, but given that this hasn't been a success so far, it's a good idea to keep in mind that there's another possibility: QFT by itself might be all that is needed, with asymptotic safety one way the gravity renormalizability problem could get solved".

3. **V_NO**
   July 17, 2009

   Lubos Motl wrote interesting comment on this talk, pointing out that quantum gravity as local quantum field theory is not compatible with the results of black hole thermodynamics. Are there any loopholes to solve this problem?

4. **Peter Woit**
   July 17, 2009

   V_NO,

   What Weinberg is talking about is the standard claim for string theory that it is needed to deal with the perturbative renormalizability problems of quantum gravity. That may not be true, either because of asymptotic safety, or also because of possible perturbative finiteness of some supergravity theories.

   Non-perturbatively, you don't really even know what string theory is, I don't see how one can claim it's the only possible way to deal with non-perturbative problems in quantum gravity. The problem is more complicated than just invoking black hole thermodynamics, which was originally discovered as a semi-classical phenomenon in QFT.

   Sorry, but the Lubos rants on this subject tend to be more ideology than science. It's quite clear that he would equally vociferously make the opposite argument if he felt that was the "pro-string theory" position.

5. **Peter Woit**
   July 17, 2009

   Getting ready to get on a plane to China. I'm not going to be able to deal with comments here for a while, so will shut off comments for now.

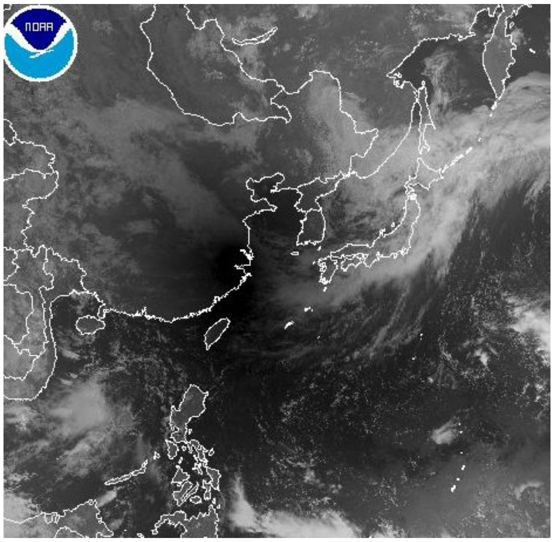
   If you want to discuss Lubos's claims that Weinberg is wrong on this point of QFT, you can do that at his blog.

Back

August 5, 2009
Categories: Experimental HEP News, Uncategorized

I've spent most of the last month traveling, first to Latvia and Russia, then to China, finally to Seattle. Back now, looking forward to staying in one time zone and not seeing the interior of a plane for a while.

In China I visited Shanghai, Suzhou, Hangzhou, Yellow Mountain, Hong Kong and Macao, all of which was an amazing experience (thanks to John Baez for, among other things, urging me to search out the few remaining sections of old Shanghai). The weather unfortunately was less than ideal, with record heat in Shanghai, rain at Yellow Mountain, and clouds the day of the eclipse. Still, it was a lot of fun to be in People's Square and see the city go dark for 6 minutes. Here's one view from about that moment:



After getting back to New York from China, I turned around and went out to Seattle to attend my friend Nathan Myhrvold's surprise 50th birthday party. This was held at the new lab of his company, Intellectual Ventures, and among the organizers were Bill Gates and Lowell Wood. In attendance were many of the luminaries of the technology and culinary worlds, with Wylie Dufresne of New York's WD-50 one of several chefs who came in to attend the party and serve amazing food to the guests. Not the sort of party I normally attend…

Regular blogging will resume imminently. Things seem to have been rather quiet the past couple weeks anyway. The news of delays at the LHC reported here earlier has been getting more media attention. There's a very good article about the LHC problems by Adrian Cho at Science here, and the New York Times ran a front-page story yesterday. For some reason, the Times decided that it was important to quote what prominent theorists have to say about this, including:

> "I've waited 15 years," said Nima Arkani-Hamed, a leading particle theorist at the Institute for Advanced Study in Princeton. "I want it to get up running. We can't tolerate another disaster. It has to run smoothly from now."

Gordon Watts has some comments about this here (including pointing out that "running smoothly from now" is probably not in the cards), and there's also a good posting at Resonaances.

My understanding is that the LMC (LHC Machine Committee) was meeting today to go over all that is known about the splices problem and discuss the question of what the highest energy is at which the machine can safely run in its current state. A smaller group of people, in consultation with the experiments and the director, will then have to decide either to run at that energy, or accept further delays for repairs to allow running at a higher energy. It's not known how long that decision will take, but presumably it will come soon. If no further repairs are to be made, the current schedule has the machine ready for injection of a beam in mid-November.

Update: It's 3.5 TeV/beam.

   August 6, 2009

   Welcome back!

   (Are you going to re-open comments on the previous post ["Weinberg at CERN"] or just let that sleeping dog lie?)

2. **Haelfix**
   August 6, 2009

   Yea the last post does deserve some scrutiny, b/c its interesting and there are some good arguments against that conclusion.

3. **Peter Woit**
   August 6, 2009

   I think I'll just leave that one closed. This particular topic in quantum gravity has been discussed repeatedly on many blogs, the likelihood of anyone having anything new and enlightening to contribute on the subject seems small, and Lubos has provided a venue to argue with Weinberg about this.

4. **sorinis**
   August 6, 2009

When is the 3.5 TeV happening? In November?

5. **woit**
August 6, 2009

 Current schedule is to try and inject a beam at low energy mid-November, with about a month required to get usable colliding beams at 3.5 TeV. But they may be shutting down for a while over Christmas/New Years…

6. **Geometrick**
August 6, 2009

 Is 3.5 TeV in the range for supersymmetry? When will we finally get some hard evidence of the existence or non-existence of SUSY?

7. **dir**
August 7, 2009

 you missed beijing?

8. **Peter Woit**
August 7, 2009

 dir,

 I figured it best to leave Beijing for my next trip to China….

9. **graviton383**
August 7, 2009

 With this reduced center of mass energy and the relatively low integrated luminosity that is expected, it may take some reasonable time to generate sufficient SUSY signals
 beyond the bounds that already exist from the Tevatron. However, the real issue is not that but how long it will be for the detectors to be understood well enough to make any new physics claims.. if the new physics is at all subtle as would be the case for general SUSY.

10. **dir**
August 7, 2009

 peter,
 if you come to beijing, let me know. i'm an expert in food in beijing.

11. **ESPOL**

 Maybe you could report if you found anything interesting in these meetings

Various Items

August 6, 2009
Categories: Uncategorized

- CERN just issued a press release announcing the decision about the energy for the initial LHC run: 3.5 TeV/beam.

> The procedure for the 2009 start-up will be to inject and capture beams in each direction, take collision data for a few shifts at the injection energy, and then commission the ramp to higher energy. The first high-energy data should be collected a few weeks after the first beam of 2009 is injected. The LHC will run at 3.5 TeV per beam until a significant data sample has been collected and the operations team has gained experience in running the machine. Thereafter, with the benefit of that experience, the energy will be taken towards 5 TeV per beam. At the end of 2010, the LHC will be run with lead ions for the first time. After that, the LHC will shut down and work will begin on moving the machine towards 7 TeV per beam.

- The Lost University will be running two courses on physics, starting September 22. The more advanced one will be taught by Jeremy Davies, based on Lynne McTaggart's book The Field:The Quest for the Secret Force of the Universe

> This book cites scientific experiments that examine the Zero Point Field, which is believed by some to be a universal energy source that connects everything.

The other physics course will be taught by Sean Carroll, Clifford Johnson and Nick Warner. It's entitled Introductory Physics of Time Travel and will be the prerequisite for a later course on "Advanced Physics of Time Travel". One of the texts will be Sean Carroll's forthcoming book.

More about this from Clifford Johnson here.

- The Anacapa Society, an organization aimed at promoting theoretical physics research at undergraduate institutions, has taken up permanent residence at Amherst, more here.
- Tommaso Dorigo is trying to stir up trouble again, this time by pointing out the intriguing fact that, looking at events with just electron-positron pairs, both D0 and CDF have seen more than expected at an invariant mass around 720 GeV. Not that this is statistically significant or anything…
- Talks from the recent FQXI conference in the Azores are available here.
- Talks from the on-going Newton Institute workshop on Non-Abelian Fundamental Groups in Arithmetic Geometry are available here. Commentary from Jordan Ellenberg about Deligne's talk is here. Jordan notes that:

> When I was first giving public lectures, someone gave me the hoary advice that I should quell nervousness by imagining the members of the audience in their underwear. Strange to think that, in this new broadband world, *most of them actually are*.

Comments

1. **spear Mark the Second**
   August 6, 2009

   We're finding out the LHC was pushed a bit far… too much reach on not enough money. An honored tradition, in its way… the original main ring at FNAL, the SLC at SLAC, and pretty much the whole CESR/CLEO program at Cornell. They all caught up by using operating funds to complete the job.

   CERN historically has gotten the resources for the reach they proposed. But now there is no competition, so why not? The only question is whether the public will turn against the LHC because the hype got a bit out of control last year. If Conan O'Brien makes a joke out of a couple billion for contacts as bad as an american toaster, that will be bad.

2. **Shantanu**
   August 6, 2009

   Peter, welcome back. Any comments on the recent review on quantum gravity
   (esp. the section on string theory) posted by Thomas in which your book is cited?
   Also videos of Planck 09 conference are online.

25 Years On…

August 6, 2009
Categories: Uncategorized

Five years ago the 20th anniversary of the "First Superstring Revolution" was being celebrated, and I wrote some postings about this history (see here, here and here). This month is the quarter-century anniversary, and I haven't seen any evidence of anyone celebrating.

25 years later, it's pretty clear that the anomaly cancellation discovered by Green and Schwarz doesn't actually provide at all the kind of explanation of some aspects of the standard model that people got excited about back then. 1984 also saw the beginning of endlessly repeated and overhyped hand-waving arguments that string theory is needed to cure the perturbative ills of quantum gravity. It turns out that these arguments don't actually work either. The latest issue of Science has an article about recent discoveries showing that N=8 supergravity amplitudes are much better behaved than expected. Zvi Bern compares the widespread belief that string theory is needed to deal with perturbative divergences to the belief that ulcers are caused by spicy food. While you could make a plausible hand-waving argument for this, it turns out that the real culprit is a bacterium, not enchiladas. According to the article:

> The work doesn't disprove string theory, but it has string theorists backpedaling a bit in their criticism of quantum field theory. "At certain points, our understanding has been incomplete, and we may have said things that weren't right," says John Schwarz of the California Institute of Technology in Pasadena. "That being said, the fact is that we still need string theory."

Forced to concede that a quarter-century's worth of argument about perturbative amplitudes was wrong, Schwarz tries to shift ground by claiming that the QFT problems are non-perturbative. That may very well be, but until one actually has a viable non-perturbative version of string theory, it will be hard to argue that string theory is the only way to go.

A new review article about quantum gravity describes how things are 25 years after the revolution, with many if not most string theorists having given up hope that string theory has anything to say about unification:

> A personal anecdote might best convey the current state of affairs. Early in the spring 2007 semester my University of Florida colleague, Charles Thorn, began a seminar by announcing his belief that:
>
> *String theory is just a technique for summing the leading terms in the 1/N expansion of QCD.*
>
> After years of hearing more ambitious assessments this was so shocking that I checked to be sure I had understood correctly. Charles confirmed that I had; in his current view, the effort to regard superstrings as a fundamental theory of everything was a blind alley. Later that year I related Charles' pronouncement to string theory colleagues on three continents and solicited their own opinions. About half of them agreed with him, more often the younger people.

Update: One more, from Martha Stewart, Some Pearls of Wisdom on String Theory.

Comments

1. **Chris W.**
   August 6, 2009

   Richard Woodard's review article is quite a piece of work—106 pages, and very readable.

2. **Chris W.**
   August 6, 2009

   PS: From page 62:

   > The most recent results about N = 8 Supergravity [88] mean something is wrong with our thinking about what sorts of divergences can happen. No one knows how high the cancellations extend in N = 8 Supergravity, or if they might apply to more realistic models. We could be witnessing the start of a revolution. The latest progress on this subject is so new that there are no books or long review articles. I highly recommend the short article by Bern, Carrasco and Johansson [100].

3. **Mirko Tarollo**
   August 7, 2009

   In 1997, at Strings in Amsterdam, I happened to sit near Nathan Seiberg. He was extremely angry because Hawking had said that N=8 supergravity was a candidate theory of everything, on par with superstings. Seiberg was really extremely angry, and when I asked to explain, he stopped talking to me.

   The day after, Seiberg gave his talk. He was still angry. I have rarely seen a man so angry. He was a missionary, not a speaker. Strings were his religion. I wonder how he deals with all this at present.

4. **Chris Oakley**
   August 7, 2009

   Hawking was saying that N=8 Supergravity was the answer in 1980.

   It's just one of the things he does.

   There is no point in anyone getting angry about it.

5. **Daniel de França MTd2**
   August 7, 2009

   How could N=8 SUGRA be a theory of everything? How could it hold the particles of the SM, any papers on that?

6. **Peter Woit**
   August 7, 2009

   Daniel,

There’s a long literature from the early 80s about this, and the problems with it.

What’s more important is that the N=8 supergravity calculations show that the conventional arguments about the perturbative problems of gravity QFTs are just wrong. The source of these new cancellations is not known, they don’t seem to necessarily require N=8 supergravity.

7. **Aaron Bergman**
   August 7, 2009

   What’s more important is that the N=8 supergravity calculations show that the conventional arguments about the perturbative problems of gravity QFTs are just wrong. The source of these new cancellations is not known, they don’t seem to necessarily require N=8 supergravity.

   I think that goes a bit too far. For example, I don’t think anything is going to make the divergence in pure gravity go away.

8. **Peter Woit**
   August 7, 2009

   Aaron,

   I wasn’t saying anything about pure gravity. Again, the point here is just that the standard “only string theory can make QG perturbatively finite” argument appears to have fallen apart. It remains very unclear what is causing these cancellations, and thus for what class of theories they might give perturbative finiteness.

   For some relevant speculation, see section 9.3 of 0907.5418 where the authors (for the case of N=4 YM) write: “This perhaps suggests that SUSY is not playing a particularly crucial
   role in the story”. They find different helicities coming not from supersymmetry , but from different charts on a Grassmannian.

   If I were to indulge in unsupported speculation, it would be that there is some class of QFTs including both gauge theory and gravity for which divergence problems in perturbation theory go away, due to symmetries we do not yet understand. Our world is described by one of these, one that has these still mysterious symmetries (as well as others…).

9. **MathPhys**
   August 7, 2009

   In 1986, at ICTP, I heard Michael Green say

   “Mr Seiberg, look around you. The sky is blue. The birds are singing. Do you really believe you explain all this with E8XE8?”

   It was great.

10. **Eric Habegger**
    August 8, 2009

    Peter,

    You said:
    “If, I were to indulge in unsupported speculation, it would be that there is some class of QFTs including both gauge theory and gravity for which divergence problems in perturbation theory go away, due to symmetries we do not yet understand. Our world is described by one of these, one that has these still mysterious symmetries (as well as others…).”

    I have it on good authority that Martha Stewart agrees with you. Oh wait… I might be mistaking her with someone else.

11. **Yatima**
    August 8, 2009

    “What kind of baking sheet do you suggest using for cookies?”

    That should be reformulated!

    “What kind of branes do you suggest using for cookies?”

    Ok, while we are on the subject of rank sillyness and it’s Saturday, let’s have some popular culture:

    http://www.youtube.com/watch?v=63S3vacxI9c

    Look out at 7:30 for “Depending on what we find, we _might_ just disprove string theory – that would really make my day!”

12. **Hontas Farmer**
    August 9, 2009

    Peter: Have you by any chance read this paper by Robert Wald “The Formulation of Quantum Field Theory in Curved Spacetime.” http://arxiv.org/abs/0907.0416 ? In one of your earlier postings to which you have linked in this one, you wrote of U Chicago doing a press release which sang the praises of string theory. A sure sign of change would be what Wald writes in that paper. He describes in detail an algebraic approach to QFT in curved space time which reminds me very much of loop quantum gravity. As if he has thought of a general formalism which describes that employed by LQG and which could work for any other QFT.

    Yatima: I love the straight answer she gives to the shredded financial documents question. Like it doesn’t bother her at all.

13. **Haelfix**
    August 9, 2009

    Certainly the conjectured finitiness of N=8 Sugra is intriguing, and I suspect will be proven sometime soon with the twistor techniques that are hot in development.

    Otoh its somewhat strange to disparage string theory using this particular theory, as its well known that it contains extended objects (pbranes and so forth) in its spectrum.

    It really begs the question.

    I think you would need to find another finite field theory that includes gravity, which explicitly does not include string theory asymptotic states to make the claim robust.

14. **jpd**
    August 9, 2009

    sounds like you are adjusting to string theory not being unique

15. **Big Vlad**
    August 10, 2009

    Haelfix,

    I have heard these arguments about N=8 sugra's relation to string theory. Could you explain a bit more? You're saying that it is known that there are stable extended field configurations in the theory. This is cool, but so what? The basic entities in the theory are still fields, not quantized strings. So isn't Peter justified in claiming the latest developments are a blow to string theory?

16. **twisting the night away**
    August 10, 2009

    Big Vlad,

    All arguments about N=8 being a 'finite field theory' are about perturbation theory *around a flat background*.

    Now you need a solution to the classical field equations to start a well-defined perturbation theory, but there are more solutions out there than the trivial one. One class of this are pbrane solutions, which you should think of as very close cousins of instantons in Yang-Mills theory. These are regular saddlepoints of the action and should be included in the full theory somehow.

    Is this important from a physical point of view? Probably, but even in the technically much simpler Yang-Mills theory related questions are hard to answer.

    Now there is an embedding of N=8 into string theory (apparently). That is, the perturbation theories is claimed to match in a certain limit. Strings also have non-perturbative effects which are to an extent understood, especially for extremal black holes.

    If N=8 is finite, a hard-core string theorist might therefore claim that is due to the fact it is string theory anyway and strings provides information about the non-perturbative sector. Really proving this is very hard to do since the limit taken can lead to unwanted effects (in principle). So hard, that to my mind at the moment it is more a question of faith than anything else.

17. **Peter Woit**
    August 10, 2009

    Hontas Farmer,

    Yes I've looked at the Wald paper. What Wald is doing is quite interesting, but it doesn't involve quantizing the metric degrees of freedom. I have no idea what Wald thinks of string theory, no reason to believe that he had anything to do with the press release of five years ago (he's in a different research group, GR, not particle theory, than the string theorists).

18. **Hontas Farmer**
    August 10, 2009

    You are correct, in the paper he show no work of his own on quantum gravity. The formalism he describes could work as well for Quantum gravity, as it would for any other QFT. If I understood it correctly all one needs to do is provide a algebra of observables for their theory. No metric, or Hilbert space is specified or required. The observables could be the operators and algebra of LQG, or QED.

    I wouldn't call Wald's formulation a theory of everything, it's more like a theory of anything.

    Was he not the overall department head of physics at U Chicago five years ago? I assumed that if he was he would have had to sign off on a press release. Shows what little I know.

19. **Peter Woit**
    August 10, 2009

    Hontas Farmer,

    What Wald describes assumes the existence of a fixed background metric (unquantized). You can't use his formalism to quantize the metric.

    An assumption that a department chair would have to sign off on press releases I think assigns far more power to that position than it carries in most American research universities…

20. **chris**
    August 11, 2009

    Aaron,

    this is not going too far. there are even claims that classical gravity could eventually be renormalizable perturbatively. essentially the argument goes like this: you have divergencies at all loop levels, but their prefactors have relations that you can describe with a finite number of equations. so you need to introduce an infinite number of counterterms, but with a finite number of parameters giving relations between them. so in a classical sense, this theory is not renormalizable, but it would still be predictive since the number of parameters is finite.

    even the perturbative nonrenormalizability of QG is far from being settled (let alone the nonperturbative one). and this relatively recent discovery of bern about N=8 SUGRA cancellations is another strong hint that we don't understand any of this as well as we should.

21. **Tim vB**
    August 11, 2009

    Hello Peter, Hontas Farmer
    Sorry if I take the discussion too far here…
    QFT in curved spacetime has been a reasearch topic at least since the 1970'ties,

you just try to quantize fields in a fixed curved spacetime instead of Minkowski spacetime.
The idea is to generalize QFT a little bit to include classical gravity effects on fields while
neglecting effects of matter on gravity, i.e. on the spacetime metric tensor.
Since there are many approaches to this topic in Minkowski spacetime, you can ask, which ones work best
in this generalized setting, Robert Wald says that algebraic QFT is what you should use.
In algebraic QFT, the basic object you work with are causal nets of von Neumann algebras.
Have a look at "Quantum Field Theory in Curved Spacetime and Black Hole Thermodynamics" from him for this approach,
or at Birrell, Davies: "Quantum Fields in Curved Space" for approaches that most people trained in "classical" QFT
will probabliy find more familiar.
All of this has nothing to do with LQG or string theory, it is just an attempt to combine two well known
frameworks (QFT and GR) without changing one of them in any radical way, to see if anything could be learned from it.
The most famous results obtained here are the Unruh-Effect, Hawking-Radiation and the formula for black hole entropy.
What keeps irritating me is that some string theorists seam to treat these as established facts while mostly ignoring
the whole framwork and some key insights of QFT in curved spacetime, e.g. that the particle concept is highly problematic.
If anyone could point out a discussion of this topic ("what do string theorists think of QFT in curved spacetime") to me I would be very thankful.

22. **Guest**
August 11, 2009

"what do string theorists think of QFT in curved spacetime"
I think that a more relevant question would be "what do string theorists think of STRINGS in curved spacetime" and the short answer is "They think about it quite a lot and consider it to be a very important problem". Quantizing strings in AdS is one of the most outstanding problems, not only because the background metric is curved but also because of the presence of the background RR flux. One particular non-trivial background where strings were successfully quantized, i.e. the string spectrum was found and multiparticle transition amplitudes were computed using the CFT techniques, is the so-called pp-wave background. For a reference see this paper:
http://arxiv.org/abs/hep-th/0202109

23. **James**
August 12, 2009

Off topic: but it seems that cosmic variance has fallen out of favour amongst your physics weblog links?

24. **Peter Woit**
August 12, 2009

Thanks James,

That's very odd and kind of disturbing. It looks like a bunch of links have disappeared (also interactions.org and Lubos) and I have no idea why. Will try and fix later today…

25. **Tim vB**
August 13, 2009

Dear Guest,

thanks for the answer and the link, I will take a look at the paper.
What I mean by "QFT in curved spacetime" is taking GR as it stands, choose
a "physically realistic" spacetime in the sense of classical GR and put quantum fields on it.
"Physically realistic spacetime" in this context usually means a 4 dimensional causal (let's agree on globally hyperbolic)
classical spacetime. In this sense the moment you think about AdS (5 dimensional or AdS_5 × S_5 as in the paper you referenced), you are not doing "QFT in curved spacetime".
I do not wish to imply that AdS and quantizing strings in AdS is irrelevant, but can we agree that it is a totally different topic than
"QFT in curved spacetime" as understood here?
I would still be interested in an answer to my original question then…

26. **Guest**
August 13, 2009

To Tim vB, if you are interested in this topic, check out these arXiv papers: http://tinyurl.com/mdxobn

27. **James**
August 15, 2009

Re Links: some have been restored but, for example, Chad Orzel is still left out in the cold.

Incidentally, I'm not just trying to nitpick! As well as visiting your blog because I enjoy reading it, I use it as a jumping off point to other good blogs (except I can't if the links have vanished!)

Please restore order to my blogverse! 🙂

28. **Guido**
August 20, 2009

Peter wrote:" … the anomaly cancellation discovered by Green and Schwarz doesn't actually provide at all the kind of explanation of some aspects of the standard model … "

Once I made the mistake to email Distler for some details of the anomaly argument. Though I sent him a friendly mail, I got no answer, but a series of really unfriendly ad hominem remarks. He is clearly a person to avoid contact with, even if you want to talk about string theory.

29. **Tim vB**
August 20, 2009

Hi Guido,
please do not judge people by an episode like this, I am very glad that some string theorists like Jaques Distler

still care to discuss and explain basic topics online.

This Week's Hype

August 12, 2009
Categories: This Week's Hype

From Softpedia this week, the news is of a Universal Theory of the Universe in the Works. According to the article,

> The theory of quantum mechanics was devised around 1920, and explains all this, but without accounting for gravity. Therefore, uniting the two ideas has since been an effort taken on by a large number of physicists. Now, an international group believes it is closer than ever to finally managing a breakthrough.
>
> Professors A.A. Coley, from the Dalhousie University, in Halifax, G.W. Gibbons at the University of Cambridge, in the UK, and C.N. Pope at the Texas A&M University, in the United States, led by young mathematician Sigbjørn Hervik, at the University of Stavanger, in Norway, believe that string theory is the best option physics has at bringing the two together.

It's hard to tell what this is based on, but the only paper I see with those authors is this one, which doesn't really have much of anything to do with string theory.

The source of the Softpedia article is one from Science Daily entitled A Grand Idea About the Universal Universe that tells us that:

> A mathematician in Norway and international fellow scientists have now conceived a grand idea about the universal universe. They have developed a method that may provide answers to universal problems and characterize and describe the universe….
>
> "The problem is that quantum mechanics does not include gravity and the theory of relativity does not include quantum mechanics", Hervik says.
>
> Many attempts have been made to find a unifying theory of both. String theory is the best candidate so far, according to Hervik.

Ultimately this all goes back to yet another university press release, this one about Hervik's Universe.

Comments

1. **Bee**
   August 12, 2009

   Well, quantum mechanics doesn't "include" electrodynamics either. These two just happen to be compatible if done the right way.

2. **Vid**
   August 12, 2009

   "…which doesn't really have much of anything to do with string theory."

   Don't know about the rest, but where does the notion of quantum correction come from if not string theory?

3. **Justin**
   August 12, 2009

   On one hand, Hervik talks about string theory being the best candidate for unifying quantum mechanics and gravity, but, from what I can gather, what he's actually doing is looking for an alternative to string theory.

   In fact, if you read further in the ScienceDaily article, it looks like his work might be more in line with approaches like loop quantum gravity rather than string theory, in that he's looking for operators that produce a discrete spectrum of spactime:

   > "The idea is to construct curvature or projection operators that split geometry into small entities. It is a tool or a method based on mathematical formulas designed to find such operators."

4. **Peter Woit**
   August 12, 2009

   Vid,

   I think the notion of "quantum correction" comes from quantum mechanics, not string theory.

   From what I can tell, these authors are just looking at a class of solutions to a generalization of the Einstein equations. There's no indication in the paper of why this generalization is what you are supposed to get from a quantum gravity theory or from string theory in particular, so no good reason to refer to "quantum corrections". The idea seems to be to find things that are solutions to "almost any set of covariant equations involving the metric and its derivatives", so you have solutions to all conceivable quantum gravities, but it's not clear to me that that makes any sense.

   In the standard story about how string theory is supposed to give corrections to the Einstein equations, one normally is talking about six dimensional compactification spaces, and modified equations such that solutions are no longer quite Ricci flat. This paper is about 4d and something completely different.

   Justin,

   It's hard to tell from the article what Hervik is referring to, but I see no reason to believe it has anything to do with the discrete spectrum ideas from LQG.

5. **H-I-G-G-S**
   August 13, 2009

   Thank goodness you're back so you can protect us from string hype we wouldn't have otherwise noticed.

6. **a-n-o-n**
   August 13, 2009

   and Thank goodness H-I-G-G-S is back to provide the yang to the yin to keep me distracted during work..

7. **Tim vB**
August 14, 2009

Taken directly from the University press release:
"Naturally, it is personally very satisfactory for me to discover something new in the world of mathematics on a par with Columbus' discovery of America".
It would seem we need another item in the crackpot index:
20 points for comparing your discovery to Columbus' "discovery" of America, 5 points for any signs that you do not know that the Vikings "discovered" America some hundred years before Columbus.

8. **Chris Oakley**
August 14, 2009

Yeah, but the Vikings didn't do much about it. You know – a few Magic Mountain rides, Disneyworld and then they were back in their longboats for the return trip to Norway.

9. **capitalistimperialistpig**
August 14, 2009

If you don't want to become the math/physics version of late night comedy material, think twice (thrice -etc) before you talk to your schools press office about your latest brilliant idea – at least not until you collect a Nobel or two!

10. **Tom Whicker**
August 14, 2009

Hervik points out the great adaptability of string theory:

"What we can do, however, is to consider the problem from another angle as if we did not know what the theory could be. We can describe phenomena, for example the universe, as a consequence of the unknown theory, in spite of the fact that we do not know what the exact theory is", Hervik explains.

11. **Sebastian Thaler**
August 15, 2009

Peter,

The new book STRING THEORY FOR DUMMIES, which is being released in November, includes a list of "Ten String Theory Skeptics". You are included, along with Richard Feynman, Lee Smolin, Robert B. Laughlin, Roger Penrose, Lawrence Krauss, Sheldon Glashow, John Moffat, Andreas Albrecht, and Joao Magueijo.

12. **G**
August 17, 2009

Embrace the duality.

13. **John A**
August 18, 2009

"Embrace the duality"

Then there'll be two books?

"The new book STRING THEORY FOR DUMMIES, which is being released in November, includes a list of "Ten String Theory Skeptics"….

I've operated on the assumption for a while that "String Theory for Dummies" is rather like "Sexual intercourse for Eunuchs", that is, if it were possible to explain string theory to actual dummies, then it wouldn't be string theory or they wouldn't really be dummies.

14. **Chris Oakley**
August 18, 2009

It could be dummy in the sense of a life-size sex toy, and the book is an instruction manual for turning one into a string theorist for those kinky enough to want that.

15. **Tim vB**
August 18, 2009

There already is a book in the same spirit, "String Theory Demystified" by D. McMahon, and yes, it works quite well for everyone
who had problems with the introductory quantum field course or needs a book one can hold with one hand only
(because the other hand has to hold that cocktail while you sit at the pool) but nevertheless would like to learn a bit about string theory.
But what is the point in listing sceptics (or fans) ?
Of course you could try to weigh the most prominent 100 sceptics and fans (like in Lev Landau's logarithmic classification) of string theory and compute the likelihood of the theory to be true…
BTW: Most people find books with a QED title more impressive than string theory, so maybe you would rather like to read some of these at the pool.
If you are unlucky the person you try to impress is a software developer and thinks you didn't get the concept of a string variable when you failed to learn to program BASIC in highschool, and that is not funny.

Various and Sundry

August 20, 2009
Categories: Uncategorized

Back from a final short summer vacation, with no further travel plans for the indefinite future. Some things I've recently come across that might be of interest:

- Tommaso Dorigo has posted his contribution to a session on "Blogs, big physics and breaking news" held at last month's World Conference of Science Journalists in London. There's a recording of the session available here. Besides Tommaso, one speaker was Matthew Chalmers, who talked a bit about the "String Wars", including the role of blogs in it. The last speaker was CERN's James Gillies who discussed CERN's efforts to do a better job of putting out information about progress on the LHC project, under some pressure from the phenomenon of others disseminating such information if they don't…. They've done a much better job of this recently, putting out informative press releases almost immediately after major decisions are taken. I'm glad to hear that he finds the role of blogs to have been a positive one.

For a recent LHC update, see these slides from a talk at the Lepton-Photon Symposium. On page 35 there's a copy of the latest detailed schedule that I've seen, which one can compare to the continuing updates on progress here.

- Also at Lepton-Photon, here's a talk by Shamit Kachru about using AdS/CFT to build technicolor-type models of electroweak symmetry breaking that involve strongly coupled gauge theories. He and his wife Eva Silverstein will be leaving Stanford and joining the KITP in Santa Barbara this fall, see the press release here.

For lots more about the KITP, its programs and its finances, see this presentation by David Gross to the NSF.

- I see there's an interesting sounding workshop at the Fields Institute this fall, but it scares me to see that it is described as a celebration of Allen Knutson's 40th birthday. I seem to have gotten old very quickly, with conferences now devoted not only to people younger than me, but to people much younger than me that I recall meeting when they were just starting graduate school…
- My nomination for the all-time highest quality discussion ever held in a blog comment section goes to the comments on this posting at Secret Blogging Seminar, where several of the best (relatively)-young algebraic geometers in the business discuss the foundations of the subject and how it should be taught.
- There's a long and well-informed article here on the multiverse, bringing together the "What the Bleep" crowd, mainstream physicists, theologians, and the logo of the Stanford Institute for Theoretical Physics (the one Kachru and Silverstein are escaping from).
- For a selection of the latest in cutting-edge applications of new internet technology related to physics, there's Gordon Watts with his Deeptalk, the nLab site of the n-category cafe, and the Twitter feed of Cosmic Variance.

Comments

1. **M**
   August 21, 2009

   As string theorists like to say, String Theory is a conceptual framework that unifies all good ideas, like supersymmetry, extra dimensions and now theology. In the multidisciplinary conference you pointed out, theology gave a decisive contribution to the string swampland program, pointing out a common feature of all string vacua: "the multiverse would not contain morally unacceptable worlds, such as those in which evil significantly predominated over good"

2. **Chris Oakley**
   August 21, 2009

   What about the Land of Oz, where, until Dorothy arrives, the Munchkins are ruled by the Wicked Witch of the East?

3. **Ben Webster**
   August 21, 2009

   I wouldn't read too much into the Knutson conference. Mostly it's just that he has a lot students who are wags.

4. **Tim vB**
   August 21, 2009

   Hi Chris,
   the evil witch of the east was killed and the evil witch of the west was defeated in the end, right? So that is a conclusive proof of the statement.
   The "multiverse" idea is too embarrassing and too easy to make fun of, so I will try to refrain from doing that.
   But it would be nice to have a careful explanation of some of the errors in the "Pluralistic Universe" that one could refer to, namely:
   – It is 10 to the power of 500 string vacua, not 10500, does anyone know a popular article that get's that right?
   – The multiverse idea that originates from the string landscape has no connection whatsoever to the multiple universe interpretation of quantum mechanics.
   – To be a Boltzman brain does not imply that one has to be a solipsist, or the very existence of philosophers that are not solipsists would prove that they are not Boltzman brains.
   – What does it mean to prove the existence of the multiverse? How could one do that?
   I would devote the rest of my life to try to un-cook an egg if that could prove the mutliverse idea to be wrong, but I suppose any success would just prove the multiverse idea to be true:"Hey see, we live in one of the universes that allows that kind of thing, what a triumph for the theory".

5. **Bob**
   August 21, 2009

   Surely Gross did not present all 180 slides to the NSF? Inflicting death by stupefaction is a guaranteed way to make sure KITP will never get another dime!

   LOL

6. **Peter Woit**
   August 21, 2009

   Thanks Ben,

   I feel better already….

7. **E. Silverstein**
   August 21, 2009

Dear Peter,

You write that Shamit and I are "escaping" from the Stanford Institute of Theoretical Physics, but nothing could be further from the truth.

The SITP is a phenomenal group of physicists. These are people who played a leading role in brining us early universe inflation, phenomenology beyond the Standard model, and holography and string theory. Together we have had tremendous fun and real synergy, for example developing primordial cosmology and its potential connections with string theory, among many other topics. We also treasure our interactions with students and postdocs, and the open, broad, and ambitious style of research in the group, as well as its unique sense of humor. In short, we have been delighted to be part of SITP and SLAC theory as well as the broader departments and university.

KITP/UCSB is also a spectacular, unique institute with great physicists who we deeply admire, as reported at length in the press release you cite, and we indeed decided to try that amazing new experience.

Best wishes, Eva Silverstein

8. **Peter Woit**
   August 21, 2009

   Eva,

   Sorry for the inaccurate implication, that was just my own (possibly defective) sense of humor at work. Good luck with the move to Santa Barbara!

   Peter

9. **Allen Knutson**
   August 21, 2009

   he has a lot of students who are wags.

   Surely that counts for something.

Percontations

August 24, 2009
Categories: Multiverse Mania

The Templeton Foundation has recently been sponsoring a series of Bloggingheads diavlogs, under the name Percontations. This week's episode is Fiddling With the Knobs of the Universe, and it has cosmologist Anthony Aguirre and string theorist Clifford Johnson doing their best to hype string theory and the landscape. Critics are dismissed as people who believe obviously wrong things like "if it's statistical it's not science".

Johnson argues that string theory landscape research is just like any other kind of science, capable of making testable statistical predictions, predictions based on generic properties of the theory (e.g. T-duality), and predictions of some parameters based upon fixing others by observation. He neglects to mention that decades of work by people trying to do such things have shown that there are very solid reasons why they don't work. Not only have no predictions come out of this, but the reasons why have become clear.

While hyping the landscape, he acknowledges that string theory has had a problem with hype in the past. "We all bought into it to some extent" that string theory was going to give the Standard Model, and it was bad that this was promoted in the press as a polished, definitive story of how the world works. He claims to be happy that this has been backed away from in the last several years (although he never seems to have been happy about the existence of string theory critics who have raised the issue of the problems publicly).

In a recent posting, Johnson partially resolves a mystery I'd always wondered about, that of why he left Cosmic Variance. He explains that one reason was that Cosmic Variance was taking "the obnoxious route of calling someone an idiot or stupid for their religious beliefs at the outset." Bloggingheads has recently featured Sean Carroll and Mark Trodden of Cosmic Variance also discussing cosmology and the multiverse (see here and here), but these episodes were not sponsored by Templeton.

Comments

1. **NonScientist**
   August 24, 2009

   "He neglects to mention that decades of work by people trying to do such things have shown that there are very solid reasons why they don't work. Not only have no predictions come out of this, but the reasons why have become clear."

   This may be an omission, but I don't think it's a fault. How many theories or other scientific discoveries have come to light after such a small quantum of time as decades were not fruitful?

   Don't confuse this as a slight to, or promotion of string theory. I'm more speaking about Johnson's desire to promote his research.

2. **Marcus**
   August 24, 2009

   Was "Bloggingheads diavlogs"
   a diavolical Sleudian Frip?

3. **Peter Woit**
   August 24, 2009

   No Marcus, "diavlog" is the word the bloggingheads people came up with to describe these things.

   NonScientist,

   I think promoting one's research by going to the public and making an argument for it that neglects to mention there are well-known and well-understood reasons why this argument doesn't work is not just an omission, but a fault.

4. **Phil**
   August 24, 2009

   Marcus,

   Diavlog is a second-order blend, by the way: it blends dialog and vlog, with the latter element representing a blend of video and blog. Or make that third-order, since blog blends Web and log.

   http://languagelog.ldc.upenn.edu/nll/?p=1684

5. **Marcus**
   August 24, 2009

   thutch

   that means thanks very much.

6. **M**
   August 25, 2009

   I would say that the main problem was not the hype, but that hyping the Unique Theory with the Unique Vacuum, string theorists collectively misunderstood the physics of strings. Being very smart in formal stuff and doing good physics are two different things.

7. **alex**
   August 25, 2009

   lapimacuote

   that means the last paragraph is missing a closing quote (for the one that opens "the obnoxious…)

8. **Peter Woit**
August 25, 2009

Thanks alex, fixed.

I'm learning all sorts of new words….

9. **Tim vB**
August 25, 2009

Just listened to the "Fiddling With the Knobs of the Universe" episode.
Another interesting remark of Clifford Johnson is that one should not expect anymore that string theory will explain all input parameters of the standard model (that would mean that one's concept of what a scientific theory should be like or could do for you is too narrow), or that string theory will be a theory of everything (because it is no longer clear what that would even mean).
Seems to be quite a strategic withdrawal.

10. **per**
August 25, 2009

Well, I think Clifford deserves credit if he left Cosmicvariance for the reasons states in his post. Starting out a discussion with arrogance usually does not lead down a fruitful path (which I am sure you Peter are aware of after all the pro / con string theory discussions)

P

11. **Peter Woit**
August 25, 2009

Tim,

At this point, I think just about all string theorists think it unlikely that "string theory will explain all input parameters of the standard model".

But this is really a misleading way of putting things. All evidence is that if the landscape picture is correct, string theory not only can't explain "all" parameters of the standard model, but it can't explain a single one. It's completely vacuous, exactly what you would expect of a wrong idea.

In dealing with the public, string theory proponents often use this misleading tactic, referring to string theory's problems with predicting everything, when the problem is that it predicts nothing.

12. **Tim vB**
August 25, 2009

Hello Peter,
agreed, Clifford uses a very interesting multiple tactics approach that clearly shows that he has learned some politics during the string wars:
– repetition of well known hype arguments ("strings are beautiful, string theory is the only game in town"),
– references to tremendous successes of the theory and of (verified?) predictions (maybe I missed the point but I think he does not explain which ones),
– a nearly complete retreat from the original research program ("you cannot expect that string theory has to explain anything, e.g. the electron mass, and fits on a T-shirt", "string theory is just a tool that can be of use in many different contexts"),
– and the promise that the string theory hive is still open to new ideas, as any scientists should be ("as soon as something more promising shows up, we will stop the string theory business and think about that").
I've always wondered if the "only game in town" is some sort of insider joke, because according to the original anecdote the player that plays that game loses all the time…

13. **DB**
August 25, 2009

Propaganda was a major weapon in the arsenal of String Theorists during their period of advance, as they acquired funding and tenured positions. It's just as important during their retreat, to preserve funding and protect the careers of postdocs and non-tenured staff as far as possible.
They are masters of cynical media manipulation and spin.
The long-term damage to the discipline of theoretical physics is hard to quantify but is substantial.

14. **Nigel Cook**
August 25, 2009

I think that the string theorists are able to ride over critics easily because they have got the big advantage of a critical mass. They have each other to discuss ideas with. Whenever you have a group of people all enthusiastic about something, they can't resist talking the easy road to ignore critics.

E.g., the 'only game in town' claim is infuriating because it's untrue. But when you point out that it's untrue, they always (without any shame) shift to claiming that it's the 'best claim in town' by arguing that it's had more people, money, and time spent working on it than all other speculative ideas.

15. **Andrew Zimmerman Jones**
August 25, 2009

When I was researching my upcoming book, String Theory for Dummies, I found the landscape to be one of the hardest things to deal with logically. I finally used an analogy of the "texas sharpshooter" – he shoots at a wall and then draws the target around where the bullets landed. You basically look around where you're at and then redefine that position as the goal of what you were working toward. This doesn't necessarily mean he's a bad shot, but it certainly makes him look like a far better shot than he is in reality.

16. **Chris W.**
August 25, 2009

Despite or rather because of its accuracy, I don't think string theorists will be too fond of that analogy, Andrew. Good luck…

17. **nbutsomebody**
August 26, 2009

Clifford is completely vague in what he is saying. The information content is zero but the comedic content is high. is it a stand up (phone up maybe) comedy !

"String theory or method of string theory" (humm subtle, a person of finer articulation)
"It is telling us to grow up" (have I heard it correct, hope not !)
"Interesting to regime of physics … blah blah" (zzz, sleepy),
String theory USEFUL (🙂)

well, what is going on?

Anyway such a bad performance by a string theorist is really concerning.

18. **chris**
August 26, 2009

Tim vB,

string theory indeed was tremendously successful recently. i actually think it is close to a breakthrough right now. give it just a few more years and you will see, that it is a fabulous phenomenological model for strongly coupled electron systems. and maybe – in some more distant future – it will come close to lattice gauge theory in describing the IR part of QCD.

19. **Tim vB**
August 26, 2009

allow me to be a bit naive and demagogic here: If you could replace the standard model lagrangian
with, say, the nambu-goto lagrangian of naive string theory with one free parameter
(e.g. the string tension), that would be beautiful. I would be very grateful if I would
not have to memorize the standard model lagrangian any more.
So let's assume for the moment that the impression "string theory is beautiful" stems from this observation.
If you give up the hope that string theory will ever explain resp. replace the standard model, why is it still beautiful?
This is one of the main points I do not get, I mean: Clifford cites many of the arguments pro string theory
that originated from the hope that the standard model could be explained by it, while (nearly) giving up all the hope that this could ever happen.

20. **it works!**
August 26, 2009

I don't know whether you guys have come across this claim, but one string theorist told me he did string theory "because it works." I don't know what he meant by that, but I kept quiet just for the sake of politeness….

21. **Sorinis**
August 26, 2009

http://cdsweb.cern.ch/journal/article?name=CERNBulletin&issue=35/2009&number=1&category=News%20Articles&ln=en

Here we go again . . . for the millionth time.

22. **Peter Woit**
August 26, 2009

Sorinis,

That's not really news, just a good explanation of the complexity of the LHC startup schedule.

Latest estimate I've seen has first beam injection around Nov. 18, with sector 67 the last one to be ready (its cooldown recently had to be interrupted to fix a short-circuit).

23. **Peter Orland**
August 26, 2009

Chris,

I have hear such promises before…

Right now string theory can describe strongly-coupled gauge theory (by the way, so can non-numerical lattice gauge theories). OK, fine, one can play with the idea and try some phenomenology. There are also stringy ideas for summing planar diagrams, and a lot of other interesting ideas.

BUT… no one can show that string theory methods gives the RIGHT strongly-coupled gauge theory, i.e. that obtained by integrating out all the short-distance degrees of freedom from QCD, starting near the UV-free fixed point. My impression is similar for approaches to condensed-matter physics.

Promising a breakthrough doesn't count as much as delivering one. Any good physicist who truly has a breakthrough in the works, would work on finishing it, and not making promises (that only spurs the competition).

24. **Marcus**
August 26, 2009

Peter Orland,
you took Chris's post seriously, as perhaps was proper, but to me it seemed humorous, somewhere on the scale between subtle and sidesplitting. He said:

"…string theory indeed was tremendously successful recently. i actually think it is close to a breakthrough right now. give it just a few more years and you will see, that it is a fabulous phenomenological model for strongly coupled electron systems. and maybe – in some more distant future – it will come close to lattice gauge theory in describing the IR part of QCD."

25. **Peter Orland**
August 26, 2009

Hi Marcus,

It could be that I'm the guy in the room who doesn't get the joke (especially if it's on him), but in this case, I suspect Chris was serious. I think he is expressing the feeling of a lot of younger people in the field. If I'm right about this, they need to hear that promises mean nothing (except in the public-relations world), and only results count.

Regards,
Peter O.

26. **onymous**
August 26, 2009

Peter Orland said:

BUT… no one can show that string theory methods gives the RIGHT strongly-coupled gauge theory, i.e. that obtained by integrating out all the short-distance degrees of freedom from QCD, starting near the UV-free fixed point.

Indeed, one knows that they do *not*, and the reason, amusingly, is their failure to be sufficiently stringy. Calculability in these models relies on a hierarchy between the AdS curvature scale and the string scale. On the field theory side this means a large gap in operator dimensions that does not exist in QCD. In principle one can imagine a model that gets closer to QCD — or even *is* QCD — but in such a model this hierarchy would not exist, and one would have to do string theory rather than effective field theory in the AdS background. So far this is an insurmountable technical obstacle. The AdS/QCD models remain compelling and amusing toy models, but everyone working on them should (and, for the most part, does) understand that they are, in many ways, toys.

As far as I can tell all the same objections apply to AdS/CMT. They might be valuable toy models that shed light on interesting phenomena, but they are unlikely to ever be models of real physical systems until the technical obstacle of doing string theory on highly curved spacetimes is overcome.

27. **TomInCalif**
August 26, 2009

Peter wrote: "… string theory proponents often use this misleading tactic, referring to string theory's problems with predicting everything, when the problem is that it predicts nothing… "

As a layman in this field, I have a question: Can the proponents even construct all the correct parameters of our actual universe, in a consistent way, just by twiddling whatever "free parameter knobs" exist in string "theory" ?

Or is even that challenge akin to recreating all the content of the Sunday NY Times, from a pile of burned ash?

28. **Greek**
August 26, 2009

Hi,
as a European practitioner in the field that you may call String Theory, it is amusing to see that the String Wars is – perhaps – more than an urban legend! I see that (some) serious people take it seriously and (sometimes) use serious arguments. So here is mine:

perhaps there is reason to be optimistic – whichever side of the trench one sees oneself. On the one hand, it is by now obvious to the honest physicists that the Scherk-Schwartz leap to connect the spin-2 string state to the graviton is probably misleading. It has lead to an enormous amount of work, much of which is of high quality both in physics and maths, however it has produced a "doomsday" religion regarding string theory: i.e. that string theory is a T.O.E. This nicely fit the old "particle" ideas regarding "effective field theory", which are based on the philosophical conceptions such as the "atomic" theory of the ancient Greeks! Unfortunately, both the ancient Greeks and the modern non-Greeks are proven – by experiment – wrong.

On the other hand, the honest physicist now observes that String Theory rather helps in the deconstruction of the old particle physics "effective field theory" philosophy! Indeed, "fundamental d.o.f" such as strings and (M)branes describe low energy phenomena in condensed matter. So what is "fundamental", the string or the superconducting vortex observed in the lab? But this is supporting the idea (see P. Anderson etc) of "emergent physics".

So, if the recent AdS/CMT ideas work – even a little bit – String Theory will close a circle and get back to where it started; to a model describing the "phenomenology" of matter!

Then, for one that is not a string-religion-fanatic, there is a clear winner in the String vs LQW war. It is String Theory of course – but viewed from this newer perspective. Indeed, many of the young generation view things that way – so in 10 years time when the old guard will retire the field will be completely different.

So, cheer up, indeed.

PS: Sorry for the long comment, I am completely new to blogging.

29. **Peter Woit**
August 26, 2009

Greek,

Thanks a lot for the interesting comment. I agree with what I take to be your perspective that a lot of the string theory community, especially the younger part, has given up on the idea of using string/M-theory in 10/11 dimensions to unify physics, and moved on to trying to do other things, typically related in one way or another to AdS/CFT duality.

That's fine, but to me there still remains the problem that, non-perturbatively, QFT still remains mysterious in many ways, often in ways that AdS/CFT has no relevance to. It would be nice if the giving up on one failed idea could lead to people being willing to investigate a variety of new ideas, not just one particular one that historically grew out of the TOE failure.

TomInCalif,

The problem is that the string theory machine used to construct "string theory backgrounds" that might look like our world turns out to have to be very complicated, without much calculational control. So, the state of the art is that as far as anyone can tell, in principle you can get our physics with the right parameters (and just about any parameters you want) out of such a "string theory background". But actually doing this in a precise and well-defined way is way beyond current calculational capabilities, and to me it has never been clear that these calculational problems are not problems of principle, not just practicality.

30. **Greek**
August 26, 2009

Hi Peter,

sure one should try new ideas, away from AdS/CFT. In fact, a particularly interesting clue has recently emerged in d=3. It seems that one needs to go beyond the usual group-based gauge-theory structures to understand three-dimensional theories. More complicated structures (based on 3-algebras) seem to be needed. Other ideas are welcome too!
e.g. keep the term "systolic geometry" for the time when it will be applied to critical systems and the black-hole entropy..

Again on the philosophical side (its very late here in the "old world" so I am allowed): this ear looks very much like the beginning of the 21s century when people would construct everything from machines -then came quantum mechanics. It also looks like the 70's when people were seeing UFOs everywhere and nuclear science would explain everything – then came quantum gravity to spoil the party. It seems that in the coming decade something else will emerge that will change our current views.. hopefully.

31. **Pawl**
August 26, 2009

Greek,

I am puzzled by your comment that String Theory "viewed from this newer perspective" is the winner in the "String vs LQW [sic] war." Do you mean LQG (Loop Quantum Gravity)?

If you mean that String Theory provides a more successful approach to quantum gravity, I don't really see, based on what you've written, why you would hold that view — much less how it could be presented as something more than an opinion. But perhaps I'm just not understanding your point.

32. **Greek**
August 26, 2009

Pawl,
my point was that "dreams of a quantum gravity" (to paraphrase Weinberg) is not such a big thing after all.. There is much more to physics than QG.i.e. turbulence to just name a cliche' example. Even if LQG provides the path to QG (which I believe is at least as doubtful as the opposite statement), it will not be relevant! On the other hand, ideas and maths that are spin-offs of String Theory touch upon much more physical structures (turbulence included!). That is why I think that the winner in String Theory. I hope I am clearer now.

33. **Pawl**
August 26, 2009

Greek,

Thanks; I understand you now.

I do not really agree that reconciling quantum theory with gravity is "not such a big thing" — although I agree strongly that there are many other important problems in physics. (I'll point out too that I was not arguing that LQG was likely to be correct, but I was comparing its progress versus string theory's on quantum gravity.)

34. **chris**
August 27, 2009

Peter Orland,

unfortunately i am not as young as you imply – i wish i were. and just to clarify:

if i was working on a candidate TOE and after 20 years discover that it might be a passable effective description for some solid state physics or quark gluon plasma, i'd not really call it a breakthrough.

35. **Peter Orland**
August 27, 2009

Well, Chris, I have to say, if it were true that string theory could solve real problems, I would consider that a success, not a disappointment. Having said that, I don't see any sign of success.

Any new solution in theoretical physics is a breakthrough. I personally would be much more happy and excited to solve Yang-Mills or High-T_{c} superconductivity than find a FUT (Fully Unified Theory – a more strident-sounding moniker than the melifluous TOE), since the former are related to experiments. I don't understand the feeling of some physicists that all life begins at the Planck scale.

What I said above (and see onymous's comment also) is that string-theory ideas have hit a wall in field-theoretic applications. In fact, they hit this wall very soon after the ideas were proposed.

The promise of a breakthrough means little. I wish people would stop making promises. People on the verge of breakthroughs don't advertise – they break through!

ICM 2010

August 27, 2009
Categories: Uncategorized

The International Congress of Mathematicians is held every four years, and the next iteration, ICM 2010, will be held about a year from now, in Hyderabad, India. These are huge conferences, planned well in advance, with 1465 mathematicians already pre-registered.

The list of speakers gives a good indication of what the mathematical establishment views as the most important research activity of the past four years, and this list is now available here. There are a large number of parallel sessions, and a limited number (20) of plenary talks.

The winners of the Fields medal are announced at the ICM, at the same time as the composition of the committee that made the choice (the chair of the committee, Laszlo Lovasz, is known). One way to help guess who will win a Fields medal is to take a look at those on the speakers list who are under forty. I'm not privy to any inside information, but many people think Ngo is a shoo-in for his work on the fundamental lemma (he's a plenary speaker), and there's some speculation about Jacob Lurie (who is a parallel session speaker).

This year there's a new prize to be awarded at the ICM, the Chern Medal, for "an individual whose accomplishments warrant the highest level of recognition for outstanding achievements in the field of mathematics." This one, unlike the Fields, comes with a significant amount of money ($250,000, and another $250,000 for the medalists favorite mathematical organization).

Comments

1. **Manel**
   August 27, 2009

   "there's some speculation about Jacob Lurie"

   What has we done?

   Regarding the Chern Medal, is it for people <40 years old as the Fields Medal?

2. **Marcus**
   August 27, 2009

   I see Matilde Marcolli is one of around ten invited speakers in the Mathematical Physics section.
   She just posted http://arxiv.org/abs/0908.3683
   Early Universe models from Noncommutative Geometry

3. **egan**
   August 28, 2009

   In the ICM list of plenary speakers why there is "USA" for Ngo Bao Chau?

   He is vietnamese and studied in France under Gerard Laumon : http://en.wikipedia.org/wiki/Ngo_Bao_Chau

4. **Peter Woit**
   August 28, 2009

   egan,

   I believe Ngo is now at the IAS in Princeton.

5. **Peter Woit**
   August 28, 2009

   Manel,

   The Chern Medal has no age restriction.

   For Lurie's work, see his home page, or search the n-category cafe or secret blogging seminar for blog entries about this.

6. **Manel**
   August 28, 2009

   Thanks Peter.

   PS: I obviously intended to write "What has **he** done?"

7. **simplyAnonymous**
   August 28, 2009

   Actually, 4 years ago the math blogosphere wasn't as developped as it is today, so let's hope the gossiping still remains minimal.

   Yet, since I'm no insider, and since your post is an invitation for gossiping 🙂 let me venture an opinion, namely that I'm not surprised to see Avila getting a plenary, he has the typical Field medalist pedigree (PhD aged 21, still only 30 today, many major papers and large output, former IMO gold medalist… ticks all the boxes).

8. **french anonymous**
   August 28, 2009

   Avila…

9. **egan**
August 29, 2009

>>>I believe Ngo is now at the IAS in Princeton

Peter,

So what ? Ngo is vietnamese and not american.
If you look at the ICM speaker list for Artur Avila you will see he is brazilian. He work in Paris but near his name on the ICM list there is “Brazil” and not “France”.
Near Ngo’s name it should be “Vietnam” and not “USA”.

10. **Peter Woit**
August 29, 2009

egan,

Avila’s CV has him with a French CNRS position, but now on leave from Paris and affiliated with IMPA in Rio. The countries listed seem to be not citizenship but location of current academic affiliation.

11. **harrison**
August 29, 2009

Irit Dinur looks like a shoe-in for the Nevanlinna (she’s under 40, right? she certainly looks it…) although it’d be fantastic if she won the Fields. (Why do I say this? Because she’s a plenary speaker without the status of a Goldwasser or a Wigderson, and her work on PCP certainly qualifies her for a Nevanlinna. It’s possible that Aharanov could get it, though, although I’m less certain that she’s under 40.)

Manjul Bhargava is conspicuously absent from the speakers list, although I’m pretty sure he has another cycle of eligibility. Chandrashekhar Khare was born in 1968, and is ineligible. Avila has two more cycles of eligibility, and most of the time the Fields committee tends to wait in such cases. (Think of Deligne; think of Drinfeld, who could have won in ’82, ’86 or maybe even ’78 without anyone batting an eye.) Lurie also has two more cycles. I think by far the best bet is on Ngo, with Avila strongly in the running.

12. **simplyAnonymous**
August 29, 2009

Yes, there are many deserving candidates obviously, so indeed it may ultimately push things more and more towards recipients in their late thirties, with twenty-something winners not occuring anymore.

Looking at the list of speakers a little more and crossing it with winners of prizes like European Math Soc. and Salem, it looks like Assaf Naor especially is another strong young contender, at least for future cycles.

13. **anon**
August 29, 2009

Kisin?

14. **Voltberg**
August 29, 2009

Manjul Bhargava, Ben Green, Cedric Villani and Bao Chau Ngo.

15. **perestroika**
August 30, 2009

cedric villani or alexander kuznetsov

16. **anon**
August 30, 2009

Christopher Hacon..
(Lurie and Venkatesh in 2014?)

17. **Walter Mondale**
August 30, 2009

I think they’d wait for Lurie… his work still is unpublished and he’s well under 40. Avila is a good candidate although young himself.

18. **Huron Lovett**
August 30, 2009

I’ve heard rumors about Kiran Kedlaya from MIT. And sure enough, he’s an invited speaker in the number theory session.

19. **chickenbreeder**
August 30, 2009

Slightly related, any news about Grigori Perelman lately?

20. **Peter Woit**
August 31, 2009

chickenbreeder,

I haven’t heard anything at all about Perelman recently. There the interesting question is what Clay is going to do about the million bucks for the proof of the Poincare conjecture.

21. **terence**
    September 2, 2009

    yun zhiwei

22. **terence**
    September 2, 2009

    yuan xinyi

23. **Chicken**
    September 3, 2009

    Look at the papers of Kiran Kedlaya, given that Laszlo Lovasz is the chair he would be my best bet with Bao Chau Ngo who is a certainty

24. **Sunny**
    September 4, 2009

    I guess all those Clay Math scholars and award winners are all potential candidates. Don't you think it would be interesting to have a first female Fields Medal winner in the history of math? The third winner's name may not have been heard of by us in the US.
    As you can see from the list of speakers in each field, there are many new names. But the ultimate question goes to "what has he or she done so significant?"

    If for age priority, the chance that Venkatesh and Rodnianski are also good candidates. But you will never know. Ngo is the only certainty.

25. **Sunny**
    September 4, 2009

    By the way, Who would be the candidates for Chern Medal? Serre?

26. **Walter Mondale**
    September 4, 2009

    I don't think there are any certainties in the fields medal this time around. Last time there was Perelman who was pretty certain, Tao was pretty certain to get one eventually, but I don't see now anyone standing head and shoulders above the rest… I guess we'll have to just wait and speculate 🙂

27. **anon**
    September 5, 2009

    I was under the impression that the Fields was given to people who solved big or hard problems. So, that rules out some of the people listed, right?

28. **Anonymous**
    September 5, 2009

    I was under the impression that the Fields was given to people who solved big or hard problems. So, that rules out some of the people listed, right?

    It's hard to say. The committee has a lot of discretion, and there's no clear cut-off for what constitutes a "big or hard problem". Some of the people mentioned here seem an awful lot more likely to me than others, but that's what you'd expect from blog comments, and there's enough unpredictability that I wouldn't bet my life savings against the less likely candidates.

29. **Andy**
    September 5, 2009

    With regard to hard problems, it is useful to recall the old joke : Thurston proved that you could win a Fields medal without ever writing out a proof, but then Witten proved that you could win one without even stating a theorem!

    That said, Ngo is the only person I feel at all confident about.

30. **observer**
    September 8, 2009

    Bao Chau Ngo, is working on Langlands and solved some important issues, and that was probably a reason why he was brought to the IAS. Avila could be a deserving choice too. As athird choice I think Jacob Lurie could be in the run.

31. **Andreas**
    October 4, 2009

    If you ask me: As Richard Schoen is a plenary speaker, in my opinion Simon Brendle from Stanford is a good guess for the fields medal. As far as I know he is not even 30 years old.

32. **Sunny**
    October 8, 2009

    Simon Brendle is a great mathematician. But they have given it last time to Perelman (in differential geometry/geometric analysis). So it may not be likely to give the Prize to mathematicians who are in the same field again unless they have some astonishing breakthrough comparable to the resolution of Poincare Conjecture. Brendle's works are excellent but he's got many competitors in the field. He has a chance though, but maybe not this time.

    For the field of Number Theory, it's competition is even more intense: Bhargava, Venkatesh, Soundararajan, Mark Kisin, Ben Green, etc. As Lovasz in the chair position, Sudakov is a good candidate for combinatorics (though not sure if he's still under 40 by the time). For Algebraic Geometry, there are many competitors as well: Christopher Hacon, Jacob Lurie,

    I think all those who are Clay, AMS, AIM, or EMS Award Recipients under 40 are stronger candidates. Reading the ClayMath winners, Rodnianski, Ian Agol and D. Calegari are another strong candidates for it.

    I think all the above mentioned are currently in the US. (Ngo is a sure fire; Avila comes in 2nd;) But Europe is getting very strong in math nowadays as well as Asia.

Well, I am more curious about the Chern Medal than the Fields. It seems to me somehow that this is a Prize for “an individual whose accomplishments warrant the highest level of recognition for outstanding achievements in the field of mathematics” So this means a lot. It seems to be THEEE Prize in math. I wonder who have the chances?

33. **Pascal J.**
October 8, 2009

What do you think about one of these Bonn guys? Take for example Bringmann.

String Theory Skeptic

September 2, 2009
Categories: Uncategorized

The latest Forbes magazine has an article entitled String Theory Skeptic, which gives me a lot more credit for the problems of string theory than I deserve.

The article as I just saw it online appears to have a minor editing problem, with the quote

> It's common in physics for people to have incredibly ambitious ideas that don't pan out but lead to rich mathematical ideas that end up being very useful.

which is attributed to Peskin in the middle of the article, appearing a second time at the end, right after a quote from me. In any case, even if Peskin is the one who said it, not me, it's something I very much agree with, and perhaps a good summary of the string theory situation.

Update: I gather that the Peskin quote is the "knockout quote" of the piece, set off and summarizing things, with the online formatting what makes it appear to be in the body, at the end.

Comments

1. **Doug Natelson**
   September 2, 2009

   That sounds like Peskin. He taught me graduate mechanics.

2. **DaveC**
   September 2, 2009

   Peskin wrote a theory of 'Cooper pair mass' which had condensed matter theorists I know wincing at its 'ambitious' nature, ie, the fact that it completely ignores pretty much everything that's understood about superconductivity in real stuff!

3. **dan**
   September 2, 2009

   "Princeton's Witten declines to discuss Woit, saying in an e-mail that he prefers to debate these issues only with "critics who are distinguished scientists rather than with people who have become known by writing books.""

   OUCH. I infer that Witten remains a strong string theorist believer

4. **Peter Woit**
   September 2, 2009

   dan,

   From what I've seen, my impression is that Witten has decided he'd rather not debate these issues at all, a choice I respect. If he only debates people at least as distinguished as himself, he may not have anyone to argue with…

5. **Garrett**
   September 3, 2009

   Not a bad article. They made things sound pretty grim for strings. And apparently you're equal to Q?

6. **Chris Oakley**
   September 3, 2009

   I think I get it. God talks only to Witten, and Witten talks only to God. String Theory is God's revelation to Witten, and he will only impart more to mankind when they are ready.

7. **dan**
   September 3, 2009

   Ok but Marcus has posted over at PF that Witten was having "doubts" about strings and was working on other fields but apparently that's just wishful thinking.

   "String theory was a bubble waiting to be pricked," says Woit, 51. "The fundamentals just weren't there anymore."Fans of string theory are well aware that the tide has turned. said his very brightest string theory graduate students are having trouble getting work.

   Is that true? No wonder you've become a lightening rod for string theorists like LM & others

8. **H-I-G-G-S**
   September 3, 2009

   You've got to love how the logic progresses here:

   "Princeton's Witten declines to discuss Woit, saying in an e-mail that he prefers to debate these issues only with "critics who are distinguished scientists rather than with people who have become known by writing books."

   "If he only debates people at least as distinguished as himself, he may not have anyone to argue with…" -PW

   "I think I get it. God talks only to Witten, and Witten talks only to God. " -CO

9. **Marcus**
   September 3, 2009

To dan,
What I reported over at PF is a matter of record. I don't speculate about Witten's state of belief or non-belief, as you unfortunately do. Like several other top researchers he has given clear signs recently that his interests are not confined to string. (Perhaps they never were, and we are simply being reminded of an obvious fact.)

At Strings 2007 he presented his work on 3D QG. He did not attend Strings 2008. He did not present a paper at Strings 2009, but gave a public lecture which was about nonstring physics. His talk this summer at Cern was about prospects for new physics away from the high energy frontier.

I think it's ridiculous to focus such attention on Witten or to speculate about one person's state of "doubt" or non-doubt. You implied I ascribed "doubt", but I don't recall even using the word. I think you need to look at the overall picture. That includes looking at the makeup of recent research by *several* prominent people who were formerly more focused on core string topics. What are they actually doing? Where is the significant creative work occurring, in which areas and directions?

10. **Peter Woit**
September 3, 2009

Garrett,

The photographer asked me to write something on the board, I think what I wrote was an expression for a BRST-like operator as a supercommutator with a Dirac operator. Then I stood in front of it…

H-I-G-G-S,

I suspect that Witten would be even less likely to be willing to debate anonymous blog commenters than book-writers.

11. **Martin**
September 3, 2009

Hi Peter,

Wow! It seems string theorists must really be on the defensive if Witten isn't active in this field anymore.

Have you considered what you will blog about when nobody is interested in string theory anymore? Reminisce about the times when an unkind comment by you provoked angry retorts: "I always used to enjoy a good bash with old Lubos", etc.?

Cheers Martin

12. **Peter Woit**
September 3, 2009

Martin,

I suspect string theory will be around in various forms for quite a while. However, I can already reminisce about the the days when string theorists argued that string theory had won the battle in the marketplace of ideas…

13. **Marcus**
September 3, 2009

Wow! It seems string theorists must really be on the defensive if Witten isn't active in this field anymore.

?

Inaccurate premise. The comment does not appear to make sense even as sarcasm.

14. **Peter Woit**
September 3, 2009

One can debate whether this matters, but from what I can tell, Witten has not given up on the idea of string theory based unification, but, not seeing how to make progress on this, has generally been working on other things.

The main problem for string theory unification in recent years is not me, nor Witten, but just that evidence against the workability of the idea continues to mount. The high visibility of string theory landscape anthropic pseudo-science has also taken its toll.

15. **David Nataf**
September 3, 2009

Why would Forbes Magazine have an article on string theory?

16. **Peter Woit**
September 3, 2009

David,

They have a column called "Ideas and Opinions", presumably they thought their readers might find this story interesting. This is far from the first time they have had articles related to string theory, see for instance

http://www.forbes.com/2008/10/07/nobel-prize-physics-oped-cx_mk_1007kaku.html

http://www.forbes.com/forbes/2002/0204/068.html

I once remarked to a friend of mine that business magazines seemed to have an unusual interest in my critique of string theory. He pointed out that they tend to be on the lookout for contrarians and contrarian ideas. If you could have sold string theory short a few years ago, you could have made a lot of money….

17. **Mitch Miller**
September 3, 2009

Interesting to see Baez's crackpot index quoted by a journalist in a major publication.

18. **Don Murphy**
September 3, 2009

I believe the interest from business magazines stems from their believe that there may be an exploitable technology resulting from string theory that could make them all rich some day.

19. **Don Murphy**
September 3, 2009

Sorry for the typo in the previous post: believe vs. belief

20. **Peter Woit**
September 3, 2009

Don,

I seriously doubt that a significant number of the readers of Forbes or any other business magazine are so far gone that they think string theory technology is an investment opportunity worth considering.

21. **dan**
September 3, 2009

"The main problem for string theory unification in recent years is not me, nor Witten, but just that evidence against the workability of the idea continues to mount. The high visibility of string theory landscape anthropic pseudo-science has also taken its toll."

"said his very brightest string theory graduate students are having trouble getting work. "

Is there any evidence that the reason fewer openings offered to string theory is specifically the result of bursting the string theory hype?

22. **Don Murphy**
September 3, 2009

Perhaps they're not that far gone, yet. But I do know they mine seriously all that goes on in the world of scientific theory hoping to find that one nugget that will emerge as potential technology. I mean think about it. To the uninitiated the thought of strings as the fundamental unit of existence could mean the ability to create life from scratch, to become the architect of new worlds. Science fiction? There is no doubt. But that is what all the hype has been about.

23. **John Baez**
September 3, 2009

What I really like is how they used the crackpot index to determine that Peter is *not* a crackpot. It does indeed work both ways.

He's never sent anyone a letter in green ink saying that he has a revolutionary theory he wants them to examine, but they have to promise first not to tell anyone about it. Nor has he threatened string theorists with show trials in which they will be forced to repent of their misguided views. Nor has he called Witten a "self-appointed defender of the orthodoxy".

Of course this doesn't mean he's *right*. But the writer at Forbes was wise to run him through these tests before writing the article.

24. **Koray**
September 3, 2009

"Princeton's Witten declines to discuss Woit, saying in an e-mail that he prefers to debate these issues only with "critics who are distinguished scientists rather than with people who have become known by writing books.""

Ouch. I infer that Witten is calling Smolin not a distinguished scientist?

25. **Marcus**
September 3, 2009

John Baez wrote: *But the writer at Forbes was wise to run him through these tests before writing the article.*

It is reassuring to see a member of the financial community prudently performing such due diligence regarding his source. Perhaps you could also provide financiers with a similar checklist for detecting nutcase derivatives and credit swaps.

26. **intrigued**
September 3, 2009

Dear Peter,

What do you think of the work done in twistor theory and twistor-string theory by Arkani-Hamed and collaborators?

Do you also feel that research in this direction is futile? If not, why is it different from the situation in string theory?

27. **capitalistimperialistpig**
September 3, 2009

There have been some famous debates in physics and astronomy: Bohr vs Einstein, the nebulae, the big bang. String theory isn't really ready for that – you need at least something that can be tested, at least in principle. I suspect that there are a couple of Nobelists who would duke it out with Witten, but he doesn't seem to be willing to take them on either.

He's probably right. What would they talk about? Einstein formulated a number of clever thought experiments to challenge Bohr and clarify the foundations of QM, but what could either side say on strings?

'Tis pretty!
'Tis not!

The problem, as someone might once have mentioned, is that so far, at least, string theory is not even wrong.

28. **Peter Woit**
September 3, 2009

intrigued,

The work you mention certainly isn't futile. Unlike string theory, it's not making grandiose but unsupportable claims about unifying all of physics. Instead it's an investigation of the structure of 4d gauge theory amplitudes using new ideas about how to work in twistor space rather than the usual space-time. We know 4d gauge theory is important and part of real physics. Ideas about how to reformulate it to uncover new structure are obviously interesting, with final significance depending on what new structure one finds.

The idea of using replacing space-time variables with twistor variables goes back to Penrose 40 years ago, and I've always found it very intriguing. Lots of people are working on this now, and there seem to be some quite beautiful new mathematical ideas emerging. So far this seems to all be about scattering amplitudes, I'm curious whether there will be some way to reformulate the theory itself in twistor variables.

29. **chris**
September 4, 2009

"Perhaps you could also provide financiers with a similar checklist for detecting nutcase derivatives and credit swaps."

This, indeed, is a fabulous idea!

30. **milkshake**
September 4, 2009

The Forbes article uses the String Wars as illustration how theoretical physics is actually done – I think its unfortunate.

31. **Marcus**
September 4, 2009

The Forbes article uses the String Wars as illustration how theoretical physics is actually done – I think its unfortunate.

Has something abnormal occurred? If so, what exactly was it?
What I remember goes back to 2003—a vehement attack on Loop conducted at sci.physics.research: numerous reasons why it could never work and why people working on it must be feebleminded. The inappropriateness of this attack—which appeared phony or diversionary—is what got me interested in Loop in the first place.

2003 was before Peter's blog, or book, and before Lee's book which did not appear until 2006. What had, however, happened was the KKLT result and Susskind's anthropic string landscape response. These were intrinsic string infirmities, not warfare originating from outside.

Making it look like the ensuing gradual deflation was a war between two rival camps is either cheap journalism or a face-saving cover. The most trenchant criticism of string has always come from senior physicists with no connection to Loop or any other rival approach. I assume these key critics have been motivated to dump anthropery, get the bubble agony over and done with, and restore credibility to the field. So "War" is simply the wrong journalistic cliché, maybe string "Blister" would be a better image.

But is this not how science is actually done? theoretical physics being no exception. How otherwise do scientific communities correct for mistakes and restore integrity?

32. **The Wombat**
September 4, 2009

G'day,

Jeffrey Kooistra had an article in the September 09 issue of ANALOG titled THE TROUBLE WITH PHYSICS.

He discusses some of the same topics as here.

You might find it of interest.

The Wombat

33. **Marcus**
September 4, 2009

Wombat, thanks for the pointer to this book review:

34. **The Baron**
September 4, 2009

"Analyzing why people play golf is like exploring the intricacies of string theory – there are so many permutations lacking scientific observation that physicists or golfers can pretty darn well say anything they like and the explanation might stick."

–Bill Gross, CEO of Pimco

http://www.pimco.com/LeftNav/Featured+Market+Commentary/IO/2009/Gross+Sept+On+the+Course+to+a+New+Normal.htm

35. **Martin**
September 6, 2009

Hi Peter,

"… The work you mention certainly isn't futile."

How far along are Arkani-Hamed and friends in making testable predictions for twistor theory?

Cheers,
Martin

36. **Janne**
September 6, 2009

Why would Forbes be interested? Maybe because these days economics and theoretical physics have much in common. Similar challenges are faced in both fields.

37. **Peter Woit**
September 6, 2009

Martin,

Working on better understanding a theory that has passed thousands of experimental tests is rather different than working on a very speculative idea where you need to find some sort of connection to observable physics. In this case you are starting with an already tested theory, so the real question is whether the methods you are working on allow you to do computations more efficiently, or give other insight into the theory.

38. **onlooker**
September 6, 2009

The Forbes article appears to be the first instance of bad press that Witten has ever gotten. He earned it with the catty personal attack on Woit (and/or Smolin) and the implication that scientist skeptics of string theory are too dumb for their criticisms to be entertained.

39. **Marcus**
September 6, 2009

I didn't hear catty, and I didn't even hear bad press. I heard the tense restlessness of someone being forced into an uncomfortable role. The journalist was bugging him by casting him as Mister String Theory. I can imagine someone would hate to be put into that role, especially now.

Everything Witten has done lately, in major appearances, has pointedly signaled that he's not wearing the string label. I listened to three 90-minute lectures here at UC Berkeley in 2006 where he didn't once mention string or M-theory. Then at the end someone on the other side of the hall, I couldn't tell who, asked what about string, and he gave them a one sentence answer conveying hope, but not conviction.
Sure he writes some string papers but he also does Langlands.

What may have sounded like disdain for less eminent fellow academics could just as well have been disdain for the journalist. What business had the journalist suggesting that Witten debate string with anybody? whether grand or modest. He has other things to think about.

40. **Paul Jackson**
September 7, 2009

Marcus commented that: "you need to look at the overall picture. That includes looking at the makeup of recent research by *several* prominent people who were formerly more focused on core string topics. What are they actually doing? Where is the significant creative work occurring, in which areas and directions?"

As the string bubble collapses I get the impression that string folk, so adept at rationalising theory, are migrating into cosmology. Let's hope that they don't infect this now evidence-based subject with their bubble-bursting disregard for confirmed predictions.

41. **antipodal**
September 7, 2009

Not sure what thread to post this in, but it seems to be the kind of thing you like commenting on.

Magnetic monopoles detected in a real magnet for the first time

http://www.physorg.com/news171209923.html

42. **Peter Woit**
September 7, 2009

antipodal,

If you look at the paper in question, you see these aren't actually magnetic monopoles, they're

"emergent quasiparticles resembling monopoles"

which is much less interesting. I'll leave discussion of them to condensed matter physicists.

43. **onlooker**
September 10, 2009

"

You're inventing silly, forced explanations for a silly, unforced error by Witten. He is quite precise with language and knows quite well how to express concepts such as not being Mr String Theory, or Mr Strings-Only, or not wishing to debate string theory, or string theory's critics not having points worthy of debate. What he actually said doesn't have any such charitable interpretation, which is why the piece was explicitly and implicitly "bad press" as it concerns this particular utterance by Witten.

It's not all bad; the article has the usual material, some of it from Woit, about how brilliant Witten is. This one remark was very far from brilliant , and it is easy for any reader, physicist or not, to understand that.

44. **Marcus**
September 10, 2009

==quoting onlooker==

==endquote==

I may have misinterpreted and you may have summed things up correctly.

I think of Paul Steinhardt as the string critic par ex.
His reply to the 2005 Edge question
http://www.edge.org/q2005/q05_print.html#steinhardt
is the most concentrated critique I've seen. It is hard hitting, focused and constructive. I'd like to hear his views now, almost five years later.

I'd like to hear a threeway conversation between Steinhardt, Peskin, and Strominger. They are all three about the same age (born around 1952-1954) and might be prepared to discuss matters openly.

Debate is not quite the right word. But something is missing. The string episode may have been a folly, and whatever it was, no one seems to want to be held accountable.

Leonard Susskind continues to mythologize. David Gross tears his hair with quiet dignity. Witten has better things to do. Maybe senior superstars should not be expected to take responsibility.

But a frank discussion by two or three slightly junior stars could help clear the air. I'm interested to know what you think, onlooker.

45. **Shantanu**
September 10, 2009

Hi
Peter,
Have you looked at Susskind's most recent colloquium at PI?

46. **Peter Woit**
September 10, 2009

Shantanu,
From a quick glance it looks like the standard story he has been selling for years now, without finding a lot of buyers. He seems however to have become delusional, calling it the "post-standard-model" standard model.

47. **onlooker**
September 10, 2009

(marcus writes)
"
But a frank discussion by two or three slightly junior stars could help clear the air. I'm interested to know what you think, onlooker.
"

There's an accumulated public explanatory burden resulting from all the evangelism and PR that dominated the discussion since the 1980's. The smartest people (or at least, an incredibly talented group by any math/science research standard) have been working on this for decades with thousands of papers and no physical output. Either they know something we don't, and can explain it both in general terms and with specific refutations of any technical criticisms by skeptics; or there is a serious problem with the structure of the field.

I don't think it matters how senior the researchers are who address these points. It could be Lubos Motl for all I care. But any string respondents will need to do more than reiterate cliches about "the only game in town", or point to emerging mathematical structures and holography as clear indicators of progress toward a unified physical theory. Having better computational tools in QFT is nice but that isn't what the publicity was about for the past 20 years. If the theory was heavily and deliberately oversold it would be refreshing to have some public admission that such is now the consensus (or becoming the consensus) within the field.

48. **Shantanu**
September 12, 2009

Peter, its interesting that Lee introduced him (from what I could tell).

Mathematicians: An Outer View of the Inner World

September 7, 2009
Categories: Book Reviews

A friend recently loaned me a wonderful book, the recently published [Mathematicians: An Outer View of the Inner World](), which consists mainly of photographs of mathematicians by Mariana Cook, paired with a page of comments from the mathematician being photographed. For more of the photos, see Mariana Cook's [web-site](). The comments typically deal with the story of what led the person into mathematics, or a summary of their career, or some general thoughts on mathematics and the pleasures of studying it.

Many of these mini-essays are well-worth reading. The Viscount Deligne describes working with Grothendieck and contrasts this to some of his later experience:

> When I was in Paris as a student, I would go to Grothendieck's seminar at IHES and Jean-Pierre Serre's seminar at the Collège de France. To understand what was being done in each seminar would fill my week. I learned a lot doing so. Grothendieck asked me to write up some of the seminars and gave me his notes. He was extremely generous with his ideas. One could not be lazy or he would reject you. But if you were really interested and doing things he liked, then he helped you a lot. I enjoyed the atmosphere around him very much. He had the main ideas and the aim was to prove theories and understand a sector of mathematics. We did not care much about priority because Grothendieck had the ideas we were working on and priority would have meant nothing. I later met other areas of mathematics where people were worried about doing something first and were hiding what they were doing form one another. I didn't like it. There are all kinds of mathematicians, even competitive ones.

Michele Vergne has an intriguing comment about the "quantization commutes with reduction" question, which is a fundamental issue for how symmetries work in quantum physics. When you have a gauge symmetry, do you get the same thing if you first eliminate the gauge variables (go to the symplectic reduction) and then quantize, or if you quantize and then take the gauge-invariant subspace? This turns out to be a remarkably interesting mathematical question. Perhaps the best way to think about its physical significance is to take it as a criterion for any viable notion of exactly what "quantization" is, and how it is supposed to interact with the notion of symmetry.

> Today I can see a dim light on a problem that has been on my mind for a long time. This is the assertion: quantization commutes with reduction. It was a beautiful conjecture of Guillemin-Sternberg, which was clearly true, but revealed itself hard to prove in general. I was able to prove an easy case. A much more difficult case was then proved by another mathematician ten years ago, using surgery. For me, this method via cuts is ugly. I would have liked to prove this conjecture with my own methods. Long after the full proof was found, I kept reorganizing my own arguments in all possible ways. If I repeated them over and over, the difficulties were bound to disappear. But they did not. These ceaseless failed attempts left a scar. I do still hope to discover where exactly the difficulty was, and today I feel I know the small hole where the difficulty was hiding. I think it can be grasped easily. Then, maybe, I will be able to formulate and prove the theorem in a much more general way. True, for thiat I need someone else's idea, but just recently, I used a brilliant idea of one of my students to explain a very similar phenomenon. I believe it can also be used to understand this case. Anyway, I will try. Tomorrow.

Comments

1. **theoreticalminimum**
   September 7, 2009

   Nice 🙂

   I actually came across Cook's 'Mathematician Gallery' some time ago, when I was looking for a photo of Don Zagier. May I point out that that she published another photo book [Faces of Science](), which is worth having a look into. By the way, all the pictures figuring in the galleries can be viewed in higher resolution if you right-click on any one of them, and select "View Image".

   It's quite nice to see young brilliant mathematicians like Tao and [Mirzakhani]() in the album 🙂 (following on your post about matters ICM, may I say that I carry the hope that the latter might become the first female Fields medalist). My favourite picture is that of my *maître*, J.-P. Serre 🙂

   I would finally suggest [The Unravelers]() as a great addition to Cook's book (but it's exclusively about mathematicians who have spent time at the *Institut des Hautes Études Scientifiques*).

2. **Anon**
   September 7, 2009

   Thanks for the post. The comments by Deligne were interesting.

3. **MathPhys**
   September 8, 2009

   Yes, that's a very nice comment by Deligne.

   PS I didn't know he became a Viscount.

4. **Deane**
   September 8, 2009

   I first noticed Cook's photos on the front cover of a Princeton University Press mailing. It had photos of authors of books listed in the mailing, but they were the nicest photos I had ever seen of mathematicians. I even emailed PUP asking if there was any way I could get a poster version of the cover or the individual photos. I am still disappointed that none are available. But I did pre-order the book (Amazon had it at a very reasonable price). I agree that the photos and essays are both wonderful.

5. **Chris W.**
   September 10, 2009

   Loosely related: The [Oded Schramm Memorial Conference]() was held at Microsoft Research on August 30-31.

   One of the talks given was this:

   > **Random triangulations as dynamical variables in quantum mechanical models**
   > [Michael Freedman]()

Abstract: I'll discuss a simple calculation which Oded showed me how to do and its implications for taking quantum mechanical models off lattice.

6. **Chris Oakley**
   September 11, 2009

   Happy birthday, Peter!

   I am actually in NY now working for the client. As we are not far from the WTC site I was a bit worried that Al Qaeda might be back for old time's sake. But then I realised they would not use our calendar. September 11, 2001 was 23rd Jumada all-thani 1422 (give or take a day), the anniversary of which would have been on June 16.

7. **Peter Woit**
   September 11, 2009

   Thanks Chris, both for the birthday greetings and for the obscure calendar reassurance…

8. **Chris Oakley**
   September 11, 2009

   A pleasure, and I hope that it is a better day than the one eight years ago. FWIW the dates of 23 Jumada al-thani, according to the Saudi calendar are

   1422 11-Sep-2001
   1423 01-Sep-2002
   1424 21-Aug-2003
   1425 09-Aug-2004
   1426 29-Jul-2005
   1427 18-Jul-2006
   1428 08-Jul-2007
   1429 27-Jun-2008
   1430 16-Jun-2009
   1431 06-Jun-2010
   1432 26-May-2011
   1433 14-May-2012
   1434 03-May-2013
   1435 23-Apr-2014
   1436 12-Apr-2015
   1437 01-Apr-2016

9. **YBM**
   September 13, 2009

   About mathematicians and would-be mathematicians, you could be amused to know that the Bogdanov brothers are now claiming that Alain Connes is stealing their key ideas without quoting them.

Latest From the LHC

September 11, 2009
Categories: Experimental HEP News

Things seems to have been going well at the LHC recently, with the current schedule expecting injection of beams in a little more than two months from now, on Thursday November 19. After that, the plan is for a week and a half of beam commissioning at 450 GeV, and 450 GeV collisions at the beginning of December. The machine will then be ramped up to first 1 TeV, then 3.5 TeV, with 3.5 TeV collisions on December 14.

Soon after that (December 17), the machine will go into a technical stop period for the holidays, starting back up January 7. From then on, the plan is for a month of more commissioning work and pilot physics. The first regular physics run at 3.5 TeV will last about 3 months, with expected luminosity of 54 pb^{-1}. Then in May, the energy will be increased to somewhere in the range of 4-5 TeV, with a run beginning in June at that energy lasting until mid-October, with expected luminosity of 274 pb^{-1}. The machine will then be reconfigured for a one-month run with heavy ions, and then go into a long shutdown at the end of November.

Anyway, that's the latest plan, reality may turn out differently. For up to the minute information on how things are going, you can follow along here. The last sector to be ready is now supposed to be sector 67, which is in cooldown, the magnets currently around 200K.

See here for a recent Science Magazine story on the subject from Adrian Cho.

Comments

1. **dan**
   September 11, 2009

   "and then go into a long shutdown at the end of November."

   What is the benefit of a long shutdown?

2. **Peter Woit**
   September 11, 2009

   dan,

   A lot of work on the machine may be needed in order to get it to run not at 3.5-5 TeV/beam, but at the design energy of 7 TeV/beam. This may, for instance, require warming up and then cooling down the entire ring, which would be a time-consuming process.

3. **neo**
   September 12, 2009

   How did they fix all those badly soldered connections?

4. **dan**
   September 13, 2009

   ok, if everything goes according to schedule, when will data from LHC start pouring in? Presumably the Tevatron will continue to hunt for Higgs/sparticles

5. **Peter Woit**
   September 13, 2009

   dan,

   Well, the schedule has enough data to be interesting coming in during 2010, but not enough to really compete with the Tevatron on the Higgs. Tommaso Dorigo has a relevant posting about this

   http://www.scientificblogging.com/quantum_diaries_survivor/worst_nightmare_scenario_cern_150_gev_higgs

6. **dan**
   September 15, 2009

   Thanks,

   "f superpartners don't show up at 7 TeV/beam"

   What year at the earliest if everything goes to schedule would the LHC collect enough data from 7 TeV collusions due to luminosity to be able to show or suggest sparticles or rule it out?

7. **Peter Woit**
   September 16, 2009

   dan,

   Since we don't the masses of superpartners, there's no answer to your question. Depending on different choices of the masses, you can come up with cases where the LHC should see something quickly, or not for a very long time, if ever.

8. **dan**
   September 16, 2009

   Hi,

   I am well aware that SUSY could be broken at any scale.

I was thinking if MSSM or next to MSSM Distler seems to promote, and if SS is the correct explanation for EW stabilization. What range of mass would rule out SS as the explanation for higgs hierarchy-EW based on LHC energy and luminosities?

9. **Peter Woit**
   September 16, 2009

   dan,

   As far as I know, you can push all the superpartner masses high enough to be invisible at the LHC, at the cost of requiring higher amounts of fine-tuning to explain the hierarchy problem. So, depends what degree of fine-tuning you are willing to accept.

Bloggingheads Diavlog With Craig Callender

September 13, 2009
Categories: Uncategorized

There's a new Bloggingheads Diavlog up today, where philosopher of science Craig Callender and I discuss the topic of Philosophy and the String Wars. Regular readers of the blog will just get to see me make the same points as usual in video format, more interesting might be to hear Craig's point of view on some of this. We agree about the anthropic principle.

Those who follow science-blogging controversies will have heard that certain science bloggers have announced a boycott of Bloggingheads, based on the fact that two creationist/ID types had recently been allowed to participate. I heard about this after agreeing to do this latest one, and initially the idea of such a boycott sounded to me completely bizarre. Why would anyone boycott a media outlet that produces a lot of serious and interesting content on the grounds that two out of its hundreds of participants were cranks (I can't think of ANY completely crank-free media outlet)? So, I recently read much of the on-line discussion, including that of the original boycotters, some non-boycotters (here and here), and the discussion here with Bloggingheads founder Robert Wright, who put up a clarification of the organization's policy here. After wading through all this, I concluded that, yes, the boycott thing is completely bizarre. For one take on the question that I pretty much fully agree with, see this one by John Horgan.

Comments

1. **Thomas R Love**
   September 13, 2009

   Interesting discussion. Even the ID types should be allowed to speak, then we can all see how silly their ideas are.

   I especially enjoyed your discussion of the beauty of mathematics.

2. **David Nataf**
   September 13, 2009

   I don't know Peter, I think "bizarre" might be a bit strong. Progress is not inevitable on a global scale and certainly not on a local scale, I don't think it's obvious what the best way to deal with these kinds of questions is.

   What the Mainstream media does on GW for example is present two sides as equal, get a quote from each, etc. Is that parity the right way to go?

3. **Roger Schlafly**
   September 13, 2009

   Complaints about Behe seemed to have caused the boycott, but he is not even a creationist in the sense of a young Earth creationist. He accepted much of evolution. His views were clearly labeled as being outside the mainstream. Yes, the boycott is bizarre. It is odd that anyone would be so threatened by Behe.

4. **Peter Woit**
   September 13, 2009

   David,

   I just don't think what Bloggingheads is doing is anything like giving parity to cranks. See their announced policy, which is what the boycotters find worth boycotting.

   Roger and others,

   Please avoid any temptation to start debate here about creationism, ID, evolution, Behe, etc. etc. It will be ruthlessly suppressed. My strongly held belief is that the last thing the internet needs is more discussion of this in more places…

5. **Geoff**
   September 14, 2009

   I can think of at least four different completely crank-free outlets: Physical Review, Classical & Quantum Gravity, Journal of Mathematical Physics and of course everyone's favorite ArXiv. So should a string oriented cosmologist peruse any of the above and come across a paper about LQG they should immediately conclude that the outlet has been taken over by crackpots and stop publishing in those places. No, really, please stop publishing.

   Now if you'll excuse me I've got to go back to the kitchen where I'm trying to get my clock to run backwards by unscrambling an egg.

   September 14, 2009

   Geoff,

   There are several reasons to characterize this particular boycott as "completely bizarre"….

7. **Giotis**
   September 14, 2009

   This bizarre boycott has a simple explanation. Some people are obsessed with certain topics and their obsession dim their judgment. You are not obsessed with the whole ID thing and thus you have correctly identified their bizarre behaviour.

   September 15, 2009

   Peter, I think you missed the point by being too cerebral about this "boycott." I followed the controversy closely on Bheads, and my impression is that it has little to do with science v creationism and much to do with a personal misunderstanding between Bob W. on the one hand and Carl and Sean on the other.

   After the first creationist appeared, Bob has a conference call with people who included Carl and Sean. Carl and Sean felt (perhaps mistakenly) that Bob had committed to pulling the plug on future creationists. Then when Behe appeared, they felt betrayed. They quit defending a principle, but there was a lot of emotional baggage. The issue got further muddled when other bloggers, like PK Myer, boycotted Bheads out of solidarity with Carl and Sean.

   wonderment,

   I agree that the whole boycott thing cannot be understood “cerebrally”, it’s pretty clearly irrational…

The Holy Patron of String Theory and its Holy Grail

Categories: Uncategorized

Science News is running a long interview with Murray Gell-Mann, who will be celebrating his 80th birthday tomorrow. Gell-Mann was arguably (Feynman is one who would argue..) the most influential figure in theoretical particle physics throughout the 1950s and 1960s. In the interview, he gives the standard story about the cosmological constant/supersymmetry/hierarchy problem, expecting superpartners to be accessible at the LHC design energy, although perhaps not at its initial energy of 3.5 TeV/beam. If superpartners don't show up at 7 TeV/beam, he says:

> Well, we'd have to see exactly how bad it is. I mean how high up you go and still don't find anything and so on. But yes, one might have to discard this whole line of reasoning.

Gell-Mann describes himself as not a string theorist, but someone who thought it was promising and continues to do so, claiming:

> I was a sort of patron of string theory — as a conservationist I set up a nature reserve for endangered superstring theorists at Caltech, and from 1972 to 1984 a lot of the work in string theory was done there.

He speculates about what is missing in string theory as follows:

> I am puzzled by what seems to me the paucity of effort to find the underlying principle of superstring theory-based unified theory. Einstein didn't just cobble together his general relativistic theory of gravitation. Instead he found the principle, which was general relativity, general invariance under change of coordinate system. Very deep result. And all that was necessary then to write down the equation was to contact Einstein's classmate Marcel Grossmann, who knew about Riemannian geometry and ask him what was the equation, and he gave Einstein the formula. Once you find the principle, the theory is not that far behind. And that principle is in some sense a symmetry principle always.
>
> Well, why isn't there more effort on the part of theorists in this field to uncover that principle? Also, back in the days when the superstring theory was thought to be connected with hadrons rather than all the particles and all the forces, back in that day the underlying theory for hadrons was thought to be capable of being formulated as a bootstrap theory, where all the hadrons were made up of one another in a self-consistent bootstrap scheme. And that's where superstring theory originated, in that bootstrap situation. Well, why not investigate that further? Why not look further into the notion of the bootstrap and see if there is some sort of modern symmetry principle that would underlie the superstring-based theory of all the forces and all the particles. Some modern equivalent of the bootstrap idea, perhaps related to something that they call modular invariance. Whenever I talk with wonderful brilliant people who work on this stuff, I ask what don't you look more at the bootstrap and why don't you look more at the underlying principle. . . .

Lubos Motl seems to have calmed down a bit recently, and his latest posting is about the Gell-Mann interview. He describes Gell-Mann as not just a patron of string theory, but a holy patron of string theory, with the comments quoted above "the holy word". They inspire him as he continues to work a few hours a day towards finding the holy grail of string theory: some fundamental principle that defines the theory non-perturbatively.

Searches for such a principle go back at least 25 years, to 1984 and the explosion of interest in string theory as a unified theory. After the first efforts to base unification on a Calabi-Yau, it soon became clear that more was needed than string perturbation theory. Just one of many such attempts that I remember was that of Friedan/Shenker in 1986, who hoped that in some sense the moduli space of all Riemann surfaces would somehow carry a unique vector bundle with flat connection. There were many others.

Lubos entered the field ten years later, after discoveries about dualities had led to Witten's conjecture of the existence of an "M-theory" that would reduce in various limits to the known string theories. At the time, the hot candidate for such a theory was something called Matrix theory, and Lubos made his reputation with work on this. His thinking these days grows out of the "M-theory" conjecture that he first started working on as an undergraduate 13 years ago, and probably reflects well the kind of speculative hopes that drove this area of research from the beginning:

> It also seems extremely likely that some UV/IR links – modeled by the modular invariance in the context of perturbative closed strings – will be important for the formulation of the ultimate principle. Non-perturbatively, it seems obvious that such a link will have to constrain the black hole microstates, i.e. the generic high-mass particle species in any theory of quantum gravity. The spectrum and detailed structure of the black hole microstates must be linked to low-energy fields and all of their higher-order interactions. These conditions will admit a limited number of solutions that will coincide with the allowed configurations of string/M-theory.
>
> Moreover, it's conceivable that we won't be able to work "fully on the worldsheet" or "fully in the spacetime". I feel that the ultimate set of consistency rules for quantum gravity will work "simultaneously" for the generalized worldvolumes as well as spacetime. So I am spending a lot of time by attempts to import some lessons – and methods to derive or generate new degrees of freedom – from spacetimes to the worldvolumes, and vice versa.
